# CHAPTER 1 The AJAX Toolkit

## In this chapter ...

- [When to Use the AJAX Toolkit](#)
- [AJAX Toolkit Support Policy](#)
- [Other Resources](#)
- [AJAX Typographical Conventions](#)
- [Sample Visualforce Page Using the AJAX Toolkit](#)

The AJAX Toolkit is a JavaScript wrapper around the API:

- The AJAX Toolkit is available for any organization that has API access.
- The AJAX Toolkit supports Microsoft® Internet Explorer® versions 9, 10, and 11 with the latest Microsoft hot fixes applied, and Mozilla® Firefox®, most recent stable version.
- The AJAX Toolkit is based on the partner WSDL. Because there is no type checking in JavaScript, the type information available in the enterprise WSDL is not needed.
- You can execute any call in the API, and access any API object that you normally have access to.
- You can issue asynchronous calls, and use callback functions to handle the results. For more information, see [API Calls and the AJAX Toolkit](#).
- You can use header options with a different syntax than in the API. For more information, see [Using SOAP Header Options with the AJAX Toolkit](#).
- You can handle errors with the AJAX Toolkit. For more information, see [Error Handling with the AJAX Toolkit](#).
- The AJAX Toolkit supports relationship queries. See [Synchronous Examples](#) for examples of relationship queries.

**Note:** Before you use the AJAX Toolkit, you should be familiar with JavaScript and with the information about the API in the [SOAP API Developer's Guide](#).

This document explains how to use the AJAX Toolkit in JavaScript to embed API calls and processes, such as within a Visualforce page.

## When to Use the AJAX Toolkit

---

For best performance, use the AJAX Toolkit when working with small amounts of data.

Because information is delivered via a browser, AJAX works best with relatively small amounts of data (up to 200 records, approximately six fields with 50 characters of data each). The larger the data set returned, the more time it will take to construct and deconstruct a SOAP message, and as the size of an individual record gets larger, the impact on performance becomes greater. Also, as more HTML nodes are created from the data, the potential for poor performance increases. Because browsers are not efficient, careful consideration needs to be given to browser memory management if you intend to display a large amount of data.

The following are examples of appropriate uses:

- Display or modify a single record.
- Display two or three fields from many records.
- Perform one or more simple calculations, then update a record.

The following are examples of scenarios that require case-by-case analysis:

- Update more than 200 records.
- Update records that are unusually large. For example, what happens if the user clicks the browser stop button?
- Recalculate a complex value for more than 200 records.

An example of inappropriate usage is providing a sortable grid of many records. This would require too much processing time, and browser rendering would be too slow.

## AJAX Toolkit Support Policy

---

The current release of the AJAX Toolkit is the only version that receives bug fixes and enhancements. When a new version is released, the previous version continues to be available, but is not supported.

## Other Resources

---

In addition to the content of this document, there are other resources available for you as you learn to use the AJAX Toolkit:

- Eclipse plug-in: [Force.com IDE](#)
- Message boards: [Salesforce Developers](#)

## AJAX Typographical Conventions

---

Topics about the AJAX Toolkit use the following typographical conventions:

Convention	Description
<code>&lt;script src="/soap/ajax/35.0/connection.js" type="text/javascript"&gt;&lt;/script&gt;</code>	In an example, Courier font indicates items that you should type the information as shown. This includes sample code, literals, methods, calls, functions, and events from a variety of languages.
<code>sforce.connection.<i>header_option_name</i>="value";</code>	In an example or syntax statement, italics represent variables. You supply the actual value.

## Sample Visualforce Page Using the AJAX Toolkit

---

This example demonstrates using the AJAX Toolkit in a Visualforce page.

To add JavaScript to an Visualforce page, use the following procedure:

1. Create the Visualforce page. For more information on this, see the [Visualforce Developer's Guide](#).
2. Cut and paste the following sample code into your Visualforce page.

The JavaScript code queries your organization and returns every account ID, account name, and industry type, if any:

```
<apex:page >
  <script type="text/javascript">
    var __sfmcSessionId = '{!GETSESSIONID()}';
  </script>
  <script src="../../soap/ajax/35.0/connection.js"
    type="text/javascript"></script>
  <script type="text/javascript">    window.onload = setupPage;
  function setupPage() {
    //function contains all code to execute after page is rendered

    var state = { //state that you need when the callback is called
      output : document.getElementById("output"),
      startTime : new Date().getTime() };

    var callback = {
      //call layoutResult if the request is successful
      onSuccess: layoutResults,

      //call queryFailed if the api request fails
      onFailure: queryFailed,
      source: state};

    sforce.connection.query(
      "Select Id, Name, Industry From Account order by Industry",
      callback);
  }

  function queryFailed(error, source) {
    source.output.innerHTML = "An error has occurred: " + error;
  }

  /**
   * This method will be called when the toolkit receives a successful
   * response from the server.
   * @queryResult - result that server returned
   * @source - state passed into the query method call.
   */
  function layoutResults(queryResult, source) {
    if (queryResult.size > 0) {
      var output = "";

      //get the records array
      var records = queryResult.getArray('records');
```

```

//loop through the records and construct html string
for (var i = 0; i < records.length; i++) {
    var account = records[i];

    output += account.Id + " " + account.Name +
        " [Industry - " + account.Industry + "]"<br>";
}

//render the generated html string
source.output.innerHTML = output;
}
}
</script>

<div id="output"> </div>

</apex:page>

```

After creating and navigating to the above Visualforce page, you should see text similar to this image:

```

001x0000002qsIWAAY HQAccount [Industry - null]
001x0000002qsJJAAY SecondTestUser [Industry - null]
001x0000002qpoZAAQ Myriad Pubs [Industry - Media]
001x0000002qsIIAAY TestUserAccount [Industry - null]
001x0000002sqFnAAI Joe Bob [Industry - null]
001x0000002vCwvAAE API Doc Tracking [Industry - null]
001x0000003BfXyAAK Mysti [Industry - null]

```

**Note:** An easier way to create this page is by using an Apex controller. However, the sample is intended to show basic functionality with the AJAX Toolkit that contains API calls and processes Salesforce data.

## CHAPTER 2 Working with the AJAX Toolkit

### In this chapter ...

- [Connecting to the API](#)
- [Embedding API Calls in JavaScript](#)
- [Processing Results](#)

Most JavaScript that you add to Visualforce pages, buttons, or links has three sections: first, connecting to the AJAX Toolkit, next, embedding the API methods in JavaScript, and finally, processing the results. This section explains each of these steps.

## Connecting to the API

The first portion of any JavaScript code that uses the AJAX Toolkit must make the toolkit available to the JavaScript code. The syntax for this is different depending on whether you are embedding JavaScript in a Visualforce page, or a button or link.

- For Visualforce pages or any source other than a custom `onclick` JavaScript button, specify a `<script>` tag that points to the toolkit file:

```
<apex:page>
  <script src="../../soap/ajax/35.0/connection.js"
  type="text/javascript"></script>
  <script>
    sforce.connection.sessionId='{!GETSESSIONID()}' ;
    ...
  </script>
  ...
</apex:page>
```

- For a custom `onclick` JavaScript button, use `!requireScript` to point to the toolkit file:

```
<body>
  {!requireScript("/soap/ajax/35.0/connection.js")}
  ...
```

The AJAX Toolkit picks up the endpoint and manages the session ID. You do not need to set them.

The version of the AJAX Toolkit is in the URL.

After this script executes, the toolkit is loaded and a global object, `sforce.connection`, is created. This object contains all of the API calls and AJAX Toolkit methods, and manages the session ID. No other session management is needed.

Salesforce checks the IP address from which the client application is logging in, and blocks logins from unknown IP addresses. For a blocked login via the API, Salesforce returns a login fault. Then, the user must add their security token to the end of their password in order to log in. A security token is an automatically-generated key from Salesforce. For example, if a user's password is *mypassword*, and their security token is *xxxxxxxxxxx*, then the user must enter *mypasswordxxxxxxxxxxx* to log in. Users can obtain their security token by changing their password or resetting their security token via the Salesforce user interface. When a user changes their password or resets their security token, Salesforce sends a new security token to the email address on the user's Salesforce record. The security token is valid until a user resets their security token, changes their password, or has their password reset. When the security token is invalid, the user must repeat the login process to log in. To avoid this, the administrator can make sure the client's IP address is added to the organization's list of trusted IP addresses. For more information, see "Security Token" in the [SOAP API Developer's Guide](#).

 **Tip:** It is recommended that you obtain your security token via the Salesforce user interface from a trusted network prior to attempting to access Salesforce from a new location.

If Single Sign-On (SSO) is enabled for your organization, users who access the API or a desktop client cannot log in to Salesforce unless their IP address is included on your organization's list of trusted IP addresses or on their profile, if their profile has IP address restrictions set. Furthermore, the delegated authentication authority usually handles login lockout policies for users with the "Uses Single Sign-On" permission. However, if the security token is enabled for your organization, then your organization's login lockout settings determine the number of times a user can attempt to log in with an invalid security token before being locked out of Salesforce. For more information, see "Setting Login Restrictions" and "Setting Password Policies" in the online help.

## Embedding API Calls in JavaScript

After you have made the toolkit available using the procedure in [Connecting to the API](#), you can write the JavaScript code that contains your API calls and processing. Be sure to check the [SOAP API Developer's Guide](#) for information about each call that you wish to use. The syntax for calls is different in the AJAX Toolkit; for details see [API Calls and the AJAX Toolkit](#).

The following example shows a simple synchronized call that you can issue after connecting. This query returns the `Name` and `Id` for every `User` and writes them to the log.

```
result = sforce.connection.query("Select Name, Id from User");
records = result.toArray("records");

for (var i=0; i< records.length; i++) {
    var record = records[i];
    log(record.Name + " -- " + record.Id);
}
```

We recommend that you wrap your JavaScript code so that the entire HTML page is rendered by the browser before the code executes, to avoid errors. For example:

```
<body onload="setupPage();">
    <div id="output"></div>
</body>
```

When you specify `setupPage()` in the `body onload`, the browser initializes all HTML elements before it calls `setupPage()`. For example, the following code could be added to a Visualforce page to retrieve data:

```
<script type="text/javascript">
    function setupPage() {
        sforce.connection.query("Select Id, Name, Industry From Account order by
Industry",
        {onSuccess : layoutResults,
        onFailure : queryFailed,
        source : {
            output : document.getElementById("output"),
            startTime : new Date().getTime()
        }
        });
    }
</script>
```

The API interaction in the code above is accomplished in the first line of the `setupPage` function. A SOQL statement specifies what data to return. For more information about the `source` context variable, see [The source Context Variable](#).

After fetching the data in this example, you should handle error conditions, for example:

```
function queryFailed(error, source) {
    source.output.innerHTML = "<font color 'red'">
        An error has occurred: </font> <p>" + error;
}
```

For more about error handling, see [Error Handling with the AJAX Toolkit](#).

Use a callback function to handle the results of this asynchronous call. A callback function is a function that is passed by reference to the AJAX Toolkit. The AJAX Toolkit calls the callback function under defined conditions, for example, upon completion. For more information about callback function syntax, see [API Calls and the AJAX Toolkit](#).

For example, the following code verifies that at least one result was returned, and iterates through the result set if it exists:

```
/**
 * This method will be called when the toolkit receives a successful
 * response from the server.
 * @queryResult - result that server returned
 * @source - state passed into the query method call.
 */

function layoutResults(queryResult, source) {

    if (queryResult.size > 0) {
        var output = "";

        //get the records array
        var records = queryResult.getArray('records');

        //loop through the records and construct html string
        for (var i = 0; i < records.length; i++) {
            var account = records[i];
            output += account.Id + " " + account.Name +
                " [Industry - " + account.Industry + "]"<br>";
        }

        //render the generated html string
        source.output.innerHTML = output;
    }
}
```

A suggested best practice is to use JavaScript `onFailure` as the callback function for failure conditions and JavaScript `onSuccess` for processing results that are successfully returned.

For more information about embedding API calls in JavaScript with the AJAX Toolkit, especially the differences in syntax and availability of asynchronous calls, see [API Calls and the AJAX Toolkit](#).

## Processing Results

---

You can process the results of a query that returns enough rows to require `queryMore` and `queryLocator`, much as you do now, iterating across the results:

```
var result = sforce.connection.query("select name, id from account");
var queryMore = true;
while (queryMore) {
    var records = result.getArray("records");
    for (var i = 0; i < records.length; i++) {
        //process records[i]
    }
    if (result.getBoolean("done")) {
        queryMore = false;
    } else {
        result = sforce.connection.queryMore(result.queryLocator);
    }
}
```

However, the AJAX Toolkit provides the `QueryResultIterator` object so that you can easily iterate through results without invoking `queryMore` and `queryLocator`. If you are experienced with the API and JavaScript, see [QueryResultIterator](#).

For other calls, you must handle the batching of up to 200 records at a time yourself. For example, the following sample shows how to batch files for a `create()` call:

```
var accounts = [];  
  
for (var i=0; i<10; i++) {  
    var account = new sforce.SObject("Account");  
    account.Name = "my new account " + i;  
    accounts.push(account);  
}  
  
var result = sforce.connection.create(accounts);  
  
var sb = "";  
  
for (var i=0; i<result.length; i++) {  
    if (result[i].getBoolean("success")) {  
        sb += "\n new account created with id " + result[i].id;  
    } else {  
        sb += "\n failed to create account " + result[i];  
    }  
}  
  
alert("Result : " + sb);
```

For more examples, see [Synchronous Examples](#).

## CHAPTER 3 API Calls and the AJAX Toolkit

### In this chapter ...

- Synchronous and Asynchronous Calls with the AJAX Toolkit
- API Call Syntax in the AJAX Toolkit
- Object Functions
- Data Types in AJAX Toolkit
- The source Context Variable
- Debugging with the AJAX Toolkit
- Using the Samples
- Synchronous Examples
- Asynchronous Examples

Use the following sections to understand how API calls are used with the AJAX Toolkit. All calls described in the [SOAP API Developer's Guide](#), plus the `runTests` call documented in the [Force.com Apex Code Developer's Guide](#) can be used with the AJAX Toolkit.

## Synchronous and Asynchronous Calls with the AJAX Toolkit

The AJAX Toolkit supports both synchronous and asynchronous calls.

The AJAX Toolkit allows you to issue synchronous or asynchronous calls. Asynchronous calls allow the client side process to continue while waiting for a call back from the server. To issue an asynchronous call, you must include an additional parameter with the API call, referred to as a callback function. Once the result is ready, the server invokes the callback method with the result.

## API Call Syntax in the AJAX Toolkit

SOAP API calls use slightly different syntax in AJAX Toolkit.

Synchronous syntax:

```
sforce.connection.method("arg1","arg2", ...);
```

For example:

```
sforce.connection.login("MyName@MyOrg.com","myPassword1");
```

Asynchronous syntax:

```
method("arg1","arg2", ..., callback_method);
```

For example:

```
var callback = {onSuccess: handleSuccess, onFailure: handleFailure};
function handleSuccess(result) {}
function handleFailure(error) {}
sforce.connection.query("Select name from Account", callback);
```

In this example, `onSuccess` is the callback function, which will return the results when they are ready.

See [Core Calls](#) in the *SOAP API Developer's Guide* for call usage, arguments, and best practices, but use the AJAX Toolkit syntax for methods you embed in JavaScript.

**Note:** Because `delete` is a JavaScript keyword, use `deleteIds` instead of the API call `delete`.

## Object Functions

AJAX Toolkit has several ways of accessing object information.

Property values can be accessed directly or by using a generic `set` or `get` method:

- A `get` function for each field in the object. For example, an Account object has a `get ("Name")` function. This can be used instead of `object.Field` (for example, `account.Name`).
- A `set` function for each field in the object. For example, an Account object has a `set ("Name")` function. This can be used instead of `object.Field = value`.

For example, you can get the value of the `Name` field from an Account using either of these methods:

- `account.get ("Name")`
- `account.Name`
- `account ["Name"]`

You can set the value of the `Name` field from an `Account` using either of these methods:

- `account.set("Name", "MyAccount");`
- `account.Name = "MyAccount";`
- `account["Name"]="MyAccount";`

For information about processing results, see [Processing Results](#).

## Data Types in AJAX Toolkit

---

AJAX Toolkit provides ways of converting between different data types.

The AJAX Toolkit returns all data as strings. If needed, you can convert the data into an appropriate datatype by using one of the functions supplied with the returned object:

- `getDate` maps dates to JavaScript Date.
- `getDateTime` maps dateTime values to JavaScript Date.
- `getInt` maps integer values to JavaScript Int.
- `getFloat` maps float values to JavaScript Float.
- `getBoolean` maps boolean values to JavaScript Boolean.
- `getArray` retrieves arrays of values.
- `getBase64Binary` returns the decoded value of a Base64 binary encoded string. This is typically used for working with documents and attachments. See [Working with Base64 Binary Encoded Strings](#) for information about working with Base64 binary encoded strings.

If you request a field whose value is null in a query, the returned value will be null. If you do not request a field, whether the value is null or not, the value is not returned, and is therefore undefined.

## The source Context Variable

---

The AJAX Toolkit provides a context variable, `source`, which allows you to pass in any context and get it back in the callback method. For an example of how to use `source` in an error handling context, see [Error Handling with the AJAX Toolkit](#).

## Debugging with the AJAX Toolkit

---

The AJAX Toolkit provides a debugging window that pops up when certain errors are encountered.

You can invoke logging explicitly using the `log` method. For example, if you wanted to display the debugging window with the value of a variable at a certain point in your client application, you could add this line at the appropriate place:

```
sforce.debug.log(myVar);
```

You can open the debugging window at any point by using this command:

```
sforce.debug.open();
```

## Using the Samples

---

The next two sections contain examples of synchronous and asynchronous calls.

The AJAX Toolkit provides a debugging window that pops up when certain errors are encountered.

You can invoke logging explicitly using the `log()` method. For example, if you wanted to display the debugging window with the value of a variable at a certain point in your client application, you could add this line at the appropriate place:

```
sforce.debug.log(myVar);
```

The AJAX Toolkit samples in the following sections use `log()`. To use the samples in the following sections, add this simple version of the `log` code before the first use of `log`:

```
function log(message) {
    alert(message);
}
```

You can make `log()` as sophisticated as you wish.

## Synchronous Examples

---

The following examples are synchronous calls. No callback methods are required.

### Data Call Examples

login Example:

```
try{
    var result = sforce.connection.login("myname@myemail.com", "password");
    log("logged in with session id " + result.sessionId);
}catch(error) {
    if (error.faultcode.indexOf("INVALID_LOGIN") != -1) {
        log("check your username and passwd, invalid login");
    } else {
        log(error);
    }
}
```

query Example:

```
result = sforce.connection.query("Select Name, Id from User");
records = result.getArray("records");

for (var i=0; i< records.length; i++) {
    var record = records[i];
    log(record.Name + " -- " + record.Id);
}
```

queryMore Example:

```
var result = sforce.connection.query("select name, id from account");

var queryMore = true;
while (queryMore) {
    var records = result.getArray("records");
    var sb = new sforce.StringBuffer();

    for (var i = 0; i < records.length; i++) {
```

```

        sb.append(records[i].Name).append(",");
    }

    log(records.length);
    log(sb.toString());

    if (result.getBoolean("done")) {
        queryMore = false;
    } else {

        result = sforce.connection.queryMore(result.queryLocator);
    }
}

```

queryAll Example:

```

var result = sforce.connection.queryAll("Select Name, Id from Account");
var records = result.getArray("records");

for (var i=0; i<records.length; i++) {
    var record = records[i];
    log(record.Name + " -- " + record.Id);
}

```

Relationship Query Example—Child to Parent:

```

var result = sforce.connection.query("SELECT c.Id, c.firstname, " +
    "c.lastname, c.leadsource, a.Id, a.name, a.industry, c.accountId " +
    "FROM Contact c, c.account a ORDER BY leadsource LIMIT 10");

var it = new sforce.QueryResultIterator(result);

while(it.hasNext()) {
    var record = it.next();
    var accountName = record.Account ? record.Account.Name : null;

    log( record.FirstName + " " + record.LastName +
        " in account " + accountName);
}

```

**Note:** Relationship name formats differ depending on the direction of the relationship (parent-to-child or child-to-parent), and also depending on whether the objects are standard or custom objects. For more information, see Relationship Queries in the *Salesforce SOQL and SOSL Reference Guide* at [www.salesforce.com/us/developer/docs/soql\\_sosl/index.htm](http://www.salesforce.com/us/developer/docs/soql_sosl/index.htm).

Relationship Query Example—Parent to Child:

```

var result = sforce.connection.query("select a.Name, a.Industry, " +
    "(select c.LastName, c.LeadSource from a.Contacts c) " +
    "from account a order by industry limit 100");

var ait = new sforce.QueryResultIterator(result);

while(ait.hasNext()) {
    var account = ait.next();
}

```

```

var contacts = [];
if (account.Contacts) {
    var cit = new sforce.QueryResultIterator(account.Contacts);
    while(cit.hasNext()) {
        var contact = cit.next();
        contacts.push(contact.LastName);
    }
}

log(account.Name + ": " + contacts.join(", "));
}

```

create Example:

```

var account = new sforce.SObject("Account");
account.Name = "my new account";
var result = sforce.connection.create([account]);

if (result[0].getBoolean("success")) {
    log("new account created with id " + result[0].id);
} else {
    log("failed to create account " + result[0]);
}

```

Batch create Example:

```

var accounts = [];

for (var i=0; i<10; i++) {
    var account = new sforce.SObject("Account");
    account.Name = "my new account " + i;
    accounts.push(account);
}

var result = sforce.connection.create(accounts);

for (var i=0; i<result.length; i++) {
    if (result[i].getBoolean("success")) {
        log("new account created with id " + result[i].id);
    } else {
        log("failed to create account " + result[i]);
    }
}

```

delete Example:

```

//create an example account
var account = new sforce.SObject("Account");
account.Name = "my new account";
var result = sforce.connection.create([account]);

if (result[0].getBoolean("success")) {
    log("new account created with id " + result[0].id);
    account.Id = result[0].id;
} else {
    throw ("failed to create account " + result[0]);
}

```

```

}

//now delete the example account
var delResult = sforce.connection.deleteIds([account.Id]);
if (delResult[0].getBoolean("success")) {
    log("account with id " + result[0].id + " deleted");
} else {
    log("failed to delete account " + result[0]);
}

```

merge Example:

```

//create two accounts
var account1 = new sforce.SObject("Account");
account1.Name = "myName";
account1.Phone = "2837484894";

var account2 = new sforce.SObject("Account");
account2.Name = "anotherName";
account2.Phone = "938475950";

var result = sforce.connection.create([account1, account2]);
if (result.length != 2) throw "create failed";

account1.id = result[0].id;
account2.id = result[1].id;

//create merge request
var request = new sforce.MergeRequest();
request.masterRecord = account1;
request.recordToMergeIds = account2.id;

//call merge
result = sforce.connection.merge([request]);

if (result[0].getBoolean("success")) {
    log("merge success " + result[0]);
} else {
    log("merge failed " + result[0]);
}

```

process Example:

```

var request = new sforce.ProcessSubmitRequest();
request.objectId = "id of object that has a workflow rule on it"; // valid id
request.comments = "automated approval";

var request2 = new sforce.ProcessSubmitRequest();
request2.objectId = 'id of object that does NOT have a workflow rule on it' ; // valid id,
    not useful for workflow
request2.comments = "approval that will fail";

var processRes = sforce.connection.process([request, request2]);

```

```

if(!processRes[0].getBoolean('success')){
    log("The first process request failed and it should not have");
}

if(processRes[1].getBoolean('success')){
    log("The second process request succeeded and it should not have");
}

log(processRes[0].errors);
log(processRes[1].errors);

```

update Example:

```

//create an account
var account = new sforce.SObject("Account");
account.Name = "myName";
account.Phone = "2837484894";
result = sforce.connection.create([account]);

//update that account
account.id = result[0].id;
account.Phone = "12398238";
result = sforce.connection.update([account]);

if (result[0].getBoolean("success")) {
    log("account with id " + result[0].id + " updated");
} else {
    log("failed to update account " + result[0]);
}

```

undelele Example:

```

var account = new sforce.SObject("Account");
account.Name = "account to delete";
account.Phone = "2837484894";
result = sforce.connection.create([account]);
account.id = result[0].id;
log("account created " + account);

result = sforce.connection.deleteIds([account.id]);
if (!result[0].getBoolean("success")) throw "delete failed";
log("account deleted " + result);

result = sforce.connection.undelete([account.id]);
if (!result[0].getBoolean("success")) throw "undelete failed";
log("account undeleted " + result[0]);

```

upsert Example:

```

var account = new sforce.SObject("Account");
account.Name = "TestingAjaxUpsert";
account.Phone = "2837484894";
// this will insert an account
var result = sforce.connection.upsert("Id", [account]);

account.Id = result[0].id;

```

```

account.Name = "TestingAjaxUpsert2";
// this will update the account
result = sforce.connection.upsert("Id", [account]);

if(result[0].getBoolean("success") && result[0].id == account.Id) {
log("upsert updated the account as expected");
}
else {
log("upsert failed!");
}

```

retrieve Example:

```

var account = new sforce.SObject("Account");
account.Name = "retrieve update test";
account.Phone = "2837484894";
var result = sforce.connection.create([account]);
if (result[0].getBoolean("success") == false) throw "create failed";
log("account created " + result[0]);

result = sforce.connection.retrieve("Name,Phone", "Account", [result[0].id]);
if (result[0] == null) throw "retrive failed";
log("account retrieved: " + result[0]);

result[0].Phone = "111111111111";
result = sforce.connection.update(result);
if (result[0].getBoolean("success") == false) throw "update failed";
log("account updated: " + result[0]);

```

search Example:

```

var result = sforce.connection.search(
    "find {manoj} in Name fields RETURNING Account(name, id)");

if (result) {
    var records = result.getJSONArray("searchRecords");

    for (var i=0; i<records.length; i++) {
        var record = records[i].record;
        log(record.Id + " -- " + record.Name);
    }
}

```

getDeleted Example:

```

var start = new Date();
var end = new Date();
start.setDate(end.getDate() - 1);

var result = sforce.connection.getDeleted("Account", start, end);

var records = result.getJSONArray("deletedRecords");

log("following records are deleted:");

for (var i=0; i<records.length; i++) {

```

```
    log(records[i].id);  
}
```

getUpdated Example:

```
var start = new Date();  
var end = new Date();  
start.setDate(end.getDate() - 1);  
  
var result = sforce.connection.getUpdated("Account", start, end);  
  
var records = result.getJSONArray("ids");  
  
log("following records are updated:");  
for (var i=0; i<records.length; i++) {  
    log(records[i]);  
}
```

convertLead Example:

```
var account = new sforce.SObject("Account");  
account.Name = "convert lead sample";  
account.Phone = "2837484894";  
result = sforce.connection.create([account]);  
account.Id = result[0].id;  
  
var lead = new sforce.SObject("Lead");  
lead.Country = "US";  
lead.Description = "This is a description";  
lead.Email = "someone@somewhere.com";  
lead.FirstName = "first";  
lead.LastName = "last";  
lead.Company = account.Name;  
result = sforce.connection.create([lead]);  
lead.Id = result[0].id;  
  
var convert = new sforce.LeadConvert();  
convert.accountId = account.Id;  
convert.leadId = lead.Id;  
convert.convertedStatus = "Qualified";  
  
result = sforce.connection.convertLead([convert]);  
if (result[0].getBoolean("success")) {  
    log("lead converted " + result[0]);  
} else {  
    log("lead convert failed " + result[0]);  
}
```

## Describe Examples

describeSObject Account Example:

```
var result = sforce.connection.describeSObject("Account");  
  
log(result.label + " : " + result.name + " : ");
```

```

log("----- fields -----");
for (var i=0; i<result.fields.length; i++) {
    var field = result.fields[i];
    log(field.name + " : " + field.label + " : " + field.length + " : ");
}

log("----- child relationships -----");

for (var i=0; i<result.childRelationships.length; i++) {
    var cr = result.childRelationships[i];
    log(cr.field + " : " + cr.childSObject);
}

log("----- record type info -----");
for (var i=0; i<result.recordTypeInfo.length; i++) {
    var rt = result.recordTypeInfo[i];
    log(rt.name);
}

```

describeSObjects Example:

```

var result = sforce.connection.describeSObjects(["Account", "Contact"]);

for (var i=0; i<result.length; i++) {
    log(result[i].label + " : " + result[i].name + " : ");
}

```

describeGlobal Example:

```

var result = sforce.connection.describeGlobal();

var subjects = result.getJSONArray("subjects");
for (var i=0; i<subjects.length; i++) {
    log(subjects[i].name);
}

```

describeLayout Example:

```

var result = sforce.connection.describeLayout("Account");

var layouts = result.getJSONArray("layouts");

for (var i=0; i<layouts.length; i++) {
    var layout = layouts[i];
    detailLayoutSections(layout.detailLayoutSections);
}

function detailLayoutSections(sections) {
    for (var i=0; i<sections.length; i++) {
        var section = sections[i];
        log(section.columns + " : " + section.heading + " : ");
        layoutRows(section.getJSONArray("layoutRows"));
    }
}

```

```
function layoutRows(rows) {
    for (var i=0; i<rows.length; i++) {
        var row = rows[i];
        layoutItems(row.getArray("layoutItems"));
    }
}

function layoutItems(items) {
    for (var i=0; i<items.length; i++) {
        var item = items[i];
        log(" " + item.label);
    }
}
```

describeTabs Example:

```
var result = sforce.connection.describeTabs();

for (var i=0; i<result.length; i++) {
    var tabSet = result[i];
    log( tabSet.label);
    displayTabs(tabSet.get("tabs"));
}

function displayTabs(tabs) {
    for( var i=0; i<tabs.length; i++) {
        var tab = tabs[i];
        log( " " + tab.label + " " + tab.url);
    }
}
```

## Utility Examples

getServerTimestamp Example:

```
var result = sforce.connection.getServerTimestamp();
log(result.timestamp);
```

getUserInfo Example:

```
var user = sforce.connection.getUserInfo();
log("Hello " + user.userName);
log("Your email id is " + user.userEmail);
log("and you work for " + user.organizationName);
```

resetPassword and setPassword Example:

```
var username = "myname@myemail.com";

var result = sforce.connection.query(
    "SELECT ID from User WHERE User.username='" + username + "'");

var records = result.getArray("records");
if (records.length != 1) throw "unable to find user";
var id = records[0].Id;
```

```
sforce.connection.resetPassword(id);
sforce.connection.setPassword(id, "123456");
```

sendEmail Example:

```
// single mail request
var singleRequest = new sforce.SingleEmailMessage();
singleRequest.replyTo = "jsmith@acme.com";
singleRequest.subject = "sent through ajax test driver";

singleRequest.plainTextBody = "this test went through ajax";
singleRequest.toAddresses = ["noone@nowhere.com"];

// mass mail request - need to get email template ID

var queryResponse = sforce.connection.query("select id from emailtemplate");
var templatedId = queryResponse.getArray("records")[0].Id;
var massRequest = new sforce.MassEmailMessage();
massRequest.targetObjectIds = [globalContact.id];
massRequest.replyTo = "jsmith@acme.com";
massRequest.subject = "sent through ajax test driver";
massRequest.templateId = templateId;

var sendMailRes = sforce.connection.sendEmail([singleRequest, massRequest]);
```

The following sample shows best practice techniques by putting all processing in a function that does not execute until the HTML page is loaded.

```
<html>
<head>
  <script src="/soap/ajax/35.0/connection.js"></script>
  <script>
    var contactId = "{!Contact_ID}";
    function initPage() {
    try{
      var contact = sforce.connection.retrieve("AccountId", "Contact", [contactId])[0];

      var accountsRetrieved = sforce.connection.retrieve("Id, Name, Industry,
        LastModifiedDate", "Account", [contact.AccountId]);
      if (accountsRetrieved.length > 0) {
        var account = accountsRetrieved.records[0];
        document.body.innerHTML += "Account name: <a href='/' + account.Id;
        document.body.innerHTML += "' target='_blank'>" + account.Name + "</a><br>";
        document.body.innerHTML += "Industry: " + account.Industry + "<br>";
      }
    } catch (e) {
      document.body.innerHTML += "Error retrieving contact information";
      document.body.innerHTML += "<br>Fault code: " + e.faultcode;
      document.body.innerHTML += "<br>Fault string: " + e.faultstring;
    }
  }
</script>
</head>
<body onload="initPage();">
```

```
</body>
</html>
```

## Asynchronous Examples

The following examples are asynchronous calls. These samples use callback methods to the API call.

query Example:

```
var result = sforce.connection.query("Select Name,Id from User", {
    onSuccess : success,
    onFailure : failure
});

function success(result) {
    var records = result.toArray("records");

    for (var i=0; i<records.length; i++) {
        var record = records[i];
        log(record.Name + " -- " + record.Id);
    }
}

function failure(error) {
    log("An error has occurred " + error);
}
```

query Inline Function Example:

```
var result = sforce.connection.query("Select Name,Id from User", {
    onSuccess : function(result) {
        var records = result.toArray("records");

        for (var i=0; i<records.length; i++) {
            var record = records[i];
            log(record.Name + " -- " + record.Id);
        }
    },
    onFailure : function(error) {
        log("An error has occurred " + error);
    }
});
```

query With LIMIT Example:

```
var result = sforce.connection.query("Select Name, Id from Account
    order by Name limit 10", {
    onSuccess : success, onFailure : failure});

function success(result) {
    var it = new sforce.QueryResultIterator(result);
    while(it.hasNext()){
```

```

        var record = it.next();
        log(record.Name + " -- " + record.Id);
    }
}

function failure(error) {
    log("An error has occurred " + error);
}

```

queryResultIterator Example:

```

var result = sforce.connection.query("Select Name,Id from User", {
    onSuccess : success, onFailure : failure});

function success(result) {
    var it = new sforce.QueryResultIterator(result);
    while(it.hasNext()){
        var record = it.next();
        log(record.Name + " -- " + record.Id);
    }
}

function failure(error) {
    log("An error has occurred " + error);
}

```

queryMore Example:

```

sforce.connection.query("Select Name,Id from Account", {
    onSuccess : success, onFailure : log });

function success(result) {
    var records = result.getArray("records");

    var sb = new sforce.StringBuffer();
    for (var i=0; i<records.length; i++) {
        var record = records[i];
        sb.append(record.Name).append(",");
    }

    log(records.length);
    log(sb.toString());

    if (result.queryLocator) {
        sforce.connection.queryMore(result.queryLocator, {
            onSuccess : success, onFailure : log});
    }
}

```

create Example:

```

var account = new sforce.SObject("Account");
account.Name = "my new account";

sforce.connection.create([account],
    {onSuccess : success, onFailure : failed});

```

```
function success(result) {
    if (result[0].getBoolean("success")) {
        log("new account created with id " + result[0].id);
    } else {
        log("failed to create account " + result[0]);
    }
}

function failed(error) {
    log("An error has occurred " + error);
}
```

create Other Objects Example:

```
var campaign = new sforce.SObject("Campaign");
campaign.Name = "new campaign";
campaign.ActualCost = 12938.23;
campaign.EndDate = new Date();
campaign.IsActive = true;

sforce.connection.create([campaign ],
    {onSuccess : success, onFailure : log});

function success(result) {
    if (result[0].getBoolean("success")) {
        log("new campaign created with id " + result[0].id);
    } else {
        log("failed to create campaign " + result[0]);
    }
}
```

retrieve Account Example:

```
var account = new sforce.SObject("Account");
account.Name = "retrieve update test";
account.Phone = "2837484894";
var result = sforce.connection.create([account]);
if (result[0].getBoolean("success") == false) throw "create failed";
log("account created " + result[0]);

var callback = {
    onSuccess: function(result) {
        if (result[0] == null) throw "retrive failed";
        log("account retrieved: " + result[0]);
    },
    onFailure: function(error) {
        log("failed due to " + error);
    }
};

result = sforce.connection.retrieve("Name,Phone", "Account",
    [result[0].id], callback);
```

# CHAPTER 4 Using SOAP Header Options with the AJAX Toolkit

All header options in the API are supported in the toolkit, but they are specified differently than in the API. Use the following syntax for specifying header options:

- For headers that have only one option such as `CallOptions` and `QueryOptions`:

```
sforce.connection.header_option_name="value";
```

- For headers that have more than one option such as `AssignmentRuleHeader`:

```
sforce.connection.header_name = {}  
sforce.connection.header_name.header_option_name="value";
```

The following table lists each valid option and a description (and the corresponding SOAP header name in the API for your reference).

- From the `AssignmentRuleHeader`:

## **assignmentRuleId**

ID of a specific assignment rule to run for the case or lead. Can be an inactive assignment rule. The ID can be retrieved by querying the `AssignmentRule` object. If specified, do not specify `useDefaultRule`. This element is ignored for accounts, because all territory assignment rules are applied. If the value is not in correct ID format (15-character or 18-character Salesforce ID), the call fails and a `MALFORMED_ID` exception is returned.

## **useDefaultRule**

If true for a Case or Lead, uses the default (active) assignment rule for a Case or Lead. If specified, do not specify an `assignmentRuleId`. If true for an account, all territory assignment rules are applied, and if false, no territory assignment rules are applied.

- From `CallOptions`:

## **client**

A string that identifies a particular client.

## **defaultNamespace**

A string that identifies a developer namespace prefix.

- From `EmailHeader`:

## **triggerAutoResponseEmail**

Indicates whether to trigger auto-response rules (`true`) or not (`false`), for leads and cases. In the Salesforce user interface, this email can be automatically triggered by a number of events, for example resetting a user password.

## **triggerOtherEmail**

Indicates whether to trigger email outside the organization (`true`) or not (`false`). In the Salesforce user interface, this email can be automatically triggered by creating, editing, or deleting a contact for a case.

## **triggerUserEmail**

Indicates whether to trigger email that is sent to users in the organization (`true`) or not (`false`). In the Salesforce user interface, this email can be automatically triggered by a number of events; resetting a password, creating a new user, adding comments to a case, or creating or modifying a task.

- From `LoginScopeHeader`:

**organizationId**

The ID of the organization against which you will authenticate Self-Service users.

**portalId**

Specify only if user is a Customer Portal user. The ID of the portal for this organization. The ID is available in the Salesforce user interface:

- From Setup, enter *Customer Portal Settings* in the *Quick Find* box, then select **Customer Portal Settings**
- Select a Customer Portal name, and on the Customer Portal detail page, the URL of the Customer Portal displays. The Portal ID is in the URL.

- From MruHeader:

**updateMru**

Indicates whether to update the list of most recently used items (`true`) or not (`false`). For retrieve, if the result has only one row, MRU is updated to the ID of the retrieve result. For query, if the result has only one row and the ID field is selected, the MRU is updated to the ID of the query result.

- From QueryOptions:

**batchSize**

Batch size for the number of records returned in a query or queryMore call. Child objects count toward the number of records for the batch size. For example, in relationship queries, multiple child objects may be returned per parent row returned. The default is 500; the minimum is 200, and the maximum is 2,000.

- From SessionHeader:

**sessionId**

Session ID returned by the login call to be used for subsequent call authentication. Since session management is done for you by the AJAX Toolkit, most scripts won't need to use this header option.

- From UserTerritoryDeleteHeader:

**transferToUserId**

The ID of the user to whom open opportunities in that user's territory will be assigned when an opportunity's owner (user) is removed from a territory.

For more information about SOAP headers in the API, see the [SOAP API Developer's Guide](#).

# CHAPTER 5 Error Handling with the AJAX Toolkit

The AJAX Toolkit provides the ability to handle errors for synchronous and asynchronous calls:

## Error Handling for Synchronous Calls

---

If the API call fails, then the AJAX Toolkit throws an exception. The exception contains all the available error information. For example:

```
<html>
<head>
  <script src="/soap/ajax/35.0/connection.js" type="text/javascript"></script>

  <script>

    function setupPage() {
      var output = document.getElementById("output");
      var startTime = new Date().getTime()

      try {
        var queryResult = sforce.connection.query("Select Id, Name, Industry From

          Account order by Industry limit 30");
        layoutResults(queryResult, output, startTime);
      } catch(error) {
        queryFailed(error, output);
      }
    }

    function queryFailed(error, out) {
      out.innerHTML = "<font color=red>An error has occurred:</font> <p>" + error;
    }

    function layoutResults(queryResult, out, startTime) {
      var timeTaken = new Date().getTime() - startTime;

      if (queryResult.size > 0) {
        var output = "";
        var records = queryResult.getArray('records');

        for (var i = 0; i < records.length; i++) {
          var account = records[i];
          output += account.Id + " " + account.Name + " [Industry - "
            + account.Industry + "]<BR>";
        }

        out.innerHTML = output + "<BR> query complexed in: " + timeTaken + " ms.";
      } else {
        out.innerHTML = "No records matched.";
      }
    }
  </script>
</head>
<body>
  <div id="output">
  </div>
</body>
</html>
```

```
        }  
    }  
  
    </script>  
</head>  
  
    <body onload="setupPage()">  
    <div id="output"></div>  
</body>  
</html>
```

## Error Handling for Asynchronous Calls

---

For asynchronous calls, the `onFailure` property of the asynchronous object is called. For example:

```
connection.query("Select Name From Account",  
    {onSuccess: displayResult,  
      onFailure: queryFailed});  
  
function displayResult(result) {}  
function queryFailed(error) {}
```

If the `onFailure` property was not defined, the AJAX Toolkit pops up a new read-only browser window showing the error.

## CHAPTER 6 Advanced Topics

### In this chapter ...

- [QueryResultIterator](#)
- [Differences in Escaping Reserved Characters](#)
- [Working with Base64 Binary Encoded Strings](#)
- [Using the Timeout Parameter with Asynchronous Calls](#)
- [AJAX Proxy](#)

This chapter contains information about advanced activities in the AJAX Toolkit.

## QueryResultIterator

The AJAX Toolkit provides the `QueryResultIterator` object so that you can easily iterate through results without invoking `queryMore` and `queryLocator`.

You can use the `QueryResultIterator` object and functions to iterate over query results returned by the AJAX Toolkit:

```
var result = sforce.connection.query("select id, name from account");
var it = new sforce.QueryResultIterator(result);

while (it.hasNext()) {
    var account = it.next();
    sforce.debug.log(account.Name);
}
```

1. The `sforce.connection.query` method returns a `QueryResult` object.
2. A `QueryResultIterator` object is created and passed the `QueryResult` object.
3. The code iterates through the records.

## Differences in Escaping Reserved Characters

The AJAX Toolkit has special escaping rules for some reserved characters.

If you have a single quote or backslash in a string literal, you must use two backslashes instead of one to escape it. For example, the following statement in a Java client program is valid for finding account names like Bob's B-B-Q:

```
SELECT ID from ACCOUNT WHERE Name LIKE 'Bob\'s B-B-Q%'
```

But if you are using the AJAX Toolkit, you need to escape the single quote literal character twice:

```
SELECT ID from ACCOUNT WHERE Name LIKE 'Bob\\\'s B-B-Q%'
```

## Working with Base64 Binary Encoded Strings

When working with Base64 encoded binary documents, you should access the document directly using the `Id`, rather than decoding Base64 in JavaScript.

Base64 encoding and decoding is very slow in JavaScript. Also, encoding and decoding does not work correctly for binary or multibyte strings. We do not recommend that you manipulate Base64 binary encoded strings with the AJAX Toolkit. However, if you want to read a document with Base64 binary encoding, you can use the API to query for the `Id` of the document and then download it directly from the server.

The following example demonstrates how to query for the document `Id` and then download it from the server:

```
<html>
<head>
<script type="text/javascript"
src="//ajax.googleapis.com/ajax/libs/dojo/1.10.4/dojo/dojo.js"></script>
<script src="/soap/ajax/35.0/connection.js"></script>

<script>
function setup() {
```

```

var document_ta = document.getElementById("document-ta");

sforce.connection.query("select name, id from document limit 1",
  {onSuccess : querySuccess,
   onFailure : function(error, doc_ta) {
     doc_ta.value = "Oops something went wrong: " + error;
   },
   source: document_ta});
}

function querySuccess(result, doc_ta) {
  var records = result.getJSONArray("records");

  if (records.length == 1) {
    dojo.io.bind({
      url: "/servlet/servlet.FileDownload?file=" + records[0].Id,
      load: loadDocument});
  } else {
    doc_ta.value = "no records found";
  }
}

function loadDocument(type, data, event) {
  var document_ta = document.getElementById("document-ta");
  document_ta.value = data;
}

</script>
</head>

<body onload="setup()">
<textarea id="document-ta" cols="80" rows="20">
</textarea>
</body>
</html>

```

 **Note:** This example uses the JavaScript toolkit Dojo, which you'll need to upload as a static resource, reference from a CDN, or otherwise provide. For more information, see <http://dojotoolkit.org/>.

## Using the Timeout Parameter with Asynchronous Calls

If necessary, you can specify a maximum timeout for an asynchronous call with AJAX Toolkit.

If an asynchronous call does not complete in an appropriate amount of time, you can end the call. To do this, specify the `timeout` parameter in the callback section of any asynchronous call:

```

var account = new sforce.SObject("Account");
account.Name = "my new account";

sforce.connection.create([account], {onSuccess: print, onFailure: printerr, timeout: 100});

```

Values for this parameter are in milliseconds, and valid values are integers beginning with 1.

If the call is successful within the time specified by the callout, no additional actions are taken. If the call is not successful, the `onFailure` action is performed.

**Warning:** Use this parameter with caution. Because the `timeout` is performed on the client side, it is possible that the call may complete on the server but the `timeout` is still triggered. For example, you might issue a create call to create 100 new accounts, and any number of them, 1 or 100, might be created just before the `timeout` is triggered; your `onFailure` action would still occur, but the accounts would have been created.

## AJAX Proxy

AJAX Toolkit provides an AJAX proxy for browsers with external services limitations.

Some browsers don't allow JavaScript code to connect to external servers directly. Therefore, you may need to send requests through the AJAX proxy.

**Note:** To use the AJAX proxy, you must register all external services in the Salesforce user interface. From Setup, enter *Remote Site Settings* in the Quick Find box, then select **Remote Site Settings**.

For security reasons, Salesforce restricts the outbound ports you may specify to one of the following:

- 80: This port only accepts HTTP connections.
- 443: This port only accepts HTTPS connections.
- 1024–66535 (inclusive): These ports accept HTTP or HTTPS connections.

The AJAX proxy is part of the AJAX Toolkit. Access it using `remoteFunction` defined in `connection.js`. You can specify any HTTP method in `remoteFunction`, for example HTTP GET or POST, and it will be forwarded to the external service.

The following examples illustrate typical approaches for GET and POST:

GET Example:

```
sforce.connection.remoteFunction({
    url : "http://www.myExternalServer.com",
    onSuccess : function(response) {
        alert("result" + response);
    }
});
```

POST Example:

```
var envelope = ""; //request envelope, empty for this example
sforce.connection.remoteFunction({
    url : "http://services.xmethods.net:80/soap",
    requestHeaders: {"Content-Type":"text/xml",
        "SOAPAction": "\"\""},
    },
    requestData: envelope,
    method: "POST",
    onSuccess : function(response) {
        sforce.debug.log(response);
    },
    onFailure : function(response) {
        alert("Failed" + response)
    }
});
```

## remoteFunction Syntax and Parameters

AJAX proxy uses `remoteFunction` to proxy calls.

The `remoteFunction` syntax and parameters:

```
sforce.connection.remoteFunction({  
  url : endpoint_url,  
  onSuccess : callback_method  
  onFailure : error_callback  
  method : http_method  
  mimeType : "text/plain" | "text/xml"  
  async : true | false  
  requestHeaders : http_headers  
  requestData : http_post_data  
  cache : true | false  
  timeout : client_side_timeout_in_ms  
});
```

 **Note:** `cache` and `timeout` are available in version 10.0 and later.

## Downloading the Salesforce Client Certificate

When using AJAX proxy, you might need to validate Salesforce using client certificates.

Your application (endpoint) server's SSL/TLS may be configured to require client certificates (two-way SSL/TLS), in order to validate the identity of the Salesforce server when it takes the role of client to your server. If this is the case, you can download the Salesforce client certificate from the Salesforce API page.

To download the certificate, use this procedure:

- From Setup, enter *API* in the **Quick Find** box, then select **API** to display the WSDL download page.
- In the WSDL download page, right-click **Generate Client Certificate** and save it to an appropriate location on your local drive.
- Import the downloaded certificate into your application server, and configure your application server to request the client certificate. The application server then checks that the certificate used in the SSL/TLS handshake matches the one you downloaded.

 **Note:** Your application (endpoint) server must send any intermediate certificates in the certificate chain, and the certificate chain must be in the correct order. The correct order is:

1. Server certificate.
2. Intermediate certificate that signed the server certificate if the server certificate was not signed directly by a root certificate.
3. Intermediate certificate that signed the certificate in step 2.
4. Any remaining intermediate certificates. Do not include the root certificate authority certificate. The root certificate is not sent by your server. Salesforce already has its own list of trusted certificates on file, and a certificate in the chain must be signed by one of those root certificate authority certificates.

# GLOSSARY

[A](#) | [B](#) | [C](#) | [D](#) | [E](#) | [F](#) | [G](#) | [H](#) | [I](#) | [J](#) | [K](#) | [L](#) | [M](#) | [N](#) | [O](#) | [P](#) | [Q](#) | [R](#) | [S](#) | [T](#) | [U](#) | [V](#) | [W](#) | [X](#) | [Y](#) | [Z](#)

## A

---

### **AJAX Toolkit**

A JavaScript wrapper around the API that allows you to execute any API call and access any object you have permission to view from within JavaScript code. For more information, see the [AJAX Toolkit Developer's Guide](#).

### **Anonymous Block, Apex**

Apex code that does not get stored in Salesforce, but that can be compiled and executed through the use of the `ExecuteAnonymousResult()` API call, or the equivalent in the AJAX Toolkit.

### **Apex**

Apex is a strongly typed, object-oriented programming language that allows developers to execute flow and transaction control statements on the Force.com platform server in conjunction with calls to the Force.com API. Using syntax that looks like Java and acts like database stored procedures, Apex enables developers to add business logic to most system events, including button clicks, related record updates, and Visualforce pages. Apex code can be initiated by Web service requests and from triggers on objects.

### **Application Programming Interface (API)**

The interface that a computer system, library, or application provides to allow other computer programs to request services from it and exchange data.

## B

---

### **Boolean Operators**

You can use Boolean operators in report filters to specify the logical relationship between two values. For example, the AND operator between two values yields search results that include both values. Likewise, the OR operator between two values yields search results that include either value.

### **Bulk API**

The REST-based Bulk API is optimized for processing large sets of data. It allows you to query, insert, update, upsert, or delete a large number of records asynchronously by submitting a number of batches which are processed in the background by Salesforce. See also SOAP API.

## C

---

### **Callout, Apex**

An Apex callout enables you to tightly integrate your Apex with an external service by making a call to an external Web service or sending a HTTP request from Apex code and then receiving the response.

### **Child Relationship**

A relationship that has been defined on an sObject that references another sObject as the “one” side of a one-to-many relationship. For example, contacts, opportunities, and tasks have child relationships with accounts.

See also sObject.

**Class, Apex**

A template or blueprint from which Apex objects are created. Classes consist of other classes, user-defined methods, variables, exception types, and static initialization code. In most cases, Apex classes are modeled on their counterparts in Java.

**Component, Visualforce**

Something that can be added to a Visualforce page with a set of tags, for example, `<apex:detail>`. Visualforce includes a number of standard components, or you can create your own custom components.

**Component Reference, Visualforce**

A description of the standard and custom Visualforce components that are available in your organization. You can access the component library from the development footer of any Visualforce page or the [Visualforce Developer's Guide](#).

**Controller, Visualforce**

An Apex class that provides a Visualforce page with the data and business logic it needs to run. Visualforce pages can use the standard controllers that come by default with every standard or custom object, or they can use custom controllers.

**Custom Field**

A field that can be added in addition to the standard fields to customize Salesforce for your organization's needs.

**Custom Help**

Custom text administrators create to provide users with on-screen information specific to a standard field, custom field, or custom object.

**Custom Links**

Custom links are URLs defined by administrators to integrate your Salesforce data with external websites and back-office systems. Formerly known as Web links.

**Custom Object**

Custom records that allow you to store information unique to your organization.

**Custom S-Control**

**Note:** S-controls have been superseded by Visualforce pages. After March 2010 organizations that have never created s-controls, as well as new organizations, won't be allowed to create them. Existing s-controls will remain unaffected, and can still be edited.

Custom Web content for use in custom links. Custom s-controls can contain any type of content that you can display in a browser, for example a Java applet, an Active-X control, an Excel file, or a custom HTML Web form.

## D

---

**Data Loader**

A Force.com platform tool used to import and export data from your Salesforce organization.

**Data Manipulation Language (DML)**

An Apex method or operation that inserts, updates, or deletes records.

**Date Literal**

A keyword in a SOQL or SOSL query that represents a relative range of time such as `last month` or `next year`.

**Delegated Authentication**

A security process where an external authority is used to authenticate Force.com platform users.

**Developer Edition**

A free, fully-functional Salesforce organization designed for developers to extend, integrate, and develop with the Force.com platform. Developer Edition accounts are available on [developer.salesforce.com](https://developer.salesforce.com).

**Salesforce Developers**

The Salesforce Developers website at [developer.salesforce.com](https://developer.salesforce.com) provides a full range of resources for platform developers, including sample code, toolkits, an online developer community, and the ability to obtain limited Force.com platform environments.

**Document Library**

A place to store documents without attaching them to accounts, contacts, opportunities, or other records.

## E

---

**Email Alert**

Email alerts are workflow and approval actions that are generated using an email template by a workflow rule or approval process and sent to designated recipients, either Salesforce users or others.

**Email Template**

A form email that communicates a standard message, such as a welcome letter to new employees or an acknowledgement that a customer service request has been received. Email templates can be personalized with merge fields, and can be written in text, HTML, or custom format.

**Enterprise Edition**

A Salesforce edition designed for larger, more complex businesses.

**Enterprise WSDL**

A strongly-typed WSDL for customers who want to build an integration with their Salesforce organization only, or for partners who are using tools like Tibco or webMethods to build integrations that require strong typecasting. The downside of the Enterprise WSDL is that it only works with the schema of a single Salesforce organization because it is bound to all of the unique objects and fields that exist in that organization's data model.

**Entity Relationship Diagram (ERD)**

A data modeling tool that helps you organize your data into entities (or objects, as they are called in the Force.com platform) and define the relationships between them. ERD diagrams for key Salesforce objects are published in the [SOAP API Developer's Guide](#).

## F

---

**Field**

A part of an object that holds a specific piece of information, such as a text or currency value.

**Field-Level Security**

Settings that determine whether fields are hidden, visible, read only, or editable for users. Available in Enterprise, Unlimited, Performance, and Developer Editions only.

**Force.com**

The Salesforce platform for building applications in the cloud. Force.com combines a powerful user interface, operating system, and database to allow you to customize and deploy applications in the cloud for your entire enterprise.

**Foreign Key**

A field whose value is the same as the primary key of another table. You can think of a foreign key as a copy of a primary key from another table. A relationship is made between two tables by matching the values of the foreign key in one table with the values of the primary key in another.

**Formula Field**

A type of custom field. Formula fields automatically calculate their values based on the values of merge fields, expressions, or other values.

**Function**

Built-in formulas that you can customize with input parameters. For example, the DATE function creates a date field type from a given year, month, and day.

## G

---

**Gregorian Year**

A calendar based on a 12-month structure used throughout much of the world.

**Group Edition**

A product designed for small businesses and workgroups with a limited number of users.

## H

---

**HTTP Debugger**

An application that can be used to identify and inspect SOAP requests that are sent from the AJAX Toolkit. They behave as proxy servers running on your local machine and allow you to inspect and author individual requests.

## I

---

**ID**

See Salesforce Record ID.

**Inline S-Control**

**Note:** S-controls have been superseded by Visualforce pages. After March 2010 organizations that have never created s-controls, as well as new organizations, won't be allowed to create them. Existing s-controls will remain unaffected, and can still be edited.

An s-control that displays within a record detail page or dashboard, rather than on its own page.

**Instance**

The cluster of software and hardware represented as a single logical server that hosts an organization's data and runs their applications. The Force.com platform runs on multiple instances, but data for any single organization is always stored on a single instance.

**Integration User**

A Salesforce user defined solely for client apps or integrations. Also referred to as the logged-in user in a SOAP API context.

**ISO Code**

The International Organization for Standardization country code, which represents each country by two letters.

## J

---

**Junction Object**

A custom object with two master-detail relationships. Using a custom junction object, you can model a "many-to-many" relationship between two objects. For example, you may have a custom object called "Bug" that relates to the standard case object such that a bug could be related to multiple cases and a case could also be related to multiple bugs.

## K

---

No Glossary items for this entry.

## L

---

### **License Management Application (LMA)**

A free AppExchange app that allows you to track sales leads and accounts for every user who downloads your managed package (app) from the AppExchange.

### **License Management Organization (LMO)**

The Salesforce organization that you use to track all the Salesforce users who install your package. A license management organization must have the License Management Application (LMA) installed. It automatically receives notification every time your package is installed or uninstalled so that you can easily notify users of upgrades. You can specify any Enterprise, Unlimited, Performance, or Developer Edition organization as your license management organization. For more information, go to <http://www.salesforce.com/docs/en/lma/index.htm>.

### **Logged-in User**

In a SOAP API context, the username used to log into Salesforce. Client applications run with the permissions and sharing of the logged-in user. Also referred to as an integration user.

## M

---

### **Manual Sharing**

Record-level access rules that allow record owners to give read and edit permissions to other users who might not have access to the record any other way.

### **Many-to-Many Relationship**

A relationship where each side of the relationship can have many children on the other side. Many-to-many relationships are implemented through the use of junction objects.

### **Master-Detail Relationship**

A relationship between two different types of records that associates the records with each other. For example, accounts have a master-detail relationship with opportunities. This type of relationship affects record deletion, security, and makes the lookup relationship field required on the page layout.

### **Metadata**

Information about the structure, appearance, and functionality of an organization and any of its parts. Force.com uses XML to describe metadata.

### **Metadata WSDL**

A WSDL for users who want to use the Force.com Metadata API calls.

### **Multitenancy**

An application model where all users and apps share a single, common infrastructure and code base.

## N

---

### **Namespace**

In a packaging context, a one- to 15-character alphanumeric identifier that distinguishes your package and its contents from packages of other developers on AppExchange, similar to a domain name. Salesforce automatically prepends your namespace prefix, followed by two underscores ("\_\_"), to all unique component names in your Salesforce organization.

## O

---

### **Object**

An object allows you to store information in your Salesforce organization. The object is the overall definition of the type of information you are storing. For example, the case object allow you to store information regarding customer inquiries. For each object, your organization will have multiple records that store the information about specific instances of that type of data. For example, you might have a case record to store the information about Joe Smith's training inquiry and another case record to store the information about Mary Johnson's configuration issue.

### **Object-Level Help**

Custom help text that you can provide for any custom object. It displays on custom object record home (overview), detail, and edit pages, as well as list views and related lists.

### **Object-Level Security**

Settings that allow an administrator to hide whole objects from users so that they don't know that type of data exists. Object-level security is specified with object permissions.

### **One-to-Many Relationship**

A relationship in which a single object is related to many other objects. For example, an account may have one or more related contacts.

### **Organization-Wide Defaults**

Settings that allow you to specify the baseline level of data access that a user has in your organization. For example, you can set organization-wide defaults so that any user can see any record of a particular object that is enabled via their object permissions, but they need extra permissions to edit one.

### **Outbound Call**

Any call that originates from a user to a number outside of a call center in Salesforce CRM Call Center.

### **Outbound Message**

An outbound message is a workflow, approval, or milestone action that sends the information you specify to an endpoint you designate, such as an external service. Outbound messaging is configured in the Salesforce setup menu. Then you must configure the external endpoint. You can create a listener for the messages using the SOAP API.

### **Overlay**

An overlay displays additional information when you hover your mouse over certain user interface elements. Depending on the overlay, it will close when you move your mouse away, click outside of the overlay, or click a close button.

### **Owner**

Individual user to which a record (for example, a contact or case) is assigned.

## P

---

### **Parent Account**

An organization or company that an account is affiliated. By specifying a parent for an account, you can get a global view of all parent/subsidiary relationships using the **View Hierarchy** link.

### **Partner WSDL**

A loosely-typed WSDL for customers, partners, and ISVs who want to build an integration or an AppExchange app that can work across multiple Salesforce organizations. With this WSDL, the developer is responsible for marshaling data in the correct object representation, which typically involves editing the XML. However, the developer is also freed from being dependent on any particular data model or Salesforce organization. Contrast this with the Enterprise WSDL, which is strongly typed.

### **Personal Edition**

Product designed for individual sales representatives and single users.

### **Platform Edition**

A Salesforce edition based on Enterprise, Unlimited, or Performance Edition that does not include any of the standard Salesforce apps, such as Sales or Service & Support.

### **Primary Key**

A relational database concept. Each table in a relational database has a field in which the data value uniquely identifies the record. This field is called the primary key. The relationship is made between two tables by matching the values of the foreign key in one table with the values of the primary key in another.

### **Production Organization**

A Salesforce organization that has live users accessing data.

### **Professional Edition**

A Salesforce edition designed for businesses who need full-featured CRM functionality.

## Q

---

### **Queue**

A holding area for items before they are processed. Salesforce uses queues in a number of different features and technologies.

### **Query Locator**

A parameter returned from the `query()` or `queryMore()` API call that specifies the index of the last result record that was returned.

### **Query String Parameter**

A name-value pair that's included in a URL, typically after a '?' character. For example:

```
http://na1.salesforce.com/001/e?name=value
```

## R

---

### **Record**

A single instance of a Salesforce object. For example, "John Jones" might be the name of a contact record.

### **Record Name**

A standard field on all Salesforce objects. Whenever a record name is displayed in a Force.com application, the value is represented as a link to a detail view of the record. A record name can be either free-form text or an autonumber field. `Record Name` does not have to be a unique value.

**Record Type**

A record type is a field available for certain records that can include some or all of the standard and custom picklist values for that record. You can associate record types with profiles to make only the included picklist values available to users with that profile.

**Record-Level Security**

A method of controlling data in which you can allow a particular user to view and edit an object, but then restrict the records that the user is allowed to see.

**Recycle Bin**

A page that lets you view and restore deleted information. Access the Recycle Bin by using the link in the sidebar.

**Related Object**

Objects chosen by an administrator to display in the Agent console's mini view when records of a particular type are shown in the console's detail view. For example, when a case is in the detail view, an administrator can choose to display an associated account, contact, or asset in the mini view.

**Relationship**

A connection between two objects, used to create related lists in page layouts and detail levels in reports. Matching values in a specified field in both objects are used to link related data; for example, if one object stores data about companies and another object stores data about people, a relationship allows you to find out which people work at the company.

**Relationship Query**

In a SOQL context, a query that traverses the relationships between objects to identify and return results. Parent-to-child and child-to-parent syntax differs in SOQL queries.

**Report Type**

A *report type* defines the set of records and fields available to a report based on the relationships between a primary object and its related objects. Reports display only records that meet the criteria defined in the report type. Salesforce provides a set of pre-defined standard report types; administrators can create custom report types as well.

**Role Hierarchy**

A record-level security setting that defines different levels of users such that users at higher levels can view and edit information owned by or shared with users beneath them in the role hierarchy, regardless of the organization-wide sharing model settings.

**Roll-Up Summary Field**

A field type that automatically provides aggregate values from child records in a master-detail relationship.

**Running User**

Each dashboard has a *running user*, whose security settings determine which data to display in a dashboard. If the running user is a specific user, all dashboard viewers see data based on the security settings of that user—regardless of their own personal security settings. For dynamic dashboards, you can set the running user to be the logged-in user, so that each user sees the dashboard according to his or her own access level.

## S

---

**SaaS**

See Software as a Service (SaaS).

**Salesforce SOA (Service-Oriented Architecture)**

A powerful capability of Force.com that allows you to make calls to external Web services from within Apex.

**Sandbox**

A nearly identical copy of a Salesforce production organization for development, testing, and training. The content and size of a sandbox varies depending on the type of sandbox and the edition of the production organization associated with the sandbox.

**Session ID**

An authentication token that is returned when a user successfully logs in to Salesforce. The Session ID prevents a user from having to log in again every time he or she wants to perform another action in Salesforce. Different from a record ID or Salesforce ID, which are terms for the unique ID of a Salesforce record.

**Session Timeout**

The period of time after login before a user is automatically logged out. Sessions expire automatically after a predetermined length of inactivity, which can be configured in Salesforce from Setup by clicking **Security Controls**. The default is 120 minutes (two hours). The inactivity timer is reset to zero if a user takes an action in the Web interface or makes an API call.

**Setup**

A menu where administrators can customize and define organization settings and Force.com apps. Depending on your organization's user interface settings, Setup may be a link in the user interface header or in the drop-down list under your name.

**Sharing**

Allowing other users to view or edit information you own. There are different ways to share data:

- **Sharing Model**—defines the default organization-wide access levels that users have to each other's information and whether to use the hierarchies when determining access to data.
- **Role Hierarchy**—defines different levels of users such that users at higher levels can view and edit information owned by or shared with users beneath them in the role hierarchy, regardless of the organization-wide sharing model settings.
- **Sharing Rules**—allow an administrator to specify that all information created by users within a given group or role is automatically shared to the members of another group or role.
- **Manual Sharing**—allows individual users to share records with other users or groups.
- **Apex-Managed Sharing**—enables developers to programmatically manipulate sharing to support their application's behavior. See Apex-Managed Sharing.

**Sharing Model**

Behavior defined by your administrator that determines default access by users to different types of records.

**Sharing Rule**

Type of default sharing created by administrators. Allows users in a specified group or role to have access to all information created by users within a given group or role.

**Sites**

Force.com Sites enables you to create public websites and applications that are directly integrated with your Salesforce organization—without requiring users to log in with a username and password.

**SOAP (Simple Object Access Protocol)**

A protocol that defines a uniform way of passing XML-encoded data.

**Software as a Service (SaaS)**

A delivery model where a software application is hosted as a service and provided to customers via the Internet. The SaaS vendor takes responsibility for the daily maintenance, operation, and support of the application and each customer's data. The service alleviates the need for customers to install, configure, and maintain applications with their own hardware, software, and related IT resources. Services can be delivered using the SaaS model to any market segment.

**SOQL (Salesforce Object Query Language)**

A query language that allows you to construct simple but powerful query strings and to specify the criteria that should be used to select data from the Force.com database.

**SOSL (Salesforce Object Search Language)**

A query language that allows you to perform text-based searches using the Force.com API.

**Standard Object**

A built-in object included with the Force.com platform. You can also build custom objects to store information that is unique to your app.

**Syndication Feeds**

Give users the ability to subscribe to changes within Force.com sites and receive updates in external news readers.

**System Log**

Part of the Developer Console, a separate window console that can be used for debugging code snippets. Enter the code you want to test at the bottom of the window and click Execute. The body of the System Log displays system resource information, such as how long a line took to execute or how many database calls were made. If the code did not run to completion, the console also displays debugging information.

## T

---

**Test Method**

An Apex class method that verifies whether a particular piece of code is working properly. Test methods take no arguments, commit no data to the database, and can be executed by the `runTests()` system method either through the command line or in an Apex IDE, such as the Force.com IDE.

**Translation Workbench**

The Translation Workbench lets you specify languages you want to translate, assign translators to languages, create translations for customizations you've made to your Salesforce organization, and override labels and translations from managed packages. Everything from custom picklist values to custom fields can be translated so your global users can use all of Salesforce in their language.

**Trigger**

A piece of Apex that executes before or after records of a particular type are inserted, updated, or deleted from the database. Every trigger runs with a set of context variables that provide access to the records that caused the trigger to fire, and all triggers run in bulk mode—that is, they process several records at once, rather than just one record at a time.

**Trigger Context Variable**

Default variables that provide access to information about the trigger and the records that caused it to fire.

## U

---

**Unit Test**

A unit is the smallest testable part of an application, usually a method. A unit test operates on that piece of code to make sure it works correctly. See also Test Method.

**Unlimited Edition**

Unlimited Edition is Salesforce's solution for maximizing your success and extending that success across the entire enterprise through the Force.com platform.

## V

---

**Validation Rule**

A rule that prevents a record from being saved if it does not meet the standards that are specified.

**Visualforce**

A simple, tag-based markup language that allows developers to easily define custom pages and components for apps built on the platform. Each tag corresponds to a coarse or fine-grained component, such as a section of a page, a related list, or a field. The

components can either be controlled by the same logic that is used in standard Salesforce pages, or developers can associate their own logic with a controller written in Apex.

## W

---

### **Web Service**

A mechanism by which two applications can easily exchange data over the Internet, even if they run on different platforms, are written in different languages, or are geographically remote from each other.

### **WebService Method**

An Apex class method or variable that can be used by external systems, like a mash-up with a third-party application. Web service methods must be defined in a global class.

### **Web Services API**

A Web services application programming interface that provides access to your Salesforce organization's information. See also SOAP API and Bulk API.

### **Workflow and Approval Actions**

Workflow and approval actions, such as email alerts, tasks, field updates, and outbound messages, can be triggered by a workflow rule or approval process.

### **Workflow Action**

A workflow action, such as an email alert, field update, outbound message, or task, fires when the conditions of a workflow rule are met.

### **Workflow Email Alert**

A workflow action that sends an email when a workflow rule is triggered. Unlike workflow tasks, which can only be assigned to application users, workflow alerts can be sent to any user or contact, as long as they have a valid email address.

### **Workflow Field Update**

A workflow action that changes the value of a particular field on a record when a workflow rule is triggered.

### **Workflow Outbound Message**

A workflow action that sends data to an external Web service, such as another cloud computing application. Outbound messages are used primarily with composite apps.

### **Workflow Queue**

A list of workflow actions that are scheduled to fire based on workflow rules that have one or more time-dependent workflow actions.

### **Workflow Rule**

A workflow rule sets workflow actions into motion when its designated conditions are met. You can configure workflow actions to execute immediately when a record meets the conditions in your workflow rule, or set time triggers that execute the workflow actions on a specific day.

### **Workflow Task**

A workflow action that assigns a task to an application user when a workflow rule is triggered.

### **Wrapper Class**

A class that abstracts common functions such as logging in, managing sessions, and querying and batching records. A wrapper class makes an integration more straightforward to develop and maintain, keeps program logic in one place, and affords easy reuse across components. Examples of wrapper classes in Salesforce include the `AJAX Toolkit`, which is a JavaScript wrapper around the Salesforce SOAP API, wrapper classes such as `CCriticalSection` in the CTI Adapter for Salesforce CRM Call Center, or wrapper classes created as part of a client integration application that accesses Salesforce using the SOAP API.

**WSDL (Web Services Description Language) File**

An XML file that describes the format of messages you send and receive from a Web service. Your development environment's SOAP client uses the Salesforce Enterprise WSDL or Partner WSDL to communicate with Salesforce using the SOAP API.

## C

- callback function
  - and API calls [10](#)
  - defined [1](#)
  - in sample s-control [3](#)
- Calls
  - API with AJAX Toolkit [10](#)
  - different syntax with AJAX Toolkit [11](#)
- Client certificate download [34](#)
- client header option [26](#)
- Connecting to AJAX Toolkit [6](#)
- connection.js [6](#)
- Context variable source [12](#)

## D

- Data types
  - Base64 issues [12](#)
  - converting [12](#)
- Debugging window [12](#)

## E

- Embedding calls in JavaScript [7](#)
- Error handling [28](#)

## G

- get method [11](#)
- Getting started [7](#)
- Getting started examples [7](#)

## H

- Header options for SOAP messages [26](#)

## I

- Introduction [1](#)

## L

- log method [12](#)

## O

- Object functions [11](#)
- onclick JavaScript button [6](#)
- organizationId header option [26](#)
- Other resources [2](#)
- Outbound port restrictions [33](#)

## P

- Port restrictions [33](#)
- Processing results [8](#)
- Proxy for AJAX [33](#)

## Q

- queryLocator, see [QueryResultIterator](#) [31](#)
- queryMore, see [QueryResultIterator](#) [31](#)
- [QueryResultIterator](#) [31](#)

## R

- remoteFunction [34](#)
- requireScript [6](#)
- Reserved characters, differences in escaping [31](#)
- Resources for developers [2](#)
- Results processing [8](#)

## S

- S-control sample [3](#)
- Samples
  - asynchronous calls [23](#)
  - how to use [12](#)
  - s-control [3](#)
  - synchronous calls [13](#)
- sessionId header option [26](#)
- set method [11](#)
- SOAP headers [26](#)
- source context variable [12](#)
- Support policy [2](#)

## Index

Synchronous calls  
  error handling [28](#)  
  introduction [10](#)  
  samples [13](#)

## T

timeout parameter with asynchronous calls [32](#)  
transferToUserId [26](#)  
triggerAutoResponseEmail header option [26](#)  
triggerOtherEmail header option [26](#)

triggerUserEmail [26](#)  
Typographical conventions [2](#)

## U

updateMru header option [26](#)  
useDefaultRule header option [26](#)

## W

When to use the AJAX Toolkit [2](#)
