IN THIS SECTION:

getDefaultValue()
Returns the default value for the standard filter picklist.

getFilterValues()
Returns a list of standard filter picklist values.

getLabel()
Returns the display name of the standard filter picklist.

getType()
Returns the type of the standard filter picklist.

`getDefaultValue()`

Returns the default value for the standard filter picklist.

Signature

```
public String getDefaultValue()
```

Return Value

Type: String

`getFilterValues()`

Returns a list of standard filter picklist values.

Signature

```
public List<Reports.FilterValue> getFilterValues()
```

Return Value

Type: List<Reports.FilterValue>

`getLabel()`

Returns the display name of the standard filter picklist.

Signature

```
public String getLabel()
```

Return Value

Type: String

`getType()`

Returns the type of the standard filter picklist.

Signature

```
public Reports.StandardFilterType getType()
```

Return Value

Type: Reports.StandardFilterType

StandardFilterType Enum

The `StandardFilterType` enum describes the type of standard filters in a report. The `getType()` method returns a `Reports.StandardFilterType` enum value.

Namespace

Reports

Enum Values

The following are the values of the `Reports.StandardFilterType` enum.

Value	Description
`PICKLIST`	Values for the standard filter type.
`STRING`	String values.

SummaryValue Class

Contains summary data for a cell of the report.

Namespace

Reports

SummaryValue Methods

The following are methods for `SummaryValue`. All are instance methods.

IN THIS SECTION:

getLabel()
Returns the formatted summary data for a specified cell.

getValue()
Returns the numeric value of the summary data for a specified cell.

`getLabel()`

Returns the formatted summary data for a specified cell.

Syntax

```
public String getLabel()
```

Return Value

Type: String

`getValue()`

Returns the numeric value of the summary data for a specified cell.

Syntax

```
public Object getValue()
```

Return Value

Type: Object

ThresholdInformation Class

Contains a list of evaluated conditions for a report notification.

Namespace

Reports

IN THIS SECTION:

ThresholdInformation Constructors

ThresholdInformation Methods

ThresholdInformation Constructors

The following are constructors for `ThresholdInformation`.

IN THIS SECTION:

ThresholdInformation(evaluatedConditions)
Creates a new instance of the `Reports.EvaluatedCondition` class.

`ThresholdInformation(evaluatedConditions)`

Creates a new instance of the `Reports.EvaluatedCondition` class.

Signature

```
public ThresholdInformation(List<Reports.EvaluatedCondition> evaluatedConditions)
```

Parameters

`evaluatedConditions`
Type: List<Reports.EvaluatedCondition>

A list of `Reports.EvaluatedCondition` objects.

ThresholdInformation Methods

The following are methods for `ThresholdInformation`.

IN THIS SECTION:

getEvaluatedConditions()
Returns a list of evaluated conditions for a report notification.

`getEvaluatedConditions()`

Returns a list of evaluated conditions for a report notification.

Signature

```
public List<Reports.EvaluatedCondition> getEvaluatedConditions()
```

Return Value

Type: List<Reports.EvaluatedCondition>

TopRows Class

Contains methods and constructors for working with information about a row limit filter.

Namespace

Reports

IN THIS SECTION:

TopRows Constructors

TopRows Methods

TopRows Constructors

The following are constructors for `TopRows`.

IN THIS SECTION:

TopRows(rowLimit, direction)

Creates an instance of the `Reports.TopRows` class using the specified parameters.

TopRows()

Creates an instance of the `Reports.TopRows` class. You can then set values by using the class's `set` methods.

`TopRows(rowLimit, direction)`

Creates an instance of the `Reports.TopRows` class using the specified parameters.

Signature

```
public TopRows(Integer rowLimit, Reports.ColumnSortOrder direction)
```

Parameters

`rowLimit`
Type: Integer

The number of rows returned in the report.

`direction`
Type: Reports.ColumnSortOrder

The sort order of the report rows.

`TopRows()`

Creates an instance of the `Reports.TopRows` class. You can then set values by using the class's `set` methods.

Signature

```
public TopRows()
```

TopRows Methods

The following are methods for `TopRows`.

IN THIS SECTION:

getDirection()
Returns the sort order of the report rows.

getRowLimit()
Returns the maximum number of rows shown in the report.

setDirection(value)
Sets the sort order of the report's rows.

setDirection(direction)
Sets the sort order of the report's rows.

setRowLimit(rowLimit)
Sets the maximum number of rows included in the report.

toString()
Returns a string.

getDirection()

Returns the sort order of the report rows.

Signature

```
public Reports.ColumnSortOrder getDirection()
```

Return Value

Type: Reports.ColumnSortOrder

getRowLimit()

Returns the maximum number of rows shown in the report.

Signature

```
public Integer getRowLimit()
```

Return Value

Type: Integer

setDirection(value)

Sets the sort order of the report's rows.

Signature

```
public void setDirection(String value)
```

Parameters

value
Type: String

For possible values, see Reports.ColumnSortOrder.

Return Value

Type: void

setDirection(direction)

Sets the sort order of the report's rows.

Signature

```
public void setDirection(Reports.ColumnSortOrder direction)
```

Parameters

direction
Type: Reports.ColumnSortOrder

Return Value

Type: void

setRowLimit(rowLimit)

Sets the maximum number of rows included in the report.

Signature

```
public void setRowLimit(Integer rowLimit)
```

Parameters

rowLimit
Type: Integer

Return Value

Type: void

toString()

Returns a string.

Signature

```
public String toString()
```

Return Value

Type: String

Reports Exceptions

The `Reports` namespace contains exception classes.

All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions on page 2649.

The `Reports` namespace contains these exceptions:

Exception	Description	Methods
`Reports.FeatureNotSupportedException`	Invalid report format	
`Reports.InstanceAccessException`	Unable to access report instance	
`Reports.InvalidFilterException`	Filter validation error	`List<String> getFilterErrors()` returns a list of filter errors
`Reports.InvalidReportMetadataException`	Missing metadata for filters	`List<String> getReportMetadataErrors()` returns a list of metadata errors
`Reports.InvalidSnapshotDateException`	Invalid historical report format	`List<String> getSnapshotDateErrors()` returns a list of snapshot date errors
`Reports.MetadataException`	No selected report columns	
`Reports.ReportRunException`	Error running report	
`Reports.UnsupportedOperationException`	Missing permissions for running reports	

Schema Namespace

The `Schema` namespace provides classes and methods for schema metadata information.

The following are the classes in the `Schema` namespace.

IN THIS SECTION:

ChildRelationship Class

Contains methods for accessing the child relationship as well as the child sObject for a parent sObject.

DataCategory Class

Represents the categories within a category group.

DataCategoryGroupSobjectTypePair Class

Specifies a category group and an associated object.

DescribeColorResult Class

Contains color metadata information for a tab.

DescribeDataCategoryGroupResult Class

Contains the list of the category groups associated with KnowledgeArticleVersion and Question.

DescribeDataCategoryGroupStructureResult Class

Contains the category groups and categories associated with KnowledgeArticleVersion and Question.

DescribeFieldResult Class

Contains methods for describing sObject fields.

DescribeIconResult Class

Contains icon metadata information for a tab.

DescribeSObjectResult Class

Contains methods for describing sObjects.

DescribeTabResult Class

Contains tab metadata information for a tab in a standard or custom app available in the Salesforce user interface.

DescribeTabSetResult Class

Contains metadata information about a standard or custom app available in the Salesforce user interface.

DisplayType Enum

A `Schema.DisplayType` enum value is returned by the field describe result's `getType` method.

FieldSet Class

Contains methods for discovering and retrieving the details of field sets created on sObjects.

FieldSetMember Class

Contains methods for accessing the metadata for field set member fields.

PicklistEntry Class

Represents a picklist entry.

RecordTypeInfo Class

Contains methods for accessing record type information for an sObject with associated record types.

SOAPType Enum

A `Schema.SOAPType` enum value is returned by the field describe result `getSoapType` method.

SObjectField Class

A `Schema.sObjectField` object is returned from the field describe result using the `getControler` and `getSObjectField` methods.

SObjectType Class

A `Schema.sObjectType` object is returned from the field describe result using the `getReferenceTo` method, or from the sObject describe result using the `getSObjectType` method.

ChildRelationship Class

Contains methods for accessing the child relationship as well as the child sObject for a parent sObject.

Namespace

Schema

Example

A ChildRelationship object is returned from the sObject describe result using the `getChildRelationship` method. For example:

```
Schema.DescribeSObjectResult R = Account.SObjectType.getDescribe();
List<Schema.ChildRelationship> C = R.getChildRelationships();
```

ChildRelationship Methods

The following are methods for `ChildRelationship`. All are instance methods.

IN THIS SECTION:

getChildSObject()
Returns the token of the child sObject on which there is a foreign key back to the parent sObject.

getField()
Returns the token of the field that has a foreign key back to the parent sObject.

getRelationshipName()
Returns the name of the relationship.

isCascadeDelete()
Returns `true` if the child object is deleted when the parent object is deleted, `false` otherwise.

isDeprecatedAndHidden()
Reserved for future use.

isRestrictedDelete()
Returns `true` if the parent object can't be deleted because it is referenced by a child object, `false` otherwise.

`getChildSObject()`

Returns the token of the child sObject on which there is a foreign key back to the parent sObject.

Signature

```
public Schema.SObjectType getChildSObject()
```

Return Value

Type: Schema.SObjectType

`getField()`

Returns the token of the field that has a foreign key back to the parent sObject.

Signature

```
public Schema.SObjectField getField()
```

Return Value

Type: Schema.SObjectField

getRelationshipName()

Returns the name of the relationship.

Signature

```
public String getRelationshipName()
```

Return Value

Type: String

isCascadeDelete()

Returns `true` if the child object is deleted when the parent object is deleted, `false` otherwise.

Signature

```
public Boolean isCascadeDelete()
```

Return Value

Type: Boolean

isDeprecatedAndHidden()

Reserved for future use.

Signature

```
public Boolean isDeprecatedAndHidden()
```

Return Value

Type: Boolean

isRestrictedDelete()

Returns `true` if the parent object can't be deleted because it is referenced by a child object, `false` otherwise.

Signature

```
public Boolean isRestrictedDelete()
```

Return Value

Type: Boolean

DataCategory Class

Represents the categories within a category group.

Namespace

Schema

Usage

The `Schema.DataCategory` object is returned by the `getTopCategories` method.

DataCategory Methods

The following are methods for `DataCategory`. All are instance methods.

IN THIS SECTION:

getChildCategories()
Returns a recursive object that contains the visible sub categories in the data category.

getLabel()
Returns the label for the data category used in the Salesforce user interface.

getName()
Returns the unique name used by the API to access to the data category.

`getChildCategories()`

Returns a recursive object that contains the visible sub categories in the data category.

Signature

```
public Schema.DataCategory getChildCategories()
```

Return Value

Type: List<Schema.DataCategory>

`getLabel()`

Returns the label for the data category used in the Salesforce user interface.

Signature

```
public String getLabel()
```

Return Value

Type: String

`getName()`

Returns the unique name used by the API to access to the data category.

Signature

```
public String getName()
```

Return Value

Type: String

DataCategoryGroupSobjectTypePair Class

Specifies a category group and an associated object.

Namespace

Schema

Usage

Schema.DataCategoryGroupSobjectTypePair is used by the `describeDataCategory GroupStructures` method to return the categories available to this object.

IN THIS SECTION:

DataCategoryGroupSobjectTypePair Constructors

DataCategoryGroupSobjectTypePair Methods

DataCategoryGroupSobjectTypePair Constructors

The following are constructors for `DataCategoryGroupSobjectTypePair`.

IN THIS SECTION:

DataCategoryGroupSobjectTypePair()
Creates a new instance of the `Schema.DataCategoryGroupSobjectTypePair` class.

`DataCategoryGroupSobjectTypePair()`

Creates a new instance of the `Schema.DataCategoryGroupSobjectTypePair` class.

Signature

```
public DataCategoryGroupSobjectTypePair()
```

DataCategoryGroupSobjectTypePair Methods

The following are methods for `DataCategoryGroupSobjectTypePair`. All are instance methods.

IN THIS SECTION:

getDataCategoryGroupName()
Returns the unique name used by the API to access the data category group.

getSobject()
Returns the object name associated with the data category group.

setDataCategoryGroupName(name)
Specifies the unique name used by the API to access the data category group.

setSobject(sObjectName)
Sets the sObject associated with the data category group.

getDataCategoryGroupName()

Returns the unique name used by the API to access the data category group.

Signature

```
public String getDataCategoryGroupName()
```

Return Value

Type: String

getSobject()

Returns the object name associated with the data category group.

Signature

```
public String getSobject()
```

Return Value

Type: String

setDataCategoryGroupName(name)

Specifies the unique name used by the API to access the data category group.

Signature

```
public String setDataCategoryGroupName(String name)
```

Parameters

name
Type: String

Return Value

Type: Void

`setSobject(sObjectName)`

Sets the sObject associated with the data category group.

Signature

```
public Void setSobject(String sObjectName)
```

Parameters

`sObjectName`
Type: String

The *`sObjectName`* is the object name associated with the data category group. Valid values are:

- `KnowledgeArticleVersion`—for article types.
- `Question`—for questions from Answers.

Return Value

Type: Void

DescribeColorResult Class

Contains color metadata information for a tab.

Namespace

Schema

Usage

The `getColors` method of the `Schema.DescribeTabResult` class returns a list of `Schema.DescribeColorResult` objects that describe colors used in a tab.

The methods in the `Schema.DescribeColorResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses `()` to call the property counterpart. For example, `colorResultObj.color` is equivalent to `colorResultObj.getColor()`.

Example

This sample shows how to get the color information in the Sales app for the first tab's first color.

```
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.DescribeTabs();

// Iterate through each tab set describe for each app and display the info
for(Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Display tab info for the Sales app
```

```
    if (tsr.getLabel() == 'Sales') {
        // Get color information for the first tab
        List<Schema.DescribeColorResult> colorDesc = tsr.getTabs()[0].getColors();
        // Display the icon color, theme, and context of the first color returned
        System.debug('Color: ' + colorDesc[0].getColor());
        System.debug('Theme: ' + colorDesc[0].getTheme());
        System.debug('Context: ' + colorDesc[0].getContext());
    }
}

// Example debug statement output
// DEBUG|Color: 1797C0
// DEBUG|Theme: theme4
// DEBUG|Context: primary
```

DescribeColorResult Methods

The following are methods for `DescribeColorResult`. All are instance methods.

IN THIS SECTION:

getColor()
Returns the Web RGB color code, such as `00FF00`.

getContext()
Returns the color context. The context determines whether the color is the main color for the tab or not.

getTheme()
Returns the color theme.

`getColor()`

Returns the Web RGB color code, such as `00FF00`.

Signature

```
public String getColor()
```

Return Value

Type: String

`getContext()`

Returns the color context. The context determines whether the color is the main color for the tab or not.

Signature

```
public String getContext()
```

Return Value

Type: String

`getTheme()`

Returns the color theme.

Signature

```
public String getTheme()
```

Return Value

Type: String

Possible theme values include `theme3`, `theme4`, and `custom`.

- `theme3` is the Salesforce theme introduced during Spring '10.
- `theme4` is the Salesforce theme introduced in Winter '14 for the mobile touchscreen version of Salesforce.
- `custom` is the theme name associated with a custom icon.

DescribeDataCategoryGroupResult Class

Contains the list of the category groups associated with KnowledgeArticleVersion and Question.

Namespace

Schema

Usage

The `describeDataCategoryGroups` method returns a `Schema.DescribeDataCategoryGroupResult` object containing the list of the category groups associated with the specified object.

For additional information and code examples using `describeDataCategoryGroups`, see Accessing All Data Categories Associated with an sObject.

Example

The following is an example of how to instantiate a data category group describe result object:

```
List <String> objType = new List<String>();
objType.add('KnowledgeArticleVersion');
objType.add('Question');

List<Schema.DescribeDataCategoryGroupResult> describeCategoryResult =
   Schema.describeDataCategoryGroups(objType);
```

DescribeDataCategoryGroupResult Methods

The following are methods for `DescribeDataCategoryGroupResult`. All are instance methods.

IN THIS SECTION:

getCategoryCount()
Returns the number of visible data categories in the data category group.

getDescription()
Returns the description of the data category group.

getLabel()
Returns the label for the data category group used in the Salesforce user interface.

getName()
Returns the unique name used by the API to access to the data category group.

getSobject()
Returns the object name associated with the data category group.

getCategoryCount()

Returns the number of visible data categories in the data category group.

Signature

```
public Integer getCategoryCount()
```

Return Value

Type: Integer

getDescription()

Returns the description of the data category group.

Signature

```
public String getDescription()
```

Return Value

Type: String

getLabel()

Returns the label for the data category group used in the Salesforce user interface.

Signature

```
public String getLabel()
```

Return Value

Type: String

`getName()`

Returns the unique name used by the API to access to the data category group.

Signature

```
public String getName()
```

Return Value

Type: String

`getSobject()`

Returns the object name associated with the data category group.

Signature

```
public String getSobject()
```

Return Value

Type: String

DescribeDataCategoryGroupStructureResult Class

Contains the category groups and categories associated with KnowledgeArticleVersion and Question.

Namespace

Schema

Usage

The `describeDataCategoryGroupStructures` method returns a list of `Schema.DescribeDataCategoryGroupStructureResult` objects containing the category groups and categories associated with the specified object.

For additional information and code examples, see Accessing All Data Categories Associated with an sObject.

Example

The following is an example of how to instantiate a data category group structure describe result object:

```
List <DataCategoryGroupSobjectTypePair> pairs =
      new List<DataCategoryGroupSobjectTypePair>();

DataCategoryGroupSobjectTypePair pair1 =
      new DataCategoryGroupSobjectTypePair();
pair1.setSobject('KnowledgeArticleVersion');
pair1.setDataCategoryGroupName('Regions');
```

```
DataCategoryGroupSobjectTypePair pair2 =
      new DataCategoryGroupSobjectTypePair();
pair2.setSobject('Questions');
pair2.setDataCategoryGroupName('Regions');

pairs.add(pair1);
pairs.add(pair2);

List<Schema.DescribeDataCategoryGroupStructureResult>results =
      Schema.describeDataCategoryGroupStructures(pairs, true);
```

DescribeDataCategoryGroupStructureResult Methods

The following are methods for `DescribeDataCategoryGroupStructureResult`. All are instance methods.

IN THIS SECTION:

getDescription()
Returns the description of the data category group.

getLabel()
Returns the label for the data category group used in the Salesforce user interface.

getName()
Returns the unique name used by the API to access to the data category group.

getSobject()
Returns the name of object associated with the data category group.

getTopCategories()
Returns a `Schema.DataCategory` object, that contains the top categories visible depending on the user's data category group visibility settings.

`getDescription()`

Returns the description of the data category group.

Signature

```
public String getDescription()
```

Return Value

Type: String

`getLabel()`

Returns the label for the data category group used in the Salesforce user interface.

Signature

```
public String getLabel()
```

Return Value

Type: String

getName()

Returns the unique name used by the API to access to the data category group.

Signature

```
public String getName()
```

Return Value

Type: String

getSobject()

Returns the name of object associated with the data category group.

Signature

```
public String getSobject()
```

Return Value

Type: String

getTopCategories()

Returns a `Schema.DataCategory` object, that contains the top categories visible depending on the user's data category group visibility settings.

Signature

```
public List<Schema.DataCategory> getTopCategories()
```

Return Value

Type: List<Schema.DataCategory>

Usage

For more information on data category group visibility, see "Data Category Visibility" in the Salesforce online help.

DescribeFieldResult Class

Contains methods for describing sObject fields.

Namespace

Schema

Example

The following is an example of how to instantiate a field describe result object:

```
Schema.DescribeFieldResult dfr = Account.Description.getDescribe();
```

DescribeFieldResult Methods

The following are methods for `DescribeFieldResult`. All are instance methods.

IN THIS SECTION:

getByteLength()
For variable-length fields (including binary fields), returns the maximum size of the field, in bytes.

getCalculatedFormula()
Returns the formula specified for this field.

getController()
Returns the token of the controlling field.

getDefaultValue()
Returns the default value for this field.

getDefaultValueFormula()
Returns the default value specified for this field if a formula is not used.

getDigits()
Returns the maximum number of digits specified for the field. This method is only valid with Integer fields.

getInlineHelpText()
Returns the content of the field-level help.

getLabel()
Returns the text label that is displayed next to the field in the Salesforce user interface. This label can be localized.

getLength()
Returns the maximum size of the field for the DescribeFieldResult object in Unicode characters (not bytes) or 40, whichever is less. The maximum value returned by the getLength() method is 40, even if the field's maximum length is greater than 40.

getLocalName()
Returns the name of the field, similar to the `getName` method. However, if the field is part of the current namespace, the namespace portion of the name is omitted.

getName()
Returns the field name used in Apex.

getPicklistValues()
Returns a list of PicklistEntry objects. A runtime error is returned if the field is not a picklist.

getPrecision()
For fields of type Double, returns the maximum number of digits that can be stored, including all numbers to the left and to the right of the decimal point (but excluding the decimal point character).

getReferenceTargetField()

Returns the name of the custom field on the parent standard or custom object whose values are matched against the values of the child external object's indirect lookup relationship field. The match is done to determine which records are related to each other.

getReferenceTo()

Returns a list of Schema.sObjectType objects for the parent objects of this field. If the `isNamePointing` method returns `true`, there is more than one entry in the list, otherwise there is only one.

getRelationshipName()

Returns the name of the relationship.

getRelationshipOrder()

Returns 1 if the field is a child, 0 otherwise.

getScale()

For fields of type Double, returns the number of digits to the right of the decimal point. Any extra digits to the right of the decimal point are truncated.

getSOAPType()

Returns one of the SoapType enum values, depending on the type of field.

getSObjectField()

Returns the token for this field.

getType()

Returns one of the DisplayType enum values, depending on the type of field.

isAccessible()

Returns `true` if the current user can see this field, `false` otherwise.

isAiPredictionField() (Beta)

Returns `true` if the current field is enabled to display Einstein prediction data, `false` otherwise.

isAutoNumber()

Returns `true` if the field is an Auto Number field, `false` otherwise.

isCalculated()

Returns `true` if the field is a custom formula field, `false` otherwise. Note that custom formula fields are always read-only.

isCascadeDelete()

Returns `true` if the child object is deleted when the parent object is deleted, `false` otherwise.

isCaseSensitive()

Returns `true` if the field is case sensitive, `false` otherwise.

isCreateable()

Returns `true` if the field can be created by the current user, `false` otherwise.

isCustom()

Returns `true` if the field is a custom field, `false` if it is a standard field, such as `Name`.

isDefaultedOnCreate()

Returns `true` if the field receives a default value when created, `false` otherwise.

isDependentPicklist()

Returns `true` if the picklist is a dependent picklist, `false` otherwise.

isDeprecatedAndHidden()

Reserved for future use.

isExternalID()

Returns `true` if the field is used as an external ID, `false` otherwise.

isFilterable()

Returns `true` if the field can be used as part of the filter criteria of a `WHERE` statement, `false` otherwise.

isFormulaTreatNullNumberAsZero()

Returns `true` if `null` is treated as zero in a formula field, `false` otherwise.

isGroupable()

Returns `true` if the field can be included in the `GROUP BY` clause of a SOQL query, `false` otherwise. This method is only available for Apex classes and triggers saved using API version 18.0 and higher.

isHtmlFormatted()

Returns `true` if the field has been formatted for HTML and should be encoded for display in HTML, `false` otherwise. One example of a field that returns `true` for this method is a hyperlink custom formula field. Another example is a custom formula field that has an `IMAGE` text function.

isIdLookup()

Returns `true` if the field can be used to specify a record in an `upsert` method, `false` otherwise.

isNameField()

Returns `true` if the field is a name field, `false` otherwise.

isNamePointing()

Returns `true` if the field can have multiple types of objects as parents. For example, a task can have both the `Contact/Lead ID` (`WhoId`) field and the `Opportunity/Account ID` (`WhatId`) field return `true` for this method. because either of those objects can be the parent of a particular task record. This method returns `false` otherwise.

isNillable()

Returns `true` if the field is nillable, `false` otherwise. A nillable field can have empty content. A non-nillable field must have a value for the object to be created or saved.

isPermissionable()

Returns `true` if field permissions can be specified for the field, `false` otherwise.

isRestrictedDelete()

Returns `true` if the parent object can't be deleted because it is referenced by a child object, `false` otherwise.

isRestrictedPicklist()

Returns `true` if the field is a restricted picklist, `false` otherwise

isSearchPrefilterable()

Returns `true` if a foreign key can be included in prefiltering when used in a SOSL `WHERE` clause, `false` otherwise.

isSortable()

Returns `true` if a query can sort on the field, `false` otherwise

isUnique()

Returns `true` if the value for the field must be unique, `false` otherwise

isUpdateable()

Returns `true` if the field can be edited by the current user, or child records in a master-detail relationship field on a custom object can be reparented to different parent records; `false` otherwise.

isWriteRequiresMasterRead()

Returns `true` if writing to the detail object requires read sharing instead of read/write sharing of the parent.

getByteLength()

For variable-length fields (including binary fields), returns the maximum size of the field, in bytes.

Signature

```
public Integer getByteLength()
```

Return Value

Type: Integer

getCalculatedFormula()

Returns the formula specified for this field.

Signature

```
public String getCalculatedFormula()
```

Return Value

Type: String

getController()

Returns the token of the controlling field.

Signature

```
public Schema.sObjectField getController()
```

Return Value

Type: Schema.SObjectField

getDefaultValue()

Returns the default value for this field.

Signature

```
public Object getDefaultValue()
```

Return Value

Type: Object

getDefaultValueFormula()

Returns the default value specified for this field if a formula is not used.

Signature

```
public String getDefaultValueFormula()
```

Return Value

Type: String

getDigits()

Returns the maximum number of digits specified for the field. This method is only valid with Integer fields.

Signature

```
public Integer getDigits()
```

Return Value

Type: Integer

getInlineHelpText()

Returns the content of the field-level help.

Signature

```
public String getInlineHelpText()
```

Return Value

Type: String

Usage

For more information, see "Define Field-Level Help" in the Salesforce online help.

getLabel()

Returns the text label that is displayed next to the field in the Salesforce user interface. This label can be localized.

Signature

```
public String getLabel()
```

Return Value

Type: String

Usage

Note: For the Type field on standard objects, `getLabel` returns a label different from the default label. It returns a label of the form *`Object Type`*, where *Object* is the standard object label. For example, for the Type field on Account, `getLabel` returns

`Account Type` instead of the default label `Type`. If the Type label is renamed, `getLabel` returns the new label. You can check or change the labels of all standard object fields from Setup by entering *`Rename Tabs and Labels`* in the `Quick Find box`, then selecting **Rename Tabs and Labels**.

getLength()

Returns the maximum size of the field for the DescribeFieldResult object in Unicode characters (not bytes) or 40, whichever is less. The maximum value returned by the getLength() method is 40, even if the field's maximum length is greater than 40.

Signature

```
public Integer getLength()
```

Return Value

Type: Integer

Usage

For example, the length of the FinancialPackage__Account_Id field is 27, so getLength() returns 27 for this field. However, the length of the FinancialPackage__Account_Revenue_Forecast__c field is 45, so getLength() returns 40 in this case.

getLocalName()

Returns the name of the field, similar to the `getName` method. However, if the field is part of the current namespace, the namespace portion of the name is omitted.

Signature

```
public String getLocalName()
```

Return Value

Type: String

getName()

Returns the field name used in Apex.

Signature

```
public String getName()
```

Return Value

Type: String

getPicklistValues()

Returns a list of PicklistEntry objects. A runtime error is returned if the field is not a picklist.

Signature

```
public List<Schema.PicklistEntry> getPicklistValues()
```

Return Value

Type: List<Schema.PicklistEntry>

getPrecision()

For fields of type Double, returns the maximum number of digits that can be stored, including all numbers to the left and to the right of the decimal point (but excluding the decimal point character).

Signature

```
public Integer getPrecision()
```

Return Value

Type: Integer

getReferenceTargetField()

Returns the name of the custom field on the parent standard or custom object whose values are matched against the values of the child external object's indirect lookup relationship field. The match is done to determine which records are related to each other.

Signature

```
public String getReferenceTargetField()
```

Return Value

Type: String

Usage

For information about indirect lookup relationships, see "Indirect Lookup Relationship Fields on External Objects" in the Salesforce Help.

getReferenceTo()

Returns a list of Schema.sObjectType objects for the parent objects of this field. If the `isNamePointing` method returns `true`, there is more than one entry in the list, otherwise there is only one.

Signature

```
public List <Schema.sObjectType> getReferenceTo()
```

Return Value

Type: List<Schema.sObjectType>

getRelationshipName()

Returns the name of the relationship.

Signature

```
public String getRelationshipName()
```

Return Value

Type: String

Usage

For more information about relationships and relationship names, see Understanding Relationship Names in the *SOQL and SOSL Reference*.

getRelationshipOrder()

Returns 1 if the field is a child, 0 otherwise.

Signature

```
public Integer getRelationshipOrder()
```

Return Value

Type: Integer

Usage

For more information about relationships and relationship names, see Understanding Relationship Names in the *SOQL and SOSL Reference*.

getScale()

For fields of type Double, returns the number of digits to the right of the decimal point. Any extra digits to the right of the decimal point are truncated.

Signature

```
public Integer getScale()
```

Return Value

Type: Integer

Usage

This method returns a fault response if the number has too many digits to the left of the decimal point.

getSOAPType()

Returns one of the SoapType enum values, depending on the type of field.

Signature

```
public Schema.SOAPType getSOAPType()
```

Return Value

Type: Schema.SOAPType

getSObjectField()

Returns the token for this field.

Signature

```
public Schema.sObjectField getSObjectField()
```

Return Value

Type: Schema.SObjectField

getType()

Returns one of the DisplayType enum values, depending on the type of field.

Signature

```
public Schema.DisplayType getType()
```

Return Value

Type: Schema.DisplayType

isAccessible()

Returns `true` if the current user can see this field, `false` otherwise.

Signature

```
public Boolean isAccessible()
```

Return Value

Type: Boolean

isAiPredictionField() (Beta)

Returns `true` if the current field is enabled to display Einstein prediction data, `false` otherwise.

Signature

```
public Boolean isAiPredictionField()
```

Return Value

Type: Boolean

Usage

Custom number fields can be set to display Einstein prediction values. If you are participating in the Einstein Prediction Builder Beta program, use Einstein Prediction Builder to set up the value to display. Use this method to find out if a field is enabled to display an Einstein prediction value.

isAutoNumber()

Returns `true` if the field is an Auto Number field, `false` otherwise.

Signature

```
public Boolean isAutoNumber()
```

Return Value

Type: Boolean

Usage

Analogous to a SQL IDENTITY type, Auto Number fields are read-only, non-createable text fields with a maximum length of 30 characters. Auto Number fields are used to provide a unique ID that is independent of the internal object ID (such as a purchase order number or invoice number). Auto Number fields are configured entirely in the Salesforce user interface.

isCalculated()

Returns `true` if the field is a custom formula field, `false` otherwise. Note that custom formula fields are always read-only.

Signature

```
public Boolean isCalculated()
```

Return Value

Type: Boolean

isCascadeDelete()

Returns `true` if the child object is deleted when the parent object is deleted, `false` otherwise.

Signature

```
public Boolean isCascadeDelete()
```

Return Value

Type: Boolean

isCaseSensitive()

Returns `true` if the field is case sensitive, `false` otherwise.

Signature

```
public Boolean isCaseSensitive()
```

Return Value

Type: Boolean

isCreateable()

Returns `true` if the field can be created by the current user, `false` otherwise.

Signature

```
public Boolean isCreateable()
```

Return Value

Type: Boolean

isCustom()

Returns `true` if the field is a custom field, `false` if it is a standard field, such as `Name`.

Signature

```
public Boolean isCustom()
```

Return Value

Type: Boolean

isDefaultedOnCreate()

Returns `true` if the field receives a default value when created, `false` otherwise.

Signature

```
public Boolean isDefaultedOnCreate()
```

Return Value

Type: Boolean

Usage

If this method returns `true`, Salesforce implicitly assigns a value for this field when the object is created, even if a value for this field is not passed in on the create call. For example, in the Opportunity object, the Probability field has this attribute because its value is derived

from the Stage field. Similarly, the Owner has this attribute on most objects because its value is derived from the current user (if the Owner field is not specified).

isDependentPicklist()

Returns `true` if the picklist is a dependent picklist, `false` otherwise.

Signature

```
public Boolean isDependentPicklist()
```

Return Value

Type: Boolean

isDeprecatedAndHidden()

Reserved for future use.

Signature

```
public Boolean isDeprecatedAndHidden()
```

Return Value

Type: Boolean

isExternalID()

Returns `true` if the field is used as an external ID, `false` otherwise.

Signature

```
public Boolean isExternalID()
```

Return Value

Type: Boolean

isFilterable()

Returns `true` if the field can be used as part of the filter criteria of a `WHERE` statement, `false` otherwise.

Signature

```
public Boolean isFilterable()
```

Return Value

Type: Boolean

isFormulaTreatNullNumberAsZero()

Returns `true` if `null` is treated as zero in a formula field, `false` otherwise.

Signature

```
public Boolean isFormulaTreatNullNumberAsZero()
```

Return Value

Type: Boolean

isGroupable()

Returns `true` if the field can be included in the `GROUP BY` clause of a SOQL query, `false` otherwise. This method is only available for Apex classes and triggers saved using API version 18.0 and higher.

Signature

```
public Boolean isGroupable()
```

Return Value

Type: Boolean

isHtmlFormatted()

Returns `true` if the field has been formatted for HTML and should be encoded for display in HTML, `false` otherwise. One example of a field that returns `true` for this method is a hyperlink custom formula field. Another example is a custom formula field that has an `IMAGE` text function.

Signature

```
public Boolean isHtmlFormatted()
```

Return Value

Type: Boolean

isIdLookup()

Returns `true` if the field can be used to specify a record in an `upsert` method, `false` otherwise.

Signature

```
public Boolean isIdLookup()
```

Return Value

Type: Boolean

isNameField()

Returns `true` if the field is a name field, `false` otherwise.

Signature

```
public Boolean isNameField()
```

Return Value

Type: Boolean

Usage

This method is used to identify the name field for standard objects (such as `AccountName` for an Account object) and custom objects. Objects can only have one name field, except where the `FirstName` and `LastName` fields are used instead (such as on the Contact object).

If a compound name is present, for example, the `Name` field on a person account, `isNameField` is set to `true` for that record.

isNamePointing()

Returns `true` if the field can have multiple types of objects as parents. For example, a task can have both the `Contact/Lead ID` (`WhoId`) field and the `Opportunity/Account ID` (`WhatId`) field return `true` for this method. because either of those objects can be the parent of a particular task record. This method returns `false` otherwise.

Signature

```
public Boolean isNamePointing()
```

Return Value

Type: Boolean

isNillable()

Returns `true` if the field is nillable, `false` otherwise. A nillable field can have empty content. A non-nillable field must have a value for the object to be created or saved.

Signature

```
public Boolean isNillable()
```

Return Value

Type: Boolean

isPermissionable()

Returns `true` if field permissions can be specified for the field, `false` otherwise.

Signature

```
public Boolean isPermissionable()
```

Return Value

Type: Boolean

isRestrictedDelete()

Returns `true` if the parent object can't be deleted because it is referenced by a child object, `false` otherwise.

Signature

```
public Boolean isRestrictedDelete()
```

Return Value

Type: Boolean

isRestrictedPicklist()

Returns `true` if the field is a restricted picklist, `false` otherwise

Signature

```
public Boolean isRestrictedPicklist()
```

Return Value

Type: Boolean

isSearchPrefilterable()

Returns `true` if a foreign key can be included in prefiltering when used in a SOSL `WHERE` clause, `false` otherwise.

Signature

```
public Boolean isSearchPrefilterable()
```

Return Value

Type: Boolean

Usage

Prefiltering means to filter by a specific field value before executing the full search query. Prefiltering is supported only in `WHERE` clauses with the equals (=) operator.

isSortable()

Returns `true` if a query can sort on the field, `false` otherwise

Signature

```
public Boolean isSortable()
```

Return Value

Type: Boolean

isUnique()

Returns `true` if the value for the field must be unique, `false` otherwise

Signature

```
public Boolean isUnique()
```

Return Value

Type: Boolean

isUpdateable()

Returns `true` if the field can be edited by the current user, or child records in a master-detail relationship field on a custom object can be reparented to different parent records; `false` otherwise.

Signature

```
public Boolean isUpdateable()
```

Return Value

Type: Boolean

isWriteRequiresMasterRead()

Returns `true` if writing to the detail object requires read sharing instead of read/write sharing of the parent.

Signature

```
public Boolean isWriteRequiresMasterRead()
```

Return Value

Type: Boolean

DescribeIconResult Class

Contains icon metadata information for a tab.

Namespace

Schema

Usage

The `getIcons` method of the `Schema.DescribeTabResult` class returns a list of `Schema.DescribeIconResult` objects that describe colors used in a tab.

The methods in the `Schema.DescribeIconResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses `()` to call the property counterpart. For example, `iconResultObj.url` is equivalent to `iconResultObj.getUrl()`.

Example

This sample shows how to get the icon information in the Sales app for the first tab's first icon.

```
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set
for(Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Get tab info for the Sales app
    if (tsr.getLabel() == 'Sales') {
        // Get icon information for the first tab
        List<Schema.DescribeIconResult> iconDesc = tsr.getTabs()[0].getIcons();
        // Display the icon height and width of the first icon
        System.debug('Height: ' + iconDesc[0].getHeight());
        System.debug('Width: ' + iconDesc[0].getWidth());
    }
}

// Example debug statement output
// DEBUG|Height: 32
// DEBUG|Width: 32
```

DescribeIconResult Methods

The following are methods for `DescribeIconResult`. All are instance methods.

IN THIS SECTION:

- getContentType()
  Returns the tab icon's content type, such as `image/png`.
- getHeight()
  Returns the tab icon's height in pixels.
- getTheme()
  Returns the tab's icon theme.
- getUrl()
  Returns the tab's icon fully qualified URL.

getWidth()
Returns the tab's icon width in pixels.

getContentType()

Returns the tab icon's content type, such as `image/png`.

Signature

```
public String getContentType()
```

Return Value

Type: String

getHeight()

Returns the tab icon's height in pixels.

Signature

```
public Integer getHeight()
```

Return Value

Type: Integer

Usage

Note: If the icon content type is SVG, the icon won't have a size and its height is zero.

getTheme()

Returns the tab's icon theme.

Signature

```
public String getTheme()
```

Return Value

Type: String

Possible theme values include `theme3`, `theme4`, and `custom`.

- `theme3` is the Salesforce theme introduced during Spring '10.
- `theme4` is the Salesforce theme introduced in Winter '14 for the mobile touchscreen version of Salesforce.
- `custom` is the theme name associated with a custom icon.

`getUrl()`

Returns the tab's icon fully qualified URL.

Signature

```
public String getUrl()
```

Return Value

Type: String

`getWidth()`

Returns the tab's icon width in pixels.

Signature

```
public Integer getWidth()
```

Return Value

Type: Integer

Usage

Note: If the icon content type is SVG, the icon won't have a size and its width is zero.

DescribeSObjectResult Class

Contains methods for describing sObjects.

Namespace

Schema

Usage

None of the methods take an argument.

DescribeSObjectResult Methods

The following are methods for `DescribeSObjectResult`. All are instance methods.

IN THIS SECTION:

fields

Follow `fields` with a field member variable name or with the `getMap` method.

fieldSets

Follow `fieldSets` with a field set name or with the `getMap` method.

getChildRelationships()

Returns a list of child relationships, which are the names of the sObjects that have a foreign key to the sObject being described.

getHasSubtypes()

Indicates whether the object has subtypes. The Account object, which has subtype PersonAccount, is the only object that will return `true`.

getKeyPrefix()

Returns the three-character prefix code for the object. Record IDs are prefixed with three-character codes that specify the type of the object (for example, accounts have a prefix of `001` and opportunities have a prefix of `006`).

getLabel()

Returns the object's label, which may or may not match the object name.

getLabelPlural()

Returns the object's plural label, which may or may not match the object name.

getLocalName()

Returns the name of the object, similar to the `getName` method. However, if the object is part of the current namespace, the namespace portion of the name is omitted.

getName()

Returns the name of the object.

getRecordTypeInfos()

Returns a list of the record types supported by this object. The current user is not required to have access to a record type to see it in this list.

getRecordTypeInfosByDeveloperName()

Returns a map that matches developer names to their associated record type. The current user is not required to have access to a record type to see it in this map.

getRecordTypeInfosById()

Returns a map that matches record IDs to their associated record types. The current user is not required to have access to a record type to see it in this map.

getRecordTypeInfosByName()

Returns a map that matches record labels to their associated record type. The current user is not required to have access to a record type to see it in this map.

getSobjectType()

Returns the Schema.SObjectType object for the sObject. You can use this to create a similar sObject.

isAccessible()

Returns `true` if the current user can see this object, `false` otherwise.

isCreateable()

Returns `true` if the object can be created by the current user, `false` otherwise.

isCustom()

Returns `true` if the object is a custom object, `false` if it is a standard object.

isCustomSetting()

Returns `true` if the object is a custom setting, `false` otherwise.

isDeletable()

Returns `true` if the object can be deleted by the current user, `false` otherwise.

isDeprecatedAndHidden()

Reserved for future use.

isFeedEnabled()

Returns `true` if Chatter feeds are enabled for the object, `false` otherwise. This method is only available for Apex classes and triggers saved using SalesforceAPI version 19.0 and later.

isMergeable()

Returns `true` if the object can be merged with other objects of its type by the current user, `false` otherwise. `true` is returned for leads, contacts, and accounts.

isMruEnabled()

Returns `true` if Most Recently Used (MRU) list functionality is enabled for the object, `false` otherwise.

isQueryable()

Returns `true` if the object can be queried by the current user, `false` otherwise

isSearchable()

Returns `true` if the object can be searched by the current user, `false` otherwise.

isUndeletable()

Returns `true` if the object cannot be undeleted by the current user, `false` otherwise.

isUpdateable()

Returns `true` if the object can be updated by the current user, `false` otherwise.

fields

Follow `fields` with a field member variable name or with the `getMap` method.

Signature

```
public Schema.SObjectTypeFields fields()
```

Return Value

Type: The return value is a special data type. See the example to learn how to use `fields`.

Usage

Note: When you describe sObjects and their fields from within an Apex class, custom fields of new field types are returned regardless of the API version that the class is saved in. If a field type, such as the geolocation field type, is available only in a recent API version, components of a geolocation field are returned even if the class is saved in an earlier API version.

Example

```
Schema.DescribeFieldResult dfr = Schema.SObjectType.Account.fields.Name;
```

To get a custom field name, specify the custom field name.

SEE ALSO:

- Using Field Tokens
- Describing sObjects Using Schema Method
- Understanding Apex Describe Information

fieldSets

Follow `fieldSets` with a field set name or with the `getMap` method.

Signature

```
public Schema.SObjectTypeFields fieldSets()
```

Return Value

Type: The return value is a special data type. See the example to learn how to use `fieldSets`.

Example

```
Schema.DescribeSObjectResult d =
  Account.sObjectType.getDescribe();
Map<String, Schema.FieldSet> FsMap =
  d.fieldSets.getMap();
```

SEE ALSO:

- Using Field Tokens
- Describing sObjects Using Schema Method
- Understanding Apex Describe Information

getChildRelationships()

Returns a list of child relationships, which are the names of the sObjects that have a foreign key to the sObject being described.

Signature

```
public Schema.ChildRelationship getChildRelationships()
```

Return Value

Type: List<Schema.ChildRelationship>

Example

For example, the Account object includes `Contacts` and `Opportunities` as child relationships.

getHasSubtypes()

Indicates whether the object has subtypes. The Account object, which has subtype PersonAccount, is the only object that will return `true`.

Signature

```
public Boolean getHasSubtypes()
```

Return Value

Type: Boolean

getKeyPrefix()

Returns the three-character prefix code for the object. Record IDs are prefixed with three-character codes that specify the type of the object (for example, accounts have a prefix of `001` and opportunities have a prefix of `006`).

Signature

```
public String getKeyPrefix()
```

Return Value

Type: String

Usage

The DescribeSobjectResult object returns a value for objects that have a stable prefix. For object types that do not have a stable or predictable prefix, this field is blank. Client applications that rely on these codes can use this way of determining object type to ensure forward compatibility.

getLabel()

Returns the object's label, which may or may not match the object name.

Signature

```
public String getLabel()
```

Return Value

Type: String

Usage

The object's label might not always match the object name. For example, an organization in the medical industry might change the label for Account to Patient. This label is then used in the Salesforce user interface. See the Salesforce online help for more information.

getLabelPlural()

Returns the object's plural label, which may or may not match the object name.

Signature

```
public String getLabelPlural()
```

Return Value

Type: String

Usage

The object's plural label might not always match the object name. For example, an organization in the medical industry might change the plural label for Account to Patients. This label is then used in the Salesforce user interface. See the Salesforce online help for more information.

getLocalName()

Returns the name of the object, similar to the `getName` method. However, if the object is part of the current namespace, the namespace portion of the name is omitted.

Signature

```
public String getLocalName()
```

Return Value

Type: String

getName()

Returns the name of the object.

Signature

```
public String getName()
```

Return Value

Type: String

getRecordTypeInfos()

Returns a list of the record types supported by this object. The current user is not required to have access to a record type to see it in this list.

Signature

```
public List<Schema.RecordTypeInfo> getRecordTypeInfos()
```

Return Value

Type: List<Schema.RecordTypeInfo>

getRecordTypeInfosByDeveloperName()

Returns a map that matches developer names to their associated record type. The current user is not required to have access to a record type to see it in this map.

Signature

```
public Map<String,Schema.RecordTypeInfo> getRecordTypeInfosByDeveloperName()
```

Return Value

Type: Map<StringSchema.RecordTypeInfo>

getRecordTypeInfosById()

Returns a map that matches record IDs to their associated record types. The current user is not required to have access to a record type to see it in this map.

Signature

```
public Schema.RecordTypeInfo getRecordTypeInfosById()
```

Return Value

Type: Map<ID, Schema.RecordTypeInfo>

getRecordTypeInfosByName()

Returns a map that matches record labels to their associated record type. The current user is not required to have access to a record type to see it in this map.

Signature

```
public Schema.RecordTypeInfo getRecordTypeInfosByName()
```

Return Value

Type: Map<String, Schema.RecordTypeInfo>

getSobjectType()

Returns the Schema.SObjectType object for the sObject. You can use this to create a similar sObject.

Signature

```
public Schema.SObjectType getSobjectType()
```

Return Value

Type: Schema.SObjectType

isAccessible()

Returns `true` if the current user can see this object, `false` otherwise.

Signature

```
public Boolean isAccessible()
```

Return Value

Type: Boolean

isCreateable()

Returns `true` if the object can be created by the current user, `false` otherwise.

Signature

```
public Boolean isCreateable()
```

Return Value

Type: Boolean

isCustom()

Returns `true` if the object is a custom object, `false` if it is a standard object.

Signature

```
public Boolean isCustom()
```

Return Value

Type: Boolean

isCustomSetting()

Returns `true` if the object is a custom setting, `false` otherwise.

Signature

```
public Boolean isCustomSetting()
```

Return Value

Type: Boolean

isDeletable()

Returns `true` if the object can be deleted by the current user, `false` otherwise.

Signature

```
public Boolean isDeletable()
```

Return Value

Type: Boolean

isDeprecatedAndHidden()

Reserved for future use.

Signature

```
public Boolean isDeprecatedAndHidden()
```

Return Value

Type: Boolean

isFeedEnabled()

Returns `true` if Chatter feeds are enabled for the object, `false` otherwise. This method is only available for Apex classes and triggers saved using SalesforceAPI version 19.0 and later.

Signature

```
public Boolean isFeedEnabled()
```

Return Value

Type: Boolean

isMergeable()

Returns `true` if the object can be merged with other objects of its type by the current user, `false` otherwise. `true` is returned for leads, contacts, and accounts.

Signature

```
public Boolean isMergeable()
```

Return Value

Type: Boolean

isMruEnabled()

Returns `true` if Most Recently Used (MRU) list functionality is enabled for the object, `false` otherwise.

Signature

```
public Boolean isMruEnabled()
```

Return Value

Type: Boolean

isQueryable()

Returns `true` if the object can be queried by the current user, `false` otherwise

Signature

```
public Boolean isQueryable()
```

Return Value

Type: Boolean

isSearchable()

Returns `true` if the object can be searched by the current user, `false` otherwise.

Signature

```
public Boolean isSearchable()
```

Return Value

Type: Boolean

isUndeletable()

Returns `true` if the object cannot be undeleted by the current user, `false` otherwise.

Signature

```
public Boolean isUndeletable()
```

Return Value

Type: Boolean

isUpdateable()

Returns `true` if the object can be updated by the current user, `false` otherwise.

Signature

```
public Boolean isUpdateable()
```

Return Value

Type: Boolean

DescribeTabResult Class

Contains tab metadata information for a tab in a standard or custom app available in the Salesforce user interface.

Namespace

Schema

Usage

The `getTabs` method of the `Schema.DescribeTabSetResult` returns a list of `Schema.DescribeTabResult` objects that describe the tabs of one app.

The methods in the `Schema.DescribeTabResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses `()` to call the property counterpart. For example, `tabResultObj.label` is equivalent to `tabResultObj.getLabel()`. Similarly, for each method starting with `is`, omit the `is` prefix and the ending parentheses `()`. For example, `tabResultObj.isCustom` is equivalent to `tabResultObj.custom`.

DescribeTabResult Methods

The following are methods for `DescribeTabResult`. All are instance methods.

IN THIS SECTION:

getColors()
Returns a list of color metadata information for all colors associated with this tab. Each color is associated with a theme and context.

getIconUrl()
Returns the URL for the main 32 x 32-pixel icon for a tab. This icon corresponds to the current theme (theme3) and appears next to the heading at the top of most pages.

getIcons()
Returns a list of icon metadata information for all icons associated with this tab. Each icon is associated with a theme and context.

getLabel()
Returns the display label of this tab.

getMiniIconUrl()
Returns the URL for the 16 x 16-pixel icon that represents a tab. This icon corresponds to the current theme (theme3) and appears in related lists and other locations.

getSobjectName()
Returns the name of the sObject that is primarily displayed on this tab (for tabs that display a particular SObject).

getUrl()
Returns a fully qualified URL for viewing this tab.

isCustom()
Returns `true` if this is a custom tab, or `false` if this is a standard tab.

getColors()

Returns a list of color metadata information for all colors associated with this tab. Each color is associated with a theme and context.

Signature

```
public List<Schema.DescribeColorResult> getColors()
```

Return Value

Type: List<Schema.DescribeColorResult>

getIconUrl()

Returns the URL for the main 32 x 32-pixel icon for a tab. This icon corresponds to the current theme (theme3) and appears next to the heading at the top of most pages.

Signature

```
public String getIconUrl()
```

Return Value

Type: String

getIcons()

Returns a list of icon metadata information for all icons associated with this tab. Each icon is associated with a theme and context.

Signature

```
public List<Schema.DescribeIconResult> getIcons()
```

Return Value

Type: List<Schema.DescribeIconResult>

getLabel()

Returns the display label of this tab.

Signature

```
public String getLabel()
```

Return Value

Type: String

`getMiniIconUrl()`

Returns the URL for the 16 x 16-pixel icon that represents a tab. This icon corresponds to the current theme (theme3) and appears in related lists and other locations.

Signature

```
public String getMiniIconUrl()
```

Return Value

Type: String

`getSobjectName()`

Returns the name of the sObject that is primarily displayed on this tab (for tabs that display a particular SObject).

Signature

```
public String getSobjectName()
```

Return Value

Type: String

`getUrl()`

Returns a fully qualified URL for viewing this tab.

Signature

```
public String getUrl()
```

Return Value

Type: String

`isCustom()`

Returns `true` if this is a custom tab, or `false` if this is a standard tab.

Signature

```
public Boolean isCustom()
```

Return Value

Type: Boolean

DescribeTabSetResult Class

Contains metadata information about a standard or custom app available in the Salesforce user interface.

Namespace

Schema

Usage

The `Schema.describeTabs` method returns a list of `Schema.DescribeTabSetResult` objects that describe standard and custom apps.

The methods in the `Schema.DescribeTabSetResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses `()` to call the property counterpart. For example, `tabSetResultObj.label` is equivalent to `tabSetResultObj.getLabel()`. Similarly, for each method starting with `is`, omit the `is` prefix and the ending parentheses `()`. For example, `tabSetResultObj.isSelected` is equivalent to `tabSetResultObj.selected`.

Example

This example shows how to call the `Schema.describeTabs` method to get describe information for all available apps. This example iterates through each describe result and gets more metadata information for the Sales app.

```
// App we're interested to get more info about
String appName = 'Sales';

// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set describe for each app and display the info
for(Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Get more information for the Sales app
    if (tsr.getLabel() == appName) {
        // Find out if the app is selected
        if (tsr.isSelected()) {
            System.debug('The ' + appName + ' app is selected. ');
        }
        // Get the app's Logo URL and namespace
        String logo = tsr.getLogoUrl();
        System.debug('Logo URL: ' + logo);
        String ns = tsr.getNamespace();
        if (ns == '') {
            System.debug('The ' + appName + ' app has no namespace defined.');
        }
        else {
            System.debug('Namespace: ' + ns);
        }
        // Get the number of tabs
        System.debug('The ' + appName + ' app has ' + tsr.getTabs().size() + ' tabs.');
    }
}

// Example debug statement output
// DEBUG|The Sales app is selected.
// DEBUG|Logo URL:
https://https://yourInstance.salesforce.com/img/seasonLogos/2014_winter_aloha.png
```

```
// DEBUG|The Sales app has no namespace defined.
// DEBUG|The Sales app has 14 tabs.
```

DescribeTabSetResult Methods

The following are methods for `DescribeTabSetResult`. All are instance methods.

IN THIS SECTION:

getDescription()
Returns the display description for the standard or custom app.

getLabel()
Returns the display label for the standard or custom app.

getLogoUrl()
Returns a fully qualified URL to the logo image associated with the standard or custom app.

getNamespace()
Returns the developer namespace prefix of a Salesforce AppExchange managed package.

getTabs()
Returns metadata information about the standard or custom app's displayed tabs.

isSelected()
Returns `true` if this standard or custom app is the user's currently selected app. Otherwise, returns `false`.

`getDescription()`

Returns the display description for the standard or custom app.

Signature

```
public String getDescription()
```

Return Value

Type: String

`getLabel()`

Returns the display label for the standard or custom app.

Signature

```
public String getLabel()
```

Return Value

Type: String

Usage

The display label changes when tabs are renamed in the Salesforce user interface. See the Salesforce online help for more information.

getLogoUrl()

Returns a fully qualified URL to the logo image associated with the standard or custom app.

Signature

```
public String getLogoUrl()
```

Return Value

Type: String

getNamespace()

Returns the developer namespace prefix of a Salesforce AppExchange managed package.

Signature

```
public String getNamespace()
```

Return Value

Type: String

Usage

This namespace prefix corresponds to the namespace prefix of the Developer Edition organization that was enabled to allow publishing a managed package. This method applies to a custom app containing a set of tabs and installed as part of a managed package.

getTabs()

Returns metadata information about the standard or custom app's displayed tabs.

Signature

```
public List<Schema.DescribeTabResult> getTabs()
```

Return Value

Type: List<Schema.DescribeTabResult>

isSelected()

Returns `true` if this standard or custom app is the user's currently selected app. Otherwise, returns `false`.

Signature

```
public Boolean isSelected()
```

Return Value

Type: Boolean

DisplayType Enum

A `Schema.DisplayType` enum value is returned by the field describe result's `getType` method.

Namespace

Schema

Type Field Value	What the Field Object Contains
`address`	Address values
`anytype`	Any value of the following types: `String`, `Picklist`, `Boolean`, `Integer`, `Double`, `Percent`, `ID`, `Date`, `DateTime`, `URL`, or `Email`.
`base64`	Base64-encoded arbitrary binary data (of type base64Binary)
`Boolean`	Boolean (`true` or `false`) values
`Combobox`	Comboboxes, which provide a set of enumerated values and allow the user to specify a value not in the list
`Currency`	Currency values
`DataCategoryGroupReference`	Reference to a data category group or a category unique name
`Date`	Date values
`DateTime`	DateTime values
`Double`	Double values
`Email`	Email addresses
`EncryptedString`	Encrypted string
`ID`	Primary key field for an object
`Integer`	Integer values
`Long`	Long values
`MultiPicklist`	Multi-select picklists, which provide a set of enumerated values from which multiple values can be selected
`Percent`	Percent values
`Phone`	Phone numbers. Values can include alphabetic characters. Client applications are responsible for phone number formatting.
`Picklist`	Single-select picklists, which provide a set of enumerated values from which only one value can be selected
`Reference`	Cross-references to a different object, analogous to a foreign key field

Type Field Value	What the Field Object Contains
`String`	String values
`TextArea`	String values that are displayed as multiline text fields
`Time`	Time values
`URL`	URL values that are displayed as hyperlinks

Usage

For more information, see Field Types in the *Object Reference for Salesforce* . For more information about the methods shared by all enums, see Enum Methods.

FieldSet Class

Contains methods for discovering and retrieving the details of field sets created on sObjects.

Namespace

Schema

Usage

Use the methods in the `Schema.FieldSet` class to discover the fields contained within a field set, and get details about the field set itself, such as the name, namespace, label, and so on. The following example shows how to get a collection of field set describe result objects for an sObject. The key of the returned Map is the field set name, and the value is the corresponding field set describe result.

```
Map<String, Schema.FieldSet> FsMap =
    Schema.SObjectType.Account.fieldSets.getMap();
```

Field sets are also available from sObject describe results. The following lines of code are equivalent to the prior sample:

```
Schema.DescribeSObjectResult d =
  Account.sObjectType.getDescribe();
Map<String, Schema.FieldSet> FsMap =
  d.fieldSets.getMap();
```

To work with an individual field set, you can access it via the map of field sets on an sObject or, when you know the name of the field set in advance, using an explicit reference to the field set. The following two lines of code retrieve the same field set:

```
Schema.FieldSet fs1 = Schema.SObjectType.Account.fieldSets.getMap().get('field_set_name');
Schema.FieldSet fs2 = Schema.SObjectType.Account.fieldSets.field_set_name;
```

Example: Displaying a Field Set on a Visualforce Page

This sample uses `Schema.FieldSet` and `Schema.FieldSetMember` methods to dynamically get all the fields in the Dimensions field set for the Merchandise custom object. The list of fields is then used to construct a SOQL query that ensures those fields are available for display. The Visualforce page uses the `MerchandiseDetails` class as its controller.

```
public class MerchandiseDetails {

```

```
    public Merchandise__c merch { get; set; }

    public MerchandiseDetails() {
        this.merch = getMerchandise();
    }

    public List<Schema.FieldSetMember> getFields() {
        return SObjectType.Merchandise__c.FieldSets.Dimensions.getFields();
    }

    private Merchandise__c getMerchandise() {
        String query = 'SELECT ';
        for(Schema.FieldSetMember f : this.getFields()) {
            query += f.getFieldPath() + ', ';
        }
        query += 'Id, Name FROM Merchandise__c LIMIT 1';
        return Database.query(query);
    }
}
```

The Visualforce page using the above controller is simple:

```
<apex:page controller="MerchandiseDetails">
    <apex:form >

      <apex:pageBlock title="Product Details">
          <apex:pageBlockSection title="Product">
              <apex:inputField value="{!merch.Name}"/>
          </apex:pageBlockSection>

          <apex:pageBlockSection title="Dimensions">
              <apex:repeat value="{!fields}" var="f">
                  <apex:inputField value="{!merch[f.fieldPath]}"
                      required="{!OR(f.required, f.dbrequired)}"/>
              </apex:repeat>
          </apex:pageBlockSection>

        </apex:pageBlock>

    </apex:form>
</apex:page>
```

One thing to note about the above markup is the expression used to determine if a field on the form should be indicated as being a required field. A field in a field set can be required by either the field set definition, or the field's own definition. The expression handles both cases.

FieldSet Methods

The following are methods for `FieldSet`. All are instance methods.

IN THIS SECTION:

getDescription()
Returns the field set's description.

getFields()
Returns a list of `Schema.FieldSetMember` objects for the fields making up the field set.

getLabel()
Returns the translation of the text label that is displayed next to the field in the Salesforce user interface.

getName()
Returns the field set's name.

getNamespace()
Returns the field set's namespace.

getSObjectType()
Returns the `Schema.sObjectType` of the sObject containing the field set definition.

getDescription()

Returns the field set's description.

Signature

```
public String getDescription()
```

Return Value

Type: `String`

Usage

Description is a required field for a field set, intended to describe the context and content of the field set. It's often intended for administrators who might be configuring a field set defined in a managed package, rather than for end users.

getFields()

Returns a list of `Schema.FieldSetMember` objects for the fields making up the field set.

Signature

```
public List<FieldSetMember> getFields()
```

Return Value

Type: List<Schema.FieldSetMember>

getLabel()

Returns the translation of the text label that is displayed next to the field in the Salesforce user interface.

Signature

```
public String getLabel()
```

Return Value

Type: `String`

getName()

Returns the field set's name.

Signature

```
public String getName()
```

Return Value

Type: `String`

getNamespace()

Returns the field set's namespace.

Signature

```
public String getNamespace()
```

Return Value

Type: `String`

Usage

The returned namespace is an empty string if your organization hasn't set a namespace, and the field set is defined in your organization. Otherwise, it's the namespace of your organization, or the namespace of the managed package containing the field set.

getSObjectType()

Returns the `Schema.sObjectType` of the sObject containing the field set definition.

Signature

```
public Schema.SObjectType getSObjectType()
```

Return Value

Type: `Schema.SObjectType`

FieldSetMember Class

Contains methods for accessing the metadata for field set member fields.

Namespace

Schema

Usage

Use the methods in the `Schema.FieldSetMember` class to get details about fields contained within a field set, such as the field label, type, a dynamic SOQL-ready field path, and so on. The following example shows how to get a collection of field set member describe result objects for a specific field set on an sObject:

```
List<Schema.FieldSetMember> fields =
    Schema.SObjectType.Account.fieldSets.getMap().get('field_set_name').getFields();
```

If you know the name of the field set in advance, you can access its fields more directly using an explicit reference to the field set:

```
List<Schema.FieldSetMember> fields =
    Schema.SObjectType.Account.fieldSets.field_set_name.getFields();
```

SEE ALSO:

FieldSet Class

FieldSetMember Methods

The following are methods for `FieldSetMember`. All are instance methods.

IN THIS SECTION:

getDBRequired()
Returns `true` if the field is required by the field's definition in its sObject, otherwise, `false`.

getFieldPath()
Returns a field path string in a format ready to be used in a dynamic SOQL query.

getLabel()
Returns the text label that's displayed next to the field in the Salesforce user interface.

getRequired()
Returns `true` if the field is required by the field set, otherwise, `false`.

getType()
Returns the field's Apex data type.

`getDBRequired()`

Returns `true` if the field is required by the field's definition in its sObject, otherwise, `false`.

Signature

```
public Boolean getDBRequired()
```

Return Value

Type: `Boolean`

getFieldPath()

Returns a field path string in a format ready to be used in a dynamic SOQL query.

Signature

```
public String getFieldPath()
```

Return Value

Type: `String`

Example

See Displaying a Field Set on a Visualforce Page for an example of how to use this method.

getLabel()

Returns the text label that's displayed next to the field in the Salesforce user interface.

Signature

```
public String getLabel()
```

Return Value

Type: `String`

getRequired()

Returns `true` if the field is required by the field set, otherwise, `false`.

Signature

```
public Boolean getRequired()
```

Return Value

Type: `Boolean`

getType()

Returns the field's Apex data type.

Signature

```
public Schema.DisplayType getType()
```

Return Value

Type: `Schema.DisplayType`

PicklistEntry Class

Represents a picklist entry.

Namespace

Schema

Usage

Picklist fields contain a list of one or more items from which a user chooses a single item. They display as drop-down lists in the Salesforce user interface. One of the items can be configured as the default item.

A `Schema.PicklistEntry` object is returned from the field describe result using the `getPicklistValues` method. For example:

```
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
List<Schema.PicklistEntry> P = F.getPicklistValues();
```

PicklistEntry Methods

The following are methods for `PicklistEntry`. All are instance methods.

IN THIS SECTION:

getLabel()
Returns the display name of this item in the picklist.

getValue()
Returns the value of this item in the picklist.

isActive()
Returns `true` if this item must be displayed in the drop-down list for the picklist field in the user interface, `false` otherwise.

isDefaultValue()
Returns `true` if this item is the default value for the picklist, `false` otherwise. Only one item in a picklist can be designated as the default.

`getLabel()`

Returns the display name of this item in the picklist.

Signature

```
public String getLabel()
```

Return Value

Type: String

`getValue()`

Returns the value of this item in the picklist.

Signature

```
public String getValue()
```

Return Value

Type: String

isActive()

Returns `true` if this item must be displayed in the drop-down list for the picklist field in the user interface, `false` otherwise.

Signature

```
public Boolean isActive()
```

Return Value

Type: Boolean

isDefaultValue()

Returns `true` if this item is the default value for the picklist, `false` otherwise. Only one item in a picklist can be designated as the default.

Signature

```
public Boolean isDefaultValue()
```

Return Value

Type: Boolean

RecordTypeInfo Class

Contains methods for accessing record type information for an sObject with associated record types.

Namespace

Schema

Usage

A RecordTypeInfo object is returned from the sObject describe result using the `getRecordTypeInfos` method. For example:

```
Schema.DescribeSObjectResult R = Account.SObjectType.getDescribe();
List<Schema.RecordTypeInfo> RT = R.getRecordTypeInfos();
```

In addition to the `getRecordTypeInfos` method, you can use the `getRecordTypeInfosById` and the `getRecordTypeInfosByName` methods. These methods return maps that associate RecordTypeInfo with record IDs and record labels, respectively.

Example

The following example assumes at least one record type has been created for the Account object:

```
RecordType rt = [SELECT Id,Name FROM RecordType WHERE SobjectType='Account' LIMIT 1];
Schema.DescribeSObjectResult d = Schema.SObjectType.Account;
Map<Id,Schema.RecordTypeInfo> rtMapById = d.getRecordTypeInfosById();
Schema.RecordTypeInfo rtById =  rtMapById.get(rt.id);
Map<String,Schema.RecordTypeInfo> rtMapByName = d.getRecordTypeInfosByName();
Schema.RecordTypeInfo rtByName =  rtMapByName.get(rt.name);
System.assertEquals(rtById,rtByName);
```

RecordTypeInfo Methods

The following are methods for `RecordTypeInfo`. All are instance methods.

IN THIS SECTION:

getDeveloperName()
Returns the developer name for this record type.

getName()
Returns the UI label of this record type. The label can be translated into any language that Salesforce supports.

getRecordTypeId()
Returns the ID of this record type.

isActive()
Returns `true` if this record type is active, `false` otherwise.

isAvailable()
Returns `true` if this record type is available to the current user, `false` otherwise. Use this method to display a list of available record types to the user when he or she is creating a new record.

isDefaultRecordTypeMapping()
Returns `true` if this is the default record type for the user, `false` otherwise.

isMaster()
Returns `true` if this is the master record type and `false` otherwise. The master record type is the default record type that's used when a record has no custom record type associated with it.

`getDeveloperName()`

Returns the developer name for this record type.

Signature

```
public String getDeveloperName()
```

Return Value

Type: String

getName()

Returns the UI label of this record type. The label can be translated into any language that Salesforce supports.

Signature

```
public String getName()
```

Return Value

Type: String

getRecordTypeId()

Returns the ID of this record type.

Signature

```
public ID getRecordTypeId()
```

Return Value

Type: ID

isActive()

Returns `true` if this record type is active, `false` otherwise.

Signature

```
public Boolean isActive()
```

Return Value

Type: Boolean

isAvailable()

Returns `true` if this record type is available to the current user, `false` otherwise. Use this method to display a list of available record types to the user when he or she is creating a new record.

Signature

```
public Boolean isAvailable()
```

Return Value

Type: Boolean

isDefaultRecordTypeMapping()

Returns `true` if this is the default record type for the user, `false` otherwise.

Signature

```
public Boolean isDefaultRecordTypeMapping()
```

Return Value

Type: Boolean

isMaster()

Returns `true` if this is the master record type and `false` otherwise. The master record type is the default record type that's used when a record has no custom record type associated with it.

Signature

```
public Boolean isMaster()
```

Return Value

Type: Boolean

SOAPType Enum

A `Schema.SOAPType` enum value is returned by the field describe result `getSoapType` method.

Namespace

Schema

Type Field Value	What the Field Object Contains
`anytype`	Any value of the following types: `String`, `Boolean`, `Integer`, `Double`, `ID`, `Date` or `DateTime`.
`base64binary`	Base64-encoded arbitrary binary data (of type base64Binary)
`Boolean`	Boolean (`true` or `false`) values
`Date`	Date values
`DateTime`	DateTime values
`Double`	Double values
`ID`	Primary key field for an object
`Integer`	Integer values
`String`	String values
`Time`	Time values

Usage

For more information, see SOAPTypes in the *SOAP API Developer Guide*. For more information about the methods shared by all enums, see Enum Methods.

SObjectField Class

A `Schema.sObjectField` object is returned from the field describe result using the `getControler` and `getSObjectField` methods.

Namespace

Schema

Example

```
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
Schema.sObjectField T = F.getSObjectField();
```

sObjectField Methods

The following are instance methods for `sObjectField`.

IN THIS SECTION:

getDescribe()
Returns the describe field result for this field.

`getDescribe()`

Returns the describe field result for this field.

Signature

```
public Schema.DescribeFieldResult getDescribe()
```

Return Value

Type: Schema.DescribeFieldResult

SObjectType Class

A `Schema.sObjectType` object is returned from the field describe result using the `getReferenceTo` method, or from the sObject describe result using the `getSObjectType` method.

Namespace

Schema

Usage

```
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
List<Schema.sObjectType> P = F.getReferenceTo();
```

SObjectType Methods

The following are methods for `SObjectType`. All are instance methods.

IN THIS SECTION:

getDescribe()
Returns the describe sObject result for this field.

newSObject()
Constructs a new sObject of this type.

newSObject(id)
Constructs a new sObject of this type, with the specified ID.

newSObject(recordTypeId, loadDefaults)
Constructs a new sObject of this type, and optionally, of the specified record type ID and with default custom field values.

`getDescribe()`

Returns the describe sObject result for this field.

Signature

```
public Schema.DescribeSObjectResult getDescribe()
```

Return Value

Type: Schema.DescribeSObjectResult

`newSObject()`

Constructs a new sObject of this type.

Signature

```
public sObject newSObject()
```

Return Value

Type: sObject

Example

For an example, see Dynamic sObject Creation Example.

newSObject(id)

Constructs a new sObject of this type, with the specified ID.

Signature

```
public sObject newSObject(ID id)
```

Parameters

id
Type: ID

Return Value

Type: sObject

Usage

For the argument, pass the ID of an existing record in the database.

After you create a new sObject, the sObject returned has all fields set to `null`. You can set any updateable field to desired values and then update the record in the database. Only the fields you set new values for are updated and all other fields which are not system fields are preserved.

newSObject(recordTypeId, loadDefaults)

Constructs a new sObject of this type, and optionally, of the specified record type ID and with default custom field values.

Signature

```
public sObject newSObject(ID recordTypeId, Boolean loadDefaults)
```

Parameters

recordTypeId
Type: ID

Specifies the record type ID of the sObject to create. If no record type exists for this sObject, use `null`. If the sObject has record types and you specify `null`, the default record type is used.

loadDefaults
Type: Boolean

Specifies whether to populate custom fields with their predefined default values (`true`) or not (`false`).

Return Value

Type: sObject

Usage

- For required fields that have no default values, make sure to provide a value before inserting the new sObject. Otherwise, the insertion results in an error. An example is the Account Name field or a master-detail relationship field.

- Since picklists and multi-select picklists can have default values specified per record type, this method populates the default value corresponding to the record type specified.
- If fields have no predefined default values and the *loadDefaults* argument is `true`, this method creates the sObject with field values of `null`.
- If the *loadDefaults* argument is `false`, this method creates the sObject with field values of `null`.
- This method populates read-only custom fields of the new sObject with default values. You can then insert the new sObject with the read-only fields, even though these fields cannot be edited after they're inserted.
- If a custom field is marked as unique and also provides a default value, inserting more than one new sObject will cause a run-time exception because of duplicate field values.

To learn more about default field values, see "Default Field Values" in the Salesforce online help.

Example: Creating New sObject with Default Values

This sample creates an account with any default values populated for its custom fields, if any, using the `newSObject` method. It also creates a second account for a specific record type. For both accounts, the sample sets the Name field, which is a required field that doesn't have a default value, before inserting the new accounts.

```
// Create an account with predefined default values
Account acct = (Account)Account.sObjectType.newSObject(null, true);
// Provide a value for Name
acct.Name = 'Acme';
// Insert new account
insert acct;

// This is for record type RT1 of Account
ID rtId = [SELECT Id FROM RecordType WHERE sObjectType='Account' AND Name='RT1'].Id;
Account acct2 = (Account)Account.sObjectType.newSObject(rtId, true);
// Provide a value for Name
acct2.Name = 'Acme2';
// Insert new account
insert acct2;
```

Search Namespace

The `Search` namespace provides classes for getting search results and suggestion results.

The following are the classes in the `Search` namespace.

IN THIS SECTION:

KnowledgeSuggestionFilter Class

Filter settings that narrow the results from a call to `System.Search.suggest(searchQuery, sObjectType, options)` when the SOSL search query contains a KnowledgeArticleVersion object.

QuestionSuggestionFilter Class

The `Search.QuestionSuggestionFilter` class filters results from a call to `System.Search.suggest(searchQuery, sObjectType, options)` when the SOSL `searchQuery` contains a `FeedItem` object.

SearchResult Class

A wrapper object that contains an sObject and search metadata.

SearchResults Class

Wraps the results returned by the `Search.find(String)` method.

SuggestionOption Class

Options that narrow record and article suggestion results returned from a call to `System.Search.suggest(String, String, Search.SuggestionOption)`.

SuggestionResult Class

A wrapper object that contains an sObject.

SuggestionResults Class

Wraps the results returned by the `Search.suggest(String, String, Search.SuggestionOption)` method.

SEE ALSO:

find(searchQuery)

suggest(searchQuery, sObjectType, suggestions)

KnowledgeSuggestionFilter Class

Filter settings that narrow the results from a call to `System.Search.suggest(searchQuery, sObjectType, options)` when the SOSL search query contains a KnowledgeArticleVersion object.

Namespace

Search

KnowledgeSuggestionFilter Methods

The following are methods for `KnowledgeSuggestionFilter`.

IN THIS SECTION:

addArticleType(articleType)

Adds a filter that narrows suggestion results to display the specified article type. This filter is optional.

addDataCategory(dataCategoryGroupName, dataCategoryName)

Adds a filter that narrows suggestion results to display articles in the specified data category. This filter is optional.

addTopic(topic)

Specifies the article topic to return. This filter is optional.

setChannel(channelName)

Sets a channel to narrow the suggestion results to articles in the specified channel. This filter is optional.

setDataCategories(dataCategoryFilters)

Adds filters that narrow suggestion results to display articles in the specified data categories. Use this method to set multiple data category group and name pairs in one call. This filter is optional.

setLanguage(localeCode)

Sets a language to narrow the suggestion results to display articles in that language. This filter value is required in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`.

setPublishStatus(publishStatus)

Sets a publish status to narrow the suggestion results to display articles with that status. This filter value is required in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`.

setValidationStatus(validationStatus)

Sets a validation status to narrow the suggestion results to display articles with that status. This filter is optional.

addArticleType(articleType)

Adds a filter that narrows suggestion results to display the specified article type. This filter is optional.

Signature

```
public void addArticleType(String articleType)
```

Parameters

articleType

Type: String

A three-character ID prefix indicating the desired article type.

Return Value

Type: void

Usage

To add more than 1 article type, call the method multiple times.

addDataCategory(dataCategoryGroupName, dataCategoryName)

Adds a filter that narrows suggestion results to display articles in the specified data category. This filter is optional.

Signature

```
public void addDataCategory(String dataCategoryGroupName, String dataCategoryName)
```

Parameters

dataCategoryGroupName

Type: String

The name of the data category group

dataCategoryName

Type: String

The name of the data category.

Return Value

Type: void

Usage

To set multiple data categories, call the method multiple times. The name of the data category group and name of the data category for desired articles, expressed as a mapping, for example, `Search.KnowledgeSuggestionFilter.addDataCategory('Regions', 'Asia')`.

addTopic(topic)

Specifies the article topic to return. This filter is optional.

Signature

```
public void addTopic(String topic)
```

Parameters

addTopic
Type: String

The name of the article topic.

Return Value

Type: void

Usage

To add more than 1 article topic, call the method multiple times.

setChannel(channelName)

Sets a channel to narrow the suggestion results to articles in the specified channel. This filter is optional.

Signature

```
public void setChannel(String channelName)
```

Parameters

channelName
Type: String

The name of a channel. Valid values are:

- `AllChannels`–Visible in all channels the user has access to
- `App`–Visible in the internal Salesforce Knowledge application
- `Pkb`–Visible in the public knowledge base
- `Csp`–Visible in the Customer Portal
- `Prm`–Visible in the Partner Portal

If `channel` isn't specified, the default value is determined by the type of user.

- `Pkb` for a guest user

- `Csp` for a Customer Portal user
- `Prm` for a Partner Portal user
- `App` for any other type of user

If `channel` is specified, the specified value may not be the actual value requested, because of certain requirements.

- For guest, Customer Portal, and Partner Portal users, the specified value must match the default value for each user type. If the values don't match or `AllChannels` is specified, then `App` replaces the specified value.
- For all users other than guest, Customer Portal, and Partner Portal users:
  - If `Pkb`, `Csp`, `Prm`, or `App` are specified, then the specified value is used.
  - If `AllChannels` is specified, then `App` replaces the specified value.

Return Value

Type: void

setDataCategories(dataCategoryFilters)

Adds filters that narrow suggestion results to display articles in the specified data categories. Use this method to set multiple data category group and name pairs in one call. This filter is optional.

Signature

```
public void setDataCategories(Map dataCategoryFilters)
```

Parameters

dataCategoryFilters
Type: Map

A map of data category group and data category name pairs.

Return Value

Type: void

setLanguage(localeCode)

Sets a language to narrow the suggestion results to display articles in that language. This filter value is required in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`.

Signature

```
public void setLanguage(String localeCode)
```

Parameters

localeCode
Type: String

A locale code. For example, `'en_US'` (English–United States), or `'es'` (Spanish).

Return Value

Type: void

SEE ALSO:

Supported Locales

setPublishStatus(publishStatus)

Sets a publish status to narrow the suggestion results to display articles with that status. This filter value is required in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`.

Signature

```
public void setPublishStatus(String publishStatus)
```

Parameters

publishStatus
Type: String

A publish status. Valid values are:

- `Draft`–Articles aren't published in Salesforce Knowledge.
- `Online`–Articles are published in Salesforce Knowledge.
- `Archived`–Articles aren't published and are available in Archived Articles view.

setValidationStatus(validationStatus)

Sets a validation status to narrow the suggestion results to display articles with that status. This filter is optional.

Signature

```
public void setValidationStatus(String validationStatus)
```

Parameters

validationStatus
Type: String

An article validation status. These values are available in the `ValidationStatus` field on the KnowledgeArticleVersion object.

Return Value

Type: void

QuestionSuggestionFilter Class

The `Search.QuestionSuggestionFilter` class filters results from a call to `System.Search.suggest(searchQuery, sObjectType, options)` when the SOSL `searchQuery` contains a `FeedItem` object.

Namespace

Search

IN THIS SECTION:

QuestionSuggestionFilter Methods

QuestionSuggestionFilter Methods

The following are methods for `QuestionSuggestionFilter`.

IN THIS SECTION:

addGroupId(groupId)
Adds a filter to display questions associated with the single specified group whose ID is passed in as an argument. This filter is optional.

addNetworkId(networkId)
Adds a filter to display questions associated with the single specified network whose ID is passed in as an argument. This filter is optional.

addUserId(userId)
Adds a filter to display questions belonging to the single specified user whose ID is passed in as an argument. This filter is optional.

setGroupIds(groupIds)
Sets a new list of groups to replace the current list of groups where the group IDs are passed in as an argument. This filter is optional.

setNetworkIds(networkIds)
Sets a new list of networks to replace the current list of networks where the network IDs are passed in as an argument. This filter is optional.

setTopicId(topicId)
Sets a filter to display questions associated with the single specified topic whose ID is passed in as an argument. This filter is optional.

setUserIds(userIds)
Sets a new list of users to replace the current list of users where the users IDs are passed in as an argument. This filter is optional.

`addGroupId(groupId)`

Adds a filter to display questions associated with the single specified group whose ID is passed in as an argument. This filter is optional.

Signature

```
public void addGroupId(String groupId)
```

Parameters

`groupId`
Type: String

The ID for a group.

Return Value

Type: void

Usage

To add more than one group, call the method multiple times.

addNetworkId(networkId)

Adds a filter to display questions associated with the single specified network whose ID is passed in as an argument. This filter is optional.

Signature

```
public void addNetworkId(String networkId)
```

Parameters

networkId
Type: String

The ID of the community about which you're retrieving this information.

Return Value

Type: void

Usage

To add more than one network, call the method multiple times.

addUserId(userId)

Adds a filter to display questions belonging to the single specified user whose ID is passed in as an argument. This filter is optional.

Signature

```
public void addUserId(String userId)
```

Parameters

userId
Type: String

The ID for the user.

Return Value

Type: void

Usage

To add more than one user, call the method multiple times.

setGroupIds(groupIds)

Sets a new list of groups to replace the current list of groups where the group IDs are passed in as an argument. This filter is optional.

Signature

```
public void setGroupIds(List<String> groupIds)
```

Parameters

groupIds
Type: List<String>

A list of group IDs.

Return Value

Type: void

setNetworkIds(networkIds)

Sets a new list of networks to replace the current list of networks where the network IDs are passed in as an argument. This filter is optional.

Signature

```
public void setNetworkIds(List<String> networkIds)
```

Parameters

networkIds
Type: List<String>

A list of network IDs.

Return Value

Type: void

setTopicId(topicId)

Sets a filter to display questions associated with the single specified topic whose ID is passed in as an argument. This filter is optional.

Signature

```
public void setTopicId(String topicId)
```

Parameters

topicId
Type: String

The ID for a topic.

Return Value

Type: void

setUserIds(userIds)

Sets a new list of users to replace the current list of users where the users IDs are passed in as an argument. This filter is optional.

Signature

```
public void setUserIds(List<String> userIds)
```

Parameters

userIds
Type: List<String>

A list of user IDs.

Return Value

Type: void

SearchResult Class

A wrapper object that contains an sObject and search metadata.

Namespace

Search

SearchResult Methods

The following are methods for `SearchResult`.

IN THIS SECTION:

getSObject()
Returns an sObject from a SearchResult object.

getSnippet(fieldName)
Returns a snippet from a Case, Feed, or Knowledge Article SearchResult object based on the specified field name.

getSnippet()
Returns a snippet from a SearchResult object based on the default field.

getSObject()

Returns an sObject from a SearchResult object.

Signature

```
public SObject getSObject()
```

Return Value

Type: SObject

SEE ALSO:

find(searchQuery)

Dynamic SOSL

`getSnippet(fieldName)`

Returns a snippet from a Case, Feed, or Knowledge Article SearchResult object based on the specified field name.

Signature

```
public String getSnippet(String fieldName)
```

Parameters

`fieldName`

Type: String

The field name to use for creating the snippet.

Valid values: `Case.Casenumber`, `FeedPost.Title`, `KnowledgeArticleVersion.Title`

Return Value

Type: String

SEE ALSO:

find(searchQuery)

Dynamic SOSL

`getSnippet()`

Returns a snippet from a SearchResult object based on the default field.

Signature

```
public String getSnippet()
```

Return Value

Type: String

SEE ALSO:

find(searchQuery)

Dynamic SOSL

SearchResults Class

Wraps the results returned by the `Search.find(String)` method.

Namespace

Search

SearchResults Methods

The following are methods for `SearchResults`.

IN THIS SECTION:

get(sObjectType)
Returns a list of `Search.SearchResult` objects that contain an sObject of the specified type.

`get(sObjectType)`

Returns a list of `Search.SearchResult` objects that contain an sObject of the specified type.

Signature

```
public List<Search.SearchResult> get(String sObjectType)
```

Parameters

`sObjectType`
Type: String

The name of an sObject in the dynamic SOSL query passed to the `Search.find(String)` method.

Return Value

Type: List<Search.SearchResult>

Usage

SOSL queries passed to the `Search.find(String)` method can return results for multiple objects. For example, the query `Search.find('FIND \'map\' IN ALL FIELDS RETURNING Account, Contact, Opportunity')` includes results for 3 objects. You can call `get(string)` to retrieve search results for 1 object at a time. For example, to get results for the Account object, call `Search.SearchResults.get('Account')`.

SEE ALSO:

find(searchQuery)
SearchResult Methods
Dynamic SOSL

SuggestionOption Class

Options that narrow record and article suggestion results returned from a call to `System.Search.suggest(String, String, Search.SuggestionOption)`.

Namespace

Search

SuggestionOption Methods

The following are methods for `SuggestionOption`.

IN THIS SECTION:

setFilter(knowledgeSuggestionFilter)

Set filters that narrow Salesforce Knowledge article results in a call to `System.Search.suggest(String, String, Search.SuggestionOption)`.

setLimit(limit)

The maximum number of record or article suggestions to retrieve.

`setFilter(knowledgeSuggestionFilter)`

Set filters that narrow Salesforce Knowledge article results in a call to `System.Search.suggest(String, String, Search.SuggestionOption)`.

Signature

```
public void setFilter(Search.KnowledegeSuggestionFilter knowledgeSuggestionFilter)
```

Parameters

`knowledgeSuggestionFilter`
Type: KnowledgeSuggestionFilter

An object containing filters that narrow the search results.

Return Value

Type: void

Usage

```
Search.KnowledgeSuggestionFilter filters = new Search.KnowledgeSuggestionFilter();
filters.setLanguage('en_US');
filters.setPublishStatus('Online');
filters.setChannel('app');

Search.SuggestionOption options = new Search.SuggestionOption();
options.setFilter(filters);
```

```
Search.SuggestionResults suggestionResults = Search.suggest('all', 'KnowledgeArticleVersion',
 options);

for (Search.SuggestionResult searchResult : suggestionResults.getSuggestionResults()) {

  KnowledgeArticleVersion article = (KnowledgeArticleVersion)result.getSObject();
  System.debug(article.title);
}
```

`setLimit(limit)`

The maximum number of record or article suggestions to retrieve.

Signature

```
public void setLimit(Integer limit)
```

Parameters

`limit`
Type: Integer

The maximum number of record or article suggestions to retrieve.

Return Value

Type: void

Usage

By default, the `System.Search.suggest(String, String, Search.SuggestionOption)` method returns the 5 most relevant results. However, if your query is broad, it could match more than 5 results. If `Search.SuggestionResults.hasMoreResults()` returns `true`, there are more than 5 results. To retrieve them, call `setLimit(Integer)` to increase the number of suggestions results.

```
Search.SuggestionOption option = new Search.SuggestionOption();
option.setLimit(10);
Search.suggest('my query', 'mySObjectType', option);
```

SuggestionResult Class

A wrapper object that contains an sObject.

Namespace

Search

SuggestionResult Methods

The following are methods for `SuggestionResult`.

IN THIS SECTION:

getSObject()
Returns the sObject from a SuggestionResult object.

getSObject()

Returns the sObject from a SuggestionResult object.

Signature

```
public SObject getSObject()
```

Return Value

Type: SObject

SuggestionResults Class

Wraps the results returned by the `Search.suggest(String, String, Search.SuggestionOption)` method.

Namespace

Search

SuggestionResults Methods

The following are methods for `SuggestionResults`.

IN THIS SECTION:

getSuggestionResults()
Returns a list of SuggestionResult objects from the response to a call to `Search.suggest(String, String, Search.SuggestionOption)`.

hasMoreResults()
Indicates whether a call to `System.Search.suggest(String, String, Search.SuggestionOption)` has more results available than were returned.

getSuggestionResults()

Returns a list of SuggestionResult objects from the response to a call to `Search.suggest(String, String, Search.SuggestionOption)`.

Signature

```
public List<Search.SuggestionResult> getSuggestionResults()
```

Return Value

Type: List<SuggestionResult>

`hasMoreResults()`

Indicates whether a call to `System.Search.suggest(String, String, Search.SuggestionOption)` has more results available than were returned.

Signature

```
public Boolean hasMoreResults()
```

Return Value

Type: Boolean

Usage

If a limit isn't specified, 5 records are returned in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`. If there are more suggested records than the limit specified, a call to `hasMoreResults()` returns `true`.

Sfc Namespace

The Sfc namespace contains classes used in Salesforce Files.

The following are the classes in the `Sfc` namespace.

IN THIS SECTION:

ContentDownloadContext Enum
This enum specifies the download context.

ContentDownloadHandler Class
Use ContentDownloadHandler to define a custom download handler that controls how content is downloaded.

ContentDownloadHandlerFactory Interface
Use this interface to provide a class factory that Salesforce can call to create instances of your custom ContentDownloadHandler.

ContentDownloadContext Enum

This enum specifies the download context.

Enum Values

The following are the values of the `Sfc.ContentDownloadContext` enum.

Value	Description
`CHATTER`	Download from Chatter.
`CONTENT`	Default value. Downloads from the Salesforce CRM Content product.
`DELIVERY`	Download of a content delivery.
`MOBILE`	Download from a mobile device.

Value	Description
`REST_API`	Download from the Connect API (`/connect/files/${fileId}/content` endpoint).
`RETRIEVE`	Retrieve VersionData from SObject API.
`S1`	Download from Salesforce mobile.
`SOQL`	Select VersionData from SOQL.

ContentDownloadHandler Class

Use ContentDownloadHandler to define a custom download handler that controls how content is downloaded.

Namespace

Sfc on page 2467

IN THIS SECTION:

ContentDownloadHandler Properties

ContentDownloadHandler Properties

The following are properties for `ContentDownloadHandler`.

IN THIS SECTION:

downloadErrorMessage

A customized error message explaining why the download isn't allowed.

isDownloadAllowed

Indicates whether or not download is allowed.

redirectUrl

The URL the user should be redirected to, for applying Information Rights Management (IRM) control, virus scanning, or other behavior.

`downloadErrorMessage`

A customized error message explaining why the download isn't allowed.

Signature

```
public String downloadErrorMessage {get; set;}
```

Property Value

Type: String

This message is used if a `redirectUrl` is not provided. If the download is not allowed, Salesforce will throw a `ContentCustomizedDownloadException` exception that contains the `downloadErrorMessage`.

`isDownloadAllowed`

Indicates whether or not download is allowed.

Signature

```
public Boolean isDownloadAllowed {get; set;}
```

Property Value

Type: Boolean

`redirectUrl`

The URL the user should be redirected to, for applying Information Rights Management (IRM) control, virus scanning, or other behavior.

Signature

```
public String redirectUrl {get; set;}
```

Property Value

Type: String

The URL must be a valid relative URL. For example, the redirect can be a custom Visualforce page such as "/apex/IRMControl". URLs with no path, such as "www.domain.com", will result in an `InvalidParameterValueException`.

ContentDownloadHandlerFactory Interface

Use this interface to provide a class factory that Salesforce can call to create instances of your custom ContentDownloadHandler.

Namespace

Sfc on page 2467

Usage

ContentDownloadHandler getContentDownloadHandler(List<ID> ids, ContentDownloadContext context);

IN THIS SECTION:

ContentDownloadHandlerFactory Methods

ContentDownloadHandlerFactory Example Implementation

ContentDownloadHandlerFactory Methods

The following are methods for `ContentDownloadHandlerFactory`.

IN THIS SECTION:

getContentDownloadHandler(var1, var2)
Returns a ContentDownloadHandler for a given list of content IDs and a download context.

getContentDownloadHandler(var1, var2)

Returns a ContentDownloadHandler for a given list of content IDs and a download context.

Signature

```
public Sfc.ContentDownloadHandler getContentDownloadHandler(List<Id> var1,
Sfc.ContentDownloadContext var2)
```

Parameters

var1
Type: List<Id>

var2
Type: Sfc.ContentDownloadContext on page 2467

Return Value

Type: Sfc.ContentDownloadHandler on page 2468

ContentDownloadHandlerFactory Example Implementation

This example creates a class that implements the `Sfc.ContentDownloadHandlerFactory` interface and returns a download handler that blocks downloading content to mobile devices.

```
// Allow customization of the content Download experience
public class ContentDownloadHandlerFactoryImpl implements Sfc.ContentDownloadHandlerFactory
 {

  public Sfc.ContentDownloadHandler getContentDownloadHandler(Id id,
Sfc.ContentDownloadContext context) {
    Sfc.ContentDownloadHandler contentDownloadHandler = new Sfc.ContentDownloadHandler();

    if(context == Sfc.ContentDownloadContext.MOBILE) {
      contentDownloadHandler.isDownloadAllowed = false;
      contentDownloadHandler.downloadErrorMessage = 'Downloading a file from a mobile
device isn't allowed.';
      return contentDownloadHandler;
    }
    contentDownloadHandler.isDownloadAllowed = true;
    return contentDownloadHandler;
  }
}
```

Site Namespace

The `Site` namespace provides an interface for rewriting Sites URLs.

The following is the interface in the `Site` namespace.

IN THIS SECTION:

UrlRewriter Interface
Enables rewriting Sites URLs.

Site Exceptions
The `Site` namespace contains an exception class.

UrlRewriter Interface

Enables rewriting Sites URLs.

Namespace

Site

Usage

Sites provides built-in logic that helps you display user-friendly URLs and links to site visitors. Create rules to rewrite URL requests typed into the address bar, launched from bookmarks, or linked from external websites. You can also create rules to rewrite the URLs for links within site pages. URL rewriting not only makes URLs more descriptive and intuitive for users, it allows search engines to better index your site pages.

For example, let's say that you have a blog site. Without URL rewriting, a blog entry's URL might look like this:
`http://myblog.force.com/posts?id=003D000000Q0PcN`

To rewrite URLs for a site, create an Apex class that maps the original URLs to user-friendly URLs, and then add the Apex class to your site.

UrlRewriter Methods

The following are methods for `UrlRewriter`. All are instance methods.

IN THIS SECTION:

generateUrlFor(salesforceUrls)
Maps a list of Salesforce URLs to a list of user-friendly URLs.

mapRequestUrl(userFriendlyUrl)
Maps a user-friendly URL to a Salesforce URL.

`generateUrlFor(salesforceUrls)`

Maps a list of Salesforce URLs to a list of user-friendly URLs.

Signature

```
public System.PageReference[] generateUrlFor(System.PageReference[] salesforceUrls)
```

Parameters

salesforceUrls
Type: System.PageReference[]

Return Value

Type: System.PageReference[]

Usage

You can use `List<PageReference>` instead of `PageReference[]`, if you prefer.

Important: The size and order of the input list of Salesforce URLs must exactly correspond to the size and order of the generated list of user-friendly URLs. The `generateUrlFor` method maps input URLs to output URLs based on the order in the lists.

`mapRequestUrl(userFriendlyUrl)`

Maps a user-friendly URL to a Salesforce URL.

Signature

```
public System.PageReference mapRequestUrl(System.PageReference userFriendlyUrl)
```

Parameters

userFriendlyUrl
Type: System.PageReference

Return Value

Type: System.PageReference

Site Exceptions

The `Site` namespace contains an exception class.

All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions.

The `Site` namespace contains this exception:

Exception	Description	Methods
`Site.ExternalUserCreateException`	Unable to create external user	Use the `String getMessage()` to get the error message and write it to debug log. Use `List<String> getDisplayMessages()` to get a list of errors displayed to the end user.

Exception	Description	Methods
		This exception can't be subclassed or thrown in code.

Support Namespace

The `Support` namespace provides an interface used for Case Feed.

The following is the interface in the `Support` namespace.

IN THIS SECTION:

EmailTemplateSelector Interface

The `Support.EmailTemplateSelector` interface enables providing default email templates in Case Feed. With default email templates, specified email templates are preloaded for cases based on criteria such as case origin or subject.

MilestoneTriggerTimeCalculator Interface

The `Support.MilestoneTriggerTimeCalculator` interface calculates the time trigger for a milestone.

EmailTemplateSelector Interface

The `Support.EmailTemplateSelector` interface enables providing default email templates in Case Feed. With default email templates, specified email templates are preloaded for cases based on criteria such as case origin or subject.

Namespace

Support

To specify default templates, you must create a class that implements `Support.EmailTemplateSelector`.

When you implement this interface, provide an empty parameterless constructor.

IN THIS SECTION:

EmailTemplateSelector Methods

EmailTemplateSelector Example Implementation

EmailTemplateSelector Methods

The following are methods for `EmailTemplateSelector`.

IN THIS SECTION:

getDefaultTemplateId(caseId)

Returns the ID of the email template to preload for the case currently being viewed in the case feed using the specified case ID.

`getDefaultTemplateId(caseId)`

Returns the ID of the email template to preload for the case currently being viewed in the case feed using the specified case ID.

Signature

```
public ID getDefaultTemplateId(ID caseId)
```

Parameters

caseId
Type: ID

Return Value

Type: ID

EmailTemplateSelector Example Implementation

This is an example implementation of the `Support.EmailTemplateSelector` interface.

The `getDefaultEmailTemplateId` method implementation retrieves the subject and description of the case corresponding to the specified case ID. Next, it selects an email template based on the case subject and returns the email template ID.

```
global class MyCaseTemplateChooser implements Support.EmailTemplateSelector {
    // Empty constructor
    global MyCaseTemplateChooser() {    }

    // The main interface method
    global ID getDefaultEmailTemplateId(ID caseId) {
        // Select the case we're interested in, choosing any fields that are relevant to
our decision
        Case c = [SELECT Subject, Description FROM Case WHERE Id=:caseId];

        EmailTemplate et;

        if (c.subject.contains('LX-1150')) {
            et = [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1150_template'];
        } else if(c.subject.contains('LX-1220')) {
            et = [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1220_template'];
        }

        // Return the ID of the template selected
        return et.id;
    }
}
```

The following example tests the above code:

```
@isTest
private class MyCaseTemplateChooserTest {

    static testMethod void testChooseTemplate() {

        MyCaseTemplateChooser chooser = new MyCaseTemplateChooser();

        // Create a simulated case to test with
        Case c = new Case();
        c.Subject = 'I\'m having trouble with my LX-1150';
```

```
        Database.insert(c);

        // Make sure the proper template is chosen for this subject
        Id actualTemplateId = chooser.getDefaultEmailTemplateId(c.Id);
        EmailTemplate expectedTemplate =
          [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1150_template'];
        Id expectedTemplateId = expectedTemplate.Id;
        System.assertEquals(actualTemplateId, expectedTemplateId);

        // Change the case properties to match a different template
        c.Subject = 'My LX1220 is overheating';
        Database.update(c);

        // Make sure the correct template is chosen in this case
       actualTemplateId = chooser.getDefaultEmailTemplateId(c.Id);
        expectedTemplate =
          [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1220_template'];
        expectedTemplateId = expectedTemplate.Id;
        System.assertEquals(actualTemplateId, expectedTemplateId);

    }
}
```

MilestoneTriggerTimeCalculator Interface

The `Support.MilestoneTriggerTimeCalculator` interface calculates the time trigger for a milestone.

Namespace

Support

Implement the `Support.MilestoneTriggerTimeCalculator` interface to calculate a dynamic time trigger for a milestone based on the milestone type, the properties of the case, and case-related objects. To implement the `Support.MilestoneTriggerTimeCalculator` interface, you must first declare a class with the `implements` keyword as follows:

```
global class Employee implements Support.MilestoneTriggerTimeCalculator {
```

Next, your class must provide an implementation for the following method:

```
global Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId)
```

The implemented method must be declared as `global` or `public`.

IN THIS SECTION:

- MilestoneTriggerTimeCalculator Methods
- MilestoneTriggerTimeCalculator Example Implementation

MilestoneTriggerTimeCalculator Methods

The following are instance methods for `MilestoneTriggerTimeCalculator`.

IN THIS SECTION:

calculateMilestoneTriggerTime(caseId, milestoneTypeId)
Calculates the milestone trigger time based on the specified case and milestone type and returns the time in minutes.

calculateMilestoneTriggerTime(caseId, milestoneTypeId)

Calculates the milestone trigger time based on the specified case and milestone type and returns the time in minutes.

Syntax

```
public Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId)
```

Parameters

caseId
Type: String

ID of the case the milestone is applied to.

milestoneTypeId
Type: String

ID of the milestone type.

Return Value

Type: Integer

The calculated trigger time in minutes.

MilestoneTriggerTimeCalculator Example Implementation

This sample class demonstrates the implementation of the `Support.MilestoneTriggerTimeCalculator` interface. In this sample, the case's priority and the milestone `m1` determine that the time trigger is 18 minutes.

```
global class myMilestoneTimeCalculator implements Support.MilestoneTriggerTimeCalculator
{
     global Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId){

        Case c = [SELECT Priority FROM Case WHERE Id=:caseId];
        MilestoneType mt = [SELECT Name FROM MilestoneType WHERE Id=:milestoneTypeId];
        if (c.Priority != null && c.Priority.equals('High')){
              if (mt.Name != null && mt.Name.equals('m1')) { return 7;}
              else { return 5; }
        }
        else {
            return 18;
        }
     }
}
```

This test class can be used to test the implementation of `Support.MilestoneTriggerTimeCalculator`.

```
@isTest
private class MilestoneTimeCalculatorTest {
```

```
    static testMethod void testMilestoneTimeCalculator() {

        // Select an existing milestone type to test with
        MilestoneType[] mtLst = [SELECT Id, Name FROM MilestoneType LIMIT 1];
        if(mtLst.size() == 0) { return; }
        MilestoneType mt = mtLst[0];

        // Create case data.
        // Typically, the milestone type is related to the case,
        // but for simplicity, the case is created separately for this test.
        Case c = new Case(priority = 'High');
        insert c;

        myMilestoneTimeCalculator calculator = new myMilestoneTimeCalculator();
       Integer actualTriggerTime = calculator.calculateMilestoneTriggerTime(c.Id, mt.Id);

        if(mt.name != null && mt.Name.equals('m1')) {
            System.assertEquals(actualTriggerTime, 7);
        }
        else {
            System.assertEquals(actualTriggerTime, 5);
        }

        c.priority = 'Low';
        update c;
        actualTriggerTime = calculator.calculateMilestoneTriggerTime(c.Id, mt.Id);
        System.assertEquals(actualTriggerTime, 18);
    }
}
```

System Namespace

The `System` namespace provides classes and methods for core Apex functionality.

The following are the classes in the `System` namespace.

IN THIS SECTION:

Address Class
Contains methods for accessing the component fields of address compound fields.

Answers Class
Represents zone answers.

ApexPages Class
Use `ApexPages` to add and check for messages associated with the current page, as well as to reference the current page.

Approval Class
Contains methods for processing approval requests and setting approval-process locks and unlocks on records.

Blob Class
Contains methods for the Blob primitive data type.

Boolean Class

Contains methods for the Boolean primitive data type.

BusinessHours Class

Use the `BusinessHours` methods to set the business hours at which your customer support team operates.

Callable Interface

Enables developers to use a common interface to build loosely coupled integrations between Apex classes or triggers, even for code in separate packages. Agreeing upon a common interface enables developers from different companies or different departments to build upon one another's solutions. Implement this interface to enable the broader community, which might have different solutions than the ones you had in mind, to extend your code's functionality.

Cases Class

Use the `Cases` class to interact with case records.

Comparable Interface

Adds sorting support for Lists that contain non-primitive types, that is, Lists of user-defined types.

Continuation Class

Use the `Continuation` class to make callouts asynchronously to a SOAP or REST Web service.

Cookie Class

The `Cookie` class lets you access cookies for your Salesforce site using Apex.

Crypto Class

Provides methods for creating digests, message authentication codes, and signatures, as well as encrypting and decrypting information.

Custom Settings Methods

Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data can then be used by formula fields, validation rules, flows, Apex, and the SOAP API.

Database Class

Contains methods for creating and manipulating data.

Date Class

Contains methods for the Date primitive data type.

Datetime Class

Contains methods for the Datetime primitive data type.

Decimal Class

Contains methods for the Decimal primitive data type.

Double Class

Contains methods for the Double primitive data type.

EncodingUtil Class

Use the methods in the `EncodingUtil` class to encode and decode URL strings, and convert strings to hexadecimal format.

Enum Methods

An enum is an abstract data type with values that each take on exactly one of a finite set of identifiers that you specify. Apex provides built-in enums, such as `LoggingLevel`, and you can define your own enum.

EventBus Class

Contains methods for publishing platform events.

Exception Class and Built-In Exceptions

An exception denotes an error that disrupts the normal flow of code execution. You can use Apex built-in exceptions or create custom exceptions. All exceptions have common methods.

FlexQueue Class

Contains methods that reorder batch jobs in the Apex flex queue.

FeatureManagement Class

Use the methods in the `System.FeatureManagement` class to check and modify the values of feature parameters, and to show or hide custom objects and custom permissions in your subscribers' orgs.

Http Class

Use the `Http` class to initiate an HTTP request and response.

HttpCalloutMock Interface

Enables sending fake responses when testing HTTP callouts.

HttpRequest Class

Use the `HttpRequest` class to programmatically create HTTP requests like GET, POST, PUT, and DELETE.

HttpResponse Class

Use the `HttpResponse` class to handle the HTTP response returned by the `Http` class.

Id Class

Contains methods for the ID primitive data type.

Ideas Class

Represents zone ideas.

InstallHandler Interface

Enables custom code to run after a managed package installation or upgrade.

Integer Class

Contains methods for the Integer primitive data type.

JSON Class

Contains methods for serializing Apex objects into JSON format and deserializing JSON content that was serialized using the `serialize` method in this class.

JSONGenerator Class

Contains methods used to serialize objects into JSON content using the standard JSON encoding.

JSONParser Class

Represents a parser for JSON-encoded content.

JSONToken Enum

Contains all token values used for parsing JSON content.

Limits Class

Contains methods that return limit information for specific resources.

List Class

Contains methods for the List collection type.

Location Class

Contains methods for accessing the component fields of geolocation compound fields.

Long Class

Contains methods for the Long primitive data type.

Map Class

Contains methods for the Map collection type.

Matcher Class

Matchers use Patterns to perform match operations on a character string.

Math Class

Contains methods for mathematical operations.

Messaging Class

Contains messaging methods used when sending a single or mass email.

MultiStaticResourceCalloutMock Class

Utility class used to specify a fake response using multiple resources for testing HTTP callouts.

Network Class

Represents a community.

PageReference Class

A PageReference is a reference to an instantiation of a page. Among other attributes, PageReferences consist of a URL and a set of query parameter names and values.

Pattern Class

Represents a compiled representation of a regular expression.

Queueable Interface

Enables the asynchronous execution of Apex jobs that can be monitored.

QueueableContext Interface

Represents the parameter type of the `execute()` method in a class that implements the `Queueable` interface and contains the job ID. This interface is implemented internally by Apex.

QuickAction Class

Use Apex to request and process actions on objects that allow custom fields, on objects that appear in a Chatter feed, or on objects that are available globally.

RemoteObjectController

Use `RemoteObjectController` to access the standard Visualforce Remote Objects operations in your Remote Objects override methods.

ResetPasswordResult Class

Represents the result of a password reset.

RestContext Class

Contains the `RestRequest` and `RestResponse` objects.

RestRequest Class

Represents an object used to pass data from an HTTP request to an Apex RESTful Web service method.

RestResponse Class

Represents an object used to pass data from an Apex RESTful Web service method to an HTTP response.

SandboxPostCopy Interface

To make your sandbox environment business ready, automate data manipulation or business logic tasks. Extend this interface and add methods to perform post-copy tasks, then specify the class during sandbox creation.

Schedulable Interface

The class that implements this interface can be scheduled to run at different intervals.

SchedulableContext Interface

Represents the parameter type of a method in a class that implements the `Schedulable` interface and contains the scheduled job ID. This interface is implemented internally by Apex.

Schema Class

Contains methods for obtaining schema describe information.

Search Class

Use the methods of the Search class to perform dynamic SOSL queries.

SelectOption Class

A `SelectOption` object specifies one of the possible values for a Visualforce `selectCheckboxes`, `selectList`, or `selectRadio` component.

Set Class

Represents a collection of unique elements with no duplicate values.

Site Class

Use the `Site` Class to manage your Lightning Platform sites.

SObject Class

Contains methods for the sObject data type.

StaticResourceCalloutMock Class

Utility class used to specify a fake response for testing HTTP callouts.

String Class

Contains methods for the String primitive data type.

StubProvider Interface

`StubProvider` is a callback interface that you can use as part of the Apex stub API to implement a mocking framework. Use this interface with the `Test.createStub()` method to create stubbed Apex objects for testing.

System Class

Contains methods for system operations, such as writing debug messages and scheduling jobs.

Test Class

Contains methods related to Visualforce tests.

Time Class

Contains methods for the Time primitive data type.

TimeZone Class

Represents a time zone. Contains methods for creating a new time zone and obtaining time zone properties, such as the time zone ID, offset, and display name.

Trigger Class

Use the `Trigger` class to access run-time context information in a trigger, such as the type of trigger or the list of sObject records that the trigger operates on.

TriggerOperation Enum

System.TriggerOperation enum values are associated with trigger events.

Type Class

Contains methods for getting the Apex type that corresponds to an Apex class and for instantiating new types.

UninstallHandler Interface

Enables custom code to run after a managed package is uninstalled.

URL Class

Represents a uniform resource locator (URL) and provides access to parts of the URL. Enables access to the Salesforce instance URL.

UserInfo Class

Contains methods for obtaining information about the context user.

UserManagement Class

Contains methods to manage end users, for example, to register verification methods or handle requests for Salesforce to forget them.

Version Class

Use the Version methods to get the version of a managed package of a subscriber and to compare package versions.

WebServiceCallout Class

Enables making callouts to SOAP operations on an external Web service. This class is used in the Apex stub class that is auto-generated from a WSDL.

WebServiceMock Interface

Enables sending fake responses when testing Web service callouts of a class auto-generated from a WSDL.

XmlStreamReader Class

The `XmlStreamReader` class provides methods for forward, read-only access to XML data. You can pull data from XML or skip unwanted events. You can parse nested XML content that's up to 50 nodes deep.

XmlStreamWriter Class

The `XmlStreamWriter` class provides methods for writing XML data.

Address Class

Contains methods for accessing the component fields of address compound fields.

Namespace

System

Usage

Each of these methods is also equivalent to a read-only property. For each getter method, you can access the property using dot notation. For example, `myAddress.getCity()` is equivalent to `myAddress.city`.

You can't use dot notation to access compound fields' subfields directly on the parent field. Instead, assign the parent field to a variable of type `Address`, and then access its components. For example, to access the `City` field in `myAccount.BillingAddress`, do the following:

```
Address addr = myAccount.BillingAddress;
String acctCity = addr.City;
```

Important: "Address" in Salesforce can also refer to the Address standard object. When referencing the Address object in your Apex code, always use `Schema.Address` instead of `Address` to prevent confusion with the standard Address compound field. If referencing both the Address object and the Address standard field in the same snippet, you can differentiate between the two by using `System.Address` for the field and `Schema.Address` for the object.

Example

```
// Select and access Address fields.
// Call the getDistance() method in different ways.
Account[] records = [SELECT id, BillingAddress FROM Account LIMIT 10];
for(Account acct : records) {
   Address addr = acct.BillingAddress;
   Double lat = addr.latitude;
   Double lon = addr.longitude;
   Location loc1 = Location.newInstance(30.1944,-97.6682);
   Double apexDist1 = addr.getDistance(loc1, 'mi');
   Double apexDist2 = loc1.getDistance(addr, 'mi');
   System.assertEquals(apexDist1, apexDist2);
   Double apexDist3 = Location.getDistance(addr, loc1, 'mi');
   System.assertEquals(apexDist2, apexDist3);
}
```

IN THIS SECTION:

Address Methods

Address Methods

The following are methods for `Address`.

IN THIS SECTION:

getCity()
Returns the city field of this address.

getCountry()
Returns the text-only country name component of this address.

getCountryCode()
Returns the country code of this address if state and country picklists are enabled in your organization. Otherwise, returns `null`.

getDistance(toLocation, unit)
Returns the distance from this location to the specified location using the specified unit.

getGeocodeAccuracy()
When using geolocation data for a given address, this method gives you relative location information based on latitude and longitude values. For example, you can find out if the latitude and longitude values point to the middle of the street, instead of the exact address.

getLatitude()
Returns the latitude field of this address.

getLongitude()
Returns the longitude field of this address.

getPostalCode()
Returns the postal code of this address.

getState()
Returns the text-only state name component of this address.

getStateCode()
Returns the state code of this address if state and country picklists are enabled in your organization. Otherwise, returns `null`.

getStreet()
Returns the street field of this address.

getCity()

Returns the city field of this address.

Signature

```
public String getCity()
```

Return Value

Type: String

getCountry()

Returns the text-only country name component of this address.

Signature

```
public String getCountry()
```

Return Value

Type: String

getCountryCode()

Returns the country code of this address if state and country picklists are enabled in your organization. Otherwise, returns `null`.

Signature

```
public String getCountryCode()
```

Return Value

Type: String

getDistance(toLocation, unit)

Returns the distance from this location to the specified location using the specified unit.

Signature

```
public Double getDistance(Location toLocation, String unit)
```

Parameters

toLocation
Type: Location

The `Location` to which you want to calculate the distance from the current `Location`.

unit
Type: String

The distance unit you want to use: `mi` or `km`.

Return Value

Type: Double

getGeocodeAccuracy()

When using geolocation data for a given address, this method gives you relative location information based on latitude and longitude values. For example, you can find out if the latitude and longitude values point to the middle of the street, instead of the exact address.

Signature

```
public String getGeocodeAccuracy()
```

Return Value

Type: String

The `getGeocodeAccuracy()` return value tells you more about the location at a latitude and longitude for a given address. For example, `Zip` means the latitude and longitude point to the center of the zip code area, in case a match for an exact street address can't be found.

Accuracy Value	Description
`Address`	In the same building
`NearAddress`	Near the address
`Block`	Midway point of the block
`Street`	Midway point of the street
`ExtendedZip`	Center of the extended zip code area
`Zip`	Center of the zip code area
`Neighborhood`	Center of the neighborhood
`City`	Center of the city
`County`	Center of the county
`State`	Center of the state
`Unknown`	No match for the address was found

Geocodes are added only for some standard addresses.

- `Billing Address` on accounts
- `Shipping Address` on accounts
- `Mailing Address` on contacts
- `Address` on leads

Person accounts are not supported.

Note: For `getGeocodeAccuracy()` to work, set up and activate the geocode data integration rules for the related address fields.

`getLatitude()`

Returns the latitude field of this address.

Signature

```
public Double getLatitude()
```

Return Value

Type: Double

`getLongitude()`

Returns the longitude field of this address.

Signature

```
public Double getLongitude()
```

Return Value

Type: Double

`getPostalCode()`

Returns the postal code of this address.

Signature

```
public String getPostalCode()
```

Return Value

Type: String

`getState()`

Returns the text-only state name component of this address.

Signature

```
public String getState()
```

Return Value

Type: String

`getStateCode()`

Returns the state code of this address if state and country picklists are enabled in your organization. Otherwise, returns `null`.

Signature

```
public String getStateCode()
```

Return Value

Type: String

`getStreet()`

Returns the street field of this address.

Signature

```
public String getStreet()
```

Return Value

Type: String

Answers Class

Represents zone answers.

Namespace

System

Usage

Answers is a feature of the Community application that enables users to ask questions and have community members post replies. Community members can then vote on the helpfulness of each reply, and the person who asked the question can mark one reply as the best answer.

For more information on answers, see "Answers Overview" in the Salesforce online help.

Example

The following example finds questions in an internal zone that have similar titles as a new question:

```
public class FindSimilarQuestionController {

   public static void test() {
   // Instantiate a new question
   Question question = new Question ();

   // Specify a title for the new question
   question.title = 'How much vacation time do full-time employees get?';

   // Specify the communityID (INTERNAL_COMMUNITY) in which to find similar questions.
   Community community = [ SELECT Id FROM Community WHERE Name = 'INTERNAL_COMMUNITY' ];

   question.communityId = community.id;

   ID[] results = Answers.findSimilar(question);
   }
}
```

The following example marks a reply as the best reply:

```
ID questionId = [SELECT Id FROM Question WHERE Title = 'Testing setBestReplyId' LIMIT
1].Id;
ID replyID = [SELECT Id FROM Reply WHERE QuestionId = :questionId LIMIT 1].Id;
Answers.setBestReply(questionId,replyId);
```

Answers Methods

The following are methods for `Answers`. All methods are static.

IN THIS SECTION:

findSimilar(yourQuestion)

Returns a list of similar questions based on the title of the specified question.

setBestReply(questionId, replyId)

Sets the specified reply for the specified question as the best reply. Because a question can have multiple replies, setting the best reply helps users quickly identify the reply that contains the most helpful information.

`findSimilar(yourQuestion)`

Returns a list of similar questions based on the title of the specified question.

Signature

```
public static ID[] findSimilar(Question yourQuestion)
```

Parameters

`yourQuestion`
Type: Question

Return Value

Type: ID[]

Usage

Each `findSimilar` call counts against the SOSL statements governor limit allowed for the process.

`setBestReply(questionId, replyId)`

Sets the specified reply for the specified question as the best reply. Because a question can have multiple replies, setting the best reply helps users quickly identify the reply that contains the most helpful information.

Signature

```
public static Void setBestReply(String questionId, String replyId)
```

Parameters

`questionId`
Type: String

`replyId`
Type: String

Return Value

Type: Void

ApexPages Class

Use `ApexPages` to add and check for messages associated with the current page, as well as to reference the current page.

Namespace

System

Usage

In addition, `ApexPages` is used as a namespace for the PageReference Class and the Message Class.

ApexPages Methods

The following are methods for `ApexPages`. All are instance methods.

IN THIS SECTION:

addMessage(message)
Add a message to the current page context.

addMessages(exceptionThrown)
Adds a list of messages to the current page context based on a thrown exception.

currentPage()
Returns the current page's PageReference.

getMessages()
Returns a list of the messages associated with the current context.

hasMessages()
Returns `true` if there are messages associated with the current context, `false` otherwise.

hasMessages(severity)
Returns `true` if messages of the specified severity exist, `false` otherwise.

addMessage(message)

Add a message to the current page context.

Signature

```
public Void addMessage(ApexPages.Message message)
```

Parameters

message
Type: ApexPages.Message

Return Value

Type: Void

addMessages(exceptionThrown)

Adds a list of messages to the current page context based on a thrown exception.

Signature

```
public Void addMessages(Exception exceptionThrown)
```

Parameters

exceptionThrown
Type: Exception

Return Value

Type: Void

currentPage()

Returns the current page's PageReference.

Signature

```
public System.PageReference currentPage()
```

Return Value

Type: System.PageReference

Example

This code segment returns the id parameter of the current page.

```
public MyController() {
    account = [
        SELECT Id, Name, Site
        FROM Account
        WHERE Id =
            :ApexPages.currentPage().
             getParameters().
             get('id')
    ];
}
```

getMessages()

Returns a list of the messages associated with the current context.

Signature

```
public ApexPages.Message[] getMessages()
```

Return Value

Type: ApexPages.Message[]

hasMessages()

Returns `true` if there are messages associated with the current context, `false` otherwise.

Signature

```
public Boolean hasMessages()
```

Return Value

Type: Boolean

hasMessages(severity)

Returns `true` if messages of the specified severity exist, `false` otherwise.

Signature

```
public Boolean hasMessages(ApexPages.Severity severity)
```

Parameters

sev
Type: ApexPages.Severity

Return Value

Type: Boolean

Approval Class

Contains methods for processing approval requests and setting approval-process locks and unlocks on records.

Namespace

System

Usage

Salesforce admins can edit locked records. Depending on your approval process configuration settings, an assigned approver can also edit locked records. Locks and unlocks that are set programmatically use the same record editability settings as other approval-process locks and unlocks.

Record locks and unlocks are treated as DML. They're blocked before a callout, they count toward your DML limits, and if a failure occurs, they're rolled back along with the rest of your transaction. To change this rollback behavior, use an `allOrNone` parameter.

Approval is also used as a namespace for the `ProcessRequest` and `ProcessResult` classes.

SEE ALSO:

Approval Process Considerations

Approval Methods

The following are methods for `Approval`. All methods are static.

IN THIS SECTION:

isLocked(id)
Returns `true` if the record with the ID `id` is locked, or `false` if it's not.

isLocked(ids)
Returns a map of record IDs and their lock statuses. If the record is locked the status is `true`. If the record is not locked the status is `false`.

isLocked(sobject)
Returns `true` if the `sobject` record is locked, or `false` if it's not.

isLocked(sobjects)
Returns a map of record IDs to lock statuses. If the record is locked the status is `true`. If the record is not locked the status is `false`.

lock(recordId)

Locks an object, and returns the lock results.

lock(recordIds)

Locks a set of objects, and returns the lock results, including failures.

lock(recordToLock)

Locks an object, and returns the lock results.

lock(recordsToLock)

Locks a set of objects, and returns the lock results, including failures.

lock(recordId, allOrNothing)

Locks an object, with the option for partial success, and returns the lock result.

lock(recordIds, allOrNothing)

Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

lock(recordToLock, allOrNothing)

Locks an object, with the option for partial success, and returns the lock result.

lock(recordsToLock, allOrNothing)

Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

process(approvalRequest)

Submits a new approval request and approves or rejects existing approval requests.

process(approvalRequests, allOrNone)

Submits a new approval request and approves or rejects existing approval requests.

process(approvalRequests)

Submits a list of new approval requests, and approves or rejects existing approval requests.

process(approvalRequests, allOrNone)

Submits a list of new approval requests, and approves or rejects existing approval requests.

unlock(recordId)

Unlocks an object, and returns the unlock results.

unlock(recordIds)

Unlocks a set of objects, and returns the unlock results, including failures.

unlock(recordToUnlock)

Unlocks an object, and returns the unlock results.

unlock(recordsToUnlock)

Unlocks a set of objects, and returns the unlock results, including failures.

unlock(recordId, allOrNothing)

Unlocks an object, with the option for partial success, and returns the unlock result.

unlock(recordIds, allOrNothing)

Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

unlock(recordToUnlock, allOrNothing)

Unlocks an object, with the option for partial success, and returns the unlock result.

unlock(recordsToUnlock, allOrNothing)

Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

isLocked(id)

Returns `true` if the record with the ID `id` is locked, or `false` if it's not.

Signature

```
public static Boolean isLocked(Id id)
```

Parameters

id
Type: Id

The ID of the record whose lock or unlock status is in question.

Return Value

Type: Boolean

isLocked(ids)

Returns a map of record IDs and their lock statuses. If the record is locked the status is `true`. If the record is not locked the status is `false`.

Signature

```
public static Map<Id,Boolean> isLocked(List<Id> ids)
```

Parameters

ids
Type: List<Id>

The IDs of the records whose lock or unlock statuses are in question.

Return Value

Type: Map<Id,Boolean>

isLocked(sobject)

Returns `true` if the `sobject` record is locked, or `false` if it's not.

Signature

```
public static Boolean isLocked(SObject sobject)
```

Parameters

sobject
Type: SObject

The record whose lock or unlock status is in question.

Return Value

Type: Boolean

isLocked(sobjects)

Returns a map of record IDs to lock statuses. If the record is locked the status is `true`. If the record is not locked the status is `false`.

Signature

```
public static Map<Id,Boolean> isLocked(List<SObject> sobjects)
```

Parameters

sobjects
Type: List<SObject>

The records whose lock or unlock statuses are in question.

Return Value

Type: Map<Id,Boolean>

lock(recordId)

Locks an object, and returns the lock results.

Signature

```
public static Approval.LockResult lock(Id recordId)
```

Parameters

recordId
Type: Id

ID of the object to lock.

Return Value

Type: Approval.LockResult

lock(recordIds)

Locks a set of objects, and returns the lock results, including failures.

Signature

```
public static List<Approval.LockResult> lock(List<Id> ids)
```

Parameters

ids
Type: List<Id>

IDs of the objects to lock.

Return Value

Type: List<Approval.LockResult>

lock(recordToLock)

Locks an object, and returns the lock results.

Signature

```
public static Approval.LockResult lock(SObject recordToLock)
```

Parameters

recordToLock
Type: SObject

Return Value

Type: Approval.LockResult

lock(recordsToLock)

Locks a set of objects, and returns the lock results, including failures.

Signature

```
public static List<Approval.LockResult> lock(List<SObject> recordsToLock)
```

Parameters

recordsToLock
Type: List<SObject>

Return Value

Type: List<Approval.LockResult>

lock(recordId, allOrNothing)

Locks an object, with the option for partial success, and returns the lock result.

Signature

```
public static Approval.LockResult lock(Id recordId, Boolean allOrNothing)
```

Parameters

recordId
Type: Id

ID of the object to lock.

allOrNothing
Type: Boolean

Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value

Type: Approval.LockResult

lock(recordIds, allOrNothing)

Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

Signature

```
public static List<Approval.LockResult> lock(List<Id> recordIds, Boolean allOrNothing)
```

Parameters

recordIds
Type: List<Id>

IDs of the objects to lock.

allOrNothing
Type: Boolean

Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value

Type: List<Approval.LockResult>

lock(recordToLock, allOrNothing)

Locks an object, with the option for partial success, and returns the lock result.

Signature

```
public static Approval.LockResult lock(SObject recordToLock, Boolean allOrNothing)
```

Parameters

recordToLock
Type: SObject

allOrNothing
Type: Boolean

Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value

Type: Approval.LockResult

lock(recordsToLock, allOrNothing)

Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

Signature

```
public static List<Approval.LockResult> lock(List<SObject> recordsToLock, Boolean
allOrNothing)
```

Parameters

recordsToLock
Type: List<SObject>

allOrNothing
Type: Boolean

Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value

Type: List<Approval.LockResult>

process(approvalRequest)

Submits a new approval request and approves or rejects existing approval requests.

Signature

```
public static Approval.ProcessResult process(Approval.ProcessRequest approvalRequest)
```

Parameters

approvalRequest
Type: Approval.ProcessRequest

Return Value

Type: Approval.ProcessResult

Example

```
// Insert an account

Account a = new Account(Name='Test',
                    annualRevenue=100.0);

insert a;

// Create an approval request for the account
Approval.ProcessSubmitRequest req1 =
      new Approval.ProcessSubmitRequest();
req1.setObjectId(a.id);

// Submit the approval request for the account
Approval.ProcessResult result =
                  Approval.process(req1);
```

process(approvalRequests, allOrNone)

Submits a new approval request and approves or rejects existing approval requests.

Signature

```
public static Approval.ProcessResult process(Approval.ProcessRequest approvalRequests,
Boolean allOrNone)
```

Parameters

approvalRequests
Approval.ProcessRequest

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows for partial success. If you specify `false` for this parameter and an approval fails, the remainder of the approval processes can still succeed.

Return Value

Approval.ProcessResult

process(approvalRequests)

Submits a list of new approval requests, and approves or rejects existing approval requests.

Signature

```
public static Approval.ProcessResult [] process(Approval.ProcessRequest[]
approvalRequests)
```

Parameters

approvalRequests
Approval.ProcessRequest []

Return Value

Approval.ProcessResult []

process(approvalRequests, allOrNone)

Submits a list of new approval requests, and approves or rejects existing approval requests.

Signature

```
public static Approval.ProcessResult [] process(Approval.ProcessRequest[]
approvalRequests, Boolean allOrNone)
```

Parameters

approvalRequests
Approval.ProcessRequest []

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows for partial success. If you specify `false` for this parameter and an approval fails, the remainder of the approval processes can still succeed.

Return Value

Approval.ProcessResult []

unlock(recordId)

Unlocks an object, and returns the unlock results.

Signature

```
public static Approval.UnlockResult unlock(Id recordId)
```

Parameters

recordId
Type: Id

ID of the object to unlock.

Return Value

Type: Approval.UnlockResult

unlock(recordIds)

Unlocks a set of objects, and returns the unlock results, including failures.

Signature

```
public static List<Approval.UnlockResult> unlock(List<Id> recordIds)
```

Parameters

recordIds
Type: List<Id>

IDs of the objects to unlock.

Return Value

Type: List<Approval.UnlockResult>

unlock(recordToUnlock)

Unlocks an object, and returns the unlock results.

Signature

```
public static Approval.UnlockResult unlock(SObject recordToUnlock)
```

Parameters

recordToUnlock
Type: SObject

Return Value

Type: Approval.UnlockResult

unlock(recordsToUnlock)

Unlocks a set of objects, and returns the unlock results, including failures.

Signature

```
public static List<Approval.UnlockResult> unlock(List<SObject> recordsToUnlock)
```

Parameters

recordsToUnlock
Type: List<SObject>

Return Value

Type: List<Approval.UnlockResult>

unlock(recordId, allOrNothing)

Unlocks an object, with the option for partial success, and returns the unlock result.

Signature

```
public static Approval.UnlockResult unlock(Id recordId, Boolean allOrNothing)
```

Parameters

recordId
Type: Id

ID of the object to lock.

allOrNothing
Type: Boolean

Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value

Type: Approval.UnlockResult

unlock(recordIds, allOrNothing)

Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

Signature

```
public static List<Approval.UnlockResult> unlock(List<Id> recordIds, Boolean
allOrNothing)
```

Parameters

recordIds
Type: List<Id>

IDs of the objects to unlock.

allOrNothing
Type: Boolean

Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value

Type: List<Approval.UnlockResult>

unlock(recordToUnlock, allOrNothing)

Unlocks an object, with the option for partial success, and returns the unlock result.

Signature

```
public static Approval.UnlockResult unlock(SObject recordToUnlock, Boolean allOrNothing)
```

Parameters

recordToUnlock
Type: SObject

allOrNothing
Type: Boolean

Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value

Type: Approval.UnlockResult

unlock(recordsToUnlock, allOrNothing)

Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

Signature

```
public static List<Approval.UnlockResult> unlock(List<SObject> recordsToUnlock, Boolean
allOrNothing)
```

Parameters

recordsToUnlock
Type: List<SObject>

allOrNothing
Type: Boolean

Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value

Type: List<Approval.UnlockResult>

Blob Class

Contains methods for the Blob primitive data type.

Namespace

System

Usage

For more information on Blobs, see Primitive Data Types on page 26.

Blob Methods

The following are methods for `Blob`.

IN THIS SECTION:

size()
Returns the number of characters in the Blob.

toPdf(stringToConvert)
Creates a binary object out of the given string, encoding it as a PDF file.

toString()
Casts the Blob into a String.

valueOf(stringToBlob)
Casts the specified String to a Blob.

size()

Returns the number of characters in the Blob.

Signature

```
public Integer size()
```

Return Value

Type: Integer

Example

```
String myString = 'StringToBlob';
Blob myBlob = Blob.valueof(myString);
Integer size = myBlob.size();
```

toPdf(stringToConvert)

Creates a binary object out of the given string, encoding it as a PDF file.

Signature

```
public static Blob toPdf(String stringToConvert)
```

Parameters

stringToConvert
Type: String

Return Value

Type: Blob

Example

```
String pdfContent = 'This is a test string';
Account a = new account(name = 'test');
insert a;
Attachment attachmentPDF = new Attachment();
attachmentPdf.parentId = a.id;
attachmentPdf.name = a.name + '.pdf';
attachmentPdf.body = blob.toPDF(pdfContent);
insert attachmentPDF;
```

toString()

Casts the Blob into a String.

Signature

```
public String toString()
```

Return Value

Type: String

Example

```
String myString = 'StringToBlob';
Blob myBlob = Blob.valueof(myString);
System.assertEquals('StringToBlob', myBlob.toString());
```

valueOf(stringToBlob)

Casts the specified String to a Blob.

Signature

```
public static Blob valueOf(String stringToBlob)
```

Parameters

stringToBlob
Type: String

Return Value

Type: Blob

Example

```
String myString = 'StringToBlob';
Blob myBlob = Blob.valueof(myString);
```

Boolean Class

Contains methods for the Boolean primitive data type.

Namespace

System

Boolean Methods

The following are methods for `Boolean`. All methods are static.

IN THIS SECTION:

valueOf(stringToBoolean)
Converts the specified string to a Boolean value and returns `true` if the specified string value is `true`. Otherwise, returns `false`.

valueOf(fieldValue)
Converts the specified object to a Boolean value. Use this method to convert a history tracking field value or an object that represents a Boolean value.

valueOf(stringToBoolean)

Converts the specified string to a Boolean value and returns `true` if the specified string value is `true`. Otherwise, returns `false`.

Signature

```
public static Boolean valueOf(String stringToBoolean)
```

Parameters

stringToBoolean
Type: String

Return Value

Type: Boolean

Usage

If the specified argument is null, this method throws an exception.

Example

```
Boolean b = Boolean.valueOf('true');
System.assertEquals(true, b);
```

`valueOf(fieldValue)`

Converts the specified object to a Boolean value. Use this method to convert a history tracking field value or an object that represents a Boolean value.

Signature

```
public static Boolean valueOf(Object fieldValue)
```

Parameters

`fieldValue`
Type: Object

Return Value

Type: Boolean

Usage

Use this method with the `OldValue` or `NewValue` fields of history sObjects, such as `AccountHistory`, when the field type corresponds to a Boolean type, like a checkbox field.

Example

```
List<AccountHistory> ahlist =
  [SELECT Field,OldValue,NewValue
   FROM AccountHistory];
for(AccountHistory ah : ahlist) {
  System.debug('Field: ' + ah.Field);
  if (ah.field == 'IsPlatinum__c') {
    Boolean oldValue =
      Boolean.valueOf(ah.OldValue);
    Boolean newValue =
      Boolean.valueOf(ah.NewValue);
}
```

BusinessHours Class

Use the `BusinessHours` methods to set the business hours at which your customer support team operates.

Namespace

System

BusinessHours Methods

The following are methods for `BusinessHours`. All methods are static.

IN THIS SECTION:

add(businessHoursId, startDate, intervalMilliseconds)
Adds an interval of time from a start Datetime traversing business hours only. Returns the result Datetime in the local time zone.

addGmt(businessHoursId, startDate, intervalMilliseconds)
Adds an interval of milliseconds from a start Datetime traversing business hours only. Returns the result Datetime in GMT.

diff(businessHoursId, startDate, endDate)
Returns the difference in milliseconds between a start and end Datetime based on a specific set of business hours.

isWithin(businessHoursId, targetDate)
Returns `true` if the specified target date occurs within business hours. Holidays are included in the calculation.

nextStartDate(businessHoursId, targetDate)
Starting from the specified target date, returns the next date when business hours are open. If the specified target date falls within business hours, this target date is returned.

add(businessHoursId, startDate, intervalMilliseconds)

Adds an interval of time from a start Datetime traversing business hours only. Returns the result Datetime in the local time zone.

Signature

```
public static Datetime add(String businessHoursId, Datetime startDate, Long
intervalMilliseconds)
```

Parameters

businessHoursId
Type: String

startDate
Type: Datetime

intervalMilliseconds
Type: Long

Interval value should be provided in milliseconds, however time precision smaller than one minute is ignored.

Return Value

Type: Datetime

addGmt(businessHoursId, startDate, intervalMilliseconds)

Adds an interval of milliseconds from a start Datetime traversing business hours only. Returns the result Datetime in GMT.

Signature

```
public static Datetime addGmt(String businessHoursId, Datetime startDate, Long
intervalMilliseconds)
```

Parameters

businessHoursId
Type: String

startDate
Type: Datetime

intervalMilliseconds
Type: Long

Return Value

Type: Datetime

diff(businessHoursId, startDate, endDate)

Returns the difference in milliseconds between a start and end Datetime based on a specific set of business hours.

Signature

```
public static Long diff(String businessHoursId, Datetime startDate, Datetime endDate)
```

Parameters

businessHoursId
Type: String

startDate
Type: Datetime

endDate
Type: Datetime

Return Value

Type: Long

isWithin(businessHoursId, targetDate)

Returns `true` if the specified target date occurs within business hours. Holidays are included in the calculation.

Signature

```
public static Boolean isWithin(String businessHoursId, Datetime targetDate)
```

Parameters

businessHoursId
Type: String

The business hours ID.

targetDate
Type: Datetime

The date to verify.

Return Value

Type: Boolean

Example

The following example finds whether a given time is within the default business hours.

```
// Get the default business hours
BusinessHours bh = [SELECT Id FROM BusinessHours WHERE IsDefault=true];

// Create Datetime on May 28, 2013 at 1:06:08 AM in the local timezone.
Datetime targetTime = Datetime.newInstance(2013, 5, 28, 1, 6, 8);

// Find whether the time is within the default business hours
Boolean isWithin= BusinessHours.isWithin(bh.id, targetTime);
```

nextStartDate(businessHoursId, targetDate)

Starting from the specified target date, returns the next date when business hours are open. If the specified target date falls within business hours, this target date is returned.

Signature

```
public static Datetime nextStartDate(String businessHoursId, Datetime targetDate)
```

Parameters

businessHoursId
Type: String

The business hours ID.

targetDate
Type: Datetime

The date used as a start date to obtain the next date.

Return Value

Type: Datetime

Example

The following example finds the next date starting from the target date when business hours reopens. If the target date is within the given business hours, the target date is returned. The returned time is in the local time zone.

```
// Get the default business hours
BusinessHours bh = [SELECT Id FROM BusinessHours WHERE IsDefault=true];

// Create Datetime on May 28, 2013 at 1:06:08 AM in the local timezone.
Datetime targetTime = Datetime.newInstance(2013, 5, 28, 1, 6, 8);
```

```
// Starting from the targetTime, find the next date when business hours reopens. Return
the target time.

// if it is within the business hours. The returned time will be in the local time zone
Datetime nextStart = BusinessHours.nextStartDate(bh.id, targetTime);
```

Callable Interface

Enables developers to use a common interface to build loosely coupled integrations between Apex classes or triggers, even for code in separate packages. Agreeing upon a common interface enables developers from different companies or different departments to build upon one another's solutions. Implement this interface to enable the broader community, which might have different solutions than the ones you had in mind, to extend your code's functionality.

Note: This interface is not an analog of the Java Callable interface, which is used for asynchronous invocation. Don't confuse the two.

Namespace

System

Usage

To implement the `Callable` interface, you need to write only one method: `call(String action, Map<String, Object> args)`.

In code that utilizes or tests an implementation of `Callable`, cast an instance of your type to `Callable`.

This interface is not intended to replace defining more specific interfaces. Rather, the `Callable` interface allows integrations in which code from different classes or packages can use common base types.

IN THIS SECTION:

Callable Methods

Callable Example Implementation

Callable Methods

The following are methods for `Callable`.

IN THIS SECTION:

call(action, args)
Provides functionality that other classes or packages can utilize and build upon.

`call(action, args)`

Provides functionality that other classes or packages can utilize and build upon.

Signature

```
public Object call(String action, Map<String,Object> args)
```

Parameters

action
Type: String

The behavior for the method to exhibit.

args
Type: Map on page 2759<String,Object>

Arguments to be used by the specified action.

Return Value

Type: Object

The result of the method invocation.

Callable Example Implementation

This class is an example implementation of the `System.Callable` interface.

```
public class Extension implements Callable {

   // Actual method
   String concatStrings(String stringValue) {
     return stringValue + stringValue;
   }

   // Actual method
   Decimal multiplyNumbers(Decimal decimalValue) {
     return decimalValue * decimalValue;
   }

   // Dispatch actual methods
   public Object call(String action, Map<String, Object> args) {
     switch on action {
       when 'concatStrings' {
         return this.concatStrings((String)args.get('stringValue'));
       }
       when 'multiplyNumbers' {
         return this.multiplyNumbers((Decimal)args.get('decimalValue'));
       }
       when else {
        throw new ExtensionMalformedCallException('Method not implemented');
       }
     }
   }

   public class ExtensionMalformedCallException extends Exception {}
}
```

The following test code illustrates how calling code utilizes the interface to call a method.

```
@IsTest
private with sharing class ExtensionCaller {
```

```
    @IsTest
    private static void givenConfiguredExtensionWhenCalledThenValidResult() {

        // Given
        String extensionClass = 'Extension'; // Typically set via configuration
        Decimal decimalTestValue = 10;

        // When
        Callable extension =
            (Callable) Type.forName(extensionClass).newInstance();
        Decimal result = (Decimal)
            extension.call('multiplyNumbers', new Map<String, Object> {
                'decimalValue' => decimalTestValue
            });

        // Then
        System.assertEquals(100, result);
    }
}
```

SEE ALSO:

Classes and Casting

Cases Class

Use the `Cases` class to interact with case records.

Namespace

System

Cases Methods

The following are static methods for `Cases`.

IN THIS SECTION:

getCaseIdFromEmailThreadId(emailThreadId)
Returns the case ID corresponding to the specified email thread ID.

`getCaseIdFromEmailThreadId(emailThreadId)`

Returns the case ID corresponding to the specified email thread ID.

Signature

```
public static ID getCaseIdFromEmailThreadId(String emailThreadId)
```

Parameters

emailThreadId
Type: String

Return Value

Type: ID

Usage

The *emailThreadId* argument should have the following format: `_00Dxx1gEW._500xxYktg`. Other formats, such as `ref:_00Dxx1gEW._500xxYktl:ref` and `[ref:_00Dxx1gEW._500xxYktl:ref]`, are invalid.

Comparable Interface

Adds sorting support for Lists that contain non-primitive types, that is, Lists of user-defined types.

Namespace

System

Usage

To add List sorting support for your Apex class, you must implement the `Comparable` interface with its `compareTo` method in your class.

To implement the `Comparable` interface, you must first declare a class with the `implements` keyword as follows:

```
global class Employee implements Comparable {
```

Next, your class must provide an implementation for the following method:

```
global Integer compareTo(Object compareTo) {
    // Your code here
}
```

The implemented method must be declared as `global` or `public`.

IN THIS SECTION:

Comparable Methods

Comparable Example Implementation

SEE ALSO:

List Class

Comparable Methods

The following are methods for `Comparable`.

IN THIS SECTION:

compareTo(objectToCompareTo)
Returns an Integer value that is the result of the comparison.

compareTo(objectToCompareTo)

Returns an Integer value that is the result of the comparison.

Signature

```
public Integer compareTo(Object objectToCompareTo)
```

Parameters

objectToCompareTo
Type: Object

Return Value

Type: Integer

Usage

The implementation of this method should return the following values:

- 0 if this instance and *objectToCompareTo* are equal
- > 0 if this instance is greater than *objectToCompareTo*
- < 0 if this instance is less than *objectToCompareTo*

Comparable Example Implementation

This is an example implementation of the `Comparable` interface. The `compareTo` method in this example compares the employee of this class instance with the employee passed in the argument. The method returns an Integer value based on the comparison of the employee IDs.

```
global class Employee implements Comparable {

    public Long id;
    public String name;
    public String phone;

    // Constructor
    public Employee(Long i, String n, String p) {
        id = i;
        name = n;
        phone = p;
    }

    // Implement the compareTo() method
    global Integer compareTo(Object compareTo) {
        Employee compareToEmp = (Employee)compareTo;
        if (id == compareToEmp.id) return 0;
```

```
        if (id > compareToEmp.id) return 1;
        return -1;
    }
}
```

This example tests the sort order of a list of `Employee` objects.

```
@isTest
private class EmployeeSortingTest {
    static testmethod void test1() {
        List<Employee> empList = new List<Employee>();
        empList.add(new Employee(101,'Joe Smith', '4155551212'));
        empList.add(new Employee(101,'J. Smith', '4155551212'));
        empList.add(new Employee(25,'Caragh Smith', '4155551000'));
        empList.add(new Employee(105,'Mario Ruiz', '4155551099'));

        // Sort using the custom compareTo() method
        empList.sort();

        // Write list contents to the debug log
        System.debug(empList);

        // Verify list sort order.
        System.assertEquals('Caragh Smith', empList[0].Name);
        System.assertEquals('Joe Smith', empList[1].Name);
        System.assertEquals('J. Smith', empList[2].Name);
        System.assertEquals('Mario Ruiz', empList[3].Name);
    }
}
```

Continuation Class

Use the `Continuation` class to make callouts asynchronously to a SOAP or REST Web service.

Namespace

System

Example

For a code example, see Make Long-Running Callouts from a Visualforce Page.

IN THIS SECTION:

Continuation Constructors

Continuation Properties

Continuation Methods

Continuation Constructors

The following are constructors for `Continuation`.

IN THIS SECTION:

Continuation(timeout)
Creates an instance of the `Continuation` class by using the specified timeout in seconds. The timeout maximum is 120 seconds.

`Continuation(timeout)`

Creates an instance of the `Continuation` class by using the specified timeout in seconds. The timeout maximum is 120 seconds.

Signature

```
public Continuation(Integer timeout)
```

Parameters

`timeout`
Type: Integer

The timeout for this continuation in seconds.

Continuation Properties

The following are properties for `Continuation`.

IN THIS SECTION:

continuationMethod
The name of the callback method that is called after the callout response returns.

timeout
The timeout of the continuation in seconds. Maximum: 120 seconds seconds.

state
Data that is stored in this continuation and that can be retrieved after the callout is finished and the callback method is invoked.

`continuationMethod`

The name of the callback method that is called after the callout response returns.

Signature

```
public String continuationMethod {get; set;}
```

Property Value

Type: String

Usage

Note: If the `continuationMethod` property is not set for a Continuation, the same action method that made the asynchronous callout is called again when the callout response returns.

timeout

The timeout of the continuation in seconds. Maximum: 120 seconds seconds.

Signature

```
public Integer timeout {get; set;}
```

Property Value

Type: Integer

state

Data that is stored in this continuation and that can be retrieved after the callout is finished and the callback method is invoked.

Signature

```
public Object state {get; set;}
```

Property Value

Type: Object

Example

This example shows how to save state information for a continuation in a controller.

```
// Declare inner class to hold state info
private class StateInfo {
    String msg { get; set; }
    List<String> urls  { get; set; }
    StateInfo(String msg, List<String> urls) {
        this.msg = msg;
        this.urls = urls;
    }
}

// Then in the action method, set state for the continuation
continuationInstance.state = new StateInfo('Some state data', urls);
```

Continuation Methods

The following are methods for `Continuation`.

IN THIS SECTION:

addHttpRequest(request)
Adds the HTTP request for the callout that is associated with this continuation.

getRequests()
Returns all labels and requests that are associated with this continuation as key-value pairs.

getResponse(requestLabel)
Returns the response for the request that corresponds to the specified label.

addHttpRequest(request)

Adds the HTTP request for the callout that is associated with this continuation.

Signature

```
public String addHttpRequest(System.HttpRequest request)
```

Parameters

request
Type: HttpRequest

The HTTP request to be sent to the external service by this continuation.

Return Value

Type: String

A unique label that identifies the HTTP request that is associated with this continuation. This label is used in the map that getRequests() returns to identify individual requests in a continuation.

Usage

You can add up tothree requests to a continuation.

Note: The timeout that is set in each passed-in request is ignored. Only the global timeout maximum of 120 seconds applies for a continuation.

getRequests()

Returns all labels and requests that are associated with this continuation as key-value pairs.

Signature

```
public Map<String,System.HttpRequest> getRequests()
```

Return Value

Type: Map<String,HttpRequest>

A map of all requests that are associated with this continuation. The map key is the request label, and the map value is the corresponding HTTP request.

getResponse(requestLabel)

Returns the response for the request that corresponds to the specified label.

Signature

```
public static HttpResponse getResponse(String requestLabel)
```

Parameters

requestLabel
Type: String

The request label to get the response for.

Return Value

Type: HttpResponse

Usage

The status code is returned in the HttpResponse object and can be obtained by calling `getStatusCode()` on the response. A status code of `200` indicates that the request was successful. Other status code values indicate the type of problem that was encountered.

Sample of Error Status Codes

When a problem occurs with the response, some possible status code values are:

- `2000`: The timeout was reached, and the server didn't get a chance to respond.
- `2001`: There was a connection failure.
- `2002`: Exceptions occurred.
- `2003`: The response hasn't arrived (which also means that the Apex asynchronous callout framework hasn't resumed).
- `2004`: The response size is too large (greater than 1 MB).

Cookie Class

The `Cookie` class lets you access cookies for your Salesforce site using Apex.

Namespace

System

Usage

Use the `setCookies` method of the PageReference Class to attach cookies to a page.

Important:

- Cookie names and values set in Apex are URL encoded, that is, characters such as @ are replaced with a percent sign and their hexadecimal representation.
- The `setCookies` method adds the prefix "`apex__`" to the cookie names.
- Setting a cookie's value to `null` sends a cookie with an empty string value instead of setting an expired attribute.
- After you create a cookie, the properties of the cookie can't be changed.
- Be careful when storing sensitive information in cookies. Pages are cached regardless of a cookie value. If you use a cookie value to generate dynamic content, you should disable page caching. For more information, see "Cache Salesforce Sites Pages" in the Salesforce online help.

Consider the following limitations when using the `Cookie` class:

- The `Cookie` class can only be accessed using Apex that is saved using the Salesforce API version 19 and above.
- The maximum number of cookies that can be set per Salesforce Sites domain depends on your browser. Newer browsers have higher limits than older ones.
- Cookies must be less than 4K, including name and attributes.

For more information on sites, see "Salesforce Sites" in the Salesforce online help.

Example

The following example creates a class, `CookieController`, which is used with a Visualforce page (see markup below) to update a counter each time a user displays a page. The number of times a user goes to the page is stored in a cookie.

```
// A Visualforce controller class that creates a cookie
// used to keep track of how often a user displays a page
public class CookieController {

    public CookieController() {
        Cookie counter = ApexPages.currentPage().getCookies().get('counter');

        // If this is the first time the user is accessing the page,
        // create a new cookie with name 'counter', an initial value of '1',
        // path 'null', maxAge '-1', and isSecure 'false'.
        if (counter == null) {
            counter = new Cookie('counter','1',null,-1,false);
        } else {
        // If this isn't the first time the user is accessing the page
        // create a new cookie, incrementing the value of the original count by 1
            Integer count = Integer.valueOf(counter.getValue());
            counter = new Cookie('counter', String.valueOf(count+1),null,-1,false);
        }

        // Set the new cookie for the page
        ApexPages.currentPage().setCookies(new Cookie[]{counter});
    }

    // This method is used by the Visualforce action {!count} to display the current
    // value of the number of times a user had displayed a page.
    // This value is stored in the cookie.
    public String getCount() {
        Cookie counter = ApexPages.currentPage().getCookies().get('counter');
        if(counter == null) {
            return '0';
        }
        return counter.getValue();
    }
}
```

```
// Test class for the Visualforce controller
@isTest
private class CookieControllerTest {
  // Test method for verifying the positive test case
  static testMethod void testCounter() {
```

```
    //first page view
    CookieController controller = new CookieController();
    System.assert(controller.getCount() == '1');

    //second page view
    controller = new CookieController();
    System.assert(controller.getCount() == '2');
  }
}
```

The following is the Visualforce page that uses the `CookieController` Apex controller above. The action `{!count}` calls the `getCount` method in the controller above.

```
<apex:page controller="CookieController">
You have seen this page {!count} times
</apex:page>
```

IN THIS SECTION:

Cookie Constructors

Cookie Methods

Cookie Constructors

The following are constructors for `Cookie`.

IN THIS SECTION:

Cookie(name, value, path, maxAge, isSecure)
Creates a new instance of the `Cookie` class using the specified name, value, path, age, and the secure setting.

`Cookie(name, value, path, maxAge, isSecure)`

Creates a new instance of the `Cookie` class using the specified name, value, path, age, and the secure setting.

Signature

```
public Cookie(String name, String value, String path, Integer maxAge, Boolean isSecure)
```

Parameters

name
Type: String

The cookie name. It can't be `null`.

value
Type: String

The cookie data, such as session ID.

path
Type: String

The path from where you can retrieve the cookie.

maxAge
Type: Integer

A number representing how long a cookie is valid for in seconds. If set to less than zero, a session cookie is issued. If set to zero, the cookie is deleted.

isSecure
Type: Boolean

A value indicating whether the cookie can only be accessed through HTTPS (`true`) or not (`false`).

Cookie Methods

The following are methods for `Cookie`. All are instance methods.

IN THIS SECTION:

getDomain()
Returns the name of the server making the request.

getMaxAge()
Returns a number representing how long the cookie is valid for, in seconds. If set to `< 0`, a session cookie is issued. If set to `0`, the cookie is deleted.

getName()
Returns the name of the cookie. Can't be `null`.

getPath()
Returns the path from which you can retrieve the cookie. If `null` or blank, the location is set to root, or "/".

getValue()
Returns the data captured in the cookie, such as Session ID.

isSecure()
Returns `true` if the cookie can only be accessed through HTTPS, otherwise returns `false`.

`getDomain()`

Returns the name of the server making the request.

Signature

```
public String getDomain()
```

Return Value

Type: String

`getMaxAge()`

Returns a number representing how long the cookie is valid for, in seconds. If set to `< 0`, a session cookie is issued. If set to `0`, the cookie is deleted.

Signature

```
public Integer getMaxAge()
```

Return Value

Type: Integer

getName()

Returns the name of the cookie. Can't be `null`.

Signature

```
public String getName()
```

Return Value

Type: String

getPath()

Returns the path from which you can retrieve the cookie. If `null` or blank, the location is set to root, or "/".

Signature

```
public String getPath()
```

Return Value

Type: String

getValue()

Returns the data captured in the cookie, such as Session ID.

Signature

```
public String getValue()
```

Return Value

Type: String

isSecure()

Returns `true` if the cookie can only be accessed through HTTPS, otherwise returns `false`.

Signature

```
public Boolean isSecure()
```

Return Value

Type: Boolean

Crypto Class

Provides methods for creating digests, message authentication codes, and signatures, as well as encrypting and decrypting information.

Namespace

System

Usage

The methods in the `Crypto` class can be used for securing content in Lightning Platform, or for integrating with external services such as Google or Amazon WebServices (AWS).

Encrypt and Decrypt Exceptions

The following exceptions can be thrown for these methods:

- `decrypt`
- `encrypt`
- `decryptWithManagedIV`
- `encryptWithManagedIV`

Exception	Message	Description
`InvalidParameterValue`	Unable to parse initialization vector from encrypted data.	Thrown if you're using managed initialization vectors, and the cipher text is less than 16 bytes.
`InvalidParameterValue`	Invalid algorithm *`algoName`*. Must be AES128, AES192, or AES256.	Thrown if the algorithm name isn't one of the valid values.
`InvalidParameterValue`	Invalid private key. Must be *`size`* bytes.	Thrown if size of the private key doesn't match the specified algorithm.
`InvalidParameterValue`	Invalid initialization vector. Must be 16 bytes.	Thrown if the initialization vector isn't 16 bytes.
`InvalidParameterValue`	Invalid data. Input data is *`size`* bytes, which exceeds the limit of 1048576 bytes.	Thrown if the data is greater than 1 MB. For decryption, 1048608 bytes are allowed for the initialization vector header, plus any additional padding the encryption added to align to block size.
`NullPointerException`	Argument cannot be null.	Thrown if one of the required method arguments is null.
`SecurityException`	Given final block not properly padded.	Thrown if the data isn't properly block-aligned or similar issues occur during encryption or decryption.

Exception	Message	Description
`SecurityException`	*`Message Varies`*	Thrown if something goes wrong during either encryption or decryption.

Crypto Methods

The following are methods for `Crypto`. All methods are static.

IN THIS SECTION:

decrypt(algorithmName, privateKey, initializationVector, cipherText)

Decrypts the Blob *`cipherText`* using the specified algorithm, private key, and initialization vector. Use this method to decrypt blobs encrypted using a third party application or the `encrypt` method.

decryptWithManagedIV(algorithmName, privateKey, IVAndCipherText)

Decrypts the Blob *`IVAndCipherText`* using the specified algorithm and private key. Use this method to decrypt blobs encrypted using a third party application or the `encryptWithManagedIV` method.

encrypt(algorithmName, privateKey, initializationVector, clearText)

Encrypts the Blob *`clearText`* using the specified algorithm, private key and initialization vector. Use this method when you want to specify your own initialization vector.

encryptWithManagedIV(algorithmName, privateKey, clearText)

Encrypts the Blob *`clearText`* using the specified algorithm and private key. Use this method when you want Salesforce to generate the initialization vector for you.

generateAesKey(size)

Generates an Advanced Encryption Standard (AES) key.

generateDigest(algorithmName, input)

Computes a secure, one-way hash digest based on the supplied input string and algorithm name.

generateMac(algorithmName, input, privateKey)

Computes a message authentication code (MAC) for the input string, using the private key and the specified algorithm.

getRandomInteger()

Returns a random Integer.

getRandomLong()

Returns a random Long.

sign(algorithmName, input, privateKey)

Computes a unique digital signature for the input string, using the specified algorithm and the supplied private key.

signWithCertificate(algorithmName, input, certDevName)

Computes a unique digital signature for the input string, using the specified algorithm and the supplied certificate and key pair.

signXML(algorithmName, node, idAttributeName, certDevName)

Envelops the signature into an XML document.

signXML(algorithmName, node, idAttributeName, certDevName, refChild)

Inserts the signature envelope before the specified child node.

verify(String algorithmName, Blob data, Blob signature, Blob publicKey)

Verifies the digital signature for the Blob *data* using the specified algorithm and the supplied public key. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

verify(String algorithmName, Blob data, Blob signature, String certDevName)

Verifies the digital signature for the Blob *data* using the specified algorithm and the public key associated with the certDevName. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

verifyMac(String algorithmName, Blob input, Blob privateKey, Blob macToVerify)

Verifies the HMAC signature for Blob *data* using the specified algorithm, input data, privateKey, and the mac. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

decrypt(algorithmName, privateKey, initializationVector, cipherText)

Decrypts the Blob *cipherText* using the specified algorithm, private key, and initialization vector. Use this method to decrypt blobs encrypted using a third party application or the `encrypt` method.

Signature

```
public static Blob decrypt(String algorithmName, Blob privateKey, Blob
initializationVector, Blob cipherText)
```

Parameters

algorithmName
Type: String

privateKey
Type: Blob

initializationVector
Type: Blob

cipherText
Type: Blob

Return Value

Type: Blob

Usage

Valid values for *algorithmName* are:

- AES128
- AES192
- AES256

These are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS5 padding.

The length of *privateKey* must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16, 24, or 32 bytes, respectively. You can use a third-party application or the `generateAesKey` method to generate this key for you.

The initialization vector must be 128 bits (16 bytes.)

Example

```
Blob exampleIv = Blob.valueOf('Example of IV123');
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encrypt('AES128', key, exampleIv, data);

Blob decrypted = Crypto.decrypt('AES128', key, exampleIv, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

decryptWithManagedIV(algorithmName, privateKey, IVAndCipherText)

Decrypts the Blob *IVAndCipherText* using the specified algorithm and private key. Use this method to decrypt blobs encrypted using a third party application or the `encryptWithManagedIV` method.

Signature

```
public static Blob decryptWithManagedIV(String algorithmName, Blob privateKey, Blob
IVAndCipherText)
```

Parameters

algorithmName
Type: String

privateKey
Type: Blob

IVAndCipherText
Type: Blob

The first 128 bits (16 bytes) of *IVAndCipherText* must contain the initialization vector.

Return Value

Type: Blob

Usage

Valid values for *algorithmName* are:

- AES128
- AES192
- AES256

These are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS5 padding.

The length of *privateKey* must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16, 24, or 32 bytes, respectively. You can use a third-party application or the `generateAesKey` method to generate this key for you.

Example

```
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encryptWithManagedIV('AES128', key, data);

Blob decrypted = Crypto.decryptWithManagedIV('AES128', key, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

encrypt(algorithmName, privateKey, initializationVector, clearText)

Encrypts the Blob *clearText* using the specified algorithm, private key and initialization vector. Use this method when you want to specify your own initialization vector.

Signature

```
public static Blob encrypt(String algorithmName, Blob privateKey, Blob
initializationVector, Blob clearText)
```

Parameters

algorithmName
Type: String

privateKey
Type: Blob

initializationVector
Type: Blob

clearText
Type: Blob

Return Value

Type: Blob

Usage

The initialization vector must be 128 bits (16 bytes.) Use either a third-party application or the `decrypt` method to decrypt blobs encrypted using this method. Use the `encryptWithManagedIV` method if you want Salesforce to generate the initialization vector for you. It is stored as the first 128 bits (16 bytes) of the encrypted Blob.

Valid values for *algorithmName* are:

- AES128
- AES192
- AES256

These are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS5 padding.

The length of *privateKey* must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16, 24, or 32 bytes, respectively. You can use a third-party application or the `generateAesKey` method to generate this key for you.

Example

```
Blob exampleIv = Blob.valueOf('Example of IV123');
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encrypt('AES128', key, exampleIv, data);

Blob decrypted = Crypto.decrypt('AES128', key, exampleIv, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

encryptWithManagedIV(algorithmName, privateKey, clearText)

Encrypts the Blob *clearText* using the specified algorithm and private key. Use this method when you want Salesforce to generate the initialization vector for you.

Signature

```
public static Blob encryptWithManagedIV(String algorithmName, Blob privateKey, Blob
clearText)
```

Parameters

algorithmName
Type: String

privateKey
Type: Blob

clearText
Type: Blob

Return Value

Type: Blob

Usage

The initialization vector is stored as the first 128 bits (16 bytes) of the encrypted Blob. Use either third-party applications or the `decryptWithManagedIV` method to decrypt blobs encrypted with this method. Use the `encrypt` method if you want to generate your own initialization vector.

Valid values for *algorithmName* are:

- AES128
- AES192
- AES256

These are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS5 padding.

The length of *privateKey* must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16, 24, or 32 bytes, respectively. You can use a third-party application or the `generateAesKey` method to generate this key for you.

Example

```
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encryptWithManagedIV('AES128', key, data);

Blob decrypted = Crypto.decryptWithManagedIV('AES128', key, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

generateAesKey(size)

Generates an Advanced Encryption Standard (AES) key.

Signature

```
public static Blob generateAesKey(Integer size)
```

Parameters

size
Type: Integer

The key's size in bits. Valid values are:

- 128
- 192
- 256

Return Value

Type: Blob

Example

```
Blob key = Crypto.generateAesKey(128);
```

generateDigest(algorithmName, input)

Computes a secure, one-way hash digest based on the supplied input string and algorithm name.

Signature

```
public static Blob generateDigest(String algorithmName, Blob input)
```

Parameters

algorithmName
Type: String

Valid values for *algorithmName* are:

- MD5

- SHA1
- SHA-256
- SHA-512

input
Type: Blob

Return Value

Type: Blob

Example

```
Blob targetBlob = Blob.valueOf('ExampleMD5String');
Blob hash = Crypto.generateDigest('MD5', targetBlob);
```

generateMac(algorithmName, input, privateKey)

Computes a message authentication code (MAC) for the input string, using the private key and the specified algorithm.

Signature

```
public static Blob generateMac(String algorithmName, Blob input, Blob privateKey)
```

Parameters

algorithmName
Type: String

The valid values for *algorithmName* are:

- hmacMD5
- hmacSHA1
- hmacSHA256
- hmacSHA512

input
Type: Blob

privateKey
Type: Blob

The value of *privateKey* does not need to be in decoded form. The value cannot exceed 4 KB.

Return Value

Type: Blob

Example

```
String salt = String.valueOf(Crypto.getRandomInteger());
String key = 'key';
```

```
Blob data = crypto.generateMac('HmacSHA256',
Blob.valueOf(salt), Blob.valueOf(key));
```

getRandomInteger()

Returns a random Integer.

Signature

```
public static Integer getRandomInteger()
```

Return Value

Type: Integer

Example

```
Integer randomInt = Crypto.getRandomInteger();
```

getRandomLong()

Returns a random Long.

Signature

```
public static Long getRandomLong()
```

Return Value

Type: Long

Example

```
Long randomLong = Crypto.getRandomLong();
```

sign(algorithmName, input, privateKey)

Computes a unique digital signature for the input string, using the specified algorithm and the supplied private key.

Signature

```
public static Blob sign(String algorithmName, Blob input, Blob privateKey)
```

Parameters

algorithmName
Type: String

The algorithm name. The valid values for *algorithmName* are `RSA-SHA1`, `RSA-SHA256`, or `RSA`.

`RSA-SHA1` is an RSA signature (with an asymmetric key pair) of a SHA1 hash.

`RSA-SHA256` is an RSA signature of a SHA256 hash.

`RSA` is the same as `RSA-SHA1`.

`input`
Type: Blob

The data to sign.

`privateKey`
Type: Blob

The value of *`privateKey`* must be decoded using the `EncodingUtilbase64Decode` method, and should be in RSA's PKCS #8 (1.2) Private-Key Information Syntax Standard form. The value cannot exceed 4 KB.

Return Value

Type: Blob

Example

The following snippet shows how to call the `sign` method.

```
String algorithmName = 'RSA';
String key = '';
Blob privateKey = EncodingUtil.base64Decode(key);
Blob input = Blob.valueOf('12345qwerty');
Crypto.sign(algorithmName, input, privateKey);
```

signWithCertificate(algorithmName, input, certDevName)

Computes a unique digital signature for the input string, using the specified algorithm and the supplied certificate and key pair.

Signature

```
public static Blob signWithCertificate(String algorithmName, Blob input, String
certDevName)
```

Parameters

`algorithmName`
Type: String

The algorithm name. The valid values for *`algorithmName`* are `RSA-SHA1`, `RSA-SHA256`, or `RSA`.

`RSA-SHA1` is an RSA signature (with an asymmetric key pair) of a SHA1 hash.

`RSA-SHA256` is an RSA signature of a SHA256 hash.

`RSA` is the same as `RSA-SHA1`.

`input`
Type: Blob

The data to sign.

`certDevName`
Type: String

The `Unique Name` for a certificate stored in the Salesforce organization's Certificate and Key Management page to use for signing.

To access the Certificate and Key Management page from Setup, enter *`Certificate and Key Management`* in the `Quick Find` box, then select **Certificate and Key Management**.

Return Value

Type: Blob

Example

The following snippet is an example of the method for signing the content referenced by `data`.

```
Blob data = Blob.valueOf('12345qwerty');
System.Crypto.signWithCertificate('RSA-SHA256', data, 'signingCert');
```

signXML(algorithmName, node, idAttributeName, certDevName)

Envelops the signature into an XML document.

Signature

```
public Void signXML(String algorithmName, Dom.XmlNode node, String idAttributeName,
String certDevName)
```

Parameters

`algorithmName`
Type: String

The algorithm name. Valid names are RSA-SHA1, RSA-SHA256, or RSA.

RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.

RSA-SHA256 is an RSA signature of an SHA256 hash.

RSA is the same as RSA-SHA1.

`node`
Type: Dom.XmlNode

The XML node to sign and insert the signature into.

`idAttributeName`
Type: String

The full name (including the namespace) of the attribute on the node (XmlNode) to use as the reference ID. If `null`, this method uses the `ID` attribute on the node. If there is no `ID` attribute, Salesforce generates a new ID and adds it to the node.

`certDevName`
Type: String

The unique name for a certificate stored in the Salesforce org's Certificate and Key Management page to use for signing.

To access the Certificate and Key Management page from Setup, enter *`Certificate and Key Management`* in the `Quick Find` box, then select **Certificate and Key Management**.

Return Value

Type: void

Example

The following is an example declaration and initialization.

```
Dom.Document doc = new dom.Document();
doc.load(...);
System.Crypto.signXml('RSA-SHA256', doc.getRootElement(), null, 'signingCert');
return doc.toXmlString();
```

signXML(algorithmName, node, idAttributeName, certDevName, refChild)

Inserts the signature envelope before the specified child node.

Signature

```
public static void signXml(String algorithmName, Dom.XmlNode node, String
idAttributeName, String certDevName, Dom.XmlNode refChild)
```

Parameters

algorithmName
Type: String

The RSA encryption algorithm name. Valid names are RSA-SHA1, RSA-SHA256, or RSA.

RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.

RSA-SHA256 is an RSA signature of an SHA256 hash.

RSA is the same as RSA-SHA1.

node
Type: Dom.XmlNode

The XML node to sign and insert the signature into.

idAttributeName
Type: String

The full name (including the namespace) of the attribute on the node (XmlNode) to use as the reference ID. If `null`, this method uses the `ID` attribute on the node. If there is no `ID` attribute, Salesforce generates a new ID and adds it to the node.

certDevName
Type: String

The unique name for a certificate stored in the Salesforce org's Certificate and Key Management page to use for signing.

To access the Certificate and Key Management page from Setup, enter *`Certificate and Key Management`* in the `Quick Find` box, then select **Certificate and Key Management**.

refChild
Dom.XmlNode

The XML node before which to insert the signature. If *`refChild`* is `null`, the signature is added at the end.

Return Value

Type: Void

verify(String algorithmName, Blob data, Blob signature, Blob publicKey)

Verifies the digital signature for the Blob *data* using the specified algorithm and the supplied public key. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

Signature

```
public static Blob verify(String algorithmName, Blob data, Blob signature, Blob
publicKey)
```

Parameters

algorithmName
Type: String

The algorithm name. The valid values for *algorithmName* are `RSA-SHA1`, `RSA-SHA256`, or `RSA`.

`RSA-SHA1` is an RSA signature (with an asymmetric key pair) of an SHA1 hash.

`RSA-SHA256` is an RSA signature of an SHA256 hash.

`RSA` is the same as `RSA-SHA1`.

data
Type: Blob

The data to sign.

signature
Type:

Blob

The RSA signature.

publicKey
Type: Blob

The value of *publicKey* must be decoded using the `EncodingUtilbase64Decode` method, and be in X.509 standard.

Return Value

Type: Blob

Example

```
String algorithmName = 'RSA';
String privateKey = '';
String publicKey = '';
Blob privateKey = EncodingUtil.base64Decode(privateKey);
Blob publicKey = EncodingUtil.base64Decode(publicKey);
Blob input = Blob.valueOf('12345qwerty');
Blob signature = Crypto.sign(algorithmName, input, privateKey);
Boolean verified = Crypto.verify(algorithmName, input, signature, publicKey);
```

verify(String algorithmName, Blob data, Blob signature, String certDevName)

Verifies the digital signature for the Blob *data* using the specified algorithm and the public key associated with the certDevName. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

Signature

```
public static Blob verify(String algorithmName, Blob data, Blob signature, String
certDevName)
```

Parameters

algorithmName
Type: String

The algorithm name. The valid values for *algorithmName* are `RSA-SHA1`, `RSA-SHA256`, or `RSA`.

`RSA-SHA1` is an RSA signature (with an asymmetric key pair) of an SHA1 hash.

`RSA-SHA256` is an RSA signature of an SHA256 hash.

`RSA` is the same as `RSA-SHA1`.

data
Type: Blob

The data to sign.

signature
Type:

Blob

The RSA signature.

certDevName
Type: String

The `Unique Name` for a certificate stored in the Salesforce organization's Certificate and Key Management page to use for signing.

To access the Certificate and Key Management page from Setup, enter *Certificate and Key Management* in the `Quick Find` box, then select **Certificate and Key Management**.

Return Value

Type: Blob

Example

```
Blob data = Blob.valueOf('12345qwerty');
Blob signature = Crypto.signWithCertificate('RSA-SHA256', data, 'signingCert');
Boolean verified = Crypto.verify('RSA-SHA256', data, signature, 'signingCert');
```

verifyMac(String algorithmName, Blob input, Blob privateKey, Blob macToVerify)

Verifies the HMAC signature for Blob *data* using the specified algorithm, input data, privateKey, and the mac. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

Signature

```
public static Blob verifyMac(String algorithmName, Blob input, Blob privateKey, Blob
macToVerify)
```

Parameters

algorithmName
Type: String

The valid values for *algorithmName* are:

- hmacMD5
- hmacSHA1
- hmacSHA256
- hmacSHA512

data
Type: Blob

The data to sign.

privateKey
Type: Blob

The value of *privateKey* does not need to be in decoded form. The value cannot exceed 4 KB.

hmacToVerify
Type: Blob

The value of the mac must be verified against the provided privateKey, data, and algorithm.

Return Value

Type: Boolean

Example

```
String salt = String.valueOf(Crypto.getRandomInteger());
String key = 'key';
Blob mac = Crypto.generateMac('HmacSHA256', Blob.valueOf(salt), Blob.valueOf(key));
Boolean verified = Crypto.verifyMac('HmacSHA256', Blob.valueOf(salt), Blob.valueOf(key),
mac);
```

Custom Settings Methods

Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data can then be used by formula fields, validation rules, flows, Apex, and the SOAP API.

Usage

Custom settings methods are all instance methods, that is, they are called by and operate on a particular instance of a custom setting. There are two types of custom settings: hierarchy and list. The methods are divided into those that work with list custom settings, and those that work with hierarchy custom settings.

Note: All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. However, querying custom settings data using Standard Object Query Language (SOQL) doesn't make use of the application cache and is similar to querying a custom object. To benefit from caching, use other methods for accessing custom settings data such as the Apex Custom Settings methods.

For more information on creating custom settings in the Salesforce user interface, see "Create Custom Data Sets" in the Salesforce online help.

Custom Setting Examples

The following example uses a list custom setting called Games. Games has a field called `GameType`. This example determines if the value of the first data set is equal to the string `PC`.

```
List<Games__C> mcs = Games__c.getall().values();
boolean textField = null;
if (mcs[0].GameType__c == 'PC') {
  textField = true;
}
system.assertEquals(textField, true);
```

The following example uses a custom setting from Country and State Code Custom Settings Example. This example demonstrates that the `getValues` and `getInstance` methods list custom setting return identical values.

```
Foundation_Countries__c myCS1 = Foundation_Countries__c.getValues('United States');
String myCCVal = myCS1.Country_code__c;
Foundation_Countries__c myCS2 = Foundation_Countries__c.getInstance('United States');
String myCCInst = myCS2.Country_code__c;
system.assertEquals(myCCinst, myCCVal);
```

Hierarchy Custom Setting Examples

In the following example, the hierarchy custom setting GamesSupport has a field called `Corporate_number`. The code returns the value for the profile specified with `pid`.

```
GamesSupport__c mhc = GamesSupport__c.getInstance(pid);
string mPhone = mhc.Corporate_number__c;
```

The example is identical if you choose to use the `getValues` method.

The following example shows how to use hierarchy custom settings methods. For `getInstance`, the example shows how field values that aren't set for a specific user or profile are returned from fields defined at the next lowest level in the hierarchy. The example also shows how to use `getOrgDefaults`.

Finally, the example demonstrates how `getValues` returns fields in the custom setting record only for the specific user or profile, and doesn't merge values from other levels of the hierarchy. Instead, `getValues` returns `null` for any fields that aren't set. This example uses a hierarchy custom setting called Hierarchy. Hierarchy has two fields: `OverrideMe` and `DontOverrideMe`. In addition, a user named Robert has a System Administrator profile. The organization, profile, and user settings for this example are as follows:

Organization settings

`OverrideMe`: Hello

`DontOverrideMe`: World

Profile settings

`OverrideMe`: Goodbye

`DontOverrideMe` is not set.

User settings

`OverrideMe`: Fluffy

`DontOverrideMe` is not set.

The following example demonstrates the result of the `getInstance` method if Robert calls it in his organization:

```
Hierarchy__c CS = Hierarchy__c.getInstance();
System.Assert(CS.OverrideMe__c == 'Fluffy');
System.assert(CS.DontOverrideMe__c == 'World');
```

If Robert passes his user ID specified by `RobertId` to `getInstance`, the results are the same. This is because the lowest level of data in the custom setting is specified at the user level.

```
Hierarchy__c CS = Hierarchy__c.getInstance(RobertId);
System.Assert(CS.OverrideMe__c == 'Fluffy');
System.assert(CS.DontOverrideMe__c == 'World');
```

If Robert passes the System Administrator profile ID specified by `SysAdminID` to `getInstance`, the result is different. The data specified for the profile is returned:

```
Hierarchy__c CS = Hierarchy__c.getInstance(SysAdminID);
System.Assert(CS.OverrideMe__c == 'Goodbye');
System.assert(CS.DontOverrideMe__c == 'World');
```

When Robert tries to return the data set for the organization using `getOrgDefaults`, the result is:

```
Hierarchy__c CS = Hierarchy__c.getOrgDefaults();
System.Assert(CS.OverrideMe__c == 'Hello');
System.assert(CS.DontOverrideMe__c == 'World');
```

By using the `getValues` method, Robert can get the hierarchy custom setting values specific to his user and profile settings. For example, if Robert passes his user ID `RobertId` to `getValues`, the result is:

```
Hierarchy__c CS = Hierarchy__c.getValues(RobertId);
System.Assert(CS.OverrideMe__c == 'Fluffy');
// Note how this value is null, because you are returning
// data specific for the user
System.assert(CS.DontOverrideMe__c == null);
```

If Robert passes his System Administrator profile ID `SysAdminID` to `getValues`, the result is:

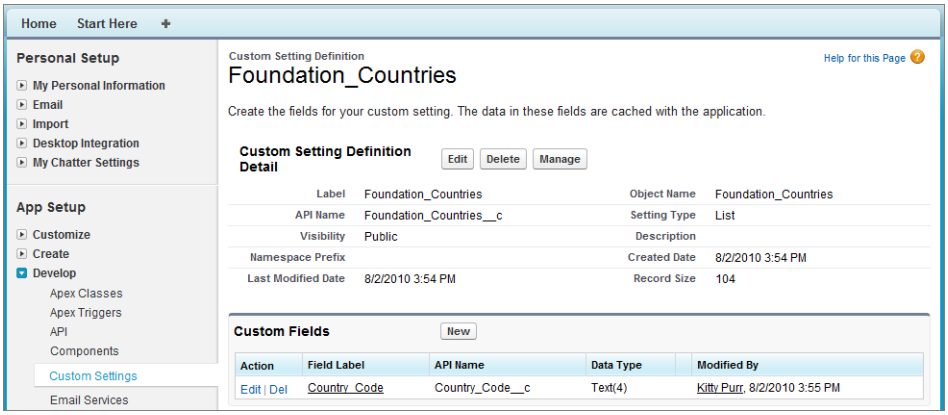
```
Hierarchy__c CS = Hierarchy__c.getValues(SysAdminID);
System.Assert(CS.OverrideMe__c == 'Goodbye');
// Note how this value is null, because you are returning
// data specific for the profile
System.assert(CS.DontOverrideMe__c == null);
```

Country and State Code Custom Settings Example

This example illustrates using two custom setting objects for storing related information, and a Visualforce page to display the data in a set of related picklists.

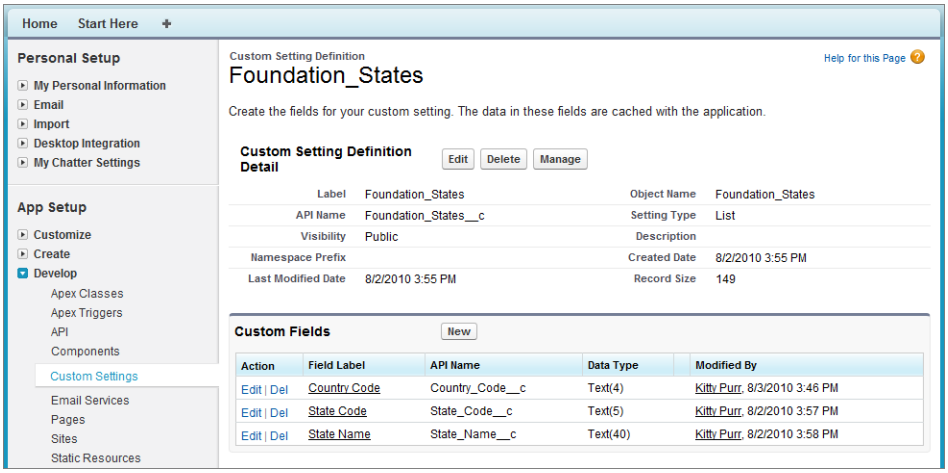
In the following example, country and state codes are stored in two different custom settings: Foundation_Countries and Foundation_States.

The Foundation_Countries custom setting is a list type custom setting and has a single field, `Country_Code`.

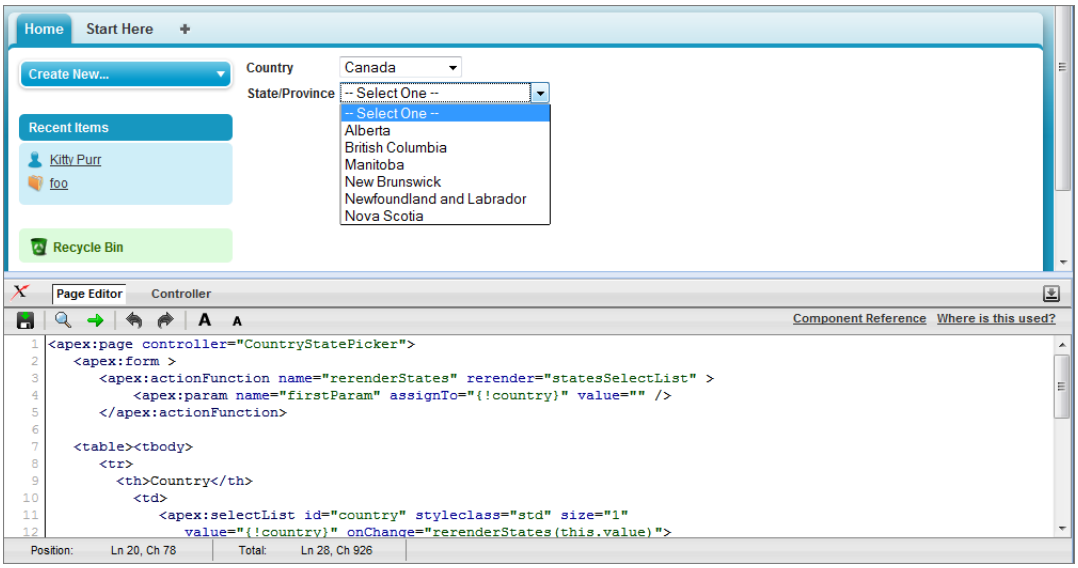


The Foundation_States custom setting is also a List type of custom setting and has the following fields:

- `Country Code`
- `State Code`
- `State Name`



The Visualforce page shows two picklists: one for country and one for state.



```
<apex:page controller="CountryStatePicker">
   <apex:form >
      <apex:actionFunction name="rerenderStates" rerender="statesSelectList" >
          <apex:param name="firstParam" assignTo="{!country}" value="" />
      </apex:actionFunction>

   <table><tbody>
      <tr>
        <th>Country</th>
          <td>
             <apex:selectList id="country" styleclass="std" size="1"
                value="{!country}" onChange="rerenderStates(this.value)">
                    <apex:selectOptions value="{!countriesSelectList}"/>
             </apex:selectList>
          </td>
      </tr>
      <tr id="state_input">
        <th>State/Province</th>
          <td>
            <apex:selectList id="statesSelectList" styleclass="std" size="1"
                 value="{!state}">
                   <apex:selectOptions value="{!statesSelectList}"/>
            </apex:selectList>
          </td>
      </tr>
   </tbody></table>
   </apex:form>
</apex:page>
```

The Apex controller `CountryStatePicker` finds the values entered into the custom settings, then returns them to the Visualforce page.

```
public with sharing class CountryStatePicker {

// Variables to store country and state selected by user
```

```
    public String state { get; set; }
    public String country {get; set;}

    // Generates country dropdown from country settings
    public List<SelectOption> getCountriesSelectList() {
        List<SelectOption> options = new List<SelectOption>();
        options.add(new SelectOption('', '-- Select One --'));

        // Find all the countries in the custom setting
       Map<String, Foundation_Countries__c> countries = Foundation_Countries__c.getAll();

        // Sort them by name
        List<String> countryNames = new List<String>();
        countryNames.addAll(countries.keySet());
        countryNames.sort();

        // Create the Select Options.
        for (String countryName : countryNames) {
            Foundation_Countries__c country = countries.get(countryName);
            options.add(new SelectOption(country.country_code__c, country.Name));
        }
        return options;
    }

    // To generate the states picklist based on the country selected by user.
    public List<SelectOption> getStatesSelectList() {
        List<SelectOption> options = new List<SelectOption>();
        // Find all the states we have in custom settings.
        Map<String, Foundation_States__c> allstates = Foundation_States__c.getAll();

        // Filter states that belong to the selected country
       Map<String, Foundation_States__c> states = new Map<String, Foundation_States__c>();

        for(Foundation_States__c state : allstates.values()) {
            if (state.country_code__c == this.country) {
                states.put(state.name, state);
            }
        }

        // Sort the states based on their names
        List<String> stateNames = new List<String>();
        stateNames.addAll(states.keySet());
        stateNames.sort();

        // Generate the Select Options based on the final sorted list
        for (String stateName : stateNames) {
            Foundation_States__c state = states.get(stateName);
            options.add(new SelectOption(state.state_code__c, state.state_name__c));
        }

        // If no states are found, just say not required in the dropdown.
        if (options.size() > 0) {
            options.add(0, new SelectOption('', '-- Select One --'));
```

```
        } else {
            options.add(new SelectOption('', 'Not Required'));
        }
        return options;
    }
}
```

List Custom Setting Methods

Hierarchy Custom Setting Methods

SEE ALSO:

Custom Settings

List Custom Setting Methods

The following are instance methods for list custom settings.

IN THIS SECTION:

getAll()
Returns a map of the data sets defined for the custom setting.

getInstance(dataSetName)
Returns the custom setting data set record for the specified data set name. This method returns the exact same object as `getValues(dataSetName)`.

getValues(dataSetName)
Returns the custom setting data set record for the specified data set name. This method returns the exact same object as `getInstance(dataSetName)`.

`getAll()`

Returns a map of the data sets defined for the custom setting.

Signature

```
public Map<String, CustomSetting__c> getAll()
```

Return Value

Type: Map<String, CustomSetting__c>

Usage

If no data set is defined, this method returns an empty map.

Note: For Apex saved using Salesforce API version 20.0 or earlier, the data set names, which are the keys in the returned map, are converted to lower case. For Apex saved using Salesforce API version 21.0 and later, the case of the data set names in the returned map keys is not changed and the original case is preserved.

`getInstance(dataSetName)`

Returns the custom setting data set record for the specified data set name. This method returns the exact same object as `getValues(dataSetName)`.

Signature

```
public CustomSetting__c getInstance(String dataSetName)
```

Parameters

dataSetName
Type: String

Return Value

Type: CustomSetting__c

Usage

If no data is defined for the specified data set, this method returns `null`.

`getValues(dataSetName)`

Returns the custom setting data set record for the specified data set name. This method returns the exact same object as `getInstance(dataSetName)`.

Signature

```
public CustomSetting__c getValues(String dataSetName)
```

Parameters

dataSetName
Type: String

Return Value

Type: CustomSetting__c

Usage

If no data is defined for the specified data set, this method returns `null`.

Hierarchy Custom Setting Methods

The following are instance methods for hierarchy custom settings.

Note:

- In API version 41.0 and below, each method in an Apex test class, including `testSetup` methods, are able to insert hierarchy custom setting values. This behavior is true even when the methods have the same `SetupOwnerId` value as a hierarchy custom setting record inserted in a different test method.
- In API version 42.0 and later, if a hierarchy custom setting is inserted in a `testSetup` method, inserting a hierarchy custom setting record with the same `SetupOwnerId` in a test method throws a `DUPLICATE_VALUE` exception.

IN THIS SECTION:

getInstance()
Returns a custom setting data set record for the current user. The fields returned in the custom setting record are merged based on the lowest level fields that are defined in the hierarchy.

getInstance(userId)
Returns the custom setting data set record for the specified user ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the user level.

getInstance(profileId)
Returns the custom setting data set record for the specified profile ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the profile level.

getOrgDefaults()
Returns the custom setting data set record for the organization.

getValues(userId)
Returns the custom setting data set record for the specified user ID.

getValues(profileId)
Returns the custom setting data set for the specified profile ID.

`getInstance()`

Returns a custom setting data set record for the current user. The fields returned in the custom setting record are merged based on the lowest level fields that are defined in the hierarchy.

Signature

```
public CustomSetting__c getInstance()
```

Return Value

Type: CustomSetting__c

Usage

If no custom setting data is defined for the user, this method returns a new custom setting object. The new custom setting object contains an ID set to `null` and merged fields from higher in the hierarchy. You can add this new custom setting record for the user by using `insert` or `upsert`. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the `SetupOwnerId` field which contains the user ID.

Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the user. Also, if no custom setting data is defined in the hierarchy, this method returns `null`.

This method is equivalent to a method call to `getInstance(User_Id)` for the current user.

Example

- Custom setting data set defined for the user: If you have a custom setting data set defined for the user "Uriel Jones," for the profile "System Administrator," and for the organization as a whole, and the user running the code is Uriel Jones, this method returns the custom setting record defined for Uriel Jones.
- Merged fields: If you have a custom setting data set with fields A and B for the user "Uriel Jones" and for the profile "System Administrator," and field A is defined for Uriel Jones, field B is `null` but is defined for the System Adminitrator profile, this method returns the custom setting record for Uriel Jones with field A for Uriel Jones and field B from the System Administrator profile.
- No custom setting data set record defined for the user: If the current user is "Barbara Mahonie," who also shares the "System Administrator" profile, but no data is defined for Barbara as a user, this method returns a new custom setting record with the ID set to `null` and with fields merged based on the fields defined in the lowest level in the hierarchy.

`getInstance(userId)`

Returns the custom setting data set record for the specified user ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the user level.

Signature

```
public CustomSetting__c getInstance(ID userId)
```

Parameters

`userId`
Type: ID

Return Value

Type: CustomSetting__c

Usage

If no custom setting data is defined for the user, this method returns a new custom setting object. The new custom setting object contains an ID set to `null` and merged fields from higher in the hierarchy. You can add this new custom setting record for the user by using `insert` or `upsert`. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the `SetupOwnerId` field which contains the user ID.

Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the user. Also, if no custom setting data is defined in the hierarchy, this method returns `null`.

`getInstance(profileId)`

Returns the custom setting data set record for the specified profile ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the profile level.

Signature

```
public CustomSetting__c getInstance(ID profileId)
```

Parameters

profileId
Type: ID

Return Value

Type: CustomSetting__c

Usage

If no custom setting data is defined for the profile, this method returns a new custom setting record. The new custom setting object contains an ID set to `null` and with merged fields from your organization's default values. You can add this new custom setting for the profile by using `insert` or `upsert`. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the `SetupOwnerId` field which contains the profile ID.

Note: For Apex saved using SalesforceAPI version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the profile. Also, if no custom setting data is defined in the hierarchy, this method returns `null`.

`getOrgDefaults()`

Returns the custom setting data set record for the organization.

Signature

```
public CustomSetting__c getOrgDefaults()
```

Return Value

Type: CustomSetting__c

Usage

If no custom setting data is defined for the organization, this method returns an empty custom setting object.

Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns `null` if no custom setting data is defined for the organization.

`getValues(userId)`

Returns the custom setting data set record for the specified user ID.

Signature

```
public CustomSetting__c getValues(ID userId)
```

Parameters

userId
Type: ID

Return Value

Type: CustomSetting__c

Usage

Use this if you only want the subset of custom setting data that has been defined at the user level. For example, suppose you have a custom setting field that has been assigned a value of "alpha" at the organizational level, but has no value assigned at the user or profile level. Using `getValues(UserId)` returns `null` for this custom setting field.

getValues(profileId)

Returns the custom setting data set for the specified profile ID.

Signature

```
public CustomSetting__c getValues(ID profileId)
```

Parameters

profileId
Type: ID

Return Value

Type: CustomSetting__c

Usage

Use this if you only want the subset of custom setting data that has been defined at the profile level. For example, suppose you have a custom setting field that has been assigned a value of "alpha" at the organizational level, but has no value assigned at the user or profile level. Using `getValues(ProfileId)` returns `null` for this custom setting field.

Database Class

Contains methods for creating and manipulating data.

Namespace

System

Usage

Some Database methods also exist as DML statements.

SEE ALSO:

Apex DML Operations

Database Methods

The following are methods for `Database`. All methods are static.

IN THIS SECTION:

convertLead(leadToConvert, allOrNone)

Converts a lead into an account and contact, as well as (optionally) an opportunity.

convertLead(leadsToConvert, allOrNone)

Converts a list of LeadConvert objects into accounts and contacts, as well as (optionally) opportunities.

countQuery(query)

Returns the number of records that a dynamic SOQL query would return when executed.

delete(recordToDelete, allOrNone)

Deletes an existing sObject record, such as an individual account or contact, from your organization's data.

delete(recordsToDelete, allOrNone)

Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization's data.

delete(recordID, allOrNone)

Deletes existing sObject records, such as individual accounts or contacts, from your organization's data.

delete(recordIDs, allOrNone)

Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization's data.

deleteAsync(sobjects, callback)

Initiates requests to delete the external data that corresponds to the specified external object records. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processDelete` method is called for each record after deletion.

deleteAsync(sobject, callback)

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processDelete` method is called after deletion.

deleteAsync(sobjects)

Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.

deleteAsync(sobject)

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.

deleteImmediate(sobjects)

Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can't be completed and throw exceptions.

deleteImmediate(sobject)

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed synchronously and is sent to the external system that's defined by the external object's associated external data source. If the Apex transaction contains pending changes, the synchronous operation can't be completed and throws an exception.

emptyRecycleBin(recordIds)

Permanently deletes the specified records from the Recycle Bin.

emptyRecycleBin(obj)

Permanently deletes the specified sObject from the Recycle Bin.

emptyRecycleBin(listOfSObjects)

Permanently deletes the specified sObjects from the Recycle Bin.

executeBatch(batchClassObject)

Submits a batch Apex job for execution corresponding to the specified class.

executeBatch(batchClassObject, scope)

Submits a batch Apex job for execution using the specified class and scope.

getAsyncDeleteResult(deleteResult)

Retrieves the status of an asynchronous delete operation that's identified by a `Database.DeleteResult` object.

getAsyncDeleteResult(asyncLocator)

Retrieves the result of an asynchronous delete operation based on the result's unique identifier.

getAsyncLocator(result)

Returns the `asyncLocator` associated with the result of a specified asynchronous insert, update, or delete operation.

getAsyncSaveResult(saveResult)

Returns the status of an asynchronous insert or update operation that's identified by a `Database.SaveResult` object.

getAsyncSaveResult(asyncLocator)

Returns the status of an asynchronous insert or update operation based on the unique identifier associated with each modification.

getDeleted(sObjectType, startDate, endDate)

Returns the list of individual records that have been deleted for an sObject type within the specified start and end dates and times and that are still in the Recycle Bin.

getQueryLocator(listofQueries)

Creates a QueryLocator object used in batch Apex or Visualforce.

getQueryLocator(query)

Creates a QueryLocator object used in batch Apex or Visualforce.

getUpdated(sobjectType, startDate, endDate)

Returns the list of individual records that have been updated for an sObject type within the specified start and end dates and times.

insert(recordToInsert, allOrNone)

Adds an sObject, such as an individual account or contact, to your organization's data.

insert(recordsToInsert, allOrNone)

Adds one or more sObjects, such as individual accounts or contacts, to your organization's data.

insert(recordToInsert, dmlOptions)

Adds an sObject, such as an individual account or contact, to your organization's data.

insert(recordsToInsert, dmlOptions)

Adds one or more sObjects, such as individual accounts or contacts, to your organization's data.

insertAsync(sobjects, callback)

Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources. Allows referencing a callback class whose `processSave` method is called for each record after the remote operations are completed.

insertAsync(sobject, callback)

Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processSave` method is called after the remote operation is completed.

insertAsync(sobjects)

Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.

insertAsync(sobject)

Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.

insertImmediate(sobjects)

Initiates requests to add external object data to the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can't be completed and throw exceptions.

insertImmediate(sobject)

Initiates a request to add external object data to the relevant external system. The request is executed synchronously and is sent to the external system that's defined by the external object's associated external data source. If the Apex transaction contains pending changes, the synchronous operation can't be completed and throws an exception.

merge(masterRecord, duplicateId)

Merges the specified duplicate record into the master sObject record of the same type, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

merge(masterRecord, duplicateRecord)

Merges the specified duplicate sObject record into the master sObject of the same type, deleting the duplicate, and reparenting any related records.

merge(masterRecord, duplicateIds)

Merges up to two records of the same sObject type into the master sObject record, deleting the others, and reparenting any related records.

merge(masterRecord, duplicateRecords)

Merges up to two records of the same object type into the master sObject record, deleting the others, and reparenting any related records.

merge(masterRecord, duplicateId, allOrNone)

Merges the specified duplicate record into the master sObject record of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

merge(masterRecord, duplicateRecord, allOrNone)

Merges the specified duplicate sObject record into the master sObject of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records.

merge(masterRecord, duplicateIds, allOrNone)

Merges up to two records of the same sObject type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

merge(masterRecord, duplicateRecords, allOrNone)

Merges up to two records of the same object type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

query(queryString)

Creates a dynamic SOQL query at runtime.

rollback(databaseSavepoint)

Restores the database to the state specified by the savepoint variable. Any emails submitted since the last savepoint are also rolled back and not sent.

setSavepoint()

Returns a savepoint variable that can be stored as a local variable, then used with the `rollback` method to restore the database to that point.

undelete(recordToUndelete, allOrNone)

Restores an existing sObject record, such as an individual account or contact, from your organization's Recycle Bin.

undelete(recordsToUndelete, allOrNone)

Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

undelete(recordID, allOrNone)

Restores an existing sObject record, such as an individual account or contact, from your organization's Recycle Bin.

undelete(recordIDs, allOrNone)

Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

update(recordToUpdate, allOrNone)

Modifies an existing sObject record, such as an individual account or contact, in your organization's data.

update(recordsToUpdate, allOrNone)

Modifies one or more existing sObject records, such as individual accounts or contactsinvoice statements, in your organization’s data.

update(recordToUpdate, dmlOptions)

Modifies an existing sObject record, such as an individual account or contact, in your organization's data.

update(recordsToUpdate, dmlOptions)

Modifies one or more existing sObject records, such as individual accounts or contactsinvoice statements, in your organization’s data.

upsert(recordToUpsert, externalIdField, allOrNone)

Creates a new sObject record or updates an existing sObject record within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

upsert(recordsToUpsert, externalIdField, allOrNone)

Creates new sObject records or updates existing sObject records within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

updateAsync(sobjects, callback)

Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources. Allows referencing a callback class whose `processSave` method is called for each record after the remote operations are completed.

updateAsync(sobject, callback)

Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processSave` method is called after the remote operation is completed.

updateAsync(sobjects)

Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.

updateAsync(sobject)

Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.

updateImmediate(sobjects)

Initiates requests to update external object data on the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can't be completed and throw exceptions.

updateImmediate(sobject)

Initiates a request to update external object data on the relevant external system. The request is executed synchronously and is sent to the external system that's defined by the external object's associated external data source. If the Apex transaction contains pending changes, the synchronous operation can't be completed and throws an exception.

convertLead(leadToConvert, allOrNone)

Converts a lead into an account and contact, as well as (optionally) an opportunity.

Signature

```
public static Database.LeadConvertResult convertLead(Database.LeadConvert leadToConvert,
Boolean allOrNone)
```

Parameters

leadToConvert
Type: Database.LeadConvert

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.LeadConvertResult

Usage

The `convertLead` method accepts up to 100 `LeadConvert` objects.

Each executed `convertLead` method counts against the governor limit for DML statements.

`convertLead(leadsToConvert, allOrNone)`

Converts a list of LeadConvert objects into accounts and contacts, as well as (optionally) opportunities.

Signature

```
public static Database.LeadConvertResult[] convertLead(Database.LeadConvert[]
leadsToConvert, Boolean allOrNone)
```

Parameters

`leadsToConvert`
Type: Database.LeadConvert[]

`allOrNone`
Type: Boolean

The optional *`allOrNone`* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.LeadConvertResult[]

Usage

The `convertLead` method accepts up to 100 `LeadConvert` objects.

Each executed `convertLead` method counts against the governor limit for DML statements.

`countQuery(query)`

Returns the number of records that a dynamic SOQL query would return when executed.

Signature

```
public static Integer countQuery(String query)
```

Parameters

`query`
Type: String

Return Value

Type: Integer

Usage

For more information, see Dynamic SOQL on page 182.

Each executed `countQuery` method counts against the governor limit for SOQL queries.

Example

```
String QueryString =
    'SELECT count() FROM Account';
Integer i =
    Database.countQuery(QueryString);
```

delete(recordToDelete, allOrNone)

Deletes an existing sObject record, such as an individual account or contact, from your organization's data.

Signature

```
public static Database.DeleteResult delete(SObject recordToDelete, Boolean allOrNone)
```

Parameters

recordToDelete
Type: sObject

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.DeleteResult

Usage

`delete` is analogous to the `delete()` statement in the SOAP API.

Each executed `delete` method counts against the governor limit for DML statements.

delete(recordsToDelete, allOrNone)

Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization's data.

Signature

```
public static Database.DeleteResult[] delete(SObject[] recordsToDelete, Boolean
allOrNone)
```

Parameters

recordsToDelete
Type: sObject[]

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.DeleteResult[]

Usage

`delete` is analogous to the `delete()` statement in the SOAP API.

Each executed `delete` method counts against the governor limit for DML statements.

Example

The following example deletes an account named 'DotCom':

```
Account[] doomedAccts = [SELECT Id, Name FROM Account WHERE Name = 'DotCom'];
Database.DeleteResult[] DR_Dels = Database.delete(doomedAccts);
```

`delete(recordID, allOrNone)`

Deletes existing sObject records, such as individual accounts or contacts, from your organization's data.

Signature

```
public static Database.DeleteResult delete(ID recordID, Boolean allOrNone)
```

Parameters

recordID
Type: ID

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.DeleteResult

Usage

`delete` is analogous to the `delete()` statement in the SOAP API.

Each executed `delete` method counts against the governor limit for DML statements.

delete(recordIDs, allOrNone)

Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization's data.

Signature

```
public static Database.DeleteResult[] delete(ID[] recordIDs, Boolean allOrNone)
```

Parameters

recordIDs
Type: ID[]

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.DeleteResult[]

Usage

`delete` is analogous to the `delete()` statement in the SOAP API.

Each executed `delete` method counts against the governor limit for DML statements.

deleteAsync(sobjects, callback)

Initiates requests to delete the external data that corresponds to the specified external object records. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processDelete` method is called for each record after deletion.

Signature

```
public static List<Database.DeleteResult> deleteAsync(List<SObject> sobjects,
DataSource.AsyncDeleteCallback callback)
```

Parameters

sobjects
Type: List<SObject>

List of external object records to delete.

callback
Type: DataSource.AsyncDeleteCallback

The callback that contains the state in the originating context and an action (the `processDelete` method) that is executed after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncDeleteCallback`.

Return Value

Type: List<Database.DeleteResult>

Status results for the delete operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncDeleteResult()`.

deleteAsync(sobject, callback)

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processDelete` method is called after deletion.

Signature

```
public static Database.DeleteResult deleteAsync(SObject sobject,
DataSource.AsyncDeleteCallback callback)
```

Parameters

sobject
Type: SObject

The external object record to delete.

callback
Type: DataSource.AsyncDeleteCallback

The callback that contains the state in the originating context and an action (the `processDelete` method) that is executed after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncDeleteCallback`.

Return Value

Type: Database.DeleteResult

Status result for the delete operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncDeleteResult()`.

deleteAsync(sobjects)

Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.

Signature

```
public static List<Database.DeleteResult> deleteAsync(List<SObject> sobjects)
```

Parameters

sobjects
Type: List<SObject>

List of external object records to delete.

Return Value

Type: List<Database.DeleteResult>

Status results for the delete operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncDeleteResult()`.

`deleteAsync(sobject)`

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.

Signature

```
public static Database.DeleteResult deleteAsync(SObject sobject)
```

Parameters

sobject
Type: SObject

The external object record to delete.

Return Value

Type: Database.DeleteResult

Status result for the delete operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncDeleteResult()`.

`deleteImmediate(sobjects)`

Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can't be completed and throw exceptions.

Signature

```
public static List<Database.DeleteResult> deleteImmediate(List<SObject> sobjects)
```

Parameters

sobjects
Type: List<SObject>

List of external object records to delete.

Return Value

Type: List<Database.DeleteResult>

Status results for the delete operation.

deleteImmediate(sobject)

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed synchronously and is sent to the external system that's defined by the external object's associated external data source. If the Apex transaction contains pending changes, the synchronous operation can't be completed and throws an exception.

Signature

```
public static Database.DeleteResult deleteImmediate(SObject sobject)
```

Parameters

sobject
Type: SObject

The external object record to delete.

Return Value

Type: Database.DeleteResult

Status result for the delete operation.

emptyRecycleBin(recordIds)

Permanently deletes the specified records from the Recycle Bin.

Signature

```
public static Database.EmptyRecycleBinResult[] emptyRecycleBin(ID [] recordIds)
```

Parameters

recordIds
Type: ID[]

Return Value

Type: Database.EmptyRecycleBinResult[]

Usage

Note the following:

- After records are deleted using this method, they cannot be undeleted.
- Only 10,000 records can be specified for deletion.
- Logged in users can delete any record that they can query in their Recycle Bin, or the recycle bins of any subordinates. If logged in users have "Modify All Data" permission, they can query and delete records from any Recycle Bin in the organization.
- Cascade delete record IDs should not be included in the list of IDs; otherwise an error occurs. For example, if an account record is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include the Id of the top-level account. All related records are automatically removed.
- Deleted items are added to the number of items processed by a DML statement, and the method call is added to the total number of DML statements issued. Each executed `emptyRecycleBin` method counts against the governor limit for DML statements.

`emptyRecycleBin(obj)`

Permanently deletes the specified sObject from the Recycle Bin.

Signature

```
public static Database.EmptyRecycleBinResult emptyRecycleBin(sObject obj)
```

Parameters

obj
Type: sObject

Return Value

Type: Database.EmptyRecycleBinResult

Usage

Note the following:

- After an sObject is deleted using this method it cannot be undeleted.
- Only 10,000 sObjects can be specified for deletion.
- The logged-in user can delete any sObject that he or she can query in their Recycle Bin, or the recycle bins of any subordinates. If the logged-in user has "Modify All Data" permission, he or she can query and delete sObjects from any Recycle Bin in the organization.
- Do not include an sObject that was deleted due to a cascade delete; otherwise an error occurs. For example, if an account is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include sObjects of the top-level account. All related sObjects are automatically removed.
- Deleted items are added to the number of items processed by a DML statement, and the method call is added to the total number of DML statements issued. Each executed `emptyRecycleBin` method counts against the governor limit for DML statements.

`emptyRecycleBin(listOfSObjects)`

Permanently deletes the specified sObjects from the Recycle Bin.

Signature

```
public static Database.EmptyRecycleBinResult[] emptyRecycleBin(sObject[] listOfSObjects)
```

Parameters

listOfSObjects
Type: sObject[]

Return Value

Type: Database.EmptyRecycleBinResult[]

Usage

Note the following:

- After an sObject is deleted using this method it cannot be undeleted.
- Only 10,000 sObjects can be specified for deletion.
- The logged-in user can delete any sObject that he or she can query in their Recycle Bin, or the recycle bins of any subordinates. If the logged-in user has "Modify All Data" permission, he or she can query and delete sObjects from any Recycle Bin in the organization.
- Do not include an sObject that was deleted due to a cascade delete; otherwise an error occurs. For example, if an account is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include sObjects of the top-level account. All related sObjects are automatically removed.
- Deleted items are added to the number of items processed by a DML statement, and the method call is added to the total number of DML statements issued. Each executed `emptyRecycleBin` method counts against the governor limit for DML statements.

executeBatch(batchClassObject)

Submits a batch Apex job for execution corresponding to the specified class.

Signature

```
public static ID executeBatch(Object batchClassObject)
```

Parameters

batchClassObject
Type: Object

An instance of a class that implements the Database.Batchable interface.

Return Value

Type: ID

The ID of the new batch job (AsyncApexJob).

If the `executeBatch` call fails to acquire an Apex flex queue lock, the call returns an empty ID, "000000000000000", instead of throwing an exception.

Usage

When calling this method, Salesforce chunks the records returned by the `start` method of the batch class into batches of 200, and then passes each batch to the `execute` method. Apex governor limits are reset for each execution of `execute`.

For more information, see Using Batch Apex on page 247.

executeBatch(batchClassObject, scope)

Submits a batch Apex job for execution using the specified class and scope.

Signature

```
public static ID executeBatch(Object batchClassObject, Integer scope)
```

Parameters

batchClassObject
Type: Object

An instance of a class that implements the Database.Batchable interface.

scope
Type: Integer

Number of records to be passed into the `execute` method for batch processing.

Return Value

Type: ID

The ID of the new batch job (AsyncApexJob).

If the `executeBatch` call fails to acquire an Apex flex queue lock, the call returns an empty ID, "000000000000000", instead of throwing an exception.

Usage

The value for *scope* must be greater than 0.

If the `start` method of the batch class returns a Database.QueryLocator, the scope parameter of `Database.executeBatch` can have a maximum value of 2,000. If set to a higher value, Salesforce chunks the records returned by the QueryLocator into smaller batches of up to 200 records. If the `start` method of the batch class returns an iterable, the scope parameter value has no upper limit; however, if you use a very high number, you could run into other limits.

Apex governor limits are reset for each execution of `execute`.

For more information, see Using Batch Apex on page 247.

getAsyncDeleteResult(deleteResult)

Retrieves the status of an asynchronous delete operation that's identified by a `Database.DeleteResult` object.

Signature

```
public static Database.DeleteResult getAsyncDeleteResult(Database.DeleteResult
deleteResult)
```

Parameters

deleteResult
Type: Database.DeleteResult

The result record for the delete operation being retrieved.

Return Value

Type: Database.DeleteResult

The result of a completed asynchronous delete of a record or records.

getAsyncDeleteResult(asyncLocator)

Retrieves the result of an asynchronous delete operation based on the result's unique identifier.

Signature

```
public static Database.DeleteResult getAsyncDeleteResult(String asyncLocator)
```

Parameters

asyncLocator
Type: String

The unique identifier associated with the result of an asynchronous operation.

Return Value

Type: Database.DeleteResult

The result of a completed asynchronous delete of a record or records.

getAsyncLocator(result)

Returns the `asyncLocator` associated with the result of a specified asynchronous insert, update, or delete operation.

Signature

```
public static String getAsyncLocator(Object result)
```

Parameters

result
Type: Object

The saved result of an asynchronous insert, update, or delete operation. The result object can be of type `Database.SaveResult` or `Database.DeleteResult`.

Return Value

Type: String

The unique identifier associated with the result of the specified operation.

getAsyncSaveResult(saveResult)

Returns the status of an asynchronous insert or update operation that's identified by a `Database.SaveResult` object.

Signature

```
public static Database.SaveResult getAsyncSaveResult(Database.SaveResult saveResult)
```

Parameters

saveResult
Type: Database.SaveResult

The result record for the insert or update operation being retrieved.

Return Value

Database.SaveResult

The result of a completed asynchronous operation on a record or records.

getAsyncSaveResult(asyncLocator)

Returns the status of an asynchronous insert or update operation based on the unique identifier associated with each modification.

Signature

```
public static Database.SaveResult getAsyncSaveResult(String asyncLocator)
```

Parameters

asyncLocator
Type: String

The unique identifier associated with the result of an asynchronous operation.

Return Value

Database.SaveResult

The result of a completed asynchronous operation on a record or records.

getDeleted(sObjectType, startDate, endDate)

Returns the list of individual records that have been deleted for an sObject type within the specified start and end dates and times and that are still in the Recycle Bin.

Signature

```
public static Database.GetDeletedResult getDeleted(String sObjectType, Datetime
startDate, Datetime endDate)
```

Parameters

sObjectType
Type: String

The *sObjectType* argument is the sObject type name for which to get the deleted records, such as account or merchandise__c.

startDate
Type: Datetime

Start date and time of the deleted records time window.

endDate
Type: Datetime

End date and time of the deleted records time window.

Return Value

Type: Database.GetDeletedResult

Usage

Because the Recycle Bin holds records up to 15 days, results are returned for no more than 15 days previous to the day the call is executed (or earlier if an administrator has purged the Recycle Bin).

Example

```
Database.GetDeletedResult r =
 Database.getDeleted(
  'Merchandise__c',
  Datetime.now().addHours(-1),
  Datetime.now());
```

getQueryLocator(listofQueries)

Creates a QueryLocator object used in batch Apex or Visualforce.

Signature

```
public static Database. QueryLocator getQueryLocator(sObject [] listOfQueries)
```

Parameters

listOfQueries
Type: sObject []

Return Value

Type: Database.QueryLocator

Usage

You can't use `getQueryLocator` with any query that contains an aggregate function.

Each executed `getQueryLocator` method counts against the governor limit of 10,000 total records retrieved and the total number of SOQL queries issued.

For more information, see Understanding Apex Managed Sharing, and IdeaStandardSetController Class.

`getQueryLocator(query)`

Creates a QueryLocator object used in batch Apex or Visualforce.

Signature

```
public static Database.QueryLocator getQueryLocator(String query)
```

Parameters

`query`
Type: String

Return Value

Type: Database.QueryLocator

Usage

You can't use `getQueryLocator` with any query that contains an aggregate function.

Each executed `getQueryLocator` method counts against the governor limit of 10,000 total records retrieved and the total number of SOQL queries issued.

For more information, see Understanding Apex Managed Sharing, and StandardSetController Class.

`getUpdated(sobjectType, startDate, endDate)`

Returns the list of individual records that have been updated for an sObject type within the specified start and end dates and times.

Signature

```
public static Database.GetUpdatedResult getUpdated(String sobjectType, Datetime
startDate, Datetime endDate)
```

Parameters

`sobjectType`
Type: String

The *`sObjectType`* argument is the sObject type name for which to get the updated records, such as account or merchandise__c.

`startDate`
Type: Datetime

The *`startDate`* argument is the start date and time of the updated records time window.

`endDate`
Type: Datetime

The *`endDate`* argument is the end date and time of the updated records time window.

Return Value

Type: Database.GetUpdatedResult

Usage

The date range for the returned results is no more than 30 days previous to the day the call is executed.

Example

```
Database.GetUpdatedResult r =
 Database.getUpdated(
  'Merchandise__c',
  Datetime.now().addHours(-1),
  Datetime.now());
```

insert(recordToInsert, allOrNone)

Adds an sObject, such as an individual account or contact, to your organization's data.

Signature

```
public static Database.SaveResult insert(sObject recordToInsert, Boolean allOrNone)
```

Parameters

recordToInsert
Type: sObject

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.SaveResult

Usage

`insert` is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `insert` method counts against the governor limit for DML statements.

insert(recordsToInsert, allOrNone)

Adds one or more sObjects, such as individual accounts or contacts, to your organization's data.

Signature

```
public static Database.SaveResult[] insert(sObject[] recordsToInsert, Boolean allOrNone)
```

Parameters

recordsToInsert
Type: sObject []

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.SaveResult[]

Usage

`insert` is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `insert` method counts against the governor limit for DML statements.

Example

Example:

The following example inserts two accounts:

```
Account a = new Account(name = 'Acme1');
Database.SaveResult[] lsr = Database.insert(
    new Account[]{a, new Account(Name = 'Acme2')},
    false);
```

insert(recordToInsert, dmlOptions)

Adds an sObject, such as an individual account or contact, to your organization's data.

Signature

```
public static Database.SaveResult insert(sObject recordToInsert, Database.DMLOptions
dmlOptions)
```

Parameters

recordToInsert
Type: sObject

dmlOptions
Type: Database.DMLOptions

The optional *dmlOptions* parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value

Type: Database.SaveResult

Usage

`insert` is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `insert` method counts against the governor limit for DML statements.

insert(recordsToInsert, dmlOptions)

Adds one or more sObjects, such as individual accounts or contacts, to your organization's data.

Signature

```
public static Database.SaveResult insert(sObject[] recordsToInsert, Database.DMLOptions dmlOptions)
```

Parameters

recordsToInsert
Type: sObject[]

dmlOptions
Type: Database.DMLOptions

The optional *dmlOptions* parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value

Type: Database.SaveResult[]

Usage

`insert` is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `insert` method counts against the governor limit for DML statements.

`insertAsync(sobjects, callback)`

Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources. Allows referencing a callback class whose `processSave` method is called for each record after the remote operations are completed.

Signature

```
public static List<Database.SaveResult> insertAsync(List<SObject> sobjects,
DataSource.AsyncSaveCallback callback)
```

Parameters

`sobjects`
Type: List<SObject>

List of external object records to insert.

`callback`
Type: DataSource.AsyncSaveCallback

The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncSaveCallback`.

Return Value

Type: List<Database.SaveResult>

Status results for the insert operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

Usage

`Database.insertAsync()` methods can't be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use `Database.insertImmediate()` methods.

`insertAsync(sobject, callback)`

Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processSave` method is called after the remote operation is completed.

Signature

```
public static Database.SaveResult insertAsync(SObject sobject,
DataSource.AsyncSaveCallback callback)
```

Parameters

`sobject`
Type: SObject

The external object record to insert.

callback
Type: DataSource.AsyncSaveCallback

The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncSaveCallback`.

Return Value

Type: Database.SaveResult

Status result for the insert operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

Usage

`Database.insertAsync()` methods can't be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use `Database.insertImmediate()` methods.

insertAsync(sobjects)

Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.

Signature

```
public static List<Database.SaveResult> insertAsync(List<SObject> sobjects)
```

Parameters

sobjects
Type: List<SObject>

List of external object records to insert.

Return Value

Type: List<Database.SaveResult>

Status results for the insert operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

Usage

`Database.insertAsync()` methods can't be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use `Database.insertImmediate()` methods.

`insertAsync(sobject)`

Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.

Signature

```
public static Database.SaveResult insertAsync(SObject sobject)
```

Parameters

`sobject`
Type: SObject

The external object record to insert.

Return Value

Type: Database.SaveResult

Status result for the insert operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

Usage

`Database.insertAsync()` methods can't be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use `Database.insertImmediate()` methods.

`insertImmediate(sobjects)`

Initiates requests to add external object data to the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can't be completed and throw exceptions.

Signature

```
public static List<Database.SaveResult> insertImmediate(List<SObject> sobjects)
```

Parameters

`sobjects`
Type: List<SObject>

List of external object records to insert.

Return Value

Type: List<Database.SaveResult>

Status results for the insert operation.

`insertImmediate(sobject)`

Initiates a request to add external object data to the relevant external system. The request is executed synchronously and is sent to the external system that's defined by the external object's associated external data source. If the Apex transaction contains pending changes, the synchronous operation can't be completed and throws an exception.

Signature

```
public static Database.SaveResult insertImmediate(SObject sobject)
```

Parameters

sobject
Type: SObject

The external object record to insert.

Return Value

Type: Database.SaveResult

Status result for the insert operation.

`merge(masterRecord, duplicateId)`

Merges the specified duplicate record into the master sObject record of the same type, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

Signature

```
public static Database.MergeResult merge(sObject masterRecord, Id duplicateId)
```

Parameters

masterRecord
Type: sObject

The master sObject record the duplicate record is merged into.

duplicateId
Type: ID

The ID of the record to merge with the master. This record must be of the same sObject type as the master.

Return Value

Type: Database.MergeResult

Usage

Each executed `merge` method counts against the governor limit for DML statements.

merge(masterRecord, duplicateRecord)

Merges the specified duplicate sObject record into the master sObject of the same type, deleting the duplicate, and reparenting any related records.

Signature

```
public static Database.MergeResult merge(sObject masterRecord, sObject duplicateRecord)
```

Parameters

masterRecord
Type: sObject

The master sObject record the duplicate record is merged into.

duplicateRecord
Type: sObject

The sObject record to merge with the master. This sObject must be of the same type as the master.

Return Value

Type: Database.MergeResult

Usage

Each executed `merge` method counts against the governor limit for DML statements.

merge(masterRecord, duplicateIds)

Merges up to two records of the same sObject type into the master sObject record, deleting the others, and reparenting any related records.

Signature

```
public static List<Database.MergeResult> merge(sObject masterRecord, List<Id>
duplicateIds)
```

Parameters

masterRecord
Type: SObject

The master sObject record the other records are merged into.

duplicateIds
Type: List<Id>

A list of IDs of up to two records to merge with the master. These records must be of the same sObject type as the master.

Return Value

Type: List<Database.MergeResult>

Usage

Each executed `merge` method counts against the governor limit for DML statements.

merge(masterRecord, duplicateRecords)

Merges up to two records of the same object type into the master sObject record, deleting the others, and reparenting any related records.

Signature

```
public static List<Database.MergeResult> merge(sObject masterRecord, List<SObject>
duplicateRecords)
```

Parameters

masterRecord
Type: SObject

The master sObject record the other sObjects are merged into.

duplicateRecords
Type: List<SObject>

A list of up to two sObject records to merge with the master. These sObjects must be of the same type as the master.

Return Value

Type: List<Database.MergeResult>

Usage

Each executed `merge` method counts against the governor limit for DML statements.

merge(masterRecord, duplicateId, allOrNone)

Merges the specified duplicate record into the master sObject record of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

Signature

```
public static Database.MergeResult merge(sObject masterRecord, Id duplicateId, Boolean
allOrNone)
```

Parameters

masterRecord
Type: sObject

The master sObject record the duplicate record is merged into.

duplicate
Type: ID

The ID of the record to merge with the master. This record must be of the same sObject type as the master.

allOrNone
Type: Boolean

Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

Return Value

Type: Database.MergeResult

Usage

Each executed `merge` method counts against the governor limit for DML statements.

merge(masterRecord, duplicateRecord, allOrNone)

Merges the specified duplicate sObject record into the master sObject of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records.

Signature

```
public static Database.MergeResult merge(sObject masterRecord, sObject duplicateRecord,
Boolean allOrNone)
```

Parameters

masterRecord
Type: sObject

The master sObject record the duplicate record is merged into.

duplicateRecord
Type: sObject

The sObject record to merge with the master. This sObject must be of the same type as the master.

allOrNone
Type: Boolean

Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

Return Value

Type: Database.MergeResult

Usage

Each executed `merge` method counts against the governor limit for DML statements.

merge(masterRecord, duplicateIds, allOrNone)

Merges up to two records of the same sObject type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

Signature

```
public static List<Database.MergeResult> merge(sObject masterRecord, List<Id>
duplicateIds, Boolean allOrNone)
```

Parameters

masterRecord
Type: SObject

The master sObject record the other records are merged into.

duplicateIds
Type: List<Id>

A list of IDs of up to two records to merge with the master. These records must be of the same sObject type as the master.

allOrNone
Type: Boolean

Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

Return Value

Type: List<Database.MergeResult>

Usage

Each executed `merge` method counts against the governor limit for DML statements.

`merge(masterRecord, duplicateRecords, allOrNone)`

Merges up to two records of the same object type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

Signature

```
public static List<Database.MergeResult> merge(sObject masterRecord, List<SObject>
duplicateRecords, Boolean allOrNone)
```

Parameters

masterRecord
Type: sObject

The master sObject record the other sObjects are merged into.

duplicateRecords
Type: List<SObject>

A list of up to two sObject records to merge with the master. These sObjects must be of the same type as the master.

allOrNone
Type: Boolean

Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

Return Value

Type: List<Database.MergeResult>

Usage

Each executed `merge` method counts against the governor limit for DML statements.

query(queryString)

Creates a dynamic SOQL query at runtime.

Signature

```
public static sObject[] query(String queryString)
```

Parameters

queryString
Type: String

Return Value

Type: sObject[]

Usage

This method can be used wherever a static SOQL query can be used, such as in regular assignment statements and `for` loops. Unlike inline SOQL, fields in bind variables are not supported.

For more information, see Dynamic SOQL on page 182.

Each executed `query` method counts against the governor limit for SOQL queries.

rollback(databaseSavepoint)

Restores the database to the state specified by the savepoint variable. Any emails submitted since the last savepoint are also rolled back and not sent.

Signature

```
public static Void rollback(System.Savepoint databaseSavepoint)
```

Parameters

databaseSavepoint
Type: System.Savepoint

Return Value

Type: Void

Usage

Note the following:

- Static variables are not reverted during a rollback. If you try to run the trigger again, the static variables retain the values from the first run.
- Each rollback counts against the governor limit for DML statements. You will receive a runtime error if you try to rollback the database additional times.
- The ID on an sObject inserted after setting a savepoint is not cleared after a rollback. Create an sObject to insert after a rollback. Attempting to insert the sObject using the variable created before the rollback fails because the sObject variable has an ID. Updating or upserting the sObject using the same variable also fails because the sObject is not in the database and, thus, cannot be updated.

For an example, see Transaction Control.

`setSavepoint()`

Returns a savepoint variable that can be stored as a local variable, then used with the `rollback` method to restore the database to that point.

Signature

```
public static System.Savepoint setSavepoint()
```

Return Value

Type: System.Savepoint

Usage

Note the following:

- If you set more than one savepoint, then roll back to a savepoint that is not the last savepoint you generated, the later savepoint variables become invalid. For example, if you generated savepoint `SP1` first, savepoint `SP2` after that, and then you rolled back to `SP1`, the variable `SP2` would no longer be valid. You will receive a runtime error if you try to use it.
- References to savepoints cannot cross trigger invocations because each trigger invocation is a new trigger context. If you declare a savepoint as a static variable then try to use it across trigger contexts, you will receive a run-time error.
- Each savepoint you set counts against the governor limit for DML statements.

For an example, see Transaction Control.

`undelete(recordToUndelete, allOrNone)`

Restores an existing sObject record, such as an individual account or contact, from your organization's Recycle Bin.

Signature

```
public static Database.UndeleteResult undelete(sObject recordToUndelete, Boolean
allOrNone)
```

Parameters

recordToUndelete
Type: sObject

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.UndeleteResult

Usage

`undelete` is analogous to the UNDELETE statement in SQL.

Each executed `undelete` method counts against the governor limit for DML statements.

`undelete(recordsToUndelete, allOrNone)`

Restores one or more existing sObject records, such as individual accounts or contacts, from your organization's Recycle Bin.

Signature

```
public static Database.UndeleteResult[] undelete(sObject[] recordsToUndelete, Boolean allOrNone)
```

Parameters

recordsToUndelete
Type: sObject []

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.UndeleteResult[]

Usage

`undelete` is analogous to the UNDELETE statement in SQL.

Each executed `undelete` method counts against the governor limit for DML statements.

Example

The following example restores all accounts named 'Universal Containers'. The `ALL ROWS` keyword queries all rows for both top-level and aggregate relationships, including deleted records and archived activities.

```
Account[] savedAccts = [SELECT Id, Name FROM Account
                                                    WHERE Name = 'Universal
 Containers' ALL ROWS];
Database.UndeleteResult[] UDR_Dels = Database.undelete(savedAccts);
```

undelete(recordID, allOrNone)

Restores an existing sObject record, such as an individual account or contact, from your organization's Recycle Bin.

Signature

```
public static Database.UndeleteResult undelete(ID recordID, Boolean allOrNone)
```

Parameters

recordID
Type: ID

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.UndeleteResult

Usage

`undelete` is analogous to the UNDELETE statement in SQL.

Each executed `undelete` method counts against the governor limit for DML statements.

undelete(recordIDs, allOrNone)

Restores one or more existing sObject records, such as individual accounts or contacts, from your organization's Recycle Bin.

Signature

```
public static Database.UndeleteResult[] undelete(ID[] recordIDs, Boolean allOrNone)
```

Parameters

RecordIDs
Type: ID[]

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.UndeleteResult[]

Usage

`undelete` is analogous to the UNDELETE statement in SQL.

Each executed `undelete` method counts against the governor limit for DML statements.

update(recordToUpdate, allOrNone)

Modifies an existing sObject record, such as an individual account or contact, in your organization's data.

Signature

```
public static Database.SaveResult update(sObject recordToUpdate, Boolean allOrNone)
```

Parameters

recordToUpdate
Type: sObject

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.SaveResult

Usage

`update` is analogous to the UPDATE statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `update` method counts against the governor limit for DML statements.

Example

The following example updates the `BillingCity` field on a single account.

```
Account a = new Account(Name='SFDC');
insert(a);

Account myAcct =
  [SELECT Id, Name, BillingCity
   FROM Account WHERE Id = :a.Id];
myAcct.BillingCity = 'San Francisco';

Database.SaveResult SR =
  Database.update(myAcct);
```

update(recordsToUpdate, allOrNone)

Modifies one or more existing sObject records, such as individual accounts or contactsinvoice statements, in your organization's data.

Signature

```
public static Database.SaveResult[] update(sObject[] recordsToUpdate, Boolean allOrNone)
```

Parameters

recordsToUpdate
Type: sObject []

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.SaveResult[]

Usage

`update` is analogous to the UPDATE statement in SQL.

Each executed `update` method counts against the governor limit for DML statements.

update(recordToUpdate, dmlOptions)

Modifies an existing sObject record, such as an individual account or contact, in your organization's data.

Signature

```
public static Database.SaveResult update(sObject recordToUpdate, Database.DmlOptions
dmlOptions)
```

Parameters

recordToUpdate
Type: sObject

dmlOptions
Type: Database.DMLOptions

The optional *dmlOptions* parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value

Type: Database.SaveResult

Usage

`update` is analogous to the UPDATE statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `update` method counts against the governor limit for DML statements.

update(recordsToUpdate, dmlOptions)

Modifies one or more existing sObject records, such as individual accounts or contactsinvoice statements, in your organization's data.

Signature

```
public static Database.SaveResult[] update(sObject[] recordsToUpdate, Database.DMLOptions
dmlOptions)
```

Parameters

recordsToUpdate
Type: sObject []

dmlOptions
Type: Database.DMLOptions

The optional *dmlOptions* parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value

Type: Database.SaveResult[]

Usage

`update` is analogous to the UPDATE statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `update` method counts against the governor limit for DML statements.

`upsert(recordToUpsert, externalIdField, allOrNone)`

Creates a new sObject record or updates an existing sObject record within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

Signature

```
public static Database.UpsertResult upsert(sObject recordToUpsert, Schema.SObjectField externalIDField, Boolean allOrNone)
```

Parameters

recordToUpsert
Type: sObject

externalIdField
Type: Schema.SObjectField

The *externalIdField* is of type `Schema.SObjectField`, that is, a field token. Find the token for the field by using the `fields` special method. For example, `Schema.SObjectField f = Account.Fields.MyExternalId`. The *externalIdField* parameter is the field that `upsert()` uses to match sObjects with existing records. This field can be a custom field marked as external ID, or a standard field with the `idLookup` attribute.

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.UpsertResult

Usage

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `upsert` method counts against the governor limit for DML statements.

For more information on how the upsert operation works, see the upsert() statement.

`upsert(recordsToUpsert, externalIdField, allOrNone)`

Creates new sObject records or updates existing sObject records within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

Signature

```
public static Database.UpsertResult[] upsert(sObject[] recordsToUpsert,
Schema.SObjectField externalIdField, Boolean allOrNone)
```

Parameters

recordsToUpsert
Type: sObject []

externalIdField
Type: Schema.SObjectField

The *externalIdField* is of type `Schema.SObjectField`, that is, a field token. Find the token for the field by using the `fields` special method. For example, `Schema.SObjectField f = Account.Fields.MyExternalId`. The *externalIdField* parameter is the field that `upsert()` uses to match sObjects with existing records. This field can be a custom field marked as external ID, or a standard field with the `idLookup` attribute.

allOrNone
Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: Database.UpsertResult[]

Usage

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `upsert` method counts against the governor limit for DML statements.

For more information on how the upsert operation works, see the upsert() statement.

updateAsync(sobjects, callback)

Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources. Allows referencing a callback class whose `processSave` method is called for each record after the remote operations are completed.

Signature

```
public static List<Database.SaveResult> updateAsync(List<SObject> sobjects,
DataSource.AsyncSaveCallback callback)
```

Parameters

sobjects
Type: List<SObject>

List of external object records to modify.

callback
Type: DataSource.AsyncSaveCallback

The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncSaveCallback`.

Return Value

Type: List<Database.SaveResult>

Status results for the update operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

`updateAsync(sobject, callback)`

Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processSave` method is called after the remote operation is completed.

Signature

```
public static Database.SaveResult updateAsync(SObject sobject,
DataSource.AsyncSaveCallback callback)
```

Parameters

`sobject`
Type: SObject

External object record to modify.

`callback`
Type: DataSource.AsyncSaveCallback

The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncSaveCallback`.

Return Value

Type: Database.SaveResult

Status result for the insert operation. The result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

`updateAsync(sobjects)`

Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.

Signature

```
public static List<Database.SaveResult> updateAsync(List<SObject> sobjects)
```

Parameters

sobjects
Type: List<SObject>

List of external object records to modify.

Return Value

Type: List<Database.SaveResult>

Status results for the update operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

`updateAsync(sobject)`

Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.

Signature

```
public static Database.SaveResult updateAsync(SObject sobject)
```

Parameters

sobject
Type: SObject

External object record to modify.

Return Value

Type: Database.SaveResult

Status result for the insert operation. The result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

`updateImmediate(sobjects)`

Initiates requests to update external object data on the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can't be completed and throw exceptions.

Signature

```
public static List<Database.SaveResult> updateImmediate(List<SObject> sobjects)
```

Parameters

sobjects
Type: List<SObject>

List of external object records to modify.

Return Value

Type: List<Database.SaveResult>

Status results for the update operation.

`updateImmediate(sobject)`

Initiates a request to update external object data on the relevant external system. The request is executed synchronously and is sent to the external system that's defined by the external object's associated external data source. If the Apex transaction contains pending changes, the synchronous operation can't be completed and throws an exception.

Signature

```
public static Database.SaveResult updateImmediate(SObject sobject)
```

Parameters

sobject
Type: SObject

External object record to modify.

Return Value

Type: Database.SaveResult

Status result for the update operation.

Date Class

Contains methods for the Date primitive data type.

Namespace

System

Usage

For more information on Dates, see Primitive Data Types on page 26.

Date Methods

The following are methods for `Date`.

IN THIS SECTION:

addDays(additionalDays)
Adds the specified number of additional days to a Date.

addMonths(additionalMonths)

Adds the specified number of additional months to a Date

addYears(additionalYears)

Adds the specified number of additional years to a Date

day()

Returns the day-of-month component of a Date.

dayOfYear()

Returns the day-of-year component of a Date.

daysBetween(secondDate)

Returns the number of days between the Date that called the method and the specified date.

daysInMonth(year, month)

Returns the number of days in the month for the specified *`year`* and *`month`* (1=Jan).

format()

Returns the Date as a string using the locale of the context user

isLeapYear(year)

Returns `true` if the specified year is a leap year.

isSameDay(dateToCompare)

Returns `true` if the Date that called the method is the same as the specified date.

month()

Returns the month component of a Date (1=Jan).

monthsBetween(secondDate)

Returns the number of months between the Date that called the method and the specified date, ignoring the difference in days.

newInstance(year, month, date)

Constructs a Date from Integer representations of the *`year`*, *`month`* (1=Jan), and *`day`*.

parse(stringDate)

Constructs a Date from a String. The format of the String depends on the local date format.

today()

Returns the current date in the current user's time zone.

toStartOfMonth()

Returns the first of the month for the Date that called the method.

toStartOfWeek()

Returns the start of the week for the Date that called the method, depending on the context user's locale.

valueOf(stringDate)

Returns a Date that contains the value of the specified String.

valueOf(fieldValue)

Converts the specified object to a Date. Use this method to convert a history tracking field value or an object that represents a Date value.

year()

Returns the year component of a Date

addDays(additionalDays)

Adds the specified number of additional days to a Date.

Signature

```
public Date addDays(Integer additionalDays)
```

Parameters

additionalDays
Type: Integer

Return Value

Type: Date

Example

```
Date myDate = Date.newInstance(1960, 2, 17);
Date newDate = mydate.addDays(2);
```

addMonths(additionalMonths)

Adds the specified number of additional months to a Date

Signature

```
public Date addMonths(Integer additionalMonths)
```

Parameters

additionalMonths
Type: Integer

Return Value

Type: Date

Example

```
date myDate = date.newInstance(1990, 11, 21);
date newDate = myDate.addMonths(3);
date expectedDate = date.newInstance(1991, 2, 21);
system.assertEquals(expectedDate, newDate);
```

addYears(additionalYears)

Adds the specified number of additional years to a Date

Signature

```
public Date addYears(Integer additionalYears)
```

Parameters

additionalYears
Type: Integer

Return Value

Type: Date

Example

```
date myDate = date.newInstance(1983, 7, 15);
date newDate = myDate.addYears(2);
date expectedDate = date.newInstance(1985, 7, 15);
system.assertEquals(expectedDate, newDate);
```

day()

Returns the day-of-month component of a Date.

Signature

```
public Integer day()
```

Return Value

Type: Integer

Example

```
date myDate = date.newInstance(1989, 4, 21);
Integer day = myDate.day();
system.assertEquals(21, day);
```

dayOfYear()

Returns the day-of-year component of a Date.

Signature

```
public Integer dayOfYear()
```

Return Value

Type: Integer

Example

```
date myDate = date.newInstance(1998, 10, 21);
Integer day = myDate.dayOfYear();
system.assertEquals(294, day);
```

daysBetween(secondDate)

Returns the number of days between the Date that called the method and the specified date.

Signature

```
public Integer daysBetween(Date secondDate)
```

Parameters

secondDate
Type: Date

Return Value

Type: Integer

Usage

If the Date that calls the method occurs after the *secondDate*, the return value is negative.

Example

```
Date startDate = Date.newInstance(2008, 1, 1);
Date dueDate = Date.newInstance(2008, 1, 30);
Integer numberDaysDue = startDate.daysBetween(dueDate);
```

daysInMonth(year, month)

Returns the number of days in the month for the specified *year* and *month* (1=Jan).

Signature

```
public static Integer daysInMonth(Integer year, Integer month)
```

Parameters

year
Type: Integer

month
Type: Integer

Return Value

Type: Integer

Example

The following example finds the number of days in the month of February in the year 1960.

```
Integer numberDays = date.daysInMonth(1960, 2);
```

format()

Returns the Date as a string using the locale of the context user

Signature

```
public String format()
```

Return Value

Type: String

Example

```
// In American-English locale
date myDate = date.newInstance(2001, 3, 21);
String dayString = myDate.format();
system.assertEquals('3/21/2001', dayString);
```

isLeapYear(year)

Returns `true` if the specified year is a leap year.

Signature

```
public static Boolean isLeapYear(Integer year)
```

Parameters

year
Type: Integer

Return Value

Type: Boolean

Example

```
system.assert(Date.isLeapYear(2004));
```

isSameDay(dateToCompare)

Returns `true` if the Date that called the method is the same as the specified date.

Signature

```
public Boolean isSameDay(Date dateToCompare)
```

Parameters

dateToCompare
Type: Date

Return Value

Type: Boolean

Example

```
date myDate = date.today();
date dueDate = date.newInstance(2008, 1, 30);
boolean dueNow = myDate.isSameDay(dueDate);
```

month()

Returns the month component of a Date (1=Jan).

Signature

```
public Integer month()
```

Return Value

Type: Integer

Example

```
date myDate = date.newInstance(2004, 11, 21);
Integer month = myDate.month();
system.assertEquals(11, month);
```

monthsBetween(secondDate)

Returns the number of months between the Date that called the method and the specified date, ignoring the difference in days.

Signature

```
public Integer monthsBetween(Date secondDate)
```

Parameters

secondDate
Type: Date

Return Value

Type: Integer

Example

```
Date firstDate = Date.newInstance(2006, 12, 2);
Date secondDate = Date.newInstance(2012, 12, 8);
Integer monthsBetween = firstDate.monthsBetween(secondDate);
System.assertEquals(72, monthsBetween);
```

newInstance(year, month, date)

Constructs a Date from Integer representations of the *year*, *month* (1=Jan), and *day*.

Signature

```
public static Date newInstance(Integer year, Integer month, Integer date)
```

Parameters

year
Type: Integer

month
Type: Integer

date
Type: Integer

Return Value

Type: Date

Example

The following example creates the date February 17th, 1960:

```
Date myDate = date.newinstance(1960, 2, 17);
```

parse(stringDate)

Constructs a Date from a String. The format of the String depends on the local date format.

Signature

```
public static Date parse(String stringDate)
```

Parameters

stringDate
Type: String

Return Value

Type: Date

Example

The following example works in some locales.

```
date mydate = date.parse('12/27/2009');
```

today()

Returns the current date in the current user's time zone.

Signature

```
public static Date today()
```

Return Value

Type: Date

toStartOfMonth()

Returns the first of the month for the Date that called the method.

Signature

```
public Date toStartOfMonth()
```

Return Value

Type: Date

Example

```
date myDate = date.newInstance(1987, 12, 17);
date firstDate = myDate.toStartOfMonth();
date expectedDate = date.newInstance(1987, 12, 1);
system.assertEquals(expectedDate, firstDate);
```

toStartOfWeek()

Returns the start of the week for the Date that called the method, depending on the context user's locale.

Signature

```
public Date toStartOfWeek()
```

Return Value

Type: Date

Example

For example, the start of a week is Sunday in the United States locale, and Monday in European locales. For example:

```
Date myDate = Date.today();
Date weekStart = myDate.toStartofWeek();
```

valueOf(stringDate)

Returns a Date that contains the value of the specified String.

Signature

```
public static Date valueOf(String stringDate)
```

Parameters

stringDate
Type: String

Return Value

Type: Date

Usage

The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the local time zone.

Example

```
string year = '2008';
string month = '10';
string day = '5';
string hour = '12';
string minute = '20';
string second = '20';
string stringDate = year + '-' + month
 + '-' + day + ' ' + hour + ':' +
minute + ':' + second;

Date myDate = date.valueOf(stringDate);
```

valueOf(fieldValue)

Converts the specified object to a Date. Use this method to convert a history tracking field value or an object that represents a Date value.

Signature

```
public static Date valueOf(Object fieldValue)
```

Parameters

fieldValue
Type: Object

Return Value

Type: Date

Usage

Use this method with the `OldValue` or `NewValue` fields of history sObjects, such as `AccountHistory`, when the field is a Date field.

Note: In API version 33.0 or earlier, if you call `Date.valueOf` with an object that represents a `Datetime`, the method returns a `Date` value that contains the hours, minutes, and seconds. In version 34.0 and later, `Date.valueOf` converts the object to a valid `Date` without the time information. To convert a variable of type `Datetime` to a `Date`, use the Datetime.date method.

Example

This example converts history tracking fields to `Date` values.

```
List<AccountHistory> ahlist = [SELECT Field,OldValue,NewValue FROM AccountHistory];
for(AccountHistory ah : ahlist) {
  System.debug('Field: ' + ah.Field);
  if (ah.field == 'MyDate__c') {
    Date oldValue = Date.valueOf(ah.OldValue);
    Date newValue = Date.valueOf(ah.NewValue);
  }
}
```

year()

Returns the year component of a Date

Signature

```
public Integer year()
```

Return Value

Type: Integer

Example

```
date myDate = date.newInstance(1988, 12, 17);
system.assertEquals(1988, myDate.year());
```

Datetime Class

Contains methods for the Datetime primitive data type.

Namespace

System

Usage

For more information about the Datetime, see Primitive Data Types on page 26.

Datetime Methods

The following are methods for `Datetime`.

IN THIS SECTION:

addDays(additionalDays)
Adds the specified number of days to a Datetime.

addHours(additionalHours)
Adds the specified number of hours to a Datetime.

addMinutes(additionalMinutes)
Adds the specified number of minutes to a Datetime.

addMonths(additionalMonths)
Adds the specified number of months to a Datetime.

addSeconds(additionalSeconds)
Adds the specified number of seconds to a Datetime.

addYears(additionalYears)
Adds the specified number of years to a Datetime.

date()
Returns the Date component of a Datetime in the local time zone of the context user.

dateGMT()
Return the Date component of a Datetime in the GMT time zone.

day()
Returns the day-of-month component of a Datetime in the local time zone of the context user.

dayGmt()
Returns the day-of-month component of a Datetime in the GMT time zone.

dayOfYear()
Returns the day-of-year component of a Datetime in the local time zone of the context user.

dayOfYearGmt()
Returns the day-of-year component of a Datetime in the GMT time zone.

format()
Converts the date to the local time zone and returns the converted date as a formatted string using the locale of the context user. If the time zone cannot be determined, GMT is used.

format(dateFormatString)
Converts the date to the local time zone and returns the converted date as a string using the supplied Java simple date format. If the time zone cannot be determined, GMT is used.

format(dateFormatString, timezone)

Converts the date to the specified time zone and returns the converted date as a string using the supplied Java simple date format. If the supplied time zone is not in the correct format, GMT is used.

formatGmt(dateFormatString)

Returns a Datetime as a string using the supplied Java simple date format and the GMT time zone.

formatLong()

Converts the date to the local time zone and returns the converted date in long date format.

getTime()

Returns the number of milliseconds since January 1, 1970, 00:00:00 GMT represented by this DateTime object.

hour()

Returns the hour component of a Datetime in the local time zone of the context user.

hourGmt()

Returns the hour component of a Datetime in the GMT time zone.

isSameDay(dateToCompare)

Returns true if the Datetime that called the method is the same as the specified Datetime in the local time zone of the context user.

millisecond()

Return the millisecond component of a Datetime in the local time zone of the context user.

millisecondGmt()

Return the millisecond component of a Datetime in the GMT time zone.

minute()

Returns the minute component of a Datetime in the local time zone of the context user.

minuteGmt()

Returns the minute component of a Datetime in the GMT time zone.

month()

Returns the month component of a Datetime in the local time zone of the context user (1=Jan).

monthGmt()

Returns the month component of a Datetime in the GMT time zone (1=Jan).

newInstance(milliseconds)

Constructs a Datetime and initializes it to represent the specified number of milliseconds since January 1, 1970, 00:00:00 GMT.

newInstance(date, time)

Constructs a DateTime from the specified date and time in the local time zone.

newInstance(year, month, day)

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the local time zone.

newInstance(year, month, day, hour, minute, second)

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the local time zone.

newInstanceGmt(date, time)

Constructs a DateTime from the specified date and time in the GMT time zone.

newInstanceGmt(year, month, date)

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the GMT time zone

newInstanceGmt(year, month, date, hour, minute, second)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the GMT time zone

now()
Returns the current Datetime based on a GMT calendar.

parse(datetimeString)
Constructs a Datetime from the given String in the local time zone and in the format of the user locale.

second()
Returns the second component of a Datetime in the local time zone of the context user.

secondGmt()
Returns the second component of a Datetime in the GMT time zone.

time()
Returns the time component of a Datetime in the local time zone of the context user.

timeGmt()
Returns the time component of a Datetime in the GMT time zone.

valueOf(dateTimeString)
Returns a Datetime that contains the value of the specified string.

valueOf(fieldValue)
Converts the specified object to a Datetime. Use this method to convert a history tracking field value or an object that represents a Datetime value.

valueOfGmt(dateTimeString)
Returns a Datetime that contains the value of the specified String.

year()
Returns the year component of a Datetime in the local time zone of the context user.

yearGmt()
Returns the year component of a Datetime in the GMT time zone.

addDays(additionalDays)

Adds the specified number of days to a Datetime.

Signature

```
public Datetime addDays(Integer additionalDays)
```

Parameters

additionalDays
Type: Integer

Return Value

Type: Datetime

Example

```
Datetime myDateTime = Datetime.newInstance(1960, 2, 17);
Datetime newDateTime = myDateTime.addDays(2);
Datetime expected = Datetime.newInstance(1960, 2, 19);
System.assertEquals(expected, newDateTime);
```

addHours(additionalHours)

Adds the specified number of hours to a Datetime.

Signature

```
public Datetime addHours(Integer additionalHours)
```

Parameters

additionalHours
Type: Integer

Return Value

Type: Datetime

Example

```
DateTime myDateTime = DateTime.newInstance(1997, 1, 31, 7, 8, 16);
DateTime newDateTime = myDateTime.addHours(3);
DateTime expected = DateTime.newInstance(1997, 1, 31, 10, 8, 16);
System.assertEquals(expected, newDateTime);
```

addMinutes(additionalMinutes)

Adds the specified number of minutes to a Datetime.

Signature

```
public Datetime addMinutes(Integer additionalMinutes)
```

Parameters

additionalMinutes
Type: Integer

Return Value

Type: Datetime

Example

```
DateTime myDateTime = DateTime.newInstance(1999, 2, 11, 8, 6, 16);
DateTime newDateTime = myDateTime.addMinutes(7);
DateTime expected = DateTime.newInstance(1999, 2, 11, 8, 13, 16);
System.assertEquals(expected, newDateTime);
```

addMonths(additionalMonths)

Adds the specified number of months to a Datetime.

Signature

```
public Datetime addMonths(Integer additionalMonths)
```

Parameters

additionalMonths
Type: Integer

Return Value

Type: Datetime

Example

```
DateTime myDateTime = DateTime.newInstance(2000, 7, 7, 7, 8, 12);
DateTime newDateTime = myDateTime.addMonths(1);
DateTime expected = DateTime.newInstance(2000, 8, 7, 7, 8, 12);
System.assertEquals(expected, newDateTime);
```

addSeconds(additionalSeconds)

Adds the specified number of seconds to a Datetime.

Signature

```
public Datetime addSeconds(Integer additionalSeconds)
```

Parameters

additionalSeconds
Type: Integer

Return Value

Type: Datetime

Example

```
DateTime myDateTime = DateTime.newInstance(2001, 7, 19, 10, 7, 12);
DateTime newDateTime = myDateTime.addSeconds(4);
DateTime expected = DateTime.newInstance(2001, 7, 19, 10, 7, 16);
System.assertEquals(expected, newDateTime);
```

addYears(additionalYears)

Adds the specified number of years to a Datetime.

Signature

```
public Datetime addYears(Integer additionalYears)
```

Parameters

additionalYears
Type: Integer

Return Value

Type: Datetime

Example

```
DateTime myDateTime = DateTime.newInstance(2009, 12, 17, 13, 6, 6);
DateTime newDateTime = myDateTime.addYears(1);
DateTime expected = DateTime.newInstance(2010, 12, 17, 13, 6, 6);
System.assertEquals(expected, newDateTime);
```

date()

Returns the Date component of a Datetime in the local time zone of the context user.

Signature

```
public Date date()
```

Return Value

Type: Date

Example

```
DateTime myDateTime = DateTime.newInstance(2006, 3, 16, 12, 6, 13);
Date myDate = myDateTime.date();
Date expected = Date.newInstance(2006, 3, 16);
System.assertEquals(expected, myDate);
```

dateGMT()

Return the Date component of a Datetime in the GMT time zone.

Signature

```
public Date dateGMT()
```

Return Value

Type: Date

Example

```
// California local time, PST
DateTime myDateTime = DateTime.newInstance(2006, 3, 16, 23, 0, 0);
Date myDate = myDateTime.dateGMT();
Date expected = Date.newInstance(2006, 3, 17);
System.assertEquals(expected, myDate);
```

day()

Returns the day-of-month component of a Datetime in the local time zone of the context user.

Signature

```
public Integer day()
```

Return Value

Type: Integer

Example

```
DateTime myDateTime = DateTime.newInstance(1986, 2, 21, 23, 0, 0);
System.assertEquals(21, myDateTime.day());
```

dayGmt()

Returns the day-of-month component of a Datetime in the GMT time zone.

Signature

```
public Integer dayGmt()
```

Return Value

Type: Integer

Example

```
// California local time, PST
DateTime myDateTime = DateTime.newInstance(1987, 1, 14, 23, 0, 3);
System.assertEquals(15, myDateTime.dayGMT());
```

dayOfYear()

Returns the day-of-year component of a Datetime in the local time zone of the context user.

Signature

```
public Integer dayOfYear()
```

Return Value

Type: Integer

Example

For example, February 5, 2008 08:30:12 would be day 36.

```
Datetime myDate = Datetime.newInstance(2008, 2, 5, 8, 30, 12);
system.assertEquals(myDate.dayOfYear(), 36);
```

dayOfYearGmt()

Returns the day-of-year component of a Datetime in the GMT time zone.

Signature

```
public Integer dayOfYearGmt()
```

Return Value

Type: Integer

Example

```
// This sample assumes we are in the PST timezone
DateTime myDateTime = DateTime.newInstance(1999, 2, 5, 23, 0, 3);
// January has 31 days + 5 days in February = 36 days
// dayOfYearGmt() adjusts the time zone from the current time zone to GMT
// by adding 8 hours to the PST time zone, so it's 37 days and not 36 days
System.assertEquals(37, myDateTime.dayOfYearGmt());
```

format()

Converts the date to the local time zone and returns the converted date as a formatted string using the locale of the context user. If the time zone cannot be determined, GMT is used.

Signature

```
public String format()
```

Return Value

Type: String

Example

```
DateTime myDateTime = DateTime.newInstance(1993, 6, 6, 3, 3, 3);
system.assertEquals('6/6/1993 3:03 AM', mydatetime.format());
```

format(dateFormatString)

Converts the date to the local time zone and returns the converted date as a string using the supplied Java simple date format. If the time zone cannot be determined, GMT is used.

Signature

```
public String format(String dateFormatString)
```

Parameters

dateFormatString
Type: String

Return Value

Type: String

Usage

For more information on the Java simple date format, see Java SimpleDateFormat.

Example

```
Datetime myDT = Datetime.now();
String myDate = myDT.format('h:mm a');
```

format(dateFormatString, timezone)

Converts the date to the specified time zone and returns the converted date as a string using the supplied Java simple date format. If the supplied time zone is not in the correct format, GMT is used.

Signature

```
public String format(String dateFormatString, String timezone)
```

Parameters

dateFormatString
Type: String

timezone
Type: String

Valid time zone values for the *timezone* argument are the time zones of the Java TimeZone class that correspond to the time zones returned by the TimeZone.getAvailableIDs method in Java. We recommend you use full time zone names, not the three-letter abbreviations.

Return Value

Type: String

Usage

For more information on the Java simple date format, see Java SimpleDateFormat.

Example

This example uses `format` to convert a GMT date to the America/New_York time zone and formats the date using the specified date format.

```
Datetime GMTDate =
  Datetime.newInstanceGmt(2011,6,1,12,1,5);
String strConvertedDate =
  GMTDate.format('MM/dd/yyyy HH:mm:ss',
                 'America/New_York');
// Date is converted to
// the new time zone and is adjusted
// for daylight saving time.
System.assertEquals(
  '06/01/2011 08:01:05', strConvertedDate);
```

formatGmt(dateFormatString)

Returns a Datetime as a string using the supplied Java simple date format and the GMT time zone.

Signature

```
public String formatGmt(String dateFormatString)
```

Parameters

dateFormatString
Type: String

Return Value

Type: String

Usage

For more information on the Java simple date format, see Java SimpleDateFormat.

Example

```
DateTime myDateTime = DateTime.newInstance(1993, 6, 6, 3, 3, 3);
String formatted = myDateTime.formatGMT('EEE, MMM d yyyy HH:mm:ss');
String expected = 'Sun, Jun 6 1993 10:03:03';
System.assertEquals(expected, formatted);
```

formatLong()

Converts the date to the local time zone and returns the converted date in long date format.

Signature

```
public String formatLong()
```

Return Value

Type: String

Example

```
// Passing local date based on the PST time zone
Datetime dt = DateTime.newInstance(2012,12,28,10,0,0);
// Writes 12/28/2012 10:00:00 AM PST
System.debug('dt.formatLong()=' + dt.formatLong());
```

getTime()

Returns the number of milliseconds since January 1, 1970, 00:00:00 GMT represented by this DateTime object.

Signature

```
public Long getTime()
```

Return Value

Type: Long

Example

```
DateTime dt = DateTime.newInstance(2007, 6, 23, 3, 3, 3);
Long gettime = dt.getTime();
Long expected = 1182592983000L;
System.assertEquals(expected, gettime);
```

hour()

Returns the hour component of a Datetime in the local time zone of the context user.

Signature

```
public Integer hour()
```

Return Value

Type: Integer

Example

```
DateTime myDateTime = DateTime.newInstance(1998, 11, 21, 3, 3, 3);
System.assertEquals(3 , myDateTime.hour());
```

hourGmt()

Returns the hour component of a Datetime in the GMT time zone.

Signature

```
public Integer hourGmt()
```

Return Value

Type: Integer

Example

```
// California local time
DateTime myDateTime = DateTime.newInstance(2000, 4, 27, 3, 3, 3);
System.assertEquals(10 , myDateTime.hourGMT());
```

isSameDay(dateToCompare)

Returns true if the Datetime that called the method is the same as the specified Datetime in the local time zone of the context user.

Signature

```
public Boolean isSameDay(Datetime dateToCompare)
```

Parameters

dateToCompare
Type: Datetime

Return Value

Type: Boolean

Example

```
datetime myDate = datetime.now();
datetime dueDate =
     datetime.newInstance(2008, 1, 30);
boolean dueNow = myDate.isSameDay(dueDate);
```

millisecond()

Return the millisecond component of a Datetime in the local time zone of the context user.

Signature

```
public Integer millisecond()
```

Return Value

Type: Integer

Example

```
DateTime myDateTime = DateTime.now();
system.debug(myDateTime.millisecond());
```

millisecondGmt()

Return the millisecond component of a Datetime in the GMT time zone.

Signature

```
public Integer millisecondGmt()
```

Return Value

Type: Integer

Example

```
DateTime myDateTime = DateTime.now();
system.debug(myDateTime.millisecondGMT());
```

minute()

Returns the minute component of a Datetime in the local time zone of the context user.

Signature

```
public Integer minute()
```

Return Value

Type: Integer

Example

```
DateTime myDateTime = DateTime.newInstance(2001, 2, 27, 3, 3, 3);
system.assertEquals(3, myDateTime.minute());
```

minuteGmt()

Returns the minute component of a Datetime in the GMT time zone.

Signature

```
public Integer minuteGmt()
```

Return Value

Type: Integer

Example

```
DateTime myDateTime = DateTime.newInstance(2002, 12, 3, 3, 3, 3);
system.assertEquals(3, myDateTime.minuteGMT());
```

month()

Returns the month component of a Datetime in the local time zone of the context user (1=Jan).

Signature

```
public Integer month()
```

Return Value

Type: Integer

Example

```
DateTime myDateTime = DateTime.newInstance(2004, 11, 4, 3, 3, 3);
system.assertEquals(11, myDateTime.month());
```

monthGmt()

Returns the month component of a Datetime in the GMT time zone (1=Jan).

Signature

```
public Integer monthGmt()
```

Return Value

Type: Integer

Example

```
DateTime myDateTime = DateTime.newInstance(2006, 11, 19, 3, 3, 3);
system.assertEquals(11, myDateTime.monthGMT());
```

newInstance(milliseconds)

Constructs a Datetime and initializes it to represent the specified number of milliseconds since January 1, 1970, 00:00:00 GMT.

Signature

```
public static Datetime newInstance(Long milliseconds)
```

Parameters

milliseconds
Type: Long

Return Value

Type: Datetime

The returned date is in the GMT time zone.

Example

```
Long longtime = 1341828183000L;
DateTime dt = DateTime.newInstance(longtime);
DateTime expected = DateTime.newInstance(2012, 7, 09, 3, 3, 3);
System.assertEquals(expected, dt);
```

newInstance(date, time)

Constructs a DateTime from the specified date and time in the local time zone.

Signature

```
public static Datetime newInstance(Date date, Time time)
```

Parameters

date
Type: Date

time
Type: Time

Return Value

Type: Datetime

The returned date is in the GMT time zone.

Example

```
Date myDate = Date.newInstance(2011, 11, 18);
Time myTime = Time.newInstance(3, 3, 3, 0);
DateTime dt = DateTime.newInstance(myDate, myTime);
DateTime expected = DateTime.newInstance(2011, 11, 18, 3, 3, 3);
System.assertEquals(expected, dt);
```

newInstance(year, month, day)

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the local time zone.

Signature

```
public static Datetime newInstance(Integer year, Integer month, Integer day)
```

Parameters

year
Type: Integer

month
Type: Integer

day
Type: Integer

Return Value

Type: Datetime

The returned date is in the GMT time zone.

Example

```
datetime myDate = datetime.newInstance(2008, 12, 1);
```

newInstance(year, month, day, hour, minute, second)

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the local time zone.

Signature

```
public static Datetime newInstance(Integer year, Integer month, Integer day, Integer
hour, Integer minute, Integer second)
```

Parameters

year
Type: Integer

month
Type: Integer

day
Type: Integer

hour
Type: Integer

minute
Type: Integer

second
Type: Integer

Return Value

Type: Datetime

The returned date is in the GMT time zone.

Example

```
Datetime myDate = Datetime.newInstance(2008, 12, 1, 12, 30, 2);
```

newInstanceGmt(date, time)

Constructs a DateTime from the specified date and time in the GMT time zone.

Signature

```
public static Datetime newInstanceGmt(Date date, Time time)
```

Parameters

date
Type: Date

time
Type: Time

Return Value

Type: Datetime

Example

```
Date myDate = Date.newInstance(2013, 11, 12);
Time myTime = Time.newInstance(3, 3, 3, 0);
DateTime dt = DateTime.newInstanceGMT(myDate, myTime);
```

```
DateTime expected = DateTime.newInstanceGMT(2013, 11, 12, 3, 3, 3);
System.assertEquals(expected, dt);
```

newInstanceGmt(year, month, date)

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the GMT time zone

Signature

```
public static Datetime newInstanceGmt(Integer year, Integer month, Integer date)
```

Parameters

year
Type: Integer

month
Type: Integer

date
Type: Integer

Return Value

Type: Datetime

Example

```
DateTime dt = DateTime.newInstanceGMT(1996, 3, 22);
```

newInstanceGmt(year, month, date, hour, minute, second)

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the GMT time zone

Signature

```
public static Datetime newInstanceGmt(Integer year, Integer month, Integer date, Integer
hour, Integer minute, Integer second)
```

Parameters

year
Type: Integer

month
Type: Integer

date
Type: Integer

hour
Type: Integer

minute
Type: Integer

second
Type: Integer

Return Value

Type: Datetime

Example

```
//California local time
DateTime dt = DateTime.newInstanceGMT(1998, 1, 29, 2, 2, 3);
DateTime expected = DateTime.newInstance(1998, 1, 28, 18, 2, 3);
System.assertEquals(expected, dt);
```

now()

Returns the current Datetime based on a GMT calendar.

Signature

```
public static Datetime now()
```

Return Value

Type: Datetime

The format of the returned datetime is: `'MM/DD/YYYY HH:MM PERIOD'`

Example

```
datetime myDateTime = datetime.now();
```

parse(datetimeString)

Constructs a Datetime from the given String in the local time zone and in the format of the user locale.

Signature

```
public static Datetime parse(String datetimeString)
```

Parameters

datetimeString
Type: String

Return Value

Type: Datetime

The returned date is in the GMT time zone.

Example

This example uses `parse` to create a Datetime from a date passed in as a string and that is formatted for the English (United States) locale. You may need to change the format of the date string if you have a different locale.

```
Datetime dt = DateTime.parse('10/14/2011 11:46 AM');
String myDtString = dt.format();
system.assertEquals(myDtString, '10/14/2011 11:46 AM');
```

`second()`

Returns the second component of a Datetime in the local time zone of the context user.

Signature

```
public Integer second()
```

Return Value

Type: Integer

Example

```
DateTime dt = DateTime.newInstanceGMT(1999, 9, 22, 3, 1, 2);
System.assertEquals(2, dt.second());
```

`secondGmt()`

Returns the second component of a Datetime in the GMT time zone.

Signature

```
public Integer secondGmt()
```

Return Value

Type: Integer

Example

```
DateTime dt = DateTime.newInstance(2000, 2, 3, 3, 1, 5);
System.assertEquals(5, dt.secondGMT());
```

`time()`

Returns the time component of a Datetime in the local time zone of the context user.

Signature

```
public Time time()
```

Return Value

Type: Time

Example

```
DateTime dt = DateTime.newInstance(2002, 11, 21, 0, 2, 2);
Time expected = Time.newInstance(0, 2, 2, 0);
System.assertEquals(expected, dt.time());
```

timeGmt()

Returns the time component of a Datetime in the GMT time zone.

Signature

```
public Time timeGmt()
```

Return Value

Type: Time

Example

```
// This sample is based on the PST time zone
DateTime dt = DateTime.newInstance(2004, 1, 27, 4, 1, 2);
Time expected = Time.newInstance(12, 1, 2, 0);
// 8 hours are added to the time to convert it from
// PST to GMT
System.assertEquals(expected, dt.timeGMT());
```

valueOf(dateTimeString)

Returns a Datetime that contains the value of the specified string.

Signature

```
public static Datetime valueOf(String dateTimeString)
```

Parameters

dateTimeString
Type: String

Return Value

Type: Datetime

The returned date is in the GMT time zone.

Usage

The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the local time zone.

Example

```
string year = '2008';
string month = '10';
string day = '5';
string hour = '12';
string minute = '20';
string second = '20';
string stringDate = year + '-' + month + '-' + day + ' ' + hour + ':'
    + minute +  ':' + second;

Datetime myDate = Datetime.valueOf(stringDate);
```

valueOf(fieldValue)

Converts the specified object to a Datetime. Use this method to convert a history tracking field value or an object that represents a Datetime value.

Signature

```
public static Datetime valueOf(Object fieldValue)
```

Parameters

fieldValue
Type: Object

Return Value

Type: Datetime

Usage

Use this method with the `OldValue` or `NewValue` fields of history sObjects, such as `AccountHistory`, when the field is a Date/Time field.

Example

```
List<AccountHistory> ahlist = [SELECT Field,OldValue,NewValue FROM AccountHistory];
for(AccountHistory ah : ahlist) {
  System.debug('Field: ' + ah.Field);
  if (ah.field == 'MyDatetime__c') {
    Datetime oldValue = Datetime.valueOf(ah.OldValue);
    Datetime newValue = Datetime.valueOf(ah.NewValue);
```

```
    }
}
```

valueOfGmt(dateTimeString)

Returns a Datetime that contains the value of the specified String.

Signature

```
public static Datetime valueOfGmt(String dateTimeString)
```

Parameters

dateTimeString
Type: String

Return Value

Type: Datetime

Usage

The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the GMT time zone.

Example

```
// California locale time
string year = '2009';
string month = '3';
string day = '5';
string hour = '5';
string minute = '2';
string second = '2';
string stringDate = year + '-' + month + '-' + day + ' ' + hour + ':'
    + minute +  ':' + second;

Datetime myDate = Datetime.valueOfGMT(stringDate);

DateTime expected = DateTime.newInstance(2009, 3, 4, 21, 2, 2);
System.assertEquals(expected, myDate);
```

year()

Returns the year component of a Datetime in the local time zone of the context user.

Signature

```
public Integer year()
```

Return Value

Type: Integer

Example

```
DateTime dt = DateTime.newInstance(2012, 1, 26, 5, 2, 4);
System.assertEquals(2012, dt.year());
```

yearGmt()

Returns the year component of a Datetime in the GMT time zone.

Signature

```
public Integer yearGmt()
```

Return Value

Type: Integer

Example

```
DateTime dt = DateTime.newInstance(2012, 10, 4, 6, 4, 6);
System.assertEquals(2012, dt.yearGMT());
```

Decimal Class

Contains methods for the Decimal primitive data type.

Namespace

System

Usage

For more information on Decimal, see Primitive Data Types on page 26.

IN THIS SECTION:

Rounding Mode

Rounding mode specifies the rounding behavior for numerical operations capable of discarding precision.

Decimal Methods

Rounding Mode

Rounding mode specifies the rounding behavior for numerical operations capable of discarding precision.

Each rounding mode indicates how the least significant returned digit of a rounded result is to be calculated. The following are the valid values for *roundingMode*.

Name	Description

CEILING	Rounds towards positive infinity. That is, if the result is positive, this mode behaves the same as the UP rounding mode; if the result is negative, it behaves the same as the DOWN rounding mode. Note that this rounding mode never decreases the calculated value. For example:
	• Input number 5.5: CEILING round mode result: 6
	• Input number 1.1: CEILING round mode result: 2
	• Input number -1.1: CEILING round mode result: -1
	• Input number -2.7: CEILING round mode result: -2
	`Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};`
	`Long[] expected = new Long[]{6, 2, -1, -2};`
	`for(integer x = 0; x < example.size(); x++){`
	`  System.assertEquals(expected[x],`
	`  example[x].round(System.RoundingMode.CEILING));`
	`}`

DOWN	Rounds towards zero. This rounding mode always discards any fractions (decimal points) prior to executing. Note that this rounding mode never increases the magnitude of the calculated value. For example:
	• Input number 5.5: DOWN round mode result: 5
	• Input number 1.1: DOWN round mode result: 1
	• Input number -1.1: DOWN round mode result: -1
	• Input number -2.7: DOWN round mode result: -2
	`Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};`
	`Long[] expected = new Long[]{5, 1, -1, -2};`
	`for(integer x = 0; x < example.size(); x++){`
	`  System.assertEquals(expected[x],`
	`  example[x].round(System.RoundingMode.DOWN));`
	`}`

FLOOR	Rounds towards negative infinity. That is, if the result is positive, this mode behaves the same as theDOWN rounding mode; if negative, this mode behaves the same as the UP rounding mode. Note that this rounding mode never increases the calculated value. For example:
	• Input number 5.5: FLOOR round mode result: 5
	• Input number 1.1: FLOOR round mode result: 1
	• Input number -1.1: FLOOR round mode result: -2
	• Input number -2.7: FLOOR round mode result: -3
	`Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};`
	`Long[] expected = new Long[]{5, 1, -2, -3};`
	`for(integer x = 0; x < example.size(); x++){`
	`  System.assertEquals(expected[x],`
	`  example[x].round(System.RoundingMode.FLOOR));`
	`}`

Name	Description

HALF_DOWN	Rounds towards the "nearest neighbor" unless both neighbors are equidistant, in which case this mode rounds down. This rounding mode behaves the same as the UP rounding mode if the discarded fraction (decimal point) is > 0.5; otherwise, it behaves the same as DOWN rounding mode. For example:
	• Input number 5.5: HALF_DOWN round mode result: 5
	• Input number 1.1: HALF_DOWN round mode result: 1
	• Input number -1.1: HALF_DOWN round mode result: -1
	• Input number -2.7: HALF_DOWN round mode result: -3
	`Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};`
	`Long[] expected = new Long[]{5, 1, -1, -3};`
	`for(integer x = 0; x < example.size(); x++){`
	`System.assertEquals(expected[x],`
	`example[x].round(System.RoundingMode.HALF_DOWN));`
	`}`

HALF_EVEN	Rounds towards the "nearest neighbor" unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor. This rounding mode behaves the same as the HALF_UP rounding mode if the digit to the left of the discarded fraction (decimal point) is odd. It behaves the same as the HALF_DOWN rounding method if it is even. For example:
	• Input number 5.5: HALF_EVEN round mode result: 6
	• Input number 1.1: HALF_EVEN round mode result: 1
	• Input number -1.1: HALF_EVEN round mode result: -1
	• Input number -2.7: HALF_EVEN round mode result: -3
	`Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};`
	`Long[] expected = new Long[]{6, 1, -1, -3};`
	`for(integer x = 0; x < example.size(); x++){`
	`System.assertEquals(expected[x],`
	`example[x].round(System.RoundingMode.HALF_EVEN));`
	`}`
	Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

HALF_UP	Rounds towards the "nearest neighbor" unless both neighbors are equidistant, in which case, this mode rounds up. This rounding method behaves the same as the UP rounding method if the discarded fraction (decimal point) is >= 0.5; otherwise, this rounding method behaves the same as the DOWN rounding method. For example:
	• Input number 5.5: HALF_UP round mode result: 6
	• Input number 1.1: HALF_UP round mode result: 1
	• Input number -1.1: HALF_UP round mode result: -1
	• Input number -2.7: HALF_UP round mode result: -3
	`Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};`
	`Long[] expected = new Long[]{6, 1, -1, -3};`
	`for(integer x = 0; x < example.size(); x++){`

Name	Description

	``
	    System.assertEquals(expected[x],
	        example[x].round(System.RoundingMode.HALF_UP));
	}
	``

UNNECESSARY	Asserts that the requested operation has an exact result, which means that no rounding is necessary. If this rounding mode is specified on an operation that yields an inexact result, a MathException is thrown. For example:
	• Input number 5.5: UNNECESSARY round mode result: MathException
	• Input number 1.1: UNNECESSARY round mode result: MathException
	• Input number 1.0: UNNECESSARY round mode result: 1
	• Input number -1.0: UNNECESSARY round mode result: -1
	• Input number -2.2: UNNECESSARY round mode result: MathException
	``
	Decimal example1 = 5.5;
	Decimal example2 = 1.0;
	system.assertEquals(1,
	    example2.round(System.RoundingMode.UNNECESSARY));
	try{
	    example1.round(System.RoundingMode.UNNECESSARY);
	} catch(Exception E) {
	   system.assertEquals('System.MathException', E.getTypeName());
	}
	``

UP	Rounds away from zero. This rounding mode always truncates any fractions (decimal points) prior to executing. Note that this rounding mode never decreases the magnitude of the calculated value. For example:
	• Input number 5.5: UP round mode result: 6
	• Input number 1.1: UP round mode result: 2
	• Input number -1.1: UP round mode result: -2
	• Input number -2.7: UP round mode result: -3
	``
	Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
	Long[] expected = new Long[]{6, 2, -2, -3};
	for(integer x = 0; x < example.size(); x++){
	    System.assertEquals(expected[x],
	        example[x].round(System.RoundingMode.UP));
	}
	``

Decimal Methods

The following are methods for `Decimal`.

IN THIS SECTION:

abs()

Returns the absolute value of the Decimal.

divide(divisor, scale)

Divides this Decimal by the specified divisor, and sets the scale, that is, the number of decimal places, of the result using the specified scale.

divide(divisor, scale, roundingMode)

Divides this Decimal by the specified divisor, sets the scale, that is, the number of decimal places, of the result using the specified scale, and if necessary, rounds the value using the rounding mode.

doubleValue()

Returns the Double value of this Decimal.

format()

Returns the String value of this Decimal using the locale of the context user.

intValue()

Returns the Integer value of this Decimal.

longValue()

Returns the Long value of this Decimal.

pow(exponent)

Returns the value of this decimal raised to the power of the specified exponent.

precision()

Returns the total number of digits for the Decimal.

round()

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

round(roundingMode)

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using the rounding mode specified by the rounding mode.

scale()

Returns the scale of the Decimal, that is, the number of decimal places.

setScale(scale)

Returns the Decimal scaled to the specified number of decimal places, using half-even rounding, if necessary. Half-even rounding mode rounds toward the “nearest neighbor.” If both neighbors are equidistant, the number is rounded toward the even neighbor.

setScale(scale, roundingMode)

Returns the Decimal scaled to the specified number of decimal places, using the specified rounding mode, if necessary.

stripTrailingZeros()

Returns the Decimal with any trailing zeros removed.

toPlainString()

Returns the String value of this Decimal, without using scientific notation.

valueOf(doubleToDecimal)

Returns a Decimal that contains the value of the specified Double.

valueOf(longToDecimal)

Returns a Decimal that contains the value of the specified Long.

valueOf(stringToDecimal)
Returns a Decimal that contains the value of the specified String. As in Java, the string is interpreted as representing a signed Decimal.

abs()

Returns the absolute value of the Decimal.

Signature

```
public Decimal abs()
```

Return Value

Type: Decimal

Example

```
Decimal myDecimal = -6.02214129;
System.assertEquals(6.02214129, myDecimal.abs());
```

divide(divisor, scale)

Divides this Decimal by the specified divisor, and sets the scale, that is, the number of decimal places, of the result using the specified scale.

Signature

```
public Decimal divide(Decimal divisor, Integer scale)
```

Parameters

divisor
Type: Decimal

scale
Type: Integer

Return Value

Type: Decimal

Example

```
Decimal decimalNumber = 19;
Decimal result = decimalNumber.divide(100, 3);
System.assertEquals(0.190, result);
```

divide(divisor, scale, roundingMode)

Divides this Decimal by the specified divisor, sets the scale, that is, the number of decimal places, of the result using the specified scale, and if necessary, rounds the value using the rounding mode.

Signature

```
public Decimal divide(Decimal divisor, Integer scale, System.RoundingMode roundingMode)
```

Parameters

divisor
Type: Decimal

scale
Type: Integer

roundingMode
Type: System.RoundingMode

Return Value

Type: Decimal

Example

```
Decimal myDecimal = 12.4567;
Decimal divDec = myDecimal.divide(7, 2, System.RoundingMode.UP);
System.assertEquals(divDec, 1.78);
```

doubleValue()

Returns the Double value of this Decimal.

Signature

```
public Double doubleValue()
```

Return Value

Type: Double

Example

```
Decimal myDecimal = 6.62606957;
Double value = myDecimal.doubleValue();
System.assertEquals(6.62606957, value);
```

format()

Returns the String value of this Decimal using the locale of the context user.

Signature

```
public String format()
```

Return Value

Type: String

Usage

Scientific notation will be used if an exponent is needed.

Example

```
// U.S. locale
Decimal myDecimal = 12345.6789;
system.assertEquals('12,345.679', myDecimal.format());
```

intValue()

Returns the Integer value of this Decimal.

Signature

```
public Integer intValue()
```

Return Value

Type: Integer

Example

```
Decimal myDecimal = 1.602176565;
system.assertEquals(1, myDecimal.intValue());
```

longValue()

Returns the Long value of this Decimal.

Signature

```
public Long longValue()
```

Return Value

Type: Long

Example

```
Decimal myDecimal = 376.730313461;
system.assertEquals(376, myDecimal.longValue());
```

pow(exponent)

Returns the value of this decimal raised to the power of the specified exponent.

Signature

```
public Decimal pow(Integer exponent)
```

Parameters

exponent
Type: Integer

The value of *exponent* must be between 0 and 32,767.

Return Value

Type: Decimal

Usage

If you use `MyDecimal.pow(0)`, 1 is returned.

The `Math.pow` method does accept negative values.

Example

```
Decimal myDecimal = 4.12;
Decimal powDec = myDecimal.pow(2);
System.assertEquals(powDec, 16.9744);
```

precision()

Returns the total number of digits for the Decimal.

Signature

```
public Integer precision()
```

Return Value

Type: Integer

Example

For example, if the Decimal value was 123.45, `precision` returns 5. If the Decimal value is 123.123, `precision` returns 6.

```
Decimal D1 = 123.45;
Integer precision1 = D1.precision();
system.assertEquals(precision1, 5);
Decimal D2 = 123.123;
Integer precision2 = D2.precision();
system.assertEquals(precision2, 6);
```

round()

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the "nearest neighbor" unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

Signature

```
public Long round()
```

Return Value

Type: Long

Usage

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

Example

```
Decimal D = 4.5;
Long L = D.round();
System.assertEquals(4, L);

Decimal D1 = 5.5;
Long L1 = D1.round();
System.assertEquals(6, L1);

Decimal D2 = 5.2;
Long L2 = D2.round();
System.assertEquals(5, L2);

Decimal D3 = -5.7;
Long L3 = D3.round();
System.assertEquals(-6, L3);
```

round(roundingMode)

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using the rounding mode specified by the rounding mode.

Signature

```
public Long round(System.RoundingMode roundingMode)
```

Parameters

roundingMode
Type: System.RoundingMode

Return Value

Type: Long

scale()

Returns the scale of the Decimal, that is, the number of decimal places.

Signature

```
public Integer scale()
```

Return Value

Type: Integer

Example

```
Decimal myDecimal = 9.27400968;
system.assertEquals(8, myDecimal.scale());
```

setScale(scale)

Returns the Decimal scaled to the specified number of decimal places, using half-even rounding, if necessary. Half-even rounding mode rounds toward the "nearest neighbor." If both neighbors are equidistant, the number is rounded toward the even neighbor.

Signature

```
public Decimal setScale(Integer scale)
```

Parameters

scale

Type: Integer

The value of *scale* must be between –33 and 33. If the value of *scale* is negative, your unscaled value is multiplied by 10 to the power of the negation of *scale*. For example, after this operation, the value of *d* is `4*10^3`.

```
Decimal d = 4000;
d = d.setScale(-3);
```

Return Value

Type: Decimal

Usage

If you do not explicitly set the scale for a Decimal, the item from which the Decimal is created determines the scale.

- If the Decimal is created as part of a query, the scale is based on the scale of the field returned from the query.
- If the Decimal is created from a String, the scale is the number of characters after the decimal point of the String.

- If the Decimal is created from a non-decimal number, the number is first converted to a String. Scale is then set using the number of characters after the decimal point.

Example

```
Decimal myDecimal = 8.987551787;
Decimal setScaled = myDecimal.setscale(3);
System.assertEquals(8.988, setScaled);
```

setScale(scale, roundingMode)

Returns the Decimal scaled to the specified number of decimal places, using the specified rounding mode, if necessary.

Signature

```
public Decimal setScale(Integer scale, System.RoundingMode roundingMode)
```

Parameters

scale
Type: Integer

The value of *scale* must be between –33 and 33. If the value of *scale* is negative, your unscaled value is multiplied by 10 to the power of the negation of *scale*. For example, after this operation, the value of *d* is `4*10^3`.

```
Decimal d = 4000;
d = d.setScale(-3);
```

roundingMode
Type: System.RoundingMode

Return Value

Type: Decimal

Usage

If you do not explicitly set the scale for a Decimal, the item from which the Decimal is created determines the scale.

- If the Decimal is created as part of a query, the scale is based on the scale of the field returned from the query.
- If the Decimal is created from a String, the scale is the number of characters after the decimal point of the String.
- If the Decimal is created from a non-decimal number, the number is first converted to a String. Scale is then set using the number of characters after the decimal point.

stripTrailingZeros()

Returns the Decimal with any trailing zeros removed.

Signature

```
public Decimal stripTrailingZeros()
```

Return Value

Type: Decimal

Example

```
Decimal myDecimal = 1.10000;
Decimal stripped = myDecimal.stripTrailingZeros();
System.assertEquals(stripped, 1.1);
```

toPlainString()

Returns the String value of this Decimal, without using scientific notation.

Signature

```
public String toPlainString()
```

Return Value

Type: String

Example

```
Decimal myDecimal = 12345.6789;
System.assertEquals('12345.6789', myDecimal.toPlainString());
```

valueOf(doubleToDecimal)

Returns a Decimal that contains the value of the specified Double.

Signature

```
public static Decimal valueOf(Double doubleToDecimal)
```

Parameters

doubleToDecimal
Type: Double

Return Value

Type: Decimal

Example

```
Double myDouble = 2.718281828459045;
Decimal myDecimal = Decimal.valueOf(myDouble);
System.assertEquals(2.718281828459045, myDecimal);
```

valueOf(longToDecimal)

Returns a Decimal that contains the value of the specified Long.

Signature

```
public static Decimal valueOf(Long longToDecimal)
```

Parameters

longToDecimal
Type: Long

Return Value

Type: Decimal

Example

```
Long myLong = 299792458;
Decimal myDecimal = Decimal.valueOf(myLong);
System.assertEquals(299792458, myDecimal);
```

valueOf(stringToDecimal)

Returns a Decimal that contains the value of the specified String. As in Java, the string is interpreted as representing a signed Decimal.

Signature

```
public static Decimal valueOf(String stringToDecimal)
```

Parameters

stringToDecimal
Type: String

Return Value

Type: Decimal

Example

```
String temp = '12.4567';
Decimal myDecimal = Decimal.valueOf(temp);
```

Double Class

Contains methods for the Double primitive data type.

Namespace

System

Usage

For more information on Double, see Primitive Data Types on page 26.

Double Methods

The following are methods for `Double`.

IN THIS SECTION:

format()
Returns the String value for this Double using the locale of the context user

intValue()
Returns the Integer value of this Double by casting it to an Integer.

longValue()
Returns the Long value of this Double.

round()
Returns the closest Long to this Double value.

valueOf(stringToDouble)
Returns a Double that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal.

valueOf(fieldValue)
Converts the specified object to a Double value. Use this method to convert a history tracking field value or an object that represents a Double value.

format()

Returns the String value for this Double using the locale of the context user

Signature

```
public String format()
```

Return Value

Type: String

Example

```
Double myDouble = 1261992;
system.assertEquals('1,261,992', myDouble.format());
```

intValue()

Returns the Integer value of this Double by casting it to an Integer.

Signature

```
public Integer intValue()
```

Return Value

Type: Integer

Example

```
Double DD1 = double.valueOf('3.14159');
Integer value = DD1.intValue();
system.assertEquals(value, 3);
```

longValue()

Returns the Long value of this Double.

Signature

```
public Long longValue()
```

Return Value

Type: Long

Example

```
Double myDouble = 421994;
Long value = myDouble.longValue();
System.assertEquals(421994, value);
```

round()

Returns the closest Long to this Double value.

Signature

```
public Long round()
```

Return Value

Type: Long

Example

```
Double D1 = 4.5;
Long L1 = D1.round();
System.assertEquals(5, L1);

Double D2= 4.2;
```

```
Long L2= D2.round();
System.assertEquals(4, L2);

Double D3= -4.7;
Long L3= D3.round();
System.assertEquals(-5, L3);
```

valueOf(stringToDouble)

Returns a Double that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal.

Signature

```
public static Double valueOf(String stringToDouble)
```

Parameters

stringToDouble
Type: String

Return Value

Type: Double

Example

```
Double DD1 = double.valueOf('3.14159');
```

valueOf(fieldValue)

Converts the specified object to a Double value. Use this method to convert a history tracking field value or an object that represents a Double value.

Signature

```
public static Double valueOf(Object fieldValue)
```

Parameters

fieldValue
Type: Object

Return Value

Type: Double

Usage

Use this method with the `OldValue` or `NewValue` fields of history sObjects, such as `AccountHistory`, when the field type corresponds to a Double type, like a number field.

Example

```
List<AccountHistory> ahlist =
  [SELECT Field,OldValue,NewValue
   FROM AccountHistory];
for(AccountHistory ah : ahlist) {
  System.debug('Field: ' + ah.Field);
  if (ah.field == 'NumberOfEmployees') {
    Double oldValue =
      Double.valueOf(ah.OldValue);
    Double newValue =
      Double.valueOf(ah.NewValue);
}
```

EncodingUtil Class

Use the methods in the `EncodingUtil` class to encode and decode URL strings, and convert strings to hexadecimal format.

Namespace

System

Usage

Note: You cannot use the EncodingUtil methods to move documents with non-ASCII characters to Salesforce. You can, however, download a document from Salesforce. To do so, query the ID of the document using the API `query` call, then request it by ID.

EncodingUtil Methods

The following are methods for `EncodingUtil`. All methods are static.

IN THIS SECTION:

base64Decode(inputString)

Converts a Base64-encoded String to a Blob representing its normal form.

base64Encode(inputBlob)

Converts a Blob to an unencoded String representing its normal form.

convertFromHex(inputString)

Converts the specified hexadecimal (base 16) string to a Blob value and returns this Blob value.

convertToHex(inputBlob)

Returns a hexadecimal (base 16) representation of the *`inputBlob`*. This method can be used to compute the client response (for example, HA1 or HA2) for HTTP Digest Authentication (RFC2617).

urlDecode(inputString, encodingScheme)

Decodes a string in `application/x-www-form-urlencoded` format using a specific encoding scheme, for example "UTF-8."

urlEncode(inputString, encodingScheme)

Encodes a string into the `application/x-www-form-urlencoded` format using a specific encoding scheme, for example "UTF-8."

base64Decode(inputString)

Converts a Base64-encoded String to a Blob representing its normal form.

Signature

```
public static Blob base64Decode(String inputString)
```

Parameters

inputString
Type: String

Return Value

Type: Blob

base64Encode(inputBlob)

Converts a Blob to an unencoded String representing its normal form.

Signature

```
public static String base64Encode(Blob inputBlob)
```

Parameters

inputBlob
Type: Blob

Return Value

Type: String

convertFromHex(inputString)

Converts the specified hexadecimal (base 16) string to a Blob value and returns this Blob value.

Signature

```
public static Blob convertFromHex(String inputString)
```

Parameters

inputString
Type: String

The hexadecimal string to convert. The string can contain only valid hexadecimal characters (0-9, a-f, A-F) and must have an even number of characters.

Return Value

Type: Blob

Usage

Each byte in the Blob is constructed from two hexadecimal characters in the input string.

The `convertFromHex` method throws the following exceptions.

- `NullPointerException` — the *`inputString`* is `null`.
- `InvalidParameterValueException` — the *`inputString`* contains invalid hexadecimal characters or doesn't contain an even number of characters.

Example

```
Blob blobValue = EncodingUtil.convertFromHex('4A4B4C');
System.assertEquals('JKL', blobValue.toString());
```

convertToHex(inputBlob)

Returns a hexadecimal (base 16) representation of the *`inputBlob`*. This method can be used to compute the client response (for example, HA1 or HA2) for HTTP Digest Authentication (RFC2617).

Signature

```
public static String convertToHex(Blob inputBlob)
```

Parameters

`inputBlob`
Type: Blob

Return Value

Type: String

urlDecode(inputString, encodingScheme)

Decodes a string in `application/x-www-form-urlencoded` format using a specific encoding scheme, for example "UTF-8."

Signature

```
public static String urlDecode(String inputString, String encodingScheme)
```

Parameters

`inputString`
Type: String

`encodingScheme`
Type: String

Return Value

Type: String

Usage

This method uses the supplied encoding scheme to determine which characters are represented by any consecutive sequence of the from `\"%xy\"`. For more information about the format, see The form-urlencoded Media Type in *Hypertext Markup Language - 2.0*.

`urlEncode(inputString, encodingScheme)`

Encodes a string into the `application/x-www-form-urlencoded` format using a specific encoding scheme, for example "UTF-8."

Signature

```
public static String urlEncode(String inputString, String encodingScheme)
```

Parameters

`inputString`
Type: String

`encodingScheme`
Type: String

Return Value

Type: String

Usage

This method uses the supplied encoding scheme to obtain the bytes for unsafe characters. For more information about the format, see The form-urlencoded Media Type in *Hypertext Markup Language - 2.0*.

Example

```
String encoded = EncodingUtil.urlEncode(url, 'UTF-8');
```

Enum Methods

An enum is an abstract data type with values that each take on exactly one of a finite set of identifiers that you specify. Apex provides built-in enums, such as `LoggingLevel`, and you can define your own enum.

All Apex enums, whether user-defined enums or built-in enums, have the following common method that takes no arguments.

`values`
This method returns the values of the Enum as a list of the same Enum type.

Each Enum value has the following methods that take no arguments.

`name`
Returns the name of the Enum item as a String.

ordinal
Returns the position of the item, as an Integer, in the list of Enum values starting with zero.

Enum values cannot have user-defined methods added to them.

For more information about Enum, see Enums on page 35.

Example

```
Integer i = StatusCode.DELETE_FAILED.ordinal();

String s = StatusCode.DELETE_FAILED.name();

List<StatusCode> values = StatusCode.values();
```

EventBus Class

Contains methods for publishing platform events.

Namespace

System

IN THIS SECTION:

EventBus Methods

SEE ALSO:

Platform Events Developer Guide: Publishing Platform Events

EventBus Methods

The following are methods for `EventBus`. All methods are static.

IN THIS SECTION:

publish(event)
Publishes the given platform event.

publish(events)
Publishes the given list of platform events.

publish(event)

Publishes the given platform event.

Signature

```
public static Database.SaveResult publish(SObject event)
```

Parameters

event
Type: SObject

An instance of a platform event. For example, an instance of *MyEvent__e*. You must first define your platform event object in your org.

Return Value

Type: Database.SaveResult

The result of publishing the given event. `Database.SaveResult` contains information about whether the operation was successful and the errors encountered. If the `isSuccess()` method returns `true`, the event was published for a standard-volume event. For a high-volume event, the publish request is queued in Salesforce and the event message might not be published immediately. For more information, see High-Volume Platform Event Persistence. If `isSuccess()` returns `false`, the event publish operation resulted in errors, which are returned in the `Database.Error` object. This method doesn't throw an exception due to an unsuccessful publish operation.

`Database.SaveResult` also contains the `Id` system field. The `Id` field value is not included in the event message delivered to subscribers. It is not used to identify an event message, and is not always unique.

Usage

Note:

- The event insertion occurs non-transactionally. As a result, you can't roll back published events.
- Apex governor limits apply, including DML limits. Each method execution is counted as one DML statement.

`publish(events)`

Publishes the given list of platform events.

Signature

```
public static List<Database.SaveResult> publish(List<SObject> events)
```

Parameters

events
Type: List<sObject>

A list of platform event instances. For example, a list of *MyEvent__e* objects. You must first define your platform event object in your org.

Return Value

Type: List<Database.SaveResult>

A list of results, each corresponding to the result of publishing one event. For each event, `Database.SaveResult` contains information about whether the operation was successful and the errors encountered. If the `isSuccess()` method returns `true`, the event was published for a standard-volume event. For a high-volume event, the publish request is queued in Salesforce and the event message might not be published immediately. For more information, see High-Volume Platform Event Persistence. If `isSuccess()` returns `false`, the event publish operation resulted in errors which are returned in the `Database.Error` object.

`EventBus.publish()` can publish some passed-in events, even when other events can't be published due to errors. The `EventBus.publish()` method doesn't throw exceptions caused by an unsuccessful publish operation. It is similar in behavior to the Apex `Database.insert` method when called with the partial success option.

`Database.SaveResult` also contains the `Id` system field. The `Id` field value is not included in the event message delivered to subscribers. It is not used to identify an event message, and is not always unique.

Usage

Note:

- The event insertion occurs non-transactionally. As a result, you can't roll back published events.
- Apex governor limits apply, including DML limits. Each method execution is counted as one DML statement.

Exception Class and Built-In Exceptions

An exception denotes an error that disrupts the normal flow of code execution. You can use Apex built-in exceptions or create custom exceptions. All exceptions have common methods.

All exceptions support built-in methods for returning the error message and exception type. In addition to the standard `exception` class, there are several different types of exceptions:

The following are exceptions in the `System` namespace.

Exception	Description
`AsyncException`	Any problem with an asynchronous operation, such as failing to enqueue an asynchronous call.
`CalloutException`	Any problem with a Web service operation, such as failing to make a callout to an external system.
`DmlException`	Any problem with a DML statement, such as an `insert` statement missing a required field on a record.
`EmailException`	Any problem with email, such as failure to deliver. For more information, see Outbound Email.
`ExternalObjectException`	Any problem with external object records, such as connection timeouts during attempts to access the data that's stored on external systems.
`InvalidParameterValueException`	An invalid parameter was supplied for a method or any problem with a URL used with Visualforce pages. For more information on Visualforce, see the *Visualforce Developer's Guide*.
`LimitException`	A governor limit has been exceeded. This exception can't be caught.
`JSONException`	Any problem with JSON serialization and deserialization operations. For more information, see the methods of `System.JSON`, `System.JSONParser`, and `System.JSONGenerator`.
`ListException`	Any problem with a list, such as attempting to access an index that is out of bounds.
`MathException`	Any problem with a mathematical operation, such as dividing by zero.

Exception	Description
`NoAccessException`	Any problem with unauthorized access, such as trying to access an sObject that the current user does not have access to. This is generally used with Visualforce pages. For more information on Visualforce, see the *Visualforce Developer's Guide*.
`NoDataFoundException`	Any problem with data that does not exist, such as trying to access an sObject that has been deleted. This is generally used with Visualforce pages. For more information on Visualforce, see the *Visualforce Developer's Guide*.
`NoSuchElementException`	This exception is thrown if you try to access items that are outside the bounds of a list. This exception is used by the Iterator `next` method. For example, if `iterator.hasNext() == false` and you call `iterator.next()`, this exception is thrown. This exception is also used by the Apex Flex Queue methods and is thrown if you attempt to access a job at an invalid position in the flex queue.

`NullPointerException`	Any problem with dereferencing null, such as in the following code:
	`String s;`
	`s.toLowerCase(); // Since s is null, this call causes`
	`// a NullPointerException`

`QueryException`	Any problem with SOQL queries, such as assigning a query that returns no records or more than one record to a singleton sObject variable.
`RequiredFeatureMissing`	A Chatter feature is required for code that has been deployed to an organization that does not have Chatter enabled.
`SearchException`	Any problem with SOSL queries executed with SOAP API `search()` call, for example, when the `searchString` parameter contains less than two characters. For more information, see the *SOAP API Developer Guide*.
`SecurityException`	Any problem with static methods in the Crypto utility class. For more information, see Crypto Class.
`SerializationException`	Any problem with the serialization of data. This is generally used with Visualforce pages. For more information on Visualforce, see the *Visualforce Developer's Guide*.
`SObjectException`	Any problem with sObject records, such as attempting to change a field in an `update` statement that can only be changed during `insert`.
`StringException`	Any problem with Strings, such as a String that is exceeding your heap size.
`TypeException`	Any problem with type conversions, such as attempting to convert the String 'a' to an Integer using the `valueOf` method.
`VisualforceException`	Any problem with a Visualforce page. For more information on Visualforce, see the *Visualforce Developer's Guide*.
`XmlException`	Any problem with the XmlStream classes, such as failing to read or write XML.

The following is an example using the DmlException exception:

```
Account[] accts = new Account[]{new Account(billingcity = 'San Jose')};
try {
    insert accts;
} catch (System.DmlException e) {
    for (Integer i = 0; i < e.getNumDml(); i++) {
        // Process exception here
        System.debug(e.getDmlMessage(i));
    }
}
```

For exceptions in other namespaces, see:

- Canvas Exceptions
- `ConnectApi` Exceptions
- DataSource Exceptions
- Reports Exceptions
- Site Exceptions

Common Exception Methods

Exception methods are all called by and operate on a particular instance of an exception. The table below describes all instance exception methods. All types of exceptions have the following methods in common:

Name	Arguments	Return Type	Description
`getCause`		Exception	Returns the cause of the exception as an exception object.
`getLineNumber`		Integer	Returns the line number from where the exception was thrown.
`getMessage`		String	Returns the error message that displays for the user.
`getStackTraceString`		String	Returns the stack trace as a string.
`getTypeName`		String	Returns the type of exception, such as DmlException, ListException, MathException, and so on.
`initCause`	Exception *`cause`*	Void	Sets the cause for this exception, if one has not already been set.
`setMessage`	String *`s`*	Void	Sets the error message that displays for the user.

DMLException and EmailException Methods

In addition to the common exception methods, DMLExceptions and EmailExceptions have the following additional methods:

Name	Arguments	Return Type	Description
`getDmlFieldNames`	Integer *`i`*	String []	Returns the names of the field or fields that caused the error described by the *`i`*th failed row.

Name	Arguments	Return Type	Description
`getDmlFields`	Integer *i*	Schema.sObjectField []	Returns the field token or tokens for the field or fields that caused the error described by the *i*th failed row. For more information on field tokens, see Dynamic Apex.
`getDmlId`	Integer *i*	String	Returns the ID of the failed record that caused the error described by the *i*th failed row.
`getDmlIndex`	Integer *i*	Integer	Returns the original row position of the *i*th failed row.
`getDmlMessage`	Integer *i*	String	Returns the user message for the *i*th failed row.
`getDmlStatusCode`	Integer *i*	String	Deprecated. Use getDmlType instead. Returns the Apex failure code for the *i*th failed row.
`getDmlType`	Integer *i*	System.StatusCode	Returns the value of the System.StatusCode enum. For example: `try { insert new Account(); } catch (System.DmlException ex) { System.assertEquals( StatusCode.REQUIRED_FIELD_MISSING, ex.getDmlType(0)); }` For more information about System.StatusCode, see Enums.
`getNumDml`		Integer	Returns the number of failed rows for DML exceptions.

FlexQueue Class

Contains methods that reorder batch jobs in the Apex flex queue.

Namespace

System

Usage

You can place up to 100 batch jobs in a holding status for future execution. When system resources become available, the jobs are taken from the top of the Apex flex queue and moved to the batch job queue. Up to five queued or active jobs can be processed simultaneously for each org. When a job is moved out of the flex queue for processing, its status changes from Holding to Queued. Queued jobs are executed when the system is ready to process new jobs.

Use this class's methods to reorder your `Holding` jobs in the flex queue.

Example

This example moves a job in the flex queue so that it is executed immediately before the specified job in the queue. Ensure that you have jobs in the flex queue before execution. To move the job, call the `System.FlexQueue.moveBeforeJob()` method and pass it both jobs' IDs.

```
ID jobToMoveId = System.enqueueJob(new MyQueueableClass());
AsyncApexJob a = [SELECT Id FROM AsyncApexJob WHERE ApexClassId IN
                    (SELECT Id from ApexClass WHERE NamespacePrefix = null
                     AND Name = 'MyBatchClass')];
ID jobInQueueId = a.ID;
Boolean isSuccess = FlexQueue.moveBeforeJob(jobToMoveId, jobInQueueId);
```

IN THIS SECTION:

FlexQueue Methods

SEE ALSO:

Monitoring the Apex Flex Queue

Using Batch Apex

FlexQueue Methods

The following are methods for `FlexQueue`.

IN THIS SECTION:

moveAfterJob(jobToMoveId, jobInQueueId)

Moves the job with the ID *`jobToMoveId`* immediately after the job with the ID *`jobInQueueId`* in the flex queue. You can move *`jobToMoveId`* forward or backward in the queue. If either job isn't in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if *`jobToMoveId`* is already immediately after *`jobInQueueId`*, so no change is made.

moveBeforeJob(jobToMoveId, jobInQueueId)

Moves the job with the ID *`jobToMoveId`* immediately before the job with the ID *`jobInQueueId`* in the flex queue. You can move *`jobToMoveId`* forward or backward in the queue. If either job isn't in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if *`jobToMoveId`* is already immediately before *`jobInQueueId`*, so no change is made.

moveJobToEnd(jobId)

Moves the specified job the end of the flex queue, to index position `(size - 1)`. All jobs after the job's starting position move one spot forward. If the job isn't in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if the job is already at the end of the queue, so no change is made.

moveJobToFront(jobId)

Moves the specified job to the front of the flex queue, to index position `0`. All other jobs move back one spot. If the job isn't in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if the job is already at the front of the queue, so no change is made.

moveAfterJob(jobToMoveId, jobInQueueId)

Moves the job with the ID *jobToMoveId* immediately after the job with the ID *jobInQueueId* in the flex queue. You can move *jobToMoveId* forward or backward in the queue. If either job isn't in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if *jobToMoveId* is already immediately after *jobInQueueId*, so no change is made.

Signature

```
public static Boolean moveAfterJob(Id jobToMoveId, Id jobInQueueId)
```

Parameters

jobToMoveId
Type: Id

The ID of the job to move.

jobInQueueId
Type: Id

The ID of the job to move after.

Return Value

Type: Boolean

moveBeforeJob(jobToMoveId, jobInQueueId)

Moves the job with the ID *jobToMoveId* immediately before the job with the ID *jobInQueueId* in the flex queue. You can move *jobToMoveId* forward or backward in the queue. If either job isn't in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if *jobToMoveId* is already immediately before *jobInQueueId*, so no change is made.

Signature

```
public static Boolean moveBeforeJob(Id jobToMoveId, Id jobInQueueId)
```

Parameters

jobToMoveId
Type: Id

The ID of the job to move.

jobInQueueId
Type: Id

The ID of the job to use as a reference point.

Return Value

Type: Boolean

`moveJobToEnd(jobId)`

Moves the specified job the end of the flex queue, to index position `(size - 1)`. All jobs after the job's starting position move one spot forward. If the job isn't in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if the job is already at the end of the queue, so no change is made.

Signature

```
public static Boolean moveJobToEnd(Id jobId)
```

Parameters

jobId
Type: Id

The ID of the job to move.

Return Value

Type: Boolean

`moveJobToFront(jobId)`

Moves the specified job to the front of the flex queue, to index position `0`. All other jobs move back one spot. If the job isn't in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if the job is already at the front of the queue, so no change is made.

Signature

```
public static Boolean moveJobToFront(Id jobId)
```

Parameters

jobId
Type: Id

The ID of the job to move.

Return Value

Type: Boolean

FeatureManagement Class

Use the methods in the `System.FeatureManagement` class to check and modify the values of feature parameters, and to show or hide custom objects and custom permissions in your subscribers' orgs.

Namespace

System

Usage

For information about feature parameters, see "Get Started with the Feature Management App" in the *ISVforce Guide*.

IN THIS SECTION:

FeatureManagement Methods

FeatureManagement Methods

The following are methods for `FeatureManagement`.

IN THIS SECTION:

changeProtection(apiName, typeApiName, protection)
Hides or reveals custom permissions, or reveals custom objects, in your subscriber's org.

checkPackageBooleanValue(apiName)
Checks the `value__c` value of the `FeatureParameterBoolean__c` record for a feature parameter in your subscriber's org. You set the record's value using `setPackageBooleanValue(apiName, value)`.

checkPackageDateValue(apiName)
Checks the `value__c` value of the `FeatureParameterDate__c` record for a feature parameter in your subscriber's org. You can set the record's value using `setPackageDateValue(apiName, value)`.

checkPackageIntegerValue(apiName)
Checks the `value__c` value of the `FeatureParameterInteger__c` record for a feature parameter in your subscriber's org. You can set the record's value using `setPackageIntegerValue(apiName, value)`.

checkPermission(apiName)
Checks whether a custom permission is enabled.

setPackageBooleanValue(apiName, value)
Sets the `value__c` value of the `FeatureParameterBoolean__c` record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using `checkPackageBooleanValue(apiName)`.

setPackageDateValue(apiName, value)
Sets the `value__c` value of the `FeatureParameterDate__c` record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using `checkPackageDateValue(apiName)`.

setPackageIntegerValue(apiName, value)
Sets the `value__c` value of the `FeatureParameterInteger__c` record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using `checkPackageIntegerValue(apiName)`.

`changeProtection(apiName, typeApiName, protection)`

Hides or reveals custom permissions, or reveals custom objects, in your subscriber's org.

Signature

```
public static void changeProtection(String apiName, String typeApiName, String
protection)
```

Parameters

apiName
Type: String

The API name of the custom object or custom permission to show or hide—for example, `'MyCustomObject__c'` or `'MyCustomPermission'`.

typeApiName
Type: String

The API name of the type that you want to show or hide: `'CustomObject'` or `'CustomPermission'`.

protection
Type: String

To show a custom object or custom permission, `'Unprotected'`.

To hide a custom permission, `'Protected'`.

Return Value

Type: void

Usage

Warning: For custom permissions, you can toggle the protected value indefinitely. However, after you've released unprotected objects to subscribers, you can't set visibility to `Protected`. Be sure to protect any custom objects that you want to hide before you release the first package version that contains them.

To hide custom permissions in released packages:

```
FeatureManagement.changeProtection('YourCustomPermissionName', 'CustomPermission',
    'Protected');
```

To unhide custom permissions and custom objects in released packages:

```
FeatureManagement.changeProtection('YourCustomPermissionName', 'CustomPermission',
    'Unprotected');
```

```
FeatureManagement.changeProtection('YourCustomObjectName__c', 'CustomObject',
    'Unprotected');
```

checkPackageBooleanValue(apiName)

Checks the `value__c` value of the `FeatureParameterBoolean__c` record for a feature parameter in your subscriber's org. You set the record's value using `setPackageBooleanValue(apiName, value)`.

Signature

```
public static Boolean checkPackageBooleanValue(String apiName)
```

Parameters

apiName
Type: String

The `fullName__c` value of the feature parameter whose value you want to check—for example, `'SpecialAccessAvailable'`.

Return Value

Type: Boolean

The value that's currently assigned to the `value__c` field on the `FeatureParameterBoolean__c` record that associates the feature parameter with its related license.

checkPackageDateValue(apiName)

Checks the `value__c` value of the `FeatureParameterDate__c` record for a feature parameter in your subscriber's org. You can set the record's value using `setPackageDateValue(apiName, value)`.

Signature

```
public static Date checkPackageDateValue(String apiName)
```

Parameters

apiName
Type: String

The `fullName__c` value of the feature parameter whose value you want to check—for example, `'TrialExpirationDate'`.

Return Value

Type: Date

The value that's currently assigned to the `value__c` field on the `FeatureParameterDate__c` record that associates the feature parameter with its related license.

checkPackageIntegerValue(apiName)

Checks the `value__c` value of the `FeatureParameterInteger__c` record for a feature parameter in your subscriber's org. You can set the record's value using `setPackageIntegerValue(apiName, value)`.

Signature

```
public static Integer checkPackageIntegerValue(String apiName)
```

Parameters

apiName
Type: String

The `fullName__c` value of the feature parameter whose value you want to check—for example, `'NumberOfLicenses'`.

Return Value

Type: Integer

The value that's currently assigned to the `value__c` field on the `FeatureParameterInteger__c` record that associates the feature parameter with its related license.

checkPermission(apiName)

Checks whether a custom permission is enabled.

Signature

```
public static Boolean checkPermission(String apiName)
```

Parameters

apiName
Type: String

The API name of the custom permission to check the value of—for example, `'MyCustomPermission'`.

Return Value

Type: Boolean

Shows whether the permission is enabled (`true`) or disabled (`false`).

setPackageBooleanValue(apiName, value)

Sets the `value__c` value of the `FeatureParameterBoolean__c` record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using `checkPackageBooleanValue(apiName)`.

Signature

```
public static void setPackageBooleanValue(String apiName, Boolean value)
```

Parameters

apiName
Type: String

The `fullName__c` value of the feature parameter whose value you want to set—for example, `'SpecialAccessAvailable'`.

value
Type: Boolean

The value to assign to the `value__c` field on the `FeatureParameterBoolean__c` record that associates the feature parameter with its related license.

Return Value

Type: void

`setPackageDateValue(apiName, value)`

Sets the `value__c` value of the `FeatureParameterDate__c` record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using `checkPackageDateValue(apiName)`.

Signature

```
public static void setPackageDateValue(String apiName, Date value)
```

Parameters

`apiName`
Type: String

The `fullName__c` value of the feature parameter whose value you want to set—for example, `'TrialExpirationDate'`.

`value`
Type: Date

The value to assign to the `value__c` field on the `FeatureParameterDate__c` record that associates the feature parameter with its related license.

Return Value

Type: void

`setPackageIntegerValue(apiName, value)`

Sets the `value__c` value of the `FeatureParameterInteger__c` record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using `checkPackageIntegerValue(apiName)`.

Signature

```
public static void setPackageIntegerValue(String apiName, Integer value)
```

Parameters

`apiName`
Type: String

The `fullName__c` value of the feature parameter whose value you want to set—for example, `'NumberOfLicenses'`.

`value`
Type: Integer

The value to assign to the `value__c` field on the `FeatureParameterInteger__c` record that associates the feature parameter with its related license.

Return Value

Type: void

Http Class

Use the `Http` class to initiate an HTTP request and response.

Namespace

System

Http Methods

The following are methods for `Http`. All are instance methods.

IN THIS SECTION:

send(request)
Sends an HttpRequest and returns the response.

toString()
Returns a string that displays and identifies the object's properties.

`send(request)`

Sends an HttpRequest and returns the response.

Signature

```
public HttpResponse send(HttpRequest request)
```

Parameters

`request`
Type: System.HttpRequest

Return Value

Type: System.HttpResponse

`toString()`

Returns a string that displays and identifies the object's properties.

Signature

```
public String toString()
```

Return Value

Type: String

HttpCalloutMock Interface

Enables sending fake responses when testing HTTP callouts.

Namespace

System

Usage

For an implementation example, see Testing HTTP Callouts by Implementing the `HttpCalloutMock` Interface.

HttpCalloutMock Methods

The following are methods for `HttpCalloutMock`.

IN THIS SECTION:

respond(request)
Returns an HTTP response for the given request. The implementation of this method is called by the Apex runtime to send a fake response when an HTTP callout is made after `Test.setMock` has been called.

`respond(request)`

Returns an HTTP response for the given request. The implementation of this method is called by the Apex runtime to send a fake response when an HTTP callout is made after `Test.setMock` has been called.

Signature

```
public HttpResponse respond(HttpRequest request)
```

Parameters

`request`
Type: System.HttpRequest

Return Value

Type: System.HttpResponse

HttpRequest Class

Use the `HttpRequest` class to programmatically create HTTP requests like GET, POST, PUT, and DELETE.

Namespace

System

Usage

Use the XML classes or JSON classes to parse XML or JSON content in the body of a request created by `HttpRequest`.

Example

The following example illustrates how you can use an authorization header with a request and handle the response.

```
public class AuthCallout {

   public void basicAuthCallout(){
```

```
    HttpRequest req = new HttpRequest();
    req.setEndpoint('http://www.yahoo.com');
    req.setMethod('GET');

    // Specify the required user name and password to access the endpoint
    // As well as the header and header information

    String username = 'myname';
    String password = 'mypwd';

    Blob headerValue = Blob.valueOf(username + ':' + password);
    String authorizationHeader = 'BASIC ' +
    EncodingUtil.base64Encode(headerValue);
    req.setHeader('Authorization', authorizationHeader);

    // Create a new http object to send the request object
    // A response object is generated as a result of the request

    Http http = new Http();
    HTTPResponse res = http.send(req);
    System.debug(res.getBody());
  }
}
```

Note: You can set the endpoint as a named credential URL. A named credential URL contains the scheme `callout:`, the name of the named credential, and an optional path. For example: `callout:My_Named_Credential/some_path`. A named credential specifies the URL of a callout endpoint and its required authentication parameters in one definition. Salesforce manages all authentication for Apex callouts that specify a named credential as the callout endpoint so that your code doesn't have to. See Named Credentials as Callout Endpoints on page 484.

Compression

To compress the data you send, use `setCompressed`.

```
HttpRequest req = new HttpRequest();
req.setEndPoint('my_endpoint');
req.setCompressed(true);
req.setBody('some post body');
```

If a response comes back in compressed format, `getBody` recognizes the format, uncompresses it, and returns the uncompressed value.

IN THIS SECTION:

HttpRequest Constructors

HttpRequest Methods

SEE ALSO:

JSON Support

XML Support

HttpRequest Constructors

The following are constructors for `HttpRequest`.

IN THIS SECTION:

HttpRequest()
Creates a new instance of the `HttpRequest` class.

`HttpRequest()`

Creates a new instance of the `HttpRequest` class.

Signature

```
public HttpRequest()
```

HttpRequest Methods

The following are methods for `HttpRequest`. All are instance methods.

IN THIS SECTION:

getBody()
Retrieves the body of this request.

getBodyAsBlob()
Retrieves the body of this request as a Blob.

getBodyDocument()
Retrieves the body of this request as a DOM document.

getCompressed()
If `true`, the request body is compressed, `false` otherwise.

getEndpoint()
Retrieves the URL for the endpoint of the external server for this request.

getHeader(key)
Retrieves the contents of the request header.

getMethod()
Returns the type of method used by `HttpRequest`.

setBody(body)
Sets the contents of the body for this request.

setBodyAsBlob(body)
Sets the contents of the body for this request using a Blob.

setBodyDocument(document)
Sets the contents of the body for this request. The contents represent a DOM document.

setClientCertificate(clientCert, password)
This method is deprecated. Use `setClientCertificateName` instead.

setClientCertificateName(certDevName)
If the external service requires a client certificate for authentication, set the certificate name.

setCompressed(flag)
If `true`, the data in the body is delivered to the endpoint in the gzip compressed format. If `false`, no compression format is used.

setEndpoint(endpoint)
Specifies the endpoint for this request.

setHeader(key, value)
Sets the contents of the request header.

setMethod(method)
Sets the type of method to be used for the HTTP request.

setTimeout(timeout)
Sets the timeout in milliseconds for the request.

toString()
Returns a string containing the URL for the endpoint of the external server for this request and the method used, for example, `Endpoint=http://YourServer, Method=POST`

getBody()

Retrieves the body of this request.

Signature

```
public String getBody()
```

Return Value

Type: String

getBodyAsBlob()

Retrieves the body of this request as a Blob.

Signature

```
public Blob getBodyAsBlob()
```

Return Value

Type: Blob

getBodyDocument()

Retrieves the body of this request as a DOM document.

Signature

```
public Dom.Document getBodyDocument()
```

Return Value

Type: Dom.Document

Example

Use this method as a shortcut for:

```
String xml = httpRequest.getBody();
Dom.Document domDoc = new Dom.Document(xml);
```

getCompressed()

If `true`, the request body is compressed, `false` otherwise.

Signature

```
public Boolean getCompressed()
```

Return Value

Type: Boolean

getEndpoint()

Retrieves the URL for the endpoint of the external server for this request.

Signature

```
public String getEndpoint()
```

Return Value

Type: String

getHeader(key)

Retrieves the contents of the request header.

Signature

```
public String getHeader(String key)
```

Parameters

key
Type: String

Return Value

Type: String

`getMethod()`

Returns the type of method used by `HttpRequest`.

Signature

```
public String getMethod()
```

Return Value

Type: String

Usage

Examples of return values:

- DELETE
- GET
- HEAD
- POST
- PUT
- TRACE

`setBody(body)`

Sets the contents of the body for this request.

Signature

```
public Void setBody(String body)
```

Parameters

body
Type: String

Return Value

Type: Void

Usage

Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.

The HTTP request and response sizes count towards the total heap size.

`setBodyAsBlob(body)`

Sets the contents of the body for this request using a Blob.

Signature

```
public Void setBodyAsBlob(Blob body)
```

Parameters

body
Type: Blob

Return Value

Type: Void

Usage

Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.

The HTTP request and response sizes count towards the total heap size.

setBodyDocument(document)

Sets the contents of the body for this request. The contents represent a DOM document.

Signature

```
public Void setBodyDocument(Dom.Document document)
```

Parameters

document
Type: Dom.Document

Return Value

Type: Void

Usage

Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.

setClientCertificate(clientCert, password)

This method is deprecated. Use `setClientCertificateName` instead.

Signature

```
public Void setClientCertificate(String clientCert, String password)
```

Parameters

clientCert
Type: String

password
Type: String

Return Value

Type: Void

Usage

If the server requires a client certificate for authentication, set the client certificate PKCS12 key store and password.

setClientCertificateName(certDevName)

If the external service requires a client certificate for authentication, set the certificate name.

Signature

```
public Void setClientCertificateName(String certDevName)
```

Parameters

certDevName
Type: String

Return Value

Type: Void

Usage

See Using Certificates with HTTP Requests.

setCompressed(flag)

If `true`, the data in the body is delivered to the endpoint in the gzip compressed format. If `false`, no compression format is used.

Signature

```
public Void setCompressed(Boolean flag)
```

Parameters

flag
Type: Boolean

Return Value

Type: Void

`setEndpoint(endpoint)`

Specifies the endpoint for this request.

Signature

```
public Void setEndpoint(String endpoint)
```

Parameters

`endpoint`
Type: String

Possible values for the endpoint:

- Endpoint URL

  ```
  https://my_endpoint.example.com/some_path
  ```

- Named credential URL, which contains the scheme `callout`, the name of the named credential, and, optionally, an appended path

  ```
  callout:My_Named_Credential/some_path
  ```

Return Value

Type: Void

SEE ALSO:

Named Credentials as Callout Endpoints

`setHeader(key, value)`

Sets the contents of the request header.

Signature

```
public Void setHeader(String key, String value)
```

Parameters

`key`
Type: String

`value`
Type: String

Return Value

Type: Void

Usage

Limit 100 KB.

`setMethod(method)`

Sets the type of method to be used for the HTTP request.

Signature

```
public Void setMethod(String method)
```

Parameters

`method`
Type: String

Possible values for the method type include:

- DELETE
- GET
- HEAD
- POST
- PUT
- TRACE

Return Value

Type: Void

Usage

You can also use this method to set any required options.

`setTimeout(timeout)`

Sets the timeout in milliseconds for the request.

Signature

```
public Void setTimeout(Integer timeout)
```

Parameters

`timeout`
Type: Integer

Return Value

Type: Void

Usage

The timeout can be any value between 1 and 120,000 milliseconds.

`toString()`

Returns a string containing the URL for the endpoint of the external server for this request and the method used, for example, `Endpoint=http://YourServer, Method=POST`

Signature

```
public String toString()
```

Return Value

Type: String

HttpResponse Class

Use the `HttpResponse` class to handle the HTTP response returned by the `Http` class.

Namespace

System

Usage

Use the XML classes or JSON Classes to parse XML or JSON content in the body of a response accessed by `HttpResponse`.

Example

In the following `getXmlStreamReader` example, content is retrieved from an external Web server, then the XML is parsed using the `XmlStreamReader` class.

```
public class ReaderFromCalloutSample {

  public void getAndParse() {

    // Get the XML document from the external server
    Http http = new Http();
    HttpRequest req = new HttpRequest();
    req.setEndpoint('https://docsample.herokuapp.com/xmlSample');
    req.setMethod('GET');
    HttpResponse res = http.send(req);

    // Log the XML content
    System.debug(res.getBody());

    // Generate the HTTP response as an XML stream
    XmlStreamReader reader = res.getXmlStreamReader();

    // Read through the XML
```

```
    while(reader.hasNext()) {
      System.debug('Event Type:' + reader.getEventType());
      if (reader.getEventType() == XmlTag.START_ELEMENT) {
        System.debug(reader.getLocalName());
      }
      reader.next();
    }

  }
}
```

SEE ALSO:

JSON Support

XML Support

HttpResponse Methods

The following are methods for `HttpResponse`. All are instance methods.

IN THIS SECTION:

getBody()

Retrieves the body returned in the response.

getBodyAsBlob()

Retrieves the body returned in the response as a Blob.

getBodyDocument()

Retrieves the body returned in the response as a DOM document.

getHeader(key)

Retrieves the contents of the response header.

getHeaderKeys()

Retrieves an array of header keys returned in the response.

getStatus()

Retrieves the status message returned for the response.

getStatusCode()

Retrieves the value of the status code returned in the response.

getXmlStreamReader()

Returns an `XmlStreamReader` that parses the body of the callout response.

setBody(body)

Specifies the body returned in the response.

setBodyAsBlob(body)

Specifies the body returned in the response using a Blob.

setHeader(key, value)

Specifies the contents of the response header.

setStatus(status)
Specifies the status message returned in the response.

setStatusCode(statusCode)
Specifies the value of the status code returned in the response.

toString()
Returns the status message and status code returned in the response, for example:

getBody()

Retrieves the body returned in the response.

Signature

```
public String getBody()
```

Return Value

Type: String

Usage

Limit 6 MB for synchronous Apex or 12 MB for asynchronous Apex. The HTTP request and response sizes count towards the total heap size.

getBodyAsBlob()

Retrieves the body returned in the response as a Blob.

Signature

```
public Blob getBodyAsBlob()
```

Return Value

Type: Blob

Usage

Limit 6 MB for synchronous Apex or 12 MB for asynchronous Apex. The HTTP request and response sizes count towards the total heap size.

getBodyDocument()

Retrieves the body returned in the response as a DOM document.

Signature

```
public Dom.Document getBodyDocument()
```

Return Value

Type: `Dom.Document`

Example

Use it as a shortcut for:

```
String xml = httpResponse.getBody();
Dom.Document domDoc = new Dom.Document(xml);
```

getHeader(key)

Retrieves the contents of the response header.

Signature

```
public String getHeader(String key)
```

Parameters

key
Type: String

Return Value

Type: String

getHeaderKeys()

Retrieves an array of header keys returned in the response.

Signature

```
public String[] getHeaderKeys()
```

Return Value

Type: String[]

getStatus()

Retrieves the status message returned for the response.

Signature

```
public String getStatus()
```

Return Value

Type: String

getStatusCode()

Retrieves the value of the status code returned in the response.

Signature

```
public Integer getStatusCode()
```

Return Value

Type: Integer

getXmlStreamReader()

Returns an `XmlStreamReader` that parses the body of the callout response.

Signature

```
public XmlStreamReader getXmlStreamReader()
```

Return Value

Type: System.XmlStreamReader

Usage

Use it as a shortcut for:

```
String xml = httpResponse.getBody();
XmlStreamReader xsr = new XmlStreamReader(xml);
```

setBody(body)

Specifies the body returned in the response.

Signature

```
public Void setBody(String body)
```

Parameters

body
Type: String

Return Value

Type: Void

setBodyAsBlob(body)

Specifies the body returned in the response using a Blob.

Signature

```
public Void setBodyAsBlob(Blob body)
```

Parameters

body
Type: Blob

Return Value

Type: Void

setHeader(key, value)

Specifies the contents of the response header.

Signature

```
public Void setHeader(String key, String value)
```

Parameters

key
Type: String

value
Type: String

Return Value

Type: Void

setStatus(status)

Specifies the status message returned in the response.

Signature

```
public Void setStatus(String status)
```

Parameters

status
Type: String

Return Value

Type: Void

`setStatusCode(statusCode)`

Specifies the value of the status code returned in the response.

Signature

```
public Void setStatusCode(Integer statusCode)
```

Parameters

statusCode
Type: Integer

Return Value

Type: Void

`toString()`

Returns the status message and status code returned in the response, for example:

Signature

```
public String toString()
```

Return Value

Type: String

Example

```
Status=OK, StatusCode=200
```

Id Class

Contains methods for the ID primitive data type.

Namespace

System

Example: Getting an sObject Token From an ID

This sample shows how to use the `getSObjectType` method to obtain an sObject token from an ID. The `updateOwner` method in this sample accepts a list of IDs of the sObjects to update the ownerId field of. This list contains IDs of sObjects of the same type. The second parameter is the new owner ID. Note that since it is a future method, it doesn't accept sObject types as parameters; this is why it accepts IDs of sObjects. This method gets the sObject token from the first ID in the list, then does a describe to obtain the object name and constructs a query dynamicallly. It then queries for all sObjects and updates their owner ID fields to the new owner ID.

```
public class MyDynamicSolution {
    @future
```

```
    public static void updateOwner(List<ID> objIds, ID newOwnerId) {
        // Validate input
        System.assert(objIds != null);
        System.assert(objIds.size() > 0);
        System.assert(newOwnerId != null);

        // Get the sObject token from the first ID
        // (the List contains IDs of sObjects of the same type).
        Schema.SObjectType token = objIds[0].getSObjectType();

        // Using the token, do a describe
        // and construct a query dynamically.
        Schema.DescribeSObjectResult dr = token.getDescribe();
        String queryString = 'SELECT ownerId FROM ' + dr.getName() +
            ' WHERE ';
        for(ID objId : objIds) {
            queryString += 'Id=\'' + objId + '\' OR ';
        }
        // Remove the last ' OR'
        queryString = queryString.subString(0, queryString.length() - 4);

        sObject[] objDBList = Database.query(queryString);
        System.assert(objDBList.size() > 0);

        // Update the owner ID on the sObjects
        for(Integer i=0;i<objDBList.size();i++) {
            objDBList[i].put('ownerId', newOwnerId);
        }
        Database.SaveResult[] srList = Database.update(objDBList, false);
        for(Database.SaveResult sr : srList) {
            if (sr.isSuccess()) {
                System.debug('Updated owner ID successfully for ' +
                    dr.getName() + ' ID ' + sr.getId());
            }
            else {
              System.debug('Updating ' + dr.getName() + ' returned the following errors.');

                for(Database.Error e : sr.getErrors()) {
                    System.debug(e.getMessage());
                }
            }
        }
    }
}
```

Id Methods

The following are methods for `Id`.

IN THIS SECTION:

addError(errorMsg)

Marks a trigger record with a custom error message and prevents any DML operation from occurring.

addError(errorMsg, escape)

Marks a trigger record with a custom error message, specifies whether or not the error message should be escaped, and prevents any DML operation from occurring.

addError(exceptionError)

Marks a trigger record with a custom error message and prevents any DML operation from occurring.

addError(exceptionError, escape)

Marks a trigger record with a custom error message and prevents any DML operation from occurring.

getSObjectType()

Returns the token for the sObject corresponding to this ID. This method is primarily used with describe information.

valueOf(toID)

Converts the specified String into an ID and returns the ID.

addError(errorMsg)

Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature

```
public Void addError(String errorMsg)
```

Parameters

errorMsg

Type: String

The error message to mark the record with.

Return Value

Type: Void

Usage

This method is similar to the `addError(errorMsg)` sObject method.

Note: This method escapes any HTML markup in the specified error message. The escaped characters are: `\n`, `<`, `>`, `&`, `"`, `\`, `\u2028`, `\u2029`, and `\u00a9`. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

Example

```
Trigger.new[0].Id.addError('bad');
```

addError(errorMsg, escape)

Marks a trigger record with a custom error message, specifies whether or not the error message should be escaped, and prevents any DML operation from occurring.

Signature

```
public Void addError(String errorMsg, Boolean escape)
```

Parameters

errorMsg
Type: String

The error message to mark the record with.

escape
Type: Boolean

Indicates whether any HTML markup in the custom error message should be escaped (`true`) or not (`false`). This parameter is ignored in Lightning Experience and the Salesforce app and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value

Type: Void

Usage

The escaped characters are: `\n`, `<`, `>`, `&`, `"`, `\`, `\u2028`, `\u2029`, and `\u00a9`. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

Warning: Be cautious if you specify `false` for the *escape* argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false` *escape* argument and make sure you escape any dynamic content, such as input field values. Otherwise, specify `true` for the *escape* argument or call `addError(String errorMsg)` instead.

Example

```
Trigger.new[0].Id.addError('Fix & resubmit', false);
```

addError(exceptionError)

Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature

```
public Void addError(Exception exceptionError)
```

Parameters

exceptionError
Type: System.Exception

An Exception object or a custom exception object that contains the error message to mark the record with.

Return Value

Type: Void

Usage

This method is similar to the `addError(exceptionError)` sObject method.

Note: This method escapes any HTML markup in the specified error message. The escaped characters are: `\n`, `<`, `>`, `&`, `"`, `\`, `\u2028`, `\u2029`, and `\u00a9`. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

Example

```
public class MyException extends Exception{}

Trigger.new[0].Id.addError(new myException('Invalid Id'));
```

addError(exceptionError, escape)

Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature

```
public Void addError(Exception exceptionError, Boolean escape)
```

Parameters

exceptionError
Type: System.Exception

An Exception object or a custom exception object that contains the error message to mark the record with.

escape
Type: Boolean

Indicates whether any HTML markup in the custom error message should be escaped (`true`) or not (`false`). This parameter is ignored in Lightning Experience and the Salesforce app and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value

Type: Void

Usage

The escaped characters are: `\n`, `<`, `>`, `&`, `"`, `\`, `\u2028`, `\u2029`, and `\u00a9`. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

Warning: Be cautious if you specify `false` for the *escape* argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false` *escape* argument and make sure you escape any dynamic

content, such as input field values. Otherwise, specify `true` for the *`escape`* argument or call `addError(Exception e)` instead.

Example

```
public class MyException extends Exception{}

account a = new account();
a.addError(new MyException('Invalid Id & other issues'), false);
```

getSObjectType()

Returns the token for the sObject corresponding to this ID. This method is primarily used with describe information.

Signature

```
public Schema.SObjectType getSObjectType()
```

Return Value

Type: Schema.SObjectType

Usage

For more information about describes, see Understanding Apex Describe Information.

Example

```
account a = new account(name = 'account');
insert a;
Id myId = a.id;
system.assertEquals(Schema.Account.SObjectType, myId.getSobjectType());
```

valueOf(toID)

Converts the specified String into an ID and returns the ID.

Signature

```
public static ID valueOf(String toID)
```

Parameters

`toID`
Type: String

Return Value

Type: ID

Example

```
Id myId = Id.valueOf('001xa000003DIlo');
```

Ideas Class

Represents zone ideas.

Namespace

System

Usage

Ideas is a community of users who post, vote for, and comment on ideas. An Ideas community provides an online, transparent way for you to attract, manage, and showcase innovation.

A set of *recent replies* (returned by methods, see below) includes ideas that a user has posted or commented on that already have comments posted by another user. The returned ideas are listed based on the time of the last comment made by another user, with the most recent ideas appearing first.

The *userID* argument is a required argument that filters the results so only the ideas that the specified user has posted or commented on are returned.

The *communityID* argument filters the results so only the ideas within the specified zone are returned. If this argument is the empty string, then all recent replies for the specified user are returned regardless of the zone.

For more information on ideas, see "Using Ideas" in the Salesforce online help.

Example

The following example finds ideas in a specific zone that have similar titles as a new idea:

```
public class FindSimilarIdeasController {

   public static void test() {
      // Instantiate a new idea
      Idea idea = new Idea ();

      // Specify a title for the new idea
      idea.Title = 'Increase Vacation Time for Employees';

      // Specify the communityID (INTERNAL_IDEAS) in which to find similar ideas.
      Community community = [ SELECT Id FROM Community WHERE Name = 'INTERNAL_IDEAS' ];

      idea.CommunityId = community.Id;

      ID[] results = Ideas.findSimilar(idea);
   }
}
```

The following example uses a Visualforce page in conjunction with a *custom controller*, that is, a special Apex class. For more information on Visualforce, see the *Visualforce Developer's Guide*.

This example creates an Apex method in the controller that returns unread recent replies. You can leverage this same example for the `getAllRecentReplies` and `getReadRecentReplies` methods. For this example to work, there must be ideas posted to the zone. In addition, at least one zone member must have posted a comment to another zone member's idea or comment.

```
// Create an Apex method to retrieve the recent replies marked as unread in all communities
public class IdeasController {

   public Idea[] getUnreadRecentReplies() {
        Idea[] recentReplies;
        if (recentReplies == null) {
           Id[] recentRepliesIds = Ideas.getUnreadRecentReplies(UserInfo.getUserId(), '');

            recentReplies = [SELECT Id, Title FROM Idea WHERE Id IN :recentRepliesIds];
        }
        return recentReplies;

  }

}
```

The following is the markup for a Visualforce page that uses the above custom controller to list unread recent replies.

```
<apex:page controller="IdeasController" showHeader="false">
    <apex:dataList value="{!unreadRecentReplies}" var="recentReplyIdea">
           <a href="/apex/viewIdea?id={!recentReplyIdea.Id}">
                 <apex:outputText value="{!recentReplyIdea.Title}" escape="true"/></a>
     </apex:dataList>
</apex:page>
```

The following example uses a Visualforce page in conjunction with a custom controller to list ideas. Then, a second Visualforce page and custom controller is used to display a specific idea and mark it as read. For this example to work, there must be ideas posted to the zone.

```
// Create a controller to use on a VisualForce page to list ideas
public class IdeaListController {

    public final Idea[] ideas {get; private set;}

    public IdeaListController() {
        Integer i = 0;
        ideas = new Idea[10];
        for (Idea tmp : Database.query
('SELECT Id, Title FROM Idea WHERE Id != null AND parentIdeaId = null LIMIT 10')) {
            i++;
            ideas.add(tmp);
        }
    }
}
```

The following is the markup for a Visualforce page that uses the above custom controller to list ideas:

```
<apex:page controller="IdeaListController" tabStyle="Idea" showHeader="false">
```

```
        <apex:dataList value="{!ideas}" var="idea" id="ideaList">
            <a href="/apex/viewIdea?id={!idea.id}">
<apex:outputText value="{!idea.title}" escape="true"/></a>
        </apex:dataList>

</apex:page>
```

The following example also uses a Visualforce page and custom controller, this time, to display the idea that is selected on the above idea list page. In this example, the `markRead` method marks the selected idea and associated comments as read by the user that is currently logged in. Note that the `markRead` method is in the constructor so that the idea is marked read immediately when the user goes to a page that uses this controller. For this example to work, there must be ideas posted to the zone. In addition, at least one zone member must have posted a comment to another zone member's idea or comment.

```
// Create an Apex method in the controller that marks all comments as read for the
// selected idea
public class ViewIdeaController {

   private final String id = System.currentPage().getParameters().get('id');

   public ViewIdeaController(ApexPages.StandardController controller) {
               Ideas.markRead(id);
   }

}
```

The following is the markup for a Visualforce page that uses the above custom controller to display the idea as read.

```
<apex:page standardController="Idea" extensions="ViewIdeaController" showHeader="false">

     <h2><apex:outputText value="{!idea.title}" /></h2>
     <apex:outputText value="{!idea.body}" />

</apex:page>
```

Ideas Methods

The following are methods for `Ideas`. All methods are static.

IN THIS SECTION:

findSimilar(idea)

Returns a list of similar ideas based on the title of the specified idea.

getAllRecentReplies(userID, communityID)

Returns ideas that have recent replies for the specified user or zone. This includes all read and unread replies.

getReadRecentReplies(userID, communityID)

Returns ideas that have recent replies marked as read.

getUnreadRecentReplies(userID, communityID)

Returns ideas that have recent replies marked as unread.

markRead(ideaID)

Marks all comments as read for the user that is currently logged in.

findSimilar(idea)

Returns a list of similar ideas based on the title of the specified idea.

Signature

```
public static ID[] findSimilar(Idea idea)
```

Parameters

idea
Type: Idea

Return Value

Type: ID[]

Usage

Each `findSimilar` call counts against the SOSL query limits. See Execution Governors and Limits.

getAllRecentReplies(userID, communityID)

Returns ideas that have recent replies for the specified user or zone. This includes all read and unread replies.

Signature

```
public static ID[] getAllRecentReplies(String userID, String communityID)
```

Parameters

userID
Type: String

communityID
Type: String

Return Value

Type: ID[]

Usage

Each `getAllRecentReplies` call counts against the SOQL query limits. See Execution Governors and Limits.

getReadRecentReplies(userID, communityID)

Returns ideas that have recent replies marked as read.

Signature

```
public static ID[] getReadRecentReplies(String userID, String communityID)
```

Parameters

userID
Type: String

communityID
Type: String

Return Value

Type: ID[]

Usage

Each `getReadRecentReplies` call counts against the SOQL query limits. See Execution Governors and Limits.

`getUnreadRecentReplies(userID, communityID)`

Returns ideas that have recent replies marked as unread.

Signature

```
public static ID[] getUnreadRecentReplies(String userID, String communityID)
```

Parameters

userID
Type: String

communityID
Type: String

Return Value

Type: ID[]

Usage

Each `getUnreadRecentReplies` call counts against the SOQL query limits. See Execution Governors and Limits.

`markRead(ideaID)`

Marks all comments as read for the user that is currently logged in.

Signature

```
public static Void markRead(String ideaID)
```

Parameters

ideaID
Type: String

Return Value

Type: Void

InstallHandler Interface

Enables custom code to run after a managed package installation or upgrade.

Namespace

System

Usage

App developers can implement this interface to specify Apex code that runs automatically after a subscriber installs or upgrades a managed package. This makes it possible to customize the package install or upgrade, based on details of the subscriber's organization. For instance, you can use the script to populate custom settings, create sample data, send an email to the installer, notify an external system, or kick off a batch operation to populate a new field across a large set of data.

The post install script is invoked after tests have been run, and is subject to default governor limits. It runs as a special system user that represents your package, so all operations performed by the script appear to be done by your package. You can access this user by using UserInfo. You will only see this user at runtime, not while running tests.

If the script fails, the install/upgrade is aborted. Any errors in the script are emailed to the user specified in the **Notify on Apex Error** field of the package. If no user is specified, the install/upgrade details will be unavailable.

The post install script has the following additional properties.

- It can initiate batch, scheduled, and future jobs.
- It can't access Session IDs.
- It can only perform callouts using an async operation. The callout occurs after the script is run and the install is complete and committed.
- It can't call another Apex class in the package if that Apex class uses the `with sharing` keyword. This keyword can prevent the package from successfully installing. See the *Apex Developer Guide* to learn more.

The `InstallHandler` interface has a single method called `onInstall`, which specifies the actions to be performed on install/upgrade.

```
global interface InstallHandler {
  void onInstall(InstallContext context)
};
```

The `onInstall` method takes a context object as its argument, which provides the following information.

- The org ID of the organization in which the installation takes place.
- The user ID of the user who initiated the installation.
- The version number of the previously installed package (specified using the `Version` class). This is always a three-part number, such as 1.2.0.
- Whether the installation is an upgrade.
- Whether the installation is a push.

The context argument is an object whose type is the `InstallContext` interface. This interface is automatically implemented by the system. The following definition of the `InstallContext` interface shows the methods you can call on the context argument.

```
global interface InstallContext {
  ID organizationId();
  ID installerId();
  Boolean isUpgrade();
  Boolean isPush();
  Version previousVersion();
}
```

IN THIS SECTION:

InstallHandler Methods

InstallHandler Example Implementation

InstallHandler Methods

The following are methods for `InstallHandler`.

IN THIS SECTION:

onInstall(context)
Specifies the actions to be performed on install/upgrade.

`onInstall(context)`

Specifies the actions to be performed on install/upgrade.

Signature

```
public Void onInstall(InstallContext context)
```

Parameters

`context`
Type: System.InstallContext

Return Value

Type: Void

InstallHandler Example Implementation

The following sample post install script performs these actions on package install/upgrade.

- If the previous version is null, that is, the package is being installed for the first time, the script:
  - Creates a new Account called "Newco" and verifies that it was created.
  - Creates a new instance of the custom object Survey, called "Client Satisfaction Survey".
  - Sends an email message to the subscriber confirming installation of the package.

- If the previous version is 1.0, the script creates a new instance of Survey called “Upgrading from Version 1.0”.
- If the package is an upgrade, the script creates a new instance of Survey called “Sample Survey during Upgrade”.
- If the upgrade is being pushed, the script creates a new instance of Survey called “Sample Survey during Push”.

```
global class PostInstallClass implements InstallHandler {
  global void onInstall(InstallContext context) {
    if(context.previousVersion() == null) {
      Account a = new Account(name='Newco');
      insert(a);

      Survey__c obj = new Survey__c(name='Client Satisfaction Survey');
      insert obj;

      User u = [Select Id, Email from User where Id =:context.installerID()];
      String toAddress= u.Email;
      String[] toAddresses = new String[]{toAddress};
      Messaging.SingleEmailMessage mail =
        new Messaging.SingleEmailMessage();
      mail.setToAddresses(toAddresses);
      mail.setReplyTo('support@package.dev');
      mail.setSenderDisplayName('My Package Support');
      mail.setSubject('Package install successful');
      mail.setPlainTextBody('Thanks for installing the package.');
      Messaging.sendEmail(new Messaging.Email[] { mail });
      }
    else
      if(context.previousVersion().compareTo(new Version(1,0)) == 0) {
      Survey__c obj = new Survey__c(name='Upgrading from Version 1.0');
      insert(obj);
      }
    if(context.isUpgrade()) {
      Survey__c obj = new Survey__c(name='Sample Survey during Upgrade');
      insert obj;
      }
    if(context.isPush()) {
      Survey__c obj = new Survey__c(name='Sample Survey during Push');
      insert obj;
      }
    }
  }
```

You can test a post install script using the new `testInstall` method of the `Test` class. This method takes the following arguments.

- A class that implements the `InstallHandler` interface.
- A `Version` object that specifies the version number of the existing package.
- An optional Boolean value that is `true` if the installation is a push. The default is `false`.

This sample shows how to test a post install script implemented in the `PostInstallClass` Apex class.

```
@isTest
static void testInstallScript() {
  PostInstallClass postinstall = new PostInstallClass();
    Test.testInstall(postinstall, null);
    Test.testInstall(postinstall, new Version(1,0), true);
    List<Account> a = [Select id, name from Account where name ='Newco'];
```

```
    System.assertEquals(a.size(), 1, 'Account not found');
  }
```

Integer Class

Contains methods for the Integer primitive data type.

Namespace

System

Usage

For more information on integers, see Primitive Data Types on page 26.

Integer Methods

The following are methods for `Integer`.

IN THIS SECTION:

format()
Returns the integer as a string using the locale of the context user.

valueOf(stringToInteger)
Returns an Integer that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal integer.

valueOf(fieldValue)
Converts the specified object to an Integer. Use this method to convert a history tracking field value or an object that represents an Integer value.

`format()`

Returns the integer as a string using the locale of the context user.

Signature

```
public String format()
```

Return Value

Type: String

Example

```
integer myInt = 22;
system.assertEquals('22', myInt.format());
```

valueOf(stringToInteger)

Returns an Integer that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal integer.

Signature

```
public static Integer valueOf(String stringToInteger)
```

Parameters

stringToInteger
Type: String

Return Value

Type: Integer

Example

```
Integer myInt = Integer.valueOf('123');
```

valueOf(fieldValue)

Converts the specified object to an Integer. Use this method to convert a history tracking field value or an object that represents an Integer value.

Signature

```
public static Integer valueOf(Object fieldValue)
```

Parameters

fieldValue
Type: Object

Return Value

Type: Integer

Usage

Use this method with the `OldValue` or `NewValue` fields of history sObjects, such as `AccountHistory`, when the field type corresponds to an Integer type, like a number field.

Example:

Example

```
List<AccountHistory> ahlist =
  [SELECT Field,OldValue,NewValue
   FROM AccountHistory];
```

```
for(AccountHistory ah : ahlist) {
  System.debug('Field: ' + ah.Field);
  if (ah.field == 'NumberOfEmployees') {
    Integer oldValue =
      Integer.valueOf(ah.OldValue);
    Integer newValue =
      Integer.valueOf(ah.NewValue);
}
```

JSON Class

Contains methods for serializing Apex objects into JSON format and deserializing JSON content that was serialized using the `serialize` method in this class.

Namespace

System

Usage

Use the methods in the `System.JSON` class to perform round-trip JSON serialization and deserialization of Apex objects.

SEE ALSO:

Roundtrip Serialization and Deserialization

JSON Methods

The following are methods for `JSON`. All methods are static.

IN THIS SECTION:

createGenerator(prettyPrint)

Returns a new JSON generator.

createParser(jsonString)

Returns a new JSON parser.

deserialize(jsonString, apexType)

Deserializes the specified JSON string into an Apex object of the specified type.

deserializeStrict(jsonString, apexType)

Deserializes the specified JSON string into an Apex object of the specified type.

deserializeUntyped(jsonString)

Deserializes the specified JSON string into collections of primitive data types.

serialize(objectToSerialize)

Serializes Apex objects into JSON content.

serialize(objectToSerialize, suppressApexObjectNulls)

Suppresses `null` values when serializing Apex objects into JSON content.

serializePretty(objectToSerialize)

Serializes Apex objects into JSON content and generates indented content using the pretty-print format.

serializePretty(objectToSerialize, suppressApexObjectNulls)

Suppresses `null` values when serializing Apex objects into JSON content and generates indented content using the pretty-print format.

createGenerator(prettyPrint)

Returns a new JSON generator.

Signature

```
public static System.JSONGenerator createGenerator(Boolean prettyPrint)
```

Parameters

prettyPrint

Type: Boolean

Determines whether the JSON generator creates JSON content in pretty-print format with the content indented. Set to `true` to create indented content.

Return Value

Type: System.JSONGenerator

createParser(jsonString)

Returns a new JSON parser.

Signature

```
public static System.JSONParser createParser(String jsonString)
```

Parameters

jsonString

Type: String

The JSON content to parse.

Return Value

Type: System.JSONParser

deserialize(jsonString, apexType)

Deserializes the specified JSON string into an Apex object of the specified type.

Signature

```
public static Object deserialize(String jsonString, System.Type apexType)
```

Parameters

jsonString
Type: String

The JSON content to deserialize.

apexType
Type: System.Type

The Apex type of the object that this method creates after deserializing the JSON content.

Return Value

Type: Object

Usage

If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content into a custom object or an sObject using Salesforce API version 34.0 or earlier, this method throws a runtime exception when passed extraneous attributes. When deserializing JSON content into an Apex class in any API version, or into an object in API version 35.0 or later, no exception is thrown. When no exception is thrown, this method ignores extraneous attributes and parses the rest of the JSON content.

Example

The following example deserializes a `Decimal` value.

```
Decimal n = (Decimal)JSON.deserialize(
               '100.1', Decimal.class);
System.assertEquals(n, 100.1);
```

deserializeStrict(jsonString, apexType)

Deserializes the specified JSON string into an Apex object of the specified type.

Signature

```
public static Object deserializeStrict(String jsonString, System.Type apexType)
```

Parameters

jsonString
Type: String

The JSON content to deserialize.

apexType
Type: System.Type

The Apex type of the object that this method creates after deserializing the JSON content.

Return Value

Type: Object

Usage

All attributes in the JSON string must be present in the specified type. If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content with extraneous attributes into an Apex class, this method throws an exception in all API versions. However, no exception is thrown when you use this method to deserialize JSON content into a custom object or an sObject.

Example

The following example deserializes a JSON string into an object of a user-defined type represented by the `Car` class, which this example also defines.

```
public class Car {
    public String make;
    public String year;
}

public void parse() {
    Car c = (Car)JSON.deserializeStrict(
        '{"make":"SFDC","year":"2020"}',
        Car.class);
    System.assertEquals(c.make, 'SFDC');
    System.assertEquals(c.year, '2020');
}
```

deserializeUntyped(jsonString)

Deserializes the specified JSON string into collections of primitive data types.

Signature

```
public static Object deserializeUntyped(String jsonString)
```

Parameters

jsonString
Type: String

The JSON content to deserialize.

Return Value

Type: Object

Example

The following example deserializes a JSON representation of an appliance object into a map that contains primitive data types and further collections of primitive types. It then verifies the deserialized values.

```
String jsonInput = '{\n' +
    ' "description" :"An appliance",\n' +
    ' "accessories" : [ "powerCord", ' +
      '{ "right":"door handle1", ' +
```

```
        '"left":"door handle2" } ],\n' +
    ' "dimensions" : ' +
      '{ "height" : 5.5 , ' +
        '"width" : 3.0 , ' +
        '"depth" : 2.2 },\n' +
    ' "type" : null,\n' +
    ' "inventory" : 2000,\n' +
    ' "price" : 1023.45,\n' +
    ' "isShipped" : true,\n' +
    ' "modelNumber" : "123"\n' +
    '}';

Map<String, Object> m =
   (Map<String, Object>)
      JSON.deserializeUntyped(jsonInput);

System.assertEquals(
   'An appliance', m.get('description'));

List<Object> a =
   (List<Object>)m.get('accessories');
System.assertEquals('powerCord', a[0]);
Map<String, Object> a2 =
   (Map<String, Object>)a[1];
System.assertEquals(
   'door handle1', a2.get('right'));
System.assertEquals(
   'door handle2', a2.get('left'));

Map<String, Object> dim =
   (Map<String, Object>)m.get('dimensions');
System.assertEquals(
   5.5, dim.get('height'));
System.assertEquals(
   3.0, dim.get('width'));
System.assertEquals(
   2.2, dim.get('depth'));

System.assertEquals(null, m.get('type'));
System.assertEquals(
   2000, m.get('inventory'));
System.assertEquals(
   1023.45, m.get('price'));
System.assertEquals(
   true, m.get('isShipped'));
System.assertEquals(
   '123', m.get('modelNumber'));
```

serialize(objectToSerialize)

Serializes Apex objects into JSON content.

Signature

```
public static String serialize(Object objectToSerialize)
```

Parameters

objectToSerialize
Type: Object

The Apex object to serialize.

Return Value

Type: String

Example

The following example serializes a new `Datetime` value.

```
Datetime dt = Datetime.newInstance(
                Date.newInstance(
                   2011, 3, 22),
                Time.newInstance(
                   1, 15, 18, 0));
    String str = JSON.serialize(dt);
    System.assertEquals(
       '"2011-03-22T08:15:18.000Z"',
       str);
```

serialize(objectToSerialize, suppressApexObjectNulls)

Suppresses `null` values when serializing Apex objects into JSON content.

Signature

```
public static String serialize(Object objectToSerialize, Boolean suppressApexObjectNulls)
```

Parameters

objectToSerialize
Type: Object

The Apex object to serialize.

suppressApexObjectNulls
Type: Boolean

If true, remove `null` values before serializing the JSON object.

Return Value

Type: String

Usage

This method allows you to specify whether to suppress `null` values when serializing Apex objects into JSON content.

`serializePretty(objectToSerialize)`

Serializes Apex objects into JSON content and generates indented content using the pretty-print format.

Signature

```
public static String serializePretty(Object objectToSerialize)
```

Parameters

`objectToSerialize`
Type: Object

The Apex object to serialize.

Return Value

Type: String

`serializePretty(objectToSerialize, suppressApexObjectNulls)`

Suppresses `null` values when serializing Apex objects into JSON content and generates indented content using the pretty-print format.

Signature

```
public static String serializePretty(Object objectToSerialize, Boolean
suppressApexObjectNulls)
```

Parameters

`objectToSerialize`
Type: Object

The Apex object to serialize.

`suppressApexObjectNulls`
Type: Boolean

If true, remove `null` values before serializing the JSON object.

Return Value

Type: String

JSONGenerator Class

Contains methods used to serialize objects into JSON content using the standard JSON encoding.

Namespace

System

Usage

The `System.JSONGenerator` class is provided to enable the generation of standard JSON-encoded content and gives you more control on the structure of the JSON output.

SEE ALSO:

JSON Generator

JSONGenerator Methods

The following are methods for `JSONGenerator`. All are instance methods.

IN THIS SECTION:

close()
Closes the JSON generator.

getAsString()
Returns the generated JSON content.

isClosed()
Returns `true` if the JSON generator is closed; otherwise, returns `false`.

writeBlob(blobValue)
Writes the specified `Blob` value as a base64-encoded string.

writeBlobField(fieldName, blobValue)
Writes a field name and value pair using the specified field name and BLOB value.

writeBoolean(blobValue)
Writes the specified Boolean value.

writeBooleanField(fieldName, booleanValue)
Writes a field name and value pair using the specified field name and Boolean value.

writeDate(dateValue)
Writes the specified date value in the ISO-8601 format.

writeDateField(fieldName, dateValue)
Writes a field name and value pair using the specified field name and date value. The date value is written in the ISO-8601 format.

writeDateTime(datetimeValue)
Writes the specified date and time value in the ISO-8601 format.

writeDateTimeField(fieldName, datetimeValue)
Writes a field name and value pair using the specified field name and date and time value. The date and time value is written in the ISO-8601 format.

writeEndArray()
Writes the ending marker of a JSON array (']').

writeEndObject()
Writes the ending marker of a JSON object ('}').

writeFieldName(fieldName)
Writes a field name.

writeId(identifier)
Writes the specified ID value.

writeIdField(fieldName, identifier)
Writes a field name and value pair using the specified field name and identifier value.

writeNull()
Writes the JSON null literal value.

writeNullField(fieldName)
Writes a field name and value pair using the specified field name and the JSON null literal value.

writeNumber(number)
Writes the specified decimal value.

writeNumber(number)
Writes the specified double value.

writeNumber(number)
Writes the specified integer value.

writeNumber(number)
Writes the specified long value.

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and decimal value.

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and double value.

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and integer value.

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and long value.

writeObject(anyObject)
Writes the specified Apex object in JSON format.

writeObjectField(fieldName, value)
Writes a field name and value pair using the specified field name and Apex object.

writeStartArray()
Writes the starting marker of a JSON array ('[').

writeStartObject()
Writes the starting marker of a JSON object ('{').

writeString(stringValue)
Writes the specified string value.

writeStringField(fieldName, stringValue)
Writes a field name and value pair using the specified field name and string value.

writeTime(timeValue)

Writes the specified time value in the ISO-8601 format.

writeTimeField(fieldName, timeValue)

Writes a field name and value pair using the specified field name and time value in the ISO-8601 format.

close()

Closes the JSON generator.

Signature

```
public Void close()
```

Return Value

Type: Void

Usage

No more content can be written after the JSON generator is closed.

getAsString()

Returns the generated JSON content.

Signature

```
public String getAsString()
```

Return Value

Type: String

Usage

This method closes the JSON generator if it isn't closed already.

isClosed()

Returns `true` if the JSON generator is closed; otherwise, returns `false`.

Signature

```
public Boolean isClosed()
```

Return Value

Type: Boolean

writeBlob(blobValue)

Writes the specified `Blob` value as a base64-encoded string.

Signature

```
public Void writeBlob(Blob blobValue)
```

Parameters

blobValue
Type: Blob

Return Value

Type: Void

writeBlobField(fieldName, blobValue)

Writes a field name and value pair using the specified field name and BLOB value.

Signature

```
public Void writeBlobField(String fieldName, Blob blobValue)
```

Parameters

fieldName
Type: String

blobValue
Type: Blob

Return Value

Type: Void

writeBoolean(blobValue)

Writes the specified Boolean value.

Signature

```
public Void writeBoolean(Boolean blobValue)
```

Parameters

blobValue
Type: Boolean

Return Value

Type: Void

writeBooleanField(fieldName, booleanValue)

Writes a field name and value pair using the specified field name and Boolean value.

Signature

```
public Void writeBooleanField(String fieldName, Boolean booleanValue)
```

Parameters

fieldName
Type: String

booleanValue
Type: Boolean

Return Value

Type: Void

writeDate(dateValue)

Writes the specified date value in the ISO-8601 format.

Signature

```
public Void writeDate(Date dateValue)
```

Parameters

dateValue
Type: Date

Return Value

Type: Void

writeDateField(fieldName, dateValue)

Writes a field name and value pair using the specified field name and date value. The date value is written in the ISO-8601 format.

Signature

```
public Void writeDateField(String fieldName, Date dateValue)
```

Parameters

fieldName
Type: String

dateValue
Type: Date

Return Value

Type: Void

writeDateTime(datetimeValue)

Writes the specified date and time value in the ISO-8601 format.

Signature

```
public Void writeDateTime(Datetime datetimeValue)
```

Parameters

datetimeValue
Type: Datetime

Return Value

Type: Void

writeDateTimeField(fieldName, datetimeValue)

Writes a field name and value pair using the specified field name and date and time value. The date and time value is written in the ISO-8601 format.

Signature

```
public Void writeDateTimeField(String fieldName, Datetime datetimeValue)
```

Parameters

fieldName
Type: String

datetimeValue
Type: Datetime

Return Value

Type: Void

writeEndArray()

Writes the ending marker of a JSON array (']').

Signature

```
public Void writeEndArray()
```

Return Value

Type: Void

writeEndObject()

Writes the ending marker of a JSON object ('}').

Signature

```
public Void writeEndObject()
```

Return Value

Type: Void

writeFieldName(fieldName)

Writes a field name.

Signature

```
public Void writeFieldName(String fieldName)
```

Parameters

fieldName
Type: String

Return Value

Type: Void

writeId(identifier)

Writes the specified ID value.

Signature

```
public Void writeId(ID identifier)
```

Parameters

identifier
Type: ID

Return Value

Type: Void

writeIdField(fieldName, identifier)

Writes a field name and value pair using the specified field name and identifier value.

Signature

```
public Void writeIdField(String fieldName, Id identifier)
```

Parameters

fieldName
Type: String

identifier
Type: ID

Return Value

Type: Void

writeNull()

Writes the JSON null literal value.

Signature

```
public Void writeNull()
```

Return Value

Type: Void

writeNullField(fieldName)

Writes a field name and value pair using the specified field name and the JSON null literal value.

Signature

```
public Void writeNullField(String fieldName)
```

Parameters

fieldName
Type: String

Return Value

Type: Void

writeNumber(number)

Writes the specified decimal value.

Signature

```
public Void writeNumber(Decimal number)
```

Parameters

number
Type: Decimal

Return Value

Type: Void

writeNumber(number)

Writes the specified double value.

Signature

```
public Void writeNumber(Double number)
```

Parameters

number
Type: Double

Return Value

Type: Void

writeNumber(number)

Writes the specified integer value.

Signature

```
public Void writeNumber(Integer number)
```

Parameters

number
Type: Integer

Return Value

Type: Void

writeNumber(number)

Writes the specified long value.

Signature

```
public Void writeNumber(Long number)
```

Parameters

number
Type: Long

Return Value

Type: Void

writeNumberField(fieldName, number)

Writes a field name and value pair using the specified field name and decimal value.

Signature

```
public Void writeNumberField(String fieldName, Decimal number)
```

Parameters

fieldName
Type: String

number
Type: Decimal

Return Value

Type: Void

writeNumberField(fieldName, number)

Writes a field name and value pair using the specified field name and double value.

Signature

```
public Void writeNumberField(String fieldName, Double number)
```

Parameters

fieldName
Type: String

number
Type: Double

Return Value

Type: Void

writeNumberField(fieldName, number)

Writes a field name and value pair using the specified field name and integer value.

Signature

```
public Void writeNumberField(String fieldName, Integer number)
```

Parameters

fieldName
Type: String

number
Type: Integer

Return Value

Type: Void

writeNumberField(fieldName, number)

Writes a field name and value pair using the specified field name and long value.

Signature

```
public Void writeNumberField(String fieldName, Long number)
```

Parameters

fieldName
Type: String

number
Type: Long

Return Value

Type: Void

writeObject(anyObject)

Writes the specified Apex object in JSON format.

Signature

```
public Void writeObject(Object anyObject)
```

Parameters

anyObject
Type: Object

Return Value

Type: Void

writeObjectField(fieldName, value)

Writes a field name and value pair using the specified field name and Apex object.

Signature

```
public Void writeObjectField(String fieldName, Object value)
```

Parameters

fieldName
Type: String

value
Type: Object

Return Value

Type: Void

writeStartArray()

Writes the starting marker of a JSON array ('[').

Signature

```
public Void writeStartArray()
```

Return Value

Type: Void

writeStartObject()

Writes the starting marker of a JSON object ('{').

Signature

```
public Void writeStartObject()
```

Return Value

Type: Void

writeString(stringValue)

Writes the specified string value.

Signature

```
public Void writeString(String stringValue)
```

Parameters

stringValue
Type: String

Return Value

Type: Void

writeStringField(fieldName, stringValue)

Writes a field name and value pair using the specified field name and string value.

Signature

```
public Void writeStringField(String fieldName, String stringValue)
```

Parameters

fieldName
Type: String

stringValue
Type: String

Return Value

Type: Void

writeTime(timeValue)

Writes the specified time value in the ISO-8601 format.

Signature

```
public Void writeTime(Time timeValue)
```

Parameters

timeValue
Type: Time

Return Value

Type: Void

`writeTimeField(fieldName, timeValue)`

Writes a field name and value pair using the specified field name and time value in the ISO-8601 format.

Signature

```
public Void writeTimeField(String fieldName, Time timeValue)
```

Parameters

`fieldName`
Type: String

`timeValue`
Type: Time

Return Value

Type: Void

JSONParser Class

Represents a parser for JSON-encoded content.

Namespace

System

Usage

Use the `System.JSONParser` methods to parse a response that's returned from a call to an external service that is in JSON format, such as a JSON-encoded response of a Web service callout.

SEE ALSO:

JSON Parsing

JSONParser Methods

The following are methods for `JSONParser`. All are instance methods.

IN THIS SECTION:

clearCurrentToken()
Removes the current token.

getBlobValue()
Returns the current token as a BLOB value.

getBooleanValue()
Returns the current token as a Boolean value.

getCurrentName()
Returns the name associated with the current token.

getCurrentToken()
Returns the token that the parser currently points to or `null` if there's no current token.

getDatetimeValue()
Returns the current token as a date and time value.

getDateValue()
Returns the current token as a date value.

getDecimalValue()
Returns the current token as a decimal value.

getDoubleValue()
Returns the current token as a double value.

getIdValue()
Returns the current token as an ID value.

getIntegerValue()
Returns the current token as an integer value.

getLastClearedToken()
Returns the last token that was cleared by the `clearCurrentToken` method.

getLongValue()
Returns the current token as a long value.

getText()
Returns the textual representation of the current token or `null` if there's no current token.

getTimeValue()
Returns the current token as a time value.

hasCurrentToken()
Returns `true` if the parser currently points to a token; otherwise, returns `false`.

nextToken()
Returns the next token or `null` if the parser has reached the end of the input stream.

nextValue()
Returns the next token that is a value type or `null` if the parser has reached the end of the input stream.

readValueAs(apexType)
Deserializes JSON content into an object of the specified Apex type and returns the deserialized object.

readValueAsStrict(apexType)
Deserializes JSON content into an object of the specified Apex type and returns the deserialized object. All attributes in the JSON content must be present in the specified type.

skipChildren()
Skips all child tokens of type `JSONToken.START_ARRAY` and `JSONToken.START_OBJECT` that the parser currently points to.

clearCurrentToken()

Removes the current token.

Signature

```
public Void clearCurrentToken()
```

Return Value

Type: Void

Usage

After this method is called, a call to `hasCurrentToken` returns `false` and a call to `getCurrentToken` returns `null`. You can retrieve the cleared token by calling `getLastClearedToken`.

getBlobValue()

Returns the current token as a BLOB value.

Signature

```
public Blob getBlobValue()
```

Return Value

Type: Blob

Usage

The current token must be of type `JSONToken.VALUE_STRING` and must be Base64-encoded.

getBooleanValue()

Returns the current token as a Boolean value.

Signature

```
public Boolean getBooleanValue()
```

Return Value

Type: Boolean

Usage

The current token must be of type `JSONToken.VALUE_TRUE` or `JSONToken.VALUE_FALSE`.

The following example parses a sample JSON string and retrieves a Boolean value.

```
String JSONContent =
    '{"isActive":true}';
```

```
JSONParser parser =
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the Boolean value.
Boolean isActive = parser.getBooleanValue();
```

getCurrentName()

Returns the name associated with the current token.

Signature

```
public String getCurrentName()
```

Return Value

Type: String

Usage

If the current token is of type `JSONToken.FIELD_NAME`, this method returns the same value as `getText`. If the current token is a value, this method returns the field name that precedes this token. For other values such as array values or root-level values, this method returns `null`.

The following example parses a sample JSON string. It advances to the field value and retrieves its corresponding field name.

Example

```
String JSONContent = '{"firstName":"John"}';
JSONParser parser =
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the field name for the current value.
String fieldName = parser.getCurrentName();
// Get the textual representation
// of the value.
String fieldValue = parser.getText();
```

getCurrentToken()

Returns the token that the parser currently points to or `null` if there's no current token.

Signature

```
public System.JSONToken getCurrentToken()
```

Return Value

Type: System.JSONToken

Usage

The following example iterates through all the tokens in a sample JSON string.

```
String JSONContent = '{"firstName":"John"}';
JSONParser parser =
   JSON.createParser(JSONContent);
// Advance to the next token.
while (parser.nextToken() != null) {
    System.debug('Current token: ' +
        parser.getCurrentToken());
}
```

getDatetimeValue()

Returns the current token as a date and time value.

Signature

```
public Datetime getDatetimeValue()
```

Return Value

Type: Datetime

Usage

The current token must be of type `JSONToken.VALUE_STRING` and must represent a `Datetime` value in the ISO-8601 format.

The following example parses a sample JSON string and retrieves a Datetime value.

```
String JSONContent =
'{"transactionDate":"2011-03-22T13:01:23"}';
JSONParser parser =
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the transaction date.
Datetime transactionDate =
   parser.getDatetimeValue();
```

getDateValue()

Returns the current token as a date value.

Signature

```
public Date getDateValue()
```

Return Value

Type: Date

Usage

The current token must be of type `JSONToken.VALUE_STRING` and must represent a `Date` value in the ISO-8601 format.

The following example parses a sample JSON string and retrieves a Date value.

```
String JSONContent =
   '{"dateOfBirth":"2011-03-22"}';
JSONParser parser =
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the date of birth.
Date dob = parser.getDateValue();
```

getDecimalValue()

Returns the current token as a decimal value.

Signature

```
public Decimal getDecimalValue()
```

Return Value

Type: Decimal

Usage

The current token must be of type `JSONToken.VALUE_NUMBER_FLOAT` or `JSONToken.VALUE_NUMBER_INT` and is a numerical value that can be converted to a value of type `Decimal`.

The following example parses a sample JSON string and retrieves a Decimal value.

```
String JSONContent =
   '{"GPA":3.8}';
JSONParser parser =
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the GPA score.
Decimal gpa = parser.getDecimalValue();
```

getDoubleValue()

Returns the current token as a double value.

Signature

```
public Double getDoubleValue()
```

Return Value

Type: Double

Usage

The current token must be of type `JSONToken.VALUE_NUMBER_FLOAT` and is a numerical value that can be converted to a value of type `Double`.

The following example parses a sample JSON string and retrieves a Double value.

```
String JSONContent =
   '{"GPA":3.8}';
JSONParser parser =
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the GPA score.
Double gpa = parser.getDoubleValue();
```

getIdValue()

Returns the current token as an ID value.

Signature

```
public ID getIdValue()
```

Return Value

Type: ID

Usage

The current token must be of type `JSONToken.VALUE_STRING` and must be a valid `ID`.

The following example parses a sample JSON string and retrieves an ID value.

```
String JSONContent =
   '{"recordId":"001R0000002nO6H"}';
JSONParser parser =
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the record ID.
ID recordID = parser.getIdValue();
```

getIntegerValue()

Returns the current token as an integer value.

Signature

```
public Integer getIntegerValue()
```

Return Value

Type: Integer

Usage

The current token must be of type `JSONToken.VALUE_NUMBER_INT` and must represent an `Integer`.

The following example parses a sample JSON string and retrieves an Integer value.

```
String JSONContent =
   '{"recordCount":10}';
JSONParser parser =
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the record count.
Integer count = parser.getIntegerValue();
```

getLastClearedToken()

Returns the last token that was cleared by the `clearCurrentToken` method.

Signature

```
public System.JSONToken getLastClearedToken()
```

Return Value

Type: System.JSONToken

getLongValue()

Returns the current token as a long value.

Signature

```
public Long getLongValue()
```

Return Value

Type: Long

Usage

The current token must be of type `JSONToken.VALUE_NUMBER_INT` and is a numerical value that can be converted to a value of type `Long` .

The following example parses a sample JSON string and retrieves a Long value.

```
String JSONContent =
   '{"recordCount":2097531021}';
JSONParser parser =
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the record count.
Long count = parser.getLongValue();
```

`getText()`

Returns the textual representation of the current token or `null` if there's no current token.

Signature

```
public String getText()
```

Return Value

Type: String

Usage

No current token exists, and therefore this method returns `null`, if `nextToken` has not been called yet for the first time or if the parser has reached the end of the input stream.

`getTimeValue()`

Returns the current token as a time value.

Signature

```
public Time getTimeValue()
```

Return Value

Type: Time

Usage

The current token must be of type `JSONToken.VALUE_STRING` and must represent a `Time` value in the ISO-8601 format.

The following example parses a sample JSON string and retrieves a Datetime value.

```
String JSONContent =
   '{"arrivalTime":"18:05"}';
JSONParser parser =
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the arrival time.
Time arrivalTime = parser.getTimeValue();
```

hasCurrentToken()

Returns `true` if the parser currently points to a token; otherwise, returns `false`.

Signature

```
public Boolean hasCurrentToken()
```

Return Value

Type: Boolean

nextToken()

Returns the next token or `null` if the parser has reached the end of the input stream.

Signature

```
public System.JSONToken nextToken()
```

Return Value

Type: System.JSONToken

Usage

Advances the stream enough to determine the type of the next token, if any.

nextValue()

Returns the next token that is a value type or `null` if the parser has reached the end of the input stream.

Signature

```
public System.JSONToken nextValue()
```

Return Value

Type: System.JSONToken

Usage

Advances the stream enough to determine the type of the next token that is of a value type, if any, including a JSON array and object start and end markers.

readValueAs(apexType)

Deserializes JSON content into an object of the specified Apex type and returns the deserialized object.

Signature

```
public Object readValueAs(System.Type apexType)
```

Parameters

apexType
Type: System.Type

The *apexType* argument specifies the type of the object that this method returns after deserializing the current value.

Return Value

Type: Object

Usage

If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content into a custom object or an sObject using Salesforce API version 34.0 or earlier, this method throws a runtime exception when passed extraneous attributes. When deserializing JSON content into an Apex class in any API version, or into an object in API version 35.0 or later, no exception is thrown. When no exception is thrown, this method ignores extraneous attributes and parses the rest of the JSON content.

Example

The following example parses a sample JSON string and retrieves a Datetime value. Before being able to run this sample, you must create a new Apex class as follows:

```
public class Person {
    public String name;
    public String phone;
}
```

Next, insert the following sample in a class method:

```
// JSON string that contains a Person object.
String JSONContent =
    '{"person":{' +
        '"name":"John Smith",' +
        '"phone":"555-1212"}}';
JSONParser parser =
   JSON.createParser(JSONContent);
// Make calls to nextToken()
// to point to the second
// start object marker.
```

```
parser.nextToken();
parser.nextToken();
parser.nextToken();
// Retrieve the Person object
// from the JSON string.
Person obj =
   (Person)parser.readValueAs(
      Person.class);
System.assertEquals(
   obj.name, 'John Smith');
System.assertEquals(
   obj.phone, '555-1212');
```

readValueAsStrict(apexType)

Deserializes JSON content into an object of the specified Apex type and returns the deserialized object. All attributes in the JSON content must be present in the specified type.

Signature

```
public Object readValueAsStrict(System.Type apexType)
```

Parameters

apexType
Type: System.Type

The *apexType* argument specifies the type of the object that this method returns after deserializing the current value.

Return Value

Type: Object

Usage

If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content with extraneous attributes into an Apex class, this method throws an exception in all API versions. However, no exception is thrown when you use this method to deserialize JSON content into a custom object or an sObject.

The following example parses a sample JSON string and retrieves a Datetime value. Before being able to run this sample, you must create a new Apex class as follows:

```
public class Person {
    public String name;
    public String phone;
}
```

Next, insert the following sample in a class method:

```
// JSON string that contains a Person object.
String JSONContent =
    '{"person":{' +
        '"name":"John Smith",' +
```

```
        '"phone":"555-1212"}}';
JSONParser parser =
   JSON.createParser(JSONContent);
// Make calls to nextToken()
// to point to the second
// start object marker.
parser.nextToken();
parser.nextToken();
parser.nextToken();
// Retrieve the Person object
// from the JSON string.
Person obj =
   (Person)parser.readValueAsStrict(
      Person.class);
System.assertEquals(
   obj.name, 'John Smith');
System.assertEquals(
   obj.phone, '555-1212');
```

`skipChildren()`

Skips all child tokens of type `JSONToken.START_ARRAY` and `JSONToken.START_OBJECT` that the parser currently points to.

Signature

```
public Void skipChildren()
```

Return Value

Type: Void

JSONToken Enum

Contains all token values used for parsing JSON content.

Namespace

System

Enum Value	Description
END_ARRAY	The ending of an array value. This token is returned when ']' is encountered.
END_OBJECT	The ending of an object value. This token is returned when '}' is encountered.
FIELD_NAME	A string token that is a field name.
NOT_AVAILABLE	The requested token isn't available.

Enum Value	Description
START_ARRAY	The start of an array value. This token is returned when '[' is encountered.
START_OBJECT	The start of an object value. This token is returned when '{' is encountered.
VALUE_EMBEDDED_OBJECT	An embedded object that isn't accessible as a typical object structure that includes the start and end object tokens START_OBJECT and END_OBJECT but is represented as a raw object.
VALUE_FALSE	The literal “false” value.
VALUE_NULL	The literal “null” value.
VALUE_NUMBER_FLOAT	A float value.
VALUE_NUMBER_INT	An integer value.
VALUE_STRING	A string value.
VALUE_TRUE	A value that corresponds to the “true” string literal.

Limits Class

Contains methods that return limit information for specific resources.

Namespace

System

Usage

The Limits methods return the specific limit for the particular governor, such as the number of calls of a method or the amount of heap size remaining.

Because Apex runs in a multitenant environment, the Apex runtime engine strictly enforces a number of limits to ensure that runaway Apex doesn’t monopolize shared resources.

None of the Limits methods require an argument. The format of the limits methods is as follows:

```
myDMLLimit = Limits.getDMLStatements();
```

There are two versions of every method: the first returns the amount of the resource that has been used while the second version contains the word limit and returns the total amount of the resource that is available.

See Execution Governors and Limits on page 281.

Limits Methods

The following are methods for `Limits`. All methods are static.

IN THIS SECTION:

getAggregateQueries()
Returns the number of aggregate queries that have been processed with any SOQL query statement.

getLimitAggregateQueries()
Returns the total number of aggregate queries that can be processed with SOQL query statements.

getAsyncCalls()
Reserved for future use.

getLimitAsyncCalls()
Reserved for future use.

getCallouts()
Returns the number of Web service statements that have been processed.

getChildRelationshipsDescribes()
Deprecated. Returns the number of child relationship objects that have been returned.

getLimitCallouts()
Returns the total number of Web service statements that can be processed.

getCpuTime()
Returns the CPU time (in milliseconds) accumulated on the Salesforce servers in the current transaction.

getLimitCpuTime()
Returns the time limit (in milliseconds) of CPU usage in the current transaction.

getDMLRows()
Returns the number of records that have been processed with any statement that counts against DML limits, such as DML statements, the `Database.emptyRecycleBin` method, and other methods.

getLimitDMLRows()
Returns the total number of records that can be processed with any statement that counts against DML limits, such as DML statements, the `database.EmptyRecycleBin` method, and other methods.

getDMLStatements()
Returns the number of DML statements (such as `insert`, `update` or the `database.EmptyRecycleBin` method) that have been called.

getLimitDMLStatements()
Returns the total number of DML statements or the `database.EmptyRecycleBin` methods that can be called.

getEmailInvocations()
Returns the number of email invocations (such as `sendEmail`) that have been called.

getLimitEmailInvocations()
Returns the total number of email invocation (such as `sendEmail`) that can be called.

getFindSimilarCalls()
Deprecated. Returns the same value as `getSoslQueries`. The number of `findSimilar` methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

getLimitFindSimilarCalls()
Deprecated. Returns the same value as `getLimitSoslQueries`. The number of `findSimilar` methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

getFutureCalls()

Returns the number of methods with the `future` annotation that have been executed (not necessarily completed).

getLimitFutureCalls()

Returns the total number of methods with the `future` annotation that can be executed (not necessarily completed).

getHeapSize()

Returns the approximate amount of memory (in bytes) that has been used for the heap.

getLimitHeapSize()

Returns the total amount of memory (in bytes) that can be used for the heap.

getMobilePushApexCalls()

Returns the number of Apex calls that have been used by mobile push notifications during the current metering interval.

getLimitMobilePushApexCalls()

Returns the total number of Apex calls that are allowed per transaction for mobile push notifications.

getQueries()

Returns the number of SOQL queries that have been issued.

getLimitQueries()

Returns the total number of SOQL queries that can be issued.

getQueryLocatorRows()

Returns the number of records that have been returned by the `Database.getQueryLocator` method.

getLimitQueryLocatorRows()

Returns the total number of records that can be returned by the `Database.getQueryLocator` method.

getQueryRows()

Returns the number of records that have been returned by issuing SOQL queries.

getLimitQueryRows()

Returns the total number of records that can be returned by issuing SOQL queries.

getQueueableJobs()

Returns the number of queueable jobs that have been added to the queue per transaction. A queueable job corresponds to a class that implements the `Queueable` interface.

getLimitQueueableJobs()

Returns the maximum number of queueable jobs that can be added to the queue per transaction. A queueable job corresponds to a class that implements the `Queueable` interface.

getRunAs()

Deprecated. Returns the same value as `getDMLStatements`.

getLimitRunAs()

Deprecated. Returns the same value as `getLimitDMLStatements`.

getSavepointRollbacks()

Deprecated. Returns the same value as `getDMLStatements`.

getLimitSavepointRollbacks()

Deprecated. Returns the same value as `getLimitDMLStatements`.

getSavepoints()

Deprecated. Returns the same value as `getDMLStatements`.

getLimitSavepoints()
Deprecated. Returns the same value as `getLimitDMLStatements`.

getSoslQueries()
Returns the number of SOSL queries that have been issued.

getLimitSoslQueries()
Returns the total number of SOSL queries that can be issued.

getAggregateQueries()

Returns the number of aggregate queries that have been processed with any SOQL query statement.

Signature

```
public static Integer getAggregateQueries()
```

Return Value

Type: Integer

getLimitAggregateQueries()

Returns the total number of aggregate queries that can be processed with SOQL query statements.

Signature

```
public static Integer getLimitAggregateQueries()
```

Return Value

Type: Integer

getAsyncCalls()

Reserved for future use.

Signature

```
public static Integer getAsyncCalls()
```

Return Value

Type: Integer

getLimitAsyncCalls()

Reserved for future use.

Signature

```
public static Integer getLimitAsyncCalls()
```

Return Value

Type: Integer

getCallouts()

Returns the number of Web service statements that have been processed.

Signature

```
public static Integer getCallouts()
```

Return Value

Type: Integer

getChildRelationshipsDescribes()

Deprecated. Returns the number of child relationship objects that have been returned.

Signature

```
public static Integer getChildRelationshipsDescribes()
```

Return Value

Type: Integer

Usage

Note: Because describe limits are no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is available but is deprecated.

getLimitCallouts()

Returns the total number of Web service statements that can be processed.

Signature

```
public static Integer getLimitCallouts()
```

Return Value

Type: Integer

getCpuTime()

Returns the CPU time (in milliseconds) accumulated on the Salesforce servers in the current transaction.

Signature

```
public static Integer getCpuTime()
```

Return Value

Type: Integer

getLimitCpuTime()

Returns the time limit (in milliseconds) of CPU usage in the current transaction.

Signature

```
public static Integer getLimitCpuTime()
```

Return Value

Type: Integer

getDMLRows()

Returns the number of records that have been processed with any statement that counts against DML limits, such as DML statements, the `Database.emptyRecycleBin` method, and other methods.

Signature

```
public static Integer getDMLRows()
```

Return Value

Type: Integer

getLimitDMLRows()

Returns the total number of records that can be processed with any statement that counts against DML limits, such as DML statements, the `database.EmptyRecycleBin` method, and other methods.

Signature

```
public static Integer getLimitDMLRows()
```

Return Value

Type: Integer

getDMLStatements()

Returns the number of DML statements (such as `insert`, `update` or the `database.EmptyRecycleBin` method) that have been called.

Signature

```
public static Integer getDMLStatements()
```

Return Value

Type: Integer

getLimitDMLStatements()

Returns the total number of DML statements or the `database.EmptyRecycleBin` methods that can be called.

Signature

```
public static Integer getLimitDMLStatements()
```

Return Value

Type: Integer

getEmailInvocations()

Returns the number of email invocations (such as `sendEmail`) that have been called.

Signature

```
public static Integer getEmailInvocations()
```

Return Value

Type: Integer

getLimitEmailInvocations()

Returns the total number of email invocation (such as `sendEmail`) that can be called.

Signature

```
public static Integer getLimitEmailInvocations()
```

Return Value

Type: Integer

getFindSimilarCalls()

Deprecated. Returns the same value as `getSoslQueries`. The number of `findSimilar` methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

Signature

```
public static Integer getFindSimilarCalls()
```

Return Value

Type: Integer

`getLimitFindSimilarCalls()`

Deprecated. Returns the same value as `getLimitSoslQueries`. The number of `findSimilar` methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

Signature

```
public static Integer getLimitFindSimilarCalls()
```

Return Value

Type: Integer

`getFutureCalls()`

Returns the number of methods with the `future` annotation that have been executed (not necessarily completed).

Signature

```
public static Integer getFutureCalls()
```

Return Value

Type: Integer

`getLimitFutureCalls()`

Returns the total number of methods with the `future` annotation that can be executed (not necessarily completed).

Signature

```
public static Integer getLimitFutureCalls()
```

Return Value

Type: Integer

`getHeapSize()`

Returns the approximate amount of memory (in bytes) that has been used for the heap.

Signature

```
public static Integer getHeapSize()
```

Return Value

Type: Integer

`getLimitHeapSize()`

Returns the total amount of memory (in bytes) that can be used for the heap.

Signature

```
public static Integer getLimitHeapSize()
```

Return Value

Type: Integer

getMobilePushApexCalls()

Returns the number of Apex calls that have been used by mobile push notifications during the current metering interval.

Signature

```
public static Integer getMobilePushApexCalls()
```

Return Value

Type:Integer

getLimitMobilePushApexCalls()

Returns the total number of Apex calls that are allowed per transaction for mobile push notifications.

Signature

```
public static Integer getLimitMobilePushApexCalls()
```

Return Value

Type:Integer

getQueries()

Returns the number of SOQL queries that have been issued.

Signature

```
public static Integer getQueries()
```

Return Value

Type: Integer

getLimitQueries()

Returns the total number of SOQL queries that can be issued.

Signature

```
public static Integer getLimitQueries()
```

Return Value

Type: Integer

getQueryLocatorRows()

Returns the number of records that have been returned by the `Database.getQueryLocator` method.

Signature

```
public static Integer getQueryLocatorRows()
```

Return Value

Type: Integer

getLimitQueryLocatorRows()

Returns the total number of records that can be returned by the `Database.getQueryLocator` method.

Signature

```
public static Integer getLimitQueryLocatorRows()
```

Return Value

Type: Integer

getQueryRows()

Returns the number of records that have been returned by issuing SOQL queries.

Signature

```
public static Integer getQueryRows()
```

Return Value

Type: Integer

getLimitQueryRows()

Returns the total number of records that can be returned by issuing SOQL queries.

Signature

```
public static Integer getLimitQueryRows()
```

Return Value

Type: Integer

getQueueableJobs()

Returns the number of queueable jobs that have been added to the queue per transaction. A queueable job corresponds to a class that implements the `Queueable` interface.

Signature

```
public static Integer getQueueableJobs()
```

Return Value

Type: Integer

getLimitQueueableJobs()

Returns the maximum number of queueable jobs that can be added to the queue per transaction. A queueable job corresponds to a class that implements the `Queueable` interface.

Signature

```
public static Integer getLimitQueueableJobs()
```

Return Value

Type: Integer

getRunAs()

Deprecated. Returns the same value as `getDMLStatements`.

Signature

```
public static Integer getRunAs()
```

Return Value

Type: Integer

Usage

The number of `RunAs` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

getLimitRunAs()

Deprecated. Returns the same value as `getLimitDMLStatements`.

Signature

```
public static Integer getLimitRunAs()
```

Return Value

Type: Integer

Usage

The number of `RunAs` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

getSavepointRollbacks()

Deprecated. Returns the same value as `getDMLStatements`.

Signature

```
public static Integer getSavepointRollbacks()
```

Return Value

Type: Integer

Usage

The number of `Rollback` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

getLimitSavepointRollbacks()

Deprecated. Returns the same value as `getLimitDMLStatements`.

Signature

```
public static Integer getLimitSavepointRollbacks()
```

Return Value

Type: Integer

Usage

The number of `Rollback` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

getSavepoints()

Deprecated. Returns the same value as `getDMLStatements`.

Signature

```
public static Integer getSavepoints()
```

Return Value

Type: Integer

Usage

The number of `setSavepoint` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

`getLimitSavepoints()`

Deprecated. Returns the same value as `getLimitDMLStatements`.

Signature

```
public static Integer getLimitSavepoints()
```

Return Value

Type: Integer

Usage

The number of `setSavepoint` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

`getSoslQueries()`

Returns the number of SOSL queries that have been issued.

Signature

```
public static Integer getSoslQueries()
```

Return Value

Type: Integer

`getLimitSoslQueries()`

Returns the total number of SOSL queries that can be issued.

Signature

```
public static Integer getLimitSoslQueries()
```

Return Value

Type: Integer

List Class

Contains methods for the List collection type.

Namespace

System

Usage

The list methods are all instance methods, that is, they operate on a particular instance of a list. For example, the following removes all elements from `myList`:

```
myList.clear();
```

Even though the `clear` method does not include any parameters, the list that calls it is its implicit parameter.

Note:

- When using a custom type for the list elements, provide an `equals` method in your class. Apex uses this method to determine equality and uniqueness for your objects. For more information on providing an `equals` method, see Using Custom Types in Map Keys and Sets.
- If the list contains String elements, the elements are case-sensitive. Two list elements that differ only by case are considered distinct.

For more information on lists, see Lists on page 30.

IN THIS SECTION:

List Constructors

List Methods

List Constructors

The following are constructors for `List`.

IN THIS SECTION:

List<T>()
Creates a new instance of the `List` class. A list can hold elements of any data type T.

List<T>(listToCopy)
Creates a new instance of the `List` class by copying the elements from the specified list. T is the data type of the elements in both lists and can be any data type.

List<T>(setToCopy)
Creates a new instance of the `List` class by copying the elements from the specified set. T is the data type of the elements in the set and list and can be any data type.

List<T>()

Creates a new instance of the `List` class. A list can hold elements of any data type T.

Signature

```
public List<T>()
```

Example

```
// Create a list
List<Integer> ls1 = new List<Integer>();
```

```
// Add two integers to the list
ls1.add(1);
ls1.add(2);
```

List<T>(listToCopy)

Creates a new instance of the `List` class by copying the elements from the specified list. T is the data type of the elements in both lists and can be any data type.

Signature

```
public List<T>(List<T> listToCopy)
```

Parameters

listToCopy
Type: List<T>

The list containing the elements to initialize this list from. T is the data type of the list elements.

Example

```
List<Integer> ls1 = new List<Integer>();
ls1.add(1);
ls1.add(2);
// Create a list based on an existing one
List<Integer> ls2 = new List<Integer>(ls1);
// ls2 elements are copied from ls1
System.debug(ls2);// DEBUG|(1, 2)
```

List<T>(setToCopy)

Creates a new instance of the `List` class by copying the elements from the specified set. T is the data type of the elements in the set and list and can be any data type.

Signature

```
public List<T>(Set<T> setToCopy)
```

Parameters

setToCopy
Type: Set<T>

The set containing the elements to initialize this list with. T is the data type of the set elements.

Example

```
Set<Integer> s1 = new Set<Integer>();
s1.add(1);
s1.add(2);
// Create a list based on a set
```

```
List<Integer> ls = new List<Integer>(s1);
// ls elements are copied from s1
System.debug(ls);// DEBUG|(1, 2)
```

List Methods

The following are methods for `List`. All are instance methods.

IN THIS SECTION:

add(listElement)

Adds an element to the end of the list.

add(index, listElement)

Inserts an element into the list at the specified index position.

addAll(fromList)

Adds all of the elements in the specified list to the list that calls the method. Both lists must be of the same type.

addAll(fromSet)

Add all of the elements in specified set to the list that calls the method. The set and the list must be of the same type.

clear()

Removes all elements from a list, consequently setting the list's length to zero.

clone()

Makes a duplicate copy of a list.

contains(listElement)

Returns `true` if the list contains the specified element.

deepClone(preserveId, preserveReadonlyTimestamps, preserveAutonumber)

Makes a duplicate copy of a list of sObject records, including the sObject records themselves.

equals(list2)

Compares this list with the specified list and returns `true` if both lists are equal; otherwise, returns `false`.

get(index)

Returns the list element stored at the specified index.

getSObjectType()

Returns the token of the sObject type that makes up a list of sObjects.

hashCode()

Returns the hashcode corresponding to this list and its contents.

indexOf(listElement)

Returns the index of the first occurrence of the specified element in this list. If this list does not contain the element, returns -1.

isEmpty()

Returns true if the list has zero elements.

iterator()

Returns an instance of an iterator for this list.

remove(index)

Removes the list element stored at the specified index, returning the element that was removed.

set(index, listElement)
Sets the specified value for the element at the given index.

size()
Returns the number of elements in the list.

sort()
Sorts the items in the list in ascending order.

add(listElement)

Adds an element to the end of the list.

Signature

```
public Void add(Object listElement)
```

Parameters

listElement
Type: Object

Return Value

Type: Void

Example

```
List<Integer> myList = new List<Integer>();
myList.add(47);
Integer myNumber = myList.get(0);
system.assertEquals(47, myNumber);
```

add(index, listElement)

Inserts an element into the list at the specified index position.

Signature

```
public Void add(Integer index, Object listElement)
```

Parameters

index
Type: Integer

listElement
Type: Object

Return Value

Type: Void

Example

In the following example, a list with six elements is created, and integers are added to the first and second index positions.

```
List<Integer> myList = new Integer[6];
myList.add(0, 47);
myList.add(1, 52);
system.assertEquals(52, myList.get(1));
```

addAll(fromList)

Adds all of the elements in the specified list to the list that calls the method. Both lists must be of the same type.

Signature

```
public Void addAll(List fromList)
```

Parameters

fromList
Type: List

Return Value

Type: Void

addAll(fromSet)

Add all of the elements in specified set to the list that calls the method. The set and the list must be of the same type.

Signature

```
public Void addAll(Set fromSet)
```

Parameters

fromSet
Type: Set

Return Value

Type: Void

clear()

Removes all elements from a list, consequently setting the list's length to zero.

Signature

```
public Void clear()
```

Return Value

Type: Void

clone()

Makes a duplicate copy of a list.

Signature

```
public List<Object> clone()
```

Return Value

Type: List<Object>

Usage

The cloned list is of the same type as the current list.

Note that if this is a list of sObject records, the duplicate list will only be a shallow copy of the list. That is, the duplicate will have references to each object, but the sObject records themselves will not be duplicated. For example:

To also copy the sObject records, you must use the `deepClone` method.

Example

```
Account a = new Account(Name='Acme', BillingCity='New York');

Account b = new Account();
Account[] q1 = new Account[]{a,b};

Account[] q2 = q1.clone();
q1[0].BillingCity = 'San Francisco';

System.assertEquals(
      'San Francisco',
      q1[0].BillingCity);
System.assertEquals(
      'San Francisco',
      q2[0].BillingCity);
```

contains(listElement)

Returns `true` if the list contains the specified element.

Signature

```
public Boolean contains(Object listElement)
```

Parameters

listElement
Type: Object

Return Value

Type: Boolean

Example

```
List<String> myStrings = new List<String>{'a', 'b'};
Boolean result = myStrings.contains('z');
System.assertEquals(false, result);
```

deepClone(preserveId, preserveReadonlyTimestamps, preserveAutonumber)

Makes a duplicate copy of a list of sObject records, including the sObject records themselves.

Signature

```
public List<Object> deepClone(Boolean preserveId, Boolean preserveReadonlyTimestamps,
Boolean preserveAutonumber)
```

Parameters

preserveId
Type: Boolean

The optional *preserveId* argument determines whether the IDs of the original objects are preserved or cleared in the duplicates. If set to `true`, the IDs are copied to the cloned objects. The default is `false`, that is, the IDs are cleared.

preserveReadonlyTimestamps
Type: Boolean

The optional *preserveReadonlyTimestamps* argument determines whether the read-only timestamp and user ID fields are preserved or cleared in the duplicates. If set to `true`, the read-only fields `CreatedById`, `CreatedDate`, `LastModifiedById`, and `LastModifiedDate` are copied to the cloned objects. The default is `false`, that is, the values are cleared.

preserveAutonumber
Type: Boolean

The optional *preserveAutonumber* argument determines whether the autonumber fields of the original objects are preserved or cleared in the duplicates. If set to `true`, auto number fields are copied to the cloned objects. The default is `false`, that is, auto number fields are cleared.

Return Value

Type: List<Object>

Usage

The returned list is of the same type as the current list.

Note:

- `deepClone` only works with lists of sObjects, not with lists of primitives.
- For Apex saved using Salesforce API version 22.0 or earlier, the default value for the *`preserve_id`* argument is `true`, that is, the IDs are preserved.

To make a shallow copy of a list without duplicating the sObject records it contains, use the `clone` method.

Example

This example performs a deep clone for a list with two accounts.

```
Account a = new Account(Name='Acme', BillingCity='New York');

Account b = new Account(Name='Salesforce');

Account[] q1 = new Account[]{a,b};

Account[] q2 = q1.deepClone();
q1[0].BillingCity = 'San Francisco';

System.assertEquals(
     'San Francisco',
     q1[0].BillingCity);

System.assertEquals(
     'New York',
     q2[0].BillingCity);
```

This example is based on the previous example and shows how to clone a list with preserved read-only timestamp and user ID fields.

```
insert q1;

List<Account> accts = [SELECT CreatedById, CreatedDate, LastModifiedById,
                       LastModifiedDate, BillingCity
                       FROM Account
                       WHERE Name='Acme' OR Name='Salesforce'];

// Clone list while preserving timestamp and user ID fields.
Account[] q3 = accts.deepClone(false,true,false);

// Verify timestamp fields are preserved for the first list element.
System.assertEquals(
    accts[0].CreatedById,
    q3[0].CreatedById);
System.assertEquals(
    accts[0].CreatedDate,
    q3[0].CreatedDate);
System.assertEquals(
    accts[0].LastModifiedById,
    q3[0].LastModifiedById);
System.assertEquals(
    accts[0].LastModifiedDate,
    q3[0].LastModifiedDate);
```

equals(list2)

Compares this list with the specified list and returns `true` if both lists are equal; otherwise, returns `false`.

Signature

```
public Boolean equals(List list2)
```

Parameters

list2
Type: List

The list to compare this list with.

Return Value

Type: Boolean

Usage

Two lists are equal if their elements are equal and are in the same order. The `==` operator is used to compare the elements of the lists.

The `==` operator is equivalent to calling the `equals` method, so you can call `list1.equals(list2);` instead of `list1 == list2;`.

get(index)

Returns the list element stored at the specified index.

Signature

```
public Object get(Integer index)
```

Parameters

index
Type: Integer

Return Value

Type: Object

Usage

To reference an element of a one-dimensional list of primitives or sObjects, you can also follow the name of the list with the element's index position in square brackets as shown in the example.

Example

```
List<Integer> myList = new List<Integer>();
myList.add(47);
```

```
Integer myNumber = myList.get(0);
system.assertEquals(47, myNumber);
```

```
List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
```

getSObjectType()

Returns the token of the sObject type that makes up a list of sObjects.

Signature

```
public Schema.SObjectType getSObjectType()
```

Return Value

Type: Schema.SObjectType

Usage

Use this method with describe information to determine if a list contains sObjects of a particular type.

Note that this method can only be used with lists that are composed of sObjects.

For more information, see Understanding Apex Describe Information on page 170.

Example

```
// Create a generic sObject variable.
SObject sObj = Database.query('SELECT Id FROM Account LIMIT 1');

// Verify if that sObject  variable is an Account token.
System.assertEquals(
   Account.sObjectType,
   sObj.getSObjectType());

// Create a list of generic sObjects.
List<sObject> q = new Account[]{};

// Verify if the list of sObjects
// contains Account tokens.
System.assertEquals(
   Account.sObjectType,
   q.getSObjectType());
```

hashCode()

Returns the hashcode corresponding to this list and its contents.

Signature

```
public Integer hashCode()
```

Return Value

Type: Integer

indexOf(listElement)

Returns the index of the first occurrence of the specified element in this list. If this list does not contain the element, returns -1.

Signature

```
public Integer indexOf(Object listElement)
```

Parameters

listElement
Type: Object

Return Value

Type: Integer

Example

```
List<String> myStrings = new List<String>{'a', 'b', 'a'};
Integer result = myStrings.indexOf('a');
System.assertEquals(0, result);
```

isEmpty()

Returns true if the list has zero elements.

Signature

```
public Boolean isEmpty()
```

Return Value

Type: Boolean

iterator()

Returns an instance of an iterator for this list.

Signature

```
public Iterator iterator()
```

Return Value

Type: Iterator

Usage

From the returned iterator, you can use the iterable methods `hasNext` and `next` to iterate through the list.

Note: You do not have to implement the `iterable` interface to use the `iterable` methods with a list.

See Custom Iterators.

Example

```
global class CustomIterable
   implements Iterator<Account>{

   List<Account> accs {get; set;}
   Integer i {get; set;}

   public CustomIterable(){
       accs =
       [SELECT Id, Name,
       NumberOfEmployees
       FROM Account
       WHERE Name = 'false'];
       i = 0;
   }

   global boolean hasNext(){
       if(i >= accs.size()) {
           return false;
       } else {
           return true;
       }
   }

   global Account next(){
       // 8 is an arbitrary
       // constant in this example
       // that represents the
       // maximum size of the list.
       if(i == 8){return null;}
       i++;
       return accs[i-1];
   }
}
```

`remove(index)`

Removes the list element stored at the specified index, returning the element that was removed.

Signature

```
public Object remove(Integer index)
```

Parameters

index
Type: Integer

Return Value

Type: Object

Example

```
List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
String s1 = colors.remove(2);
system.assertEquals('Green', s1);
```

set(index, listElement)

Sets the specified value for the element at the given index.

Signature

```
public Void set(Integer index, Object listElement)
```

Parameters

index
Type: Integer

The index of the list element to set.

listElement
Type: Object

The value of the list element to set.

Return Value

Type: Void

Usage

To set an element of a one-dimensional list of primitives or sObjects, you can also follow the name of the list with the element's index position in square brackets.

Example

```
List<Integer> myList = new Integer[6];
myList.set(0, 47);
myList.set(1, 52);
system.assertEquals(52, myList.get(1));
```

```
List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
```

size()

Returns the number of elements in the list.

Signature

```
public Integer size()
```

Return Value

Type: Integer

Example

```
List<Integer> myList = new List<Integer>();
Integer size = myList.size();
system.assertEquals(0, size);

List<Integer> myList2 = new Integer[6];
Integer size2 = myList2.size();
system.assertEquals(6, size2);
```

sort()

Sorts the items in the list in ascending order.

Signature

```
public Void sort()
```

Return Value

Type: Void

Usage

Using this method, you can sort primitive types, SelectOption elements, and sObjects (standard objects and custom objects). For more information on the sort order used for sObjects, see Sorting Lists of sObjects. You can also sort custom types (your Apex classes) if they implement the Comparable Interface interface.

When you use `sort()` methods on `List<Id>`s that contain both 15-character and 18-character IDs, IDs for the same record sort together in API version 35.0 and later.

Example

In the following example, the list has three elements. When the list is sorted, the first element is null because it has no value assigned while the second element has the value of 5.

```
List<Integer> q1 = new Integer[3];

// Assign values to the first two elements.
q1[0] = 10;
q1[1] = 5;

q1.sort();
// First element is null, second is 5.
system.assertEquals(5, q1.get(1));
```

Location Class

Contains methods for accessing the component fields of geolocation compound fields.

Namespace

system

Usage

Each of these methods is also equivalent to a read-only property. For each getter method you can access the property using dot notation. For example, `myLocation.getLatitude()` is equivalent to `myLocation.latitude`.

You can't use dot notation to access compound fields' subfields directly on the parent field. Instead, assign the parent field to a variable of type `Location`, and then access its components.

```
Location loc = myAccount.MyLocation__c;
Double lat = loc.latitude;
```

Important: "Location" in Salesforce can also refer to the Location standard object. When referencing the Location object in your Apex code, always use `Schema.Location` instead of `Location` to prevent confusion with the standard Location compound field. If referencing both the location object and the Location field in the same snippet, you can differentiate between the two by using `System.Location` for the field and `Schema.Location` for the object.

Example

```
// Select and access the Location field. MyLocation__c is the name of a geolocation field
 on Account.
Account[] records = [SELECT id, MyLocation__c FROM Account LIMIT 10];
for(Account acct : records) {
   Location loc = acct.MyLocation__c;
   Double lat = loc.latitude;
   Double lon = loc.longitude;
```

```
}

// Instantiate new Location objects and compute the distance between them in different
ways.
Location loc1 = Location.newInstance(28.635308,77.22496);
Location loc2 = Location.newInstance(37.7749295,-122.4194155);
Double dist = Location.getDistance(loc1, loc2, 'mi');
Double dist2 = loc1.getDistance(loc2, 'mi');
```

IN THIS SECTION:

Location Methods

Location Methods

The following are methods for `Location`.

IN THIS SECTION:

getDistance(toLocation, unit)
Calculates the distance between this location and the specified location, using an approximation of the haversine formula and the specified unit.

getDistance(firstLocation, secondLocation, unit)
Calculates the distance between the two specified locations, using an approximation of the haversine formula and the specified unit.

getLatitude()
Returns the latitude field of this location.

getLongitude()
Returns the longitude field of this location.

newInstance(latitude, longitude)
Creates an instance of the `Location` class, with the specified latitude and longitude.

`getDistance(toLocation, unit)`

Calculates the distance between this location and the specified location, using an approximation of the haversine formula and the specified unit.

Signature

```
public Double getDistance(Location toLocation, String unit)
```

Parameters

`toLocation`
Type: Location

The `Location` to which you want to calculate the distance from the current `Location`.

`unit`
Type: String

The distance unit you want to use: `mi` or `km`.

Return Value

Type: Double

getDistance(firstLocation, secondLocation, unit)

Calculates the distance between the two specified locations, using an approximation of the haversine formula and the specified unit.

Signature

```
public static Double getDistance(Location firstLocation, Location secondLocation, String unit)
```

Parameters

firstLocation
Type: Location

The first of two locations used to calculate distance.

secondLocation
Type: Location

The second of two locations used to calculate distance.

unit
Type: String

The distance unit you want to use: `mi` or `km`.

Return Value

Type: Double

getLatitude()

Returns the latitude field of this location.

Signature

```
public Double getLatitude()
```

Return Value

Type: Double

getLongitude()

Returns the longitude field of this location.

Signature

```
public Double getLongitude()
```

Return Value

Type: Double

`newInstance(latitude, longitude)`

Creates an instance of the `Location` class, with the specified latitude and longitude.

Signature

```
public static Location newInstance(Decimal latitude, Decimal longitude)
```

Parameters

`latitude`
Type: Decimal

`longitude`
Type: Decimal

Return Value

Type: Location

Long Class

Contains methods for the Long primitive data type.

Namespace

System

Usage

For more information on Long, see Primitive Data Types on page 26.

Long Methods

The following are methods for `Long`.

IN THIS SECTION:

format()
Returns the String format for this Long using the locale of the context user.

intValue()
Returns the Integer value for this Long.

valueOf(stringToLong)

Returns a Long that contains the value of the specified String. As in Java, the string is interpreted as representing a signed decimal Long.

format()

Returns the String format for this Long using the locale of the context user.

Signature

```
public String format()
```

Return Value

Type: String

Example

```
Long myLong = 4271990;
system.assertEquals('4,271,990', myLong.format());
```

intValue()

Returns the Integer value for this Long.

Signature

```
public Integer intValue()
```

Return Value

Type: Integer

Example

```
Long myLong = 7191991;
Integer value = myLong.intValue();
system.assertEquals(7191991, myLong.intValue());
```

valueOf(stringToLong)

Returns a Long that contains the value of the specified String. As in Java, the string is interpreted as representing a signed decimal Long.

Signature

```
public static Long valueOf(String stringToLong)
```

Parameters

stringToLong
Type: String

Return Value

Type: Long

Example

```
Long L1 = long.valueOf('123456789');
```

Map Class

Contains methods for the Map collection type.

Namespace

System

Usage

The Map methods are all instance methods, that is, they operate on a particular instance of a map. The following are the instance methods for maps.

Note:

- Map keys and values can be of any data type—primitive types, collections, sObjects, user-defined types, and built-in Apex types.
- Uniqueness of map keys of user-defined types is determined by the `equals` and `hashCode` methods, which you provide in your classes. Uniqueness of keys of all other non-primitive types, such as sObject keys, is determined by comparing the objects' field values.
- Map keys of type String are case-sensitive. Two keys that differ only by the case are considered unique and have corresponding distinct Map entries. Subsequently, the Map methods, including `put`, `get`, `containsKey`, and `remove` treat these keys as distinct.

For more information on maps, see Maps on page 33.

IN THIS SECTION:

Map Constructors
Map Methods

Map Constructors

The following are constructors for `Map`.

IN THIS SECTION:

Map<T1,T2>()
Creates a new instance of the Map class. T1 is the data type of the keys and T2 is the data type of the values.

Map<T1,T2>(mapToCopy)
Creates a new instance of the Map class and initializes it by copying the entries from the specified map. T1 is the data type of the keys and T2 is the data type of the values.

Map<ID,sObject>(recordList)
Creates a new instance of the Map class and populates it with the passed-in list of sObject records. The keys are populated with the sObject IDs and the values are the sObjects.

Map<T1,T2>()

Creates a new instance of the Map class. T1 is the data type of the keys and T2 is the data type of the values.

Signature

```
public Map<T1,T2>()
```

Example

```
Map<Integer, String> m1 = new Map<Integer, String>();
m1.put(1, 'First item');
m1.put(2, 'Second item');
```

Map<T1,T2>(mapToCopy)

Creates a new instance of the Map class and initializes it by copying the entries from the specified map. T1 is the data type of the keys and T2 is the data type of the values.

Signature

```
public Map<T1,T2>(Map<T1,T2> mapToCopy)
```

Parameters

mapToCopy
Type: Map<T1, T2>

The map to initialize this map with. T1 is the data type of the keys and T2 is the data type of the values. All map keys and values are copied to this map.

Example

```
Map<Integer, String> m1 = new Map<Integer, String>();
m1.put(1, 'First item');
m1.put(2, 'Second item');
Map<Integer, String> m2 = new Map<Integer, String>(m1);
// The map elements of m2 are copied from m1
System.debug(m2);
```

`Map<ID,sObject>(recordList)`

Creates a new instance of the `Map` class and populates it with the passed-in list of sObject records. The keys are populated with the sObject IDs and the values are the sObjects.

Signature

```
public Map<ID,sObject>(List<sObject> recordList)
```

Parameters

`recordList`
Type: List<sObject>

The list of sObjects to populate the map with.

Example

```
List<Account> ls = [select Id,Name from Account];
Map<Id, Account> m = new Map<Id, Account>(ls);
```

Map Methods

The following are methods for `Map`. All are instance methods.

IN THIS SECTION:

clear()
Removes all of the key-value mappings from the map.

clone()
Makes a duplicate copy of the map.

containsKey(key)
Returns `true` if the map contains a mapping for the specified key.

deepClone()
Makes a duplicate copy of a map, including sObject records if this is a map with sObject record values.

equals(map2)
Compares this map with the specified map and returns `true` if both maps are equal; otherwise, returns `false`.

get(key)
Returns the value to which the specified key is mapped, or `null` if the map contains no value for this key.

getSObjectType()
Returns the token of the sObject type that makes up the map values.

hashCode()
Returns the hashcode corresponding to this map.

isEmpty()
Returns true if the map has zero key-value pairs.

keySet()
Returns a set that contains all of the keys in the map.

put(key, value)
Associates the specified value with the specified key in the map.

putAll(fromMap)
Copies all of the mappings from the specified map to the original map.

putAll(sobjectArray)
Adds the list of sObject records to a map declared as Map<ID, sObject> or Map<String, sObject>.

remove(key)
Removes the mapping for the specified key from the map, if present, and returns the corresponding value.

size()
Returns the number of key-value pairs in the map.

values()
Returns a list that contains all the values in the map.

clear()

Removes all of the key-value mappings from the map.

Signature

```
public Void clear()
```

Return Value

Type: Void

clone()

Makes a duplicate copy of the map.

Signature

```
public Map<Object, Object> clone()
```

Return Value

Type: Map (of same type)

Usage

If this is a map with sObject record values, the duplicate map will only be a shallow copy of the map. That is, the duplicate will have references to each sObject record, but the records themselves are not duplicated. For example:

To also copy the sObject records, you must use the `deepClone` method.

Example

```
Account a = new Account(
   Name='Acme',
   BillingCity='New York');
```

```
Map<Integer, Account> map1 = new Map<Integer, Account> {};
map1.put(1, a);

Map<Integer, Account> map2 = map1.clone();
map1.get(1).BillingCity =
'San Francisco';

System.assertEquals(
   'San Francisco',
   map1.get(1).BillingCity);

System.assertEquals(
   'San Francisco',
   map2.get(1).BillingCity);
```

containsKey(key)

Returns `true` if the map contains a mapping for the specified key.

Signature

```
public Boolean containsKey(Object key)
```

Parameters

key
Type: Object

Return Value

Type: Boolean

Usage

If the key is a string, the key value is case-sensitive.

Example

```
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

Boolean contains = colorCodes.containsKey('Blue');
System.assertEquals(true, contains);
```

deepClone()

Makes a duplicate copy of a map, including sObject records if this is a map with sObject record values.

Signature

```
public Map<Object, Object> deepClone()
```

Return Value

Type: Map (of the same type)

Usage

To make a shallow copy of a map without duplicating the sObject records it contains, use the `clone()` method.

Example

```
Account a = new Account(
   Name='Acme',
   BillingCity='New York');

Map<Integer, Account> map1 = new Map<Integer, Account> {};

map1.put(1, a);

Map<Integer, Account> map2 = map1.deepClone();

// Update the first entry of map1
map1.get(1).BillingCity = 'San Francisco';
// Verify that the BillingCity is updated in map1 but not in map2
System.assertEquals('San Francisco', map1.get(1).BillingCity);
System.assertEquals('New York', map2.get(1).BillingCity);
```

`equals(map2)`

Compares this map with the specified map and returns `true` if both maps are equal; otherwise, returns `false`.

Signature

```
public Boolean equals(Map map2)
```

Parameters

`map2`
Type: Map

The *`map2`* argument is the map to compare this map with.

Return Value

Type: Boolean

Usage

Two maps are equal if their key/value pairs are identical, regardless of the order of those pairs. The `==` operator is used to compare the map keys and values.

The == operator is equivalent to calling the `equals` method, so you can call `map1.equals(map2);` instead of `map1 == map2;`.

get(key)

Returns the value to which the specified key is mapped, or `null` if the map contains no value for this key.

Signature

```
public Object get(Object key)
```

Parameters

key
Type: Object

Return Value

Type: Object

Usage

If the key is a string, the key value is case-sensitive.

Example

```
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

String code = colorCodes.get('Blue');

System.assertEquals('0000A0', code);

// The following is not a color in the map
String code2 = colorCodes.get('Magenta');
System.assertEquals(null, code2);
```

getSObjectType()

Returns the token of the sObject type that makes up the map values.

Signature

```
public Schema.SObjectType getSObjectType()
```

Return Value

Type: Schema.SObjectType

Usage

Use this method with describe information, to determine if a map contains sObjects of a particular type.

Note that this method can only be used with maps that have sObject values.

For more information, see Understanding Apex Describe Information on page 170.

Example

```
// Create a generic sObject variable.
SObject sObj = Database.query('SELECT Id FROM Account LIMIT 1');

// Verify if that sObject variable is an Account token.
System.assertEquals(
   Account.sObjectType,
   sObj.getSObjectType());

// Create a map of generic sObjects
Map<Integer, Account> m = new Map<Integer, Account>();

// Verify if the map contains Account tokens.
System.assertEquals(
   Account.sObjectType,
   m.getSObjectType());
```

hashCode()

Returns the hashcode corresponding to this map.

Signature

```
public Integer hashCode()
```

Return Value

Type: Integer

isEmpty()

Returns true if the map has zero key-value pairs.

Signature

```
public Boolean isEmpty()
```

Return Value

Type: Boolean

Example

```
Map<String, String> colorCodes = new Map<String, String>();
Boolean empty = colorCodes.isEmpty();
System.assertEquals(true, empty);
```

keySet()

Returns a set that contains all of the keys in the map.

Signature

```
public Set<Object> keySet()
```

Return Value

Type: Set (of key type)

Example

```
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

Set <String> colorSet = new Set<String>();
colorSet = colorCodes.keySet();
```

put(key, value)

Associates the specified value with the specified key in the map.

Signature

```
public Object put(Object key, Object value)
```

Parameters

key
Type: Object

value
Type: Object

Return Value

Type: Object

Usage

If the map previously contained a mapping for this key, the old value is returned by the method and then replaced.

If the key is a string, the key value is case-sensitive.

Example

```
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'ff0000');
colorCodes.put('Red', '#FF0000');
// Red is now #FF0000
```

putAll(fromMap)

Copies all of the mappings from the specified map to the original map.

Signature

```
public Void putAll(Map fromMap)
```

Parameters

fromMap
Type: Map

Return Value

Type: Void

Usage

The new mappings from *fromMap* replace any mappings that the original map had.

Example

```
Map<String, String> map1 = new Map<String, String>();
map1.put('Red','FF0000');
Map<String, String> map2 = new Map<String, String>();
map2.put('Blue','0000FF');
// Add map1 entries to map2
map2.putAll(map1);
System.assertEquals(2, map2.size());
```

putAll(sobjectArray)

Adds the list of sObject records to a map declared as Map<ID, sObject> or Map<String, sObject>.

Signature

```
public Void putAll(sObject[] sobjectArray)
```

Parameters

sobjectArray
Type: sObject[]

Return Value

Type: Void

Usage

This method is similar to calling the Map constructor with the same input.

Example

```
List<Account> accts = new List<Account>();
accts.add(new Account(Name='Account1'));
accts.add(new Account(Name='Account2'));
// Insert accounts so their IDs are populated.
insert accts;
Map<Id, Account> m = new Map<Id, Account>();
// Add all the records to the map.
m.putAll(accts);
System.assertEquals(2, m.size());
```

remove(key)

Removes the mapping for the specified key from the map, if present, and returns the corresponding value.

Signature

```
public Object remove(Key key)
```

Parameters

key
Type: Key

Return Value

Type: Object

Usage

If the key is a string, the key value is case-sensitive.

Example

```
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

String myColor = colorCodes.remove('Blue');
String code2 = colorCodes.get('Blue');

System.assertEquals(null, code2);
```

size()

Returns the number of key-value pairs in the map.

Signature

```
public Integer size()
```

Return Value

Type: Integer

Example

```
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

Integer mSize = colorCodes.size();
system.assertEquals(2, mSize);
```

values()

Returns a list that contains all the values in the map.

Signature

```
public List<Object> values()
```

Return Value

Type: List<Object>

Usage

The order of map elements is deterministic. You can rely on the order being the same in each subsequent execution of the same code. For example, suppose the `values()` method returns a list containing `value1` and index 0 and `value2` and index 1. Subsequent runs of the same code result in those values being returned in the same order.

Example

```
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

List<String> colors = new List<String>();
colors = colorCodes.values();
```

Matcher Class

Matchers use Patterns to perform match operations on a character string.

Namespace

System

Matcher Methods

The following are methods for `Matcher`.

IN THIS SECTION:

end()

Returns the position after the last matched character.

end(groupIndex)

Returns the position after the last character of the subsequence captured by the group index during the previous match operation. If the match was successful but the group itself did not match anything, this method returns -1.

find()

Attempts to find the next subsequence of the input sequence that matches the pattern. This method returns true if a subsequence of the input sequence matches this Matcher object's pattern.

find(group)

Resets the Matcher object and then tries to find the next subsequence of the input sequence that matches the pattern. This method returns `true` if a subsequence of the input sequence matches this Matcher object's pattern.

group()

Returns the input subsequence returned by the previous match.

group(groupIndex)

Returns the input subsequence captured by the specified group index during the previous match operation. If the match was successful but the specified group failed to match any part of the input sequence, `null` is returned.

groupCount()

Returns the number of capturing groups in this Matching object's pattern. Group zero denotes the entire pattern and is not included in this count.

hasAnchoringBounds()

Returns true if the Matcher object has anchoring bounds, false otherwise. By default, a Matcher object uses anchoring bounds regions.

hasTransparentBounds()

Returns true if the Matcher object has transparent bounds, false if it uses opaque bounds. By default, a Matcher object uses opaque region boundaries.

hitEnd()

Returns true if the end of input was found by the search engine in the last match operation performed by this Matcher object. When this method returns true, it is possible that more input would have changed the result of the last search.

lookingAt()

Attempts to match the input sequence, starting at the beginning of the region, against the pattern.

matches()

Attempts to match the entire region against the pattern.

pattern()

Returns the Pattern object from which this Matcher object was created.

quoteReplacement(inputString)

Returns a literal replacement string for the specified string *`inputString`*. The characters in the returned string match the sequence of characters in *`inputString`*.

region(start, end)

Sets the limits of this Matcher object's region. The region is the part of the input sequence that is searched to find a match.

regionEnd()

Returns the end index (exclusive) of this Matcher object's region.

regionStart()

Returns the start index (inclusive) of this Matcher object's region.

replaceAll(replacementString)

Replaces every subsequence of the input sequence that matches the pattern with the replacement string.

replaceFirst(replacementString)

Replaces the first subsequence of the input sequence that matches the pattern with the replacement string.

requireEnd()

Returns true if more input could change a positive match into a negative one.

reset()

Resets this Matcher object. Resetting a Matcher object discards all of its explicit state information.

reset(inputSequence)

Resets this Matcher object with the new input sequence. Resetting a Matcher object discards all of its explicit state information.

start()

Returns the start index of the first character of the previous match.

start(groupIndex)

Returns the start index of the subsequence captured by the group specified by the group index during the previous match operation. Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression `m.start(0)` is equivalent to `m.start()`.

useAnchoringBounds(anchoringBounds)

Sets the anchoring bounds of the region for the Matcher object. By default, a Matcher object uses anchoring bounds regions.

usePattern(pattern)

Changes the Pattern object that the Matcher object uses to find matches. This method causes the Matcher object to lose information about the groups of the last match that occurred. The Matcher object's position in the input is maintained.

useTransparentBounds(transparentBounds)

Sets the transparency bounds for this Matcher object. By default, a Matcher object uses anchoring bounds regions.

`end()`

Returns the position after the last matched character.

Signature

```
public Integer end()
```

Return Value

Type: Integer

end(groupIndex)

Returns the position after the last character of the subsequence captured by the group index during the previous match operation. If the match was successful but the group itself did not match anything, this method returns -1.

Signature

```
public Integer end(Integer groupIndex)
```

Parameters

groupIndex
Type: Integer

Return Value

Type: Integer

Usage

Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression`m.end(0)` is equivalent to `m.end()`.

See Understanding Capturing Groups.

find()

Attempts to find the next subsequence of the input sequence that matches the pattern. This method returns true if a subsequence of the input sequence matches this Matcher object's pattern.

Signature

```
public Boolean find()
```

Return Value

Type: Boolean

Usage

This method starts at the beginning of this Matcher object's region, or, if a previous invocation of the method was successful and the Matcher object has not since been reset, at the first character not matched by the previous match.

If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.

For more information, see Using Regions.

find(group)

Resets the Matcher object and then tries to find the next subsequence of the input sequence that matches the pattern. This method returns `true` if a subsequence of the input sequence matches this Matcher object's pattern.

Signature

```
public Boolean find(Integer group)
```

Parameters

group
Type: Integer

Return Value

Type: Boolean

Usage

If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.

group()

Returns the input subsequence returned by the previous match.

Signature

```
public String group()
```

Return Value

Type: String

Usage

Note that some groups, such as `(a*)`, match the empty string. This method returns the empty string when such a group successfully matches the empty string in the input.

group(groupIndex)

Returns the input subsequence captured by the specified group index during the previous match operation. If the match was successful but the specified group failed to match any part of the input sequence, `null` is returned.

Signature

```
public String group(Integer groupIndex)
```

Parameters

groupIndex
Type: Integer

Return Value

Type: String

Usage

Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression `m.group(0)` is equivalent to `m.group()`.

Note that some groups, such as `(a*)`, match the empty string. This method returns the empty string when such a group successfully matches the empty string in the input.

See Understanding Capturing Groups.

groupCount()

Returns the number of capturing groups in this Matching object's pattern. Group zero denotes the entire pattern and is not included in this count.

Signature

```
public Integer groupCount()
```

Return Value

Type: Integer

Usage

See Understanding Capturing Groups.

hasAnchoringBounds()

Returns true if the Matcher object has anchoring bounds, false otherwise. By default, a Matcher object uses anchoring bounds regions.

Signature

```
public Boolean hasAnchoringBounds()
```

Return Value

Type: Boolean

Usage

If a Matcher object uses anchoring bounds, the boundaries of this Matcher object's region match start and end of line anchors such as ^ and $.

For more information, see Using Bounds.

hasTransparentBounds()

Returns true if the Matcher object has transparent bounds, false if it uses opaque bounds. By default, a Matcher object uses opaque region boundaries.

Signature

```
public Boolean hasTransparentBounds()
```

Return Value

Type: Boolean

Usage

For more information, see Using Bounds.

hitEnd()

Returns true if the end of input was found by the search engine in the last match operation performed by this Matcher object. When this method returns true, it is possible that more input would have changed the result of the last search.

Signature

```
public Boolean hitEnd()
```

Return Value

Type: Boolean

lookingAt()

Attempts to match the input sequence, starting at the beginning of the region, against the pattern.

Signature

```
public Boolean lookingAt()
```

Return Value

Type: Boolean

Usage

Like the `matches` method, this method always starts at the beginning of the region; unlike that method, it does not require the entire region be matched.

If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.

See Using Regions.

`matches()`

Attempts to match the entire region against the pattern.

Signature

```
public Boolean matches()
```

Return Value

Type: Boolean

Usage

If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.

See Using Regions.

`pattern()`

Returns the Pattern object from which this Matcher object was created.

Signature

```
public Pattern object pattern()
```

Return Value

Type: System.Pattern

`quoteReplacement(inputString)`

Returns a literal replacement string for the specified string *`inputString`*. The characters in the returned string match the sequence of characters in *`inputString`*.

Signature

```
public static String quoteReplacement(String inputString)
```

Parameters

`inputString`
Type: String

Return Value

Type: String

Usage

Metacharacters (such as `$` or `^`) and escape sequences in the input string are treated as literal characters with no special meaning.

region(start, end)

Sets the limits of this Matcher object's region. The region is the part of the input sequence that is searched to find a match.

Signature

```
public Matcher object region(Integer start, Integer end)
```

Parameters

start
Type: Integer

end
Type: Integer

Return Value

Type: Matcher

Usage

This method first resets the Matcher object, then sets the region to start at the index specified by `start` and end at the index specified by `end`.

Depending on the transparency boundaries being used, certain constructs such as anchors may behave differently at or around the boundaries of the region.

See Using Regions and Using Bounds.

regionEnd()

Returns the end index (exclusive) of this Matcher object's region.

Signature

```
public Integer regionEnd()
```

Return Value

Type: Integer

Usage

See Using Regions.

regionStart()

Returns the start index (inclusive) of this Matcher object's region.

Signature

```
public Integer regionStart()
```

Return Value

Type: Integer

Usage

See Using Regions.

replaceAll(replacementString)

Replaces every subsequence of the input sequence that matches the pattern with the replacement string.

Signature

```
public String replaceAll(String replacementString)
```

Parameters

replacementString
Type: String

Return Value

Type: String

Usage

This method first resets the Matcher object, then scans the input sequence looking for matches of the pattern. Characters that are not part of any match are appended directly to the result string; each match is replaced in the result by the replacement string. The replacement string may contain references to captured subsequences.

Note that backslashes (\) and dollar signs ($) in the replacement string may cause the results to be different than if the string was treated as a literal replacement string. Dollar signs may be treated as references to captured subsequences, and backslashes are used to escape literal characters in the replacement string.

Invoking this method changes this Matcher object's state. If the Matcher object is to be used in further matching operations it should first be reset.

Given the regular expression `a*b`, the input `"aabxyzaabxyzabxyzb"`, and the replacement string `"-"`, an invocation of this method on a Matcher object for that expression would yield the string `"-xyz-xyz-xyz-"`.

replaceFirst(replacementString)

Replaces the first subsequence of the input sequence that matches the pattern with the replacement string.

Signature

```
public String replaceFirst(String replacementString)
```

Parameters

replacementString
Type: String

Return Value

Type: String

Usage

Note that backslashes (\) and dollar signs ($) in the replacement string may cause the results to be different than if the string was treated as a literal replacement string. Dollar signs may be treated as references to captured subsequences, and backslashes are used to escape literal characters in the replacement string.

Invoking this method changes this Matcher object's state. If the Matcher object is to be used in further matching operations it should first be reset.

Given the regular expression `dog`, the input `"zzzdogzzzdogzzz"`, and the replacement string `"cat"`, an invocation of this method on a Matcher object for that expression would return the string `"zzzcatzzzdogzzz"`.

requireEnd()

Returns true if more input could change a positive match into a negative one.

Signature

```
public Boolean requireEnd()
```

Return Value

Type: Boolean

Usage

If this method returns true, and a match was found, then more input could cause the match to be lost.

If this method returns false and a match was found, then more input might change the match but the match won't be lost.

If a match was not found, then `requireEnd` has no meaning.

reset()

Resets this Matcher object. Resetting a Matcher object discards all of its explicit state information.

Signature

```
public Matcher object reset()
```

Return Value

Type: Matcher

Usage

This method does not change whether the Matcher object uses anchoring bounds. You must explicitly use the `useAnchoringBounds` method to change the anchoring bounds.

For more information, see Using Bounds.

reset(inputSequence)

Resets this Matcher object with the new input sequence. Resetting a Matcher object discards all of its explicit state information.

Signature

```
public Matcher reset(String inputSequence)
```

Parameters

inputSequence
Type: String

Return Value

Type: Matcher

start()

Returns the start index of the first character of the previous match.

Signature

```
public Integer start()
```

Return Value

Type: Integer

start(groupIndex)

Returns the start index of the subsequence captured by the group specified by the group index during the previous match operation. Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression `m.start(0)` is equivalent to `m.start()`.

Signature

```
public Integer start(Integer groupIndex)
```

Parameters

groupIndex
Type: Integer

Return Value

Type: Integer

Usage

See Understanding Capturing Groups on page 546.

useAnchoringBounds(anchoringBounds)

Sets the anchoring bounds of the region for the Matcher object. By default, a Matcher object uses anchoring bounds regions.

Signature

```
public Matcher object useAnchoringBounds(Boolean anchoringBounds)
```

Parameters

anchoringBounds
Type: Boolean

If you specify `true`, the Matcher object uses anchoring bounds. If you specify `false`, non-anchoring bounds are used.

Return Value

Type: Matcher

Usage

If a Matcher object uses anchoring bounds, the boundaries of this Matcher object's region match start and end of line anchors such as ^ and $.

For more information, see Using Bounds on page 545.

usePattern(pattern)

Changes the Pattern object that the Matcher object uses to find matches. This method causes the Matcher object to lose information about the groups of the last match that occurred. The Matcher object's position in the input is maintained.

Signature

```
public Matcher object usePattern(Pattern pattern)
```

Parameters

pattern
Type: System.Pattern

Return Value

Type: Matcher

useTransparentBounds(transparentBounds)

Sets the transparency bounds for this Matcher object. By default, a Matcher object uses anchoring bounds regions.

Signature

```
public Matcher object useTransparentBounds(Boolean transparentBounds)
```

Parameters

transparentBounds
Type: Boolean

If you specify `true`, the Matcher object uses transparent bounds. If you specify `false`, opaque bounds are used.

Return Value

Type: Matcher

Usage

For more information, see Using Bounds.

Math Class

Contains methods for mathematical operations.

Namespace

System

Math Fields

The following are fields for `Math`.

IN THIS SECTION:

E
Returns the mathematical constant *e*, which is the base of natural logarithms.

PI
Returns the mathematical constant *pi*, which is the ratio of the circumference of a circle to its diameter.

E

Returns the mathematical constant *e*, which is the base of natural logarithms.

Signature

```
public static final Double E
```

Property Value

Type: Double

PI

Returns the mathematical constant *pi*, which is the ratio of the circumference of a circle to its diameter.

Signature

```
public static final Double PI
```

Property Value

Type: Double

Math Methods

The following are methods for `Math`. All methods are static.

IN THIS SECTION:

abs(decimalValue)
Returns the absolute value of the specified Decimal.

abs(doubleValue)
Returns the absolute value of the specified Double.

abs(integerValue)
Returns the absolute value of the specified Integer.

abs(longValue)
Returns the absolute value of the specified Long.

acos(decimalAngle)
Returns the arc cosine of an angle, in the range of 0.0 through *pi*.

acos(doubleAngle)
Returns the arc cosine of an angle, in the range of 0.0 through *pi*.

asin(decimalAngle)
Returns the arc sine of an angle, in the range of -*pi*/2 through *pi*/2.

asin(doubleAngle)
Returns the arc sine of an angle, in the range of -*pi*/2 through *pi*/2.

atan(decimalAngle)
Returns the arc tangent of an angle, in the range of -*pi*/2 through *pi*/2.

atan(doubleAngle)
Returns the arc tangent of an angle, in the range of -*pi*/2 through *pi*/2.

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates (*`xCoordinate`* and *`yCoordinate`*) to polar (*`r`* and *`theta`*). This method computes the phase *`theta`* by computing an arc tangent of *`xCoordinate`*/*`yCoordinate`* in the range of -*pi* to *pi*.

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates (*`xCoordinate`* and *`yCoordinate`*) to polar (*`r`* and *`theta`*). This method computes the phase *`theta`* by computing an arc tangent of *`xCoordinate`*/*`yCoordinate`* in the range of -*pi* to *pi*.

cbrt(decimalValue)
Returns the cube root of the specified Decimal. The cube root of a negative value is the negative of the cube root of that value's magnitude.

cbrt(doubleValue)

Returns the cube root of the specified Double. The cube root of a negative value is the negative of the cube root of that value's magnitude.

ceil(decimalValue)

Returns the smallest (closest to negative infinity) Decimal that is not less than the argument and is equal to a mathematical integer.

ceil(doubleValue)

Returns the smallest (closest to negative infinity) Double that is not less than the argument and is equal to a mathematical integer.

cos(decimalAngle)

Returns the trigonometric cosine of the angle specified by `decimalAngle`.

cos(doubleAngle)

Returns the trigonometric cosine of the angle specified by `doubleAngle`.

cosh(decimalAngle)

Returns the hyperbolic cosine of `decimalAngle`. The hyperbolic cosine of `d` is defined to be $(e^x + e^{-x})/2$ where *e* is Euler's number.

cosh(doubleAngle)

Returns the hyperbolic cosine of `doubleAngle`. The hyperbolic cosine of `d` is defined to be $(e^x + e^{-x})/2$ where *e* is Euler's number.

exp(exponentDecimal)

Returns Euler's number *e* raised to the power of the specified Decimal.

exp(exponentDouble)

Returns Euler's number *e* raised to the power of the specified Double.

floor(decimalValue)

Returns the largest (closest to positive infinity) Decimal that is not greater than the argument and is equal to a mathematical integer.

floor(doubleValue)

Returns the largest (closest to positive infinity) Double that is not greater than the argument and is equal to a mathematical integer.

log(decimalValue)

Returns the natural logarithm (base *e*) of the specified Decimal.

log(doubleValue)

Returns the natural logarithm (base *e*) of the specified Double.

log10(decimalValue)

Returns the logarithm (base *10*) of the specified Decimal.

log10(doubleValue)

Returns the logarithm (base *10*) of the specified Double.

max(decimalValue1, decimalValue2)

Returns the larger of the two specified Decimals.

max(doubleValue1, doubleValue2)

Returns the larger of the two specified Doubles.

max(integerValue1, integerValue2)

Returns the larger of the two specified Integers.

max(longValue1, longValue2)

Returns the larger of the two specified Longs.

min(decimalValue1, decimalValue2)

Returns the smaller of the two specified Decimals.

min(doubleValue1, doubleValue2)

Returns the smaller of the two specified Doubles.

min(integerValue1, integerValue2)

Returns the smaller of the two specified Integers.

min(longValue1, longValue2)

Returns the smaller of the two specified Longs.

mod(integerValue1, integerValue2)

Returns the remainder of *integerValue1* divided by *integerValue2*.

mod(longValue1, longValue2)

Returns the remainder of *longValue1* divided by *longValue2*.

pow(doubleValue, exponent)

Returns the value of the first Double raised to the power of *exponent*.

random()

Returns a positive Double that is greater than or equal to 0.0 and less than 1.0.

rint(decimalValue)

Returns the value that is closest in value to *decimalValue* and is equal to a mathematical integer.

rint(doubleValue)

Returns the value that is closest in value to *doubleValue* and is equal to a mathematical integer.

round(doubleValue)

Do not use. This method is deprecated as of the Winter '08 release. Instead, use `Math.roundToLong`. Returns the closest Integer to the specified Double. If the result is less than -2,147,483,648 or greater than 2,147,483,647, Apex generates an error.

round(decimalValue)

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the "nearest neighbor" unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

roundToLong(decimalValue)

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the "nearest neighbor" unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

roundToLong(doubleValue)

Returns the closest Long to the specified Double.

signum(decimalValue)

Returns the signum function of the specified Decimal, which is 0 if *decimalValue* is 0, 1.0 if *decimalValue* is greater than 0, -1.0 if *decimalValue* is less than 0.

signum(doubleValue)

Returns the signum function of the specified Double, which is 0 if *doubleValue* is 0, 1.0 if *doubleValue* is greater than 0, -1.0 if *doubleValue* is less than 0.

sin(decimalAngle)

Returns the trigonometric sine of the angle specified by *decimalAngle*.

sin(doubleAngle)

Returns the trigonometric sine of the angle specified by *doubleAngle*.

sinh(decimalAngle)

Returns the hyperbolic sine of `decimalAngle`. The hyperbolic sine of `decimalAngle` is defined to be $(e^x - e^{-x})/2$ where e is Euler's number.

sinh(doubleAngle)

Returns the hyperbolic sine of `doubleAngle`. The hyperbolic sine of `doubleAngle` is defined to be $(e^x - e^{-x})/2$ where e is Euler's number.

sqrt(decimalValue)

Returns the correctly rounded positive square root of `decimalValue`.

sqrt(doubleValue)

Returns the correctly rounded positive square root of `doubleValue`.

tan(decimalAngle)

Returns the trigonometric tangent of the angle specified by `decimalAngle`.

tan(doubleAngle)

Returns the trigonometric tangent of the angle specified by `doubleAngle`.

tanh(decimalAngle)

Returns the hyperbolic tangent of `decimalAngle`. The hyperbolic tangent of `decimalAngle` is defined to be $(e^x - e^{-x})/(e^x + e^{-x})$ where e is Euler's number. In other words, it is equivalent to `sinh(x)/cosinh(x)`. The absolute value of the exact `tanh` is always less than 1.

tanh(doubleAngle)

Returns the hyperbolic tangent of `doubleAngle`. The hyperbolic tangent of `doubleAngle` is defined to be $(e^x - e^{-x})/(e^x + e^{-x})$ where e is Euler's number. In other words, it is equivalent to `sinh(x)/cosinh(x)`. The absolute value of the exact `tanh` is always less than 1.

abs(decimalValue)

Returns the absolute value of the specified Decimal.

Signature

```
public static Decimal abs(Decimal decimalValue)
```

Parameters

decimalValue
Type: Decimal

Return Value

Type: Decimal

abs(doubleValue)

Returns the absolute value of the specified Double.

Signature

```
public static Double abs(Double doubleValue)
```

Parameters

doubleValue
Type: Double

Return Value

Type: Double

abs(integerValue)

Returns the absolute value of the specified Integer.

Signature

```
public static Integer abs(Integer integerValue)
```

Parameters

integerValue
Type: Integer

Return Value

Type: Integer

Example

```
Integer i = -42;
Integer i2 = math.abs(i);
system.assertEquals(i2, 42);
```

abs(longValue)

Returns the absolute value of the specified Long.

Signature

```
public static Long abs(Long longValue)
```

Parameters

longValue
Type: Long

Return Value

Type: Long

acos(decimalAngle)

Returns the arc cosine of an angle, in the range of 0.0 through *pi*.

Signature

```
public static Decimal acos(Decimal decimalAngle)
```

Parameters

decimalAngle
Type: Decimal

Return Value

Type: Decimal

acos(doubleAngle)

Returns the arc cosine of an angle, in the range of 0.0 through *pi*.

Signature

```
public static Double acos(Double doubleAngle)
```

Parameters

doubleAngle
Type: Double

Return Value

Type: Double

asin(decimalAngle)

Returns the arc sine of an angle, in the range of *-pi*/2 through *pi*/2.

Signature

```
public static Decimal asin(Decimal decimalAngle)
```

Parameters

decimalAngle
Type: Decimal

Return Value

Type: Decimal

asin(doubleAngle)

Returns the arc sine of an angle, in the range of *-pi*/2 through *pi*/2.

Signature

```
public static Double asin(Double doubleAngle)
```

Parameters

doubleAngle
Type: Double

Return Value

Type: Double

atan(decimalAngle)

Returns the arc tangent of an angle, in the range of *-pi*/2 through *pi*/2.

Signature

```
public static Decimal atan(Decimal decimalAngle)
```

Parameters

decimalAngle
Type: Decimal

Return Value

Type: Decimal

atan(doubleAngle)

Returns the arc tangent of an angle, in the range of *-pi*/2 through *pi*/2.

Signature

```
public static Double atan(Double doubleAngle)
```

Parameters

doubleAngle
Type: Double

Return Value

Type: Double

atan2(xCoordinate, yCoordinate)

Converts rectangular coordinates (*xCoordinate* and *yCoordinate*) to polar (*r* and *theta*). This method computes the phase *theta* by computing an arc tangent of *xCoordinate*/*yCoordinate* in the range of -*pi* to *pi*.

Signature

```
public static Decimal atan2(Decimal xCoordinate, Decimal yCoordinate)
```

Parameters

xCoordinate
Type: Decimal

yCoordinate
Type: Decimal

Return Value

Type: Decimal

atan2(xCoordinate, yCoordinate)

Converts rectangular coordinates (*xCoordinate* and *yCoordinate*) to polar (*r* and *theta*). This method computes the phase *theta* by computing an arc tangent of *xCoordinate*/*yCoordinate* in the range of -*pi* to *pi*.

Signature

```
public static Double atan2(Double xCoordinate, Double yCoordinate)
```

Parameters

xCoordinate
Type: Double

yCoordinate
Type: Double

Return Value

Type: Double

cbrt(decimalValue)

Returns the cube root of the specified Decimal. The cube root of a negative value is the negative of the cube root of that value's magnitude.

Signature

```
public static Decimal cbrt(Decimal decimalValue)
```

Parameters

decimalValue
Type: Decimal

Return Value

Type: Decimal

cbrt(doubleValue)

Returns the cube root of the specified Double. The cube root of a negative value is the negative of the cube root of that value's magnitude.

Signature

```
public static Double cbrt(Double doubleValue)
```

Parameters

doubleValue
Type: Double

Return Value

Type: Double

ceil(decimalValue)

Returns the smallest (closest to negative infinity) Decimal that is not less than the argument and is equal to a mathematical integer.

Signature

```
public static Decimal ceil(Decimal decimalValue)
```

Parameters

decimalValue
Type: Decimal

Return Value

Type: Decimal

ceil(doubleValue)

Returns the smallest (closest to negative infinity) Double that is not less than the argument and is equal to a mathematical integer.

Signature

```
public static Double ceil(Double doubleValue)
```

Parameters

doubleValue
Type: Double

Return Value

Type: Double

cos(decimalAngle)

Returns the trigonometric cosine of the angle specified by *decimalAngle*.

Signature

```
public static Decimal cos(Decimal decimalAngle)
```

Parameters

decimalAngle
Type: Decimal

Return Value

Type: Decimal

cos(doubleAngle)

Returns the trigonometric cosine of the angle specified by *doubleAngle*.

Signature

```
public static Double cos(Double doubleAngle)
```

Parameters

doubleAngle
Type: Double

Return Value

Type: Double

cosh(decimalAngle)

Returns the hyperbolic cosine of *decimalAngle*. The hyperbolic cosine of *d* is defined to be $(e^X + e^{-X})/2$ where *e* is Euler's number.

Signature

```
public static Decimal cosh(Decimal decimalAngle)
```

Parameters

decimalAngle
Type: Decimal

Return Value

Type: Decimal

cosh(doubleAngle)

Returns the hyperbolic cosine of *doubleAngle*. The hyperbolic cosine of *d* is defined to be $(e^X + e^{-X})/2$ where *e* is Euler's number.

Signature

```
public static Double cosh(Double doubleAngle)
```

Parameters

doubleAngle
Type: Double

Return Value

Type: Double

exp(exponentDecimal)

Returns Euler's number *e* raised to the power of the specified Decimal.

Signature

```
public static Decimal exp(Decimal exponentDecimal)
```

Parameters

exponentDecimal
Type: Decimal

Return Value

Type: Decimal

exp(exponentDouble)

Returns Euler's number *e* raised to the power of the specified Double.

Signature

```
public static Double exp(Double exponentDouble)
```

Parameters

exponentDouble
Type: Double

Return Value

Type: Double

floor(decimalValue)

Returns the largest (closest to positive infinity) Decimal that is not greater than the argument and is equal to a mathematical integer.

Signature

```
public static Decimal floor(Decimal decimalValue)
```

Parameters

decimalValue
Type: Decimal

Return Value

Type: Decimal

floor(doubleValue)

Returns the largest (closest to positive infinity) Double that is not greater than the argument and is equal to a mathematical integer.

Signature

```
public static Double floor(Double doubleValue)
```

Parameters

doubleValue
Type: Double

Return Value

Type: Double

log(decimalValue)

Returns the natural logarithm (base *e*) of the specified Decimal.

Signature

```
public static Decimal log(Decimal decimalValue)
```

Parameters

decimalValue
Type: Decimal

Return Value

Type: Decimal

log(doubleValue)

Returns the natural logarithm (base *e*) of the specified Double.

Signature

```
public static Double log(Double doubleValue)
```

Parameters

doubleValue
Type: Double

Return Value

Type: Double

log10(decimalValue)

Returns the logarithm (base *10*) of the specified Decimal.

Signature

```
public static Decimal log10(Decimal decimalValue)
```

Parameters

decimalValue
Type: Decimal

Return Value

Type: Decimal

log10(doubleValue)

Returns the logarithm (base *10*) of the specified Double.

Signature

```
public static Double log10(Double doubleValue)
```

Parameters

doubleValue
Type: Double

Return Value

Type: Double

max(decimalValue1, decimalValue2)

Returns the larger of the two specified Decimals.

Signature

```
public static Decimal max(Decimal decimalValue1, Decimal decimalValue2)
```

Parameters

decimalValue1
Type: Decimal

decimalValue2
Type: Decimal

Return Value

Type: Decimal

Example

```
Decimal larger = math.max(12.3, 156.6);
system.assertEquals(larger, 156.6);
```

max(doubleValue1, doubleValue2)

Returns the larger of the two specified Doubles.

Signature

```
public static Double max(Double doubleValue1, Double doubleValue2)
```

Parameters

doubleValue1
Type: Double

doubleValue2
Type: Double

Return Value

Type: Double

max(integerValue1, integerValue2)

Returns the larger of the two specified Integers.

Signature

```
public static Integer max(Integer integerValue1, Integer integerValue2)
```

Parameters

integerValue1
Type: Integer

integerValue2
Type: Integer

Return Value

Type: Integer

max(longValue1, longValue2)

Returns the larger of the two specified Longs.

Signature

```
public static Long max(Long longValue1, Long longValue2)
```

Parameters

longValue1
Type: Long

longValue2
Type: Long

Return Value

Type: Long

min(decimalValue1, decimalValue2)

Returns the smaller of the two specified Decimals.

Signature

```
public static Decimal min(Decimal decimalValue1, Decimal decimalValue2)
```

Parameters

decimalValue1
Type: Decimal

decimalValue2
Type: Decimal

Return Value

Type: Decimal

Example

```
Decimal smaller = math.min(12.3, 156.6);
system.assertEquals(smaller, 12.3);
```

min(doubleValue1, doubleValue2)

Returns the smaller of the two specified Doubles.

Signature

```
public static Double min(Double doubleValue1, Double doubleValue2)
```

Parameters

doubleValue1
Type: Double

doubleValue2
Type: Double

Return Value

Type: Double

min(integerValue1, integerValue2)

Returns the smaller of the two specified Integers.

Signature

```
public static Integer min(Integer integerValue1, Integer integerValue2)
```

Parameters

integerValue1
Type: Integer

integerValue2
Type: Integer

Return Value

Type: Integer

min(longValue1, longValue2)

Returns the smaller of the two specified Longs.

Signature

```
public static Long min(Long longValue1, Long longValue2)
```

Parameters

longValue1
Type: Long

longValue2
Type: Long

Return Value

Type: Long

mod(integerValue1, integerValue2)

Returns the remainder of *integerValue1* divided by *integerValue2*.

Signature

```
public static Integer mod(Integer integerValue1, Integer integerValue2)
```

Parameters

integerValue1
Type: Integer

integerValue2
Type: Integer

Return Value

Type: Integer

Example

```
Integer remainder = math.mod(12, 2);
system.assertEquals(remainder, 0);

Integer remainder2 = math.mod(8, 3);
system.assertEquals(remainder2, 2);
```

mod(longValue1, longValue2)

Returns the remainder of *longValue1* divided by *longValue2*.

Signature

```
public static Long mod(Long longValue1, Long longValue2)
```

Parameters

longValue1
Type: Long

longValue2
Type: Long

Return Value

Type: Long

pow(doubleValue, exponent)

Returns the value of the first Double raised to the power of *exponent*.

Signature

```
public static Double pow(Double doubleValue, Double exponent)
```

Parameters

doubleValue
Type: Double

exponent
Type: Double

Return Value

Type: Double

random()

Returns a positive Double that is greater than or equal to 0.0 and less than 1.0.

Signature

```
public static Double random()
```

Return Value

Type: Double

rint(decimalValue)

Returns the value that is closest in value to *decimalValue* and is equal to a mathematical integer.

Signature

```
public static Decimal rint(Decimal decimalValue)
```

Parameters

decimalValue
Type: Decimal

Return Value

Type: Decimal

rint(doubleValue)

Returns the value that is closest in value to *doubleValue* and is equal to a mathematical integer.

Signature

```
public static Double rint(Double doubleValue)
```

Parameters

doubleValue
Type: Double

Return Value

Type: Double

round(doubleValue)

Do not use. This method is deprecated as of the Winter '08 release. Instead, use `Math.roundToLong`. Returns the closest Integer to the specified Double. If the result is less than -2,147,483,648 or greater than 2,147,483,647, Apex generates an error.

Signature

```
public static Integer round(Double doubleValue)
```

Parameters

doubleValue
Type: Double

Return Value

Type: Integer

round(decimalValue)

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the "nearest neighbor" unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

Signature

```
public static Integer round(Decimal decimalValue)
```

Parameters

decimalValue
Type: Decimal

Return Value

Type: Integer

Usage

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

Example

```
Decimal d1 = 4.5;
Integer i1 = Math.round(d1);
System.assertEquals(4, i1);

Decimal d2 = 5.5;
Integer i2 = Math.round(d2);
System.assertEquals(6, i2);
```

roundToLong(decimalValue)

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the "nearest neighbor" unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

Signature

```
public static Long roundToLong(Decimal decimalValue)
```

Parameters

decimalValue
Type: Decimal

Return Value

Type: Long

Usage

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

Example

```
Decimal d1 = 4.5;
Long i1 = Math.roundToLong(d1);
System.assertEquals(4, i1);

Decimal d2 = 5.5;
Long i2 = Math.roundToLong(d2);
System.assertEquals(6, i2);
```

roundToLong(doubleValue)

Returns the closest Long to the specified Double.

Signature

```
public static Long roundToLong(Double doubleValue)
```

Parameters

doubleValue
Type: Double

Return Value

Type: Long

signum(decimalValue)

Returns the signum function of the specified Decimal, which is 0 if *decimalValue* is 0, 1.0 if *decimalValue* is greater than 0, -1.0 if *decimalValue* is less than 0.

Signature

```
public static Decimal signum(Decimal decimalValue)
```

Parameters

decimalValue
Type: Decimal

Return Value

Type: Decimal

signum(doubleValue)

Returns the signum function of the specified Double, which is 0 if *doubleValue* is 0, 1.0 if *doubleValue* is greater than 0, -1.0 if *doubleValue* is less than 0.

Signature

```
public static Double signum(Double doubleValue)
```

Parameters

doubleValue
Type: Double

Return Value

Type: Double

sin(decimalAngle)

Returns the trigonometric sine of the angle specified by *decimalAngle*.

Signature

```
public static Decimal sin(Decimal decimalAngle)
```

Parameters

decimalAngle
Type: Decimal

Return Value

Type: Decimal

sin(doubleAngle)

Returns the trigonometric sine of the angle specified by *doubleAngle*.

Signature

```
public static Double sin(Double doubleAngle)
```

Parameters

doubleAngle
Type: Double

Return Value

Type: Double

sinh(decimalAngle)

Returns the hyperbolic sine of *decimalAngle*. The hyperbolic sine of *decimalAngle* is defined to be $(e^x - e^{-x})/2$ where *e* is Euler's number.

Signature

```
public static Decimal sinh(Decimal decimalAngle)
```

Parameters

decimalAngle
Type: Decimal

Return Value

Type: Decimal

sinh(doubleAngle)

Returns the hyperbolic sine of *doubleAngle*. The hyperbolic sine of *doubleAngle* is defined to be $(e^x - e^{-x})/2$ where *e* is Euler's number.

Signature

```
public static Double sinh(Double doubleAngle)
```

Parameters

doubleAngle
Type: Double

Return Value

Type: Double

sqrt(decimalValue)

Returns the correctly rounded positive square root of *decimalValue*.

Signature

```
public static Decimal sqrt(Decimal decimalValue)
```

Parameters

decimalValue
Type: Decimal

Return Value

Type: Decimal

sqrt(doubleValue)

Returns the correctly rounded positive square root of *doubleValue*.

Signature

```
public static Double sqrt(Double doubleValue)
```

Parameters

doubleValue
Type: Double

Return Value

Type: Double

tan(decimalAngle)

Returns the trigonometric tangent of the angle specified by *decimalAngle*.

Signature

```
public static Decimal tan(Decimal decimalAngle)
```

Parameters

decimalAngle
Type: Decimal

Return Value

Type: Decimal

tan(doubleAngle)

Returns the trigonometric tangent of the angle specified by *doubleAngle*.

Signature

```
public static Double tan(Double doubleAngle)
```

Parameters

doubleAngle
Type: Double

Return Value

Type: Double

tanh(decimalAngle)

Returns the hyperbolic tangent of *decimalAngle*. The hyperbolic tangent of *decimalAngle* is defined to be $(e^X - e^{-X})/(e^X + e^{-X})$ where *e* is Euler's number. In other words, it is equivalent to `sinh(x)/cosinh(x)`. The absolute value of the exact `tanh` is always less than 1.

Signature

```
public static Decimal tanh(Decimal decimalAngle)
```

Parameters

decimalAngle
Type: Decimal

Return Value

Type: Decimal

tanh(doubleAngle)

Returns the hyperbolic tangent of *doubleAngle*. The hyperbolic tangent of *doubleAngle* is defined to be $(e^X - e^{-X})/(e^X + e^{-X})$ where *e* is Euler's number. In other words, it is equivalent to `sinh(x)/cosinh(x)`. The absolute value of the exact `tanh` is always less than 1.

Signature

```
public static Double tanh(Double doubleAngle)
```

Parameters

doubleAngle
Type: Double

Return Value

Type: Double

Messaging Class

Contains messaging methods used when sending a single or mass email.

Namespace

System

Messaging Methods

The following are methods for `Messaging`. All are instance methods.

IN THIS SECTION:

extractInboundEmail(source, includeForwardedAttachments)
Use this method in your email service code to control how to parse and process forwarded or attached emails. Returns an instance of `Messaging.InboundEmail` from a stream of data that is in RFC822 format. The data stream can be a forwarded email in an attachment to an existing InboundEmail, or a stream from another source.

reserveMassEmailCapacity(amountReserved)
Reserves email capacity to send mass email to the specified number of email addresses, after the current transaction commits.

reserveSingleEmailCapacity(amountReserved)
Reserves email capacity to send single email to the specified number of email addresses, after the current transaction commits.

sendEmail(emails, allOrNothing)
Sends the list of email objects instantiated with either `SingleEmailMessage` or `MassEmailMessage` and returns a list of SendEmailResult objects.

sendEmailMessage(emailMessageIds, allOrNothing)
Sends up to 10 draft email messages as defined by the specified email message IDs and returns a list of SendEmailResult objects.

renderEmailTemplate(whoId, whatId, bodies)
Replaces merge fields in text bodies of email templates with values from Salesforce records. Returns an array of `RenderEmailTemplateBodyResult` objects, each of which corresponds to an element in the supplied array of text bodies. Each `RenderEmailTemplateBodyResult` provides a success or failure indication, along with either an error code or the rendered text.

renderStoredEmailTemplate(templateId, whoId, whatId)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of `Messaging.SingleEmailMessage`. Includes all attachment content in the returned email message.

renderStoredEmailTemplate(templateId, whoId, whatId, attachmentRetrievalOption)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of `Messaging.SingleEmailMessage`. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

renderStoredEmailTemplate(templateId, whoId, whatId, attachmentRetrievalOption, updateEmailTemplateUsage)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of `Messaging.SingleEmailMessage`. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

`extractInboundEmail(source, includeForwardedAttachments)`

Use this method in your email service code to control how to parse and process forwarded or attached emails. Returns an instance of `Messaging.InboundEmail` from a stream of data that is in RFC822 format. The data stream can be a forwarded email in an attachment to an existing InboundEmail, or a stream from another source.

Signature

```
public static Messaging.InboundEmail extractInboundEmail(Object source, Boolean
includeForwardedAttachments)
```

Parameters

source
Type: Object

An instance of `Messaging.InboundEmail.BinaryAttachment` whose MimeTypeSubtype is `message/rfc822` or a Blob. If *source* is a Blob, then supply a byte array in RFC822 format.

includeForwardedAttachments
Type: Boolean

This parameter controls how attachments to embedded or forwarded emails are handled. Set to `true` to provide all attachments, even attachments in embedded emails in the `binaryAttachments` and `textAttachments` properties of the returned value. Set to `false` to provide only the attachments that are at the top level of the source email.

Return Value

Type: Messaging.InboundEmail

reserveMassEmailCapacity(amountReserved)

Reserves email capacity to send mass email to the specified number of email addresses, after the current transaction commits.

Signature

```
public Void reserveMassEmailCapacity(Integer amountReserved)
```

Parameters

amountReserved
Type: Integer

Return Value

Type: Void

Usage

This method can be called when you know in advance how many addresses emails will be sent to as a result of the transaction.If the transaction would cause the organization to exceed its daily email limit, using this method results in the following error: `System.HandledException: The daily limit for the org would be exceeded by this request.`If the organization doesn't have permission to send API or mass email, using this method results in the following error: `System.NoAccessException: The organization is not permitted to send email.`

reserveSingleEmailCapacity(amountReserved)

Reserves email capacity to send single email to the specified number of email addresses, after the current transaction commits.

Signature

```
public Void reserveSingleEmailCapacity(Integer amountReserved)
```

Parameters

amountReserved
Type: Integer

Return Value

Type: Void

Usage

This method can be called when you know in advance how many addresses emails will be sent to as a result of the transaction.If the transaction would cause the organization to exceed its daily email limit, using this method results in the following error: `System.HandledException: The daily limit for the org would be exceeded by this request.` If the organization doesn't have permission to send API or mass email, using this method results in the following error: `System.NoAccessException: The organization is not permitted to send email.`

sendEmail(emails, allOrNothing)

Sends the list of email objects instantiated with either `SingleEmailMessage` or `MassEmailMessage` and returns a list of SendEmailResult objects.

Signature

```
public Messaging.SendEmailResult[] sendEmail(Messaging.Email[] emails, Boolean
allOrNothing)
```

Parameters

emails
Type: Messaging.Email[]

allOrNothing
Type: Boolean

The optional *opt_allOrNone* parameter specifies whether `sendEmail` prevents delivery of all other messages when any of the messages fail due to an error (`true`), or whether it allows delivery of the messages that don't have errors (`false`). The default is `true`.

Return Value

Type: Messaging.SendEmailResult[]

sendEmailMessage(emailMessageIds, allOrNothing)

Sends up to 10 draft email messages as defined by the specified email message IDs and returns a list of SendEmailResult objects.

Signature

```
public Messaging.SendEmailResult[] sendEmailMessage(List<ID> emailMessageIds, Boolean
allOrNothing)
```

Parameters

emailMessageIds
Type: List<ID>

allOrNothing
Type: Boolean

Return Value

Type: Messaging.SendEmailResult[]

Usage

The `sendEmailMessage` method assumes that the optional *opt_allOrNone* parameter is always `false` and ignores the value you set. This optional parameter specifies whether `sendEmailMessage` prevents delivery of all other messages when any of the messages fail due to an error (`true`), or whether it allows delivery of the messages that don't have errors (`false`).

Example

This example shows how to send a draft email message. It creates a case and a new email message associated with the case. Next, the example sends a draft email message and checks the results. Before running this example, make sure to replace the email address with a valid address.

```
Case c = new Case();
insert c;

EmailMessage e = new EmailMessage();
e.parentid = c.id;
// Set to draft status.
// This status is required
// for sendEmailMessage().
e.Status = '5';
e.TextBody =
  'Sample email message.';
e.Subject = 'Apex sample';
e.ToAddress = 'customer@email.com';
insert e;

List<Messaging.SendEmailResult>
  results =
  Messaging.sendEmailMessage(new ID[]
    { e.id });

System.assertEquals(1, results.size());
System.assertEquals(true,
                    results[0].success);
```

renderEmailTemplate(whoId, whatId, bodies)

Replaces merge fields in text bodies of email templates with values from Salesforce records. Returns an array of `RenderEmailTemplateBodyResult` objects, each of which corresponds to an element in the supplied array of text bodies. Each `RenderEmailTemplateBodyResult` provides a success or failure indication, along with either an error code or the rendered text.

Signature

```
public static List<Messaging.RenderEmailTemplateBodyResult> renderEmailTemplate(String whoId, String whatId, List<String> bodies)
```

Parameters

whoId
Type: String

The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

whatId
Type: String

Identifies an object in the database like an account or opportunity. The record for that object is read and used in merge field processing.

bodies
Type: List<String>

An array of strings that are examined for merge field references. The corresponding data from the object referenced by the `whoId` or `whatId` replaces the merge field reference.

Return Value

Type: List<Messaging.RenderEmailTemplateBodyResult>

Usage

Use this method in situations in which you want to dynamically compose blocks of text that are enriched with data from the database. You can then use the the rendered blocks of text to compose and send an email or update a text value in another database record.

Executing the `renderEmailTemplate` method counts toward the SOQL governor limit. The number of SOQL queries that this method consumes is the number of elements in the list of strings passed in the *bodies* parameter.

SEE ALSO:

Execution Governors and Limits

renderStoredEmailTemplate(templateId, whoId, whatId)

Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of `Messaging.SingleEmailMessage`. Includes all attachment content in the returned email message.

Signature

```
public static Messaging.SingleEmailMessage renderStoredEmailTemplate(String templateId, String whoId, String whatId)
```

Parameters

templateId
Type: String

An email template that exists in the database, such as text, HTML, custom, and Visualforce templates.

whoId
Type: String

The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

whatId
Type: String

Identifies an object in the database, like an account or opportunity. The record for that object is read and used in merge field processing.

Return Value

Type: Messaging.SingleEmailMessage

Usage

Executing the `renderStoredEmailTemplate` method counts toward the SOQL governor limit as one query.

SEE ALSO:

Execution Governors and Limits

renderStoredEmailTemplate(templateId, whoId, whatId, attachmentRetrievalOption)

Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of `Messaging.SingleEmailMessage`. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

Signature

```
public static Messaging.SingleEmailMessage renderStoredEmailTemplate(String templateId,
String whoId, String whatId, Messaging.AttachmentRetrievalOption
attachmentRetrievalOption)
```

Parameters

templateId
Type: String

An email template that exists in the database, such as text, HTML, custom, and Visualforce templates.

whoId
Type: String

The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

whatId
Type: String

Identifies an object in the database, like an account or opportunity. The record for that object is read and used in merge field processing.

attachmentRetrievalOption
Type: Messaging.AttachmentRetrievalOption

Specifies options for including attachments in the `fileAttachments` property of the returned `Messaging.SingleEmailMessage`. Set to one of the Messaging.AttachmentRetrievalOption values to include attachment metadata only, attachment metadata and content, or to exclude attachments.

Note: When the *attachmentRetrievalOption* parameter is *not* set to `NONE`, the `entityAttachments` property of `Messaging.SingleEmailMessage` contains the ID of the Salesforce content objects to attach (ContentVersion or Document). The `fileAttachments` property contains the IDs of attachments, in addition to all the IDs in the `entityAttachments` property. As a result, the ID values in `entityAttachments` are duplicates of the IDs in the `fileAttachments` property. If you call `renderStoredEmailTemplate()` by passing the `METADATA_WITH_BODY` option, and send the rendered email message, the email will contain duplicate attachments. Before using the returned email message with sendEmail(emails, allOrNothing), you can remove attachments from `fileAttachments` that are duplicated in `entityAttachments`.

Return Value

Type: Messaging.SingleEmailMessage

Usage

Executing the `renderStoredEmailTemplate` method counts toward the SOQL governor limit as one query.

renderStoredEmailTemplate(templateId, whoId, whatId, attachmentRetrievalOption, updateEmailTemplateUsage)

Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of `Messaging.SingleEmailMessage`. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

Signature

```
public static Messaging.SingleEmailMessage renderStoredEmailTemplate(String templateId,
String whoId, String whatId, Messaging.AttachmentRetrievalOption
attachmentRetrievalOption, Boolean updateEmailTemplateUsage)
```

Parameters

templateId
Type: String

An email template that exists in the database, such as text, HTML, custom, and Visualforce templates.

whoId
Type: String

The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

whatId
Type: String

Identifies an object in the database, like an account or opportunity. The record for that object is read and used in merge field processing.

attachmentRetrievalOption
Type: Messaging.AttachmentRetrievalOption

Specifies options for including attachments in the `fileAttachments` property of the returned `Messaging.SingleEmailMessage`. Set to one of the Messaging.AttachmentRetrievalOption values to include attachment metadata only, attachment metadata and content, or to exclude attachments.

Note: When the *attachmentRetrievalOption* parameter is *not* set to `NONE`, the `entityAttachments` property of `Messaging.SingleEmailMessage` contains the ID of the Salesforce content objects to attach (ContentVersion or Document). The `fileAttachments` property contains the IDs of attachments, in addition to all the IDs in the `entityAttachments` property. As a result, the ID values in `entityAttachments` are duplicates of the IDs in the `fileAttachments` property. If you call `renderStoredEmailTemplate()` by passing the `METADATA_WITH_BODY` option, and send the rendered email message, the email will contain duplicate attachments. Before using the returned email message with sendEmail(emails, allOrNothing), you can remove attachments from `fileAttachments` that are duplicated in `entityAttachments`.

updateEmailTemplateUsage
Type: Boolean

Specifies whether the usage field in the EmailTemplate record is updated upon successful rendering.

Return Value

Type: Messaging.SingleEmailMessage

Usage

Executing the `renderStoredEmailTemplate` method counts toward the SOQL governor limit as one query.

MultiStaticResourceCalloutMock Class

Utility class used to specify a fake response using multiple resources for testing HTTP callouts.

Namespace

System

Usage

Use the methods in this class to set the response properties for testing HTTP callouts. You can specify a resource for each endpoint.

IN THIS SECTION:

MultiStaticResourceCalloutMock Constructors

MultiStaticResourceCalloutMock Methods

MultiStaticResourceCalloutMock Constructors

The following are constructors for `MultiStaticResourceCalloutMock`.

IN THIS SECTION:

MultiStaticResourceCalloutMock()
Creates a new instance of the `System.MultiStaticResourceCalloutMock` class.

MultiStaticResourceCalloutMock()

Creates a new instance of the `System.MultiStaticResourceCalloutMock` class.

Signature

```
public MultiStaticResourceCalloutMock()
```

MultiStaticResourceCalloutMock Methods

The following are methods for `MultiStaticResourceCalloutMock`. All are instance methods.

IN THIS SECTION:

setHeader(headerName, headerValue)
Sets the specified header name and value for the fake response.

setStaticResource(endpoint, resourceName)
Sets the specified static resource corresponding to the endpoint. The static resource contains the response body.

setStatus(httpStatus)
Sets the specified HTTP status for the response.

setStatusCode(httpStatusCode)
Sets the specified HTTP status code for the response.

setHeader(headerName, headerValue)

Sets the specified header name and value for the fake response.

Signature

```
public Void setHeader(String headerName, String headerValue)
```

Parameters

headerName
Type: String

headerValue
Type: String

Return Value

Type: Void

setStaticResource(endpoint, resourceName)

Sets the specified static resource corresponding to the endpoint. The static resource contains the response body.

Signature

```
public Void setStaticResource(String endpoint, String resourceName)
```

Parameters

endpoint
Type: String

resourceName
Type: String

Return Value

Type: Void

setStatus(httpStatus)

Sets the specified HTTP status for the response.

Signature

```
public Void setStatus(String httpStatus)
```

Parameters

httpStatus
Type: String

Return Value

Type: Void

setStatusCode(httpStatusCode)

Sets the specified HTTP status code for the response.

Signature

```
public Void setStatusCode(Integer httpStatusCode)
```

Parameters

httpStatusCode
Type: Integer

Return Value

Type: Void

Network Class

Represents a community.

Namespace

System

Usage

Use the method in the `Network` class to determine which community a user is currently logged into.

IN THIS SECTION:

Network Constructors

Network Methods

Network Constructors

The following are constructors for `Network`.

IN THIS SECTION:

Network()
Creates a new instance of the `System.Network` class.

`Network()`

Creates a new instance of the `System.Network` class.

Signature

```
public Network()
```

Network Methods

The following are methods for `Network`. All methods are static.

IN THIS SECTION:

communitiesLanding()
Returns a Page Reference to the default landing page for the community. This is the first tab of the community.

forwardToAuthPage(startURL)
Returns a Page Reference to the default login page. StartURL is included as a query paremeter for where to redirect after a successful login.

getLoginUrl(networkId)
Returns the absolute URL of the login page used by the community.

getLogoutUrl(networkId)
Returns the absolute URL of the logout page used by the community.

getNetworkId()
Returns the user's current community.

getSelfRegUrl(networkId)
Returns the absolute URL of the self-registration page used by the community.

loadAllPackageDefaultNetworkDashboardSettings()
Maps the dashboards from the Salesforce Communities Management package onto each community's unconfigured dashboard settings. Returns the number of settings it configures.

loadAllPackageDefaultNetworkPulseSettings()
Maps the Insights reports from the Salesforce Communities Management package onto each community's unconfigured Insights settings. Returns the number of settings it configures.

`communitiesLanding()`

Returns a Page Reference to the default landing page for the community. This is the first tab of the community.

Signature

```
public static String communitiesLanding()
```

Return Value

Type: PageReference

Usage

If Communities isn't enabled for the user's organization or the user is currently in the internal organization, returns `null`.

`forwardToAuthPage(startURL)`

Returns a Page Reference to the default login page. StartURL is included as a query paremeter for where to redirect after a successful login.

Signature

```
public static PageReference forwardToAuthPage(String startURL)
```

Parameters

`startURL`
Type: String

Return Value

Type: PageReference

Usage

If Communities isn't enabled for the user's organization or the user is currently in the internal organization, returns `null`.

`getLoginUrl(networkId)`

Returns the absolute URL of the login page used by the community.

Signature

```
public static String getLoginUrl(String networkId)
```

Parameters

`networkId`
Type: String

The ID of the community you're retrieving this information for.

Return Value

Type: String

Usage

Returns the full URL for the Lightning Platform or Community Builder page used as the login page in the community.

`getLogoutUrl(networkId)`

Returns the absolute URL of the logout page used by the community.

Signature

```
public static String getLogoutUrl(String networkId)
```

Parameters

`networkId`
Type: String

The ID of the community you're retrieving this information for.

Return Value

Type: String

Usage

Returns the full URL for the Lightning Platform page, Community Builder page, or Web page used as the logout page in the community.

`getNetworkId()`

Returns the user's current community.

Signature

```
public static String getNetworkId()
```

Return Value

Type: String

Usage

If Communities isn't enabled for the user's organization or the user is currently in the internal organization, returns `null`.

`getSelfRegUrl(networkId)`

Returns the absolute URL of the self-registration page used by the community.

Signature

```
public static String getSelfRegUrl(String networkId)
```

Parameters

`networkId`
Type: String

The ID of the community you're retrieving this information for.

Return Value

Type: String

Usage

Returns the full URL for the Lightning Platform or Community Builder page used as the self-registration page in the community.

`loadAllPackageDefaultNetworkDashboardSettings()`

Maps the dashboards from the Salesforce Communities Management package onto each community's unconfigured dashboard settings. Returns the number of settings it configures.

Signature

```
public static Integer loadAllPackageDefaultNetworkDashboardSettings()
```

Return Value

Type: Integer

Usage

If Communities is enabled, and the Salesforce Communities Management package is installed, maps the dashboards provided in the package onto each community's unconfigured dashboard settings. Returns the number of settings it configures. This method is invoked automatically during community creation and package installation, but isn't typically invoked manually.

If Communities isn't enabled for the user's organization or the user is in the internal organization, returns `0`.

`loadAllPackageDefaultNetworkPulseSettings()`

Maps the Insights reports from the Salesforce Communities Management package onto each community's unconfigured Insights settings. Returns the number of settings it configures.

Signature

```
public static Integer loadAllPackageDefaultNetworkPulseSettings()
```

Return Value

Type: Integer

Usage

If Communities is enabled, and the Salesforce Communities Management package is installed, maps the Insights reports provided in the package onto each community's unconfigured Insights settings. Returns the number of settings it configures. This method is invoked automatically during community creation and package installation, but isn't typically invoked manually.

If Communities isn't enabled for the user's organization or the user is in the internal organization, returns `0`.

PageReference Class

A PageReference is a reference to an instantiation of a page. Among other attributes, PageReferences consist of a URL and a set of query parameter names and values.

Namespace

System

Use a PageReference object:

- To view or set query string parameters and values for a page
- To navigate the user to a different page as the result of an action method

Instantiation

In a custom controller or controller extension, you can refer to or instantiate a PageReference in one of the following ways:

- `Page.existingPageName`

  Refers to a PageReference for a Visualforce page that has already been saved in your organization. By referring to a page in this way, the platform recognizes that this controller or controller extension is dependent on the existence of the specified page and will prevent the page from being deleted while the controller or extension exists.

- `PageReference pageRef = new PageReference('partialURL');`

  Creates a PageReference to any page that is hosted on the Lightning platform. For example, setting `'partialURL'` to `'/apex/HelloWorld'` refers to the Visualforce page located at `http://mySalesforceInstance/apex/HelloWorld`. Likewise, setting `'partialURL'` to `'/' + 'recordID'` refers to the detail page for the specified record.

  This syntax is less preferable for referencing other Visualforce pages than `Page.existingPageName` because the PageReference is constructed at runtime, rather than referenced at compile time. Runtime references are not available to the referential integrity system. Consequently, the platform doesn't recognize that this controller or controller extension is dependent on the existence of the specified page and won't issue an error message to prevent user deletion of the page.

- `PageReference pageRef = new PageReference('fullURL');`

  Creates a PageReference for an external URL. For example:

  ```
  PageReference pageRef = new PageReference('http://www.google.com');
  ```

You can also instantiate a PageReference object for the current page with the `currentPage` ApexPages method. For example:

```
PageReference pageRef = ApexPages.currentPage();
```

Request Headers

The following table is a non-exhaustive list of headers that are set on requests.

Header	Description
Host	The host name requested in the request URL. This header is always set on Lightning Platform Site requests and My Domain requests. This header is optional on other requests when HTTP/1.0 is used instead of HTTP/1.1.
Referer	The URL that is either included or linked to the current request's URL. This header is optional.
User-Agent	The name, version, and extension support of the program that initiated this request, such as a Web browser. This header is optional and can be overridden in most browsers to be a different value. Therefore, this header should not be relied upon.
CipherSuite	If this header exists and has a non-blank value, this means that the request is using HTTPS. Otherwise, the request is using HTTP. The contents of a non-blank value are not defined by this API, and can be changed without notice.
X-Salesforce-SIP	The source IP address of the request. This header is always set on HTTP and HTTPS requests that are initiated outside of Salesforce's data centers. Note: If a request passes through a content delivery network (CDN) or proxy server, the source IP address might be altered, and no longer the original client IP address.

Header	Description
X-Salesforce-Forwarded-To	The fully qualified domain name of the Salesforce instance that is handling this request. This header is always set on HTTP and HTTPS requests that are initiated outside of Salesforce's data centers.

Example: Retrieving Query String Parameters

The following example shows how to use a PageReference object to retrieve a query string parameter in the current page URL. In this example, the `getAccount` method references the `id` query string parameter:

```
public class MyController {
   public Account getAccount() {
        return [SELECT Id, Name FROM Account
                WHERE Id = :ApexPages.currentPage().getParameters().get('Id')];
    }
}
```

The following page markup calls the `getAccount` method from the controller above:

```
<apex:page controller="MyController">
    <apex:pageBlock title="Retrieving Query String Parameters">
        You are viewing the {!account.name} account.
    </apex:pageBlock>
</apex:page>
```

Note: For this example to render properly, you must associate the Visualforce page with a valid account record in the URL. For example, if `001D000000IRt53` is the account ID, the resulting URL should be:

```
https://Salesforce_instance/apex/MyFirstPage?id=001D000000IRt53
```

The `getAccount` method uses an embedded SOQL query to return the account specified by the `id` parameter in the URL of the page. To access `id`, the `getAccount` method uses the `ApexPages` namespace:

- First the `currentPage` method returns the `PageReference` instance for the current page. `PageReference` returns a reference to a Visualforce page, including its query string parameters.
- Using the page reference, use the `getParameters` method to return a map of the specified query string parameter names and values.
- Then a call to the `get` method specifying `id` returns the value of the `id` parameter itself.

Example: Navigating to a New Page as the Result of an Action Method

Any action method in a custom controller or controller extension can return a PageReference object as the result of the method. If the `redirect` attribute on the PageReference is set to `true`, the user navigates to the URL specified by the PageReference.

The following example shows how this can be implemented with a `save` method. In this example, the PageReference returned by the `save` method redirects the user to the detail page for the account record that was just saved:

```
public class mySecondController {
    Account account;

    public Account getAccount() {
        if(account == null) account = new Account();
        return account;
```

```
    }

    public PageReference save() {
        // Add the account to the database.
        insert account;
        // Send the user to the detail page for the new account.
        PageReference acctPage = new ApexPages.StandardController(account).view();
        acctPage.setRedirect(true);
        return acctPage;
    }
}
```

The following page markup calls the `save` method from the controller above. When a user clicks **Save**, he or she is redirected to the detail page for the account just created:

```
<apex:page controller="mySecondController" tabStyle="Account">
    <apex:sectionHeader title="New Account Edit Page" />
    <apex:form>
        <apex:pageBlock title="Create a New Account">
            <apex:pageBlockButtons location="bottom">
                <apex:commandButton action="{!save}" value="Save"/>
            </apex:pageBlockButtons>
            <apex:pageBlockSection title="Account Information">
                <apex:inputField id="accountName" value="{!account.name}"/>
                <apex:inputField id="accountSite" value="{!account.site}"/>
            </apex:pageBlockSection>
       </apex:pageBlock>
    </apex:form>
</apex:page>
```

IN THIS SECTION:

PageReference Constructors

PageReference Methods

PageReference Constructors

The following are constructors for `PageReference`.

IN THIS SECTION:

PageReference(partialURL)

Creates a new instance of the `PageReference` class using the specified URL.

PageReference(record)

Generate a new instance of the `PageReference` class for the specified sObject record.

`PageReference(partialURL)`

Creates a new instance of the `PageReference` class using the specified URL.

Signature

```
public PageReference(String partialURL)
```

Parameters

partialURL
Type: String

The partial URL of a page hosted on the Lightning platform or a full external URL. The following are some examples of the *partialURL* parameter values:

- `/apex/HelloWorld`: refers to the Visualforce page located at `http://mySalesforceInstance/apex/HelloWorld`.
- */recordID*: refers to the detail page of a specified record.
- `http://www.google.com`: refers to an external URL.

PageReference(record)

Generate a new instance of the `PageReference` class for the specified sObject record.

Signature

```
public PageReference(SObject record)
```

Parameters

record
Type: SObject

The sObject record that references the `ApexPage`. The reference must be an `ApexPage`.

SEE ALSO:

Visualforce Developer Guide: apex:page

SOAP API Developer Guide: ApexPage

PageReference Methods

The following are methods for `PageReference`. All are instance methods.

IN THIS SECTION:

forResource(resourceName, path)
Create a PageReference for nested content inside a zip static resource, by name and path.

forResource(resourceName)
Create a PageReference for a static resource, by name.

getAnchor()
Returns the name of the anchor referenced in the page's URL. That is, the part of the URL after the hashtag (#).

getContent()
Returns the output of the page, as displayed to a user in a web browser.

getContentAsPDF()

Returns the page in PDF, regardless of the `<apex:page>` component's `renderAs` attribute.

getCookies()

Returns a map of cookie names and cookie objects, where the key is a String of the cookie name and the the value contains the cookie object with that name.

getHeaders()

Returns a map of the request headers, where the key string contains the name of the header, and the value string contains the value of the header.

getParameters()

Returns a map of the query string parameters for the PageReference; both POST and GET parameters are included. The key string contains the name of the parameter, while the value string contains the value of the parameter.

getRedirect()

Returns the current value of the PageReference object's `redirect` attribute.

getUrl()

Returns the relative URL associated with the PageReference when it was originally defined, including any query string parameters and anchors.

setAnchor(anchor)

Sets the URL's anchor reference to the specified string.

setCookies(cookies)

Creates a list of cookie objects. Used in conjunction with the `Cookie` class.

setRedirect(redirect)

Sets the value of the PageReference object's `redirect` attribute. If set to `true`, a redirect is performed through a client side redirect.

`forResource(resourceName, path)`

Create a PageReference for nested content inside a zip static resource, by name and path.

Signature

```
public static System.PageReference forResource(String resourceName, String path)
```

Parameters

`resourceName`
Type: String

The resource name

`path`
Type: String

The resource path

Return Value

Type: System.PageReference

forResource(resourceName)

Create a PageReference for a static resource, by name.

Signature

```
public static System.PageReference forResource(String resourceName)
```

Parameters

resourceName
Type: String

The resource name

Return Value

Type: System.PageReference

getAnchor()

Returns the name of the anchor referenced in the page's URL. That is, the part of the URL after the hashtag (#).

Signature

```
public String getAnchor()
```

Return Value

Type: String

Note: Instances of `PageReference` returned by `ApexPages.currentPage()` have a null anchor attribute, because URL fragments are not sent to the Salesforce server during a request.

getContent()

Returns the output of the page, as displayed to a user in a web browser.

Signature

```
public Blob getContent()
```

Return Value

Type: Blob

Usage

The content of the returned Blob depends on how the page is rendered. If the page is rendered as a PDF file, it returns the PDF document. If the page is not rendered as PDF, it returns HTML. To access the content of the returned HTML as a string, use the `toString` Blob method.

Note: If you use `getContent` in a test method, the test method fails. `getContent` is treated as a callout in API version 34.0 and later.

This method can't be used in:

- Triggers
- Test methods
- Apex email services

If the Visualforce page has an error, an `ExecutionException` is thrown.

`getContentAsPDF()`

Returns the page in PDF, regardless of the `<apex:page>` component's `renderAs` attribute.

Signature

```
public Blob getContentAsPDF()
```

Return Value

Type: Blob

Usage

Note: If you use `getContentAsPDF` in a test method, the test method fails. `getContentAsPDF` is treated as a callout in API version 34.0 and later.

This method can't be used in:

- Triggers
- Test methods
- Apex email services

`getCookies()`

Returns a map of cookie names and cookie objects, where the key is a String of the cookie name and the the value contains the cookie object with that name.

Signature

```
public Map<String, System.Cookie> getCookies()
```

Return Value

Type: Map<String, System.Cookie>

Usage

Used in conjunction with the `Cookie` class. Only returns cookies with the "`apex__`" prefix set by the `setCookies` method.

getHeaders()

Returns a map of the request headers, where the key string contains the name of the header, and the value string contains the value of the header.

Signature

```
public Map<String, String> getHeaders()
```

Return Value

Type: Map<String, String>

Usage

This map can be modified and remains in scope for the PageReference object. For instance, you could do:

```
PageReference.getHeaders().put('Date', '9/9/99');
```

For a description of request headers, see Request Headers.

getParameters()

Returns a map of the query string parameters for the PageReference; both POST and GET parameters are included. The key string contains the name of the parameter, while the value string contains the value of the parameter.

Signature

```
public Map<String, String> getParameters()
```

Return Value

Type: Map<String, String>

Usage

This map can be modified and remains in scope for the PageReference object. For instance, you could do:

```
PageReference.getParameters().put('id', myID);
```

Parameter keys are case-insensitive. For example:

```
System.assert(
    ApexPages.currentPage().getParameters().get('myParamName') ==
    ApexPages.currentPage().getParameters().get('myparamname'));
```

getRedirect()

Returns the current value of the PageReference object's `redirect` attribute.

Signature

```
public Boolean getRedirect()
```

Return Value

Type: Boolean

Usage

Note that if the URL of the PageReference object is set to a website outside of the `salesforce.com` domain, the redirect always occurs, regardless of whether the `redirect` attribute is set to `true` or `false`.

`getUrl()`

Returns the relative URL associated with the PageReference when it was originally defined, including any query string parameters and anchors.

Signature

```
public String getUrl()
```

Return Value

Type: String

`setAnchor(anchor)`

Sets the URL's anchor reference to the specified string.

Signature

```
public System.PageReference setAnchor(String anchor)
```

Parameters

anchor
Type: String

Return Value

Type: System.PageReference

`setCookies(cookies)`

Creates a list of cookie objects. Used in conjunction with the `Cookie` class.

Signature

```
public Void setCookies(Cookie[] cookies)
```

Parameters

cookies
Type: System.Cookie[]

Return Value

Type: Void

Usage

Important:

- Cookie names and values set in Apex are URL encoded, that is, characters such as @ are replaced with a percent sign and their hexadecimal representation.
- The `setCookies` method adds the prefix "`apex__`" to the cookie names.
- Setting a cookie's value to `null` sends a cookie with an empty string value instead of setting an expired attribute.
- After you create a cookie, the properties of the cookie can't be changed.
- Be careful when storing sensitive information in cookies. Pages are cached regardless of a cookie value. If you use a cookie value to generate dynamic content, you should disable page caching. For more information, see "Cache Salesforce Sites Pages" in the Salesforce online help.

`setRedirect(redirect)`

Sets the value of the PageReference object's `redirect` attribute. If set to `true`, a redirect is performed through a client side redirect.

Signature

```
public System.PageReference setRedirect(Boolean redirect)
```

Parameters

`redirect`
Type: Boolean

Return Value

Type: System.PageReference

Usage

This type of redirect performs an HTTP GET request, and flushes the view state, which uses POST. If set to `false`, the redirect is a server-side forward that preserves the view state if and only if the target page uses the same controller and contains the proper subset of extensions used by the source page.

Note that if the URL of the PageReference object is set to a website outside of the `salesforce.com` domain, or to a page with a different controller or controller extension, the redirect always occurs, regardless of whether the `redirect` attribute is set to `true` or `false`.

Pattern Class

Represents a compiled representation of a regular expression.

Namespace

System

Pattern Methods

The following are methods for `Pattern`.

IN THIS SECTION:

compile(regExp)
Compiles the regular expression into a Pattern object.

matcher(regExp)
Creates a Matcher object that matches the input string *`regExp`* against this Pattern object.

matches(regExp, stringtoMatch)
Compiles the regular expression *`regExp`* and tries to match it against the specified string. This method returns `true` if the specified string matches the regular expression, `false` otherwise.

pattern()
Returns the regular expression from which this Pattern object was compiled.

quote(yourString)
Returns a string that can be used to create a pattern that matches the string *`yourString`* as if it were a literal pattern.

split(regExp)
Returns a list that contains each substring of the String that matches this pattern.

split(regExp, limit)
Returns a list that contains each substring of the String that is terminated either by the regular expression *`regExp`* that matches this pattern, or by the end of the String.

`compile(regExp)`

Compiles the regular expression into a Pattern object.

Signature

```
public static Pattern compile(String regExp)
```

Parameters

`regExp`
Type: String

Return Value

Type: System.Pattern

`matcher(regExp)`

Creates a Matcher object that matches the input string *`regExp`* against this Pattern object.

Signature

```
public Matcher matcher(String regExp)
```

Parameters

regExp
Type: String

Return Value

Type: Matcher

matches(regExp, stringtoMatch)

Compiles the regular expression *regExp* and tries to match it against the specified string. This method returns `true` if the specified string matches the regular expression, `false` otherwise.

Signature

```
public static Boolean matches(String regExp, String stringtoMatch)
```

Parameters

regExp
Type: String

stringtoMatch
Type: String

Return Value

Type: Boolean

Usage

If a pattern is to be used multiple times, compiling it once and reusing it is more efficient than invoking this method each time.

Example

Note that the following code example:

```
Pattern.matches(regExp, input);
```

produces the same result as this code example:

```
Pattern.compile(regex).
matcher(input).matches();
```

pattern()

Returns the regular expression from which this Pattern object was compiled.

Signature

```
public String pattern()
```

Return Value

Type: String

quote(yourString)

Returns a string that can be used to create a pattern that matches the string *yourString* as if it were a literal pattern.

Signature

```
public static String quote(String yourString)
```

Parameters

yourString
Type: String

Return Value

Type: String

Usage

Metacharacters (such as `$` or `^`) and escape sequences in the input string are treated as literal characters with no special meaning.

split(regExp)

Returns a list that contains each substring of the String that matches this pattern.

Signature

```
public String[] split(String regExp)
```

Parameters

regExp
Type: String

Return Value

Type: String[]

Note: In API version 34.0 and earlier, a zero-width *regExp* value produces an empty list item at the beginning of the method's output.

Usage

The substrings are placed in the list in the order in which they occur in the String. If *regExp* does not match the pattern, the resulting list has just one element containing the original String.

split(regExp, limit)

Returns a list that contains each substring of the String that is terminated either by the regular expression *regExp* that matches this pattern, or by the end of the String.

Signature

```
public String[] split(String regExp, Integer limit)
```

Parameters

regExp
Type: String

limit
Type: Integer

(Optional) Controls the number of times the pattern is applied and therefore affects the length of the list.

- If *limit* is greater than zero:
  - The pattern is applied a maximum of (*limit* – 1) times.
  - The list's length is no greater than *limit*.
  - The list's last entry contains all input beyond the last matched delimiter.
- If *limit* is non-positive, the pattern is applied as many times as possible, and the list can have any length.
- If *limit* is zero, the pattern is applied as many times as possible, the list can have any length, and trailing empty strings are discarded.

Return Value

Type: String[]

Note: In API version 34.0 and earlier, a zero-width *regExp* value produces an empty list item at the beginning of the method's output.

Queueable Interface

Enables the asynchronous execution of Apex jobs that can be monitored.

Namespace

System

Usage

To execute Apex as an asynchronous job, implement the `Queueable` interface and add the processing logic in your implementation of the `execute` method.

To implement the `Queueable` interface, you must first declare a class with the `implements` keyword as follows:

```
public class MyQueueableClass implements Queueable {
```

Next, your class must provide an implementation for the following method:

```
public void execute(QueueableContext context) {
    // Your code here
}
```

Your class and method implementation must be declared as `public` or `global`.

To submit your class for asynchronous execution, call the `System.enqueueJob` by passing it an instance of your class implementation of the `Queueable` interface as follows:

```
ID jobID = System.enqueueJob(new MyQueueableClass());
```

IN THIS SECTION:

Queueable Methods

Queueable Example Implementation

SEE ALSO:

Queueable Apex

Queueable Methods

The following are methods for `Queueable`.

IN THIS SECTION:

execute(context)
Executes the queueable job.

`execute(context)`

Executes the queueable job.

Signature

```
public void execute(QueueableContext context)
```

Parameters

`context`
Type: QueueableContext

Contains the job ID.

Return Value

Type: Void

Queueable Example Implementation

This example is an implementation of the `Queueable` interface. The `execute` method in this example inserts a new account.

```
public class AsyncExecutionExample implements Queueable {
    public void execute(QueueableContext context) {
        Account a = new Account(Name='Acme',Phone='(415) 555-1212');
        insert a;
    }
}
```

To add this class as a job on the queue, call this method:

```
ID jobID = System.enqueueJob(new AsyncExecutionExample());
```

After you submit your queueable class for execution, the job is added to the queue and will be processed when system resources become available. You can monitor the status of your job programmatically by querying AsyncApexJob or through the user interface in Setup by entering *Apex Jobs* in the `Quick Find` box, then selecting **Apex Jobs**.

To query information about your submitted job, perform a SOQL query on AsyncApexJob by filtering on the job ID that the `System.enqueueJob` method returns. This example uses the jobID variable that was obtained in the previous example.

```
AsyncApexJob jobInfo = [SELECT Status,NumberOfErrors FROM AsyncApexJob WHERE Id=:jobID];
```

Similar to future jobs, queueable jobs don't process batches, and so the number of processed batches and the number of total batches are always zero.

Testing Queueable Jobs

This example shows how to test the execution of a queueable job in a test method. A queueable job is an asynchronous process. To ensure that this process runs within the test method, the job is submitted to the queue between the `Test.startTest` and `Test.stopTest` block. The system executes all asynchronous processes started in a test method synchronously after the `Test.stopTest` statement. Next, the test method verifies the results of the queueable job by querying the account that the job created.

```
@isTest
public class AsyncExecutionExampleTest {
    static testmethod void test1() {
        // startTest/stopTest block to force async processes
        //   to run in the test.
        Test.startTest();
        System.enqueueJob(new AsyncExecutionExample());
        Test.stopTest();

        // Validate that the job has run
        // by verifying that the record was created.
        // This query returns only the account created in test context by the
        // Queueable class method.
        Account acct = [SELECT Name,Phone FROM Account WHERE Name='Acme' LIMIT 1];
        System.assertNotEquals(null, acct);
        System.assertEquals('(415) 555-1212', acct.Phone);
    }
}
```

Note: The ID of a queueable Apex job isn't returned in test context—`System.enqueueJob` returns `null` in a running test.

QueueableContext Interface

Represents the parameter type of the `execute()` method in a class that implements the `Queueable` interface and contains the job ID. This interface is implemented internally by Apex.

Namespace

System

QueueableContext Methods

The following are methods for `QueueableContext`.

IN THIS SECTION:

getJobId()
Returns the ID of the submitted job that uses the `Queueable` interface.

`getJobId()`

Returns the ID of the submitted job that uses the `Queueable` interface.

Signature

```
public ID getJobId()
```

Return Value

Type: ID

The ID of the submitted job.

QuickAction Class

Use Apex to request and process actions on objects that allow custom fields, on objects that appear in a Chatter feed, or on objects that are available globally.

Namespace

System

Example

In this sample, the trigger determines if the new contacts to be inserted are created by a quick action. If so, it sets the `WhereFrom__c` custom field to a value that depends on whether the quick action is global or local to the contact. Otherwise, if the inserted contacts don't originate from a quick action, the `WhereFrom__c` field is set to `'NoAction'`.

```
trigger accTrig2 on Contact (before insert) {
    for (Contact c : Trigger.new) {
        if (c.getQuickActionName() == QuickAction.CreateContact) {
            c.WhereFrom__c = 'GlobaActionl';
```

```
        } else if (c.getQuickActionName() == Schema.Account.QuickAction.CreateContact) {
            c.WhereFrom__c = 'AccountAction';
        } else if (c.getQuickActionName() == null) {
            c.WhereFrom__c = 'NoAction';
        } else {
            System.assert(false);
        }
    }
}
```

This sample performs a global action—`QuickAction.CreateContact`–on the passed-in contact object.

```
public Id globalCreate(Contact c) {
    QuickAction.QuickActionRequest req = new QuickAction.QuickActionRequest();
    req.quickActionName = QuickAction.CreateContact;
    req.record = c;
    QuickAction.QuickActionResult res = QuickAction.performQuickAction(req);
    return c.id;
}
```

SEE ALSO:

QuickActionRequest Class

QuickActionResult Class

QuickAction Methods

The following are methods for `QuickAction`. All methods are static.

IN THIS SECTION:

describeAvailableQuickActions(parentType)
Returns metadata information for the available quick actions of the provided parent object.

describeAvailableQuickActions(sObjectNames)
Returns the metadata information for the provided quick actions.

performQuickAction(quickActionRequest)
Performs the quick action specified in the quick action request and returns the action result.

performQuickAction(quickActionRequest, allOrNothing)
Performs the quick action specified in the quick action request with the option for partial success, and returns the result.

performQuickActions(quickActionRequests)
Performs the quick actions specified in the quick action request list and returns action results.

performQuickActions(quickActionRequests, allOrNothing)
Performs the quick actions specified in the quick action request list with the option for partial success, and returns action results.

`describeAvailableQuickActions(parentType)`

Returns metadata information for the available quick actions of the provided parent object.

Signature

```
public static List<QuickAction.DescribeAvailableQuickActionResult>
describeAvailableQuickActions(String parentType)
```

Parameters

parentType
Type: String

The parent object type. This can be an object type name ('Account') or 'Global' (meaning that this method is called at a global level and not an entity level).

Return Value

Type: List<QuickAction.DescribeAvailableQuickActionResult>

The metadata information for the available quick actions of the parent object.

Example

```
// Called for Account entity.
List<QuickAction.DescribeAvailableQuickActionResult> result1 =
    QuickAction.DescribeAvailableQuickActions('Account');

// Called at global level, not entity level.
List<QuickAction.DescribeAvailableQuickActionResult> result2 =
    QuickAction.DescribeAvailableQuickActions('Global');
```

describeAvailableQuickActions(sObjectNames)

Returns the metadata information for the provided quick actions.

Signature

```
public static List<QuickAction.DescribeQuickActionResult>
describeAvailableQuickActions(List<String> sObjectNames)
```

Parameters

sObjectNames
Type: List<String>

The names of the quick actions. The quick action name can contain the entity name if it is at the entity level ('Account.QuickCreateContact'), or 'Global' if used for the action at the global level ('Global.CreateNewContact').

Return Value

Type: List<QuickAction.DescribeQuickActionResult>

The metadata information for the provided quick actions.

Example

```
// First 3 parameter values are for actions at the entity level.
// Last parameter is for an action at the global level.
List<QuickAction.DescribeQuickActionResult> result =
    QuickAction.DescribeQuickActions(new List<String> {
        'Account.QuickCreateContact', 'Opportunity.Update1',
        'Contact.Create1', 'Global.CreateNewContact' });
```

performQuickAction(quickActionRequest)

Performs the quick action specified in the quick action request and returns the action result.

Signature

```
public static QuickAction.QuickActionResult
performQuickAction(QuickAction.QuickActionRequest quickActionRequest)
```

Parameters

quickActionRequest
Type: QuickAction.QuickActionRequest

Return Value

Type: QuickAction.QuickActionResult

performQuickAction(quickActionRequest, allOrNothing)

Performs the quick action specified in the quick action request with the option for partial success, and returns the result.

Signature

```
public static QuickAction.QuickActionResult
performQuickAction(QuickAction.QuickActionRequest quickActionRequest, Boolean
allOrNothing)
```

Parameters

quickActionRequest
Type: QuickAction.QuickActionRequest

allOrNothing
Type: Boolean

Specifies whether this operation allows partial success. If you specify `false` for this argument and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value

Type: QuickAction.QuickActionResult

`performQuickActions(quickActionRequests)`

Performs the quick actions specified in the quick action request list and returns action results.

Signature

```
public static List<QuickAction.QuickActionResult>
performQuickActions(List<QuickAction.QuickActionRequest> quickActionRequests)
```

Parameters

`quickActionRequests`
Type: List<QuickAction.QuickActionRequest>

Return Value

Type: List<QuickAction.QuickActionResult>

`performQuickActions(quickActionRequests, allOrNothing)`

Performs the quick actions specified in the quick action request list with the option for partial success, and returns action results.

Signature

```
public static List<QuickAction.QuickActionResult>
performQuickActions(List<QuickAction.QuickActionRequest> quickActionRequests, Boolean
allOrNothing)
```

Parameters

`quickActionRequests`
Type: List<QuickAction.QuickActionRequest>

`allOrNothing`
Type: Boolean

Specifies whether this operation allows partial success. If you specify `false` for this argument and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value

Type: List<QuickAction.QuickActionResult>

RemoteObjectController

Use `RemoteObjectController` to access the standard Visualforce Remote Objects operations in your Remote Objects override methods.

Namespace

System

Usage

`RemoteObjectController` is supported only for use within Remote Objects methods. See "Overriding Default Remote Objects Operations" in the *Visualforce Developer's Guide* for examples of how to use `RemoteObjectController` with your Visualforce pages.

RemoteObjectController Methods

The following are methods for `RemoteObjectController`. All methods are static.

IN THIS SECTION:

create(type, fields)
Create a record in the database.

del(type, recordIds)
Delete records from the database.

retrieve(type, fields, criteria)
Retrieve records from the database.

updat(type, recordIds, fields)
Update records in the database.

`create(type, fields)`

Create a record in the database.

Signature

```
public static Map<String,Object> create(String type, Map<String,Object> fields)
```

Parameters

`type`
Type: String

The sObject type on which create is being called.

`fields`
Type: Map<String,Object>

The fields and values to set on the new record.

Return Value

Type: Map<String,Object>

The return value is a map that represents the result of the Remote Objects operation. What is returned depends on the results of the call.

Success
A map that contains a single element with the ID of the record created. For example, `{ id: 'recordId' }`.

Failure
A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

del(type, recordIds)

Delete records from the database.

Signature

```
public static Map<String,Object> del(String type, List<String> recordIds)
```

Parameters

type
Type: String

The sObject type on which delete is being called.

recordIds
Type: List<String>

The IDs of the records to be deleted.

Return Value

Type: Map<String,Object>

The return value is a map that represents the result of the Remote Objects operation. What is returned depends on how the method was called and the results of the call.

Single Delete—Success
A map that contains a single element with the ID of the record that was deleted. For example, `{ id: 'recordId' }`.

Batch Delete—Success
A map that contains a single element, an array of Map<String,Object> elements. Each element contains the ID of a record that was deleted and an array of errors, if there were any, for that record's individual delete. For example, `{ results: [ { id: 'recordId', errors: ['errorMessage', ...]}, ...] }`.

Single and Batch Delete—Failure
A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

retrieve(type, fields, criteria)

Retrieve records from the database.

Signature

```
public static Map<String,Object> retrieve(String type, List<String> fields,
Map<String,Object> criteria)
```

Parameters

type
Type: String

The sObject type on which retrieve is being called.

fields
Type: List<String>

The fields to retrieve for each record.

criteria
Type: Map<String,Object>

The criteria to use when performing the query.

Return Value

Type: Map<String,Object>

The return value is a map that represents the result of the Remote Objects operation. What is returned depends on the results of the call.

Success
A map that contains the following elements.

- `records`: An array of records that match the query conditions.
- `type`: A string that indicates the type of the sObject that was retrieved.
- `size`: The number of records in the response.

Failure
A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

updat(type, recordIds, fields)

Update records in the database.

Signature

```
public static Map<String,Object> updat(String type, List<String> recordIds,
Map<String,Object> fields)
```

Parameters

type
Type: String

The sObject type on which update is being called.

recordIds
Type: List<String>

The IDs of the records to be updated.

fields
Type: Map<String,Object>

The fields to update, and the value to update each field with.

Return Value

Type: Map<String,Object>

The return value is a map that represents the result of the Remote Objects operation. What is returned depends on how the method was called and the results of the call.

Single Update—Success
A map that contains a single element with the ID of the record that was updated. For example, `{ id: 'recordId' }`.

Batch Update—Success
A map that contains a single element, an array of Map<String,Object> elements. Each element contains the ID of the record updated and an array of errors, if there were any, for that record's individual update. For example, `{ results: [ { id: 'recordId', errors: ['errorMessage', ...]}, ...] }`.

Single and Batch Update—Failure
A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

ResetPasswordResult Class

Represents the result of a password reset.

Namespace

System

ResetPasswordResult Methods

The following are instance methods for `ResetPasswordResult`.

IN THIS SECTION:

getPassword()
Returns the password generated by the `System.resetPassword` method call.

`getPassword()`

Returns the password generated by the `System.resetPassword` method call.

Signature

```
public String getPassword()
```

Return Value

Type: String

RestContext Class

Contains the `RestRequest` and `RestResponse` objects.

Namespace

System

Usage

Use the `System.RestContext` class to access the `RestRequest` and `RestResponse` objects in your Apex REST methods.

Sample

The following example shows how to use `RestContext` to access the `RestRequest` and `RestResponse` objects in an Apex REST method.

```
@RestResource(urlMapping='/MyRestContextExample/*')
global with sharing class MyRestContextExample {

    @HttpGet
    global static Account doGet() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
        String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
        Account result = [SELECT Id, Name, Phone, Website FROM Account WHERE Id =
:accountId];
        return result;
    }

}
```

RestContext Properties

The following are properties for `RestContext`.

IN THIS SECTION:

request

Returns the `RestRequest` for your Apex REST method.

response

Returns the `RestResponse` for your Apex REST method.

request

Returns the `RestRequest` for your Apex REST method.

Signature

```
public RestRequest request {get; set;}
```

Property Value

Type: System.RestRequest

response

Returns the `RestResponse` for your Apex REST method.

Signature

```
public RestResponse response {get; set;}
```

Property Value

Type: System.RestResponse

RestRequest Class

Represents an object used to pass data from an HTTP request to an Apex RESTful Web service method.

Namespace

System

Usage

Use the `System.RestRequest` class to pass request data into an Apex RESTful Web service method that is defined using one of the REST annotations.

Example: An Apex Class with REST Annotated Methods

The following example shows you how to implement the Apex REST API in Apex. This class exposes three methods that each handle a different HTTP request: GET, DELETE, and POST. You can call these annotated methods from a client by issuing HTTP requests.

```
@RestResource(urlMapping='/Account/*')
global with sharing class MyRestResource {

    @HttpDelete
    global static void doDelete() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
        String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
        Account account = [SELECT Id FROM Account WHERE Id = :accountId];
        delete account;
    }

    @HttpGet
    global static Account doGet() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
        String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
        Account result = [SELECT Id, Name, Phone, Website FROM Account WHERE Id =
```

```
:accountId];
        return result;
    }

  @HttpPost
    global static String doPost(String name,
        String phone, String website) {
        Account account = new Account();
        account.Name = name;
        account.phone = phone;
        account.website = website;
        insert account;
        return account.Id;
    }
}
```

IN THIS SECTION:

RestRequest Constructors

RestRequest Properties

RestRequest Methods

RestRequest Constructors

The following are constructors for `RestRequest`.

IN THIS SECTION:

RestRequest()
Creates a new instance of the `System.RestRequest` class.

`RestRequest()`

Creates a new instance of the `System.RestRequest` class.

Signature

```
public RestRequest()
```

RestRequest Properties

The following are properties for `RestRequest`.

Note: While the `RestRequest` List and Map properties are read-only, their contents are read-write. You can modify them by calling the collection methods directly or you can use of the associated `RestRequest` methods shown in the previous table.

IN THIS SECTION:

headers
Returns the headers that are received by the request.

httpMethod
Returns one of the supported HTTP request methods.

params
Returns the parameters that are received by the request.

remoteAddress
Returns the IP address of the client making the request.

requestBody
Returns or sets the body of the request.

requestURI
Returns or sets everything after the host in the HTTP request string.

resourcePath
Returns the REST resource path for the request.

headers

Returns the headers that are received by the request.

Signature

```
public Map<String, String> headers {get; set;}
```

Property Value

Type: Map<String, String>

httpMethod

Returns one of the supported HTTP request methods.

Signature

```
public String httpMethod {get; set;}
```

Property Value

Type: String

Possible values returned:

- DELETE
- GET
- HEAD
- PATCH
- POST
- PUT

params

Returns the parameters that are received by the request.

Signature

```
public Map <String, String> params {get; set;}
```

Property Value

Type: Map<String, String>

remoteAddress

Returns the IP address of the client making the request.

Signature

```
public String remoteAddress {get; set;}
```

Property Value

Type: String

requestBody

Returns or sets the body of the request.

Signature

```
public Blob requestBody {get; set;}
```

Property Value

Type: Blob

Usage

If the Apex method has no parameters, then Apex REST copies the HTTP request body into the `RestRequest.requestBody` property. If there are parameters, then Apex REST attempts to deserialize the data into those parameters and the data won't be deserialized into the `RestRequest.requestBody` property.

requestURI

Returns or sets everything after the host in the HTTP request string.

Signature

```
public String requestURI {get; set;}
```

Property Value

Type: String

Example

For example, if the request string is *https://instance.salesforce.com/services/apexrest/Account/* then the `requestURI` is */services/apexrest/Account/*.

resourcePath

Returns the REST resource path for the request.

Signature

```
public String resourcePath {get; set;}
```

Property Value

Type: String

Example

For example, if the Apex REST class defines a `urlMapping` of `/MyResource/*`, the `resourcePath` property returns `/services/apexrest/MyResource/*`.

RestRequest Methods

The following are methods for `RestRequest`. All are instance methods.

Note: At runtime, you typically don't need to add a header or parameter to the `RestRequest` object because they are automatically deserialized into the corresponding properties. The following methods are intended for unit testing Apex REST classes. You can use them to add header or parameter values to the `RestRequest` object without having to recreate the REST method call.

IN THIS SECTION:

addHeader(name, value)
Adds a header to the request header map.

addParameter(name, value)
Adds a parameter to the request params map.

addHeader(name, value)

Adds a header to the request header map.

Signature

```
public Void addHeader(String name, String value)
```

Parameters

name
Type: String

value
Type: String

Return Value

Type: Void

Usage

This method is intended for unit testing of Apex REST classes.

Please note that the following headers aren't allowed:

- cookie
- set-cookie
- set-cookie2
- content-length
- authorization

If any of these are used, an Apex exception will be thrown.

`addParameter(name, value)`

Adds a parameter to the request params map.

Signature

```
public Void addParameter(String name, String value)
```

Parameters

name
Type: String

value
Type: String

Return Value

Type: Void

Usage

This method is intended for unit testing of Apex REST classes.

RestResponse Class

Represents an object used to pass data from an Apex RESTful Web service method to an HTTP response.

Namespace

System

Usage

Use the `System.RestResponse` class to pass response data from an Apex RESTful web service method that is defined using one of the REST annotations on page 97.

IN THIS SECTION:

RestResponse Constructors

RestResponse Properties

RestResponse Methods

RestResponse Constructors

The following are constructors for `RestResponse`.

IN THIS SECTION:

RestResponse()
Creates a new instance of the `System.RestResponse` class.

`RestResponse()`

Creates a new instance of the `System.RestResponse` class.

Signature

```
public RestResponse()
```

RestResponse Properties

The following are properties for `RestResponse`.

Note: While the `RestResponse` List and Map properties are read-only, their contents are read-write. You can modify them by calling the collection methods directly or you can use of the associated `RestResponse` methods shown in the previous table.

IN THIS SECTION:

responseBody
Returns or sets the body of the response.

headers
Returns the headers to be sent to the response.

statusCode
Returns or sets the response status code.

responseBody

Returns or sets the body of the response.

Signature

```
public Blob responseBody {get; set;}
```

Property Value

Type: Blob

Usage

The response is either the serialized form of the method return value or it's the value of the `responseBody` property based on the following rules:

- If the method returns void, then Apex REST returns the response in the `responseBody` property.
- If the method returns a value, then Apex REST serializes the return value as the response.

headers

Returns the headers to be sent to the response.

Signature

```
public Map<String, String> headers {get; set;}
```

Property Value

Type: Map<String, String>

statusCode

Returns or sets the response status code.

Signature

```
public Integer statuscode {get; set;}
```

Property Value

Type: Integer

Status Codes

The following are valid response status codes. The status code is returned by the `RestResponse.statusCode` property.

Note: If you set the `RestResponse.statusCode` property to a value that's not listed in the table, then an HTTP status of 500 is returned with the error message "Invalid status code for HTTP response: nnn" where nnn is the invalid status code value.

Status Code	Description
200	OK
201	CREATED
202	ACCEPTED
204	NO_CONTENT
206	PARTIAL_CONTENT
300	MULTIPLE_CHOICES
301	MOVED_PERMANENTLY
302	FOUND
304	NOT_MODIFIED
400	BAD_REQUEST
401	UNAUTHORIZED
403	FORBIDDEN
404	NOT_FOUND
405	METHOD_NOT_ALLOWED
406	NOT_ACCEPTABLE
409	CONFLICT
410	GONE
412	PRECONDITION_FAILED
413	REQUEST_ENTITY_TOO_LARGE
414	REQUEST_URI_TOO_LARGE
415	UNSUPPORTED_MEDIA_TYPE
417	EXPECTATION_FAILED
500	INTERNAL_SERVER_ERROR
503	SERVER_UNAVAILABLE

RestResponse Methods

The following are instance methods for `RestResponse`.

Note: At runtime, you typically don't need to add a header to the `RestResponse` object because it's automatically deserialized into the corresponding properties. The following methods are intended for unit testing Apex REST classes. You can use them to add header or parameter values to the `RestRequest` object without having to recreate the REST method call.

IN THIS SECTION:

addHeader(name, value)
Adds a header to the response header map.

addHeader(name, value)

Adds a header to the response header map.

Signature

```
public Void addHeader(String name, String value)
```

Parameters

name
Type: String

value
Type: String

Return Value

Type: Void

Usage

Please note that the following headers aren't allowed:

- cookie
- set-cookie
- set-cookie2
- content-length
- authorization

If any of these are used, an Apex exception will be thrown.

SandboxPostCopy Interface

To make your sandbox environment business ready, automate data manipulation or business logic tasks. Extend this interface and add methods to perform post-copy tasks, then specify the class during sandbox creation.

Namespace

System

Usage

Create an Apex class that implements this interface. Specify your class during sandbox creation. After your sandbox is created, the `runApexClass(context)` method in your class runs using the automated process user's permissions.

IN THIS SECTION:

SandboxPostCopy Methods

SandboxPostCopy Example Implementation

These examples show a simple implementation of the SandboxPostCopy interface and a test for that implementation. To test your SandboxPostCopy implementation, use the `System.Test.testSandboxPostCopyScript()` method.

SEE ALSO:

Tooling API: SandboxInfo

Tooling API: SandboxProcess

SandboxPostCopy Methods

The following method is for `SandboxPostCopy`.

IN THIS SECTION:

runApexClass(context)

Executes actions in a new sandbox to prepare it for use. For example, add logic to this method to create users, run sanitizing code on records, and perform other setup tasks.

`runApexClass(context)`

Executes actions in a new sandbox to prepare it for use. For example, add logic to this method to create users, run sanitizing code on records, and perform other setup tasks.

Signature

```
public void runApexClass(System.SandboxContext context)
```

Parameters

`context`

Type: System.SandboxContext

The org ID, sandbox ID, and sandbox name for your sandbox. To work with these values, reference `context.organizationId()`, `context.sandboxId()`, and `context.sandboxName()` in your code.

Return Value

Type: void

SandboxPostCopy Example Implementation

These examples show a simple implementation of the SandboxPostCopy interface and a test for that implementation. To test your SandboxPostCopy implementation, use the `System.Test.testSandboxPostCopyScript()` method.

This is an example implementation of the `System.SandboxPostCopy` interface.

```
global class PrepareMySandbox implements SandboxPostCopy {
    global void runApexClass(SandboxContext context) {
```

```
        System.debug('Org ID: ' + context.organizationId());
        System.debug('Sandbox ID: ' + context.sandboxId());
        System.debug('Sandbox Name: ' + context.sandboxName());

        // Insert logic here to prepare the sandbox for use.
    }
}
```

The following example tests the implementation using the `System.Test.testSandboxPostCopyScript()` method. This method takes four parameters: a reference to a class that implements the SandboxPostCopy interface, and the three fields on the context object that you pass to the `runApexClass(context)` method.

```
@isTest
class PrepareMySandboxTest {

    @isTest
    static void testMySandboxPrep() {
       // Insert logic here to create records of the objects that the class you're testing

        // manipulates.

        Test.startTest();

        Test.testSandboxPostCopyScript(
            new PrepareMySandbox(), UserInfo.getOrganizationId(),
                UserInfo.getOrganizationId(), UserInfo.getOrganizationName());

        Test.stopTest();

        // Insert assert statements here to check that the records you created above have

        // the values you expect.
    }
}
```

For more information on testing, see Testing Apex.

Schedulable Interface

The class that implements this interface can be scheduled to run at different intervals.

Namespace

System

SEE ALSO:

Apex Scheduler

Schedulable Methods

The following are methods for `Schedulable`.

IN THIS SECTION:

execute(context)
Executes the scheduled Apex job.

execute(context)

Executes the scheduled Apex job.

Signature

```
public Void execute(SchedulableContext context)
```

Parameters

context
Type: System.SchedulableContext

Contains the job ID.

Return Value

Type: Void

SchedulableContext Interface

Represents the parameter type of a method in a class that implements the `Schedulable` interface and contains the scheduled job ID. This interface is implemented internally by Apex.

Namespace

System

SEE ALSO:

Schedulable Interface

SchedulableContext Methods

The following are methods for `SchedulableContext`.

IN THIS SECTION:

getTriggerId()
Returns the ID of the CronTrigger scheduled job.

getTriggerId()

Returns the ID of the CronTrigger scheduled job.

Signature

```
public Id getTriggerId()
```

Return Value

Type: ID

Schema Class

Contains methods for obtaining schema describe information.

Namespace

System

Schema Methods

The following are methods for `Schema`. All methods are static.

IN THIS SECTION:

getGlobalDescribe()
Returns a map of all sObject names (keys) to sObject tokens (values) for the standard and custom objects defined in your organization.

describeDataCategoryGroups(sObjectNames)
Returns a list of the category groups associated with the specified objects.

describeSObjects(sObjectTypes)
Describes metadata (field list and object properties) for the specified sObject or array of sObjects.

describeTabs()
Returns information about the standard and custom apps available to the running user.

GroupStructures(pairs)
Returns available category groups along with their data category structure for objects specified in the request.

`getGlobalDescribe()`

Returns a map of all sObject names (keys) to sObject tokens (values) for the standard and custom objects defined in your organization.

Signature

```
public static Map<String, Schema.SObjectType> getGlobalDescribe()
```

Return Value

Type: Map<String, Schema.SObjectType>

Usage

For more information, see Accessing All sObjects.

Example

```
Map<String, Schema.SObjectType> gd =
Schema.getGlobalDescribe();
```

describeDataCategoryGroups(sObjectNames)

Returns a list of the category groups associated with the specified objects.

Signature

```
public static List<Schema.DescribeDataCategoryGroupResult>
describeDataCategoryGroups(List<String> sObjectNames)
```

Parameters

sObjectNames
Type: List<String>

Return Value

Type: List<Schema.DescribeDataCategoryGroupResult>

Usage

You can specify one of the following sObject names:

- KnowledgeArticleVersion—to retrieve category groups associated with article types.
- Question—to retrieve category groups associated with questions.

For more information and code examples using describeDataCategoryGroups, see Accessing All Data Categories Associated with an sObject.

For additional information about articles and questions, see "Work with Articles and Translations" and "Answers Overview" in the Salesforce online help.

describeSObjects(sObjectTypes)

Describes metadata (field list and object properties) for the specified sObject or array of sObjects.

Signature

```
public static List<Schema.DescribeSObjectResult> describeSObjects(List<String>
sObjectTypes)
```

Parameters

sObjectTypes
Type: List<String>

The *sObjectTypes* argument is a list of sObject type names you want to describe.

Return Value

Type: List<Schema.DescribeSObjectResult>

Usage

This method is similar to the `getDescribe` method on the `Schema.sObjectType` token. Unlike the `getDescribe` method, this method allows you to specify the sObject type dynamically and describe more than one sObject at a time.

You can first call `getGlobalDescribe` to retrieve a list of all objects for your organization, then iterate through the list and use `describeSObjects` to obtain metadata about individual objects.

Example

```
Schema.DescribeSObjectResult[] descResult = Schema.describeSObjects(
                                                                    new
String[]{'Account','Contact'});
```

`describeTabs()`

Returns information about the standard and custom apps available to the running user.

Signature

```
public static List<Schema.DescribeTabSetResult> describeTabs()
```

Return Value

Type: List<Schema.DescribeTabSetResult>

Usage

An app is a group of tabs that works as a unit to provide application functionality. For example, two of the standard Salesforce apps are "Sales" and "Service."

The `describeTabs` method returns the minimum required metadata that can be used to render apps in another user interface. Typically, this call is used by partner applications to render Salesforce data in another user interface, such as in a mobile or connected app.

In the Salesforce user interface, users have access to standard apps (and might also have access to custom apps) as listed in the Salesforce app menu at the top of the page. Selecting an app name in the menu allows the user to switch between the listed apps at any time.

Note: The "All Tabs" tab isn't included in the list of described tabs.

Example

This example shows how to call the `describeTabs` method.

```
Schema.DescribeTabSetResult[] tabSetDesc = Schema.describeTabs();
```

This is a longer example that shows how to obtain describe metadata information for the Sales app. For each tab, the example gets describe information, such as the icon URL, whether the tab is custom or not, and colors. The describe information is written to the debug output.

```
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set describe for each app and display the info
for(DescribeTabSetResult tsr : tabSetDesc) {
    String appLabel = tsr.getLabel();
    System.debug('Label: ' + appLabel);
    System.debug('Logo URL: ' + tsr.getLogoUrl());
    System.debug('isSelected: ' + tsr.isSelected());
    String ns = tsr.getNamespace();
    if (ns == '') {
        System.debug('The ' + appLabel + ' app has no namespace defined.');
    }
    else {
        System.debug('Namespace: ' + ns);
    }

    // Display tab info for the Sales app
    if (appLabel == 'Sales') {
        List<Schema.DescribeTabResult> tabDesc = tsr.getTabs();
        System.debug('-- Tab information for the Sales app --');
        for(Schema.DescribeTabResult tr : tabDesc) {
            System.debug('getLabel: ' + tr.getLabel());
            System.debug('getColors: ' + tr.getColors());
            System.debug('getIconUrl: ' + tr.getIconUrl());
            System.debug('getIcons: ' + tr.getIcons());
            System.debug('getMiniIconUrl: ' + tr.getMiniIconUrl());
            System.debug('getSobjectName: ' + tr.getSobjectName());
            System.debug('getUrl: ' + tr.getUrl());
            System.debug('isCustom: ' + tr.isCustom());
        }
    }
}

// Example debug statement output
// DEBUG|Label: Sales
// DEBUG|Logo URL: https://yourInstance.salesforce.com/img/seasonLogos/2014_winter_aloha.png
// DEBUG|isSelected: true
// DEBUG|The Sales app has no namespace defined.// DEBUG|-- Tab information for the Sales
 app --
// (This is an example debug output for the Accounts tab.)
// DEBUG|getLabel: Accounts
// DEBUG|getColors:
(Schema.DescribeColorResult[getColor=236FBD;getContext=primary;getTheme=theme4;],
//       Schema.DescribeColorResult[getColor=236FBD;getContext=primary;getTheme=theme3;],

//       Schema.DescribeColorResult[getColor=236FBD;getContext=primary;getTheme=theme2;])
// DEBUG|getIconUrl: https://yourInstance.salesforce.com/img/icon/accounts32.png
// DEBUG|getIcons:
(Schema.DescribeIconResult[getContentType=image/png;getHeight=32;getTheme=theme3;
```

```
//      getUrl=https://yourInstance.salesforce.com/img/icon/accounts32.png;getWidth=32;],

//       Schema.DescribeIconResult[getContentType=image/png;getHeight=16;getTheme=theme3;
//      getUrl=https://yourInstance.salesforce.com/img/icon/accounts16.png;getWidth=16;])
// DEBUG|getMiniIconUrl: https://yourInstance.salesforce.com/img/icon/accounts16.png
// DEBUG|getSobjectName: Account
// DEBUG|getUrl: https://yourInstance.salesforce.com/001/o
// DEBUG|isCustom: false
```

`GroupStructures(pairs)`

Returns available category groups along with their data category structure for objects specified in the request.

Signature

```
public static List<Schema.DescribeDataCategoryGroupStructureResult> describeDataCategory
GroupStructures(List<Schema.DataCategoryGroupSobjectTypePair> pairs)
```

Parameters

pairs

Type: List<Schema.DataCategoryGroupSobjectTypePair>

The *pairs* argument is one or more category groups and objects to query Schema.DataCategoryGroupSobjectTypePairs. Visible data categories are retrieved for the specified object. For more information on data category group visibility, see "Data Category Visibility" in the Salesforce online help.

Return Value

Type: List<Schema.DescribeDataCategoryGroupStructureResult>

Search Class

Use the methods of the Search class to perform dynamic SOSL queries.

Namespace

System

Search Methods

The following are static methods for `Search`.

IN THIS SECTION:

find(searchQuery)

Performs a dynamic SOSL query that can include the SOSL `WITH SNIPPET` clause. Snippets provide more context for users in Salesforce Knowledge article search results.

query(query)

Performs a dynamic SOSL query.

suggest(searchQuery, sObjectType, suggestions)

Returns a list of records or Salesforce Knowledge articles whose names or titles match the user's search query string. Use this method to provide users with shortcuts to navigate to relevant records or articles before they perform a search.

find(searchQuery)

Performs a dynamic SOSL query that can include the SOSL `WITH SNIPPET` clause. Snippets provide more context for users in Salesforce Knowledge article search results.

Signature

```
public static Search.SearchResults find(String searchQuery)
```

Parameters

searchQuery

Type: String

A SOSL query string.

Return Value

Type: Search.SearchResults

Usage

Use this method wherever a static SOSL query can be used, such as in regular assignment statements and `for` loops.

See Use Dynamic SOSL to Return Snippets on page 183.

SEE ALSO:

get(sObjectType)

Dynamic SOSL

query(query)

Performs a dynamic SOSL query.

Signature

```
public static sObject[sObject[]] query(String query)
```

Parameters

query

Type: String

A SOSL query string.

To create a SOSL query that includes the `WITH SNIPPET` clause, use the Search.find(String searchQuery) method instead.

Return Value

Type: sObject[sObject[]]

Usage

This method can be used wherever a static SOSL query can be used, such as in regular assignment statements and `for` loops.

For more information, see Dynamic SOSL.

`suggest(searchQuery, sObjectType, suggestions)`

Returns a list of records or Salesforce Knowledge articles whose names or titles match the user's search query string. Use this method to provide users with shortcuts to navigate to relevant records or articles before they perform a search.

Signature

```
public static Search.SuggestionResults suggest(String searchQuery, String sObjectType,
Search.SuggestionOption suggestions)
```

Parameters

`searchQuery`
Type: String

A SOSL query string.

`sObjectType`
Type: String

An sObject type.

`options`
Type: Search.SuggestionOption

This object contains options that change the suggestion results.

If the *`searchQuery`* returns KnowledgeArticleVersion objects, pass an *`options`* parameter with a Search.SuggestionOption object that contains a language KnowledgeSuggestionFilter and a publish status KnowledgeSuggestionFilter.

For suggestions for all other record types, the only supported option is a limit, which sets the maximum number of suggestions returned.

Return Value

Type: SuggestionResults

Usage

Use this method to return:

Suggestions for Salesforce Knowledge articles (KnowledgeArticleVersion)
Salesforce Knowledge must be enabled in your organization. The user must have the "View Articles" permission enabled.

The articles suggested include only the articles the user can access, based on the data categories and article types the user has permissions to view.

Suggestions for other record types

The records suggested include only the records the user can access.

This method returns a record if its name field starts with the text in the search string. This method automatically appends an asterisk wildcard (*) at the end of the search string. Records that contain the search string within a word aren't considered a match.

Records are suggested if the entire search string is found in the record name, in the same order as specified in the search string. For example, the text string `national u` is treated as `national u*` and returns "National Utility" and "National Urban Company" but not "National Company Utility" or "Urban National Company".

Note: If the user's search query contains quotation marks or wildcards, those symbols are automatically removed from the query string in the URI.

SEE ALSO:

Suggest Salesforce Knowledge Articles

SelectOption Class

A `SelectOption` object specifies one of the possible values for a Visualforce `selectCheckboxes`, `selectList`, or `selectRadio` component.

Namespace

System

`SelectOption` consists of a label that is displayed to the end user, and a value that is returned to the controller if the option is selected. A `SelectOption` can also be displayed in a disabled state, so that a user cannot select it as an option, but can still view it.

Instantiation

In a custom controller or controller extension, you can instantiate a SelectOption in one of the following ways:

- ```
  SelectOption option = new SelectOption(value, label, isDisabled);
  ```

  where *value* is the String that is returned to the controller if the option is selected by a user, *label* is the String that is displayed to the user as the option choice, and *isDisabled* is a Boolean that, if true, specifies that the user cannot select the option, but can still view it.

- ```
  SelectOption option = new SelectOption(value, label);
  ```

  where *value* is the String that is returned to the controller if the option is selected by a user, and *label* is the String that is displayed to the user as the option choice. Because a value for *isDisabled* is not specified, the user can both view and select the option.

Example

The following example shows how a list of SelectOptions objects can be used to provide possible values for a `selectCheckboxes` component on a Visualforce page. In the following custom controller, the `getItems` method defines and returns the list of possible SelectOption objects:

```
public class sampleCon {
```

```
  String[] countries = new String[]{};

  public PageReference test() {
    return null;
  }

  public List<SelectOption> getItems() {
    List<SelectOption> options = new List<SelectOption>();
    options.add(new SelectOption('US','US'));
    options.add(new SelectOption('CANADA','Canada'));
    options.add(new SelectOption('MEXICO','Mexico'));
    return options;
   }

  public String[] getCountries() {
     return countries;
  }

  public void setCountries(String[] countries) {
    this.countries = countries;
  }

}
```

In the following page markup, the `<apex:selectOptions>` tag uses the `getItems` method from the controller above to retrieve the list of possible values. Because `<apex:selectOptions>` is a child of the `<apex:selectCheckboxes>` tag, the options are displayed as checkboxes:

```
 <apex:page controller="sampleCon">
  <apex:form>
    <apex:selectCheckboxes value="{!countries}">
      <apex:selectOptions value="{!items}"/>
    </apex:selectCheckboxes><br/>
    <apex:commandButton value="Test" action="{!test}" rerender="out" status="status"/>
  </apex:form>
  <apex:outputPanel id="out">
    <apex:actionstatus id="status" startText="testing...">
      <apex:facet name="stop">
        <apex:outputPanel>
          <p>You have selected:</p>
          <apex:dataList value="{!countries}" var="c">{!c}</apex:dataList>
        </apex:outputPanel>
      </apex:facet>
    </apex:actionstatus>
  </apex:outputPanel>
</apex:page>
```

IN THIS SECTION:

SelectOption Constructors

SelectOption Methods

SelectOption Constructors

The following are constructors for `SelectOption`.

IN THIS SECTION:

SelectOption(value, label)
Creates a new instance of the `SelectOption` class using the specified value and label.

SelectOption(value, label, isDisabled)
Creates a new instance of the `SelectOption` class using the specified value, label, and disabled setting.

`SelectOption(value, label)`

Creates a new instance of the `SelectOption` class using the specified value and label.

Signature

```
public SelectOption(String value, String label)
```

Parameters

`value`
Type: String

The string that is returned to the Visualforce controller if the option is selected by a user.

`label`
Type: String

The string that is displayed to the user as the option choice.

`SelectOption(value, label, isDisabled)`

Creates a new instance of the `SelectOption` class using the specified value, label, and disabled setting.

Signature

```
public SelectOption(String value, String label, Boolean isDisabled)
```

Parameters

`value`
Type: String

The string that is returned to the Visualforce controller if the option is selected by a user.

`label`
Type: String

The string that is displayed to the user as the option choice.

`isDisabled`
Type: Boolean

If set to true, the option can't be selected by the user but can still be viewed.

SelectOption Methods

The following are methods for `SelectOption`. All are instance methods.

IN THIS SECTION:

getDisabled()
Returns the current value of the SelectOption object's `isDisabled` attribute.

getEscapeItem()
Returns the current value of the SelectOption object's `itemEscaped` attribute.

getLabel()
Returns the option label that is displayed to the user.

getValue()
Returns the option value that is returned to the controller if a user selects the option.

setDisabled(isDisabled)
Sets the value of the SelectOption object's `isDisabled` attribute.

setEscapeItem(itemsEscaped)
Sets the value of the SelectOption object's `itemEscaped` attribute.

setLabel(label)
Sets the value of the option label that is displayed to the user.

setValue(value)
Sets the value of the option value that is returned to the controller if a user selects the option.

`getDisabled()`

Returns the current value of the SelectOption object's `isDisabled` attribute.

Signature

```
public Boolean getDisabled()
```

Return Value

Type: Boolean

Usage

If `isDisabled` is set to `true`, the user can view the option, but cannot select it. If `isDisabled` is set to `false`, the user can both view and select the option.

`getEscapeItem()`

Returns the current value of the SelectOption object's `itemEscaped` attribute.

Signature

```
public Boolean getEscapeItem()
```

Return Value

Type: Boolean

Usage

If `itemEscaped` is set to `true`, sensitive HTML and XML characters are escaped in the HTML output generated by this component. If `itemEscaped` is set to `false`, items are rendered as written.

`getLabel()`

Returns the option label that is displayed to the user.

Signature

```
public String getLabel()
```

Return Value

Type: String

`getValue()`

Returns the option value that is returned to the controller if a user selects the option.

Signature

```
public String getValue()
```

Return Value

Type: String

`setDisabled(isDisabled)`

Sets the value of the SelectOption object's `isDisabled` attribute.

Signature

```
public Void setDisabled(Boolean isDisabled)
```

Parameters

`isDisabled`
Type: Boolean

Return Value

Type: Void

Usage

If `isDisabled` is set to `true`, the user can view the option, but cannot select it. If `isDisabled` is set to `false`, the user can both view and select the option.

`setEscapeItem(itemsEscaped)`

Sets the value of the SelectOption object's `itemEscaped` attribute.

Signature

```
public Void setEscapeItem(Boolean itemsEscaped)
```

Parameters

`itemsEscaped`
Type: Boolean

Return Value

Type: Void

Usage

If `itemEscaped` is set to `true`, sensitive HTML and XML characters are escaped in the HTML output generated by this component. If `itemEscaped` is set to `false`, items are rendered as written.

`setLabel(label)`

Sets the value of the option label that is displayed to the user.

Signature

```
public Void setLabel(String label)
```

Parameters

`label`
Type: String

Return Value

Type: Void

`setValue(value)`

Sets the value of the option value that is returned to the controller if a user selects the option.

Signature

```
public Void setValue(String value)
```

Parameters

value
Type: String

Return Value

Type: Void

Set Class

Represents a collection of unique elements with no duplicate values.

Namespace

System

Usage

The Set methods work on a set, that is, an unordered collection of elements that was initialized using the `set` keyword. Set elements can be of any data type—primitive types, collections, sObjects, user-defined types, and built-in Apex types. Set methods are all instance methods, that is, they all operate on a particular instance of a Set. The following are the instance methods for sets.

Note:

- Uniqueness of set elements of user-defined types is determined by the `equals` and `hashCode` methods, which you provide in your classes. Uniqueness of all other non-primitive types is determined by comparing the objects' fields.
- If the set contains String elements, the elements are case-sensitive. Two set elements that differ only by case are considered distinct.

For more information on sets, see Sets on page 32.

IN THIS SECTION:

Set Constructors

Set Methods

Set Constructors

The following are constructors for `Set`.

IN THIS SECTION:

Set<T>()

Creates a new instance of the `Set` class. A set can hold elements of any data type T.

Set<T>(setToCopy)

Creates a new instance of the `Set` class by copying the elements of the specified set. T is the data type of the elements in both sets and can be any data type.

Set<T>(listToCopy)
Creates a new instance of the `Set` class by coping the list elements. T is the data type of the elements in the set and list and can be any data type.

Set<T>()

Creates a new instance of the `Set` class. A set can hold elements of any data type T.

Signature

```
public Set<T>()
```

Example

```
// Create a set of strings
Set<String> s1 = new Set<String>();
// Add two strings to it
s1.add('item1');
s1.add('item2');
```

Set<T>(setToCopy)

Creates a new instance of the `Set` class by copying the elements of the specified set. T is the data type of the elements in both sets and can be any data type.

Signature

```
public Set<T>(Set<T> setToCopy)
```

Parameters

setToCopy
Type: Set<T>

The set to initialize this set with.

Example

```
Set<String> s1 = new Set<String>();
s1.add('item1');
s1.add('item2');
Set<String> s2 = new Set<String>(s1);
// The set elements in s2 are copied from s1
System.debug(s2);
```

Set<T>(listToCopy)

Creates a new instance of the `Set` class by coping the list elements. T is the data type of the elements in the set and list and can be any data type.

Signature

```
public Set<T>(List<T> listToCopy)
```

Parameters

listToCopy
Type: Integer

The list to copy the elements of into this set.

Example

```
List<Integer> ls = new List<Integer>();
ls.add(1);
ls.add(2);
// Create a set based on a list
Set<Integer> s1 = new Set<Integer>(ls);
// Elements are copied from the list to this set
System.debug(s1);// DEBUG|{1, 2}
```

Set Methods

The following are methods for `Set`. All are instance methods.

IN THIS SECTION:

add(setElement)
Adds an element to the set if it is not already present.

addAll(fromList)
Adds all of the elements in the specified list to the set if they are not already present.

addAll(fromSet)
Adds all of the elements in the specified set to the set that calls the method if they are not already present.

clear()
Removes all of the elements from the set.

clone()
Makes a duplicate copy of the set.

contains(setElement)
Returns `true` if the set contains the specified element.

containsAll(listToCompare)
Returns `true` if the set contains all of the elements in the specified list. The list must be of the same type as the set that calls the method.

containsAll(setToCompare)
Returns `true` if the set contains all of the elements in the specified set. The specified set must be of the same type as the original set that calls the method.

equals(set2)
Compares this set with the specified set and returns `true` if both sets are equal; otherwise, returns `false`.

hashCode()
Returns the hashcode corresponding to this set and its contents.

isEmpty()
Returns `true` if the set has zero elements.

remove(setElement)
Removes the specified element from the set if it is present.

removeAll(listOfElementsToRemove)
Removes the elements in the specified list from the set if they are present.

removeAll(setOfElementsToRemove)
Removes the elements in the specified set from the original set if they are present.

retainAll(listOfElementsToRetain)
Retains only the elements in this set that are contained in the specified list.

retainAll(setOfElementsToRetain)
Retains only the elements in the original set that are contained in the specified set.

size()
Returns the number of elements in the set (its cardinality).

add(setElement)

Adds an element to the set if it is not already present.

Signature

```
public Boolean add(Object setElement)
```

Parameters

setElement
Type: Object

Return Value

Type: Boolean

Usage

This method returns true if the original set changed as a result of the call. For example:

```
Set<String> myString = new Set<String>{'a', 'b', 'c'};
Boolean result = myString.add('d');
System.assertEquals(true, result);
```

addAll(fromList)

Adds all of the elements in the specified list to the set if they are not already present.

Signature

```
public Boolean addAll(List<Object> fromList)
```

Parameters

fromList
Type: List

Return Value

Type: Boolean

Returns `true` if the original set changed as a result of the call.

Usage

This method results in the *union* of the list and the set. The list must be of the same type as the set that calls the method.

addAll(fromSet)

Adds all of the elements in the specified set to the set that calls the method if they are not already present.

Signature

```
public Boolean addAll(Set<Object> fromSet)
```

Parameters

fromSet
Type: Set<Object>

Return Value

Type: Boolean

This method returns `true` if the original set changed as a result of the call.

Usage

This method results in the *union* of the two sets. The specified set must be of the same type as the original set that calls the method.

Example

```
Set<String> myString = new Set<String>{'a', 'b'};
Set<String> sString = new Set<String>{'c'};

Boolean result1 = myString.addAll(sString);
System.assertEquals(true, result1);
```

clear()

Removes all of the elements from the set.

Signature

```
public Void clear()
```

Return Value

Type: Void

clone()

Makes a duplicate copy of the set.

Signature

```
public Set<Object> clone()
```

Return Value

Type: Set (of same type)

contains(setElement)

Returns `true` if the set contains the specified element.

Signature

```
public Boolean contains(Object setElement)
```

Parameters

setElement
Type: Object

Return Value

Type: Boolean

Example

```
Set<String> myString = new Set<String>{'a', 'b'};
Boolean result = myString.contains('z');
System.assertEquals(false, result);
```

containsAll(listToCompare)

Returns `true` if the set contains all of the elements in the specified list. The list must be of the same type as the set that calls the method.

Signature

```
public Boolean containsAll(List<Object> listToCompare)
```

Parameters

listToCompare
Type: List<Object>

Return Value

Type: Boolean

containsAll(setToCompare)

Returns `true` if the set contains all of the elements in the specified set. The specified set must be of the same type as the original set that calls the method.

Signature

```
public Boolean containsAll(Set<Object> setToCompare)
```

Parameters

setToCompare
Type: Set<Object>

Return Value

Type: Boolean

Example

```
Set<String> myString = new Set<String>{'a', 'b'};
Set<String> sString = new Set<String>{'c'};
Set<String> rString = new Set<String>{'a', 'b', 'c'};

Boolean result1, result2;
result1 = myString.addAll(sString);
system.assertEquals(true, result1);

result2 = myString.containsAll(rString);
System.assertEquals(true, result2);
```

equals(set2)

Compares this set with the specified set and returns `true` if both sets are equal; otherwise, returns `false`.

Signature

```
public Boolean equals(Set<Object> set2)
```

Parameters

set2
Type: Set<Object>

The *set2* argument is the set to compare this set with.

Return Value

Type: Boolean

Usage

Two sets are equal if their elements are equal, regardless of their order. The `==` operator is used to compare the elements of the sets.

The `==` operator is equivalent to calling the `equals` method, so you can call `set1.equals(set2);` instead of `set1 == set2;`.

`hashCode()`

Returns the hashcode corresponding to this set and its contents.

Signature

```
public Integer hashCode()
```

Return Value

Type: Integer

`isEmpty()`

Returns `true` if the set has zero elements.

Signature

```
public Boolean isEmpty()
```

Return Value

Type: Boolean

Example

```
Set<Integer> mySet = new Set<Integer>();
Boolean result = mySet.isEmpty();
System.assertEquals(true, result);
```

`remove(setElement)`

Removes the specified element from the set if it is present.

Signature

```
public Boolean remove(Object setElement)
```

Parameters

setElement
Type: Object

Return Value

Type: Boolean

Returns `true` if the original set changed as a result of the call.

removeAll(listOfElementsToRemove)

Removes the elements in the specified list from the set if they are present.

Signature

```
public Boolean removeAll(List<Object> listOfElementsToRemove)
```

Parameters

listOfElementsToRemove
Type: List<Object>

Return Value

Type: Boolean

Returns `true` if the original set changed as a result of the call.

Usage

This method results in the *relative complement* of the two sets. The list must be of the same type as the set that calls the method.

Example

```
Set<integer> mySet = new Set<integer>{1, 2, 3};
List<integer> myList = new List<integer>{1, 3};
Boolean result = mySet.removeAll(myList);
System.assertEquals(true, result);
Integer result2 = mySet.size();
System.assertEquals(1, result2);
```

removeAll(setOfElementsToRemove)

Removes the elements in the specified set from the original set if they are present.

Signature

```
public Boolean removeAll(Set<Object> setOfElementsToRemove)
```

Parameters

setOfElementsToRemove
Type: Set<Object>

Return Value

Type: Boolean

This method returns `true` if the original set changed as a result of the call.

Usage

This method results in the *relative complement* of the two sets. The specified set must be of the same type as the original set that calls the method.

retainAll(listOfElementsToRetain)

Retains only the elements in this set that are contained in the specified list.

Signature

```
public Boolean retainAll(List<Object> listOfElementsToRetain)
```

Parameters

listOfElementsToRetain
Type: List<Object>

Return Value

Type: Boolean

This method returns `true` if the original set changed as a result of the call.

Usage

This method results in the *intersection* of the list and the set. The list must be of the same type as the set that calls the method.

Example

```
Set<integer> mySet = new Set<integer>{1, 2, 3};
List<integer> myList = new List<integer>{1, 3};
Boolean result = mySet.retainAll(myList);
System.assertEquals(true, result);
```

retainAll(setOfElementsToRetain)

Retains only the elements in the original set that are contained in the specified set.

Signature

```
public Boolean retainAll(Set setOfElementsToRetain)
```

Parameters

setOfElementsToRetain
Type: Set

Return Value

Type: Boolean

Returns `true` if the original set changed as a result of the call.

Usage

This method results in the *intersection* of the two sets. The specified set must be of the same type as the original set that calls the method.

`size()`

Returns the number of elements in the set (its cardinality).

Signature

```
public Integer size()
```

Return Value

Type: Integer

Example

```
Set<Integer> mySet = new Set<Integer>{1, 2, 3};
List<Integer> myList = new List<Integer>{1, 3};
Boolean result = mySet.retainAll(myList);

System.assertEquals(true, result);

Integer result2 = mySet.size();
System.assertEquals(2, result2);
```

Site Class

Use the `Site` Class to manage your Lightning Platform sites.

Namespace

System

Usage

If there is a exception when using `site.createPortalUser`, a null is returned and the site system administrator is sent an email. For more information on sites, see "Salesforce Sites" in the Salesforce online help.

Salesforce Sites Examples

The following example creates a class, `SiteRegisterController`, which is used with a Visualforce page (see markup below) to register new Customer Portal users.

Note: In the example below, you must enter the account ID of the account that you want to associate with new portal users. You must also add the account owner to the role hierarchy for this code example to work. For more information, see "Setting Up Your Customer Portal" in the Salesforce online help.

```
/**
 * An Apex class that creates a portal user
 */
public class SiteRegisterController {
    // PORTAL_ACCOUNT_ID is the account on which the contact will be created on
    //  and then enabled as a portal user.
    //Enter the account ID in place of <portal_account_id> below.
    private static Id PORTAL_ACCOUNT_ID = '<portal_account_id>';

    public SiteRegisterController () {
    }

    public String username {get; set;}
    public String email {get; set;}
    public String password {get; set {password = value == null ? value : value.trim(); }
}
    public String confirmPassword {get; set { confirmPassword =
        value == null ? value : value.trim(); } }
    public String communityNickname {get; set { communityNickname = \
        value == null ? value : value.trim(); } }

    private boolean isValidPassword() {
        return password == confirmPassword;
    }

    public PageReference registerUser() {
        // If password is null, a random password is sent to the user
        if (!isValidPassword()) {
           ApexPages.Message msg = new ApexPages.Message(ApexPages.Severity.ERROR,
               Label.site.passwords_dont_match);
           ApexPages.addMessage(msg);
            return null;
        }
        User u = new User();
        u.Username = username;
        u.Email = email;
        u.CommunityNickname = communityNickname;

        String accountId = PORTAL_ACCOUNT_ID;

        // lastName is a required field on user, but if it isn't specified,
           the code uses the username
        String userId = Site.createPortalUser(u, accountId, password);
        if (userId != null) {
            if (password != null && password.length() > 1) {
                return Site.login(username, password, null);
```

```
            }
            else {
                PageReference page = System.Page.SiteRegisterConfirm;
                page.setRedirect(true);
                return page;
            }
        }
        return null;
    }
}
```

```
/**
 * Test class.
 */
@isTest
private class SiteRegisterControllerTest {
    // Test method for verifying the positive test case
    static testMethod void testRegistration() {
        SiteRegisterController controller = new SiteRegisterController();
        controller.username = 'test@force.com';
        controller.email = 'test@force.com';
        controller.communityNickname = 'test';
        // registerUser always returns null when the page isn't accessed as a guest user
        System.assert(controller.registerUser() == null);
        controller.password = 'abcd1234';
        controller.confirmPassword = 'abcd123';
        System.assert(controller.registerUser() == null);
    }
}
```

The following is the Visualforce registration page that uses the `SiteRegisterController` Apex controller above:

```
<apex:page id="Registration" showHeader="false" controller=
    "SiteRegisterController" standardStylesheets="true">
  <apex:outputText value="Registration"/>
  <br/>
  <apex:form id="theForm">
   <apex:messages id="msg" styleClass="errorMsg" layout="table" style="margin-top:1em;"/>

    <apex:panelGrid columns="2" style="margin-top:1em;">
      <apex:outputLabel value="{!$Label.site.username}" for="username"/>
      <apex:inputText required="true" id="username" value="{!username}"/>
      <apex:outputLabel value="{!$Label.site.community_nickname}"
          for="communityNickname"/>
      <apex:inputText required="true" id="communityNickname" required="true"
          value="{!communityNickname}"/>
      <apex:outputLabel value="{!$Label.site.email}" for="email"/>
      <apex:inputText required="true" id="email" required="true" value="{!email}"/>
      <apex:outputLabel value="{!$Label.site.password}" for="password"/>
      <apex:inputSecret id="password" value="{!password}"/>
      <apex:outputLabel value="{!$Label.site.confirm_password}" for="confirmPassword"/>
      <apex:inputSecret id="confirmPassword" value="{!confirmPassword}"/>
      <apex:outputText value=""/>
      <apex:commandButton action="{!registerUser}" value="{!$Label.site.submit}"
          id="submit"/>
```

```
    </apex:panelGrid>
  </apex:form>
</apex:page>
```

The sample code for the `createPersonAccountPortalUser` method is nearly identical to the sample code above, with the following changes:

- Replace all instances of `PORTAL_ACCOUNT_ID` with `OWNER_ID`.
- Determine the ownerID instead of the accountID, and use the `createPersonAccountPortalUser` method instead of the `CreatePortalUser` method by replacing the following code block:

  ```
  String accountId = PORTAL_ACCOUNT_ID;
  String userId = Site.createPortalUser(u, accountId, password);
  ```

  with

  ```
  String ownerId = OWNER_ID;
  String userId = Site.createPersonAccountPortalUser(u, ownerId, password);
  ```

Site Methods

The following are methods for `Site`. All methods are static.

IN THIS SECTION:

changePassword(newPassword, verifyNewPassword, oldPassword)
Changes the password of the current user.

createExternalUser(user, accountId)
Creates a community or a portal user for the given account and associates it with the community.

createExternalUser(user, accountId, password)
Creates a community or a portal user for the given account and associates it with the community. This method sends an email with the specified password to the user.

createExternalUser(user, accountId, password, sendEmailConfirmation)
Creates a community or portal user and associates it with the given account. This method sends the user an email with the specified password and a new user confirmation email.

createPersonAccountPortalUser(user, ownerId, password)
Creates a person account using the default record type defined on the guest user's profile, then enables it for the site's portal.

createPersonAccountPortalUser(user, ownerId, recordTypeId, password)
Creates a person account using the specified *recordTypeID*, then enables it for the site's portal.

createPortalUser(user, accountId, password, sendEmailConfirmation)
Creates a portal user for the given account and associates it with the site's portal.

forgotPassword(username, emailTemplateName)
Resets the user's password and sends an email to the user with their new password. Returns a value indicating whether the password reset was successful or not.

forgotPassword(username)
Resets the user's password and sends an email to the user with their new password. Returns a value indicating whether the password reset was successful or not.

getAdminEmail()

Returns the email address of the site administrator.

getAdminId()

Returns the user ID of the site administrator.

getAnalyticsTrackingCode()

The tracking code associated with your site. This code can be used by services like Google Analytics to track page request data for your site.

getCurrentSiteUrl()

Deprecated. This method was replaced by `getBaseUrl()` in API version 30.0. Returns the base URL of the current site that references and links should use.

getBaseCustomUrl()

Returns a base URL for the current site that doesn't use a force.com subdomain. The returned URL uses the same protocol (HTTP or HTTPS) as the current request if at least one non-Force.com custom URL that supports HTTPS exists on the site. The returned value never ends with a `/` character. If all the custom URLs in this site end in Force.com or this site has no custom URLs, then this returns an empty string. If the current request is not a site request, then this method returns an empty string. This method replaced getCustomWebAddress and includes the custom URL's path prefix..

getBaseInsecureUrl()

Returns a base URL for the current site that uses HTTP instead of HTTPS. The current request's domain is used. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

getBaseRequestUrl()

Returns the base URL of the current site for the requested URL. This isn't influenced by the referring page's URL. The returned URL uses the same protocol (HTTP or HTTPS) as the current request. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

getBaseSecureUrl()

Returns a base URL for the current site that uses HTTPS instead of HTTP. The current request's domain is preferred if it supports HTTPS. Domains that are not Force.com subdomains are preferred over Force.com subdomains. A Force.com subdomain, if associated with the site, is used if no other HTTPS domains exist in the current site. If no HTTPS custom URLs exist in the site, then this method returns an empty string. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

getBaseUrl()

Returns the base URL of the current site that references and links should use. Note that this field may return the referring page's URL instead of the current request's URL. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this field returns an empty string. This field replaces getCurrentSiteUrl.

getCustomWebAddress()

Deprecated. This method was replaced by `getBaseCustomUrl()` in API version 30.0.

getDomain()

Returns the Salesforce Site domain (`force.com` subdomain URL hostname) for your organization.

getErrorDescription()

Returns the error description for the current page if it's a designated error page for the site and an error exists; otherwise, returns an empty string.

getErrorMessage()

Returns an error message for the current page if it's a designated error page for the site and an error exists; otherwise, returns an empty string.

getExperienceId()

Returns the value of the experience ID (expid). This expid value comes from a cookie in the user's web browser.

getMasterLabel()

Returns the value of the Master Label field for the current site. If the current request is not a site request, then this field returns `null`.

getName()

Returns the API name of the current site.

getOriginalUrl()

Returns the original URL for this page if it's a designated error page for the site; otherwise, returns `null`.

getPasswordPolicyStatement()

Returns the password requirements for a community created with the Customer Service template.

getPathPrefix()

Returns the URL path prefix of the current site or an empty string if none. For example, if the requested site URL is `http://myco.force.com/partners`, then `/partners` is the path prefix. If the current request is not a site request, then this method returns an empty string. This method replaced getPrefix in API version 30.0.

getPrefix()

Deprecated. This method was replaced by `getPathPrefix()` in API version 30.0.

getSiteId()

Returns the ID of the current site. If the current request is not a site request, then this field returns `null`.

getTemplate()

Returns the template name associated with the current site; returns the default template if no template has been designated.

getSiteType()

Returns the API value of the site type field for the current site. This can be Visualforce for a Salesforce site, Siteforce for a Site.com site, ChatterNetwork for a Communities site, or ChatterNetworkPicasso for a Site.com Communities site. If the current request is not a site request, then this method returns `null`.

getSiteTypeLabel()

Returns the value of the Site Type field's label for the current site. If the current request is not a site request, then this method returns `null`.

isLoginEnabled()

Returns `true` if the current site is associated with an active login-enabled portal; otherwise returns `false`.

isPasswordExpired()

For authenticated users, returns `true` if the currently logged-in user's password is expired. For non-authenticated users, returns `false`.

isRegistrationEnabled()

Returns `true` if the current site is associated with an active self-registration-enabled Customer Portal; otherwise returns `false`.

isValidUsername(username)

Returns `true` if the given username is valid; otherwise, returns `false`.

login(username, password, startUrl)

Allows users to log in to the current site with the given username and password, then takes them to the `startUrl`. If `startUrl` is not a relative path, it defaults to the site's designated index page.

passwordlessLogin(userId, methods, startUrl)

Logs in a user to a community using an identity verification method, such as email or text, instead of a password. Passwordless login is a convenient, mobile-friendly way to welcome users into your community. Give your community users an alternative to requiring passwords when they log in.

setExperienceId(expIdValue)

Sets the experience ID for the current user. Use this method to populate the value of the experience ID (expid) cookie in the user's web browser.

setPortalUserAsAuthProvider(user, contactId)

Sets the specified user information within the site's portal via an authentication provider.

validatePassword(user, password, confirmPassword)

Indicates whether a given password meets the requirements specified by org-wide or profile-based password policies in the current user's org.

changePassword(newPassword, verifyNewPassword, oldPassword)

Changes the password of the current user.

Signature

```
public static System.PageReference changePassword(String newPassword, String
verifyNewPassword, String oldPassword)
```

Parameters

newPassword
Type: String

verifyNewPassword
Type: String

oldPassword
Type: String

Optional only if the current user's password has expired; otherwise, required.

Return Value

Type: System.PageReference

Usage

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

createExternalUser(user, accountId)

Creates a community or a portal user for the given account and associates it with the community.

Signature

```
public static Id createExternalUser(SObject user, String accountId)
```

Parameters

user
Type: SObject

Information required to create a user.

The email address of the user is used to look for matching contacts associated with the specified *accountId*. If a matching contact is found and is already used by an external user, self-registration isn't successful. If a matching contact is found but isn't used by an external user, it is used for the new external user. If there is no matching contact, a new contact is created for the new external user.

accountId
Type: String

The ID of the account you want to associate the user with.

Return Value

Type: Id

The ID of the user that this method creates.

Usage

This method throws `Site.ExternalUserCreateException` when user creation fails.

The `nickname` field is required for the `User` sObject when using the `createExternalUser` method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

createExternalUser(user, accountId, password)

Creates a community or a portal user for the given account and associates it with the community. This method sends an email with the specified password to the user.

Signature

```
public static Id createExternalUser(SObject user, String accountId, String password)
```

Parameters

user
Type: SObject

Information required to create a user.

The email address of the user is used to look for matching contacts associated with the specified *accountId*. If a matching contact is found and is already used by an external user, self-registration isn't successful. If a matching contact is found but isn't used by an external user, it is used for the new external user. If there is no matching contact, a new contact is created for the new external user.

accountId
Type: String

The ID of the account you want to associate the user with.

password
Type: String

The password of the community or portal user. If not specified, or if set to `null` or an empty string, this method sends a new password email to the portal user.

Return Value

Type: Id

The ID of the user that this method creates.

Usage

This method throws `Site.ExternalUserCreateException` when user creation fails.

The `nickname` field is required for the `User` sObject when using the `createExternalUser` method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

createExternalUser(user, accountId, password, sendEmailConfirmation)

Creates a community or portal user and associates it with the given account. This method sends the user an email with the specified password and a new user confirmation email.

Signature

```
public static Id createExternalUser(SObject user, String accountId, String password,
Boolean sendEmailConfirmation)
```

Parameters

user
Type: SObject

Information required to create a user.

The email address of the user is used to look for matching contacts associated with the specified *accountId*. If a matching contact is found and is already used by an external user, self-registration isn't successful. If a matching contact is found but isn't used by an external user, it is used for the new external user. If there is no matching contact, a new contact is created for the new external user.

accountId
Type: String

The ID of the account you want to associate the user with.

password
Type: String

The password of the community or portal user. If not specified, or if set to `null` or an empty string, this method sends a new password email to the portal user.

sendEmailConfirmation
Type: Boolean

Determines whether a new user email is sent to the portal user. Set it to `true` to send a new user email to the portal user. The default is `false`, that is, the new user email isn't sent.

Return Value

Type: Id

The ID of the user that this method creates.

Usage

This method throws `Site.ExternalUserCreateException` when user creation fails.

The `nickname` field is required for the `User` sObject when using the `createExternalUser` method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

`createPersonAccountPortalUser(user, ownerId, password)`

Creates a person account using the default record type defined on the guest user's profile, then enables it for the site's portal.

Signature

```
public static ID createPersonAccountPortalUser(sObject user, String ownerId, String password)
```

Parameters

`user`
Type: sObject

`ownerId`
Type: String

`password`
Type: String

Return Value

Type: ID

Usage

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

Note: This method is only valid when a site is associated with a Customer Portal, and when the user license for the default new user profile is a high-volume portal user.

createPersonAccountPortalUser(user, ownerId, recordTypeId, password)

Creates a person account using the specified *recordTypeID*, then enables it for the site's portal.

Signature

```
public static ID createPersonAccountPortalUser(sObject user, String ownerId, String
recordTypeId, String password)
```

Parameters

user
Type: sObject

ownerId
Type: String

recordTypeId
Type: String

password
Type: String

Return Value

Type: ID

Usage

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

Note: This method is only valid when a site is associated with a Customer Portal, and when the user license for the default new user profile is a high-volume portal user.

createPortalUser(user, accountId, password, sendEmailConfirmation)

Creates a portal user for the given account and associates it with the site's portal.

Signature

```
public static ID createPortalUser(sObject user, String accountId, String password,
Boolean sendEmailConfirmation)
```

Parameters

user
Type: sObject

accountId
Type: String

password
Type: String

(Optional) The password of the portal user. If not specified, or if set to `null` or an empty string, this method sends a new password email to the portal user.

`sendEmailConfirmation`
Type: Boolean

(Optional) Determines whether a new user email is sent to the portal user. Set it to `true` to send a new user email to the portal user. The default is `false`, that is, the new user email isn't sent.

Return Value

Type: ID

Usage

If you're using API version 34.0 or later, we recommend using the `createExternalUser()` methods because they offer better error handling than this method.

The `nickname` field is required for the user sObject when using the `createPortalUser` method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

`forgotPassword(username, emailTemplateName)`

Resets the user's password and sends an email to the user with their new password. Returns a value indicating whether the password reset was successful or not.

Signature

```
public static Boolean forgotPassword(String username,String emailTemplateName)
```

Parameters

`username`
Type: String

`emailTemplateName`
Type: String

If provided, the method applies the template to the email. Otherwise, the method applies the default system template. If an email template that doesn't exist is provided, the system logs an exception.

Return Value

Type: Boolean

Note: The return value is always true unless it's called outside of a Visualforce page.

Usage

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

`forgotPassword(username)`

Resets the user's password and sends an email to the user with their new password. Returns a value indicating whether the password reset was successful or not.

Signature

```
public static Boolean forgotPassword(String username)
```

Parameters

`username`
Type: String

Return Value

Type: Boolean

Note: The return value is always true unless it's called outside of a Visualforce page.

Usage

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

`getAdminEmail()`

Returns the email address of the site administrator.

Signature

```
public static String getAdminEmail()
```

Return Value

Type: String

`getAdminId()`

Returns the user ID of the site administrator.

Signature

```
public static ID getAdminId()
```

Return Value

Type: ID

getAnalyticsTrackingCode()

The tracking code associated with your site. This code can be used by services like Google Analytics to track page request data for your site.

Signature

```
public static String getAnalyticsTrackingCode()
```

Return Value

Type: String

getCurrentSiteUrl()

Deprecated. This method was replaced by `getBaseUrl()` in API version 30.0. Returns the base URL of the current site that references and links should use.

Note that this may return the referring page's URL instead of the current request's URL. The returned value includes the path prefix and always ends with a `/` character. If the current request is not a site request, then this method returns `null`. If the current request is not a site request, then this method returns `null`. This method was replaced by getBaseUrl in API version 30.0.

Signature

```
public static String getCurrentSiteUrl()
```

Return Value

Type: String

Usage

Use `getBaseUrl()` instead.

getBaseCustomUrl()

Returns a base URL for the current site that doesn't use a force.com subdomain. The returned URL uses the same protocol (HTTP or HTTPS) as the current request if at least one non-Force.com custom URL that supports HTTPS exists on the site. The returned value never ends with a `/` character. If all the custom URLs in this site end in Force.com or this site has no custom URLs, then this returns an empty string. If the current request is not a site request, then this method returns an empty string. This method replaced getCustomWebAddress and includes the custom URL's path prefix..

Signature

```
public static String getBaseCustomUrl()
```

Return Value

Type: String

Usage

This method replaces `getCustomWebAddress()` and includes the custom URL's path prefix.

getBaseInsecureUrl()

Returns a base URL for the current site that uses HTTP instead of HTTPS. The current request's domain is used. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

Signature

```
public static String getBaseInsecureUrl()
```

Return Value

Type: String

getBaseRequestUrl()

Returns the base URL of the current site for the requested URL. This isn't influenced by the referring page's URL. The returned URL uses the same protocol (HTTP or HTTPS) as the current request. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

Signature

```
public static String getBaseRequestUrl()
```

Return Value

Type: String

getBaseSecureUrl()

Returns a base URL for the current site that uses HTTPS instead of HTTP. The current request's domain is preferred if it supports HTTPS. Domains that are not Force.com subdomains are preferred over Force.com subdomains. A Force.com subdomain, if associated with the site, is used if no other HTTPS domains exist in the current site. If no HTTPS custom URLs exist in the site, then this method returns an empty string. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

Signature

```
public static String getBaseSecureUrl()
```

Return Value

Type: String

`getBaseUrl()`

Returns the base URL of the current site that references and links should use. Note that this field may return the referring page's URL instead of the current request's URL. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this field returns an empty string. This field replaces getCurrentSiteUrl.

Signature

```
public static String getBaseUrl()
```

Return Value

Type: String

Usage

This method replaces `getCurrentSiteUrl()`.

`getCustomWebAddress()`

Deprecated. This method was replaced by `getBaseCustomUrl()` in API version 30.0.

Returns the request's custom URL if it doesn't end in Lightning Platform or returns the site's primary custom URL. If neither exist, then this returns null. Note that the URL's path is always the root, even if the request's custom URL has a path prefix. If the current request is not a site request, then this method returns null. The returned value always ends with a `/` character.

Signature

```
public static String getCustomWebAddress()
```

Return Value

Type: String

Usage

Use `getBaseCustomUrl()` instead.

`getDomain()`

Returns the Salesforce Site domain (`force.com` subdomain URL hostname) for your organization.

Signature

```
public static String getDomain()
```

Return Value

Type: String

getErrorDescription()

Returns the error description for the current page if it's a designated error page for the site and an error exists; otherwise, returns an empty string.

Signature

```
public static String getErrorDescription()
```

Return Value

Type: String

getErrorMessage()

Returns an error message for the current page if it's a designated error page for the site and an error exists; otherwise, returns an empty string.

Signature

```
public static String getErrorMessage()
```

Return Value

Type: String

getExperienceId()

Returns the value of the experience ID (expid). This expid value comes from a cookie in the user's web browser.

Signature

```
public static String getExperienceId()
```

Return Value

Type: String

Usage

Use the `getExperienceId` and `setExperienceId` methods to implement dynamic login experiences. You can set the experience ID with `setExperienceId` or by extending the following endpoints with `expid_`***`value`***.

- ***community-url***`/services/oauth2/authorize/expid_`***value***
- ***community-url***`/idp/endpoint/HttpPost/expid_`***value***
- ***community-url***`/idp/endpoint/HttpRedirect/expid_`***value***
- ***community-url_login_page***`/expid=`***{value}***
- ***community-url***`/CommunitiesSelfReg?expid=`***{value}***
- ***secur***`/forgotpassword.jsp?expid=`***{value}***

The cookie is set when the browser loads the URLs with the expid values.

`getMasterLabel()`

Returns the value of the Master Label field for the current site. If the current request is not a site request, then this field returns `null`.

Signature

```
public static String getMasterLabel()
```

Return Value

Type: String

`getName()`

Returns the API name of the current site.

Signature

```
public static String getName()
```

Return Value

Type: String

`getOriginalUrl()`

Returns the original URL for this page if it's a designated error page for the site; otherwise, returns `null`.

Signature

```
public static String getOriginalUrl()
```

Return Value

Type: String

`getPasswordPolicyStatement()`

Returns the password requirements for a community created with the Customer Service template.

Signature

```
public static String getPasswordPolicyStatement()
```

Return Value

Type: String

getPathPrefix()

Returns the URL path prefix of the current site or an empty string if none. For example, if the requested site URL is `http://myco.force.com/partners`, then `/partners` is the path prefix. If the current request is not a site request, then this method returns an empty string. This method replaced getPrefix in API version 30.0.

Signature

```
public static String getPathPrefix()
```

Return Value

Type: String

getPrefix()

Deprecated. This method was replaced by `getPathPrefix()` in API version 30.0.

Returns the URL path prefix of the current site. For example, if your site URL is `myco.force.com/partners`, `/partners` is the path prefix. Returns `null` if the prefix isn't defined. If the current request is not a site request, then this method returns a `null`.

Signature

```
public static String getPrefix()
```

Return Value

Type: String

getSiteId()

Returns the ID of the current site. If the current request is not a site request, then this field returns `null`.

Signature

```
public static String getSiteId()
```

Return Value

Type: Id

getTemplate()

Returns the template name associated with the current site; returns the default template if no template has been designated.

Signature

```
public static System.PageReference getTemplate()
```

Return Value

Type: System.PageReference

getSiteType()

Returns the API value of the site type field for the current site. This can be Visualforce for a Salesforce site, Siteforce for a Site.com site, ChatterNetwork for a Communities site, or ChatterNetworkPicasso for a Site.com Communities site. If the current request is not a site request, then this method returns `null`.

Signature

```
public static String getSiteType()
```

Return Value

Type: String

getSiteTypeLabel()

Returns the value of the Site Type field's label for the current site. If the current request is not a site request, then this method returns `null`.

Signature

```
public static String getSiteTypeLabel()
```

Return Value

Type: String

isLoginEnabled()

Returns `true` if the current site is associated with an active login-enabled portal; otherwise returns `false`.

Signature

```
public static Boolean isLoginEnabled()
```

Return Value

Type: Boolean

isPasswordExpired()

For authenticated users, returns `true` if the currently logged-in user's password is expired. For non-authenticated users, returns `false`.

Signature

```
public static Boolean isPasswordExpired()
```

Return Value

Type: Boolean

isRegistrationEnabled()

Returns `true` if the current site is associated with an active self-registration-enabled Customer Portal; otherwise returns `false`.

Signature

```
public static Boolean isRegistrationEnabled()
```

Return Value

Type: Boolean

isValidUsername(username)

Returns `true` if the given username is valid; otherwise, returns `false`.

Signature

```
public static Boolean isValidUsername(String username)
```

Parameters

username
Type: String

The username to test for validity.

Return Value

Type: Boolean

login(username, password, startUrl)

Allows users to log in to the current site with the given username and password, then takes them to the `startUrl`. If `startUrl` is not a relative path, it defaults to the site's designated index page.

Signature

```
public static System.PageReference login(String username, String password, String
startUrl)
```

Parameters

username
Type: String

password
Type: String

startUrl
Type: String

Return Value

Type: System.PageReference

Usage

All DML statements before the call to `Site.login` get committed. It's not possible to roll back to a save point that was created before a call to `Site.login`.

Note: Do not include `http://` or `https://` in the `startURL`.

`passwordlessLogin(userId, methods, startUrl)`

Logs in a user to a community using an identity verification method, such as email or text, instead of a password. Passwordless login is a convenient, mobile-friendly way to welcome users into your community. Give your community users an alternative to requiring passwords when they log in.

Signature

```
public static System.PageReference passwordlessLogin(Id userId,
List<Auth.VerificationMethod> methods, String startUrl)
```

Parameters

`userId`
Type: Id

ID of the user to log in.

`methods`
Type: List<Auth.VerificationMethod>

List of identity verification methods available to the user for passwordless login.

`startUrl`
Type: String

Path to the page that users see after they log in.

Return Value

Type: System.PageReference

Usage

Include this method in the Apex controller of a custom login page implementation.

PasswordlessLogin Example

Here's a simple code example of an Apex controller containing the `passwordlessLogin` method. The `PageReference` returned by `passwordlessLogin` redirects the user to the Salesforce verification page. If the user enters the correct code, the user is redirected to the community page specified by the start URL.

```
global with sharing class MFILoginController
{
```

```
    //Input variables
    global String input {get; set;}
    public String startURL  {get; set;}
    public List<Auth.VerificationMethod> methods;
    public String error;

    global MFILoginController()
    {
        // Add verification methods in priority order
        methods = new List<Auth.VerificationMethod>();
        methods.add(Auth.VerificationMethod.SMS);
        methods.add(Auth.VerificationMethod.EMAIL);
        methods.add(Auth.VerificationMethod.U2F);
        methods.add(Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
        methods.add(Auth.VerificationMethod.TOTP);
    }

    global PageReference login() {
         List<User> users = null;

         // Empty input
         if(input == null || input == '')
         {
             error = 'Enter Username';
             return null;
         }

         users = [select name, id, email from User where username=:input];
         if(users == null || users.isEmpty())
         {
             error = 'Can\'t find a user';
             return null;
         }

         if (startURL == null) startURL = '/';
         return Site.passwordlessLogin(users[0].id, methods, startURL);
     }
}
```

setExperienceId(expIdValue)

Sets the experience ID for the current user. Use this method to populate the value of the experience ID (expid) cookie in the user's web browser.

Signature

```
public static void setExperienceId(String expIdValue)
```

Parameters

expIdValue
Type: String

A value that indicates the user's login experience.

The value must contain alphanumeric characters only, up to 30 characters.

Usage

Use `setExperienceId` when you're implementing dynamic login experiences. A login experience refers to a login page plus any secondary pages associated with the login page (such as 2FA authentication or a login flow). You define different login experiences depending on who users are or where they're logging in from. For example, you can require a different registration process based on the user's location. In this case, `expIdValue` includes a state or country code. When the user logs in, the URL contains the experience ID parameter, `{expid}`. The `{expid}` parameter is replaced by the value stored in `expIdValue`, such as `.jp`. Then the user is redirected to the Japanese login experience.

Example

```
String expid = ApexPages.currentPage().getParameters().get('expid');
  if (expId != null) {
  Site.setExperienceId(expId);
  }
```

setPortalUserAsAuthProvider(user, contactId)

Sets the specified user information within the site's portal via an authentication provider.

Signature

```
public static Void setPortalUserAsAuthProvider(sObject user, String contactId)
```

Parameters

user
Type: sObject

contactId
Type: String

Return Value

Type: Void

Usage

- This method is only valid when a site is associated with a Customer Portal.
- Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.
- For more information on an authentication provider, see RegistrationHandler on page 755.

validatePassword(user, password, confirmPassword)

Indicates whether a given password meets the requirements specified by org-wide or profile-based password policies in the current user's org.

Signature

```
public static void validatePassword(SObject user, String password, String
confirmPassword)
```

Parameters

user
Type: SObject

The user attempting to create a password during self-registration for a community.

password
Type: String

The password entered by the user.

confirmPassword
Type: String

The password reentered by the user to confirm the password.

Return Value

Type: void

Usage

If validation fails when the method is run in a Lightning controller, this method throws an Apex exception describing the failed validation. If validation fails when the method is run in a Visualforce controller, the method provides Visualforce error messages.

SObject Class

Contains methods for the sObject data type.

Namespace

System

Usage

SObject methods are all instance methods: they are called by and operate on an sObject instance such as an account or contact. The following are the instance methods for sObjects.

For more information on sObjects, see Working with sObjects on page 113.

SObject Methods

The following are methods for `SObject`. All are instance methods.

IN THIS SECTION:

addError(errorMsg)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

addError(errorMsg, escape)

Marks a trigger record with a custom error message, specifies whether or not the error message should be escaped, and prevents any DML operation from occurring.

addError(exceptionError)

Marks a trigger record with a custom error message and prevents any DML operation from occurring.

addError(exceptionError, escape)

Marks a trigger record with a custom exception error message, specifies whether or not the exception error message should be escaped, and prevents any DML operation from occurring.

addError(errorMsg)

Places the specified error message on a trigger record field in the Salesforce user interface and prevents any DML operation from occurring.

addError(errorMsg, escape)

Places the specified error message, which can be escaped or unescaped, on a trigger record field in the Salesforce user interface, and prevents any DML operation from occurring.

clear()

Clears all field values

clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber)

Creates a copy of the SObject record.

get(fieldName)

Returns the value for the field specified by *`fieldName`*, such as `AccountNumber`.

get(field)

Returns the value for the field specified by the field token `Schema.`***`sObjectField`***, such as, `Schema.Account.AccountNumber`.

getCloneSourceId()

Returns the ID of the entity from which an object was cloned. You can use it for objects cloned through the Salesforce user interface. If you don't use a *`preserveId`* parameter, of if you use a *`preserveId`* value of `false`, you can also used it for objects created using the `System.SObject.clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber)` method.

getOptions()

Returns the database.DMLOptions object for the SObject.

getPopulatedFieldsAsMap()

Returns a map of populated field names and their corresponding values. The map contains only the fields that have been populated in memory for the SObject instance.

getSObject(fieldName)

Returns the value for the specified field. This method is primarily used with dynamic DML to access values for external IDs.

getSObject(fieldName)

Returns the value for the field specified by the field token `Schema.`***`fieldName`***, such as, `Schema.MyObj.MyExternalId`. This method is primarily used with dynamic DML to access values for external IDs.

getSObjects(fieldName)

Returns the values for the specified field. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

getSObjects(fieldName)

Returns the value for the field specified by the field token `Schema.fieldName`, such as, `Schema.Account.Contact`. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

getSObjectType()

Returns the token for this SObject. This method is primarily used with describe information.

getQuickActionName()

Retrieves the name of a quick action associated with this SObject. Typically used in triggers.

isClone()

Returns `true` if an entity is cloned from something, even if the entity hasn't been saved.

put(fieldName, value)

Sets the value for the specified field and returns the previous value for the field.

put(fieldName, value)

Sets the value for the field specified by the field token `Schema.sObjectField`, such as, `Schema.Account.AccountNumber` and returns the previous value for the field.

putSObject(fieldName, value)

Sets the value for the specified field. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

putSObject(fieldName, value)

Sets the value for the field specified by the token `Schema.SObjectType`. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

recalculateFormulas()

Recalculates all formula fields on an SObject, and sets updated field values. Rather than inserting or updating objects each time you want to test changes to your formula logic, call this method and inspect your new field values. Then make further logic changes as needed.

setOptions(DMLOptions)

Sets the DMLOptions object for the SObject.

addError(errorMsg)

Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature

```
public Void addError(String errorMsg)
```

Parameters

errorMsg

Type: String

The error message to mark the record with.

Return Value

Type: Void

Usage

When used on `Trigger.new` in `before insert` and `before update` triggers, and on `Trigger.old` in `before delete` triggers, the error message is displayed in the application interface.

See Triggers and Trigger Exceptions.

Note: This method escapes any HTML markup in the specified error message. The escaped characters are: `\n`, `<`, `>`, `&`, `"`, `\`, `\u2028`, `\u2029`, and `\u00a9`. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

When used in Visualforce controllers, the generated message is added to the collection of errors for the page. For more information, see Validation Rules and Standard Controllers in the *Visualforce Developer's Guide*.

Example

```
Trigger.new[0].addError('bad');
```

addError(errorMsg, escape)

Marks a trigger record with a custom error message, specifies whether or not the error message should be escaped, and prevents any DML operation from occurring.

Signature

```
public Void addError(String errorMsg, Boolean escape)
```

Parameters

errorMsg
Type: String

The error message to mark the record with.

escape
Type: Boolean

Indicates whether any HTML markup in the custom error message should be escaped (`true`) or not (`false`). This parameter is ignored in Lightning Experience and the Salesforce app and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value

Type: Void

Usage

The escaped characters are: `\n`, `<`, `>`, `&`, `"`, `\`, `\u2028`, `\u2029`, and `\u00a9`. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

Warning: Be cautious if you specify `false` for the *escape* argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false` *escape* argument and make sure you escape any dynamic

content, such as input field values. Otherwise, specify `true` for the *`escape`* argument or call `addError(String` ***`errorMsg`***`)` instead.

Example

```
Trigger.new[0].addError('Fix & resubmit', false);
```

addError(exceptionError)

Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature

```
public Void addError(Exception exceptionError)
```

Parameters

`exceptionError`
Type: System.Exception

An Exception object or a custom exception object that contains the error message to mark the record with.

Return Value

Type: Void

Usage

When used on `Trigger.new` in `before insert` and `before update` triggers, and on `Trigger.old` in `before delete` triggers, the error message is displayed in the application interface.

See Triggers and Trigger Exceptions.

Note: This method escapes any HTML markup in the specified error message. The escaped characters are: `\n`, `<`, `>`, `&`, `"`, `'`, `\u2028`, `\u2029`, and `\u00a9`. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

When used in Visualforce controllers, the generated message is added to the collection of errors for the page. For more information, see Validation Rules and Standard Controllers in the *Visualforce Developer's Guide*.

Example

```
public class MyException extends Exception {}
Trigger.new[0].addError(new myException('Invalid Id'));
```

addError(exceptionError, escape)

Marks a trigger record with a custom exception error message, specifies whether or not the exception error message should be escaped, and prevents any DML operation from occurring.

Signature

```
public Void addError(Exception exceptionError, Boolean escape)
```

Parameters

exceptionError
Type: System.Exception

An Exception object or a custom exception object that contains the error message to mark the record with.

escape
Type: Boolean

Indicates whether any HTML markup in the custom error message should be escaped (`true`) or not (`false`). This parameter is ignored in Lightning Experience and the Salesforce app and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value

Type: Void

Usage

The escaped characters are: `\n`, <, >, `&`, `"`, `\`, `\u2028`, `\u2029`, and `\u00a9`. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

Warning: Be cautious if you specify `false` for the *escape* argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false` *escape* argument and make sure you escape any dynamic content, such as input field values. Otherwise, specify `true` for the *escape* argument or call `addError(Exception e)` instead.

Example

```
public class MyException extends Exception {}
Trigger.new[0].addError(new myException('Invalid Id & other issues', false));
```

addError(errorMsg)

Places the specified error message on a trigger record field in the Salesforce user interface and prevents any DML operation from occurring.

Signature

```
public Void addError(String errorMsg)
```

Parameters

errorMsg
Type: String

Return Value

Type: Void

Usage

Note:

- When used on `Trigger.new` in `before insert` and `before update` triggers, and on `Trigger.old` in `before delete` triggers, the error appears in the application interface.
- When used in Visualforce controllers, if there is an `inputField` component bound to field, the message is attached to the component. For more information, see Validation Rules and Standard Controllers in the *Visualforce Developer's Guide*.
- This method is highly specialized because the field identifier is not actually the invoking object—the sObject record is the invoker. The field is simply used to identify the field that should be used to display the error.

See Triggers and Trigger Exceptions.

Note: This method escapes any HTML markup in the specified error message. The escaped characters are: `\n`, `<`, `>`, `&`, `"`, `\`, `\u2028`, `\u2029`, and `\u00a9`. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

Example

```
Trigger.new[0].myField__c.addError('bad');
```

addError(errorMsg, escape)

Places the specified error message, which can be escaped or unescaped, on a trigger record field in the Salesforce user interface, and prevents any DML operation from occurring.

Signature

```
public Void addError(String errorMsg, Boolean escape)
```

Parameters

errorMsg
Type: String

The error message to mark the record with.

escape
Type: Boolean

Indicates whether any HTML markup in the custom error message should be escaped (`true`) or not (`false`). This parameter is ignored in Lightning Experience and the Salesforce app and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value

Type:

Usage

The escaped characters are: `\n`, `<`, `>`, `&`, `"`, `\`, `\u2028`, `\u2029`, and `\u00a9`. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

Warning: Be cautious if you specify `false` for the *`escape`* argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false` *`escape`* argument and make sure you escape any dynamic content, such as input field values. Otherwise, specify `true` for the *`escape`* argument or call *`field`*`.addError(String` ***`errorMsg`***`)` instead.

Example

```
Trigger.new[0].myField__c.addError('Fix & resubmit', false);
```

clear()

Clears all field values

Signature

```
public Void clear()
```

Return Value

Type: Void

Example

```
Account acc = new account(Name = 'Acme');
acc.clear();
Account expected = new Account();
system.assertEquals(expected, acc);
```

clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber)

Creates a copy of the SObject record.

Signature

```
public SObject clone(Boolean preserveId, Boolean isDeepClone, Boolean
preserveReadonlyTimestamps, Boolean preserveAutonumber)
```

Parameters

`preserveId`
Type: Boolean

(Optional) Determines whether the ID of the original object is preserved or cleared in the duplicate. If set to `true`, the ID is copied to the duplicate. The default is `false`, that is, the ID is cleared.

isDeepClone
Type: Boolean

(Optional) Determines whether the method creates a full copy of the SObject field or just a reference:

- If set to `true`, the method creates a full copy of the SObject. All fields on the SObject are duplicated in memory, including relationship fields. Consequently, if you make changes to a field on the cloned SObject, the original SObject is not affected.
- If set to `false`, the method performs a shallow copy of the SObject fields. All copied relationship fields reference the original SObjects. Consequently, if you make changes to a relationship field on the cloned SObject, the corresponding field on the original SObject is also affected, and vice versa. The default is `false`.

preserveReadonlyTimestamps
Type: Boolean

(Optional) Determines whether the read-only timestamp fields are preserved or cleared in the duplicate. If set to `true`, the read-only fields `CreatedById`, `CreatedDate`, `LastModifiedById`, and `LastModifiedDate` are copied to the duplicate. The default is `false`, that is, the values are cleared.

preserveAutonumber
Type: Boolean

(Optional) Determines whether auto number fields of the original object are preserved or cleared in the duplicate. If set to `true`, auto number fields are copied to the cloned object. The default is `false`, that is, auto number fields are cleared.

Return Value

Type: SObject (of same type)

Usage

Note: For Apex saved using Salesforce API version 22.0 or earlier, the default value for the *preserveId* argument is `true`, that is, the ID is preserved.

Example

```
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
Account clonedAcc = acc.clone(false, false, false, false);
System.assertEquals(acc, clonedAcc);
```

get(fieldName)

Returns the value for the field specified by *fieldName*, such as `AccountNumber`.

Signature

```
public Object get(String fieldName)
```

Parameters

fieldName
Type: String

Return Value

Type: Object

Usage

For more information, see Dynamic SOQL.

Example

```
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
String description = (String)acc.get('Description');
System.assertEquals('Acme Account', description);
```

get(field)

Returns the value for the field specified by the field token `Schema.sObjectField`, such as, `Schema.Account.AccountNumber`.

Signature

```
public Object get(Schema.sObjectField field)
```

Parameters

field
Type: Schema.SObjectField

Return Value

Type: Object

Usage

For more information, see Dynamic SOQL.

Note: Field tokens aren't available for person accounts. If you access `Schema.Account.fieldname`, you'll get an exception error. Instead, specify the field name as a string.

Example

```
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
String description = (String)acc.get(Schema.Account.Description);
System.assertEquals('Acme Account', description);
```

getCloneSourceId()

Returns the ID of the entity from which an object was cloned. You can use it for objects cloned through the Salesforce user interface. If you don't use a *preserveId* parameter, of if you use a *preserveId* value of `false`, you can also used it for objects created using the `System.SObject.clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber)` method.

Signature

```
public Id getCloneSourceId()
```

Return Value

Type: Id

Usage

If A is cloned to B, B is cloned to C, and C is cloned to D, then B, C, and D all point back to A as their clone source.

Example

```
Account acc0 = new Account(Name = 'Acme');
insert acc0;
Account acc1 = acc0.clone();
Account acc2 = acc1.clone();
Account acc3 = acc2.clone();
Account acc4 = acc3.clone();
System.assert(acc0.Id != null);
System.assertEquals(acc0.Id, acc1.getCloneSourceId());
System.assertEquals(acc0.Id, acc2.getCloneSourceId());
System.assertEquals(acc0.Id, acc3.getCloneSourceId());
System.assertEquals(acc0.Id, acc4.getCloneSourceId());
System.assertEquals(null, acc0.getCloneSourceId());
```

getOptions()

Returns the database.DMLOptions object for the SObject.

Signature

```
public Database.DMLOptions getOptions()
```

Return Value

Type: Database.DMLOptions

Example

```
Database.DMLOptions dmo = new Database.dmlOptions();
dmo.assignmentRuleHeader.useDefaultRule = true;

Account acc = new Account(Name = 'Acme');
acc.setOptions(dmo);
Database.DMLOptions accDmo = acc.getOptions();
```

getPopulatedFieldsAsMap()

Returns a map of populated field names and their corresponding values. The map contains only the fields that have been populated in memory for the SObject instance.

Signature

```
public Map<String,Object> getPopulatedFieldsAsMap()
```

Return Value

Type: Map<String,Object>

A map of field names and their corresponding values.

Usage

The returned map contains only the fields that have been populated in memory for the SObject instance, which makes it easy to iterate over those fields. A field is populated in memory in the following cases.

- The field has been queried by a SOQL statement.
- The field has been explicitly set before the call to the `getPopulatedFieldsAsMap()` method.

Fields on related objects that are queried or set are also returned in the map.

The following example iterates over the map returned by the `getPopulatedFieldsAsMap()` method after a SOQL query.

```
Account a = new Account();
a.name = 'TestMapAccount1';
insert a;
a = [select Id,Name from Account where id=:a.Id];
Map<String, Object> fieldsToValue = a.getPopulatedFieldsAsMap();

for (String fieldName : fieldsToValue.keySet()){
    System.debug('field name is ' + fieldName + ', value is ' +
        fieldsToValue.get(fieldName));
}

// Example debug statement output:
// DEBUG|field name is Id, value is 001R0000003EPPkIAO
// DEBUG|field name is Name, value is TestMapAccount1
```

This example iterates over the map returned by the `getPopulatedFieldsAsMap()` method after fields on the SObject are explicitly set.

```
Account a = new Account();
a.name = 'TestMapAccount2';
a.phone = '123-4567';
insert a;
Map<String, Object> fieldsToValue = a.getPopulatedFieldsAsMap();

for (String fieldName : fieldsToValue.keySet()) {
    System.debug('field name is ' + fieldName + ', value is ' +
        fieldsToValue.get(fieldName));
}

// Example debug statement output:
// DEBUG|field name is Name, value is TestMapAccount2
// DEBUG|field name is Phone, value is 123-4567
// DEBUG|field name is Id, value is 001R0000003EPPpIAO
```

The following example shows how to use the `getPopulatedFieldsAsMap()` method with related objects.

```
Account a = new Account();
a.name='TestMapAccount3';
insert a;
Contact c = new Contact();
c.firstname='TestContactFirstName';
c.lastName ='TestContactLastName';
c.accountid = a.id;
insert c;

c = [SELECT id, Contact.Firstname, Contact.Account.Name FROM Contact
        where id=:c.id limit 1];
Map<String, Object> fieldsToValue = c.getPopulatedFieldsAsMap();

// To get the fields on Account, get the Account object
// and call getMapPopulatedFieldsAsMap() on that object.

a = (Account)fieldsToValue.get('Account');
fieldsToValue = a.getPopulatedFieldsAsMap();

for (String fieldName : fieldsToValue.keySet()) {
    System.debug('field name is ' + fieldName + ', value is ' +
        fieldsToValue.get(fieldName));
}

// Example debug statement output:
// DEBUG|field name is Id, value is 001R0000003EPPuIAO
// DEBUG|field name is Name, value is TestMapAccount3
```

getSObject(fieldName)

Returns the value for the specified field. This method is primarily used with dynamic DML to access values for external IDs.

Signature

```
public SObject getSObject(String fieldName)
```

Parameters

fieldName
Type: String

Return Value

Type: SObject

Example

```
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
insert acc;
Contact con = new Contact(Lastname = 'AcmeCon', AccountId = acc.id);
insert con;
```

```
SObject contactDB =
    [SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1];
Account a = (Account)contactDB.getSObject('Account');
System.assertEquals('Acme', a.name);
```

getSObject(fieldName)

Returns the value for the field specified by the field token `Schema.`***`fieldName`***, such as, `Schema.MyObj.MyExternalId`. This method is primarily used with dynamic DML to access values for external IDs.

Signature

```
public SObject getSObject(Schema.SObjectField fieldName)
```

Parameters

`fieldName`
Type: Schema.SObjectField

Return Value

Type: SObject

Example

```
Account acc = new account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;

Schema.DescribeFieldResult fieldResult = Contact.AccountId.getDescribe();
Schema.SObjectField field = fieldResult.getSObjectField();

SObject contactDB =
    [SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1];
Account a = (Account)contactDB.getSObject(field);
System.assertEquals('Acme', a.name);
```

getSObjects(fieldName)

Returns the values for the specified field. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

Signature

```
public SObject[] getSObjects(String fieldName)
```

Parameters

fieldName
Type: String

Return Value

Type: SObject[]

Usage

For more information, see Dynamic DML.

Example

```
Account acc = new account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;

SObject[] a = [SELECT id, (SELECT Name FROM Contacts LIMIT 1) FROM Account WHERE id =
:acc.id];
SObject[] contactsDB = a.get(0).getSObjects('Contacts');
String fieldValue = (String)contactsDB.get(0).get('Name');
System.assertEquals('AcmeCon', fieldValue);
```

getSObjects(fieldName)

Returns the value for the field specified by the field token `Schema.`***`fieldName`***, such as, `Schema.Account.Contact`. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

Signature

```
public SObject[] getSObjects(Schema.SObjectType fieldName)
```

Parameters

fieldName
Type: Schema.SObjectType

Return Value

Type: SObject[]

getSObjectType()

Returns the token for this SObject. This method is primarily used with describe information.

Signature

```
public Schema.SObjectType getSObjectType()
```

Return Value

Type: Schema.SObjectType

Usage

For more information, see Understanding Apex Describe Information.

Example

```
Account acc = new Account(name = 'Acme', description = 'Acme Account');
Schema.SObjectType expected = Schema.Account.getSObjectType();
System.assertEquals(expected, acc.getSObjectType());
```

getQuickActionName()

Retrieves the name of a quick action associated with this SObject. Typically used in triggers.

Signature

```
public String getQuickActionName()
```

Return Value

Type: String

Example

```
trigger accTrig2 on Contact (before insert) {
    for (Contact c : Trigger.new) {
        if (c.getQuickActionName() == QuickAction.CreateContact) {
            c.WhereFrom__c = 'GlobaActionl';
        } else if (c.getQuickActionName() == Schema.Account.QuickAction.CreateContact) {
            c.WhereFrom__c = 'AccountAction';
        } else if (c.getQuickActionName() == null) {
            c.WhereFrom__c = 'NoAction';
        } else {
            System.assert(false);
        }
    }
}
```

isClone()

Returns `true` if an entity is cloned from something, even if the entity hasn't been saved.

Signature

```
public Boolean isClone()
```

Return Value

Type: Boolean

Example

```
Account acc = new Account(Name = 'Acme');
insert acc;
Account acc2 = acc.clone();
// Test before saving
System.assertEquals(true, acc2.isClone());
insert acc2;
// Test after saving
System.assertEquals(true, acc2.isClone());
```

put(fieldName, value)

Sets the value for the specified field and returns the previous value for the field.

Signature

```
public Object put(String fieldName, Object value)
```

Parameters

fieldName
Type: String

value
Type: Object

Return Value

Type: Object

Example

```
Account acc = new Account(name = 'test', description = 'old desc');
String oldDesc = (String)acc.put('description', 'new desc');
System.assertEquals('old desc', oldDesc);
System.assertEquals('new desc', acc.description);
```

put(fieldName, value)

Sets the value for the field specified by the field token `Schema.sObjectField`, such as, `Schema.Account.AccountNumber` and returns the previous value for the field.

Signature

```
public Object put(Schema.SObjectField fieldName, Object value)
```

Parameters

fieldName
Type: Schema.SObjectField

value
Type: Object

Return Value

Type: Object

Example

```
Account acc = new Account(name = 'test', description = 'old desc');
String oldDesc = (String)acc.put(Schema.Account.Description, 'new desc');
System.assertEquals('old desc', oldDesc);
System.assertEquals('new desc', acc.description);
```

Note: Field tokens aren't available for person accounts. If you access `Schema.Account.fieldname`, you'll get an exception error. Instead, specify the field name as a string.

putSObject(fieldName, value)

Sets the value for the specified field. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

Signature

```
public SObject putSObject(String fieldName, SObject value)
```

Parameters

fieldName
Type: String

value
Type: SObject

Return Value

Type: SObject

Example

```
Account acc = new Account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;
Account acc2 = new account(name = 'Not Acme');

Contact contactDB =
    (Contact)[SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1];
```

```
Account a = (Account)contactDB.putSObject('Account', acc2);
System.assertEquals('Acme', a.name);
System.assertEquals('Not Acme', contactDB.Account.name);
```

putSObject(fieldName, value)

Sets the value for the field specified by the token `Schema.SObjectType`. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

Signature

```
public SObject putSObject(Schema.SObjectType fieldName, SObject value)
```

Parameters

`fieldName`
Type: Schema.SObjectType

`value`
Type: SObject

Return Value

Type: SObject

recalculateFormulas()

Recalculates all formula fields on an SObject, and sets updated field values. Rather than inserting or updating objects each time you want to test changes to your formula logic, call this method and inspect your new field values. Then make further logic changes as needed.

Signature

```
public Void recalculateFormulas()
```

Return Value

Type: Void

Usage

This method doesn't recalculate cross-object formulas. If you call this method on objects that have both cross-object and non-cross-object formula fields, only the non-cross-object formula fields are recalculated.

Each `recalculateFormulas` call counts against the SOQL query limits. See Execution Governors and Limits.

SEE ALSO:

What Are Cross-Object Formulas?

`setOptions(DMLOptions)`

Sets the DMLOptions object for the SObject.

Signature

```
public Void setOptions(database.DMLOptions DMLOptions)
```

Parameters

`DMLOptions`
Type: Database.DMLOptions

Return Value

Type: Void

Example

```
Database.DMLOptions dmo = new Database.dmlOptions();
dmo.assignmentRuleHeader.useDefaultRule = true;

Account acc = new Account(Name = 'Acme');
acc.setOptions(dmo);
```

StaticResourceCalloutMock Class

Utility class used to specify a fake response for testing HTTP callouts.

Namespace

System

Usage

Use the methods in this class to set the response properties for testing HTTP callouts.

IN THIS SECTION:

StaticResourceCalloutMock Constructors

StaticResourceCalloutMock Methods

StaticResourceCalloutMock Constructors

The following are constructors for `StaticResourceCalloutMock`.

IN THIS SECTION:

StaticResourceCalloutMock()
Creates a new instance of the `StaticResourceCalloutMock` class.

StaticResourceCalloutMock()

Creates a new instance of the `StaticResourceCalloutMock` class.

Signature

```
public StaticResourceCalloutMock()
```

StaticResourceCalloutMock Methods

The following are methods for `StaticResourceCalloutMock`. All are instance methods.

IN THIS SECTION:

setHeader(headerName, headerValue)
Sets the specified header name and value for the fake response.

setStaticResource(resourceName)
Sets the specified static resource, which contains the response body.

setStatus(httpStatus)
Sets the specified HTTP status for the response.

setStatusCode(httpStatusCode)
Sets the specified HTTP status for the response.

setHeader(headerName, headerValue)

Sets the specified header name and value for the fake response.

Signature

```
public Void setHeader(String headerName, String headerValue)
```

Parameters

headerName
Type: String

headerValue
Type: String

Return Value

Type: Void

setStaticResource(resourceName)

Sets the specified static resource, which contains the response body.

Signature

```
public Void setStaticResource(String resourceName)
```

Parameters

resourceName
Type: String

Return Value

Type: Void

setStatus(httpStatus)

Sets the specified HTTP status for the response.

Signature

```
public Void setStatus(String httpStatus)
```

Parameters

httpStatus
Type: String

Return Value

Type: Void

setStatusCode(httpStatusCode)

Sets the specified HTTP status for the response.

Signature

```
public Void setStatusCode(Integer httpStatusCode)
```

Parameters

httpStatusCode
Type: Integer

Return Value

Type: Void

String Class

Contains methods for the String primitive data type.

Namespace

System

Usage

For more information on Strings, see Primitive Data Types on page 26.

String Methods

The following are methods for `String`.

IN THIS SECTION:

abbreviate(maxWidth)

Returns an abbreviated version of the String, of the specified length and with ellipses appended if the current String is longer than the specified length; otherwise, returns the original String without ellipses.

abbreviate(maxWidth, offset)

Returns an abbreviated version of the String, starting at the specified character offset and of the specified length. The returned String has ellipses appended at the start and the end if characters have been removed at these locations.

capitalize()

Returns the current String with the first letter changed to title case.

center(size)

Returns a version of the current String of the specified size padded with spaces on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without added spaces.

center(size, paddingString)

Returns a version of the current String of the specified size padded with the specified String on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without padding.

charAt(index)

Returns the value of the character at the specified index.

codePointAt(index)

Returns the Unicode code point value at the specified index.

codePointBefore(index)

Returns the Unicode code point value that occurs before the specified index.

codePointCount(beginIndex, endIndex)

Returns the number of Unicode code points within the specified text range.

compareTo(secondString)

Compares two strings lexicographically, based on the Unicode value of each character in the Strings.

contains(substring)

Returns `true` if and only if the String that called the method contains the specified sequence of characters in *`substring`*.

containsAny(inputString)

Returns `true` if the current String contains any of the characters in the specified String; otherwise, returns `false`.

containsIgnoreCase(substring)

Returns `true` if the current String contains the specified sequence of characters without regard to case; otherwise, returns `false`.

containsNone(inputString)

Returns `true` if the current String doesn't contain any of the characters in the specified String; otherwise, returns `false`.

containsOnly(inputString)

Returns `true` if the current String contains characters only from the specified sequence of characters and not any other characters; otherwise, returns `false`.

containsWhitespace()

Returns `true` if the current String contains any white space characters; otherwise, returns `false`.

countMatches(substring)

Returns the number of times the specified substring occurs in the current String.

deleteWhitespace()

Returns a version of the current String with all white space characters removed.

difference(secondString)

Returns the difference between the current String and the specified String.

endsWith(suffix)

Returns `true` if the String that called the method ends with the specified *`suffix`*.

endsWithIgnoreCase(suffix)

Returns `true` if the current String ends with the specified suffix; otherwise, returns `false`.

equals(secondString)

Deprecated. This method is replaced by `equals(stringOrId)`. Returns `true` if the passed-in string is not null and represents the same binary sequence of characters as the current string. Use this method to perform case-sensitive comparisons.

equals(stringOrId)

Returns `true` if the passed-in object is not null and represents the same binary sequence of characters as the current string. Use this method to compare a string to an object that represents a string or an ID.

equalsIgnoreCase(secondString)

Returns `true` if the *`secondString`* is not null and represents the same sequence of characters as the String that called the method, ignoring case.

escapeCsv()

Returns a String for a CSV column enclosed in double quotes, if required.

escapeEcmaScript()

Escapes the characters in the String using EcmaScript String rules.

escapeHtml3()

Escapes the characters in a String using HTML 3.0 entities.

escapeHtml4()

Escapes the characters in a String using HTML 4.0 entities.

escapeJava()

Returns a String whose characters are escaped using Java String rules. Characters escaped include quotes and control characters, such as tab, backslash, and carriage return characters.

escapeSingleQuotes(stringToEscape)

Returns a String with the escape character (\) added before any single quotation marks in the String *`s`*.

escapeUnicode()

Returns a String whose Unicode characters are escaped to a Unicode escape sequence.

escapeXml()

Escapes the characters in a String using XML entities.

format(stringToFormat, formattingArguments)

Treat the first argument as a pattern and return a string using the second argument for substitution and formatting in the same manner as `apex:outputText` and the Java `MessageFormat` class.

fromCharArray(charArray)

Returns a String from the values of the list of integers.

getChars()

Returns an array of character values that represent the characters in this string.

getCommonPrefix(strings)

Returns the initial sequence of characters as a String that is common to all the specified Strings.

getLevenshteinDistance(stringToCompare)

Returns the Levenshtein distance between the current String and the specified String.

getLevenshteinDistance(stringToCompare, threshold)

Returns the Levenshtein distance between the current String and the specified String if it is less than or equal than the given threshold; otherwise, returns -1.

hashCode()

Returns a hash code value for this string.

indexOf(substring)

Returns the index of the first occurrence of the specified substring. If the substring does not occur, this method returns -1.

indexOf(substring, index)

Returns the zero-based index of the first occurrence of the specified substring from the point of the given index. If the substring does not occur, this method returns -1.

indexOfAny(substring)

Returns the zero-based index of the first occurrence of any character specified in the substring. If none of the characters occur, returns -1.

indexOfAnyBut(substring)

Returns the zero-based index of the first occurrence of a character that is not in the specified substring. Otherwise, returns -1.

indexOfChar(character)

Returns the index of the first occurrence of the character that corresponds to the specified character value.

indexOfChar(character, startIndex)

Returns the index of the first occurrence of the character that corresponds to the specified character value, starting from the specified index.

indexOfDifference(stringToCompare)

Returns the zero-based index of the character where the current String begins to differ from the specified String.

indexOfIgnoreCase(substring)

Returns the zero-based index of the first occurrence of the specified substring without regard to case. If the substring does not occur, this method returns -1.

indexOfIgnoreCase(substring, startPosition)

Returns the zero-based index of the first occurrence of the specified substring from the point of index *i*, without regard to case. If the substring does not occur, this method returns -1.

isAllLowerCase()

Returns `true` if all characters in the current String are lowercase; otherwise, returns `false`.

isAllUpperCase()

Returns `true` if all characters in the current String are uppercase; otherwise, returns `false`.

isAlpha()

Returns `true` if all characters in the current String are Unicode letters only; otherwise, returns `false`.

isAlphaSpace()

Returns `true` if all characters in the current String are Unicode letters or spaces only; otherwise, returns `false`.

isAlphanumeric()

Returns `true` if all characters in the current String are Unicode letters or numbers only; otherwise, returns `false`.

isAlphanumericSpace()

Returns `true` if all characters in the current String are Unicode letters, numbers, or spaces only; otherwise, returns `false`.

isAsciiPrintable()

Returns `true` if the current String contains only ASCII printable characters; otherwise, returns `false`.

isBlank(inputString)

Returns `true` if the specified String is white space, empty (''), or null; otherwise, returns `false`.

isEmpty(inputString)

Returns `true` if the specified String is empty ('') or null; otherwise, returns `false`.

isNotBlank(inputString)

Returns `true` if the specified String is not whitespace, not empty (''), and not null; otherwise, returns `false`.

isNotEmpty(inputString)

Returns `true` if the specified String is not empty ('') and not null; otherwise, returns `false`.

isNumeric()

Returns `true` if the current String contains only Unicode digits; otherwise, returns `false`.

isNumericSpace()

Returns `true` if the current String contains only Unicode digits or spaces; otherwise, returns `false`.

isWhitespace()

Returns `true` if the current String contains only white space characters or is empty; otherwise, returns `false`.

join(iterableObj, separator)

Joins the elements of the specified iterable object, such as a List, into a single String separated by the specified separator.

lastIndexOf(substring)

Returns the index of the last occurrence of the specified substring. If the substring does not occur, this method returns -1.

lastIndexOf(substring, endPosition)

Returns the index of the last occurrence of the specified substring, starting from the character at index 0 and ending at the specified index.

lastIndexOfChar(character)

Returns the index of the last occurrence of the character that corresponds to the specified character value.

lastIndexOfChar(character, endIndex)

Returns the index of the last occurrence of the character that corresponds to the specified character value, starting from the specified index.

lastIndexOfIgnoreCase(substring)

Returns the index of the last occurrence of the specified substring regardless of case.

lastIndexOfIgnoreCase(substring, endPosition)

Returns the index of the last occurrence of the specified substring regardless of case, starting from the character at index 0 and ending at the specified index.

left(length)

Returns the leftmost characters of the current String of the specified length.

leftPad(length)

Returns the current String padded with spaces on the left and of the specified length.

leftPad(length, padStr)

Returns the current String padded with String `padStr` on the left and of the specified length.

length()

Returns the number of 16-bit Unicode characters contained in the String.

mid(startIndex, length)

Returns a new String that begins with the character at the specified zero-based *`startIndex`* with the number of characters specified by *`length`*.

normalizeSpace()

Returns the current String with leading, trailing, and repeating white space characters removed.

offsetByCodePoints(index, codePointOffset)

Returns the index of the Unicode code point that is offset by the specified number of code points, starting from the given index.

remove(substring)

Removes all occurrences of the specified substring and returns the String result.

removeEnd(substring)

Removes the specified substring only if it occurs at the end of the String.

removeEndIgnoreCase(substring)

Removes the specified substring only if it occurs at the end of the String using a case-insensitive match.

removeStart(substring)

Removes the specified substring only if it occurs at the beginning of the String.

removeStartIgnoreCase(substring)

Removes the specified substring only if it occurs at the beginning of the String using a case-insensitive match.

repeat(numberOfTimes)

Returns the current String repeated the specified number of times.

repeat(separator, numberOfTimes)

Returns the current String repeated the specified number of times using the specified separator to separate the repeated Strings.

replace(target, replacement)

Replaces each substring of a string that matches the literal target sequence *`target`* with the specified literal replacement sequence *`replacement`*.

replaceAll(regExp, replacement)

Replaces each substring of a string that matches the regular expression *`regExp`* with the replacement sequence *`replacement`*.

replaceFirst(regExp, replacement)

Replaces the first substring of a string that matches the regular expression *`regExp`* with the replacement sequence *`replacement`*.

reverse()

Returns a String with all the characters reversed.

right(length)

Returns the rightmost characters of the current String of the specified length.

rightPad(length)

Returns the current String padded with spaces on the right and of the specified length.

rightPad(length, padStr)

Returns the current String padded with String `padStr` on the right and of the specified length.

split(regExp)

Returns a list that contains each substring of the String that is terminated by either the regular expression *`regExp`* or the end of the String.

split(regExp, limit)

Returns a list that contains each substring of the String that is terminated by either the regular expression *`regExp`* or the end of the String.

splitByCharacterType()

Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens.

splitByCharacterTypeCamelCase()

Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens, with the following exception: the uppercase character, if any, immediately preceding a lowercase character token belongs to the following character token rather than to the preceding.

startsWith(prefix)

Returns `true` if the String that called the method begins with the specified *`prefix`*.

startsWithIgnoreCase(prefix)

Returns `true` if the current String begins with the specified prefix regardless of the prefix case.

stripHtmlTags()

Removes HTML markup and returns plain text.

substring(startIndex)

Returns a new String that begins with the character at the specified zero-based *`startIndex`* and extends to the end of the String.

substring(startIndex, endIndex)

Returns a new String that begins with the character at the specified zero-based *`startIndex`* and extends to the character at *`endIndex`* - 1.

substringAfter(separator)

Returns the substring that occurs after the first occurrence of the specified separator.

substringAfterLast(separator)

Returns the substring that occurs after the last occurrence of the specified separator.

substringBefore(separator)

Returns the substring that occurs before the first occurrence of the specified separator.

substringBeforeLast(separator)

Returns the substring that occurs before the last occurrence of the specified separator.

substringBetween(tag)

Returns the substring that occurs between two instances of the specified *`tag`* String.

substringBetween(open, close)

Returns the substring that occurs between the two specified Strings.

swapCase()

Swaps the case of all characters and returns the resulting String by using the default (English US) locale.

toLowerCase()

Converts all of the characters in the String to lowercase using the rules of the default (English US) locale.

toLowerCase(locale)

Converts all of the characters in the String to lowercase using the rules of the specified locale.

toUpperCase()

Converts all of the characters in the String to uppercase using the rules of the default (English US) locale.

toUpperCase(locale)

Converts all of the characters in the String to the uppercase using the rules of the specified locale.

trim()

Returns a copy of the string that no longer contains any leading or trailing white space characters.

uncapitalize()

Returns the current String with the first letter in lowercase.

unescapeCsv()

Returns a String representing an unescaped CSV column.

unescapeEcmaScript()

Unescapes any EcmaScript literals found in the String.

unescapeHtml3()

Unescapes the characters in a String using HTML 3.0 entities.

unescapeHtml4()

Unescapes the characters in a String using HTML 4.0 entities.

unescapeJava()

Returns a String whose Java literals are unescaped. Literals unescaped include escape sequences for quotes (\\") and control characters, such as tab (\\t), and carriage return (\\n).

unescapeUnicode()

Returns a String whose escaped Unicode characters are unescaped.

unescapeXml()

Unescapes the characters in a String using XML entities.

valueOf(dateToConvert)

Returns a String that represents the specified Date in the standard "yyyy-MM-dd" format.

valueOf(datetimeToConvert)

Returns a String that represents the specified Datetime in the standard "yyyy-MM-dd HH:mm:ss" format for the local time zone.

valueOf(decimalToConvert)

Returns a String that represents the specified Decimal.

valueOf(doubleToConvert)

Returns a String that represents the specified Double.

valueOf(integerToConvert)

Returns a String that represents the specified Integer.

valueOf(longToConvert)

Returns a String that represents the specified Long.

valueOf(toConvert)

Returns a string representation of the specified object argument.

valueOfGmt(datetimeToConvert)

Returns a String that represents the specified Datetime in the standard "yyyy-MM-dd HH:mm:ss" format for the GMT time zone.

abbreviate(maxWidth)

Returns an abbreviated version of the String, of the specified length and with ellipses appended if the current String is longer than the specified length; otherwise, returns the original String without ellipses.

Signature

```
public String abbreviate(Integer maxWidth)
```

Parameters

maxWidth

Type: Integer

If *maxWidth* is less than four, this method throws a run-time exception.

Return Value

Type: String

Example

```
String s = 'Hello Maximillian';
String s2 = s.abbreviate(8);
System.assertEquals('Hello...', s2);
System.assertEquals(8, s2.length());
```

abbreviate(maxWidth, offset)

Returns an abbreviated version of the String, starting at the specified character offset and of the specified length. The returned String has ellipses appended at the start and the end if characters have been removed at these locations.

Signature

```
public String abbreviate(Integer maxWidth, Integer offset)
```

Parameters

maxWidth

Type: Integer

Note that the offset is not necessarily the leftmost character in the returned String or the first character following the ellipses, but it appears somewhere in the result. Regardless, `abbreviate` won't return a String of length greater than *maxWidth*.If *maxWidth* is too small, this method throws a run-time exception.

offset

Type: Integer

Return Value

Type: String

Example

```
String s = 'Hello Maximillian';
// Start at M
String s2 = s.abbreviate(9,6);
System.assertEquals('...Max...', s2);
System.assertEquals(9, s2.length());
```

capitalize()

Returns the current String with the first letter changed to title case.

Signature

```
public String capitalize()
```

Return Value

Type: String

Usage

This method is based on the `Character.toTitleCase(char)` Java method.

Example

```
String s = 'hello maximillian';
String s2 = s.capitalize();
System.assertEquals('Hello maximillian', s2);
```

center(size)

Returns a version of the current String of the specified size padded with spaces on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without added spaces.

Signature

```
public String center(Integer size)
```

Parameters

size
Type: Integer

Return Value

Type: String

Example

```
String s = 'hello';
String s2 = s.center(9);
System.assertEquals(
   '  hello  ',
   s2);
```

center(size, paddingString)

Returns a version of the current String of the specified size padded with the specified String on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without padding.

Signature

```
public String center(Integer size, String paddingString)
```

Parameters

size
Type: Integer

paddingString
Type: String

Return Value

Type: String

Example

```
String s = 'hello';
String s2 = s.center(9, '-');
System.assertEquals('--hello--', s2);
```

charAt(index)

Returns the value of the character at the specified index.

Signature

```
public Integer charAt(Integer index)
```

Parameters

index
Type: Integer

The index of the character to get the value of.

Return Value

Type: Integer

The integer value of the character.

Usage

The `charAt` method returns the value of the character pointed to by the specified index. If the index points to the beginning of a surrogate pair (the high-surrogate code point), this method returns only the high-surrogate code point. To return the supplementary code point corresponding to a surrogate pair, call `codePointAt` instead.

Example

This example gets the value of the first character at index 0.

```
String str = 'Ω is Omega.';
System.assertEquals(937, str.charAt(0));
```

This example shows the difference between `charAt` and `codePointAt`. The example calls these methods on escaped supplementary Unicode characters. `charAt(0)` returns the high surrogate value, which corresponds to `\uD835`. `codePointAt(0)` returns the value for the entire surrogate pair.

```
String str = '\uD835\uDD0A';
System.assertEquals(55349, str.charAt(0),
    'charAt(0) didn\'t return the high surrogate.');
System.assertEquals(120074, str.codePointAt(0),
    'codePointAt(0) didn\'t return the entire two-character supplementary value.');
```

codePointAt(index)

Returns the Unicode code point value at the specified index.

Signature

```
public Integer codePointAt(Integer index)
```

Parameters

index

Type: Integer

The index of the characters (Unicode code units) in the string. The index range is from zero to the string length minus one.

Return Value

Type: Integer

The Unicode code point value at the specified index.

Usage

If the *index* points to the beginning of a surrogate pair (the high-surrogate code point), and the character value at the following index points to the low-surrogate code point, this method returns the supplementary code point corresponding to this surrogate pair. Otherwise, this method returns the character value at the given index.

For more information on Unicode and surrogate pairs, see The Unicode Consortium.

Example

This example gets the code point value of the first character at index 0, which is the escaped Omega character. Also, the example gets the code point at index 20, which corresponds to the escaped supplementary Unicode characters (a pair of characters). Finally, it verifies that the escaped and unescaped forms of Omega have the same code point values.

The supplementary characters in this example (`\\uD835\\uDD0A`) correspond to mathematical fraktur capital G:

```
String str = '\u03A9 is Ω (Omega), and \uD835\uDD0A ' +
    ' is Fraktur Capital G.';
System.assertEquals(937, str.codePointAt(0));
System.assertEquals(120074, str.codePointAt(20));
// Escaped or unescaped forms of the same character have the same code point
System.assertEquals(str.codePointAt(0), str.codePointAt(5));
```

codePointBefore(index)

Returns the Unicode code point value that occurs before the specified index.

Signature

```
public Integer codePointBefore(Integer index)
```

Parameters

index
Type: Integer

The index before the Unicode code point that is to be returned. The index range is from one to the string length.

Return Value

Type: Integer

The character or Unicode code point value that occurs before the specified index.

Usage

If the character value at ***index***`-1` is the low-surrogate code point, and ***index***`-2` is not negative and the character at this index location is the high-surrogate code point, this method returns the supplementary code point corresponding to this surrogate pair. If the character value at ***index***`-1` is an unpaired low-surrogate or high-surrogate code point, the surrogate value is returned.

For more information on Unicode and surrogate pairs, see The Unicode Consortium.

Example

This example gets the code point value of the first character (before index 1), which is the escaped Omega character. Also, the example gets the code point at index 20, which corresponds to the escaped supplementary characters (the two characters before index 22).

```
String str = '\u03A9 is Ω (Omega), and \uD835\uDD0A ' +
    ' is Fraktur Capital G.';
```

```
System.assertEquals(937, str.codePointBefore(1));
System.assertEquals(120074, str.codePointBefore(22));
```

codePointCount(beginIndex, endIndex)

Returns the number of Unicode code points within the specified text range.

Signature

```
public Integer codePointCount(Integer beginIndex, Integer endIndex)
```

Parameters

beginIndex
Type: Integer

The index of the first character in the range.

endIndex
Type: Integer

The index after the last character in the range.

Return Value

Type: Integer

The number of Unicode code points within the specified range.

Usage

The specified range begins at *beginIndex* and ends at ***endIndex***—1. Unpaired surrogates within the text range count as one code point each.

Example

This example writes the count of code points in a substring that contains an escaped Unicode character and another substring that contains Unicode supplementary characters, which count as one code point.

```
String str = '\u03A9 and \uD835\uDD0A characters.';
System.debug('Count of code points for ' + str.substring(0,1)
             + ': ' + str.codePointCount(0,1));
System.debug('Count of code points for ' + str.substring(6,8)
             + ': ' + str.codePointCount(6,8));

// Output:
// Count of code points for Ω: 1
// Count of code points for □□: 1
```

compareTo(secondString)

Compares two strings lexicographically, based on the Unicode value of each character in the Strings.

Signature

```
public Integer compareTo(String secondString)
```

Parameters

secondString
Type: String

Return Value

Type: Integer

Usage

The result is:

- A negative Integer if the String that called the method lexicographically precedes *secondString*
- A positive Integer if the String that called the method lexicographically follows *compsecondStringString*
- Zero if the Strings are equal

If there is no index position at which the Strings differ, then the shorter String lexicographically precedes the longer String.

Note that this method returns 0 whenever the `equals` method returns true.

Example

```
String myString1 = 'abcde';
String myString2 = 'abcd';
Integer result =
   myString1.compareTo(myString2);
System.assertEquals(result, 1);
```

contains(substring)

Returns `true` if and only if the String that called the method contains the specified sequence of characters in *substring*.

Signature

```
public Boolean contains(String substring)
```

Parameters

substring
Type: String

Return Value

Type: Boolean

Example

```
String myString1 = 'abcde';
String myString2 = 'abcd';
Boolean result =
   myString1.contains(myString2);
System.assertEquals(result, true);
```

containsAny(inputString)

Returns `true` if the current String contains any of the characters in the specified String; otherwise, returns `false`.

Signature

```
public Boolean containsAny(String inputString)
```

Parameters

inputString
Type: String

Return Value

Type: Boolean

Example

```
String s = 'hello';
Boolean b1 = s.containsAny('hx');
Boolean b2 = s.containsAny('x');
System.assertEquals(true, b1);
System.assertEquals(false, b2);
```

containsIgnoreCase(substring)

Returns `true` if the current String contains the specified sequence of characters without regard to case; otherwise, returns `false`.

Signature

```
public Boolean containsIgnoreCase(String substring)
```

Parameters

substring
Type: String

Return Value

Type: Boolean

Example

```
String s = 'hello';
Boolean b = s.containsIgnoreCase('HE');
System.assertEquals(
   true,
   b);
```

containsNone(inputString)

Returns `true` if the current String doesn't contain any of the characters in the specified String; otherwise, returns `false`.

Signature

```
public Boolean containsNone(String inputString)
```

Parameters

inputString
Type: String

If *inputString* is an empty string or the current String is empty, this method returns `true`. If *inputString* is null, this method returns a run-time exception.

Return Value

Type: Boolean

Example

```
String s1 = 'abcde';
System.assert(s1.containsNone('fg'));
```

containsOnly(inputString)

Returns `true` if the current String contains characters only from the specified sequence of characters and not any other characters; otherwise, returns `false`.

Signature

```
public Boolean containsOnly(String inputString)
```

Parameters

inputString
Type: String

Return Value

Type: Boolean

Example

```
String s1 = 'abba';
String s2 = 'abba xyz';
Boolean b1 =
   s1.containsOnly('abcd');
System.assertEquals(
   true,
   b1);
Boolean b2 =
   s2.containsOnly('abcd');
System.assertEquals(
   false,
   b2);
```

containsWhitespace()

Returns `true` if the current String contains any white space characters; otherwise, returns `false`.

Signature

```
public Boolean containsWhitespace()
```

Return Value

Type: Boolean

Example

```
String s = 'Hello Jane';
System.assert(s.containsWhitespace()); //true
s = 'HelloJane ';
System.assert(s.containsWhitespace()); //true
s = ' HelloJane';
System.assert(s.containsWhitespace()); //true
s = 'HelloJane';
System.assert(!s.containsWhitespace()); //false
```

countMatches(substring)

Returns the number of times the specified substring occurs in the current String.

Signature

```
public Integer countMatches(String substring)
```

Parameters

substring
Type: String

Return Value

Type: Integer

Example

```
String s = 'Hello Jane';
System.assertEquals(1, s.countMatches('Hello'));
s = 'Hello Hello';
System.assertEquals(2, s.countMatches('Hello'));
s = 'Hello hello';
System.assertEquals(1, s.countMatches('Hello'));
```

deleteWhitespace()

Returns a version of the current String with all white space characters removed.

Signature

```
public String deleteWhitespace()
```

Return Value

Type: String

Example

```
String s1 = ' Hello Jane ';
String s2 = 'HelloJane';
System.assertEquals(s2, s1.deleteWhitespace());
```

difference(secondString)

Returns the difference between the current String and the specified String.

Signature

```
public String difference(String secondString)
```

Parameters

secondString

Type: String

If *secondString* is an empty string, this method returns an empty string.If *secondString* is null, this method throws a run-time exception.

Return Value

Type: String

Example

```
String s = 'Hello Jane';
String d1 =
   s.difference('Hello Max');
System.assertEquals(
   'Max',
   d1);
String d2 =
   s.difference('Goodbye');
System.assertEquals(
   'Goodbye',
   d2);
```

endsWith(suffix)

Returns `true` if the String that called the method ends with the specified *`suffix`*.

Signature

```
public Boolean endsWith(String suffix)
```

Parameters

`suffix`
Type: String

Return Value

Type: Boolean

Example

```
String s = 'Hello Jason';
System.assert(s.endsWith('Jason'));
```

endsWithIgnoreCase(suffix)

Returns `true` if the current String ends with the specified suffix; otherwise, returns `false`.

Signature

```
public Boolean endsWithIgnoreCase(String suffix)
```

Parameters

`suffix`
Type: String

Return Value

Type: Boolean

Example

```
String s = 'Hello Jason';
System.assert(s.endsWithIgnoreCase('jason'));
```

equals(secondString)

Deprecated. This method is replaced by `equals(stringOrId)`. Returns `true` if the passed-in string is not null and represents the same binary sequence of characters as the current string. Use this method to perform case-sensitive comparisons.

Signature

```
public Boolean equals(String secondString)
```

Parameters

secondString
Type: String

Return Value

Type: Boolean

Usage

This method returns `true` when the `compareTo` method returns 0.

Use this method to perform case-sensitive comparisons. In contrast, the `==` operator performs case-insensitive string comparisons to match Apex semantics.

Example

```
String myString1 = 'abcde';
String myString2 = 'abcd';
Boolean result = myString1.equals(myString2);
System.assertEquals(result, false);
```

equals(stringOrId)

Returns `true` if the passed-in object is not null and represents the same binary sequence of characters as the current string. Use this method to compare a string to an object that represents a string or an ID.

Signature

```
public Boolean equals(Object stringOrId)
```

Parameters

stringOrId
Type: Object

Return Value

Type: Boolean

Usage

If you compare ID values, the lengths of IDs don't need to be equal. For example, if you compare a 15-character ID string to an object that represents the equivalent 18-character ID value, this method returns `true`. For more information about 15-character and 18-character IDs, see the ID data type.

Use this method to perform case-sensitive comparisons. In contrast, the `==` operator performs case-insensitive string comparisons to match Apex semantics.

Example

These examples show comparisons between different types of variables with both equal and unequal values. The examples also show how Apex automatically converts certain values before comparing them.

```
// Compare a string to an object containing a string
Object obj1 = 'abc';
String str = 'abc';
Boolean result1 = str.equals(obj1);
System.assertEquals(true, result1);

// Compare a string to an object containing a number
Integer obj2 = 100;
Boolean result2 = str.equals(obj2);
System.assertEquals(false, result2);

// Compare a string to an ID of the same length.
// 15-character ID
Id idValue15 = '001D000000Ju1zH';
// 15-character ID string value
String stringValue15 = '001D000000Ju1zH';
Boolean result3 = stringValue15.equals(IdValue15);
System.assertEquals(true, result3);

// Compare two equal ID values of different lengths:
//  15-character ID and 18-character ID
Id idValue18 = '001D000000Ju1zHIAR';
Boolean result4 = stringValue15.equals(IdValue18);
System.assertEquals(true, result4);
```

equalsIgnoreCase(secondString)

Returns `true` if the *`secondString`* is not null and represents the same sequence of characters as the String that called the method, ignoring case.

Signature

```
public Boolean equalsIgnoreCase(String secondString)
```

Parameters

secondString
Type: String

Return Value

Type: Boolean

Example

```
String myString1 = 'abcd';
String myString2 = 'ABCD';
Boolean result =
myString1.equalsIgnoreCase(myString2);
System.assertEquals(result, true);
```

escapeCsv()

Returns a String for a CSV column enclosed in double quotes, if required.

Signature

```
public String escapeCsv()
```

Return Value

Type: String

Usage

If the String contains a comma, newline or double quote, the returned String is enclosed in double quotes. Also, any double quote characters in the String are escaped with another double quote.

If the String doesn't contain a comma, newline or double quote, it is returned unchanged.

Example

```
String s1 = 'Max1, "Max2"';
String s2 = s1.escapeCsv();
System.assertEquals('"Max1, ""Max2"""', s2);
```

escapeEcmaScript()

Escapes the characters in the String using EcmaScript String rules.

Signature

```
public String escapeEcmaScript()
```

Return Value

Type: String

Usage

The only difference between Apex strings and EcmaScript strings is that in EcmaScript, a single quote and forward-slash (/) are escaped.

Example

```
String s1 = '"grade": 3.9/4.0';
String s2 = s1.escapeEcmaScript();
System.debug(s2);
// Output is:
// \"grade\": 3.9\/4.0
System.assertEquals(
   '\\"grade\\": 3.9\\/4.0',
    s2);
```

escapeHtml3()

Escapes the characters in a String using HTML 3.0 entities.

Signature

```
public String escapeHtml3()
```

Return Value

Type: String

Example

```
String s1 =
   '"<Black&White>"';
String s2 =
   s1.escapeHtml3();
System.debug(s2);
// Output:
// &quot;&lt;Black&amp;
// White&gt;&quot;
```

escapeHtml4()

Escapes the characters in a String using HTML 4.0 entities.

Signature

```
public String escapeHtml4()
```

Return Value

Type: String

Example

```
String s1 =
   '"<Black&White>"';
String s2 =
   s1.escapeHtml4();
System.debug(s2);
// Output:
// &quot;&lt;Black&amp;
// White&gt;&quot;
```

escapeJava()

Returns a String whose characters are escaped using Java String rules. Characters escaped include quotes and control characters, such as tab, backslash, and carriage return characters.

Signature

```
public String escapeJava()
```

Return Value

Type: String

The escaped string.

Example

```
// Input string contains quotation marks
String s = 'Company: "Salesforce.com"';
String escapedStr = s.escapeJava();
// Output string has the quotes escpaded
System.assertEquals('Company: \\"Salesforce.com\\"', escapedStr);
```

escapeSingleQuotes(stringToEscape)

Returns a String with the escape character (\) added before any single quotation marks in the String *s*.

Signature

```
public static String escapeSingleQuotes(String stringToEscape)
```

Parameters

stringToEscape
Type: String

Return Value

Type: String

Usage

This method is useful when creating a dynamic SOQL statement, to help prevent SOQL injection. For more information on dynamic SOQL, see Dynamic SOQL.

Example

```
String s = '\'Hello Jason\'';
system.debug(s); // Outputs 'Hello Jason'
String escapedStr = String.escapeSingleQuotes(s);
// Outputs \'Hello Jason\'
system.debug(escapedStr);
// Escapes the string \\\' to string \'
system.assertEquals('\\\'Hello Jason\\\'', escapedStr);
```

escapeUnicode()

Returns a String whose Unicode characters are escaped to a Unicode escape sequence.

Signature

```
public String escapeUnicode()
```

Return Value

Type: String

The escaped string.

Example

```
String s = 'De onde você é?';
String escapedStr = s.escapeUnicode();
System.assertEquals('De onde voc\\u00EA \\u00E9?', escapedStr);
```

escapeXml()

Escapes the characters in a String using XML entities.

Signature

```
public String escapeXml()
```

Return Value

Type: String

Usage

Supports only the five basic XML entities (gt, lt, quot, amp, apos). Does not support DTDs or external entities. Unicode characters greater than 0x7f are not escaped.

Example

```
String s1 =
   '"<Black&White>"';
String s2 =
   s1.escapeXml();
System.debug(s2);
// Output:
// &quot;&lt;Black&amp;
// White&gt;&quot;
```

format(stringToFormat, formattingArguments)

Treat the first argument as a pattern and return a string using the second argument for substitution and formatting in the same manner as `apex:outputText` and the Java `MessageFormat` class.

Signature

```
public static String format(String stringToFormat, List<String> formattingArguments)
```

Parameters

stringToFormat
Type: String

formattingArguments
Type: List<String>

Return Value

Type: String

Example

```
String placeholder = 'Hello {0}, {1} is cool!';
List<String> fillers = new String[]{'Jason','Apex'};
String formatted = String.format(placeholder, fillers);
System.assertEquals('Hello Jason, Apex is cool!', formatted);
```

fromCharArray(charArray)

Returns a String from the values of the list of integers.

Signature

```
public static String fromCharArray(List<Integer> charArray)
```

Parameters

charArray
Type: List<Integer>

Return Value

Type: String

Example

```
List<Integer> charArr= new Integer[]{74};
String convertedChar = String.fromCharArray(charArr);
System.assertEquals('J', convertedChar);
```

getChars()

Returns an array of character values that represent the characters in this string.

Signature

```
public List<Integer> getChars()
```

Return Value

Type: List<String>

A list of integers, each corresponding to a character value in the string.

Example

This sample converts a string to a character array and then gets the first array element, which corresponds to the value of 'J'.

```
String str = 'Jane goes fishing.';
Integer[] chars = str.getChars();
// Get the value of 'J'
System.assertEquals(74, chars[0]);
```

getCommonPrefix(strings)

Returns the initial sequence of characters as a String that is common to all the specified Strings.

Signature

```
public static String getCommonPrefix(List<String> strings)
```

Parameters

strings
Type: List<String>

Return Value

Type: String

Example

```
List<String> ls = new List<String>{'SFDCApex', 'SFDCVisualforce'};
String prefix = String.getCommonPrefix(ls);
System.assertEquals('SFDC', prefix);
```

getLevenshteinDistance(stringToCompare)

Returns the Levenshtein distance between the current String and the specified String.

Signature

```
public Integer getLevenshteinDistance(String stringToCompare)
```

Parameters

stringToCompare
Type: String

Return Value

Type: Integer

Usage

The Levenshtein distance is the number of changes needed to change one String into another. Each change is a single character modification (deletion, insertion or substitution).

Example

```
String s = 'Hello Joe';
Integer i = s.getLevenshteinDistance('Hello Max');
System.assertEquals(3, i);
```

getLevenshteinDistance(stringToCompare, threshold)

Returns the Levenshtein distance between the current String and the specified String if it is less than or equal than the given threshold; otherwise, returns -1.

Signature

```
public Integer getLevenshteinDistance(String stringToCompare, Integer threshold)
```

Parameters

stringToCompare
Type: String

threshold
Type: Integer

Return Value

Type: Integer

Usage

The Levenshtein distance is the number of changes needed to change one String into another. Each change is a single character modification (deletion, insertion or substitution).

Example:

In this example, the Levenshtein distance is 3, but the threshold argument is 2, which is less than the distance, so this method returns -1.

Example

```
String s = 'Hello Jane';
Integer i = s.getLevenshteinDistance('Hello Max', 2);
System.assertEquals(-1, i);
```

hashCode()

Returns a hash code value for this string.

Signature

```
public Integer hashCode()
```

Return Value

Type: Integer

Usage

This value is based on the hash code computed by the Java `String.hashCode` counterpart method.

You can use this method to simplify the computation of a hash code for a custom type that contains String member variables. You can compute your type's hash code value based on the hash code of each String variable. For example:

For more details about the use of hash code methods with custom types, see Using Custom Types in Map Keys and Sets.

Example

```
public class MyCustomClass {
   String x,y;
   // Provide a custom hash code
   public Integer hashCode() {
    return
    (31*x.hashCode())^(y.hashCode());
```

```
    }
}
```

indexOf(substring)

Returns the index of the first occurrence of the specified substring. If the substring does not occur, this method returns -1.

Signature

```
public Integer indexOf(String substring)
```

Parameters

substring
Type: String

Return Value

Type: Integer

Example

```
String myString1 = 'abcde';
String myString2 = 'cd';
Integer result = myString1.indexOf(mystring2);
System.assertEquals(2, result);
```

indexOf(substring, index)

Returns the zero-based index of the first occurrence of the specified substring from the point of the given index. If the substring does not occur, this method returns -1.

Signature

```
public Integer indexOf(String substring, Integer index)
```

Parameters

substring
Type: String

index
Type: Integer

Return Value

Type: Integer

Example

```
String myString1 = 'abcdabcd';
String myString2 = 'ab';
Integer result = myString1.indexOf(mystring2, 1);
System.assertEquals(4, result);
```

indexOfAny(substring)

Returns the zero-based index of the first occurrence of any character specified in the substring. If none of the characters occur, returns -1.

Signature

```
public Integer indexOfAny(String substring)
```

Parameters

substring
Type: String

Return Value

Type: Integer

Example

```
String s1 = 'abcd';
String s2 = 'xc';
Integer result = s1.indexOfAny(s2);
System.assertEquals(2, result);
```

indexOfAnyBut(substring)

Returns the zero-based index of the first occurrence of a character that is not in the specified substring. Otherwise, returns -1.

Signature

```
public Integer indexOfAnyBut(String substring)
```

Parameters

substring
Type: String

Return Value

Type: Integer

Example

```
String s1 = 'abcd';
String s2 = 'xc';
Integer result = s1.indexOfAnyBut(s2);
System.assertEquals(0, result);
```

indexOfChar(character)

Returns the index of the first occurrence of the character that corresponds to the specified character value.

Signature

```
public Integer indexOfChar(Integer character)
```

Parameters

character
Type: Integer

The integer value of the character in the string.

Return Value

Type: Integer

The index of the first occurrence of the specified character, -1 if the character is not found.

Usage

The index that this method returns is in Unicode code units.

Example

```
String str = '\\u03A9 is Ω (Omega)';
// Returns 0, which is the first character.
System.debug('indexOfChar(937)=' + str.indexOfChar(937));

// Output:
// indexOfChar(937)=0
```

indexOfChar(character, startIndex)

Returns the index of the first occurrence of the character that corresponds to the specified character value, starting from the specified index.

Signature

```
public Integer indexOfChar(Integer character, Integer startIndex)
```

Parameters

character
Type: Integer

The integer value of the character to look for.

startIndex
Type: Integer

The index to start the search from.

Return Value

Type: Integer

The index, starting from the specified start index, of the first occurrence of the specified character, -1 if the character is not found.

Usage

The index that this method returns is in Unicode code units.

Example

This example shows different ways of searching for the index of the Omega character. The first call to `indexOfChar` doesn't specify a start index and therefore the returned index is 0, which is the first occurrence of Omega in the entire string. The subsequent calls specify a start index to find the occurrence of Omega in substrings that start at the specified index.

```
String str = 'Ω and \\u03A9 and Ω';
System.debug('indexOfChar(937)=' + str.indexOfChar(937));
System.debug('indexOfChar(937,1)=' + str.indexOfChar(937,1));
System.debug('indexOfChar(937,10)=' + str.indexOfChar(937,10));

// Output:
// indexOfChar(937)=0
// indexOfChar(937,1)=6, (corresponds to the escaped form \\u03A9)
// indexOfChar(937,10)=12
```

indexOfDifference(stringToCompare)

Returns the zero-based index of the character where the current String begins to differ from the specified String.

Signature

```
public Integer indexOfDifference(String stringToCompare)
```

Parameters

stringToCompare
Type: String

Return Value

Type: Integer

Example

```
String s1 = 'abcd';
String s2 = 'abxc';
Integer result = s1.indexOfDifference(s2);
System.assertEquals(2, result);
```

indexOfIgnoreCase(substring)

Returns the zero-based index of the first occurrence of the specified substring without regard to case. If the substring does not occur, this method returns -1.

Signature

```
public Integer indexOfIgnoreCase(String substring)
```

Parameters

substring
Type: String

Return Value

Type: Integer

Example

```
String s1 = 'abcd';
String s2 = 'BC';
Integer result = s1.indexOfIgnoreCase(s2, 0);
System.assertEquals(1, result);
```

indexOfIgnoreCase(substring, startPosition)

Returns the zero-based index of the first occurrence of the specified substring from the point of index `i`, without regard to case. If the substring does not occur, this method returns -1.

Signature

```
public Integer indexOfIgnoreCase(String substring, Integer startPosition)
```

Parameters

substring
Type: String

startPosition
Type: Integer

Return Value

Type: Integer

isAllLowerCase()

Returns `true` if all characters in the current String are lowercase; otherwise, returns `false`.

Signature

```
public Boolean isAllLowerCase()
```

Return Value

Type: Boolean

Example

```
String allLower = 'abcde';
System.assert(allLower.isAllLowerCase());
```

isAllUpperCase()

Returns `true` if all characters in the current String are uppercase; otherwise, returns `false`.

Signature

```
public Boolean isAllUpperCase()
```

Return Value

Type: Boolean

Example

```
String allUpper = 'ABCDE';
System.assert(allUpper.isAllUpperCase());
```

isAlpha()

Returns `true` if all characters in the current String are Unicode letters only; otherwise, returns `false`.

Signature

```
public Boolean isAlpha()
```

Return Value

Type: Boolean

Example

```
// Letters only
String s1 = 'abc';
// Returns true
```

```
Boolean b1 =
   s1.isAlpha();
System.assertEquals(
   true, b1);

// Letters and numbers
String s2 = 'abc 21';
// Returns false
Boolean b2 =
   s2.isAlpha();
System.assertEquals(
   false, b2);
```

isAlphaSpace()

Returns `true` if all characters in the current String are Unicode letters or spaces only; otherwise, returns `false`.

Signature

```
public Boolean isAlphaSpace()
```

Return Value

Type: Boolean

Example

```
String alphaSpace = 'aA Bb';
System.assert(alphaSpace.isAlphaSpace());
String notAlphaSpace = 'ab 12';
System.assert(!notAlphaSpace.isAlphaSpace());
notAlphaSpace = 'aA$Bb';
System.assert(!notAlphaSpace.isAlphaSpace());
```

isAlphanumeric()

Returns `true` if all characters in the current String are Unicode letters or numbers only; otherwise, returns `false`.

Signature

```
public Boolean isAlphanumeric()
```

Return Value

Type: Boolean

Example

```
// Letters only
String s1 = 'abc';
// Returns true
```

```
Boolean b1 =
   s1.isAlphanumeric();
System.assertEquals(
   true, b1);

// Letters and numbers
String s2 = 'abc021';
// Returns true
Boolean b2 =
   s2.isAlphanumeric();
System.assertEquals(
   true, b2);
```

isAlphanumericSpace()

Returns `true` if all characters in the current String are Unicode letters, numbers, or spaces only; otherwise, returns `false`.

Signature

```
public Boolean isAlphanumericSpace()
```

Return Value

Type: Boolean

Example

```
String alphanumSpace = 'AE 86';
System.assert(alphanumSpace.isAlphanumericSpace());
String notAlphanumSpace = 'aA$12';
System.assert(!notAlphanumSpace.isAlphaSpace());
```

isAsciiPrintable()

Returns `true` if the current String contains only ASCII printable characters; otherwise, returns `false`.

Signature

```
public Boolean isAsciiPrintable()
```

Return Value

Type: Boolean

Example

```
String ascii = 'abcd1234!@#$%^&*()`~-_+={[}]|:<,>.?';
System.assert(ascii.isAsciiPrintable());
String notAscii = '√';
System.assert(!notAscii.isAsciiPrintable());
```

isBlank(inputString)

Returns `true` if the specified String is white space, empty (''), or null; otherwise, returns `false`.

Signature

```
public static Boolean isBlank(String inputString)
```

Parameters

inputString
Type: String

Return Value

Type: Boolean

Example

```
String blank = '';
String nullString = null;
String whitespace = '  ';
System.assert(String.isBlank(blank));
System.assert(String.isBlank(nullString));
System.assert(String.isBlank(whitespace));
String alpha = 'Hello';
System.assert(!String.isBlank(alpha));
```

isEmpty(inputString)

Returns `true` if the specified String is empty ('') or null; otherwise, returns `false`.

Signature

```
public static Boolean isEmpty(String inputString)
```

Parameters

inputString
Type: String

Return Value

Type: Boolean

Example

```
String empty = '';
String nullString = null;
System.assert(String.isEmpty(empty));
System.assert(String.isEmpty(nullString));
String whitespace = '  ';
```

```
String alpha = 'Hello';
System.assert(!String.isEmpty(whitespace));
System.assert(!String.isEmpty(alpha));
```

isNotBlank(inputString)

Returns `true` if the specified String is not whitespace, not empty (''), and not null; otherwise, returns `false`.

Signature

```
public static Boolean isNotBlank(String inputString)
```

Parameters

inputString
Type: String

Return Value

Type: Boolean

Example

```
String alpha = 'Hello world!';
System.assert(String.isNotBlank(alpha));
String blank = '';
String nullString = null;
String whitespace = '  ';
System.assert(!String.isNotBlank(blank));
System.assert(!String.isNotBlank(nullString));
System.assert(!String.isNotBlank(whitespace));
```

isNotEmpty(inputString)

Returns `true` if the specified String is not empty ('') and not null; otherwise, returns `false`.

Signature

```
public static Boolean isNotEmpty(String inputString)
```

Parameters

inputString
Type: String

Return Value

Type: Boolean

Example

```
String whitespace = '  ';
String alpha = 'Hello world!';
System.assert(String.isNotEmpty(whitespace));
System.assert(String.isNotEmpty(alpha));
String empty = '';
String nullString = null;
System.assert(!String.isNotEmpty(empty));
System.assert(!String.isNotEmpty(nullString));
```

isNumeric()

Returns `true` if the current String contains only Unicode digits; otherwise, returns `false`.

Signature

```
public Boolean isNumeric()
```

Return Value

Type: Boolean

Usage

A decimal point (1.2) is not a Unicode digit.

Example

```
String numeric = '1234567890';
System.assert(numeric.isNumeric());
String alphanumeric = 'R32';
String decimalPoint = '1.2';
System.assert(!alphanumeric.isNumeric());
System.assert(!decimalpoint.isNumeric());
```

isNumericSpace()

Returns `true` if the current String contains only Unicode digits or spaces; otherwise, returns `false`.

Signature

```
public Boolean isNumericSpace()
```

Return Value

Type: Boolean

Usage

A decimal point (1.2) is not a Unicode digit.

Example

```
String numericSpace = '1 2 3';
System.assert(numericSpace.isNumericspace());
String notNumericspace = 'FD3S FC3S';
System.assert(!notNumericspace.isNumericspace());
```

isWhitespace()

Returns `true` if the current String contains only white space characters or is empty; otherwise, returns `false`.

Signature

```
public Boolean isWhitespace()
```

Return Value

Type: Boolean

Example

```
String whitespace = ' ';
String blank = '';
System.assert(whitespace.isWhitespace());
System.assert(blank.isWhitespace());
String alphanum = 'SIL80';
System.assert(!alphanum.isWhitespace());
```

join(iterableObj, separator)

Joins the elements of the specified iterable object, such as a List, into a single String separated by the specified separator.

Signature

```
public static String join(Object iterableObj, String separator)
```

Parameters

iterableObj
Type: Object

separator
Type: String

Return Value

Type: String

Usage

```
List<Integer> li = new
   List<Integer>
```

```
   {10, 20, 30};
String s = String.join(
   li, '/');
System.assertEquals(
   '10/20/30', s);
```

lastIndexOf(substring)

Returns the index of the last occurrence of the specified substring. If the substring does not occur, this method returns -1.

Signature

```
public Integer lastIndexOf(String substring)
```

Parameters

substring
Type: String

Return Value

Type: Integer

Example

```
String s1 = 'abcdefgc';
Integer i1 = s1.lastIndexOf('c');
System.assertEquals(7, i1);
```

lastIndexOf(substring, endPosition)

Returns the index of the last occurrence of the specified substring, starting from the character at index 0 and ending at the specified index.

Signature

```
public Integer lastIndexOf(String substring, Integer endPosition)
```

Parameters

substring
Type: String

endPosition
Type: Integer

Return Value

Type: Integer

Usage

If the substring doesn't occur or *endPosition* is negative, this method returns -1. If *endPosition* is larger than the last index in the current String, the entire String is searched.

Example

```
String s1 = 'abcdaacd';
Integer i1 =
   s1.lastIndexOf('c', 7);
System.assertEquals(
   6, i1);
Integer i2 =
   s1.lastIndexOf('c', 3);
System.assertEquals(
   2, i2);
```

lastIndexOfChar(character)

Returns the index of the last occurrence of the character that corresponds to the specified character value.

Signature

```
public Integer lastIndexOfChar(Integer character)
```

Parameters

character
Type: Integer

The integer value of the character in the string.

Return Value

Type: Integer

The index of the last occurrence of the specified character, -1 if the character is not found.

Usage

The index that this method returns is in Unicode code units.

Example

```
String str = '\u03A9 is Ω (Omega)';
// Get the last occurrence of Omega.
System.assertEquals(5, str.lastIndexOfChar(937));
```

lastIndexOfChar(character, endIndex)

Returns the index of the last occurrence of the character that corresponds to the specified character value, starting from the specified index.

Signature

```
public Integer lastIndexOfChar(Integer character, Integer endIndex)
```

Parameters

character
Type: Integer

The integer value of the character to look for.

endIndex
Type: Integer

The index to end the search at.

Return Value

Type: Integer

The index, starting from the specified start index, of the last occurrence of the specified character. -1 if the character is not found.

Usage

The index that this method returns is in Unicode code units.

Example

This example shows different ways of searching for the index of the last occurrence of the Omega character. The first call to `lastIndexOfChar` doesn't specify an end index and therefore the returned index is 12, which is the last occurrence of Omega in the entire string. The subsequent calls specify an end index to find the last occurrence of Omega in substrings.

```
String str = 'Ω and \u03A9 and Ω';
System.assertEquals(12, str.lastIndexOfChar(937));
System.assertEquals(6, str.lastIndexOfChar(937,11));
System.assertEquals(0, str.lastIndexOfChar(937,5));
```

lastIndexOfIgnoreCase(substring)

Returns the index of the last occurrence of the specified substring regardless of case.

Signature

```
public Integer lastIndexOfIgnoreCase(String substring)
```

Parameters

substring
Type: String

Return Value

Type: Integer

Usage

If the substring doesn't occur, this method returns -1.

Example

```
String s1 = 'abcdaacd';
Integer i1 =
   s1.lastIndexOfIgnoreCase('DAAC');
System.assertEquals(
   3, i1);
```

lastIndexOfIgnoreCase(substring, endPosition)

Returns the index of the last occurrence of the specified substring regardless of case, starting from the character at index 0 and ending at the specified index.

Signature

```
public Integer lastIndexOfIgnoreCase(String substring, Integer endPosition)
```

Parameters

substring
Type: String

endPosition
Type: Integer

Return Value

Type: Integer

Usage

If the substring doesn't occur or *endPosition* is negative, this method returns -1. If *endPosition* is larger than the last index in the current String, the entire String is searched.

Example

```
String s1 = 'abcdaacd';
Integer i1 =
   s1.lastIndexOfIgnoreCase('C', 7);
System.assertEquals(
   6, i1);
```

left(length)

Returns the leftmost characters of the current String of the specified length.

Signature

```
public String left(Integer length)
```

Parameters

length
Type: Integer

Return Value

Type: String

Usage

If *length* is greater than the String size, the entire String is returned.

Example

```
String s1 = 'abcdaacd';
String s2 =
   s1.left(3);
System.assertEquals(
   'abc', s2);
```

leftPad(length)

Returns the current String padded with spaces on the left and of the specified length.

Signature

```
public String leftPad(Integer length)
```

Parameters

length
Type: Integer

Usage

If *length* is less than or equal to the current String size, the entire String is returned without space padding.

Return Value

Type: String

Example

```
String s1 = 'abc';
String s2 =
   s1.leftPad(5);
```

```
System.assertEquals(
   '  abc', s2);
```

leftPad(length, padStr)

Returns the current String padded with String `padStr` on the left and of the specified length.

Signature

```
public String leftPad(Integer length, String padStr)
```

Parameters

length
Type: Integer

padStr
Type: String

String to pad with; if null or empty treated as single blank.

Usage

If *length* is less than or equal to the current String size, the entire String is returned without space padding.

Return Value

Type: String

Example

```
String s1 = 'abc';
String s2 = 'xy';
String s3 = s1.leftPad(7,s2);
System.assertEquals('xyxyabc', s3);
```

length()

Returns the number of 16-bit Unicode characters contained in the String.

Signature

```
public Integer length()
```

Return Value

Type: Integer

Example

```
String myString = 'abcd';
Integer result = myString.length();
System.assertEquals(result, 4);
```

mid(startIndex, length)

Returns a new String that begins with the character at the specified zero-based *startIndex* with the number of characters specified by *length*.

Signature

```
public String mid(Integer startIndex, Integer length)
```

Parameters

startIndex
Type: Integer

If *startIndex* is negative, it is considered to be zero.

length
Type: Integer

If *length* is negative or zero, an empty String is returned. If *length* is greater than the remaining characters, the remainder of the String is returned.

Return Value

Type: String

Usage

This method is similar to the `substring(startIndex)` and `substring(startIndex, endIndex)` methods, except that the second argument is the number of characters to return.

Example

```
String s = 'abcde';
String s2 = s.mid(2, 3);
System.assertEquals(
   'cde', s2);
```

normalizeSpace()

Returns the current String with leading, trailing, and repeating white space characters removed.

Signature

```
public String normalizeSpace()
```

Return Value

Type: String

Usage

This method normalizes the following white space characters: space, tab (\t), new line (\n), carriage return (\r), and form feed (\f).

Example

```
String s1 =
   'Salesforce \t     force.com';
String s2 =
   s1.normalizeSpace();
System.assertEquals(
   'Salesforce force.com', s2);
```

offsetByCodePoints(index, codePointOffset)

Returns the index of the Unicode code point that is offset by the specified number of code points, starting from the given index.

Signature

```
public Integer offsetByCodePoints(Integer index, Integer codePointOffset)
```

Parameters

index
Type: Integer

The start index in the string.

codePointOffset
Type: Integer

The number of code points to be offset.

Return Value

Type: Integer

The index that corresponds to the start index that is added to the offset.

Usage

Unpaired surrogates within the text range that is specified by *index* and *codePointOffset* count as one code point each.

Example

This example calls `offsetByCodePoints` on a string with a start index of 0 (to start from the first character) and an offset of three code points. The string contains one sequence of supplementary characters in escaped form (a pair of characters). After an offset of three code points when counting from the beginning of the string, the returned code point index is four.

```
String str = 'A \uD835\uDD0A BC';
System.assertEquals(4, str.offsetByCodePoints(0,3));
```

remove(substring)

Removes all occurrences of the specified substring and returns the String result.

Signature

```
public String remove(String substring)
```

Parameters

substring
Type: String

Return Value

Type: String

Example

```
String s1 = 'Salesforce and force.com';
String s2 =
   s1.remove('force');
System.assertEquals(
   'Sales and .com', s2);
```

removeEnd(substring)

Removes the specified substring only if it occurs at the end of the String.

Signature

```
public String removeEnd(String substring)
```

Parameters

substring
Type: String

Return Value

Type: String

Example

```
String s1 = 'Salesforce and force.com';
String s2 =
   s1.removeEnd('.com');
System.assertEquals(
   'Salesforce and force', s2);
```

removeEndIgnoreCase(substring)

Removes the specified substring only if it occurs at the end of the String using a case-insensitive match.

Signature

```
public String removeEndIgnoreCase(String substring)
```

Parameters

substring
Type: String

Return Value

Type: String

Example

```
String s1 = 'Salesforce and force.com';
String s2 =
   s1.removeEndIgnoreCase('.COM');
System.assertEquals(
   'Salesforce and force', s2);
```

removeStart(substring)

Removes the specified substring only if it occurs at the beginning of the String.

Signature

```
public String removeStart(String substring)
```

Parameters

substring
Type: String

Return Value

Type: String

Example

```
String s1 = 'Salesforce and force.com';
String s2 =
   s1.removeStart('Sales');
System.assertEquals(
   'force and force.com', s2);
```

removeStartIgnoreCase(substring)

Removes the specified substring only if it occurs at the beginning of the String using a case-insensitive match.

Signature

```
public String removeStartIgnoreCase(String substring)
```

Parameters

substring
Type: String

Return Value

Type: String

Example

```
String s1 = 'Salesforce and force.com';
String s2 =
   s1.removeStartIgnoreCase('SALES');
System.assertEquals(
   'force and force.com', s2);
```

repeat(numberOfTimes)

Returns the current String repeated the specified number of times.

Signature

```
public String repeat(Integer numberOfTimes)
```

Parameters

numberOfTimes
Type: Integer

Return Value

Type: String

Example

```
String s1 = 'SFDC';
String s2 =
   s1.repeat(2);
System.assertEquals(
   'SFDCSFDC', s2);
```

repeat(separator, numberOfTimes)

Returns the current String repeated the specified number of times using the specified separator to separate the repeated Strings.

Signature

```
public String repeat(String separator, Integer numberOfTimes)
```

Parameters

separator
Type: String

numberOfTimes
Type: Integer

Return Value

Type: String

Example

```
String s1 = 'SFDC';
String s2 =
   s1.repeat('-', 2);
System.assertEquals(
   'SFDC-SFDC', s2);
```

replace(target, replacement)

Replaces each substring of a string that matches the literal target sequence *target* with the specified literal replacement sequence *replacement*.

Signature

```
public String replace(String target, String replacement)
```

Parameters

target
Type: String

replacement
Type: String

Return Value

Type: String

Example

```
String s1 = 'abcdbca';
String target = 'bc';
String replacement = 'xy';
String s2 = s1.replace(target, replacement);
System.assertEquals('axydxya', s2);
```

replaceAll(regExp, replacement)

Replaces each substring of a string that matches the regular expression *regExp* with the replacement sequence *replacement*.

Signature

```
public String replaceAll(String regExp, String replacement)
```

Parameters

regExp
Type: String

replacement
Type: String

Return Value

Type: String

Usage

See the Java `Pattern` class for information on regular expressions.

Example

```
String s1 = 'a b c 5 xyz';
String regExp = '[a-zA-Z]';
String replacement = '1';
String s2 = s1.replaceAll(regExp, replacement);
System.assertEquals('1 1 1 5 111', s2);
```

replaceFirst(regExp, replacement)

Replaces the first substring of a string that matches the regular expression *regExp* with the replacement sequence *replacement*.

Signature

```
public String replaceFirst(String regExp, String replacement)
```

Parameters

regExp
Type: String

replacement
Type: String

Return Value

Type: String

Usage

See the Java `Pattern` class for information on regular expressions.

Example

```
String s1 = 'a b c 11 xyz';
String regExp = '[a-zA-Z]{2}';
String replacement = '2';
String s2 = s1.replaceFirst(regExp, replacement);
System.assertEquals('a b c 11 2z', s2);
```

reverse()

Returns a String with all the characters reversed.

Signature

```
public String reverse()
```

Return Value

Type: String

right(length)

Returns the rightmost characters of the current String of the specified length.

Signature

```
public String right(Integer length)
```

Parameters

length
Type: Integer

If *length* is greater than the String size, the entire String is returned.

Return Value

Type: String

Example

```
String s1 = 'Hello Max';
String s2 =
   s1.right(3);
System.assertEquals(
   'Max', s2);
```

rightPad(length)

Returns the current String padded with spaces on the right and of the specified length.

Signature

```
public String rightPad(Integer length)
```

Parameters

length
Type: Integer

If *length* is less than or equal to the current String size, the entire String is returned without space padding.

Return Value

Type: String

Example

```
String s1 = 'abc';
String s2 =
   s1.rightPad(5);
System.assertEquals(
   'abc  ', s2);
```

rightPad(length, padStr)

Returns the current String padded with String `padStr` on the right and of the specified length.

Signature

```
public String rightPad(Integer length, String padStr)
```

Parameters

length
Type: Integer

padStr
Type: String

String to pad with; if null or empty treated as single blank.

Usage

If *length* is less than or equal to the current String size, the entire String is returned without space padding.

Return Value

Type: String

Example

```
String s1 = 'abc';
String s2 = 'xy';
String s3 = s1.rightPad(7, s2);
System.assertEquals('abcxyxy', s3);
```

split(regExp)

Returns a list that contains each substring of the String that is terminated by either the regular expression *regExp* or the end of the String.

Signature

```
public String[] split(String regExp)
```

Parameters

regExp
Type: String

Return Value

Type: String[]

Note: In API version 34.0 and earlier, a zero-width *regExp* value produces an empty list item at the beginning of the method's output.

Usage

See the Java `Pattern` class for information on regular expressions.

The substrings are placed in the list in the order in which they occur in the String. If *regExp* does not match any part of the String, the resulting list has just one element containing the original String.

Example

In the following example, a string is split using a backslash as a delimiter.

```
public String splitPath(String filename) {
    if (filename == null)
        return null;
    List<String> parts = filename.split('\\\\');
    filename = parts[parts.size()-1];
    return filename;
}

// For example, if the file path is e:\\processed\\PPDSF100111.csv
// This method splits the path and returns the last part.
// Returned filename is PPDSF100111.csv
```

split(regExp, limit)

Returns a list that contains each substring of the String that is terminated by either the regular expression *regExp* or the end of the String.

Signature

```
public String[] split(String regExp, Integer limit)
```

Parameters

regExp
Type: String

A regular expression.

limit
Type: Integer

Return Value

Type: String[]

Note: In API version 34.0 and earlier, a zero-width *regExp* value produces an empty list item at the beginning of the method's output.

Usage

The optional *limit* parameter controls the number of times the pattern is applied and therefore affects the length of the list.

- If *limit* is greater than zero:
  - The pattern is applied a maximum of (*limit* – 1) times.
  - The list's length is no greater than *limit*.
  - The list's last entry contains all input beyond the last matched delimiter.
- If *limit* is non-positive, the pattern is applied as many times as possible, and the list can have any length.
- If *limit* is zero, the pattern is applied as many times as possible, the list can have any length, and trailing empty strings are discarded.

Example

For example, for `String s = 'boo:and:moo'`:

- `s.split(':', 2)` results in `{'boo', 'and:moo'}`
- `s.split(':', 5)` results in `{'boo', 'and', 'moo'}`
- `s.split(':', -2)` results in `{'boo', 'and', 'moo'}`
- `s.split('o', 5)` results in `{'b', '', ':and:m', '', ''}`
- `s.split('o', -2)` results in `{'b', '', ':and:m', '', ''}`
- `s.split('o', 0)` results in `{'b', '', ':and:m'}`

splitByCharacterType()

Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens.

Signature

```
public List<String> splitByCharacterType()
```

Return Value

Type: List<String>

Usage

For more information about the character types used, see java.lang.Character.getType(char).

Example

```
String s1 = 'Lightning.platform';
List<String> ls =
   s1.splitByCharacterType();
System.debug(ls);
// Writes this output:
// (L, ightning, ., platform)
```

splitByCharacterTypeCamelCase()

Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens, with the following exception: the uppercase character, if any, immediately preceding a lowercase character token belongs to the following character token rather than to the preceding.

Signature

```
public List<String> splitByCharacterTypeCamelCase()
```

Return Value

Type: List<String>

Usage

For more information about the character types used, see java.lang.Character.getType(char).

Example

```
String s1 = 'Lightning.platform';
List<String> ls =
   s1.splitByCharacterTypeCamelCase();
System.debug(ls);
// Writes this output:
// (Lightning, ., platform)
```

startsWith(prefix)

Returns `true` if the String that called the method begins with the specified *`prefix`*.

Signature

```
public Boolean startsWith(String prefix)
```

Parameters

`prefix`
Type: String

Return Value

Type: Boolean

Example

```
String s1 = 'AE86 vs EK9';
System.assert(s1.startsWith('AE86'));
```

startsWithIgnoreCase(prefix)

Returns `true` if the current String begins with the specified prefix regardless of the prefix case.

Signature

```
public Boolean startsWithIgnoreCase(String prefix)
```

Parameters

`prefix`
Type: String

Return Value

Type: Boolean

Example

```
String s1 = 'AE86 vs EK9';
System.assert(s1.startsWithIgnoreCase('ae86'));
```

stripHtmlTags()

Removes HTML markup and returns plain text.

Signature

```
public String stripHtmlTags(String htmlInput)
```

Return Value

Type: String

Usage

Warning: The stripHtmlTags function does not recursively strip tags; therefore, tags may still exist in the returned string. Do not use the stripHtmlTags function to sanitize input for inclusion as a raw HTML page. The unescaped output is not considered safe to include in an HTML document. The function will be deprecated in a future release.

Example

```
String s1 = '<b>hello world</b>';
String s2 = s1.stripHtmlTags();
System.assertEquals(
   'hello world', s2);
```

substring(startIndex)

Returns a new String that begins with the character at the specified zero-based *startIndex* and extends to the end of the String.

Signature

```
public String substring(Integer startIndex)
```

Parameters

startIndex
Type: Integer

Return Value

Type: String

Example

```
String s1 = 'hamburger';
System.assertEquals('burger', s1.substring(3));
```

substring(startIndex, endIndex)

Returns a new String that begins with the character at the specified zero-based *startIndex* and extends to the character at *endIndex* - 1.

Signature

```
public String substring(Integer startIndex, Integer endIndex)
```

Parameters

startIndex
Type: Integer

endIndex
Type: Integer

Return Value

Type: String

Example

```
'hamburger'.substring(4, 8);
// Returns "urge"

'smiles'.substring(1, 5);
// Returns "mile"
```

substringAfter(separator)

Returns the substring that occurs after the first occurrence of the specified separator.

Signature

```
public String substringAfter(String separator)
```

Parameters

separator
Type: String

Return Value

Type: String

Example

```
String s1 = 'Salesforce.Lightning.platform';
String s2 =
   s1.substringAfter('.');
System.assertEquals(
   'Lightning.platform', s2);
```

substringAfterLast(separator)

Returns the substring that occurs after the last occurrence of the specified separator.

Signature

```
public String substringAfterLast(String separator)
```

Parameters

separator
Type: String

Return Value

Type: String

Example

```
String s1 = 'Salesforce.Lightning.platform';
String s2 =
   s1.substringAfterLast('.');
System.assertEquals(
   'platform', s2);
```

substringBefore(separator)

Returns the substring that occurs before the first occurrence of the specified separator.

Signature

```
public String substringBefore(String separator)
```

Parameters

separator
Type: String

Return Value

Type: String

Example

```
String s1 = 'Salesforce.Lightning.platform';
String s2 =
   s1.substringBefore('.');
System.assertEquals(
   'Salesforce', s2);
```

substringBeforeLast(separator)

Returns the substring that occurs before the last occurrence of the specified separator.

Signature

```
public String substringBeforeLast(String separator)
```

Parameters

separator
Type: String

Return Value

Type: String

Example

```
String s1 = 'Salesforce.Lightning.platform';
String s2 =
   s1.substringBeforeLast('.');
System.assertEquals(
   'Salesforce.Lightning', s2);
```

substringBetween(tag)

Returns the substring that occurs between two instances of the specified *tag* String.

Signature

```
public String substringBetween(String tag)
```

Parameters

tag
Type: String

Return Value

Type: String

Example

```
String s1 = 'tagYellowtag';
String s2 = s1.substringBetween('tag');
System.assertEquals('Yellow', s2);
```

substringBetween(open, close)

Returns the substring that occurs between the two specified Strings.

Signature

```
public String substringBetween(String open, String close)
```

Parameters

open
Type: String

close
Type: String

Return Value

Type: String

Example

```
String s1 = 'xYellowy';
String s2 =
   s1.substringBetween('x','y');
System.assertEquals(
   'Yellow', s2);
```

swapCase()

Swaps the case of all characters and returns the resulting String by using the default (English US) locale.

Signature

```
public String swapCase()
```

Return Value

Type: String

Usage

Upper case and title case converts to lower case, and lower case converts to upper case.

Example

```
String s1 = 'Force.com';
String s2 = s1.swapCase();
System.assertEquals('fORCE.COM', s2);
```

toLowerCase()

Converts all of the characters in the String to lowercase using the rules of the default (English US) locale.

Signature

```
public String toLowerCase()
```

Return Value

Type: String

Example

```
String s1 = 'ThIs iS hArD tO rEaD';
System.assertEquals('this is hard to read',
   s1.toLowerCase());
```

toLowerCase(locale)

Converts all of the characters in the String to lowercase using the rules of the specified locale.

Signature

```
public String toLowerCase(String locale)
```

Parameters

locale
Type: String

Return Value

Type: String

Example

```
// Example in Turkish
// An uppercase dotted "i", \u0304, which is İ
// Note this contains both a İ as well as a I
String s1 = 'KIYMETLİ';
String s1Lower = s1.toLowerCase('tr');
// Dotless lowercase "i", \u0131, which is ı
// Note this has both a i and ı
String expected = 'kıymetli';
```

```
System.assertEquals(expected, s1Lower);
// Note if this was done in toLowerCase('en'), it would output 'kiymetli'
```

toUpperCase()

Converts all of the characters in the String to uppercase using the rules of the default (English US) locale.

Signature

```
public String toUpperCase()
```

Return Value

Type: String

Example

```
String myString1 = 'abcd';
String myString2 = 'ABCD';
myString1 =
   myString1.toUpperCase();
Boolean result =
   myString1.equals(myString2);
System.assertEquals(result, true);
```

toUpperCase(locale)

Converts all of the characters in the String to the uppercase using the rules of the specified locale.

Signature

```
public String toUpperCase(String locale)
```

Parameters

locale
Type: String

Return Value

Type: String

Example

```
// Example in Turkish
// Dotless lowercase "i", \u0131, which is ı
// Note this has both a i and ı
String s1 = 'imkansız';
String s1Upper = s1.toUpperCase('tr');
// An uppercase dotted "i", \u0304, which is İ
// Note this contains both a İ as well as a I
```

```
String expected = 'İMKANSIZ';
System.assertEquals(expected, s1Upper);
```

trim()

Returns a copy of the string that no longer contains any leading or trailing white space characters.

Signature

```
public String trim()
```

Return Value

Type: String

Usage

Leading and trailing ASCII control characters such as tabs and newline characters are also removed. White space and control characters that aren't at the beginning or end of the sentence aren't removed.

Example

```
String s1 = '   Hello!   ';
String trimmed = s1.trim();
system.assertEquals('Hello!', trimmed);
```

uncapitalize()

Returns the current String with the first letter in lowercase.

Signature

```
public String uncapitalize()
```

Return Value

Type: String

Example

```
String s1 =
   'Hello max';
String s2 =
   s1.uncapitalize();
System.assertEquals(
   'hello max',
    s2);
```

unescapeCsv()

Returns a String representing an unescaped CSV column.

Signature

```
public String unescapeCsv()
```

Return Value

Type: String

Usage

If the String is enclosed in double quotes and contains a comma, newline or double quote, quotes are removed. Also, any double quote escaped characters (a pair of double quotes) are unescaped to just one double quote.

If the String is not enclosed in double quotes, or is and does not contain a comma, newline or double quote, it is returned unchanged.

Example

```
String s1 =
   '"Max1, ""Max2"""';
String s2 =
   s1.unescapeCsv();
System.assertEquals(
   'Max1, "Max2"',
    s2);
```

unescapeEcmaScript()

Unescapes any EcmaScript literals found in the String.

Signature

```
public String unescapeEcmaScript()
```

Return Value

Type: String

Example

```
String s1 =
   '\"3.8\",\"3.9\"';
String s2 =
   s1.unescapeEcmaScript();
System.assertEquals(
   '"3.8","3.9"',
   s2);
```

unescapeHtml3()

Unescapes the characters in a String using HTML 3.0 entities.

Signature

```
public String unescapeHtml3()
```

Return Value

Type: String

Example

```
String s1 =
   '&amp;quot;&amp;lt;Black&amp;amp;White&amp;gt;&amp;quot;';
String s2 =
   s1.unescapeHtml3();
System.assertEquals(
   '"<Black&White>"',
   s2);
```

unescapeHtml4()

Unescapes the characters in a String using HTML 4.0 entities.

Signature

```
public String unescapeHtml4()
```

Return Value

Type: String

Usage

If an entity isn't recognized, it is kept as is in the returned string.

Example

```
String s1 =
   '&amp;quot;&amp;lt;Black&amp;amp;White&amp;gt;&amp;quot;';
String s2 =
   s1.unescapeHtml4();
System.assertEquals(
   '"<Black&White>"',
   s2);
```

unescapeJava()

Returns a String whose Java literals are unescaped. Literals unescaped include escape sequences for quotes (\\") and control characters, such as tab (\\t), and carriage return (\\n).

Signature

```
public String unescapeJava()
```

Return Value

Type: String

The unescaped string.

Example

```
String s = 'Company: \\"Salesforce.com\\"';
String unescapedStr = s.unescapeJava();
System.assertEquals('Company: "Salesforce.com"', unescapedStr);
```

unescapeUnicode()

Returns a String whose escaped Unicode characters are unescaped.

Signature

```
public String unescapeUnicode()
```

Return Value

Type: String

The unescaped string.

Example

```
String s = 'De onde voc\u00EA \u00E9?';
String unescapedStr = s.unescapeUnicode();
System.assertEquals('De onde você é?', unescapedStr);
```

unescapeXml()

Unescapes the characters in a String using XML entities.

Signature

```
public String unescapeXml()
```

Return Value

Type: String

Usage

Supports only the five basic XML entities (gt, lt, quot, amp, apos). Does not support DTDs or external entities.

Example

```
String s1 =
   '&quot;&lt;Black&amp;White&gt;&quot;';
```

```
String s2 =
   s1.unescapeXml();
System.assertEquals(
   '"<Black&White>"',
   s2);
```

valueOf(dateToConvert)

Returns a String that represents the specified Date in the standard "yyyy-MM-dd" format.

Signature

```
public static String valueOf(Date dateToConvert)
```

Parameters

dateToConvert
Type: Date

Return Value

Type: String

Example

```
Date myDate = Date.Today();
String sDate = String.valueOf(myDate);
```

valueOf(datetimeToConvert)

Returns a String that represents the specified Datetime in the standard "yyyy-MM-dd HH:mm:ss" format for the local time zone.

Signature

```
public static String valueOf(Datetime datetimeToConvert)
```

Parameters

datetimeToConvert
Type: Datetime

Return Value

Type: String

Example

```
DateTime dt = datetime.newInstance(1996, 6, 23);
String sDateTime = String.valueOf(dt);
System.assertEquals('1996-06-23 00:00:00', sDateTime);
```

valueOf(decimalToConvert)

Returns a String that represents the specified Decimal.

Signature

```
public static String valueOf(Decimal decimalToConvert)
```

Parameters

decimalToConvert
Type: Decimal

Return Value

Type: String

Example

```
Decimal dec = 3.14159265;
String sDecimal = String.valueOf(dec);
System.assertEquals('3.14159265', sDecimal);
```

valueOf(doubleToConvert)

Returns a String that represents the specified Double.

Signature

```
public static String valueOf(Double doubleToConvert)
```

Parameters

doubleToConvert
Type: Double

Return Value

Type: String

Example

```
Double myDouble = 12.34;
String myString =
   String.valueOf(myDouble);
System.assertEquals(
  '12.34', myString);
```

valueOf(integerToConvert)

Returns a String that represents the specified Integer.

Signature

```
public static String valueOf(Integer integerToConvert)
```

Parameters

integerToConvert
Type: Integer

Return Value

Type: String

Example

```
Integer myInteger = 22;
String sInteger = String.valueOf(myInteger);
System.assertEquals('22', sInteger);
```

valueOf(longToConvert)

Returns a String that represents the specified Long.

Signature

```
public static String valueOf(Long longToConvert)
```

Parameters

longToConvert
Type: Long

Return Value

Type: String

Example

```
Long myLong = 123456789;
String sLong = String.valueOf(myLong);
System.assertEquals('123456789', sLong);
```

valueOf(toConvert)

Returns a string representation of the specified object argument.

Signature

```
public static String valueOf(Object toConvert)
```

Parameters

toConvert
Type: Object

Return Value

Type: String

Usage

If the argument is not a String, the `valueOf` method converts it into a String by calling the `toString` method on the argument, if available, or any overridden `toString` method if the argument is a user-defined type. Otherwise, if no `toString` method is available, it returns a String representation of the argument.

Example

```
List<Integer> ls =
  new List<Integer>();
ls.add(10);
ls.add(20);
String strList =
   String.valueOf(ls);
System.assertEquals(
  '(10, 20)', strList);
```

valueOfGmt(datetimeToConvert)

Returns a String that represents the specified Datetime in the standard "yyyy-MM-dd HH:mm:ss" format for the GMT time zone.

Signature

```
public static String valueOfGmt(Datetime datetimeToConvert)
```

Parameters

datetimeToConvert
Type: Datetime

Return Value

Type: String

Example

```
// For a PST timezone:
DateTime dt = datetime.newInstance(2001, 9, 14);
String sDateTime = String.valueOfGmt(dt);
System.assertEquals('2001-09-14 07:00:00', sDateTime);
```

StubProvider Interface

`StubProvider` is a callback interface that you can use as part of the Apex stub API to implement a mocking framework. Use this interface with the `Test.createStub()` method to create stubbed Apex objects for testing.

Namespace

System

Usage

The `StubProvider` interface allows you to define the behavior of a stubbed Apex class. The interface specifies a single method that requires implementing: `handleMethodCall()`. You specify the behavior of each method of the stubbed class in the `handleMethodCall()` method.

In your Apex test, you create a stubbed object using the `Test.createStub()` method. When you invoke methods on the stubbed object, `StubProvider.handleMethodCall()` is called, which performs the behavior that you've specified for each method.

IN THIS SECTION:

StubProvider Methods

SEE ALSO:

Build a Mocking Framework with the Stub API

createStub(parentType, stubProvider)

StubProvider Methods

The following are methods for `StubProvider`.

IN THIS SECTION:

handleMethodCall(stubbedObject, stubbedMethodName, returnType, listOfParamTypes, listOfParamNames, listOfArgs)
Use this method to define the behavior of each method of a stubbed class.

handleMethodCall(stubbedObject, stubbedMethodName, returnType, listOfParamTypes, listOfParamNames, listOfArgs)

Use this method to define the behavior of each method of a stubbed class.

Signature

```
public Object handleMethodCall(Object stubbedObject, String stubbedMethodName,
System.Type returnType, List<System.Type> listOfParamTypes, List<String>
listOfParamNames, List<Object> var6)
```

Parameters

stubbedObject
Type: Object

The stubbed object.

stubbedMethodName
Type: String

The name of the invoked method.

returnType
Type: System.Type

The return type of the invoked method.

listOfParamTypes
Type: List<System.Type>

A list of the parameter types of the invoked method.

listOfParamNames
Type: List<String>

A list of the parameter names of the invoked method.

listOfArgs
Type: List<Object>

The actual argument values passed into this method at runtime.

Return Value

Type: Object

Usage

You can use the parameters passed into this method to identify which method on the stubbed object was invoked. Then you can define the behavior for each identified method.

SEE ALSO:

Build a Mocking Framework with the Stub API

System Class

Contains methods for system operations, such as writing debug messages and scheduling jobs.

Namespace

System

System Methods

The following are methods for `System`. All methods are static.

IN THIS SECTION:

abortJob(jobId)
Stops the specified job. The stopped job is still visible in the job queue in the Salesforce user interface.

assert(condition, msg)

Asserts that the specified condition is true. If it is not, a fatal error is returned that causes code execution to halt.

assertEquals(expected, actual, msg)

Asserts that the first two arguments are the same. If they are not, a fatal error is returned that causes code execution to halt.

assertNotEquals(expected, actual, msg)

Asserts that the first two arguments are different. If they are the same, a fatal error is returned that causes code execution to halt.

currentPageReference()

Returns a reference to the current page. This is used with Visualforce pages.

currentTimeMillis()

Returns the current time in milliseconds, which is expressed as the difference between the current time and midnight, January 1, 1970 UTC.

debug(msg)

Writes the specified message, in string format, to the execution debug log. The `DEBUG` log level is used.

debug(logLevel, msg)

Writes the specified message, in string format, to the execution debug log with the specified log level.

enqueueJob(queueableObj)

Adds a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID.

equals(obj1, obj2)

Returns `true` if both arguments are equal. Otherwise, returns `false`.

getApplicationReadWriteMode()

Returns the read write mode set for an organization during Salesforce.com upgrades and downtimes.

hashCode(obj)

Returns the hash code of the specified object.

isBatch()

Returns `true` if a batch Apex job invoked the executing code, or `false` if not. In API version 35.0 and earlier, also returns `true` if a queueable Apex job invoked the code.

isFuture()

Returns `true` if the currently executing code is invoked by code contained in a method annotated with `future`; `false` otherwise.

isQueueable()

Returns `true` if a queueable Apex job invoked the executing code. Returns `false` if not, including if a batch Apex job or a future method invoked the code.

isScheduled()

Returns `true` if the currently executing code is invoked by a scheduled Apex job; `false` otherwise.

movePassword(targetUserId,sourceUserId)

Moves the specified user's password to a different user.

now()

Returns the current date and time in the GMT time zone.

process(workItemIds, action, comments, nextApprover)

Processes the list of work item IDs.

purgeOldAsyncJobs(dt)

Deletes asynchronous Apex job records for jobs that have finished execution before the specified date with a Completed, Aborted, or Failed status, and returns the number of records deleted.

requestVersion()

Returns a two-part version that contains the major and minor version numbers of a package.

resetPassword(userId, sendUserEmail)

Resets the password for the specified user.

resetPasswordWithEmailTemplate(userId, sendUserEmail, emailTemplateName)

Resets the user's password and sends an email to the user with their new password. You specify the email template that is sent to the specified user. Use this method for external users of communities.

runAs(version)

Changes the current package version to the package version specified in the argument.

runAs(userSObject)

Changes the current user to the specified user.

schedule(jobName, cronExpression, schedulableClass)

Use `schedule` with an Apex class that implements the `Schedulable` interface to schedule the class to run at the time specified by a Cron expression.

scheduleBatch(batchable, jobName, minutesFromNow)

Schedules a batch job to run once in the future after the specified time interval and with the specified job name.

scheduleBatch(batchable, jobName, minutesFromNow, scopeSize)

Schedules a batch job to run once in the future after the specified the time interval, with the specified job name and scope size. Returns the scheduled job ID (CronTrigger ID).

setPassword(userId, password)

Sets the password for the specified user.

submit(workItemIds, comments, nextApprover)

Submits the processed approvals. The current user is the submitter and the entry criteria is evaluated for all processes applicable to the current user.

today()

Returns the current date in the current user's time zone.

`abortJob(jobId)`

Stops the specified job. The stopped job is still visible in the job queue in the Salesforce user interface.

Signature

```
public static Void abortJob(String jobId)
```

Parameters

`jobId`

Type: String

The *`jobId`* is the ID associated with either AsyncApexJob or CronTrigger.

Return Value

Type: Void

Usage

The following methods return the job ID that can be passed to `abortJob`.

- `System.schedule` method—returns the CronTrigger object ID associated with the scheduled job as a string.
- `SchedulableContext.getTriggerId` method—returns the CronTrigger object ID associated with the scheduled job as a string.
- `getJobId` method—returns the AsyncApexJob object ID associated with the batch job as a string.
- `Database.executeBatch` method—returns the AsyncApexJob object ID associated with the batch job as a string.

assert(condition, msg)

Asserts that the specified condition is true. If it is not, a fatal error is returned that causes code execution to halt.

Signature

```
public static Void assert(Boolean condition, Object msg)
```

Parameters

condition
Type: Boolean

msg
Type: Object

(Optional) Custom message returned as part of the error message.

Return Value

Type: Void

Usage

You can't catch an assertion failure using a try/catch block even though it is logged as an exception.

assertEquals(expected, actual, msg)

Asserts that the first two arguments are the same. If they are not, a fatal error is returned that causes code execution to halt.

Signature

```
public static Void assertEquals(Object expected, Object actual, Object msg)
```

Parameters

expected
Type: Object

Specifies the expected value.

actual
Type: Object

Specifies the actual value.

msg
Type: Object

(Optional) Custom message returned as part of the error message.

Return Value

Type: Void

Usage

You can't catch an assertion failure using a try/catch block even though it is logged as an exception.

assertNotEquals(expected, actual, msg)

Asserts that the first two arguments are different. If they are the same, a fatal error is returned that causes code execution to halt.

Signature

```
public static Void assertNotEquals(Object expected, Object actual, Object msg)
```

Parameters

expected
Type: Object

Specifies the expected value.

actual
Type: Object

Specifies the actual value.

msg
Type: Object

(Optional) Custom message returned as part of the error message.

Return Value

Type: Void

Usage

You can't catch an assertion failure using a try/catch block even though it is logged as an exception.

currentPageReference()

Returns a reference to the current page. This is used with Visualforce pages.

Signature

```
public static System.PageReference currentPageReference()
```

Return Value

Type: System.PageReference

Usage

For more information, see PageReference Class.

currentTimeMillis()

Returns the current time in milliseconds, which is expressed as the difference between the current time and midnight, January 1, 1970 UTC.

Signature

```
public static Long currentTimeMillis()
```

Return Value

Type: Long

debug(msg)

Writes the specified message, in string format, to the execution debug log. The `DEBUG` log level is used.

Signature

```
public static Void debug(Object msg)
```

Parameters

msg
Type: Object

Return Value

Type: Void

Usage

If the *msg* argument is not a string, the `debug` method calls `String.valueOf` to convert it into a string. The `String.valueOf` method calls the `toString` method on the argument, if available, or any overridden `toString` method if the argument is a user-defined type. Otherwise, if no `toString` method is available, it returns a string representation of the argument.

If the log level for Apex Code is set to `DEBUG` or higher, the message of this debug statement will be written to the debug log.

Note that when a map or set is printed, the output is sorted in key order and is surrounded with square brackets (`[]`). When an array or list is printed, the output is enclosed in parentheses (`()`).

Note: Calls to System.debug are not counted as part of Apex code coverage.Calls to `System.debug` are not counted as part of Apex code coverage.

For more information on log levels, see "Debug Log Levels" in the Salesforce online help.

`debug(logLevel, msg)`

Writes the specified message, in string format, to the execution debug log with the specified log level.

Signature

```
public static Void debug(LoggingLevel logLevel, Object msg)
```

Parameters

`logLevel`
Type: System.LoggingLevel

The logging level to set for this method.

`msg`
Type: Object

The message or object to write in string format to the execution debug log.

Return Value

Type: Void

Usage

If the *`msg`* argument is not a string, the `debug` method calls `String.valueOf` to convert it into a string. The `String.valueOf` method calls the `toString` method on the argument, if available, or any overridden `toString` method if the argument is a user-defined type. Otherwise, if no `toString` method is available, it returns a string representation of the argument.

Note: Calls to `System.debug` are not counted as part of Apex code coverage.

System Logging Levels

Use the `loggingLevel` enum to specify the logging level for the `debug` method.

Valid log levels are (listed from lowest to highest):

- `NONE`
- `ERROR`
- `WARN`
- `INFO`
- `DEBUG`
- `FINE`
- `FINER`
- `FINEST`

Log levels are cumulative. For example, if the lowest level, `ERROR`, is specified for Apex Code, only debug methods with the log level of `ERROR` are logged. If the next level, `WARN`, is specified, the debug log contains debug methods specified as either `ERROR` or `WARN`.

In the following example, the string `MsgTxt` is not written to the debug log because the log level is `ERROR` and the `debug` method has a level of `INFO`:

```
System.LoggingLevel level = LoggingLevel.ERROR;

System.debug(logginglevel.INFO, 'MsgTxt');
```

For more information on log levels, see "Debug Log Levels" in the Salesforce online help.

enqueueJob(queueableObj)

Adds a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID.

Signature

```
public static ID enqueueJob(Object queueableObj)
```

Parameters

queueableObj
Type: Object

An instance of the class that implements the Queueable Interface.

Return Value

Type: ID

The job ID, which corresponds to the ID of an AsyncApexJob record.

Usage

To add a job for asynchronous execution, call `System.enqueueJob` by passing in an instance of your class implementation of the `Queueable` interface for execution as follows:

```
ID jobID = System.enqueueJob(new MyQueueableClass());
```

For more information about Queueable Apex, including information about limits, see Queueable Apex.

equals(obj1, obj2)

Returns `true` if both arguments are equal. Otherwise, returns `false`.

Signature

```
public static Boolean equals(Object obj1, Object obj2)
```

Parameters

obj1
Type: Object

Object being compared.

obj2
Type: Object

Object to compare with the first argument.

Return Value

Type: Boolean

Usage

obj1 and *obj2* can be of any type. They can be values, or object references, such as sObjects and user-defined types.

The comparison rules for `System.equals` are identical to the ones for the `==` operator. For example, string comparison is case insensitive. For information about the comparison rules, see the == operator.

getApplicationReadWriteMode()

Returns the read write mode set for an organization during Salesforce.com upgrades and downtimes.

Signature

```
public static System.ApplicationReadWriteMode getApplicationReadWriteMode()
```

Return Value

Type: System.ApplicationReadWriteMode

Valid values are:

- `DEFAULT`
- `READ_ONLY`

Using the System.ApplicationReadWriteMode Enum

Use the `System.ApplicationReadWriteMode` enum returned by the `getApplicationReadWriteMode` to programmatically determine if the application is in read-only mode during Salesforce upgrades and downtimes.

Valid values for the enum are:

- `DEFAULT`
- `READ_ONLY`

Example:

```
public class myClass {
  public static void execute() {
    ApplicationReadWriteMode mode = System.getApplicationReadWriteMode();

    if (mode == ApplicationReadWriteMode.READ_ONLY) {
      // Do nothing. If DML operaton is attempted in readonly mode,
      // InvalidReadOnlyUserDmlException will be thrown.
    } else if (mode == ApplicationReadWriteMode.DEFAULT) {
      Account account = new Account(name = 'my account');
```

```
        insert account;
      }
    }
}
```

hashCode(obj)

Returns the hash code of the specified object.

Signature

```
public static Integer hashCode(Object obj)
```

Parameters

obj

Type: Object

The object to get the hash code for. This parameter can be of any type, including values or object references, such as sObjects or user-defined types.

Return Value

Type: Integer

isBatch()

Returns `true` if a batch Apex job invoked the executing code, or `false` if not. In API version 35.0 and earlier, also returns `true` if a queueable Apex job invoked the code.

Signature

```
public static Boolean isBatch()
```

Return Value

Type: Boolean

Usage

A batch Apex job can't invoke a future method. Before invoking a future method, use `isBatch()` to check whether the executing code is a batch Apex job.

isFuture()

Returns `true` if the currently executing code is invoked by code contained in a method annotated with `future`; `false` otherwise.

Signature

```
public static Boolean isFuture()
```

Return Value

Type: Boolean

Usage

Since a future method can't be invoked from another future method, use this method to check if the current code is executing within the context of a future method before you invoke a future method.

`isQueueable()`

Returns `true` if a queueable Apex job invoked the executing code. Returns `false` if not, including if a batch Apex job or a future method invoked the code.

Signature

```
public static Boolean isQueueable()
```

Return Value

Type: Boolean

Usage

```
public class SimpleQueueable implements Queueable {

    String name;

    public SimpleQueueable(String name) {
        this.name = name;
        System.assert(!System.isQueueable());    //Should return false
    }

    public void execute(QueueableContext ctx) {
        Account testAccount  = new Account();
        testAccount.name = 'testAcc';
        insert(testAccount);
        System.assert(System.isQueueable());    //Should return true
    }
}
```

```
global class ComplexBatch implements Database.Batchable<SObject> {

    global Database.QueryLocator start(Database.BatchableContext info) {
        System.assert(!System.isQueueable());    //Should return false
        return Database.getQueryLocator([SELECT Id, Name FROM Account LIMIT 1]);
    }

    global void execute(Database.BatchableContext info, SObject[] scope) {
        System.assert(!System.isQueueable());    //Should return false
        System.enqueueJob(new SimpleQueueable('CallingFromComplexBatch'));
        System.assert(!System.isQueueable());    //Should return false
    }
```

```
    global void finish(Database.BatchableContext info) {
        System.assert(!System.isQueueable());    //Should return false
    }
}
```

isScheduled()

Returns `true` if the currently executing code is invoked by a scheduled Apex job; `false` otherwise.

Signature

```
public static Boolean isScheduled()
```

Return Value

Type: Boolean

movePassword(targetUserId,sourceUserId)

Moves the specified user's password to a different user.

Signature

```
public static Void movePassword(ID targetUserId, ID sourceUserId)
```

Parameters

targetUserId
Type: ID

The user that the password is moved to.

sourceUserId
Type: ID

The user that the password is moved from.

Return Value

Type: Void

Usage

Moving a password simplifies converting a user to another type of user, such as when converting an external user to a user with less restrictive access. If you require access to the `movePassword` method, contact Salesforce.

Keep in mind these requirements.

- The *targetUserId*, *sourceUserId*, and user performing the move operation must all belong to the same Salesforce org.
- The *targetUserId* and the *sourceUserId* cannot be the same as the user performing the move operation.
- A user without a password can't be specified as the *sourceUserId*. For example, a source user who has already had their password moved is left without a password. That user can't be a source user again.

After the password is moved:

- The target user can log in with the password.
- The source user no longer has a password. To enable logins for this user, a password reset is required.

now()

Returns the current date and time in the GMT time zone.

Signature

```
public static Datetime now()
```

Return Value

Type: Datetime

process(workItemIds, action, comments, nextApprover)

Processes the list of work item IDs.

Signature

```
public static List<Id> process(List<Id> workItemIds, String action, String comments,
String nextApprover)
```

Parameters

workItemIds
Type: List<Id>

action
Type: String

comments
Type: String

nextApprover
Type: String

Return Value

Type: List<Id>

purgeOldAsyncJobs(dt)

Deletes asynchronous Apex job records for jobs that have finished execution before the specified date with a Completed, Aborted, or Failed status, and returns the number of records deleted.

Signature

```
public static Integer purgeOldAsyncJobs(Date dt)
```

Parameters

dt

Type: Date

Specifies the date up to which old records are deleted. The date comparison is based on the `CompletedDate` field of AsyncApexJob, which is in the GMT time zone.

Return Value

Type: Integer

Usage

Asynchronous Apex job records are records in AsyncApexJob.

The system cleans up asynchronous job records for jobs that have finished execution and are older than seven days. You can use this method to further reduce the size of AsyncApexJob by cleaning up more records.

Each execution of this method counts as a single row against the governor limit for DML statements.

Example

This example shows how to delete all job records for jobs that have finished before today's date.

```
Integer count = System.purgeOldAsyncJobs
    (Date.today());
System.debug('Deleted ' +
    count + ' old jobs.');
```

requestVersion()

Returns a two-part version that contains the major and minor version numbers of a package.

Signature

```
public static System.Version requestVersion()
```

Return Value

Type: System.Version

Usage

Using this method, you can determine the version of an installed instance of your package from which the calling code is referencing your package. Based on the version that the calling code has, you can customize the behavior of your package code.

The `requestVersion` method isn't supported for unmanaged packages. If you call it from an unmanaged package, an exception will be thrown.

resetPassword(userId, sendUserEmail)

Resets the password for the specified user.

Signature

```
public static System.ResetPasswordResult resetPassword(ID userId, Boolean sendUserEmail)
```

Parameters

userId
Type: ID

sendUserEmail
Type: Boolean

Return Value

Type: System.ResetPasswordResult

Usage

When the user logs in with the new password, they are prompted to enter a new password, and to select a security question and answer if they haven't already. If you specify `true` for *sendUserEmail*, the user is sent an email notifying them that their password was reset. A link to sign onto Salesforce using the new password is included in the email. Use `setPassword(userId, password)` if you don't want the user to be prompted to enter a new password when they log in.

Warning: Be careful with this method, and do not expose this functionality to end-users.

resetPasswordWithEmailTemplate(userId, sendUserEmail, emailTemplateName)

Resets the user's password and sends an email to the user with their new password. You specify the email template that is sent to the specified user. Use this method for external users of communities.

Signature

```
public static System.ResetPasswordResult resetPasswordWithEmailTemplate(Id userId,
Boolean sendUserEmail, String emailTemplateName)
```

Parameters

userId
Type: Id

The ID of the user whose password was reset.

sendUserEmail
Type: Boolean

emailTemplateName
Type: String

Name of the email template.

Return Value

Type: System.ResetPasswordResult

Usage

If you specify `true` for *`sendUserEmail`*, specify the email template that is sent to the user notifying them that their password was reset. When the user logs in with the new password in the email, they are prompted to enter a new password. A link to sign onto Salesforce using the new password is included in the email. Use `setPassword(userId, password)` if you don't want the user to be prompted to enter a new password when they log in.

Warning: Be careful with this method, and do not expose this functionality to end-users.

`runAs(version)`

Changes the current package version to the package version specified in the argument.

Signature

```
public static Void runAs(System.Version version)
```

Parameters

`version`
Type: System.Version

Return Value

Type: Void

Usage

A package developer can use Version methods to continue to support existing behavior in classes and triggers in previous package versions while continuing to evolve the code. Apex classes and triggers are saved with the version settings for each installed managed package that the class or trigger references.

This method is used for testing your component behavior in different package versions that you upload to the AppExchange. This method effectively sets a two-part version consisting of major and minor numbers in a test method so that you can test the behavior for different package versions.

You can only use `runAs` in a test method. There is no limitation to the number of calls to this method in a transaction. For sample usage of this method, see Testing Behavior in Package Versions.

`runAs(userSObject)`

Changes the current user to the specified user.

Signature

```
public static Void runAs(User userSObject)
```

Parameters

`userSObject`
Type: User

Return Value

Type: Void

Usage

All of the specified user's record sharing is enforced during the execution of `runAs`. You can only use `runAs` in a test method. For more information, see Using the `runAs` Method on page 603.

Note: The `runAs` method ignores user license limits. You can create new users with `runAs` even if your organization has no additional user licenses.

The `runAs` method implicitly inserts the user that is passed in as parameter if the user has been instantiated, but not inserted yet.

You can also use `runAs` to perform mixed DML operations in your test by enclosing the DML operations within the `runAs` block. In this way, you bypass the mixed DML error that is otherwise returned when inserting or updating setup objects together with other sObjects. See sObjects That Cannot Be Used Together in DML Operations.

Note: Every call to `runAs` counts against the total number of DML statements issued in the process.

`schedule(jobName, cronExpression, schedulableClass)`

Use `schedule` with an Apex class that implements the `Schedulable` interface to schedule the class to run at the time specified by a Cron expression.

Signature

```
public static String schedule(String jobName, String cronExpression, Object
schedulableClass)
```

Parameters

`jobName`
Type: String

`cronExpression`
Type: String

`schedulableClass`
Type: Object

Return Value

Type: String

Returns the scheduled job ID (CronTrigger ID).

Usage

Use extreme care if you're planning to schedule a class from a trigger. You must be able to guarantee that the trigger won't add more scheduled classes than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time. Use the `abortJob` method to stop the job after it has been scheduled.

Note: Salesforce schedules the class for execution at the specified time. Actual execution may be delayed based on service availability.

Using the `System.Schedule` Method

After you implement a class with the `Schedulable` interface, use the `System.Schedule` method to execute it. The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.

Note: Use extreme care if you're planning to schedule a class from a trigger. You must be able to guarantee that the trigger won't add more scheduled classes than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time.

The `System.Schedule` method takes three arguments: a name for the job, an expression used to represent the time and date the job is scheduled to run, and the name of the class. This expression has the following syntax:

```
Seconds Minutes Hours Day_of_month Month Day_of_week Optional_year
```

Note: Salesforce schedules the class for execution at the specified time. Actual execution may be delayed based on service availability.

The `System.Schedule` method uses the user's timezone for the basis of all schedules.

The following are the values for the expression:

Name	Values	Special Characters
Seconds	0–59	None
Minutes	0–59	None
Hours	0–23	None
Day_of_month	1–31	`, - * ? / L W`
Month	1–12 or the following: • JAN • FEB • MAR • APR • MAY • JUN • JUL • AUG • SEP • OCT • NOV • DEC	`, - * /`
Day_of_week	1–7 or the following: • SUN	`, - * ? / L #`

Name	Values	Special Characters
	• MON • TUE • WED • THU • FRI • SAT	
optional_year	null or 1970–2099	, - * /

The special characters are defined as follows:

Special Character	Description
,	Delimits values. For example, use JAN, MAR, APR to specify more than one month.
-	Specifies a range. For example, use JAN-MAR to specify more than one month.
*	Specifies all values. For example, if *Month* is specified as *, the job is scheduled for every month.
?	Specifies no specific value. This is only available for *Day_of_month* and *Day_of_week*, and is generally used when specifying a value for one and not the other.
/	Specifies increments. The number before the slash specifies when the intervals will begin, and the number after the slash is the interval amount. For example, if you specify 1/5 for *Day_of_month*, the Apex class runs every fifth day of the month, starting on the first of the month.
L	Specifies the end of a range (last). This is only available for *Day_of_month* and *Day_of_week*. When used with *Day of month*, L always means the last day of the month, such as January 31, February 29 for leap years, and so on. When used with *Day_of_week* by itself, it always means 7 or SAT. When used with a *Day_of_week* value, it means the last of that type of day in the month. For example, if you specify 2L, you are specifying the last Monday of the month. Do not use a range of values with L as the results might be unexpected.
W	Specifies the nearest weekday (Monday-Friday) of the given day. This is only available for *Day_of_month*. For example, if you specify 20W, and the 20th is a Saturday, the class runs on the 19th. If you specify 1W, and the first is a Saturday, the class does not run in the previous month, but on the third, which is the following Monday. Tip: Use the L and W together to specify the last weekday of the month.
#	Specifies the *nth* day of the month, in the format ***weekday*#*day_of_month***. This is only available for *Day_of_week*. The number before the # specifies weekday (SUN-SAT). The number after the # specifies the day of the month. For example, specifying 2#2 means the class runs on the second Monday of every month.

The following are some examples of how to use the expression.

Expression	Description
`0 0 13 * * ?`	Class runs every day at 1 PM.
`0 0 22 ? * 6L`	Class runs the last Friday of every month at 10 PM.
`0 0 10 ? * MON-FRI`	Class runs Monday through Friday at 10 AM.
`0 0 20 * * ? 2010`	Class runs every day at 8 PM during the year 2010.

In the following example, the class `proschedule` implements the `Schedulable` interface. The class is scheduled to run at 8 AM, on the 13th of February.

```
proschedule p = new proschedule();
        String sch = '0 0 8 13 2 ?';
        system.schedule('One Time Pro', sch, p);
```

scheduleBatch(batchable, jobName, minutesFromNow)

Schedules a batch job to run once in the future after the specified time interval and with the specified job name.

Signature

```
public static String scheduleBatch(Database.Batchable batchable, String jobName, Integer minutesFromNow)
```

Parameters

batchable
Type: Database.Batchable

An instance of a class that implements the `Database.Batchable` interface.

jobName
Type: String

The name if the job that this method will start.

minutesFromNow
Type: Integer

The time interval in minutes after which the job should start executing. This argument must be greater than zero.

Return Value

Type: String

The scheduled job ID (CronTrigger ID).

Usage

Note: Some things to note about `System.scheduleBatch`:

- When you call `System.scheduleBatch`, Salesforce schedules the job for execution at the specified time. Actual execution occurs at or after that time, depending on service availability.
- The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.
- When the job's schedule is triggered, the system queues the batch job for processing. If Apex flex queue is enabled in your org, the batch job is added at the end of the flex queue. For more information, see Holding Batch Jobs in the Apex Flex Queue.
- All scheduled Apex limits apply for batch jobs scheduled using `System.scheduleBatch`. After the batch job is queued (with a status of `Holding` or `Queued`), all batch job limits apply and the job no longer counts toward scheduled Apex limits.
- After calling this method and before the batch job starts, you can use the returned scheduled job ID to abort the scheduled job using the `System.abortJob` method.

For an example, see Using the `System.scheduleBatch` Method.

`scheduleBatch(batchable, jobName, minutesFromNow, scopeSize)`

Schedules a batch job to run once in the future after the specified the time interval, with the specified job name and scope size. Returns the scheduled job ID (CronTrigger ID).

Signature

```
public static String scheduleBatch(Database.Batchable batchable, String jobName, Integer
minutesFromNow, Integer scopeSize)
```

Parameters

batchable
Type: Database.Batchable

The batch class that implements the `Database.Batchable` interface.

jobName
Type: String

The name of the job that this method will start.

minutesFromNow
Type: Integer

The time interval in minutes after which the job should start executing.

scopeSize
Type: Integer

The number of records that should be passed to the batch `execute` method.

Return Value

Type: String

Usage

Note: Some things to note about `System.scheduleBatch`:

- When you call `System.scheduleBatch`, Salesforce schedules the job for execution at the specified time. Actual execution occurs at or after that time, depending on service availability.
- The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.
- When the job's schedule is triggered, the system queues the batch job for processing. If Apex flex queue is enabled in your org, the batch job is added at the end of the flex queue. For more information, see Holding Batch Jobs in the Apex Flex Queue.
- All scheduled Apex limits apply for batch jobs scheduled using `System.scheduleBatch`. After the batch job is queued (with a status of `Holding` or `Queued`), all batch job limits apply and the job no longer counts toward scheduled Apex limits.
- After calling this method and before the batch job starts, you can use the returned scheduled job ID to abort the scheduled job using the `System.abortJob` method.

For an example, see Using the `System.scheduleBatch` Method.

`setPassword(userId, password)`

Sets the password for the specified user.

Signature

```
public static Void setPassword(ID userId, String password)
```

Parameters

`userId`
Type: ID

`password`
Type: String

Return Value

Type: Void

Usage

When the user logs in with this password, they are not prompted to create a new password. Use `resetPassword(userId, sendUserEmail)` if you want the user to go through the reset process and create their own password.

Warning: Be careful with this method, and do not expose this functionality to end-users.

`submit(workItemIds, comments, nextApprover)`

Submits the processed approvals. The current user is the submitter and the entry criteria is evaluated for all processes applicable to the current user.

Signature

```
public static List<ID> submit(List<ID> workItemIds, String comments, String nextApprover)
```

Parameters

workItemIds
Type: List<ID>

comments
Type: String

nextApprover
Type: String

Return Value

Type: List<ID>

Usage

For enhanced submit and evaluation features, see the ProcessSubmitRequest class.

today()

Returns the current date in the current user's time zone.

Signature

```
public static Date today()
```

Return Value

Type: Date

Test Class

Contains methods related to Visualforce tests.

Namespace

System

Test Methods

The following are methods for `Test`. All methods are static.

IN THIS SECTION:

clearApexPageMessages()
Clear the messages on a Visualforce page while executing Apex test methods.

createStub(parentType, stubProvider)

Creates a stubbed version of an Apex class that you can use for testing. This method is part of the Apex stub API. You can use it with the `System.StubProvider` interface to create a mocking framework.

enqueueBatchJobs(numberOfJobs)

Adds the specified number of jobs with no-operation contents to the test-context queue. It first fills the test batch queue, up to the maximum 5 jobs, and then places jobs in the test flex queue. It throws a limit exception when the number of jobs in the test flex queue exceeds the allowed limit of 100 jobs.

getEventBus()

Returns an instance of the test event bus broker, which lets you operate on platform event messages in an Apex test. For example, you can call `Test.getEventBus().deliver()` to deliver event messages.

getFlexQueueOrder()

Returns an ordered list of job IDs for jobs in the test-context flex queue. The job at index `0` is the next job slated to run. This method returns only test-context results, even if it's annotated with `@IsTest(SeeAllData=true)`.

getStandardPricebookId()

Returns the ID of the standard price book in the organization.

invokeContinuationMethod(controller, request)

Invokes the callback method for the specified controller and continuation in a test method.

isRunningTest()

Returns `true` if the currently executing code was called by code contained in a test method, `false` otherwise. Use this method if you need to run different code depending on whether it was being called from a test.

loadData(sObjectToken, resourceName)

Inserts test records from the specified static resource .csv file and for the specified sObject type, and returns a list of the inserted sObjects.

newSendEmailQuickActionDefaults(contextId, replyToId)

Creates a new QuickAction.SendEmailQuickActionDefaults instance for testing a class implementing the QuickAction.QuickActionDefaultsHandler interface.

setContinuationResponse(requestLabel, mockResponse)

Sets a mock response for a continuation HTTP request in a test method.

setCreatedDate(recordId, createdDatetime)

Sets `CreatedDate` for a test-context sObject.

setCurrentPage(page)

A Visualforce test method that sets the current PageReference for the controller.

setCurrentPageReference(page)

A Visualforce test method that sets the current PageReference for the controller.

setFixedSearchResults(fixedSearchResults)

Defines a list of fixed search results to be returned by all subsequent SOSL statements in a test method.

setMock(interfaceType, instance)

Sets the response mock mode and instructs the Apex runtime to send a mock response whenever a callout is made through the HTTP classes or the auto-generated code from WSDLs.

setReadOnlyApplicationMode(applicationMode)

Sets the application mode for an organization to read-only in an Apex test to simulate read-only mode during Salesforce upgrades and downtimes. The application mode is reset to the default mode at the end of each Apex test run.

startTest()

Marks the point in your test code when your test actually begins. Use this method when you are testing governor limits.

stopTest()

Marks the point in your test code when your test ends. Use this method in conjunction with the `startTest` method.

testInstall(installImplementation, version, isPush)

Tests the implementation of the InstallHandler interface, which is used for specifying a post install script in packages. Tests run as the test initiator in the development environment.

testUninstall(uninstallImplementation)

Tests the implementation of the UninstallHandler interface, which is used for specifying an uninstall script in packages. Tests run as the test initiator in the development environment.

clearApexPageMessages()

Clear the messages on a Visualforce page while executing Apex test methods.

Signature

```
public static void clearApexPageMessages()
```

Return Value

Type: void

Usage

This method may only be used in tests.

Example:

```
@isTest
static void clearMessagesTest() {
    Test.setCurrentPage(new PageReference('/'));
    ApexPages.addMessage(
        new ApexPages.Message(ApexPages.Severity.WARNING, 'Sample Warning')
    );
    System.assertEquals(1, ApexPages.getMessages().size());
    Test.clearApexPageMessages();
    System.assertEquals(0, ApexPages.getMessages().size());
}
```

createStub(parentType, stubProvider)

Creates a stubbed version of an Apex class that you can use for testing. This method is part of the Apex stub API. You can use it with the `System.StubProvider` interface to create a mocking framework.

Signature

```
public static Object createStub(System.Type parentType, System.StubProvider stubProvider)
```

Parameters

parentType
Type: System.Type

The type of the Apex class to be stubbed.

stubProvider
System.StubProvider

An implementation of the `StubProvider` interface.

Return Value

Type: Object

Returns the stubbed object to use in testing.

Usage

The `createStub()` method works together with the `System.StubProvider` interface. You define the behavior of the stubbed object by implementing the `StubProvider` interface. Then you create a stubbed object using the `createStub()` method. When you invoke methods on the stubbed object, the `handleMethodCall()` method of the `StubProvider` interface is called to perform the behavior of the stubbed method.

SEE ALSO:

StubProvider Interface

Build a Mocking Framework with the Stub API

`enqueueBatchJobs(numberOfJobs)`

Adds the specified number of jobs with no-operation contents to the test-context queue. It first fills the test batch queue, up to the maximum 5 jobs, and then places jobs in the test flex queue. It throws a limit exception when the number of jobs in the test flex queue exceeds the allowed limit of 100 jobs.

Signature

```
public static List<Id> enqueueBatchJobs(Integer numberOfJobs)
```

Parameters

numberOfJobs
Type: Integer

Number of test jobs to enqueue.

Return Value

Type: List<Id>

A list of IDs of enqueued test jobs.

Usage

Use this method to reduce testing time. Instead of using your org's real batch jobs for testing, you can use this method to simulate batch-job enqueueing. Using `enqueueBatchJobs(numberOfJobs)` is faster than enqueuing real batch jobs.

`getEventBus()`

Returns an instance of the test event bus broker, which lets you operate on platform event messages in an Apex test. For example, you can call `Test.getEventBus().deliver()` to deliver event messages.

Signature

```
public static EventBus.TestBroker getEventBus()
```

Return Value

Type: EventBus.TestBroker

A broker for the test event bus.

Usage

Enclose `Test.getEventBus().deliver()` within the `Test.startTest()` and `Test.stopTest()` statement block.

```
Test.startTest();
// Create test events
// ...
// Publish test events with EventBus.publish()
// ...
// Deliver test events
Test.getEventBus().deliver();
// Perform validation
// ...
Test.stopTest();
```

SEE ALSO:

Platform Events Developer Guide

`getFlexQueueOrder()`

Returns an ordered list of job IDs for jobs in the test-context flex queue. The job at index `0` is the next job slated to run. This method returns only test-context results, even if it's annotated with `@IsTest(SeeAllData=true)`.

Signature

```
public static List<Id> getFlexQueueOrder()
```

Return Value

Type: List<Id>

An ordered list of IDs of the jobs in the test's flex queue.

getStandardPricebookId()

Returns the ID of the standard price book in the organization.

Signature

```
public static Id getStandardPricebookId()
```

Return Value

Type: Id

The ID of the standard price book.

Usage

This method returns the ID of the standard price book in your organization regardless of whether the test can query organization data. By default, tests can't query organization data unless they're annotated with `@isTest(SeeAllData=true)`.

Creating price book entries with a standard price requires the ID of the standard price book. Use this method to get the standard price book ID so that you can create price book entries in your tests.

Example

This example creates some test data for price book entries. The test method in this example gets the standard price book ID and uses this ID to create a price book entry for a product with a standard price. Next, the test creates a custom price book and uses the ID of this custom price book to add a price book entry with a custom price.

```
@isTest
public class PriceBookTest {
    // Utility method that can be called by Apex tests to create price book entries.
    static testmethod void addPricebookEntries() {
        // First, set up test price book entries.
        // Insert a test product.
        Product2 prod = new Product2(Name = 'Laptop X200',
            Family = 'Hardware');
        insert prod;

        // Get standard price book ID.
        // This is available irrespective of the state of SeeAllData.
        Id pricebookId = Test.getStandardPricebookId();

        // 1. Insert a price book entry for the standard price book.
        // Standard price book entries require the standard price book ID we got earlier.

        PricebookEntry standardPrice = new PricebookEntry(
            Pricebook2Id = pricebookId, Product2Id = prod.Id,
            UnitPrice = 10000, IsActive = true);
        insert standardPrice;

        // Create a custom price book
        Pricebook2 customPB = new Pricebook2(Name='Custom Pricebook', isActive=true);
        insert customPB;

        // 2. Insert a price book entry with a custom price.
```

```
        PricebookEntry customPrice = new PricebookEntry(
            Pricebook2Id = customPB.Id, Product2Id = prod.Id,
            UnitPrice = 12000, IsActive = true);
        insert customPrice;

        // Next, perform some tests with your test price book entries.
    }
}
```

invokeContinuationMethod(controller, request)

Invokes the callback method for the specified controller and continuation in a test method.

Signature

```
public static Object invokeContinuationMethod(Object controller, Continuation request)
```

Parameters

controller
Type: Object

An instance of the controller class that invokes the continuation request.

request
Type: Continuation

The continuation that is returned by an action method in the controller class.

Return Value

Type: Object

The response of the continuation callback method.

Usage

Use the `Test.setContinuationResponse` and `Test.invokeContinuationMethod` methods to test continuations. In test context, callouts of continuations aren't sent to the external service. By using these methods, you can set a mock response and cause the runtime to call the continuation callback method to process the mock response.

Call `Test.setContinuationResponse` before you call `Test.invokeContinuationMethod`. When you call `Test.invokeContinuationMethod`, the runtime executes the callback method that is associated with the continuation. The callback method processes the mock response that is set by `Test.setContinuationResponse`.

isRunningTest()

Returns `true` if the currently executing code was called by code contained in a test method, `false` otherwise. Use this method if you need to run different code depending on whether it was being called from a test.

Signature

```
public static Boolean isRunningTest()
```

Return Value

Type: Boolean

loadData(sObjectToken, resourceName)

Inserts test records from the specified static resource .csv file and for the specified sObject type, and returns a list of the inserted sObjects.

Signature

```
public static List<sObject> loadData(Schema.SObjectType sObjectToken, String
resourceName)
```

Parameters

sObjectToken
Type: Schema.SObjectType

The sObject type for which to insert test records.

resourceName
Type: String

The static resource that corresponds to the .csv file containing the test records to load. The name is case insensitive.

Return Value

Type: List<sObject>

Usage

You must create the static resource prior to calling this method. The static resource is a comma-delimited file ending with a .csv extension. The file contains field names and values for the test records. The first line of the file must contain the field names and subsequent lines are the field values. To learn more about static resources, see "Defining Static Resources" in the Salesforce online help.

Once you create a static resource for your .csv file, the static resource will be assigned a MIME type. Supported MIME types are:

- text/csv
- application/vnd.ms-excel
- application/octet-stream
- text/plain

newSendEmailQuickActionDefaults(contextId, replyToId)

Creates a new QuickAction.SendEmailQuickActionDefaults instance for testing a class implementing the QuickAction.QuickActionDefaultsHandler interface.

Signature

```
public static QuickAction.SendEmailQuickActionDefaults newSendEmailQuickActionDefaults(ID
contextId, ID replyToId)
```

Parameters

contextId
Type: Id

Parent record of the email message.

replyToId
Type: Id

Previous email message ID if this email message is a reply.

Return Value

Type: SendEmailQuickActionDefaults Class

The default values used for an email message quick action.

setContinuationResponse(requestLabel, mockResponse)

Sets a mock response for a continuation HTTP request in a test method.

Signature

```
public static void setContinuationResponse(String requestLabel, System.HttpResponse
mockResponse)
```

Parameters

requestLabel
Type: String

The unique label that corresponds to the continuation HTTP request. This label is returned by `Continuation.addHttpRequest`.

mockResponse
Type: HttpResponse

The fake response to be returned by `Test.invokeContinuationMethod`.

Return Value

Type: void

Usage

Use the `Test.setContinuationResponse` and `Test.invokeContinuationMethod` methods to test continuations. In test context, callouts of continuations aren't sent to the external service. By using these methods, you can set a mock response and cause the runtime to call the continuation callback method to process the mock response.

Call `Test.setContinuationResponse` before you call `Test.invokeContinuationMethod`. When you call `Test.invokeContinuationMethod`, the runtime executes the callback method that is associated with the continuation. The callback method processes the mock response that is set by `Test.setContinuationResponse`.

setCreatedDate(recordId, createdDatetime)

Sets `CreatedDate` for a test-context sObject.

Signature

```
public static void setCreatedDate(Id recordId, Datetime createdDatetime)
```

Parameters

recordId
Type: Id

The ID of an sObject.

createdDatetime
Type: Datetime

The value to assign to the sObject's `CreatedDate` field.

Return Value

Type: void

Usage

All database changes are rolled back at the end of a test. You can't use this method on records that existed before your test executed. You also can't use `setCreatedDate` in methods annotated with `@isTest(SeeAllData=true)`, because those methods have access to all data in your org. This method takes two parameters—an sObject ID and a Datetime value—neither of which can be null.

Insert your test record before you set its `CreatedDate`, as shown in this example.

```
@isTest
private class SetCreatedDateTest {
    static testMethod void testSetCreatedDate() {
        Account a = new Account(name='myAccount');
        insert a;
        Test.setCreatedDate(a.Id, DateTime.newInstance(2012,12,12));
        Test.startTest();
        Account myAccount = [SELECT Id, Name, CreatedDate FROM Account
                             WHERE Name ='myAccount' limit 1];
        System.assertEquals(myAccount.CreatedDate, DateTime.newInstance(2012,12,12));
        Test.stopTest();
    }
}
```

setCurrentPage(page)

A Visualforce test method that sets the current PageReference for the controller.

Signature

```
public static Void setCurrentPage(PageReference page)
```

Parameters

page
Type: System.PageReference

Return Value

Type: Void

setCurrentPageReference(page)

A Visualforce test method that sets the current PageReference for the controller.

Signature

```
public static Void setCurrentPageReference(PageReference page)
```

Parameters

page
Type: System.PageReference

Return Value

Type: Void

setFixedSearchResults(fixedSearchResults)

Defines a list of fixed search results to be returned by all subsequent SOSL statements in a test method.

Signature

```
public static Void setFixedSearchResults(ID[] fixedSearchResults)
```

Parameters

fixedSearchResults
Type: ID[]

The list of record IDs specified by *opt_set_search_results* replaces the results that would normally be returned by the SOSL queries if they were not subject to any `WHERE` or `LIMIT` clauses. If these clauses exist in the SOSL queries, they are applied to the list of fixed search results.

Return Value

Type: Void

Usage

If *opt_set_search_results* is not specified, all subsequent SOSL queries return no results.

For more information, see Adding SOSL Queries to Unit Tests on page 605.

setMock(interfaceType, instance)

Sets the response mock mode and instructs the Apex runtime to send a mock response whenever a callout is made through the HTTP classes or the auto-generated code from WSDLs.

Signature

```
public static Void setMock(Type interfaceType, Object instance)
```

Parameters

interfaceType
Type: System.Type

instance
Type: Object

Return Value

Type: Void

Usage

Note: To mock a callout if the code that performs the callout is in a managed package, call `Test.setMock` from a test method in the same package with the same namespace.

setReadOnlyApplicationMode(applicationMode)

Sets the application mode for an organization to read-only in an Apex test to simulate read-only mode during Salesforce upgrades and downtimes. The application mode is reset to the default mode at the end of each Apex test run.

Signature

```
public static Void setReadOnlyApplicationMode(Boolean applicationMode)
```

Parameters

applicationMode
Type: Boolean

Return Value

Type: Void

Usage

Also see the `getApplicationReadWriteMode()` System method.

Do not use `setReadOnlyApplicationMode` for purposes unrelated to Read-Only Mode testing, such as simulating DML exceptions.

Example

The following example sets the application mode to read-only and attempts to insert a new account record, which results in the exception. It then resets the application mode and performs a successful insert.

```
@isTest
private class ApplicationReadOnlyModeTestClass {
  public static testmethod void test() {
    // Create a test account that is used for querying later.
    Account testAccount = new Account(Name = 'TestAccount');
    insert testAccount;

    // Set the application read only mode.
    Test.setReadOnlyApplicationMode(true);

    // Verify that the application is in read-only mode.
    System.assertEquals(
               ApplicationReadWriteMode.READ_ONLY,
               System.getApplicationReadWriteMode());

    // Create a new account object.
    Account testAccount2 = new Account(Name = 'TestAccount2');

    try {
      // Get the test account created earlier. Should be successful.
      Account testAccountFromDb =
        [SELECT Id, Name FROM Account WHERE Name = 'TestAccount'];
      System.assertEquals(testAccount.Id, testAccountFromDb.Id);

      // Inserts should result in the InvalidReadOnlyUserDmlException
      // being thrown.
      insert testAccount2;
      System.assertEquals(false, true);
    } catch (System.InvalidReadOnlyUserDmlException e) {
      // Expected
    }
    // Insertion should work after read only application mode gets disabled.
    Test.setReadOnlyApplicationMode(false);

    insert testAccount2;
    Account testAccount2FromDb =
       [SELECT Id, Name FROM Account WHERE Name = 'TestAccount2'];
    System.assertEquals(testAccount2.Id, testAccount2FromDb.Id);
  }
}
```

startTest()

Marks the point in your test code when your test actually begins. Use this method when you are testing governor limits.

Signature

```
public static Void startTest()
```

Return Value

Type: Void

Usage

You can also use this method with `stopTest` to ensure that all asynchronous calls that come after the `startTest` method are run before doing any assertions or testing. Each test method is allowed to call this method only once. All of the code before this method should be used to initialize variables, populate data structures, and so on, allowing you to set up everything you need to run your test. Any code that executes after the call to `startTest` and before `stopTest` is assigned a new set of governor limits.

`stopTest()`

Marks the point in your test code when your test ends. Use this method in conjunction with the `startTest` method.

Signature

```
public static Void stopTest()
```

Return Value

Type: Void

Usage

Each test method is allowed to call this method only once. Any code that executes after the `stopTest` method is assigned the original limits that were in effect before `startTest` was called. All asynchronous calls made after the `startTest` method are collected by the system. When `stopTest` is executed, all asynchronous processes are run synchronously.

Note: Asynchronous calls, such as `@future` or `executeBatch`, called in a `startTest`, `stopTest` block, do not count against your limits for the number of queued jobs.

`testInstall(installImplementation, version, isPush)`

Tests the implementation of the InstallHandler interface, which is used for specifying a post install script in packages. Tests run as the test initiator in the development environment.

Signature

```
public static Void testInstall(InstallHandler installImplementation, Version version,
Boolean isPush)
```

Parameters

`installImplementation`
Type: System.InstallHandler

A class that implements the `InstallHandler` interface.

`version`
Type: System.Version

The version number of the existing package installed in the subscriber organization.

isPush
Type: Boolean

(Optional) Specifies whether the upgrade is a push. The default value is `false`.

Return Value

Type: Void

Usage

This method throws a run-time exception if the test install fails.

Example

```
@isTest static void test() {
  PostInstallClass postinstall =
    new PostInstallClass();
    Test.testInstall(postinstall,
      new Version(1,0));
  }
```

testUninstall(uninstallImplementation)

Tests the implementation of the UninstallHandler interface, which is used for specifying an uninstall script in packages. Tests run as the test initiator in the development environment.

Signature

```
public static Void testUninstall(UninstallHandler uninstallImplementation)
```

Parameters

uninstallImplementation
Type: System.UninstallHandler

A class that implements the `UninstallHandler` interface.

Return Value

Type: Void

Usage

This method throws a run-time exception if the test uninstall fails.

Example

```
@isTest static void test() {
  UninstallClass uninstall =
    new UninstallClass();
```

```
    Test.testUninstall(uninstall);
  }
```

Time Class

Contains methods for the Time primitive data type.

Namespace

System

Usage

For more information on time, see Primitive Data Types on page 26.

Time Methods

The following are methods for `Time`.

IN THIS SECTION:

addHours(additionalHours)
Adds the specified number of hours to a Time.

addMilliseconds(additionalMilliseconds)
Adds the specified number of milliseconds to a Time.

addMinutes(additionalMinutes)
Adds the specified number of minutes to a Time.

addSeconds(additionalSeconds)
Adds the specified number of seconds to a Time.

hour()
Returns the hour component of a Time.

millisecond()
Returns the millisecond component of a Time.

minute()
Returns the minute component of a Time.

newInstance(hour, minutes, seconds, milliseconds)
Constructs a Time from Integer representations of the specified hour, minutes, seconds, and milliseconds. (UTC is assumed.)

second()
Returns the second component of a Time.

`addHours(additionalHours)`

Adds the specified number of hours to a Time.

Signature

```
public Time addHours(Integer additionalHours)
```

Parameters

additionalHours
Type: Integer

Return Value

Type: Time

Example

```
Time myTime = Time.newInstance(1, 2, 3, 4);
Time expected = Time.newInstance(4, 2, 3, 4);
System.assertEquals(expected, myTime.addHours(3));
```

addMilliseconds(additionalMilliseconds)

Adds the specified number of milliseconds to a Time.

Signature

```
public Time addMilliseconds(Integer additionalMilliseconds)
```

Parameters

additionalMilliseconds
Type: Integer

Return Value

Type: Time

Example

```
Time myTime = Time.newInstance(1, 2, 3, 0);
Time expected = Time.newInstance(1, 2, 4, 400);
System.assertEquals(expected, myTime.addMilliseconds(1400));
```

addMinutes(additionalMinutes)

Adds the specified number of minutes to a Time.

Signature

```
public Time addMinutes(Integer additionalMinutes)
```

Parameters

additionalMinutes
Type: Integer

Return Value

Type: Time

Example

```
Time myTime = Time.newInstance(18, 30, 2, 20);
Integer myMinutes = myTime.minute();
myMinutes = myMinutes + 5;
System.assertEquals(myMinutes, 35);
```

addSeconds(additionalSeconds)

Adds the specified number of seconds to a Time.

Signature

```
public Time addSeconds(Integer additionalSeconds)
```

Parameters

additionalSeconds
Type: Integer

Return Value

Type: Time

Example

```
Time myTime = Time.newInstance(1, 2, 55, 0);
Time expected = Time.newInstance(1, 3, 5, 0);
System.assertEquals(expected, myTime.addSeconds(10));
```

hour()

Returns the hour component of a Time.

Signature

```
public Integer hour()
```

Return Value

Type: Integer

Example

```
Time myTime = Time.newInstance(18, 30, 2, 20);
myTime = myTime.addHours(2);
Integer myHour = myTime.hour();
System.assertEquals(myHour, 20);
```

millisecond()

Returns the millisecond component of a Time.

Signature

```
public Integer millisecond()
```

Return Value

Type: Integer

Example

```
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(926, myTime.millisecond());
```

minute()

Returns the minute component of a Time.

Signature

```
public Integer minute()
```

Return Value

Type: Integer

Example

```
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(14, myTime.minute());
```

newInstance(hour, minutes, seconds, milliseconds)

Constructs a Time from Integer representations of the specified hour, minutes, seconds, and milliseconds. (UTC is assumed.)

Signature

```
public static Time newInstance(Integer hour, Integer minutes, Integer seconds, Integer
milliseconds)
```

Parameters

hour
Type: Integer

minutes
Type: Integer

seconds
Type: Integer

milliseconds
Type: Integer

Return Value

Type: Time

Example

The following example creates a time of 18:30:2:20 (UTC).

```
Time myTime =
Time.newInstance(18, 30, 2, 20);
```

second()

Returns the second component of a Time.

Signature

```
public Integer second()
```

Return Value

Type: Integer

Example

```
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(15, myTime.second());
```

TimeZone Class

Represents a time zone. Contains methods for creating a new time zone and obtaining time zone properties, such as the time zone ID, offset, and display name.

Namespace

System

Usage

You can use the methods in this class to get properties of a time zone, such as the properties of the time zone returned by `UserInfo.getTimeZone`, or the time zone returned by `getTimeZone` of this class.

Example

This example shows how to get properties of the current user's time zone and displays them to the debug log.

```
TimeZone tz = UserInfo.getTimeZone();
System.debug('Display name: ' + tz.getDisplayName());
System.debug('ID: ' + tz.getID());
// During daylight saving time for the America/Los_Angeles time zone
System.debug('Offset: ' + tz.getOffset(DateTime.newInstance(2012,10,23,12,0,0)));
// Not during daylight saving time for the America/Los_Angeles time zone
System.debug('Offset: ' + tz.getOffset(DateTime.newInstance(2012,11,23,12,0,0)));
System.debug('String format: ' + tz.toString());
```

The output of this sample varies based on the user's time zone. This is an example output if the user's time zone is America/Los_Angeles. For this time zone, daylight saving time is -7 hours from GMT (-25200000 milliseconds) and standard time is -8 hours from GMT (-28800000 milliseconds).

```
Display name: Pacific Standard Time

ID: America/Los_Angeles

Offset: -25200000

Offset: -28800000

String format: America/Los_Angeles
```

This second example shows how to create a time zone for the New York time zone and get the offset of this time zone to the GMT time zone. The example uses two dates to get the offset from. One date is before DST, and one is after DST. In 2000, DST ended on Sunday, October 29 for the New York time zone. Because the date occurs after DST ends, the offset on the first date is –5 hours to GMT. In 2012, DST ended on Sunday, November 4. Because the date is within DST, the offset on the second date is –4 hours.

```
// Get the New York time zone
Timezone tz = Timezone.getTimeZone('America/New_York');

// Create a date before the 2007 shift of DST into November
DateTime dtpre = DateTime.newInstanceGMT(2000, 11, 1, 0, 0, 0);
system.debug(tz.getOffset(dtpre));   //-18000000 (= -5 hours = EST)

// Create a date after the 2007 shift of DST into November
DateTime dtpost = DateTime.newInstanceGMT(2012, 11, 1, 0, 0, 0);
system.debug(tz.getOffset(dtpost));   //-14400000 (= -4 hours = EDT)
```

This next example is similar to the previous one except that it gets the offset around the boundary of DST. In 2014, DST ended on Sunday, November 2 at 2:00 AM local time for the New York time zone. The first offset is obtained right before DST ends, and the second offset is obtained right after DST ends. The dates are created by using the `DateTime.newInstanceGMT` method. This method expects the passed-in date values to be based on the GMT time zone.

```
// Get the New York time zone
Timezone tz = Timezone.getTimeZone('America/New_York');

// Before DST ends
DateTime dtpre = DateTime.newInstanceGMT(2014, 11, 2, 5, 59, 59);  //1:59:59AM local
```

```
system.debug(tz.getOffset(dtpre));   //-14400000 (= -4 hours = still on DST)

// After DST ends
DateTime dtpost = DateTime.newInstanceGMT(2014, 11, 2, 6, 0, 0); //1:00:00AM local
system.debug(tz.getOffset(dtpost));  //-18000000 (= -5 hours = back one hour)
```

TimeZone Methods

The following are methods for `TimeZone`.

IN THIS SECTION:

getDisplayName()
Returns this time zone's display name.

getID()
Returns this time zone's ID.

getOffset(date)
Returns the time zone offset, in milliseconds, of the specified date to the GMT time zone.

getTimeZone(timeZoneIdString)
Returns the time zone corresponding to the specified time zone ID.

toString()
Returns the string representation of this time zone.

`getDisplayName()`

Returns this time zone's display name.

Signature

```
public String getDisplayName()
```

Return Value

Type: String

`getID()`

Returns this time zone's ID.

Signature

```
public String getID()
```

Return Value

Type: String

getOffset(date)

Returns the time zone offset, in milliseconds, of the specified date to the GMT time zone.

Signature

```
public Integer getOffset(Datetime date)
```

Parameters

date
Type: Datetime

The *date* argument is the date and time to evaluate.

Return Value

Type: Integer

Usage

Note: The returned offset is adjusted for daylight saving time if the *date* argument falls within daylight saving time for this time zone.

getTimeZone(timeZoneIdString)

Returns the time zone corresponding to the specified time zone ID.

Signature

```
public static TimeZone getTimeZone(String timeZoneIdString)
```

Parameters

timeZoneIdString
Type: String

The time zone values you can use for the *Id* argument are any valid time zone values that the Java TimeZone class supports.

Return Value

Type: TimeZone

Example

```
TimeZone tz = TimeZone.getTimeZone('America/Los_Angeles');
System.assertEquals(
  'Pacific Standard Time',
  tz.getDisplayName());
```

`toString()`

Returns the string representation of this time zone.

Signature

```
public String toString()
```

Return Value

Type: String

Trigger Class

Use the `Trigger` class to access run-time context information in a trigger, such as the type of trigger or the list of sObject records that the trigger operates on.

Namespace

System

Trigger Context Variables

The `Trigger` class provides the following context variables.

Variable	Usage
`isExecuting`	Returns true if the current context for the Apex code is a trigger, not a Visualforce page, a Web service, or an `executeanonymous()` API call.
`isInsert`	Returns `true` if this trigger was fired due to an insert operation, from the Salesforce user interface, Apex, or the API.
`isUpdate`	Returns `true` if this trigger was fired due to an update operation, from the Salesforce user interface, Apex, or the API.
`isDelete`	Returns `true` if this trigger was fired due to a delete operation, from the Salesforce user interface, Apex, or the API.
`isBefore`	Returns `true` if this trigger was fired before any record was saved.
`isAfter`	Returns `true` if this trigger was fired after all records were saved.
`isUndelete`	Returns `true` if this trigger was fired after a record is recovered from the Recycle Bin (that is, after an undelete operation from the Salesforce user interface, Apex, or the API.)
`new`	Returns a list of the new versions of the sObject records. This sObject list is only available in `insert`, `update`, and `undelete` triggers, and the records can only be modified in `before` triggers.
`newMap`	A map of IDs to the new versions of the sObject records. This map is only available in `before update`, `after insert`, `after update`, and `after undelete` triggers.

Variable	Usage
`old`	Returns a list of the old versions of the sObject records. This sObject list is only available in `update` and `delete` triggers.
`oldMap`	A map of IDs to the old versions of the sObject records. This map is only available in `update` and `delete` triggers.
`size`	The total number of records in a trigger invocation, both old and new.

Note: If any record that fires a trigger includes an invalid field value (for example, a formula that divides by zero), that value is set to `null` in the `new`, `newMap`, `old`, and `oldMap` trigger context variables.

Example

For example, in this simple trigger, `Trigger.new` is a list of sObjects and can be iterated over in a `for` loop, or used as a bind variable in the `IN` clause of a SOQL query.

```
Trigger simpleTrigger on Account (after insert) {
    for (Account a : Trigger.new) {
        // Iterate over each sObject
    }

    // This single query finds every contact that is associated with any of the
    // triggering accounts. Note that although Trigger.new is a collection of
    // records, when used as a bind variable in a SOQL query, Apex automatically
    // transforms the list of records into a list of corresponding Ids.
    Contact[] cons = [SELECT LastName FROM Contact
                      WHERE AccountId IN :Trigger.new];
}
```

This trigger uses Boolean context variables like `Trigger.isBefore` and `Trigger.isDelete` to define code that only executes for specific trigger conditions:

```
trigger myAccountTrigger on Account(before delete, before insert, before update,
                                    after delete, after insert, after update) {
if (Trigger.isBefore) {
    if (Trigger.isDelete) {

        // In a before delete trigger, the trigger accesses the records that will be
        // deleted with the Trigger.old list.
        for (Account a : Trigger.old) {
            if (a.name != 'okToDelete') {
                a.addError('You can\'t delete this record!');
            }
        }
    } else {

    // In before insert or before update triggers, the trigger accesses the new records
    // with the Trigger.new list.
        for (Account a : Trigger.new) {
            if (a.name == 'bad') {
```

```
                a.name.addError('Bad name');
            }
    }
    if (Trigger.isInsert) {
        for (Account a : Trigger.new) {
            System.assertEquals('xxx', a.accountNumber);
            System.assertEquals('industry', a.industry);
            System.assertEquals(100, a.numberofemployees);
            System.assertEquals(100.0, a.annualrevenue);
            a.accountNumber = 'yyy';
        }

// If the trigger is not a before trigger, it must be an after trigger.
} else {
    if (Trigger.isInsert) {
        List<Contact> contacts = new List<Contact>();
        for (Account a : Trigger.new) {
            if(a.Name == 'makeContact') {
                contacts.add(new Contact (LastName = a.Name,
                                          AccountId = a.Id));
            }
        }
      insert contacts;
    }
  }
}}}
```

TriggerOperation Enum

System.TriggerOperation enum values are associated with trigger events.

Enum Values

The following are the values of the `System.TriggerOperation` enum:

- AFTER_DELETE
- AFTER_INSERT
- AFTER_UNDELETE
- AFTER_UPDATE
- BEFORE_DELETE
- BEFORE_INSERT
- BEFORE_UPDATE

Type Class

Contains methods for getting the Apex type that corresponds to an Apex class and for instantiating new types.

Namespace

System

Usage

Use the `forName` methods to retrieve the type of an Apex class, which can be a built-in or a user-defined class. Also, use the `newInstance` method if you want to instantiate a Type that implements an interface and call its methods while letting someone else, such as a subscriber of your package, provide the methods' implementations.

Example: Instantiating a Type Based on Its Name

The following sample shows how to use the Type methods to instantiate a Type based on its name. A typical application of this scenario is when a package subscriber provides a custom implementation of an interface that is part of an installed package. The package can get the name of the class that implements the interface through a custom setting in the subscriber's org. The package can then instantiate the type that corresponds to this class name and invoke the methods that the subscriber implemented.

In this sample, `Vehicle` represents the interface that the `VehicleImpl` class implements. The last class contains the code sample that invokes the methods implemented in `VehicleImpl`.

This is the `Vehicle` interface.

```
global interface Vehicle {
    Long getMaxSpeed();
    String getType();
}
```

This is the implementation of the `Vehicle` interface.

```
global class VehicleImpl implements Vehicle {
    global Long getMaxSpeed() { return 100; }
    global String getType() { return 'Sedan'; }
}
```

The method in this class gets the name of the class that implements the `Vehicle` interface through a custom setting value. It then instantiates this class by getting the corresponding type and calling the `newInstance` method. Next, it invokes the methods implemented in `VehicleImpl`. This sample requires that you create a public list custom setting named *`CustomImplementation`* with a text field named *`className`*. Create one record for this custom setting with a data set name of *`Vehicle`* and a class name value of *`VehicleImpl`*.

```
public class CustomerImplInvocationClass {

    public static void invokeCustomImpl() {
        // Get the class name from a custom setting.
        // This class implements the Vehicle interface.
        CustomImplementation__c cs = CustomImplementation__c.getInstance('Vehicle');

        // Get the Type corresponding to the class name
        Type t = Type.forName(cs.className__c);

        // Instantiate the type.
        // The type of the instantiated object
        //   is the interface.
        Vehicle v = (Vehicle)t.newInstance();

        // Call the methods that have a custom implementation
        System.debug('Max speed: ' + v.getMaxSpeed());
        System.debug('Vehicle type: ' + v.getType());
    }
}
```

Class Property

The `class` property returns the `System.Type` of the type it is called on. It is exposed on all Apex built-in types including primitive data types and collections, sObject types, and user-defined classes. This property can be used instead of `forName` methods.

Call this property on the type name. For example:

```
System.Type t = Integer.class;
```

You can use this property for the second argument of `JSON.deserialize`, `deserializeStrict`, `JSONParser.readValueAs`, and `readValueAsStrict` methods to get the type of the object to deserialize. For example:

```
Decimal n = (Decimal)JSON.deserialize('100.1', Decimal.class);
```

Type Methods

The following are methods for `Type`.

IN THIS SECTION:

equals(typeToCompare)
Returns `true` if the specified type is equal to the current type; otherwise, returns `false`.

forName(fullyQualifiedName)
Returns the type that corresponds to the specified fully qualified class name.

forName(namespace, name)
Returns the type that corresponds to the specified namespace and class name.

getName()
Returns the name of the current type.

hashCode()
Returns a hash code value for the current type.

newInstance()
Creates an instance of the current type and returns this new instance.

toString()
Returns a string representation of the current type, which is the type name.

`equals(typeToCompare)`

Returns `true` if the specified type is equal to the current type; otherwise, returns `false`.

Signature

```
public Boolean equals(Object typeToCompare)
```

Parameters

`typeToCompare`
Type: Object

The type to compare with the current type.

Return Value

Type: Boolean

Example

```
Type t1 = Account.class;
Type t2 = Type.forName('Account');
System.assert(t1.equals(t2));
```

forName(fullyQualifiedName)

Returns the type that corresponds to the specified fully qualified class name.

Signature

```
public static System.Type forName(String fullyQualifiedName)
```

Parameters

fullyQualifiedName
Type: String

The fully qualified name of the class to get the type of. The fully qualified class name contains the namespace name, for example, `MyNamespace.ClassName`.

Return Value

Type: `System.Type`

Usage

Note:

- This method returns `null` if called outside a managed package to get the type of a non-global class in a managed package. This is because the non-global class is not visible outside the managed package. For Apex saved using Salesforce API version 27.0 and earlier, this method does return the corresponding class type for the non-global managed package class.
- When called from an installed managed package to get the name of a local type in an organization with no defined namespace, the `forName(fullyQualifiedName)` method returns `null`. Instead, use the `forName(namespace, name)` method and specify an empty string or `null` for the namespace argument.

forName(namespace, name)

Returns the type that corresponds to the specified namespace and class name.

Signature

```
public static System.Type forName(String namespace, String name)
```

Parameters

namespace
Type: String

The namespace of the class. If the class doesn't have a namespace, set the *namespace* argument to `null` or an empty string.

name
Type: String

The name of the class.

Return Value

Type: `System.Type`

Usage

Note:

- This method returns `null` if called outside a managed package to get the type of a non-global class in a managed package. This is because the non-global class is not visible outside the managed package. For Apex saved using Salesforce API version 27.0 and earlier, this method does return the corresponding class type for the non-global managed package class.
- Use this method instead of `forName(fullyQualifiedName)` if it will be called from a managed package installed in an organization with no defined namespace. To get the name of a local type, set the namespace argument to an empty string or `null`. For example, `Type t = Type.forName('', 'ClassName');`.

Example

This example shows how to get the type that corresponds to the `ClassName` class and the `MyNamespace` namespace.

```
Type myType =
   Type.forName('MyNamespace', 'ClassName');
```

getName()

Returns the name of the current type.

Signature

```
public String getName()
```

Return Value

Type: String

Example

This example shows how to get a Type's name. It first obtains a Type by calling `forName`, then calls `getName` on the Type object.

```
Type t =
   Type.forName('MyClassName');

String typeName =
```

```
   t.getName();
System.assertEquals('MyClassName',
   typeName);
```

hashCode()

Returns a hash code value for the current type.

Signature

```
public Integer hashCode()
```

Return Value

Type: Integer

Usage

The returned hash code value corresponds to the type name hash code that `String.hashCode` returns.

newInstance()

Creates an instance of the current type and returns this new instance.

Signature

```
public Object newInstance()
```

Return Value

Type: Object

Usage

Because `newInstance` returns the generic object type, you should cast the return value to the type of the variable that will hold this value.

This method enables you to instantiate a Type that implements an interface and call its methods while letting someone else provide the methods' implementation. For example, a package developer can provide an interface that a subscriber who installs the package can implement. The code in the package calls the subscriber's implementation of the interface methods by instantiating the subscriber's Type.

Note: Calling this method on a type corresponding to a class that has a private no-argument constructor results in a `System.TypeException`, as expected because the type can't be instantiated. For Apex saved using Salesforce API version 28.0 and earlier, this method returns an instance of the class instead.

Example

This example shows how to create an instance of a Type. It first gets a Type by calling `forName` with the name of a class (`ShapeImpl`), then calls `newInstance` on this Type object. The `newObj` instance is declared with the interface type (`Shape`) that the `ShapeImpl` class implements. The return value of the `newInstance` method is cast to the `Shape` type.

```
Type t =
   Type.forName('ShapeImpl');

Shape newObj =
   (Shape)t.newInstance();
```

`toString()`

Returns a string representation of the current type, which is the type name.

Signature

```
public String toString()
```

Return Value

Type: String

Usage

This method returns the same value as `getName`. `String.valueOf` and `System.debug` use this method to convert their Type argument into a String.

Example

This example calls `toString` on the Type corresponding to a list of Integers.

```
Type t = List<Integer>.class;
String s = t.toString();
System.assertEquals('List<Integer>', s);
```

UninstallHandler Interface

Enables custom code to run after a managed package is uninstalled.

Namespace

System

Usage

App developers can implement this interface to specify Apex code that runs automatically after a subscriber uninstalls a managed package. This makes it possible to perform cleanup and notification tasks based on details of the subscriber's organization.

The uninstall script is subject to default governor limits. It runs as a special system user that represents your package, so all operations performed by the script will appear to be done by your package. You can access this user by using UserInfo. You will only see this user at runtime, not while running tests.

If the script fails, the uninstall continues but none of the changes performed by the script are committed. Any errors in the script are emailed to the user specified in the **Notify on Apex Error** field of the package. If no user is specified, the uninstall details will be unavailable.

The uninstall script has the following restrictions. You can't use it to initiate batch, scheduled, and future jobs, to access Session IDs, or to perform callouts.

The `UninstallHandler` interface has a single method called `onUninstall`, which specifies the actions to be performed on uninstall.

```
global interface UninstallHandler {
  void onUninstall(UninstallContext context)};
```

The `onUninstall` method takes a context object as its argument, which provides the following information.

- The org ID of the organization in which the uninstall takes place.
- The user ID of the user who initiated the uninstall.

The context argument is an object whose type is the `UninstallContext` interface. This interface is automatically implemented by the system. The following definition of the `UninstallContext` interface shows the methods you can call on the context argument.

```
global interface UninstallContext {
  ID organizationId();
  ID uninstallerId();
}
```

IN THIS SECTION:

UninstallHandler Methods

UninstallHandler Example Implementation

UninstallHandler Methods

The following are methods for `UninstallHandler`.

IN THIS SECTION:

onUninstall(context)
Specifies the actions to be performed on uninstall.

onUninstall(context)

Specifies the actions to be performed on uninstall.

Signature

```
public Void onUninstall(UninstallContext context)
```

Parameters

context
Type: UninstallContext

Return Value

Type: Void

UninstallHandler Example Implementation

Example of an Uninstall Script

The sample uninstall script below performs the following actions on package uninstall.

- Inserts an entry in the feed describing which user did the uninstall and in which organization
- Creates and sends an email message confirming the uninstall to that user

```
global class UninstallClass implements UninstallHandler {
  global void onUninstall(UninstallContext ctx) {
    FeedItem feedPost = new FeedItem();
    feedPost.parentId = ctx.uninstallerID();
    feedPost.body = 'Thank you for using our application!';
    insert feedPost;

    User u = [Select Id, Email from User where Id =:ctx.uninstallerID()];
    String toAddress= u.Email;
    String[] toAddresses = new String[] {toAddress};
    Messaging.SingleEmailMessage mail = new Messaging.SingleEmailMessage();
    mail.setToAddresses(toAddresses);
    mail.setReplyTo('support@package.dev');
    mail.setSenderDisplayName('My Package Support');
    mail.setSubject('Package uninstall successful');
    mail.setPlainTextBody('Thanks for uninstalling the package.');
    Messaging.sendEmail(new Messaging.Email[] { mail });
  }
}
```

You can test an uninstall script using the `testUninstall` method of the `Test` class. This method takes as its argument a class that implements the `UninstallHandler` interface.

This sample shows how to test an uninstall script implemented in the `UninstallClass` Apex class.

```
@isTest
static void testUninstallScript() {
  Id UninstallerId = UserInfo.getUserId();
  List<FeedItem> feedPostsBefore =
    [SELECT Id FROM FeedItem WHERE parentId=:UninstallerId AND CreatedDate=TODAY];
  Test.testUninstall(new UninstallClass());
  List<FeedItem> feedPostsAfter =
    [SELECT Id FROM FeedItem WHERE parentId=:UninstallerId AND CreatedDate=TODAY];
  System.assertEquals(feedPostsBefore.size() + 1, feedPostsAfter.size(),
    'Post to uninstaller failed.');
}
```

URL Class

Represents a uniform resource locator (URL) and provides access to parts of the URL. Enables access to the Salesforce instance URL.

Namespace

System

Usage

Use the methods of the `System.URL` class to create links to objects in your organization. Such objects can be files, images, logos, or records that you want to include in external emails, in activities, or in Chatter posts. For example, you can create a link to a file uploaded as an attachment to a Chatter post by concatenating the Salesforce base URL with the file ID, as shown in the following example:

```
// Get a file uploaded through Chatter.
ContentDocument doc = [SELECT Id FROM ContentDocument
          WHERE Title = 'myfile'];
// Create a link to the file.
String fullFileURL = URL.getSalesforceBaseUrl().toExternalForm() +
   '/' + doc.id;
system.debug(fullFileURL);
```

The following example creates a link to a Salesforce record. The full URL is created by concatenating the Salesforce base URL with the record ID.

```
Account acct = [SELECT Id FROM Account WHERE Name = 'Acme' LIMIT 1];
String fullRecordURL = URL.getSalesforceBaseUrl().toExternalForm() + '/' + acct.Id;
```

Example

In this example, the base URL and the full request URL of the current Salesforce server instance are retrieved. Next, a URL pointing to a specific account object is created. Finally, components of the base and full URL are obtained. This example prints out all the results to the debug log output.

```
// Create a new account called Acme that we will create a link for later.
Account myAccount = new Account(Name='Acme');
insert myAccount;

// Get the base URL.
String sfdcBaseURL = URL.getSalesforceBaseUrl().toExternalForm();
System.debug('Base URL: ' + sfdcBaseURL );

// Get the URL for the current request.
String currentRequestURL = URL.getCurrentRequestUrl().toExternalForm();
System.debug('Current request URL: ' + currentRequestURL);

// Create the account URL from the base URL.
String accountURL = URL.getSalesforceBaseUrl().toExternalForm() +
                    '/' + myAccount.Id;
System.debug('URL of a particular account: ' + accountURL);
```

```
// Get some parts of the base URL.
System.debug('Host: ' + URL.getSalesforceBaseUrl().getHost());
System.debug('Protocol: ' + URL.getSalesforceBaseUrl().getProtocol());

// Get the query string of the current request.
System.debug('Query: ' + URL.getCurrentRequestUrl().getQuery());
```

IN THIS SECTION:

URL Constructors

URL Methods

URL Constructors

The following are constructors for `URL`.

IN THIS SECTION:

Url(spec)

Creates a new instance of the `URL` class using the specified string representation of the URL.

Url(context, spec)

Creates a new instance of the `URL` class by parsing the specified spec within the specified context.

Url(protocol, host, file)

Creates a new instance of the `URL` class using the specified protocol, host, and file on the host. The default port for the specified protocol is used.

Url(protocol, host, port, file)

Creates a new instance of the `URL` class using the specified protocol, host, port, and file on the host.

`Url(spec)`

Creates a new instance of the `URL` class using the specified string representation of the URL.

Signature

```
public Url(String spec)
```

Parameters

spec

Type: String

The string to parse as a URL.

`Url(context, spec)`

Creates a new instance of the `URL` class by parsing the specified spec within the specified context.

Signature

```
public Url(Url context, String spec)
```

Parameters

context
Type: URL on page 3064

The context in which to parse the specification.

spec
Type: String

The string to parse as a URL.

Usage

The new URL is created from the given context URL and the spec argument as described in RFC2396 "Uniform Resource Identifiers : Generic * Syntax" :

```
<scheme>://<authority><path>?<query>#<fragment>
```

For more information about the arguments of this constructor, see the corresponding URL(java.net.URL, java.lang.String) constructor for Java.

Url(protocol, host, file)

Creates a new instance of the `URL` class using the specified protocol, host, and file on the host. The default port for the specified protocol is used.

Signature

```
public Url(String protocol, String host, String file)
```

Parameters

protocol
Type: String

The protocol name for this URL.

host
Type: String

The host name for this URL.

file
Type: String

The file name for this URL.

Url(protocol, host, port, file)

Creates a new instance of the `URL` class using the specified protocol, host, port, and file on the host.

Signature

```
public Url(String protocol, String host, Integer port, String file)
```

Parameters

protocol
Type: String

The protocol name for this URL.

host
Type: String

The host name for this URL.

port
Type: Integer

The port number for this URL.

file
Type: String

The file name for this URL.

URL Methods

The following are methods for `URL`.

IN THIS SECTION:

getAuthority()
Returns the authority portion of the current URL.

getCurrentRequestUrl()
Returns the URL of an entire request on a Salesforce instance.

getDefaultPort()
Returns the default port number of the protocol associated with the current URL.

getFile()
Returns the file name of the current URL.

getFileFieldURL(entityId, fieldName)
Returns the download URL for a file attachment.

getHost()
Returns the host name of the current URL.

getOrgDomainUrl()
Returns the canonical URL for your org. For example, `https://yourDomain.my.salesforce.com` or, for orgs without My Domain enabled, `https://yourInstance.salesforce.com`.

getPath()
Returns the path portion of the current URL.

getPort()
Returns the port of the current URL.

getProtocol()
Returns the protocol name of the current URL, such as, `https`.

getQuery()
Returns the query portion of the current URL.

getRef()
Returns the anchor of the current URL.

getSalesforceBaseUrl()
Returns the URL of the Salesforce instance.

getUserInfo()
Gets the UserInfo portion of the current URL.

sameFile(URLToCompare)
Compares the current URL with the specified URL object, excluding the fragment component.

toExternalForm()
Returns a string representation of the current URL.

`getAuthority()`

Returns the authority portion of the current URL.

Signature

```
public String getAuthority()
```

Return Value

Type: String

`getCurrentRequestUrl()`

Returns the URL of an entire request on a Salesforce instance.

Signature

```
public static System.URL getCurrentRequestUrl()
```

Return Value

Type: `System.URL`

Usage

An example of a URL for an entire request is `https://yourInstance.salesforce.com/apex/myVfPage.apexp`.

`getDefaultPort()`

Returns the default port number of the protocol associated with the current URL.

Signature

```
public Integer getDefaultPort()
```

Return Value

Type: Integer

Usage

Returns -1 if the URL scheme or the stream protocol handler for the URL doesn't define a default port number.

getFile()

Returns the file name of the current URL.

Signature

```
public String getFile()
```

Return Value

Type: String

getFileFieldURL(entityId, fieldName)

Returns the download URL for a file attachment.

Signature

```
public static String getFileFieldURL(String entityId, String fieldName)
```

Parameters

entityId
Type: String

Specifies the ID of the entity that holds the file data.

fieldName
Type: String

Specifies the API name of a file field component, such as `AttachmentBody`.

Return Value

Type: String

Usage

Example:

Example

```
String fileURL =
  URL.getFileFieldURL(
    '087000000000123' ,
    'AttachmentBody');
```

getHost()

Returns the host name of the current URL.

Signature

```
public String getHost()
```

Return Value

Type: String

getOrgDomainUrl()

Returns the canonical URL for your org. For example, `https://yourDomain.my.salesforce.com` or, for orgs without My Domain enabled, `https://yourInstance.salesforce.com`.

Signature

```
public static System.Url getOrgDomainUrl()
```

Return Value

Type: `System.URL`

`getOrgDomainUrl()` always returns the same domain for your org, regardless of context. Use this method to build links to record URLs that work both in Lightning Experience and in Salesforce Classic, or as the domain when making API calls to your org.

Usage

Use `getOrgDomainUrl()` to interact with Salesforce REST and SOAP APIs in Apex code. Get endpoints for User Interface API calls, for creating and customizing picklist value sets and custom fields, and more.

`getOrgDomainUrl()` can access the domain URL only for the org in which the Apex code is running.

You don't need a RemoteSiteSetting for your org to interact with the Salesforce APIs using domain URLs retrieved with this method. To bypass remote site settings, My Domain must be enabled in your org.

Example

This example uses User Interface API to get default values so that you can clone a record.

```
Http h = new Http();
HttpRequest req = new HttpRequest();
req.setEndpoint(Url.getOrgDomainUrl().toExternalForm()
   + '/services/data/v44.0/limits');
req.setMethod('GET');
```

```
req.setHeader('Authorization', 'Bearer ' + UserInfo.getSessionId());
HttpResponse res = h.send(req);
```

SEE ALSO:

- getSalesforceBaseUrl()

`getPath()`

Returns the path portion of the current URL.

Signature

```
public String getPath()
```

Return Value

Type: String

`getPort()`

Returns the port of the current URL.

Signature

```
public Integer getPort()
```

Return Value

Type: Integer

`getProtocol()`

Returns the protocol name of the current URL, such as, `https`.

Signature

```
public String getProtocol()
```

Return Value

Type: String

`getQuery()`

Returns the query portion of the current URL.

Signature

```
public String getQuery()
```

Return Value

Type: String

Usage

Returns `null` if no query portion exists.

getRef()

Returns the anchor of the current URL.

Signature

```
public String getRef()
```

Return Value

Type: String

Usage

Returns `null` if no query portion exists.

getSalesforceBaseUrl()

Returns the URL of the Salesforce instance.

Signature

```
public static System.URL getSalesforceBaseUrl()
```

Return Value

Type: `System.URL`

Returns the host name for the current connection: for example, `https://yourDomain.my.salesforce.com`, `https://yourDomain.lightning.force.com`, or, for orgs without My Domain enabled, `https://yourInstance.salesforce.com` or `https://yourInstance.lightning.force.com`.

SEE ALSO:

- getOrgDomainUrl()

getUserInfo()

Gets the UserInfo portion of the current URL.

Signature

```
public String getUserInfo()
```

Return Value

Type: String

Usage

Returns `null` if no UserInfo portion exists.

sameFile(URLToCompare)

Compares the current URL with the specified URL object, excluding the fragment component.

Signature

```
public Boolean sameFile(System.URL URLToCompare)
```

Parameters

URLToCompare
Type: System.URL

Return Value

Type: Boolean

Returns `true` if both URL objects reference the same remote resource; otherwise, returns `false`.

Usage

For more information about the syntax of URIs and fragment components, see RFC3986.

toExternalForm()

Returns a string representation of the current URL.

Signature

```
public String toExternalForm()
```

Return Value

Type: String

UserInfo Class

Contains methods for obtaining information about the context user.

Namespace

System

UserInfo Methods

The following are methods for `UserInfo`. All methods are static.

IN THIS SECTION:

getDefaultCurrency()
Returns the context user's default currency code for multiple currency organizations or the organization's currency code for single currency organizations.

getFirstName()
Returns the context user's first name

getLanguage()
Returns the context user's language

getLastName()
Returns the context user's last name

getLocale()
Returns the context user's locale.

getName()
Returns the context user's full name. The format of the name depends on the language preferences specified for the organization.

getOrganizationId()
Returns the context organization's ID.

getOrganizationName()
Returns the context organization's company name.

getProfileId()
Returns the context user's profile ID.

getSessionId()
Returns the session ID for the current session.

getTimeZone()
Returns the current user's local time zone.

getUiTheme()
Returns the preferred theme for the current user. Use `getUiThemeDisplayed` to determine the theme actually displayed to the current user.

getUiThemeDisplayed()
Returns the theme being displayed for the current user.

getUserEmail()
Returns the current user's email address.

getUserId()
Returns the context user's ID

getUserName()
Returns the context user's login name.

getUserRoleId()
Returns the context user's role ID.

getUserType()
Returns the context user's type.

isCurrentUserLicensed(namespace)
Returns `true` if the context user has a license to the managed package denoted by the namespace. Otherwise, returns `false`.

isMultiCurrencyOrganization()
Specifies whether the organization uses multiple currencies.

getDefaultCurrency()

Returns the context user's default currency code for multiple currency organizations or the organization's currency code for single currency organizations.

Signature

```
public static String getDefaultCurrency()
```

Return Value

Type: String

Usage

Note: For Apex saved using Salesforce API version 22.0 or earlier, `getDefaultCurrency` returns `null` for single currency organizations.

getFirstName()

Returns the context user's first name

Signature

```
public static String getFirstName()
```

Return Value

Type: String

getLanguage()

Returns the context user's language

Signature

```
public static String getLanguage()
```

Return Value

Type: String

getLastName()

Returns the context user's last name

Signature

```
public static String getLastName()
```

Return Value

Type: String

getLocale()

Returns the context user's locale.

Signature

```
public static String getLocale()
```

Return Value

Type: String

Example

```
String result = UserInfo.getLocale();
System.assertEquals('en_US', result);
```

getName()

Returns the context user's full name. The format of the name depends on the language preferences specified for the organization.

Signature

```
public static String getName()
```

Return Value

Type: String

Usage

The format is one of the following:

- FirstName LastName
- LastName, FirstName

getOrganizationId()

Returns the context organization's ID.

Signature

```
public static String getOrganizationId()
```

Return Value

Type: String

getOrganizationName()

Returns the context organization's company name.

Signature

```
public static String getOrganizationName()
```

Return Value

Type: String

getProfileId()

Returns the context user's profile ID.

Signature

```
public static String getProfileId()
```

Return Value

Type: String

getSessionId()

Returns the session ID for the current session.

Signature

```
public static String getSessionId()
```

Return Value

Type: String

Usage

You can use `getSessionId()` both synchronously and asynchronously. In asynchronous Apex (Batch, Future, Queueable, or Scheduled Apex), this method returns the session ID only when the code is run by an active, valid user. When the code is run by an internal user, such as the automated process user or a proxy user, the method returns `null`.

As a best practice, ensure that your code handles both cases: when a session ID is or is not available.

getTimeZone()

Returns the current user's local time zone.

Signature

```
public static System.TimeZone getTimeZone()
```

Return Value

Type: System.TimeZone

Example

```
TimeZone tz =
  UserInfo.getTimeZone();
System.debug(
  'Display name: ' +
  tz.getDisplayName());
System.debug(
  'ID: ' +
  tz.getID());
```

getUiTheme()

Returns the preferred theme for the current user. Use `getUiThemeDisplayed` to determine the theme actually displayed to the current user.

Signature

```
public static String getUiTheme()
```

Return Value

Type: String

The preferred theme for the current user.

Valid values include:

- `Theme1`—Obsolete Salesforce theme
- `Theme2`—Salesforce Classic 2005 user interface theme
- `Theme3`—Salesforce Classic 2010 user interface theme
- `Theme4d`—Modern "Lightning Experience" Salesforce theme
- `Theme4t`—Salesforce mobile app theme

- `Theme4u`—Lightning Console theme
- `PortalDefault`—Salesforce Customer Portal theme
- `Webstore`—Salesforce AppExchange theme

`getUiThemeDisplayed()`

Returns the theme being displayed for the current user.

Signature

```
public static String getUiThemeDisplayed()
```

Return Value

Type: String

The theme being displayed for the current user

Valid values include:

- `Theme1`—Obsolete Salesforce theme
- `Theme2`—Salesforce Classic 2005 user interface theme
- `Theme3`—Salesforce Classic 2010 user interface theme
- `Theme4d`—Modern "Lightning Experience" Salesforce theme
- `Theme4t`—Salesforce mobile app theme
- `Theme4u`—Lightning Console theme
- `PortalDefault`—Salesforce Customer Portal theme
- `Webstore`—Salesforce AppExchange theme

`getUserEmail()`

Returns the current user's email address.

Signature

```
public static String getUserEmail()
```

Return Value

Type: String

Example

```
String emailAddress =
  UserInfo.getUserEmail();
System.debug(
  'Email address: ' +
  emailAddress);
```

getUserId()

Returns the context user's ID

Signature

```
public static String getUserId()
```

Return Value

Type: String

getUserName()

Returns the context user's login name.

Signature

```
public static String getUserName()
```

Return Value

Type: String

getUserRoleId()

Returns the context user's role ID.

Signature

```
public static String getUserRoleId()
```

Return Value

Type: String

getUserType()

Returns the context user's type.

Signature

```
public static String getUserType()
```

Return Value

Type: String

isCurrentUserLicensed(namespace)

Returns `true` if the context user has a license to the managed package denoted by the namespace. Otherwise, returns `false`.

Signature

```
public static Boolean isCurrentUserLicensed(String namespace)
```

Parameters

namespace
Type: String

Return Value

Type: Boolean

Usage

A `TypeException` is thrown if *namespace* is an invalid parameter.

`isMultiCurrencyOrganization()`

Specifies whether the organization uses multiple currencies.

Signature

```
public static Boolean isMultiCurrencyOrganization()
```

Return Value

Type: Boolean

UserManagement Class

Contains methods to manage end users, for example, to register verification methods or handle requests for Salesforce to forget them.

Namespace

System

Usage

Use the `register` and `deregister` methods to for your users to register and deregister identity verification methods. Use the `obfuscateUser` method to scramble user object data on a user's request. Use the `formatPhoneNumber` method to ensure the phone number properly formatted.

This class is introduced in API version 43.0. It isn't available in earlier versions.

IN THIS SECTION:

UserManagement Methods

UserManagement Methods

The following are methods for `UserManagement`.

IN THIS SECTION:

clone()
Makes a duplicate copy of the System.UserManagement object.

deregisterVerificationMethod(userId, method)
Deregisters an identity verification method. Use this method to allow users to delete an existing verification method.

formatPhoneNumber(countryCode, phoneNumber)
Formats a mobile phone number for a user. Call this method to ensure that the phone number is formatted properly before updating a user's mobile phone number.

obfuscateUser(userId, username)
Scrambles users' data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it. Use this method to set the username to a specific value after it's scrambled.

obfuscateUser(userId)
Scrambles users' data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it.

registerVerificationMethod(method, startUrl)
Registers an identity verification method. Verification methods include a time-based one-time password, email or text one-time password, Salesforce Authenticator, or U2F. End users register their verification methods.

clone()

Makes a duplicate copy of the System.UserManagement object.

Signature

```
public Object clone()
```

Return Value

Type: User Management

deregisterVerificationMethod(userId, method)

Deregisters an identity verification method. Use this method to allow users to delete an existing verification method.

Signature

```
public static void deregisterVerificationMethod(Id userId, Auth.VerificationMethod
method)
```

Parameters

userId
Type: Id

User ID of the user deregistering the verification method.

method
Type: Auth.VerificationMethod

Verification method used to verify the identity of the user.

Return Value

Type: void

Usage

Use this method to deregister an existing identity verification method. For example, your users can deregister a phone number when their phone number changes. While only end users can register an identity verification method, you and your users can deregister one. Keep this behavior in mind when you implement a custom registration page.

This method is introduced in API version 43.0. It isn't available in earlier versions.

formatPhoneNumber(countryCode, phoneNumber)

Formats a mobile phone number for a user. Call this method to ensure that the phone number is formatted properly before updating a user's mobile phone number.

Signature

```
global static String formatPhoneNumber(String countryCode, String phoneNumber)
```

Parameters

countryCode
Type: String

A valid country code.

phoneNumber
Type: String

A mobile number that contains from 3 through 49 numeric characters, without the country code. For example, (415) 555-1234.

Return Value

Type: String

Returns a user's mobile phone number in the proper format.

Usage

Use this method to ensure a user's mobile phone number is formatted as required by Salesforce. Then use the method's return value to update the `mobile` field of the user's record. This mobile number is used for SMS-based identity confirmation. For example, mobile phone numbers are stored along with other identity verification methods in Auth.VerificationMethod enum. This method is introduced in API version 43.0. It isn't available in earlier versions.

Here are some acceptable ways that users can enter their mobile number:

- +1, (415) 555-1234 (with plus signs, parentheses, and dashes)
- 1, 4155551234 (only numbers, no symbols)
- 1 , 415-555-1234 (extra spaces)

Now, consider the following examples.

- Correct examples:
  - `formatPhoneNumber('1', '4155551234');`
  - `formatPhoneNumber('+1','(415) 555-1234');`
  - `formatPhoneNumber('1', '415-555-1234');`
- Incorrect example, because the country code and mobile number aren't separated:
  - `formatPhoneNumber(null, '+1 415-555-1234');`
- Example that doesn't generate an error, but likely won't work as intended:
  - `formatPhoneNumber('+1', '+1 (415) 555-1234');`

Format Phone Number Code Example

Here's a code example that uses the `formatPhoneNumber` method. It gets the mobile number from the user and converts it to the format required by Salesforce. Then it updates the user's record with the formatted mobile number.

```
global with sharing class PhoneRegistrationController {
    //Input variables
    global String countryCode {get; set;}
    global String phoneNumber {get; set;}

    global String addPhoneNumber()
    {
        if(countryCode == null) return 'Country code is required';
        if(phoneNumber == null) return 'Phone number is required';

        String userId = UserInfo.getUserId();
        User u = [SELECT Id FROM User WHERE Id=:userId LIMIT 1];
       String formatNum = System.UserManagement.formatPhoneNumber(countryCode, phoneNumber);

        u.MobilePhone = formatNum;
        update u;
        return null;
    }

}
```

As long as the country code and phone number are separated, `formatPhoneNumber` returns a value in the proper format.

obfuscateUser(userId, username)

Scrambles users' data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it. Use this method to set the username to a specific value after it's scrambled.

Signature

```
public static void obfuscateUser(Id userId, String username)
```

Parameters

userId
Type: Id

ID of the user whose data this method scrambles.

username
Type: String

The username after the user's data is scrambled. Sets the value of the scrambled username to a specific string.

Return Value

Type: void

Usage

This method is introduced in API version 43.0. It isn't available in earlier versions.

You can use the `obfuscateUser` method to protect the personal information of your org's users. When invoked, Salesforce permanently scrambles the user's object data and replaces it with random character strings. The user's detail page exists, but the fields contain meaningless strings of characters. Salesforce merely obfuscates (scrambles) personal data because you can't delete a user in Salesforce; you can only disable or deactivate a user. In other words, the user record remains in the database and this method performs a soft delete.

Note: Take care when using this method. The users' data becomes anonymous and can never be recovered.

Considerations

- This method requires that the org's User Management setting, **Scramble Specific Users' Data**, is enabled from Setup.
- This method affects the standard fields of the user object—excluding a few fields such as the user ID, timezone, locale, and profile.
- It is recommended that you note the user's ID and other attributes for post processing, such as the email address, if you want to send the user a confirmation.
- This method changes only the user object. The association between the user and other objects is removed, but no other objects are changed. For example, contact, ThirdPartyAccountLink (TPAL), and user password authentication (UPA) objects remain unchanged.

Note: Assure your admins that invoking this method doesn't trigger an email change notification.

This method is part of our effort to protect users' personal data and privacy. For more information on what you can do to actively protect user data, see Data Protection and Privacy in Salesforce Help.

`obfuscateUser(userId)`

Scrambles users' data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it.

Signature

```
public static void obfuscateUser(Id userId)
```

Parameters

userId
Type: Id

ID of the user whose data this method scrambles.

Return Value

Type: void

Usage

This method is introduced in API version 43.0. It isn't available in earlier versions.

You can use the `obfuscateUser` method to protect the personal information of your org's users. When invoked, Salesforce permanently scrambles the user's object data and replaces it with random character strings. The user's detail page exists, but the fields contain meaningless strings of characters. Salesforce merely obfuscates (scrambles) personal data because you can't delete a user in Salesforce; you can only disable or deactivate a user. In other words, the user record remains in the database and this method performs a soft delete.

Note: Take care when using this method. The users' data becomes anonymous and can never be recovered.

Considerations

- This method requires that the org's User Management setting, **Scramble Specific Users' Data**, is enabled from Setup.
- This method affects the standard fields of the user object—excluding a few fields such as the user ID, timezone, locale, and profile.
- It is recommended that you note the user's ID and other attributes for post processing, such as the email address, if you want to send the user a confirmation.
- This method changes only the user object. The association between the user and other objects is removed, but no other objects are changed. For example, contact, ThirdPartyAccountLink (TPAL), and user password authentication (UPA) objects remain unchanged.

Note: Assure your admins that invoking this method doesn't trigger an email change notification.

This method is part of our effort to protect users' personal data and privacy. For more information on what you can do to actively protect user data, see Data Protection and Privacy in Salesforce Help.

ObfuscateUser Code Example

```
public class UserManagementController{
    public List <User> users {get; set;}

    public UserManagementController()
    {
        Profile p = [select id from profile where name = 'Customer Community User'];

        users = [select username, id from User where profileId=:p.id AND isactive=true];
    }

    //Use method with extreme caution. Data can't be recovered.
    @InvocableMethod(label='User Management' description='Obfuscate User data and more')
    static public void obfuscate(List<User> users)
    {
        String uid = ApexPages.currentPage().getParameters().get('uid');

        if(uid == null)
            return;
```

```
        User u = [select contactId from user where id=:uid];

        System.UserManagement.obfuscateUser(uid);

        if(u.contactId != null)
        {
           List <Contact> contacts = [select id from Contact where id=:u.contactId LIMIT 1];
            if (contacts == null || contacts.isEmpty() == true)
            return;

            delete contacts;
        }
    }
}
```

registerVerificationMethod(method, startUrl)

Registers an identity verification method. Verification methods include a time-based one-time password, email or text one-time password, Salesforce Authenticator, or U2F. End users register their verification methods.

Signature

```
public static System.PageReference registerVerificationMethod(Auth.VerificationMethod
method, String startUrl)
```

Parameters

method
Type: Auth.VerificationMethod

Verification method used to verify the identity of the user.

startUrl
Type: String

Path to the page that users see after they log in.

Return Value

Type:System.PageReference

Usage

Use this method to enable users to complete identity verification, such as 2FA, or to log in to their community without a password. Users register these methods to verify their identity when logging in. You create a custom registration page when implementing mobile-friendly passwordless logins. See passwordlessLogin.

The `PageReference` returned by `registerVerificationMethod` redirects the user to the Salesforce verification page. If the user enters the correct code, the user is redirected to the community page specified by the start URL. For example:

```
PageReference pr =
System.UserManagement.registerVerificationMethod(Auth.VerificationMethod.TOTP,startUrl);
PageReference p =
```

```
System.UserManagement.deregisterVerificationMethod(userId,Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
```

This method is introduced in API version 43.0. It isn't available in earlier versions.

Note: As a security measure, when users add or update mobile numbers in Advanced User Details, they must log in again to verify their identity. As a result, unsaved changes in the app are lost. To disable this security measure, contact Salesforce Support.

Version Class

Use the Version methods to get the version of a managed package of a subscriber and to compare package versions.

Namespace

System

Usage

A package version is a number that identifies the set of components uploaded in a package. The version number has the format *majorNumber.minorNumber.patchNumber* (for example, 2.1.3). The major and minor numbers increase to a chosen value during every major release. The *patchNumber* is generated and updated only for a patch release.

A called component can check the version against which the caller was compiled using the `System.requestVersion` method and behave differently depending on the caller's expectations. This allows you to continue to support existing behavior in classes and triggers in previous package versions while continuing to evolve the code.

The value returned by the `System.requestVersion` method is an instance of this class with a two-part version number containing a major and a minor number. Since the `System.requestVersion` method doesn't return a patch number, the patch number in the returned Version object is null.

The `System.Version` class can also hold also a three-part version number that includes a patch number.

Example

This example shows how to use the methods in this class, along with the `requestVersion` method, to determine the managed package version of the code that is calling your package.

```
if (System.requestVersion() == new Version(1,0))
{
    // Do something
}
if ((System.requestVersion().major() == 1)
     && (System.requestVersion().minor() > 0)
     && (System.requestVersion().minor() <=9))
{
    // Do something different for versions 1.1 to 1.9
}
else if (System.requestVersion().compareTo(new Version(2,0)) >= 0)
{
    // Do something completely different for versions 2.0 or greater
}
```

IN THIS SECTION:

Version Constructors

Version Methods

Version Constructors

The following are constructors for `Version`.

IN THIS SECTION:

Version(major, minor)

Creates a new instance of the `Version` class as a two-part package version using the specified major and minor version numbers.

Version(major, minor, patch)

Creates a new instance of the `Version` class as a three-part package version using the specified major, minor, and patch version numbers.

`Version(major, minor)`

Creates a new instance of the `Version` class as a two-part package version using the specified major and minor version numbers.

Signature

```
public Version(Integer major, Integer minor)
```

Parameters

major
Type: Integer

The major version number.

minor
Type: Integer

The minor version number.

`Version(major, minor, patch)`

Creates a new instance of the `Version` class as a three-part package version using the specified major, minor, and patch version numbers.

Signature

```
public Version(Integer major, Integer minor, Integer patch)
```

Parameters

major
Type: Integer

The major version number.

minor
Type: Integer

The minor version number.

patch
Type: Integer

The patch version number.

Version Methods

The following are methods for `Version`. All are instance methods.

IN THIS SECTION:

compareTo(version)
Compares the current version with the specified version.

major()
Returns the major package version of the of the calling code.

minor()
Returns the minor package version of the calling code.

patch()
Returns the patch package version of the calling code or `null` if there is no patch version.

compareTo(version)

Compares the current version with the specified version.

Signature

```
public Integer compareTo(System.Version version)
```

Parameters

version
Type: System.Version

Return Value

Type: Integer

Returns one of the following values:

- zero if the current package version is equal to the specified package version
- an Integer value greater than zero if the current package version is greater than the specified package version
- an Integer value less than zero if the current package version is less than the specified package version

Usage

If a two-part version is being compared to a three-part version, the patch number is ignored and the comparison is based only on the major and minor numbers.

`major()`

Returns the major package version of the of the calling code.

Signature

```
public Integer major()
```

Return Value

Type: Integer

`minor()`

Returns the minor package version of the calling code.

Signature

```
public Integer minor()
```

Return Value

Type: Integer

`patch()`

Returns the patch package version of the calling code or `null` if there is no patch version.

Signature

```
public Integer patch()
```

Return Value

Type: Integer

WebServiceCallout Class

Enables making callouts to SOAP operations on an external Web service. This class is used in the Apex stub class that is auto-generated from a WSDL.

Namespace

System

IN THIS SECTION:

WebServiceCallout Methods

SEE ALSO:

SOAP Services: Defining a Class from a WSDL Document

WebServiceCallout Methods

The following is the static method for `WebServiceCallout`.

IN THIS SECTION:

invoke(stub, request, response, infoArray)
Invokes an external SOAP web service operation based on an Apex class that is auto-generated from a WSDL.

`invoke(stub, request, response, infoArray)`

Invokes an external SOAP web service operation based on an Apex class that is auto-generated from a WSDL.

Signature

```
public static void invoke(Object stub, Object request, Map<String,Object> response,
List<String> infoArray)
```

Parameters

`stub`
Type: Object

An instance of the Apex class that is auto-generated from a WSDL (the stub class).

`request`
Type: Object

The request to the external service. The request is an instance of a type that is created as part of the auto-generated stub class.

`response`
Type: Map<String, Object>

A map of key-value pairs that represent the response that the external service sends after receiving the request. In each pair, the key is a response identifier. The value is the response object, which is an instance of a type that is created as part of the auto-generated stub class.

`infoArray`
Type: String[]

An array of strings that contains information about the callout—web service endpoint, SOAP action, request, and response. The order of the elements in the array matters.

- Element at index 0 (`[0]`): One of the following options for identifying the URL of the external web service.
  - Endpoint URL. For example: `'http://YourServer/YourService'`
  - Named credential URL, which contains the scheme `callout`, the name of the named credential, and optionally, an appended path. For example: `'callout:MyNamedCredential/some/path'`

- Element at index 1 (`[1]`): The SOAP action. For example: `'urn:dotnet.calloutest.soap.sforce.com/EchoString'`
- Element at index 2 (`[2]`): The request namespace. For example: `'http://doc.sample.com/docSample'`
- Element at index 3 (`[3]`): The request name. For example: `'EchoString'`
- Element at index 4 (`[4]`): The response namespace. For example: `'http://doc.sample.com/docSample'`
- Element at index 5 (`[5]`): The response name. For example: `'EchoStringResponse'`
- Element at index 6 (`[6]`): The response type. For example: `'docSample.EchoStringResponse_element'`

Return Value

Type: Void

SEE ALSO:

Named Credentials as Callout Endpoints

WebServiceMock Interface

Enables sending fake responses when testing Web service callouts of a class auto-generated from a WSDL.

Namespace

System

Usage

For an implementation example, see Test Web Service Callouts on page 496.

WebServiceMock Methods

The following are methods for `WebServiceMock`.

IN THIS SECTION:

doInvoke(stub, soapRequest, responseMap, endpoint, soapAction, requestName, responseNamespace, responseName, responseType)
The implementation of this method is called by the Apex runtime to send a fake response when a Web service callout is made after `Test.setMock` has been called.

doInvoke(stub, soapRequest, responseMap, endpoint, soapAction, requestName, responseNamespace, responseName, responseType)

The implementation of this method is called by the Apex runtime to send a fake response when a Web service callout is made after `Test.setMock` has been called.

Signature

```
public Void doInvoke(Object stub, Object soapRequest, Map<String,Object> responseMap,
String endpoint, String soapAction, String requestName, String responseNamespace, String
responseName, String responseType)
```

Parameters

stub
Type: Object

An instance of the auto-generated class.

soapRequest
Type: Object

The SOAP Web service request being invoked.

responseMap
Type: Map<String, Object>

A collection of key/value pairs representing the response to send for the request.

When implementing this interface, set the *responseMap* argument to a key/value pair representing the response desired.

endpoint
Type: String

The endpoint URL for the request.

soapAction
Type: String

The requested SOAP operation.

requestName
Type: String

The requested SOAP operation name.

responseNamespace
Type: String

The response namespace.

responseName
Type: String

The name of the response element as defined in the WSDL.

responseType
Type: String

The class for the response as defined in the auto-generated class.

Return Value

Type: Void

Usage

`XmlStreamReader` Class

The `XmlStreamReader` class provides methods for forward, read-only access to XML data. You can pull data from XML or skip unwanted events. You can parse nested XML content that's up to 50 nodes deep.

Namespace

System

Usage

The `XmlStreamReader` class is similar to the XMLStreamReader utility class from StAX.

Note: The `XmlStreamReader` class in Apex is based on its counterpart in Java. See `the Java XMLStreamReader class`.

IN THIS SECTION:

XmlStreamReader Constructors

XmlStreamReader Methods

SEE ALSO:

Reading XML Using Streams

XmlStreamReader Constructors

The following are constructors for `XmlStreamReader`.

IN THIS SECTION:

XmlStreamReader(xmlInput)
Creates a new instance of the `XmlStreamReader` class for the specified XML input.

`XmlStreamReader(xmlInput)`

Creates a new instance of the `XmlStreamReader` class for the specified XML input.

Signature

```
public XmlStreamReader(String xmlInput)
```

Parameters

`xmlInput`
Type: String

The XML string input.

XmlStreamReader Methods

The following are methods for `XmlStreamReader`. All are instance methods.

IN THIS SECTION:

getAttributeCount()
Returns the number of attributes on the start element, excluding namespace definitions.

getAttributeLocalName(index)

Returns the local name of the attribute at the specified index.

getAttributeNamespace(index)

Returns the namespace URI of the attribute at the specified index.

getAttributePrefix(index)

Returns the prefix of this attribute at the specified index.

getAttributeType(index)

Returns the XML type of the attribute at the specified index.

getAttributeValue(namespaceUri, localName)

Returns the value of the attribute in the specified *localName* at the specified URI.

getAttributeValueAt(index)

Returns the value of the attribute at the specified index.

getEventType()

Returns the type of XML event the cursor is pointing to.

getLocalName()

Returns the local name of the current event.

getLocation()

Return the current location of the cursor.

getNamespace()

If the current event is a start element or end element, this method returns the URI of the prefix or the default namespace.

getNamespaceCount()

Returns the number of namespaces declared on a start element or end element.

getNamespacePrefix(index)

Returns the prefix for the namespace declared at the index.

getNamespaceURI(prefix)

Return the URI for the given prefix.

getNamespaceURIAt(index)

Returns the URI for the namespace declared at the index.

getPIData()

Returns the data section of a processing instruction.

getPITarget()

Returns the target section of a processing instruction.

getPrefix()

Returns the prefix of the current XML event or `null` if the event does not have a prefix.

getText()

Returns the current value of the XML event as a string.

getVersion()

Returns the XML version specified on the XML declaration. Returns `null` if none was declared.

hasName()

Returns `true` if the current XML event has a name. Returns `false` otherwise.

hasNext()

Returns `true` if there are more XML events and `false` if there are no more XML events.

hasText()

Returns `true` if the current event has text, `false` otherwise.

isCharacters()

Returns `true` if the cursor points to a character data XML event. Otherwise, returns `false`.

isEndElement()

Returns `true` if the cursor points to an end tag. Otherwise, it returns `false`.

isStartElement()

Returns `true` if the cursor points to a start tag. Otherwise, it returns `false`.

isWhiteSpace()

Returns `true` if the cursor points to a character data XML event that consists of all white space. Otherwise it returns `false`.

next()

Reads the next XML event. A processor may return all contiguous character data in a single chunk, or it may split it into several chunks. Returns an integer which indicates the type of event.

nextTag()

Skips any white space (the `isWhiteSpace` method returns `true`), comment, or processing instruction XML events, until a start element or end element is reached. Returns the index for that XML event.

setCoalescing(returnAsSingleBlock)

If you specify `true` for *`returnAsSingleBlock`*, text is returned in a single block, from a start element to the first end element or the next start element, whichever comes first. If you specify it as `false`, the parser may return text in multiple blocks.

setNamespaceAware(isNamespaceAware)

If you specify `true` for *`isNamespaceAware`*, the parser recognizes namespace. If you specify it as `false`, the parser does not. The default value is `true`.

toString()

Returns a string containing the length of the input XML given to `XmlStreamReader` and the first 50 characters of the input XML.

`getAttributeCount()`

Returns the number of attributes on the start element, excluding namespace definitions.

Signature

```
public Integer getAttributeCount()
```

Return Value

Type: Integer

Usage

This method is only valid on a start element or attribute XML events. The count for the number of attributes for an attribute XML event starts with zero.

getAttributeLocalName(index)

Returns the local name of the attribute at the specified index.

Signature

```
public String getAttributeLocalName(Integer index)
```

Parameters

index
Type: Integer

Return Value

Type: String

Usage

If there is no name, an empty string is returned. This method is only valid with start element or attribute XML events.

getAttributeNamespace(index)

Returns the namespace URI of the attribute at the specified index.

Signature

```
public String getAttributeNamespace(Integer index)
```

Parameters

index
Type: Integer

Return Value

Type: String

Usage

If no namespace is specified, `null` is returned. This method is only valid with start element or attribute XML events.

getAttributePrefix(index)

Returns the prefix of this attribute at the specified index.

Signature

```
public String getAttributePrefix(Integer index)
```

Parameters

index
Type: Integer

Return Value

Type: String

Usage

If no prefix is specified, `null` is returned. This method is only valid with start element or attribute XML events.

getAttributeType(index)

Returns the XML type of the attribute at the specified index.

Signature

```
public String getAttributeType(Integer index)
```

Parameters

index
Type: Integer

Return Value

Type: String

Usage

For example, `id` is an attribute type. This method is only valid with start element or attribute XML events.

getAttributeValue(namespaceUri, localName)

Returns the value of the attribute in the specified *localName* at the specified URI.

Signature

```
public String getAttributeValue(String namespaceUri, String localName)
```

Parameters

namespaceUri
Type: String

localName
Type: String

Return Value

Type: String

Usage

Returns `null` if the value is not found. You must specify a value for *`localName`*. This method is only valid with start element or attribute XML events.

`getAttributeValueAt(index)`

Returns the value of the attribute at the specified index.

Signature

```
public String getAttributeValueAt(Integer index)
```

Parameters

`index`
Type: Integer

Return Value

Type: String

Usage

This method is only valid with start element or attribute XML events.

`getEventType()`

Returns the type of XML event the cursor is pointing to.

Signature

```
public System.XmlTag getEventType()
```

Return Value

Type: System.XmlTag

`XmlTag` Enum

The values for `XmlTag` are:

- `ATTRIBUTE`
- `CDATA`
- `CHARACTERS`
- `COMMENT`
- `DTD`

- `END_DOCUMENT`
- `END_ELEMENT`
- `ENTITY_DECLARATION`
- `ENTITY_REFERENCE`
- `NAMESPACE`
- `NOTATION_DECLARATION`
- `PROCESSING_INSTRUCTION`
- `SPACE`
- `START_DOCUMENT`
- `START_ELEMENT`

`getLocalName()`

Returns the local name of the current event.

Signature

```
public String getLocalName()
```

Return Value

Type: String

Usage

For start element or end element XML events, it returns the local name of the current element. For the entity reference XML event, it returns the entity name. The current XML event must be start element, end element, or entity reference.

`getLocation()`

Return the current location of the cursor.

Signature

```
public String getLocation()
```

Return Value

Type: String

Usage

If the location is unknown, returns -1. The location information is only valid until the `next` method is called.

`getNamespace()`

If the current event is a start element or end element, this method returns the URI of the prefix or the default namespace.

Signature

```
public String getNamespace()
```

Return Value

Type: String

Usage

Returns `null` if the XML event does not have a prefix.

getNamespaceCount()

Returns the number of namespaces declared on a start element or end element.

Signature

```
public Integer getNamespaceCount()
```

Return Value

Type: Integer

Usage

This method is only valid on a start element, end element, or namespace XML event.

getNamespacePrefix(index)

Returns the prefix for the namespace declared at the index.

Signature

```
public String getNamespacePrefix(Integer index)
```

Parameters

index
Type: Integer

Return Value

Type: String

Usage

Returns `null` if this is the default namespace declaration. This method is only valid on a start element, end element, or namespace XML event.

getNamespaceURI(prefix)

Return the URI for the given prefix.

Signature

```
public String getNamespaceURI(String prefix)
```

Parameters

prefix
Type: String

Return Value

Type: String

Usage

The returned URI depends on the current state of the processor.

getNamespaceURIAt(index)

Returns the URI for the namespace declared at the index.

Signature

```
public String getNamespaceURIAt(Integer index)
```

Parameters

index
Type: Integer

Return Value

Type: String

Usage

This method is only valid on a start element, end element, or namespace XML event.

getPIData()

Returns the data section of a processing instruction.

Signature

```
public String getPIData()
```

Return Value

Type: String

getPITarget()

Returns the target section of a processing instruction.

Signature

```
public String getPITarget()
```

Return Value

Type: String

getPrefix()

Returns the prefix of the current XML event or `null` if the event does not have a prefix.

Signature

```
public String getPrefix()
```

Return Value

Type: String

getText()

Returns the current value of the XML event as a string.

Signature

```
public String getText()
```

Return Value

Type: String

Usage

The valid values for the different events are:

- The string value of a character XML event
- The string value of a comment
- The replacement value for an entity reference. For example, assume `getText` reads the following XML snippet:

```
<!ENTITY
  Title "Salesforce For Dummies" >
     ]>
  <moo a=\"b\">Name &Title;</moo>';
```

The `getText` method returns `Salesforce for Dummies`, not `&Title`.

- The string value of a CDATA section
- The string value for a space XML event
- The string value of the internal subset of the DTD

`getVersion()`

Returns the XML version specified on the XML declaration. Returns `null` if none was declared.

Signature

```
public String getVersion()
```

Return Value

Type: String

`hasName()`

Returns `true` if the current XML event has a name. Returns `false` otherwise.

Signature

```
public Boolean hasName()
```

Return Value

Type: Boolean

Usage

This method is only valid for start element and stop element XML events.

`hasNext()`

Returns `true` if there are more XML events and `false` if there are no more XML events.

Signature

```
public Boolean hasNext()
```

Return Value

Type: Boolean

Usage

This method returns `false` if the current XML event is end document.

hasText()

Returns `true` if the current event has text, `false` otherwise.

Signature

```
public Boolean hasText()
```

Return Value

Type: Boolean

Usage

The following XML events have text: characters, entity reference, comment and space.

isCharacters()

Returns `true` if the cursor points to a character data XML event. Otherwise, returns `false`.

Signature

```
public Boolean isCharacters()
```

Return Value

Type: Boolean

isEndElement()

Returns `true` if the cursor points to an end tag. Otherwise, it returns `false`.

Signature

```
public Boolean isEndElement()
```

Return Value

Type: Boolean

isStartElement()

Returns `true` if the cursor points to a start tag. Otherwise, it returns `false`.

Signature

```
public Boolean isStartElement()
```

Return Value

Type: Boolean

isWhiteSpace()

Returns `true` if the cursor points to a character data XML event that consists of all white space. Otherwise it returns `false`.

Signature

```
public Boolean isWhiteSpace()
```

Return Value

Type: Boolean

next()

Reads the next XML event. A processor may return all contiguous character data in a single chunk, or it may split it into several chunks. Returns an integer which indicates the type of event.

Signature

```
public Integer next()
```

Return Value

Type: Integer

nextTag()

Skips any white space (the `isWhiteSpace` method returns `true`), comment, or processing instruction XML events, until a start element or end element is reached. Returns the index for that XML event.

Signature

```
public Integer nextTag()
```

Return Value

Type: Integer

Usage

This method throws an error if elements other than white space, comments, processing instruction, start elements or stop elements are encountered.

setCoalescing(returnAsSingleBlock)

If you specify `true` for *`returnAsSingleBlock`*, text is returned in a single block, from a start element to the first end element or the next start element, whichever comes first. If you specify it as `false`, the parser may return text in multiple blocks.

Signature

```
public Void setCoalescing(Boolean returnAsSingleBlock)
```

Parameters

returnAsSingleBlock
Type: Boolean

Return Value

Type: Void

setNamespaceAware(isNamespaceAware)

If you specify `true` for *isNamespaceAware*, the parser recognizes namespace. If you specify it as `false`, the parser does not. The default value is `true`.

Signature

```
public Void setNamespaceAware(Boolean isNamespaceAware)
```

Parameters

isNamespaceAware
Type: Boolean

Return Value

Type: Void

toString()

Returns a string containing the length of the input XML given to `XmlStreamReader` and the first 50 characters of the input XML.

Signature

```
public String toString()
```

Return Value

Type: String

XmlStreamWriter Class

The `XmlStreamWriter` class provides methods for writing XML data.

Namespace

System

Usage

You can use the `XmlStreamWriter` class to programmatically construct an XML document, then use HTTP classes to send the document to an external server.

The `XmlStreamWriter` class is similar to the XMLStreamWriter utility class from StAX.

Note: The `XmlStreamWriter` class in Apex is based on its counterpart in Java. See `the Java XMLStreamWriter class`.

IN THIS SECTION:

XmlStreamWriter Constructors

XmlStreamWriter Methods

SEE ALSO:

Http Class

HttpRequest Class

HttpResponse Class

XmlStreamWriter Constructors

The following are constructors for `XmlStreamWriter`.

IN THIS SECTION:

XmlStreamWriter()
Creates a new instance of the `XmlStreamWriter` class.

`XmlStreamWriter()`

Creates a new instance of the `XmlStreamWriter` class.

Signature

```
public XmlStreamWriter()
```

XmlStreamWriter Methods

The following are methods for `XmlStreamWriter`. All are instance methods.

IN THIS SECTION:

close()
Closes this instance of an XmlStreamWriter and free any resources associated with it.

getXmlString()
Returns the XML written by the XmlStreamWriter instance.

setDefaultNamespace(uri)
Binds the specified URI to the default namespace. This URI is bound in the scope of the current START_ELEMENT – END_ELEMENT pair.

writeAttribute(prefix, namespaceUri, localName, value)
Writes an attribute to the output stream.

writeCData(data)
Writes the specified CData to the output stream.

writeCharacters(text)
Writes the specified text to the output stream.

writeComment(comment)
Writes the specified comment to the output stream.

writeDefaultNamespace(namespaceUri)
Writes the specified namespace to the output stream.

writeEmptyElement(prefix, localName, namespaceUri)
Writes an empty element tag to the output stream.

writeEndDocument()
Closes any start tags and writes corresponding end tags to the output stream.

writeEndElement()
Writes an end tag to the output stream, relying on the internal state of the writer to determine the prefix and local name.

writeNamespace(prefix, namespaceUri)
Writes the specified namespace to the output stream.

writeProcessingInstruction(target, data)
Writes the specified processing instruction.

writeStartDocument(encoding, version)
Writes the XML Declaration using the specified XML encoding and version.

writeStartElement(prefix, localName, namespaceUri)
Writes the start tag specified by *localName* to the output stream.

close()

Closes this instance of an XmlStreamWriter and free any resources associated with it.

Signature

```
public Void close()
```

Return Value

Type: Void

getXmlString()

Returns the XML written by the XmlStreamWriter instance.

Signature

```
public String getXmlString()
```

Return Value

Type: String

`setDefaultNamespace(uri)`

Binds the specified URI to the default namespace. This URI is bound in the scope of the current START_ELEMENT – END_ELEMENT pair.

Signature

```
public Void setDefaultNamespace(String uri)
```

Parameters

uri
Type: String

Return Value

Type: Void

`writeAttribute(prefix, namespaceUri, localName, value)`

Writes an attribute to the output stream.

Signature

```
public Void writeAttribute(String prefix, String namespaceUri, String localName, String value)
```

Parameters

prefix
Type: String

namespaceUri
Type: String

localName
Type: String

Specifies the name of the attribute.

value
Type: String

Return Value

Type: Void

`writeCData(data)`

Writes the specified CData to the output stream.

Signature

```
public Void writeCData(String data)
```

Parameters

data
Type: String

Return Value

Type: Void

writeCharacters(text)

Writes the specified text to the output stream.

Signature

```
public Void writeCharacters(String text)
```

Parameters

text
Type: String

Return Value

Type: Void

writeComment(comment)

Writes the specified comment to the output stream.

Signature

```
public Void writeComment(String comment)
```

Parameters

comment
Type: String

Return Value

Type: Void

writeDefaultNamespace(namespaceUri)

Writes the specified namespace to the output stream.

Signature

```
public Void writeDefaultNamespace(String namespaceUri)
```

Parameters

namespaceUri
Type: String

Return Value

Type: Void

writeEmptyElement(prefix, localName, namespaceUri)

Writes an empty element tag to the output stream.

Signature

```
public Void writeEmptyElement(String prefix, String localName, String namespaceUri)
```

Parameters

prefix
Type: String

localName
Type: String

Specifies the name of the tag to be written.

namespaceUri
Type: String

Return Value

Type: Void

writeEndDocument()

Closes any start tags and writes corresponding end tags to the output stream.

Signature

```
public Void writeEndDocument()
```

Return Value

Type: Void

writeEndElement()

Writes an end tag to the output stream, relying on the internal state of the writer to determine the prefix and local name.

Signature

```
public Void writeEndElement()
```

Return Value

Type: Void

writeNamespace(prefix, namespaceUri)

Writes the specified namespace to the output stream.

Signature

```
public Void writeNamespace(String prefix, String namespaceUri)
```

Parameters

prefix
Type: String

namespaceUri
Type: String

Return Value

Type: Void

writeProcessingInstruction(target, data)

Writes the specified processing instruction.

Signature

```
public Void writeProcessingInstruction(String target, String data)
```

Parameters

target
Type: String

data
Type: String

Return Value

Type: Void

writeStartDocument(encoding, version)

Writes the XML Declaration using the specified XML encoding and version.

Signature

```
public Void writeStartDocument(String encoding, String version)
```

Parameters

encoding
Type: String

version
Type: String

Return Value

Type: Void

writeStartElement(prefix, localName, namespaceUri)

Writes the start tag specified by *localName* to the output stream.

Signature

```
public Void writeStartElement(String prefix, String localName, String namespaceUri)
```

Parameters

prefix
Type: String

localName
Type: String

namespaceUri
Type: String

Return Value

Type: Void

TerritoryMgmt Namespace

The `TerritoryMgmt` namespace provides an interface used for territory management.

The following is the interface in the `TerritoryMgmt` namespace.

IN THIS SECTION:

OpportunityTerritory2AssignmentFilter Global Interface
Apex interface that allows an implementing class to assign a single territory to an opportunity.

OpportunityTerritory2AssignmentFilter Global Interface

Apex interface that allows an implementing class to assign a single territory to an opportunity.

Namespace

TerritoryMgmt

Usage

Method called by Opportunity Territory Assignment job to assign territory to opportunity. Input is a list of (up to 1000) opportunityIds that have IsExcludedFromTerritory2Filter=false. Returns a map of OpportunityId to Territory2Id, which is used to update the Territory2Id field on the Opportunity object.

IN THIS SECTION:

OpportunityTerritory2AssignmentFilter Methods

OpportunityTerritory2AssignmentFilter Example Implementation

OpportunityTerritory2AssignmentFilter Methods

The following are methods for `OpportunityTerritory2AssignmentFilter`.

IN THIS SECTION:

getOpportunityTerritory2Assignments(opportunityIds)
Returns the mapping of opportunities to territory IDs. When Salesforce invokes this method, it supplies the list of opportunity IDs, except for opportunities that have been excluded from territory assignment (IsExcludedFromTerritory2Filter=false).

`getOpportunityTerritory2Assignments(opportunityIds)`

Returns the mapping of opportunities to territory IDs. When Salesforce invokes this method, it supplies the list of opportunity IDs, except for opportunities that have been excluded from territory assignment (IsExcludedFromTerritory2Filter=false).

Signature

```
public Map<Id,Id> getOpportunityTerritory2Assignments(List<Id> opportunityIds)
```

Parameters

opportunityIds
Type: List<Id>

Opportunity IDs.

Return Value

Type: Map<Id,Id>

A key value pair associating each Territory ID to an Opportunity ID.

OpportunityTerritory2AssignmentFilter Example Implementation

This is an example implementation of the `TerritoryMgmt.OpportunityTerritory2AssignmentFilter` interface.

```
/*** Apex version of the default logic.
* If opportunity's assigned account is assigned to
*  Case 1: 0 territories in active model
*            then set territory2Id = null
*  Case 2: 1 territory in active model
```

```
*            then set territory2Id = account's territory2Id
*  Case 3: 2 or more territories in active model
*            then set territory2Id = account's territory2Id that is of highest priority.
*           But if multiple territories have same highest priority, then set territory2Id
 = null
*/
global class OppTerrAssignDefaultLogicFilter implements
TerritoryMgmt.OpportunityTerritory2AssignmentFilter {
    /**
     * No-arg constructor.
     */
     global OppTerrAssignDefaultLogicFilter() {}

     /**
      * Get mapping of opportunity to territory2Id. The incoming list of opportunityIds
contains only those with IsExcludedFromTerritory2Filter=false.
      * If territory2Id = null in result map, clear the opportunity.territory2Id if set.
      * If opportunity is not present in result map, its territory2Id remains intact.
      */
    global Map<Id,Id> getOpportunityTerritory2Assignments(List<Id> opportunityIds) {
        Map<Id, Id> OppIdTerritoryIdResult = new Map<Id, Id>();

        // Get the active territory model Id
        Id activeModelId = getActiveModelId();

        if(activeModelId != null){
            List<Opportunity> opportunities =
              [Select Id, AccountId, Territory2Id from Opportunity where Id IN
:opportunityIds];
            Set<Id> accountIds = new Set<Id>();
            // Create set of parent accountIds
            for(Opportunity opp:opportunities){
                if(opp.AccountId != null){
                    accountIds.add(opp.AccountId);
                    }
                }

                Map<Id,Territory2Priority> accountMaxPriorityTerritory =
getAccountMaxPriorityTerritory(activeModelId, accountIds);

            // For each opportunity, assign the highest priority territory if there is no
 conflict, else assign null.
            for(Opportunity opp: opportunities){
               Territory2Priority tp = accountMaxPriorityTerritory.get(opp.AccountId);
               // Assign highest priority territory if there is only 1.
            if((tp != null) && (tp.moreTerritoriesAtPriority == false) && (tp.territory2Id
 != opp.Territory2Id)){
                    OppIdTerritoryIdResult.put(opp.Id, tp.territory2Id);
               }else{
                    OppIdTerritoryIdResult.put(opp.Id, null);
               }
            }
        }
        return OppIdTerritoryIdResult;
```

```
    }

    /**
      * Query assigned territoryIds in active model for given accountIds.
      * Create a map of accountId to max priority territory.
      */
     private Map<Id,Territory2Priority> getAccountMaxPriorityTerritory(Id activeModelId,
Set<Id> accountIds){
        Map<Id,Territory2Priority> accountMaxPriorityTerritory = new
Map<Id,Territory2Priority>();
        for(ObjectTerritory2Association ota:[Select ObjectId, Territory2Id,
Territory2.Territory2Type.Priority from ObjectTerritory2Association where objectId IN

        if(models.size() == 1){
            activeModelId = models.get(0).Id;
        }

        return activeModelId;
    }

    /**
    * Helper class to help capture territory2Id, its priority, and whether there are more
 territories with same priority assigned to the account.
    */
    private class Territory2Priority {
        public Id territory2Id { get; set; }
```

```
        public Integer priority { get; set; }
        public Boolean moreTerritoriesAtPriority { get; set; }

        Territory2Priority(Id territory2Id, Integer priority, Boolean
moreTerritoriesAtPriority){
            this.territory2Id = territory2Id;
            this.priority = priority;
            this.moreTerritoriesAtPriority = moreTerritoriesAtPriority;
        }
    }
}
```

TxnSecurity Namespace

The `TxnSecurity` namespace provides an interface used for transaction security.

The following is the interface and its supporting class in the `TxnSecurity` namespace.

IN THIS SECTION:

Event Class
Contains event information that the `PolicyCondition.evaluate` method uses to evaluate a transaction security policy.

PolicyCondition Interface
Apex interface that allows an implementing class to specify actions to take when certain events occur based on a transaction security policy.

Event Class

Contains event information that the `PolicyCondition.evaluate` method uses to evaluate a transaction security policy.

Namespace

TxnSecurity

Usage

The Event class contains the information needed to determine if the event triggers a Transaction Security policy. Not all class attributes are used for every type of event.

IN THIS SECTION:

Event Constructors

Event Properties

Event Constructors

The following is the constructor for `Event`.

IN THIS SECTION:

Event()
Creates an instance of the `TxnSecurity.Event` class.

Event()

Creates an instance of the `TxnSecurity.Event` class.

Signature

```
public Event()
```

Event Properties

The following are properties for `Event`.

IN THIS SECTION:

action
Specifies the action being taken on the resource for an Entity event. For example, a Login IP resource for an Entity event could have an `action` of `create`. The `action` attribute is not used by any other event type.

data
Contains data used by actions. For example, `data` for a login event includes the login history ID. Returns a map whose keys are the type of event data, like `SourceIp`.

entityId
The ID of any entity associated with the event. For example, the `entityId` of a DataExport event for an Account object contains the Account ID.

entityName
The name of the object the event acts on.

organizationId
The ID of the Salesforce org where the event occurred.

resourceType
The type of resource for the event. For example, an AccessResource event could have a Connected Application as a resource type. Not all event types have resources.

timeStamp
The time the event occurred.

userId
Identifies the user that caused the event.

action

Specifies the action being taken on the resource for an Entity event. For example, a Login IP resource for an Entity event could have an `action` of `create`. The `action` attribute is not used by any other event type.

Signature

```
public String action {get; set;}
```

Property Value

Type: String

data

Contains data used by actions. For example, `data` for a login event includes the login history ID. Returns a map whose keys are the type of event data, like `SourceIp`.

Signature

```
public Map<String,String> data {get; set;}
```

Property Value

Type: Map<String, String>

The following table lists all the available data types. Not all types appear with all event types. The data type values are always string representations. For example, the `isApi` value is a string in the map, but is actually a Boolean value. Convert the value from a string to its true type this way: `Boolean.valueOf(event.data.get('isApi'));`

Key Name	True Value Type	Events Supported
ActionName	`String` Values are: • Convert • Delete • Insert • Undelete • Update • Upsert	Entity
ApiType	`String` (Enum manifested as a String)	DataExport, Login
Application	`String`	AccessResource, DataExport
ClientId	`String` (ID of the client)	DataExport
ConnectedAppId	`String` (ID of the Connected App)	AccessResource, DataExport
ExecutionTime	milliseconds	DataExport
IsApi	`Boolean`	DataExport
IsScheduled	`Boolean`	DataExport
LoginHistoryId	`String`	DataExport, Login
NumberOfRecords	`Integer`	DataExport
PolicyId	`String` (ID of the current policy)	All events

Key Name	True Value Type	Events Supported
SessionLevel	`String` (Enum manifested as a String. Values include `STANDARD` and `HIGH_ASSURANCE`)	AccessResource
SourceIp	`String` (IPV4 Address)	AccessResource
UserName	`String`	Entity

entityId

The ID of any entity associated with the event. For example, the `entityId` of a DataExport event for an Account object contains the Account ID.

Signature

```
public String entityId {get; set;}
```

Property Value

Type: String

entityName

The name of the object the event acts on.

Signature

```
public String entityName {get; set;}
```

Property Value

Type: String

organizationId

The ID of the Salesforce org where the event occurred.

Signature

```
public String organizationId {get; set;}
```

Property Value

Type: String

resourceType

The type of resource for the event. For example, an AccessResource event could have a Connected Application as a resource type. Not all event types have resources.

Signature

```
public String resourceType {get; set;}
```

Property Value

Type: String

timeStamp

The time the event occurred.

Signature

```
public Datetime timeStamp {get; set;}
```

Property Value

Type: Datetime

userId

Identifies the user that caused the event.

Signature

```
public String userId {get; set;}
```

Property Value

Type: String

PolicyCondition Interface

Apex interface that allows an implementing class to specify actions to take when certain events occur based on a transaction security policy.

Namespace

TxnSecurity

Usage

The `evaluate` method is called upon the occurrence of an event monitored by a transaction security policy. A typical implementation first selects the item of interest from the event. Then the item is tested to see if it meets the condition being monitored. If the condition is met, the method returns `true`.

For example, imagine a transaction security policy that checks for the same user logging in more than once. For each login event, the method would check if the user logging in already has a login session in progress, and if so, `true` is returned.

If you're using the policy condition interface in the org where the policy was implemented, test classes for the policy are not required. If you move the policy to another org, you must have test classes for the Apex policy in the new org. Testing is required whether the

policy is moved from a sandbox to production, with a change set, or some other way. Why? If you're making a policy available outside of its development environment, it needs testing to make sure it works correctly.

Don't include DML statements in your custom policies because they can cause errors. When you send a custom email via Apex during transaction policy evaluation, you get an error, even if the record is not explicitly related to another record. For more information, see Apex DML Operations in the *Apex Developer Guide*.

IN THIS SECTION:

PolicyCondition Methods

Apex Policies for Transaction Security
Every Transaction Security policy must implement the Apex `TxnSecurity.PolicyCondition` interface.

PolicyCondition Methods

The following is the method for `PolicyCondition`.

IN THIS SECTION:

evaluate(event)
Evaluates an event against a transaction security policy. If the event triggers the policy, `true` is returned.

`evaluate(event)`

Evaluates an event against a transaction security policy. If the event triggers the policy, `true` is returned.

Signature

```
public Boolean evaluate(TxnSecurity.Event event)
```

Parameters

`event`
Type: TxnSecurity.Event

The event to check against the transaction security policy.

Return Value

Type: Boolean

When the policy is triggered, `True` is returned. For example, let's suppose the policy is to limit users to a single login session. If anyone tries to log in a second time, the policy's action requires that they end their current session. The policy also sends an email notification to the Salesforce admin. The `evaluate()` method only checks the login event, and returns `True` if it's the user's second login. The Transaction Security system performs the action and notification, and not the `evaluate()` method.

Apex Policies for Transaction Security

Every Transaction Security policy must implement the Apex `TxnSecurity.PolicyCondition` interface.

If you didn't specify a condition value before you generated the Apex interface for a policy, you can add the condition later. To change the condition, you can edit the Apex code to include a condition before you activate your policy. If you don't include a condition, your policy isn't triggered.

Don't include DML statements in your custom policies because they can cause errors. When you send a custom email via Apex during transaction policy evaluation, you get an error, even if the record is not explicitly related to another record. For more information, see Apex DML Operations in the *Apex Developer Guide*.

When you delete a transaction security policy, your `TxnSecurity.PolicyCondition` implementation isn't deleted. You can reuse your Apex code in other policies.

EDITIONS

Available in: Salesforce Classic and Lightning Experience

Available in: **Enterprise**, **Performance**, **Unlimited**, and **Developer** Editions

Requires purchasing Salesforce Shield or Salesforce Event Monitoring add-on subscriptions.

IN THIS SECTION:

Apex Transaction Security Implementation Examples
Here are examples of various Apex transaction security implementations.

Apex Transaction Security Implementation Examples

Here are examples of various Apex transaction security implementations.

EDITIONS

Available in: both Salesforce Classic (not available in all orgs) and Lightning Experience

Available in: **Enterprise**, **Performance**, **Unlimited**, and **Developer** Editions

Requires purchasing Salesforce Shield or Salesforce Event Monitoring add-on subscriptions.

Multiple Logins

Example: This example implements a policy that is triggered when someone logs in from different IP addresses in the past 24 hours.

```
global class LoginPolicyCondition implements
TxnSecurity.PolicyCondition {
  public boolean evaluate(TxnSecurity.Event e) {
    AggregateResult[] results = [SELECT SourceIp
                                 FROM LoginHistory
                                 WHERE UserId = :e.userId
                                       AND LoginTime =
LAST_N_DAYS:1
                                 GROUP BY SourceIp];
    if(!results.isEmpty() && results.size() > 1) {
      return true;
    }
    return false;
  }
}
```

Logins from a Specific IP Address

Example: This example implements a policy that is triggered when a session is created from a specific IP address.

```
global class SessionPolicyCondition implements TxnSecurity.PolicyCondition {
 public boolean evaluate(TxnSecurity.Event e) {

   LoginHistory eObj = [SELECT SourceIp FROM LoginHistory WHERE Id =
:e.data.get('LoginHistoryId')];
```

```
    if (eObj.SourceIp == '1.1.1.1') {
     return true;
    }
    return false;
  }
}
```

Data Export

Example: This example implements a policy that triggers when more than 1,000 leads are exported, for example, by the Data Loader. `EntityName` is a field in the event e that contains the name of the entity, such as Account or Contact.

```
global class LeadExportPolicyCondition implements TxnSecurity.PolicyCondition {
  public boolean evaluate(TxnSecurity.Event e) {

    Integer numberOfRecords = Integer.valueOf(e.data.get('NumberOfRecords'));
    String entityName = e.data.get('EntityName');

    if ('Lead'.equals(entityName) && numberOfRecords > 1000) {
      return true;
    }

    return false;
  }
}
```

Report Access

Example: This policy is triggered when someone accesses a report.

```
global class ReportsPolicyCondition implements TxnSecurity.PolicyCondition {
  public boolean evaluate(TxnSecurity.Event e) {
    if(e.data.get('SessionLevel') == 'STANDARD' ){
      return true;
    }
    return false;
  }
}
```

Connected App Access

Example: This policy is triggered when someone accesses a connected app.

```
global class ConnectedAppsPolicyCondition implements TxnSecurity.PolicyCondition {
  public boolean evaluate(TxnSecurity.Event e) {
    if(e.data.get('SessionLevel') == 'STANDARD' && (e.entityId == '0CiD00000004Cce')){

      return true;
    }
    return false;
  }
}
```

Localhost Login

Example: This example uses the IP address in a login policy. The policy is triggered when there's a login from localhost.

From the Transaction Security Policies page, create a policy to block localhost logins. Here is the generated Apex policy:

```
global class BlockLocalhostLoginPolicyCondition implements TxnSecurity.PolicyCondition
 {
  public boolean evaluate(TxnSecurity.Event e) {
    // Get the LoginHistoryId to in turn select the SourceIp address.
    String loginHistoryId = e.data.get('LoginHistoryId');
    // Retrieve SourceIp from LoginHistory.
    LoginHistory eObj =
      [SELECT SourceIp FROM LoginHistory WHERE id = :e.data.get('LoginHistoryId')];
    // If the Source IP is localhost (127.0.0.1), trigger the policy and return true.

    if(eObj.SourceIp == '127.0.0.1') {
      return true;
    }
    return false;
  }
}
```

Large Data Transfer

Example: This policy triggers when 2,000 records or more are downloaded via the API.

An admin or other customer with API privileges can download all customer data in bulk using SOAP API, REST API, or Bulk API. This security policy restricts API-based data downloads to 2,000 records and alerts the admin with a real-time notification if the policy is triggered.

```
global class DataLoaderExportPolicyCondition implements TxnSecurity.PolicyCondition {

  public boolean evaluate(TxnSecurity.Event e) {
    Boolean isApi = Boolean.valueOf(e.data.get('IsApi')) { // For any API request...
    Integer numberOfRecords = Integer.valueOf(e.data.get('NumberOfRecords'));
      if (isApi && numberOfRecords >= 2000) {
        return true;
      }
      return false;
    }
  }
}
```

Confidential Data Access

Example: This policy requires everyone to use two-factor authentication before accessing a specific report.

You can have sensitive, confidential data in your quarterly Salesforce reports. You also want to ensure that teams accessing those reports use two-factor authentication (2FA) for high assurance before viewing this data. The policy makes 2FA a requirement, but you can't provide high-assurance sessions until your teams have a way to meet the 2FA requirements. As a prerequisite, first set up 2FA in your Salesforce environment.

This example highlights the capability of a policy to enforce 2FA for a specific report. The report defined here is any report with "Quarterly Report" in its name. Anyone accessing the report is required to have a high-assurance session using 2FA.

```
global class ConfidentialDataPolicyCondition implements TxnSecurity.PolicyCondition {

  public boolean evaluate(TxnSecurity.Event e) {
```

```
    if (e.resourceType == 'Dashboard') {     // If the event is about Dashboards...
      Dashboard dashboard =
        [SELECT DeveloperName FROM Dashboard WHERE id = :e.entityId];
      String name = String.valueOf(dashboard.DeveloperName);
      // Check if this is a quarterly report.
      if (name.containsIgnoreCase('Quarterly Report')) {
        return true;
      }
    }
    return false;
  }
}
```

Browser Check

Example: This policy triggers when a user with a known operating system and browser combination tries to log in with another browser on a different operating system.

Many organizations have standard hardware and support specific versions of different browsers. You can use this standard to reduce the security risk for high impact individuals by acting when logins take place from unusual devices. For example, your CEO typically logs in from San Francisco using a MacBook or Salesforce mobile application on an iPhone to Salesforce. When a login occurs from elsewhere using a Chromebook, it's highly suspicious. Because hackers do not necessarily know which platforms corporate executives use, this policy makes a security breach less likely.

In this example, the customer organization knows that their CEO is using a MacBook running OS X with the Safari browser. Any attempt to log in using the CEO's credentials with anything else is automatically blocked.

```
global class CeoBrowserAccessPolicyCondition implements TxnSecurity.PolicyCondition {

  public boolean evaluate(TxnSecurity.Event e) {
    // If it's a Login attempt from our CEO's user account.
    if (e.action == 'Login' && e.userId == '005x0000005VmCu') {
      // Get the platform & browser from LoginHistory for this login attempt.
      LoginHistory loginAttempt =
        [SELECT Platform, Browser FROM LoginHistory
         WHERE Id = :e.data.get('LoginHistoryId')];
      String platform = loginAttempt.Platform;
      String browser = loginAttempt.Browser;
      // The policy is triggered when the CEO isn't using Safari on Mac OSX.
      if (!platform.equals('Mac OSX') || !browser.startsWith('Safari')) {
          return true;
      }
    }
    return false;
  }
}
```

Block Logins by Country

Example: This policy blocks access by country.

Your organization could have remote offices and a global presence but, due to international law, wants to restrict access to its Salesforce org.

This example builds a policy that blocks users logging in from North Korea. If users are in North Korea but using a corporate VPN, their VPN gateway would be in Singapore or the United States. The VPN gateway would make their login successful because Salesforce would see the internal U.S.-based company IP address.

```
global class BlockAccessFromNKPolicyCondition implements TxnSecurity.PolicyCondition
{
  public boolean evaluate(TxnSecurity.Event e) {
    // Get the login history.
    LoginHistory loginAttempt =
      [SELECT LoginGeoId FROM LoginHistory WHERE Id = :e.data.get('LoginHistoryId')];

    // Get the login's geographical info.
    String loginGeoId = String.valueOf(loginAttempt.LoginGeoId);
    LoginGeo loginGeo = [SELECT Country FROM LoginGeo WHERE Id = :loginGeoId];
    // Get the country at that location.
    String country = String.valueOf(loginGeo.Country);
    // Trigger policy and block access for any user trying to log in from North Korea.

    if(country.equals('North Korea')) {
        return true;
    }
    return false;
  }
}
```

You can also restrict access to other values, like postal code or city.

Block an Operating System

Example: This policy blocks access for anyone using an older version of the Android OS.

You're concerned with a specific mobile platform's vulnerabilities and its ability to capture screen shots and read data while accessing Salesforce. If the device is not running a security client, you could restrict access from device platforms using operating systems with known and well-identified vulnerabilities. This policy blocks devices using Android 5.0 or earlier.

```
global class BlockOldAndroidDevicesPolicyCondition implements TxnSecurity.PolicyCondition
 {
  public boolean evaluate(TxnSecurity.Event e) {
    LoginHistory loginAttempt =
      [SELECT Platform FROM LoginHistory WHERE Id = :e.data.get('LoginHistoryId')];
    if (loginAttempt != null) {
      String platform = loginHistory.Platform;
      if (platform.contains('Android') && platform.compareTo('Android 5') < 0) {
        return true;
      }
    }
    return false; // Allow access from Android versions greater than 5.
  }
}
```

Block Specific Content

Example: This policy blocks a specified word by searching posted Chatter text.

You can scan or filter for specific words in posts. This example looks for a post containing the word "Salesforce" and blocks those posts. You can also write conditions that loop through a list of words or keep a running total of the occurrence of the words.

```
global class ChatterMessageWordFilterPolicyCondition implements
TxnSecurity.PolicyCondition {
  public boolean evaluate(TxnSecurity.Event event) {
    String body = event.data.get('Body');

    if(body.containsIgnoreCase('Salesforce')) {
      return true;
    }
    return false;
  }
}
```

Note: If you're comparing the contents of the entire post, don't use the `equals` string method. Instead use `contains` or `containsIgnoreCase`, as shown here. If the Chatter settings allow emoticons or rich text, those items are included in the Chatter post's body. For example, with rich text, the post *"This is text."* could be stored as *" This is text. "*. If you use the `equals` method, the embedded tags prevent your otherwise identical comparison text from matching the post body.

Block Profanity

Example: This policy blocks profanity by using an external service.

Advertisers and spammers often post messages to successful communities at high rates to increase their chances of people clicking their links. The links can include unwanted content. You can use technologies outside of Salesforce to scan or filter content based on these different services.

This policy executes an API callout to see if the content is compliant, and uses a service that blocks commonly accepted English profanity as specified at www.purgomalum.com/profanitylist.

```
global class ChatterMessageProfanityFilterPolicyCondition implements
TxnSecurity.PolicyCondition {
  public boolean evaluate(TxnSecurity.Event e) {
    String body = e.data.get('Body');

    //Create HTTPRequest and specify its type and properties.
    HttpRequest request = new HttpRequest();
    request.setMethod('GET');
    request.setHeader('content-type', 'text/plain');
    request.setHeader('Connection', 'keep-alive');
    request.setEndpoint('http://www.purgomalum.com/service/containsprofanity?text=' +

                        EncodingUtil.urlEncode(body,'UTF-8'));

    Http http = new Http();
    HTTPResponse response = http.send(request);

    if (response.getStatusCode() == 200 && response.getBody().equals('true')) {
      return true; // Callout succeeded and found profanity in the message.
    }
    return false;  // Callout failed or no profanity was found.
```

```
    }
}
```

Note: If an API callout's elapsed execution time exceeds 3 seconds, the user is denied access to the resource or entity. For more information, see Transaction Security Metering.

Block a Connected App

Example: This policy blocks a connected app with API access from accessing large amounts data.

Sometimes connected apps have API privileges to access data org-wide due to sharing or account access settings definitions. However, the end user of the connected app is restricted to only a specific dataset. This conflict can result in an increased security risk by identifying the API key and performing command-line searches directly in the database to look for leads. The following policy avoids this situation and data loss around your company's lead information.

```
global class DataLoaderLeadExportPolicyCondition implements TxnSecurity.PolicyCondition
 {
  public boolean evaluate(TxnSecurity.Event e) {
    if (Boolean.valueOf(e.data.get('IsApi'))) {

      // The event data is a Map<String, String>. We need to call the
      // valueOf() method on appropriate data types to use them here.
      String resourceType         = e.data.get('resourceType');
      String connectedAppId       = e.data.get('ConnectedAppId');
      Integer numberOfRecords     = Integer.valueOf(e.data.get('NumberOfRecords'));
      Integer executionTimeMillis = Integer.valueOf(e.data.get('ExecutionTime'));

      // We're looking for leads accessed by a specific connected app that is
      // transferring more than 2,000 records a second - a large transfer.
      if ('Lead'.equals(resourceType) &&
        '0CiD00000004Cce'.equals(connectedAppId) &&
        numberOfRecords > 2000 &&
        executionTimeMillis > 1000) {
          return true;
        }
    }
    return false;
  }
}
```

UserProvisioning Namespace

The `UserProvisioning` namespace provides methods for monitoring outbound user provisioning requests.

The following is the class in the `UserProvisioning` namespace.

IN THIS SECTION:

ConnectorTestUtil Class

Enables developers to write Apex test classes for connectors used by the connected app provisioning solution. This class simulates provisioning for the associated app.

UserProvisioningLog Class

Provides methods for writing messages to monitor outbound user provisioning requests.

UserProvisioningPlugin Class

The `UserProvisioningPlugin` base class implements `Process.Plugin` for programmatic customization of the user provisioning process for connected apps.

ConnectorTestUtil Class

Enables developers to write Apex test classes for connectors used by the connected app provisioning solution. This class simulates provisioning for the associated app.

Namespace

UserProvisioning

Usage

Use this class for connector-based test accelerators. You can invoke it only from within an Apex test.

Example

This example creates an instance of a connected app, gets a value, and checks whether the value is correct. The test is simply a row inserted in the database table.

```
        @isTest
        private class SCIMCreateUserPluginTest {
        public static void callPlugin(Boolean validInputParams) {

        //Create an instance of a connected app
        ConnectedApplication capp
=UserProvisioning.ConnectorTestUtil.createConnectedApp('TestApp');
        Profile p = [SELECT Id FROM Profile WHERE Name='Standard User'];
        //Create a user
        User user = new User(username='testuser1@scimuserprov.test', Firstname= 'Test',
Lastname='User1', email='testuser1@testemail.com',
        FederationIdentifier='testuser1@testemail.com', profileId= p.Id,
communityNickName='tuser1', alias='tuser', TimeZoneSidKey='GMT',
        LocaleSidKey='en_US', EmailEncodingKey='ISO-8859-1', LanguageLocaleKey='en_US');
        //insert user into a row in the database table
        insert user;
        //Create a UPR
        UserProvisioningRequest upr = new UserProvisioningRequest(appname = capp.name,
connectedAppId=capp.id, operation='Create',
        state='New', approvalStatus='NotRequired',salesforceUserId=user.id);

        //Insert the UPR to test the flow end to end
        insert upr;
       }}
```

IN THIS SECTION:

ConnectorTestUtil Method

SEE ALSO:

Salesforce Help: User Provisioning for Connected Apps

ConnectorTestUtil Method

The `ConnectorTestUtil` class has 1 method.

IN THIS SECTION:

createConnectedApp(connectedAppName)
Creates an instance of a connected app to simulate provisioning.

`createConnectedApp(connectedAppName)`

Creates an instance of a connected app to simulate provisioning.

Signature

```
public static ConnectedApplication createConnectedApp(String connectedAppName)
```

Parameters

`connectedAppName`
Type: String

Name of the connected app to test for provisioning.

Return Value

Type: ConnectedApplication

The instance of the connected app to test for provisioning.

UserProvisioningLog Class

Provides methods for writing messages to monitor outbound user provisioning requests.

Namespace

UserProvisioning

Example

This example writes the user account information sent to a third-party system for a provisioning request to the UserProvisioningLog object.

```
String inputParamsStr = 'Input parameters: uprId=' + uprId + ',
endpointURL=' + endpointURL + ', adminUsername=' + adminUsername + ',
```

```
email=' + email + ', username=' + username + ', defaultPassword=' + defaultPassword + ',
defaultRoles =' + defaultRoles;
UserProvisioning.UserProvisioningLog.log(uprId, inputParamsStr);
```

IN THIS SECTION:

UserProvisioningLog Methods

UserProvisioningLog Methods

The following are methods for `UserProvisioningLog`. All methods are static.

IN THIS SECTION:

log(userProvisioningRequestId, details)
Writes a specific message, such as an error message, to monitor the progress of a user provisioning request.

log(userProvisioningRequestId, status, details)
Writes a specific status and message, such a status and detailed error message, to monitor the progress of a user provisioning request.

log(userProvisioningRequestId, externalUserId, externalUserName, userId, details)
Writes a specific message, such as an error message, to monitor the progress of a user provisioning request associated with a specific user.

log(userProvisioningRequestId, details)

Writes a specific message, such as an error message, to monitor the progress of a user provisioning request.

Signature

```
public void log(String userProvisioningRequestId, String details)
```

Parameters

userProvisioningRequestId
Type: String

A unique identifier for the user provisioning request.

details
Type: String

The text for the message.

Return Value

Type: void

log(userProvisioningRequestId, status, details)

Writes a specific status and message, such a status and detailed error message, to monitor the progress of a user provisioning request.

Signature

```
public void log(String userProvisioningRequestId, String status, String details)
```

Parameters

userProvisioningRequestId
Type: String

A unique identifier for the user provisioning request.

status
Type: String

A description of the current state. For example, while invoking a third-party API, the status could be `invoke`.

details
Type: String

The text for the message.

Return Value

Type: void

log(userProvisioningRequestId, externalUserId, externalUserName, userId, details)

Writes a specific message, such as an error message, to monitor the progress of a user provisioning request associated with a specific user.

Signature

```
public void log(String userProvisioningRequestId, String externalUserId, String
externalUserName, String userId, String details)
```

Parameters

userProvisioningRequestId
Type: String

A unique identifier for the user provisioning request.

externalUserId
Type: String

The unique identifier for the user in the target system.

externalUserName
Type: String

The username for the user in the target system.

userId
Type: String

Salesforce ID of the user making the request.

details
Type: String

The text for the message.

Return Value

Type: void

UserProvisioningPlugin Class

The `UserProvisioningPlugin` base class implements `Process.Plugin` for programmatic customization of the user provisioning process for connected apps.

Namespace

UserProvisioning

Usage

Extending this class gives you a plug-in that can be used in the Flow designer as an Apex plug-in, with the following input and output parameters.

Input Parameter Name	Description
`userProvisioningRequestId`	The unique ID of the request for the plug-in to process.
`userId`	The ID of the associated user for the request.
`NamedCredDevName`	The unique API name for the named credential to use for a request. The named credential identifies the third-party system and the third-party authentication settings. When the named credential is set in the User Provisioning Wizard, Salesforce stores the value in the `UserProvisioningConfig.NamedCredentialId` field.
`reconFilter`	When collecting and analyzing users on a third-party system, the plug-in uses this filter to limit the scope of the collection. When the filter is set in the User Provisioning Wizard, Salesforce stores the value in the `UserProvisioningConfig.ReconFilter` field.
`reconOffset`	When collecting and analyzing users on a third-party system, the plug-in uses this value as the starting point for the collection.

Output Parameter Name	Description
`Status`	The vendor-specific status of the provisioning operation on the third-party system.

Output Parameter Name	Description
`Details`	The vendor-specific message related to the status of the provisioning operation on the third-party system.
`ExternalUserId`	The vendor-specific ID for the associated user on the third-party system.
`ExternalUsername`	The vendor-specific username for the associated user on the third-party system.
`ExternalEmail`	The email address assigned to the user on the third-party system.
`ExternalFirstName`	The first name assigned to the user on the third-party system.
`ExternalLastName`	The last name assigned to the user on the third-party system.
`reconState`	The state of the collecting and analyzing process on the third-party system. When the value is `complete`, the process is finished and a subsequent call to the plug-in is no longer needed, nor made.
`nextReconOffset`	When collecting and analyzing users on a third-party system, the process may encounter a transaction limit and have to stop before finishing. The value specified here initiates a call to the plug-in with a new quota limit.

If you want to add more custom parameters, use the `buildDescribeCall()` method.

Example

The following example uses the `buildDescribeCall()` method to add a new input parameter and a new output parameter. The example also demonstrates how to bypass the limit of the 10,000 records processed in DML statements in an Apex transaction.

```
global class SampleConnector extends UserProvisioning.UserProvisioningPlugin {

    // Example of adding more input and output parameters to those defined in the base
class
    global override Process.PluginDescribeResult buildDescribeCall() {
        Process.PluginDescribeResult describeResult = new Process.PluginDescribeResult();

        describeResult.inputParameters = new
            List<Process.PluginDescribeResult.InputParameter>{
               new Process.PluginDescribeResult.InputParameter('testInputParam',
                       Process.PluginDescribeResult.ParameterType.STRING, false)
            };

        describeResult.outputParameters = new
            List<Process.PluginDescribeResult.OutputParameter>{
               new Process.PluginDescribeResult.OutputParameter('testOutputParam',
                       Process.PluginDescribeResult.ParameterType.STRING)
            };

        return describeResult;
    }
```

```
    // Example Plugin that demonstrates how to leverage the
reconOffset/nextReconOffset/reconState
    // parameters to create more than 10,000 users. (i.e. go beyond the 10,000 DML limit
per transaction)

    global override Process.PluginResult invoke(Process.PluginRequest request) {
        Map<String,String> result = new Map<String,String>();
        String uprId = (String) request.inputParameters.get('userProvisioningRequestId');

        UserProvisioning.UserProvisioningLog.log(uprId, 'Inserting Log from test Apex
connector');
        UserProvisioningRequest upr = [SELECT id, operation, connectedAppId, state
                    FROM userprovisioningrequest WHERE id = :uprId];
        if (upr.operation.equals('Reconcile')) {
            String reconOffsetStr = (String) request.inputParameters.get('reconOffset');
            Integer reconOffset = 0;
            if (reconOffsetStr != null) {
                reconOffset = Integer.valueOf(reconOffsetStr);
            }

            if (reconOffset > 44999) {
                result.put('reconState', 'Completed');
            }

            Integer i = 0;
            List<UserProvAccountStaging> upasList = new List<UserProvAccountStaging>();
            for (i = 0; i < 5000; i++) {
                UserProvAccountStaging upas = new UserProvAccountStaging();
                upas.Name = i + reconOffset + '';
                upas.ExternalFirstName = upas.Name;
                upas.ExternalEmail = 'externaluser@externalsystem.com';
                upas.LinkState = 'Orphaned';
                upas.Status = 'Active';
                upas.connectedAppId = upr.connectedAppId;
                upasList.add(upas);
            }
            insert upasList;
            result.put('nextReconOffset', reconOffset + 5000 + '');
        }

        return new Process.PluginResult(result);
    }
}
```

IN THIS SECTION:

UserProvisioningPlugin Methods

UserProvisioningPlugin Methods

The following are methods for `UserProvisioningPlugin`.

IN THIS SECTION:

buildDescribeCall()
Use this method to add more input and output parameters to those defined in the base class.

describe()
Returns a `Process.PluginDescribeResult` object that describes this method call.

getPluginClassName()
Returns the name of the class implementing the plugin.

invoke(request)
Primary method that the system invokes when the class that implements the interface is instantiated.

buildDescribeCall()

Use this method to add more input and output parameters to those defined in the base class.

Signature

```
public Process.PluginDescribeResult buildDescribeCall()
```

Return Value

Type: Process.PluginDescribeResult

describe()

Returns a `Process.PluginDescribeResult` object that describes this method call.

Signature

```
public Process.PluginDescribeResult describe()
```

Return Value

Type: Process.PluginDescribeResult

getPluginClassName()

Returns the name of the class implementing the plugin.

Signature

```
public String getPluginClassName()
```

Return Value

Type: String

invoke(request)

Primary method that the system invokes when the class that implements the interface is instantiated.

Signature

```
public Process.PluginResult invoke(Process.PluginRequest request)
```

Parameters

request
Type: Process.PluginRequest

Return Value

Type: Process.PluginDescribeResult

VisualEditor Namespace

The `VisualEditor` namespace provides classes and methods for interacting with the Lightning App Builder.

The following are the classes in the `VisualEditor` namespace.

IN THIS SECTION:

DataRow Class
Contains information about one item in a picklist used in a Lightning component on a Lightning page.

DesignTimePageContext Class
An abstract class that provides context information about a Lightning page. It can be used to help define the values of a picklist in a Lightning component on a Lightning page based on the page's type and the object with which it's associated.

DynamicPickList Class
An abstract class, used to display the values of a picklist in a Lightning component on a Lightning page.

DynamicPickListRows Class
Contains a list of picklist items in a Lightning component on a Lightning page.

DataRow Class

Contains information about one item in a picklist used in a Lightning component on a Lightning page.

Namespace

VisualEditor

IN THIS SECTION:

DataRow Constructors

DataRow Methods

DataRow Constructors

The following are constructors for `DataRow`.

IN THIS SECTION:

DataRow(label, value, selected)
Creates an instance of the `VisualEditor.DataRow` class using the specified label, value, and selected option.

DataRow(label, value)
Creates an instance of the `VisualEditor.DataRow` class using the specified label and value.

DataRow(label, value, selected)

Creates an instance of the `VisualEditor.DataRow` class using the specified label, value, and selected option.

Signature

```
public DataRow(String label, Object value, Boolean selected)
```

Parameters

label
Type: String

User-facing label for the picklist item.

value
Type: Object

The value of the picklist item.

selected
Type: Boolean

Specifies whether the picklist item is selected (`true`) or not (`false`).

DataRow(label, value)

Creates an instance of the `VisualEditor.DataRow` class using the specified label and value.

Signature

```
public DataRow(String label, Object value)
```

Parameters

label
Type: String

User-facing label for the picklist item.

value
Type: Object

The value of the picklist item.

DataRow Methods

The following are methods for `DataRow`.

IN THIS SECTION:

clone()
Makes a duplicate copy of the `VisualEditor.DataRow` object.

compareTo(o)
Compares the current `VisualEditor.DataRow` object to the specified one. Returns an integer value that is the result of the comparison.

getLabel()
Returns the user-facing label of the picklist item.

getValue()
Returns the value of the picklist item.

isSelected()
Returns the state of the picklist item, indicating whether it's selected or not.

clone()

Makes a duplicate copy of the `VisualEditor.DataRow` object.

Signature

```
public Object clone()
```

Return Value

Type: Object

compareTo(o)

Compares the current `VisualEditor.DataRow` object to the specified one. Returns an integer value that is the result of the comparison.

Signature

```
public Integer compareTo(VisualEditor.DataRow o)
```

Parameters

o
Type: VisualEditor.DataRow

A single item in a picklist.

Return Value

Type: Integer

Returns one of the following values:

- Zero if the current package version is equal to the specified package version
- An integer value greater than zero if the current package version is greater than the specified package version
- An integer value less than zero if the current package version is less than the specified package version

`getLabel()`

Returns the user-facing label of the picklist item.

Signature

```
public String getLabel()
```

Return Value

Type: String

`getValue()`

Returns the value of the picklist item.

Signature

```
public Object getValue()
```

Return Value

Type: Object

`isSelected()`

Returns the state of the picklist item, indicating whether it's selected or not.

Signature

```
public Boolean isSelected()
```

Return Value

Type: Boolean

DesignTimePageContext Class

An abstract class that provides context information about a Lightning page. It can be used to help define the values of a picklist in a Lightning component on a Lightning page based on the page's type and the object with which it's associated.

Namespace

VisualEditor

Usage

To use this class, create a parameterized constructor in the custom Apex class that extends `VisualEditor.DynamicPickList`.

Example

Here's an example of a custom Apex class extending the `VisualEditor.DynamicPickList` class. It includes `VisualEditor.DesignTimePageContext` to define a picklist value that is available only if the page type is `HomePage`.

```
global class MyCustomPickList extends VisualEditor.DynamicPickList{
    VisualEditor.DesignTimePageContext context;

    global MyCustomPickList(VisualEditor.DesignTimePageContext context) {
       this.context = context;
    }

    global override VisualEditor.DataRow getDefaultValue(){
        VisualEditor.DataRow defaultValue = new VisualEditor.DataRow('red', 'RED');
        return defaultValue;
    }
    global override VisualEditor.DynamicPickListRows getValues() {
        VisualEditor.DataRow value1 = new VisualEditor.DataRow('red', 'RED');
        VisualEditor.DataRow value2 = new VisualEditor.DataRow('yellow', 'YELLOW');
       VisualEditor.DynamicPickListRows  myValues = new VisualEditor.DynamicPickListRows();

        myValues.addRow(value1);
        myValues.addRow(value2);

        if (context.pageType == 'HomePage') {
            VisualEditor.DataRow value3 = new VisualEditor.DataRow('purple', 'PURPLE');
            myValues.addRow(value3);
        }

        return myValues;
    }
}
```

IN THIS SECTION:

DesignTimePageContext Properties

DesignTimePageContext Methods

DesignTimePageContext Properties

The following are properties for `DesignTimePageContext`.

IN THIS SECTION:

entityName

The API name of the sObject that a Lightning page is associated with, such as Account, Contact or Custom_object__c. Not all Lightning pages are associated with objects.

pageType

The type of Lightning page, such as `HomePage`, `AppPage`, or `RecordPage`.

entityName

The API name of the sObject that a Lightning page is associated with, such as Account, Contact or Custom_object__c. Not all Lightning pages are associated with objects.

Signature

```
public String entityName {get; set;}
```

Property Value

Type: String

pageType

The type of Lightning page, such as `HomePage`, `AppPage`, or `RecordPage`.

Signature

```
public String pageType {get; set;}
```

Property Value

Type: String

DesignTimePageContext Methods

The following are methods for `DesignTimePageContext`.

IN THIS SECTION:

clone()
Makes a duplicate copy of the `VisualEditor.DesignTimePageContext` object.

clone()

Makes a duplicate copy of the `VisualEditor.DesignTimePageContext` object.

Signature

```
public Object clone()
```

Return Value

Type: Object

DynamicPickList Class

An abstract class, used to display the values of a picklist in a Lightning component on a Lightning page.

Namespace

VisualEditor

Usage

To use this class as the datasource of a picklist in a Lightning component, it must be extended by a custom Apex class and then that class must be called in the component's design file.

Example

Here's an example of a custom Apex class extending the `VisualEditor.DynamicPickList` class.

```
global class MyCustomPickList extends VisualEditor.DynamicPickList{

    global override VisualEditor.DataRow getDefaultValue(){
        VisualEditor.DataRow defaultValue = new VisualEditor.DataRow('red', 'RED');
        return defaultValue;
    }
    global override VisualEditor.DynamicPickListRows getValues() {
        VisualEditor.DataRow value1 = new VisualEditor.DataRow('red', 'RED');
        VisualEditor.DataRow value2 = new VisualEditor.DataRow('yellow', 'YELLOW');
       VisualEditor.DynamicPickListRows  myValues = new VisualEditor.DynamicPickListRows();

        myValues.addRow(value1);
        myValues.addRow(value2);
        return myValues;
    }
}
```

Here's an example of how the custom Apex class gets called in a design file so that the picklist appears in the Lightning component.

```
<design:component>
        <design:attribute name="property1" datasource="apex://MyCustomPickList"/>
</design:component>
```

IN THIS SECTION:

DynamicPickList Methods

DynamicPickList Methods

The following are methods for `DynamicPickList`.

IN THIS SECTION:

clone()

Makes a duplicate copy of the `VisualEditor.DynamicPicklist` object.

getDefaultValue()

Returns the picklist item that is set as the default value for the picklist.

getLabel(attributeValue)

Returns the user-facing label for a specified picklist value.

getValues()

Returns the list of picklist item values.

isValid(attributeValue)

Returns the valid state of the picklist item's value. A picklist value is considered valid if it's a part of any `VisualEditor.DataRow` in the `VisualEditor.DynamicPickListRows` returned by `getValues()`.

clone()

Makes a duplicate copy of the `VisualEditor.DynamicPicklist` object.

Signature

```
public Object clone()
```

Return Value

Type: Object

getDefaultValue()

Returns the picklist item that is set as the default value for the picklist.

Signature

```
public VisualEditor.DataRow getDefaultValue()
```

Return Value

Type: VisualEditor.DataRow

getLabel(attributeValue)

Returns the user-facing label for a specified picklist value.

Signature

```
public String getLabel(Object attributeValue)
```

Parameters

attributeValue

Type: Object

The value of the picklist item.

Return Value

Type: String

`getValues()`

Returns the list of picklist item values.

Signature

```
public VisualEditor.DynamicPickListRows getValues()
```

Return Value

Type: VisualEditor.DynamicPickListRows

`isValid(attributeValue)`

Returns the valid state of the picklist item's value. A picklist value is considered valid if it's a part of any `VisualEditor.DataRow` in the `VisualEditor.DynamicPickListRows` returned by `getValues()`.

Signature

```
public Boolean isValid(Object attributeValue)
```

Parameters

`attributeValue`
Type: Object

The value of the picklist item.

Return Value

Type: Boolean

DynamicPickListRows Class

Contains a list of picklist items in a Lightning component on a Lightning page.

Namespace

VisualEditor

IN THIS SECTION:

DynamicPickListRows Constructors

DynamicPickListRows Methods

DynamicPickListRows Constructors

The following are constructors for `DynamicPickListRows`.

IN THIS SECTION:

DynamicPickListRows(rows, containsAllRows)
Creates an instance of the `VisualEditor.DynamicPickListRows` class using the specified parameters.

DynamicPickListRows(rows)
Creates an instance of the `VisualEditor.DynamicPickListRows` class using the specified parameter.

DynamicPickListRows()
Creates an instance of the `VisualEditor.DynamicPickListRows` class. You can then add rows by using the class's `addRow` or `addAllRows` methods.

DynamicPickListRows(rows, containsAllRows)

Creates an instance of the `VisualEditor.DynamicPickListRows` class using the specified parameters.

Signature

```
public DynamicPickListRows(List<VisualEditor.DataRow> rows, Boolean containsAllRows)
```

Parameters

rows
Type: List VisualEditor.DataRow

List of picklist items.

containsAllRows
Type: Boolean

Indicates if all values of the picklist are included in a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

A picklist in a Lightning component can display only the first 200 values of a list. If *containsAllRows* is set to false, when a user does a type-ahead search to find values in the picklist, the search will only look at those first 200 values that were displayed, not the complete set of picklist values.

DynamicPickListRows(rows)

Creates an instance of the `VisualEditor.DynamicPickListRows` class using the specified parameter.

Signature

```
public DynamicPickListRows(List<VisualEditor.DataRow> rows)
```

Parameters

rows
Type: List VisualEditor.DataRow

List of picklist rows.

DynamicPickListRows()

Creates an instance of the `VisualEditor.DynamicPickListRows` class. You can then add rows by using the class's `addRow` or `addAllRows` methods.

Signature

```
public DynamicPickListRows()
```

DynamicPickListRows Methods

The following are methods for `DynamicPickListRows`.

IN THIS SECTION:

addAllRows(rows)
Adds a list of picklist items to a dynamic picklist rendered in a Lightning component on a Lightning page.

addRow(row)
Adds a single picklist item to a dynamic picklist rendered in a Lightning component on a Lightning page.

clone()
Makes a duplicate copy of the `VisualEditor.DynamicPickListRows` object.

containsAllRows()
Returns a Boolean value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

get(i)
Returns a picklist element stored at the specified index.

getDataRows()
Returns a list of picklist items.

setContainsAllRows(containsAllRows)
Sets the value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

size()
Returns the size of the list of `VisualEditor.DynamicPickListRows`.

sort()
Sorts the list of `VisualEditor.DynamicPickListRows`.

addAllRows(rows)

Adds a list of picklist items to a dynamic picklist rendered in a Lightning component on a Lightning page.

Signature

```
public void addAllRows(List<VisualEditor.DataRow> rows)
```

Parameters

rows
Type: List VisualEditor.DataRow

List of picklist items.

Return Value

Type: void

addRow(row)

Adds a single picklist item to a dynamic picklist rendered in a Lightning component on a Lightning page.

Signature

```
public void addRow(VisualEditor.DataRow row)
```

Parameters

row
Type: VisualEditor.DataRow

A single picklist item.

Return Value

Type: void

clone()

Makes a duplicate copy of the `VisualEditor.DynamicPickListRows` object.

Signature

```
public Object clone()
```

Return Value

Type: Object

containsAllRows()

Returns a Boolean value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

Signature

```
public Boolean containsAllRows()
```

Return Value

Type: Boolean

A picklist in a Lightning component can display only the first 200 values of a list. If *containsAllRows* is set to false, when a user does a type-ahead search to find values in the picklist, the search will only look at those first 200 values that were displayed, not the complete set of picklist values.

get(i)

Returns a picklist element stored at the specified index.

Signature

```
public VisualEditor.DataRow get(Integer i)
```

Parameters

i

Type: Integer

The index.

Return Value

Type: VisualEditor.DataRow

getDataRows()

Returns a list of picklist items.

Signature

```
public List<VisualEditor.DataRow> getDataRows()
```

Return Value

Type: List VisualEditor.DataRow

setContainsAllRows(containsAllRows)

Sets the value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

Signature

```
public void setContainsAllRows(Boolean containsAllRows)
```

Parameters

containsAllRows

Type: Boolean

Indicates if all values of the picklist are included in a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

A picklist in a Lightning component can display only the first 200 values of a list. If *containsAllRows* is set to false, when a user does a type-ahead search to find values in the picklist, the search will only look at those first 200 values that were displayed, not the complete set of picklist values.

Return Value

Type: void

size()

Returns the size of the list of `VisualEditor.DynamicPickListRows`.

Signature

```
public Integer size()
```

Return Value

Type: Integer

sort()

Sorts the list of `VisualEditor.DynamicPickListRows`.

Signature

```
public void sort()
```

Return Value

Type: void

wave Namespace

The classes in the Wave namespace are part of the Wave Analytics SDK, designed to facilitate quering Wave data from Apex code.

The following are the classes in the `wave` namespace.

IN THIS SECTION:

QueryBuilder Class
The QueryBuilder class provides methods for constructing well-formed SAQL queries to pass to Wave Analytics.

QueryNode Class
Define each node of the query - such as projection, groups, order, filters. Execute the query.

ProjectionNode Class
Add aggregate functions to the query, or define an alias.

QueryBuilder Class

The QueryBuilder class provides methods for constructing well-formed SAQL queries to pass to Wave Analytics.

Namespace

wave

Usage

Use QueryBuilder and its associated classes, `Wave.ProjectionNode` and `Wave.QueryNode`, to incrementally build your SAQL statement. For example:

```
public static void executeApexQuery(String name){
  Wave.ProjectionNode[] projs = new Wave.ProjectionNode[]{
    Wave.QueryBuilder.get('State').alias('State'),
    Wave.QueryBuilder.get('City').alias('City'),
    Wave.QueryBuilder.get('Revenue').avg().alias('avg_Revenue'),
    Wave.QueryBuilder.get('Revenue').sum().alias('sum_Revenue'),

    Wave.QueryBuilder.count().alias('count')};

  ConnectApi.LiteralJson result = Wave.QueryBuilder.load('0FbD00000004DSzKAM',
'0FcD00000004FEZKA2')
    .group(new String[]{'State', 'City'})
    .foreach(projs)
    .execute('q');
  String response = result.json;
}
```

Examples

QueryBuilder is the core of this first phase of the Wave Apex SDK, so let's take a closer look. Here's a simple count query.

```
Wave.ProjectionNode[] projs = new
Wave.ProjectionNode[]{Wave.QueryBuilder.count().alias('c')};
String query = Wave.QueryBuilder.load('datasetId',
'datasetVersionId').group().foreach(projs).build('q');
```

The resulting SAQL query looks like this:

```
q = load "datasetId/datasetVersionId";
q = group q by all;
q = foreach q generate count as c;
```

Here's a more complex example that uses a union statement.

```
Wave.ProjectionNode[] projs = new Wave.ProjectionNode[]{Wave.QueryBuilder.get('Name'),
Wave.QueryBuilder.get('AnnualRevenue').alias('Revenue')};
Wave.QueryNode nodeOne =
Wave.QueryBuilder.load('datasetOne','datasetVersionOne').foreach(projs);
Wave.QueryNode nodeTwo = Wave.QueryBuilder.load('datasetTwo',
'datasetVersionTwo').foreach(projs);
String query = Wave.QueryBuilder.union(new List<Wave.QueryNode>{nodeOne,
nodeTwo}).build('q');
```

The resulting SAQL query has two projection streams, *qa* and *qb*.

```
qa = load "datasetOne/datasetVersionOne";
qa = foreach q generate Name,AnnualRevenue as Revenue;
qb = load "datasetTwo/datasetVersionTwo";
qb = foreach q generate Name,AnnualRevenue as Revenue;
q = union qa, qb;
```

IN THIS SECTION:

QueryBuilder Methods

QueryBuilder Methods

The following are methods for `QueryBuilder`.

IN THIS SECTION:

load(datasetID, datasetVersionID)
Load a stream from a dataset.

count()
Calculate the number of rows that match the query criteria.

get(projection)
Query by selecting specific attributes.

union(unionNodes)
Combine multiple result sets into one result set.

cogroup(cogroupNodes, groups)
Cogrouping means that two input streams are grouped independently and arranged side by side. Only data that exists in both groups appears in the results.

`load(datasetID, datasetVersionID)`

Load a stream from a dataset.

Signature

```
public static wave.QueryNode load(String datasetID, String datasetVersionID)
```

Parameters

`datasetID`
Type: String

The ID of the dataset.

`datasetVersionID`
Type: String

The ID identifying the version of the dataset.

Return Value

Type: wave.QueryNode

count()

Calculate the number of rows that match the query criteria.

Signature

```
public static wave.ProjectionNode count()
```

Return Value

Type: wave.ProjectionNode

get(projection)

Query by selecting specific attributes.

Signature

```
public static wave.ProjectionNode get(String proj)
```

Parameters

proj
Type: String

The name of the column to query.

Return Value

Type: wave.ProjectionNode

union(unionNodes)

Combine multiple result sets into one result set.

Signature

```
global static Wave.QueryNode union(List<Wave.QueryNode> unionNodes)
```

Parameters

unionNodes
Type: List<wave.QueryNode>

List of nodes to combine.

Return Value

Type: wave.QueryNode

`cogroup(cogroupNodes, groups)`

Cogrouping means that two input streams are grouped independently and arranged side by side. Only data that exists in both groups appears in the results.

Signature

```
global static Wave.QueryNode cogroup(List<Wave.QueryNode> cogroupNodes,
List<List<String>> groups)
```

Parameters

`cogroupNodes`
Type: wave.QueryNode

List of nodes to group.

`groups`
Type: String

The type of grouping.

Return Value

Type: wave.QueryNode

QueryNode Class

Define each node of the query - such as projection, groups, order, filters. Execute the query.

Namespace

wave

Usage

Refer to the QueryBuilder example.

IN THIS SECTION:

QueryNode Methods

QueryNode Methods

The following are methods for `QueryNode`.

IN THIS SECTION:

build(streamName)
Build the query string represented by this QueryNode and assign it to a stream name.

foreach(projections)
Applies a set of expressions to every row in a dataset. This action is often referred to as projection.

group(groups)
Groups matched records (group by specific dataset attributes).

group()
Groups matched records (group by all).

order(orders)
Sorts in ascending or descending order on one or more fields.

cap(cap)
Limits the number of results that are returned.

filter(filterCondition)
Selects rows from a dataset based on a filter condition (a predicate).

filter(filterConditions)
Selects rows from a dataset based on multiple filter conditions (predicates).

execute(streamName)
Execute the query and return rows as JSON.

`build(streamName)`

Build the query string represented by this QueryNode and assign it to a stream name.

Signature

```
public String build(String streamName)
```

Parameters

`streamName`
Type: String

The identifier for the stream - for example, "q".

Return Value

Type: String

The SAQL query string represented by the QueryNode.

`foreach(projections)`

Applies a set of expressions to every row in a dataset. This action is often referred to as projection.

Signature

```
public wave.QueryNode foreach(List<wave.ProjectionNode> projections)
```

Parameters

`projections`
Type: List<wave.ProjectionNode>

A list of ProjectionNodes to be added to this QueryNode.

Return Value

Type: wave.QueryNode

group(groups)

Groups matched records (group by specific dataset attributes).

Signature

```
public wave.QueryNode group(List<String> groups)
```

Parameters

groups
Type: List<String>

A list of expressions.

Return Value

Type: wave.QueryNode

Example

```
Wave.ProjectionNode[] projs = new Wave.ProjectionNode[]{Wave.QueryBuilder.get('Name'),
Wave.QueryBuilder.get('Revenue').sum().alias('REVENUE_SUM')};
ConnectApi.LiteralJson result = Wave.QueryBuilder.load('datasetId',
'datasetVersionId').group(new String[]{'Name'}).foreach(projs).build('q');
```

group()

Groups matched records (group by all).

Signature

```
public wave.QueryNode group()
```

Return Value

Type: wave.QueryNode

Example

```
String query = Wave.QueryBuilder.load('datasetId',
'datasetVersionId').group().foreach(projs).build('q');
```

order(orders)

Sorts in ascending or descending order on one or more fields.

Signature

```
public wave.QueryNode group(List<String> groups)
```

Parameters

groups
Type: List<String>

A list of column names and associated ascending or descending keywords, for example

```
List<List<String>>{new List<String>{'Name', 'asc'}, new List<String>{'Revenue', 'desc'}}
```

Return Value

Type: wave.QueryNode

cap(cap)

Limits the number of results that are returned.

Signature

```
global Wave.QueryNode cap(Integer cap)
```

Parameters

cap
Type: Integer

The maximum number of rows to return.

Return Value

Type: wave.QueryNode

filter(filterCondition)

Selects rows from a dataset based on a filter condition (a predicate).

Signature

```
public wave.QueryNode filter(String filterCondition)
```

Parameters

filterCondition
Type: String

For example: `filter('Name != \'My Name\'')`

Return Value

Type: wave.QueryNode

filter(filterConditions)

Selects rows from a dataset based on multiple filter conditions (predicates).

Signature

```
public wave.QueryNode filter(List<String> filterCondition)
```

Parameters

filterCondition
Type: List<String>

A list of filter conditions.

Return Value

Type: wave.QueryNode

execute(streamName)

Execute the query and return rows as JSON.

Signature

```
global ConnectApi.LiteralJson execute(String streamName)
```

Parameters

streamName
Type: String

The query stream to execute. For example:

```
ConnectApi.LiteralJson result = Wave.QueryBuilder.load('datasetId',
      'datasetVersionId').group().foreach(projs).execute('q');
```

Return Value

Type: ConnectApi.LiteralJson

ProjectionNode Class

Add aggregate functions to the query, or define an alias.

Namespace

wave on page 3153

Usage

Refer to the QueryBuilder example.

IN THIS SECTION:

ProjectionNode Methods

ProjectionNode Methods

The following are methods for `ProjectionNode`.

IN THIS SECTION:

sum()
Returns the sum of a numeric field.

avg()
Returns the average value of a numeric field.

min()
Returns the minimum value of a field.

max()
Returns the maximum value of a field.

count()
Returns the number of rows that match the query criteria.

unique()
Returns the count of unique values.

alias(name)
Define output column names.

`sum()`

Returns the sum of a numeric field.

Signature

```
public wave.ProjectionNode sum()
```

Return Value

Type: wave.ProjectionNode

`avg()`

Returns the average value of a numeric field.

Signature

```
public wave.ProjectionNode avg()
```

Return Value

Type: wave.ProjectionNode

min()

Returns the minimum value of a field.

Signature

```
public wave.ProjectionNode min()
```

Return Value

Type: wave.ProjectionNode

max()

Returns the maximum value of a field.

Signature

```
public wave.ProjectionNode max()
```

Return Value

Type: wave.ProjectionNode

count()

Returns the number of rows that match the query criteria.

Signature

```
public wave.ProjectionNode count()
```

Return Value

Type: wave.ProjectionNode

unique()

Returns the count of unique values.

Signature

```
public wave.ProjectionNode unique()
```

Return Value

Type: wave.ProjectionNode

alias(name)

Define output column names.

Signature

```
public wave.ProjectionNode alias(String name)
```

Parameters

name

Type: String

The name to use for this column. For example, this code defines the alias `c`:

```
Wave.ProjectionNode[] projs = new
Wave.ProjectionNode[]{Wave.QueryBuilder.count().alias('c')};
```

Return Value

Type: wave.ProjectionNode

SOAP API and SOAP Headers for Apex

This appendix details the SOAP API calls and objects that are available by default for Apex.

Note: Apex class methods can be exposed as custom SOAP Web service calls. This allows an external application to invoke an Apex Web service to perform an action in Salesforce. Use the `webservice` keyword to define these methods. For more information, see Considerations for Using the `webservice` Keyword on page 262.

Any Apex code saved using SOAP API calls uses the same version of SOAP API as the endpoint of the request. For example, if you want to use SOAP API version 44.0, use endpoint 44.0:

```
https://yourInstance.salesforce.com/services/Soap/s/44.0
```

For information on all other SOAP API calls, including those that can be used to extend or implement any existing Apex IDEs, contact your Salesforce representative.

The following API objects are available:

- ApexTestQueueItem

- ApexTestResult
- ApexTestResultLimits
- ApexTestRunResult

The following are SOAP API calls:

- `compileAndTest()`
- `compileClasses()`
- `compileTriggers()`
- `executeanonymous()`
- `runTests()`

The following SOAP headers are available in SOAP API calls for Apex:

- DebuggingHeader
- PackageVersionHeader

Also see the *Metadata API Developer Guide* for two additional calls:

- `deploy()`
- `retrieve()`

IN THIS SECTION:

1. ApexTestQueueItem
   Represents a single Apex class in the Apex job queue. This object is available in API version 23.0 and later.
2. ApexTestResult
   Represents the result of an Apex test method execution. This object is available in API version 23.0 and later.
3. ApexTestResultLimits
   Captures the Apex test limits used for a particular test method execution. An instance of this object is associated with each ApexTestResult record. This object is available in API version 37.0 and later.
4. ApexTestRunResult
   Contains summary information about all the test methods that were run in a particular Apex job. This object is available in API version 37.0 and later.
5. compileAndTest()
6. compileClasses()
7. compileTriggers()
8. executeanonymous()
9. runTests()
10. DebuggingHeader
    Return the debug log in the output header, `DebuggingInfo`, and specify the level of detail in the debug log.
11. PackageVersionHeader

ApexTestQueueItem

Represents a single Apex class in the Apex job queue. This object is available in API version 23.0 and later.

This object is available in API version 23.0 and later.

Supported Calls

`create()`, `describeSObjects()`, `query()`, `retrieve()`, `update()`, `upsert()`

Fields

Field Name	Description
`ApexClassId`	**Type** reference **Properties** Create, Filter, Group, Sort **Description** The Apex class whose tests are to be executed.
`ExtendedStatus`	**Type** string **Properties** Filter, Nillable, Sort **Description** The pass rate of the test run. For example: "(4/6)". This means that four out of a total of six tests passed. If the class fails to execute, this field contains the cause of the failure.
`ParentJobId`	**Type** reference **Properties** Filter, Group, Nillable, Sort **Description** Points to the AsyncApexJob that represents the entire test run. If you insert multiple Apex test queue items in a single bulk operation, the queue items will share the same parent job. This means that a test run can consist of the execution of the tests of several classes if all the test queue items are inserted in the same bulk operation.
`ShouldSkipCodeCoverage`	**Type** boolean **Properties** Create, Defaulted on create, Filter, Group, Sort, Update **Description** Indicates whether to opt out of collecting code coverage information during Apex test runs. Available in API version 43.0 and later.

Field Name	Description
`Status`	**Type** picklist **Properties** Filter, Group, Restricted picklist, Sort, Update **Description** The status of the job. Valid values are: • `Holding`[1] • `Queued` • `Preparing` • `Processing` • `Aborted` • `Completed` • `Failed` [1] This status applies to batch jobs in the Apex flex queue.
`TestRunResultID`	**Type** reference **Properties** Filter, Group, Nillable, Sort **Description** The ID of the associated ApexTestRunResult object.

Usage

Insert an `ApexTestQueueItem` object to place its corresponding Apex class in the Apex job queue for execution. The Apex job executes the test methods in the class.

To abort a class that is in the Apex job queue, perform an update operation on the ApexTestQueueItem object and set its `Status` field to *`Aborted`*.

If you insert multiple Apex test queue items in a single bulk operation, the queue items will share the same parent job. This means that a test run can consist of the execution of the tests of several classes if all the test queue items are inserted in the same bulk operation.

ApexTestResult

Represents the result of an Apex test method execution. This object is available in API version 23.0 and later.

Supported Calls

`create()`, `delete()`, `describeSObjects()`, `query()`, `retrieve()`, `update()`

Fields

Field Name	Details
`ApexClassId`	**Type** reference **Properties** Create, Filter, Group, Sort, Update **Description** The Apex class whose test methods were executed.
`ApexLogId`	**Type** reference **Properties** Create, Filter, Group, Nillable, Sort, Update **Description** Points to the ApexLog for this test method execution if debug logging is enabled; otherwise, `null`.
`ApexTestRunResultId`	**Type** reference **Properties** Create, Filter, Group, Nillable, Sort, Update **Description** The ID of the ApexTestRunResult that represents the entire test run.
`AsyncApexJobId`	**Type** reference **Properties** Create, Filter, Group, Nillable, Sort, Update **Description** Points to the AsyncApexJob that represents the entire test run. This field points to the same object as `ApexTestQueueItem.ParentJobId`.
`Message`	**Type** string **Properties** Create, Filter, Nillable, Sort, Update **Description** The exception error message if a test failure occurs; otherwise, `null`.

Field Name	Details
`MethodName`	**Type** string **Properties** Create, Filter, Group, Nillable, Sort, Update **Description** The test method name.
`Outcome`	**Type** picklist **Properties** Create, Filter, Group, Restricted picklist, Sort, Update **Description** The result of the test method execution. Can be one of these values: • Pass • Fail • CompileFail • Skip
`QueueItemId`	**Type** reference **Properties** Create, Filter, Group, Nillable, Sort, Update **Description** Points to the ApexTestQueueItem which is the class that this test method is part of.
`RunTime`	**Type** int **Properties** Create, Filter, Nillable, Sort, Update **Description** The time it took the test method to run, in seconds.
`StackTrace`	**Type** string **Properties** Create, Filter, Nillable, Sort, Update **Description** The Apex stack trace if the test failed; otherwise, `null`.

Field Name	Details
`TestTimestamp`	**Type** dateTime **Properties** Create, Filter, Sort, Update **Description** The start time of the test method.

Usage

You can query the fields of the `ApexTestResult` record that corresponds to a test method executed as part of an Apex class execution.

Each test method execution is represented by a single `ApexTestResult` record. For example, if an Apex test class contains six test methods, six `ApexTestResult` records are created. These records are in addition to the `ApexTestQueueItem` record that represents the Apex class.

Each ApexTestResult record has an associated ApexTestResultLimits on page 3170 record, which captures the Apex limits used during execution of the test method.

ApexTestResultLimits

Captures the Apex test limits used for a particular test method execution. An instance of this object is associated with each ApexTestResult record. This object is available in API version 37.0 and later.

Supported Calls

`create()`, `delete()`, `describeSObjects()`, `query()`, `retrieve()`, `update()`

Fields

Field Name	Details
`ApexTestResultId`	**Type** reference **Properties** Create, Filter, Group, Sort **Description** The ID of the associated ApexTestResult object.
`AsyncCalls`	**Type** int **Properties** Create, Filter, Group, Sort, Update

Field Name	Details
	Description The number of asynchronous calls made during the test run.
`Callouts`	**Type** int **Properties** Create, Filter, Group, Sort, Update **Description** The number of callouts made during the test run.
`Cpu`	**Type** int **Properties** Create, Filter, Group, Sort, Update **Description** The amount of CPU used during the test run, in milliseconds.
`Dml`	**Type** int **Properties** Create, Filter, Group, Sort, Update **Description** The number of DML statements made during the test run.
`DmlRows`	**Type** int **Properties** Create, Filter, Group, Sort, Update **Description** The number of rows accessed by DML statements during the test run.
`Email`	**Type** int **Properties** Create, Filter, Group, Sort, Update **Description** The number of email invocations made during the test run.
`LimitContext`	**Type** string

Field Name	Details
	Properties Create, Filter, Group, Nillable, Sort, Update **Description** Indicates whether the test run was synchronous or asynchronous.
`LimitExceptions`	**Type** string **Properties** Create, Filter, Group, Nillable, Sort, Update **Description** Indicates whether your org has any limits that differ from the default limits.
`MobilePush`	**Type** int **Properties** Create, Filter, Group, Sort, Update **Description** The number of mobile push calls made during the test run.
`QueryRows`	**Type** int **Properties** Create, Filter, Group, Sort, Update **Description** The number of rows queried during the test run.
`Soql`	**Type** int **Properties** Create, Filter, Group, Sort, Update **Description** The number of SOQL queries made during the test run.
`Sosl`	**Type** int **Properties** Create, Filter, Group, Sort, Update **Description** The number of SOSL queries made during the test run.

Usage

The ApexTestResultLimits object is populated for each test method execution, and it captures the limits used between the Test.startTest() and Test.stopTest() methods. If startTest() and stopTest() aren't called, limits usage is not captured. Note the following:

- The associated test method must be run asynchronously.
- Limits for asynchronous Apex operations (batch, scheduled, future, and queueable) that are called within test methods are not captured.
- Limits are captured only for the default namespace.

ApexTestRunResult

Contains summary information about all the test methods that were run in a particular Apex job. This object is available in API version 37.0 and later.

Supported Calls

`create()`, `delete()`, `describeSObjects()`, `query()`, `retrieve()`, `update()`

Fields

Field Name	Details
`AsyncApexJobId`	**Type** reference **Properties** Create, Filter, Group, Nillable, Sort, Update **Description** The parent Apex job ID for the result.
`ClassesCompleted`	**Type** int **Properties** Create, Filter, Group, Nillable, Sort, Update **Description** The total number of classes executed during the test run.
`ClassesEnqueued`	**Type** int **Properties** Create, Filter, Group, Sort, Update **Description** The total number of classes enqueued during the test run.

Field Name	Details
`EndTime`	**Type** dateTime **Properties** Create, Filter, Nillable, Sort, Update **Description** The time at which the test run ended.
`IsAllTests`	**Type** boolean **Properties** Create, Filter, Group, Sort, Update **Description** Indicates whether all Apex test classes were run.
`JobName`	**Type** string **Properties** Create, Filter, Group, Nillable, Sort, Update **Description** Reserved for future use.
`MethodsCompleted`	**Type** int **Properties** Create, Filter, Group, Nillable, Sort, Update **Description** The total number of methods completed during the test run. This value is updated after each class is run.
`MethodsEnqueued`	**Type** int **Properties** Create, Filter, Group, Nillable, Sort, Update **Description** The total number of methods enqueued for the test run. This value is initialized before the test runs.
`MethodsFailed`	**Type** int **Properties** Create, Filter, Group, Nillable, Sort, Update

Field Name	Details
	Description The total number of methods that failed during this test run. This value is updated after each class is run.
`Source`	**Type** string **Properties** Create, Filter, Group, Nillable, Sort, Update **Description** The source of the test run, such as the Developer Console.
`StartTime`	**Type** dateTime **Properties** Create, Filter, Sort, Update **Description** The time at which the test run started.
`Status`	**Type** picklist **Properties** Create, Filter, Group, Sort, Update **Description** The status of the test run. Values include: • Queued • Processing • Aborted • Completed • Failed
`TestTime`	**Type** int **Properties** Create, Filter, Group, Nillable, Sort, Update **Description** The time it took the test to run, in seconds.
`UserId`	**Type** reference

Field Name	Details
	Properties Create, Filter, Group, Nillable, Sort, Update **Description** The user who ran the test run.

`compileAndTest()`

Compile and test your Apex in a single call.

Syntax

```
CompileAndTestResult[] = compileAndTest(CompileAndTestRequest request);
```

Usage

Use this call to both compile and test the Apex you specify with a single call. Production organizations (not a Developer Edition or Sandbox Edition) must use this call instead of `compileClasses()` or `compileTriggers()`.

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the *SOAP API Developer Guide*.

All specified tests must pass, otherwise data is not saved to the database. If this call is invoked in a production organization, the RunTestsRequest property of the CompileAndTestRequest is ignored, and all unit tests defined in the organization are run and must pass.

Sample Code—Java

Note that the following example sets `checkOnly` to `true` so that this class is compiled and tested, but the classes are not saved to the database.

```
{
    CompileAndTestRequest request;
    CompileAndTestResult result = null;

    String triggerBody = "trigger t1 on Account (before insert){ " +
      "  for(Account a:Trigger.new){ " +
      "   a.description = 't1_UPDATE';}" +
      "}";

    String testClassBody = "@isTest private class TestT1{" +
      "    // Test for the trigger" +
      "    public static testmethod void test1(){" +
      "      Account a  = new Account(name='TEST');" +
      "      insert(a);" +
      "      a = [select id,description from Account where id=:a.id];" +
      "      System.assert(a.description.contains('t1_UPDATE'));" +
      "    }" +
      "    // Test for the class" +
```

```
      "    public static testmethod void test2(){" +
      "      String s = C1.method1();" +
      "      System.assert(s=='HELLO');" +
      "    }" +
      "}";

    String classBody = "public class C1{" +
      "    public static String s ='HELLO';" +
      "    public static String method1(){" +
      "      return(s);" +
      "    }" +
      "}";

    request = new CompileAndTestRequest();

    request.setClasses(new String[]{classBody, testClassBody});
    request.setTriggers(new String[]{triggerBody});
    request.setCheckOnly(true);

    try {
        result = apexBinding.compileAndTest(request);
    } catch (RemoteException e) {
        System.out.println("An unexpected error occurred: " + e.getMessage());
    }
    assert (result.isSuccess());
}
```

Arguments

Name	Type	Description
`request`	CompileAndTestRequest	A request that includes the Apex and the values for any fields that need to be set for this request.

Response

CompileAndTestResult

IN THIS SECTION:

- CompileAndTestRequest
- CompileAndTestResult

CompileAndTestRequest

The `compileAndTest()` call contains this object, a request with information about the Apex to be compiled.

A CompileAndTestRequest object has the following properties:

Name	Type	Description
`checkOnly`	boolean	If set to `true`, the Apex classes and triggers submitted are not saved to your organization, whether or not the code successfully compiles and unit tests pass.
`classes`	string	Content of the class or classes to be compiled.
`deleteClasses`	string	Name of the class or classes to be deleted.
`deleteTriggers`	string	Name of the trigger or triggers to be deleted.
`runTestsRequest`	RunTestsRequest	Specifies information about the Apex to be tested. If this request is sent in a production organization, this property is ignored and all unit tests are run for your entire organization.
`triggers`	string	Content of the trigger or triggers to be compiled.

Note the following about this object:

- This object contains the `RunTestsRequest` property. If the request is run in a production organization, the property is ignored and all tests are run.
- If any errors occur during compile, delete, testing, or if the goal of 75% code coverage is missed, no classes or triggers are saved to your organization. This is the same requirement as Salesforce AppExchange package testing.
- All triggers must have code coverage. If a trigger has no code coverage, no classes or triggers are saved to your organization.

CompileAndTestResult

The `compileAndTest()` call returns information about the compile and unit test run of the specified Apex, including whether it succeeded or failed.

A CompileAndTestResult object has the following properties:

Name	Type	Description
`classes`	CompileClassResult	Information about the success or failure of the `compileAndTest()` call if classes were being compiled.
`deleteClasses`	DeleteApexResult	Information about the success or failure of the `compileAndTest()` call if classes were being deleted.
`deleteTriggers`	DeleteApexResult	Information about the success or failure of the `compileAndTest()` call if triggers were being deleted.
`runTestsResult`	RunTestsResult	Information about the success or failure of the Apex unit tests, if any were specified.
`success`	boolean*	If `true`, all of the classes, triggers, and unit tests specified ran successfully. If any class, trigger, or unit test failed, the value is `false`, and details are reported in the corresponding result object: • CompileClassResult • CompileTriggerResult • DeleteApexResult

Name	Type	Description
		• RunTestsResult
`triggers`	CompileTriggerResult	Information about the success or failure of the `compileAndTest()` call if triggers were being compiled.

* Link goes to the *SOAP API Developer Guide*.

CompileClassResult

This object is returned as part of a `compileAndTest()` or `compileClasses()` call. It contains information about whether or not the compile and run of the specified Apex was successful.

A CompileClassResult object has the following properties:

Name	Type	Description
`bodyCrc`	int*	The CRC (cyclic redundancy check) of the class or trigger file.
`column`	int*	The column number where an error occurred, if one did.
`id`	ID*	An ID is created for each compiled class. The ID is unique within an organization.
`line`	int*	The line number where an error occurred, if one did.
`name`	string*	The name of the class.
`problem`	string*	The description of the problem if an error occurred.
`success`	boolean*	If `true`, the class or classes compiled successfully. If `false`, problems are specified in other properties of this object.

* Link goes to the *SOAP API Developer Guide*.

CompileTriggerResult

This object is returned as part of a `compileAndTest()` or `compileTriggers()` call. It contains information about whether or not the compile and run of the specified Apex was successful.

A CompileTriggerResult object has the following properties:

Name	Type	Description
`bodyCrc`	int*	The CRC (cyclic redundancy check) of the trigger file.
`column`	int*	The column where an error occurred, if one did.
`id`	ID*	An ID is created for each compiled trigger. The ID is unique within an organization.
`line`	int*	The line number where an error occurred, if one did.
`name`	string*	The name of the trigger.

Name	Type	Description
problem	string*	The description of the problem if an error occurred.
success	boolean*	If true, all the specified triggers compiled and ran successfully. If the compilation or execution of any trigger fails, the value is false.

* Link goes to the *SOAP API Developer Guide*.

DeleteApexResult

This object is returned when the compileAndTest() call returns information about the deletion of a class or trigger.

A DeleteApexResult object has the following properties:

Name	Type	Description
id	ID*	ID of the deleted trigger or class. The ID is unique within an organization.
problem	string*	The description of the problem if an error occurred.
success	boolean*	If true, all the specified classes or triggers were deleted successfully. If any class or trigger is not deleted, the value is false.

* Link goes to the *SOAP API Developer Guide*.

compileClasses()

Compile your Apex in Developer Edition or sandbox organizations.

Syntax

```
CompileClassResult[] = compileClasses(string[] classList);
```

Usage

Use this call to compile Apex classes in Developer Edition or sandbox organizations. Production organizations must use compileAndTest().

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the *SOAP API Developer Guide*.

Sample Code—Java

```
public void compileClassesSample() {
    String p1 = "public class p1 {\n"
      + "public static Integer var1 = 0;\n"
      + "public static void methodA() {\n"
      + " var1 = 1;\n" + "}\n"
      + "public static void methodB() {\n"
```

```
      + " p2.MethodA();\n" + "}\n"
      + "}";
    String p2 = "public class p2 {\n"
      + "public static Integer var1 = 0;\n"
      + "public static void methodA() {\n"
      + " var1 = 1;\n" + "}\n"
      + "public static void methodB() {\n"
      + " p1.MethodA();\n" + "}\n"
      + "}";
    CompileClassResult[] r = new CompileClassResult[0];
    try {
        r = apexBinding.compileClasses(new String[]{p1, p2});
    } catch (RemoteException e) {
        System.out.println("An unexpected error occurred: "
          + e.getMessage());
    }
    if (!r[0].isSuccess()) {
        System.out.println("Couldn't compile class p1 because: "
          + r[0].getProblem());
    }
    if (!r[1].isSuccess()) {
        System.out.println("Couldn't compile class p2 because: "
          + r[1].getProblem());
    }
}
```

Arguments

Name	Type	Description
`scripts`	string*	A request that includes the Apex classes and the values for any fields that need to be set for this request.

* Link goes to the *SOAP API Developer Guide*.

Response

CompileClassResult

`compileTriggers()`

Compile your Apex triggers in Developer Edition or sandbox organizations.

Syntax

```
CompileTriggerResult[] = compileTriggers(string[] triggerList);
```

Usage

Use this call to compile the specified Apex triggers in your Developer Edition or sandbox organization. Production organizations must use `compileAndTest()`.

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the *SOAP API Developer Guide*.

Arguments

Name	Type	Description
`scripts`	string*	A request that includes the Apex trigger or triggers and the values for any fields that need to be set for this request.

* Link goes to the *SOAP API Developer Guide*.

Response

CompileTriggerResult

`executeanonymous()`

Executes a block of Apex.

Syntax

```
ExecuteAnonymousResult[] = binding.executeanonymous(string apexcode);
```

Usage

Use this call to execute an anonymous block of Apex. This call can be executed from AJAX.

This call supports the API DebuggingHeader and SessionHeader.

If a component in a package with restricted API access issues this call, the request is blocked.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Arguments

Name	Type	Description
`apexcode`	string*	A block of Apex.

* Link goes to the *SOAP API Developer Guide*.

SOAP API Developer Guide contains information about security, access, and SOAP headers.

Response

ExecuteAnonymousResult[]

IN THIS SECTION:

ExecuteAnonymousResult

ExecuteAnonymousResult

The `executeanonymous()` call returns information about whether or not the compile and run of the code was successful.

An `ExecuteAnonymousResult` object has the following properties:

Name	Type	Description
`column`	int*	If `compiled` is False, this field contains the column number of the point where the compile failed.
`compileProblem`	string*	If `compiled` is False, this field contains a description of the problem that caused the compile to fail.
`compiled`	boolean*	If True, the code was successfully compiled. If False, the `column`, `line`, and `compileProblem` fields are not null.
`exceptionMessage`	string*	If `success` is False, this field contains the exception message for the failure.
`exceptionStackTrace`	string*	If `success` is False, this field contains the stack trace for the failure.
`line`	int*	If `compiled` is False, this field contains the line number of the point where the compile failed.
`success`	boolean*	If True, the code was successfully executed. If False, the `exceptionMessage` and `exceptionStackTrace` values are not null.

* Link goes to the *SOAP API Developer Guide*.

`runTests()`

Run your Apex unit tests.

Syntax

```
RunTestsResult[] = binding.runTests(RunTestsRequest request);
```

Usage

To facilitate the development of robust, error-free code, Apex supports the creation and execution of *unit tests*. Unit tests are class methods that verify whether a particular piece of code is working properly. Unit test methods take no arguments, commit no data to the database, send no emails, and are flagged with the `testMethod` keyword or the `@isTest` annotation in the method definition. Also, test methods must be defined in test classes, that is, classes annotated with `@isTest`. Use this call to run your Apex unit tests.

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the *SOAP API Developer Guide*.

Sample Code—Java

```
public void runTestsSample() {
   String sessionId = "sessionID goes here";
   String url = "url goes here";
   // Set the Apex stub with session ID received from logging in with the partner API
   _SessionHeader sh = new _SessionHeader();
   apexBinding.setHeader(
      new ApexServiceLocator().getServiceName().getNamespaceURI(),
      "SessionHeader", sh);
   // Set the URL received from logging in with the partner API to the Apex stub
   apexBinding._setProperty(ApexBindingStub.ENDPOINT_ADDRESS_PROPERTY, url);

   // Set the debugging header
   _DebuggingHeader dh = new _DebuggingHeader();
   dh.setDebugLevel(LogType.Profiling);
   apexBinding.setHeader(
      new ApexServiceLocator().getServiceName().getNamespaceURI(),
      "DebuggingHeader", dh);

   long start = System.currentTimeMillis();
   RunTestsRequest rtr = new RunTestsRequest();
   rtr.setAllTests(true);
   RunTestsResult res = null;
   try {
      res = apexBinding.runTests(rtr);
   } catch (RemoteException e) {
      System.out.println("An unexpected error occurred: " + e.getMessage());
   }

   System.out.println("Number of tests: " + res.getNumTestsRun());
   System.out.println("Number of failures: " + res.getNumFailures());
   if (res.getNumFailures() > 0) {
      for (RunTestFailure rtf : res.getFailures()) {
         System.out.println("Failure: " + (rtf.getNamespace() ==
         null ? "" : rtf.getNamespace() + ".")
         + rtf.getName() + "." + rtf.getMethodName() + ": "
         + rtf.getMessage() + "\n" + rtf.getStackTrace());
      }
   }
   if (res.getCodeCoverage() != null) {
      for (CodeCoverageResult ccr : res.getCodeCoverage()) {
         System.out.println("Code coverage for " + ccr.getType() +
         (ccr.getNamespace() == null ? "" : ccr.getNamespace() + ".")
         + ccr.getName() + ": "
         + ccr.getNumLocationsNotCovered()
         + " locations not covered out of "
         + ccr.getNumLocations());

      if (ccr.getNumLocationsNotCovered() > 0) {
         for (CodeLocation cl : ccr.getLocationsNotCovered())
```

```
            System.out.println("\tLine " + cl.getLine());
        }
      }
    }
    System.out.println("Finished in " +
    (System.currentTimeMillis() - start) + "ms");
}
```

Arguments

Name	Type	Description
`request`	RunTestsRequest	A request that includes the Apex unit tests and the values for any fields that need to be set for this request.

Response

RunTestsResult

IN THIS SECTION:

- RunTestsRequest
- RunTestsResult

RunTestsRequest

Specifies information about the Apex code to be tested. RunTestsRequest is part of CompileAndTestRequest, which is the request passed to the `compileAndTest()` call. This object is also passed to the Tooling SOAP API call `runTests()`. You can specify the same or different classes to be tested and compiled. Since triggers cannot be tested directly, they are not included in this object. Instead, you must specify a class that calls the trigger.

If the request is sent to a production organization, this request is ignored and all unit tests defined for your organization are run.

The RunTestsRequest object has the following properties:

Name	Type	Description
`allTests`	boolean*	If `allTests` is true, all unit tests defined for your organization are run.
`classes`	string*[]	An array of one or more objects.
`namespace`	string	If specified, the namespace that contains the unit tests to be run. Do not use this property if you specify allTests as true. Also, if you execute `compileAndTest()` in a production organization, this property is ignored, and all unit tests defined for the organization are run.
`maxFailedTests`	int	A mandatory parameter for the Tooling SOAP API call `runTests()`. To allow all tests in a run to execute, set `maxFailedTests` to `-1`. To stop the test run from executing new tests after a given number of tests fail, set `maxFailedTests` to an integer value from `0` to `1,000,000`. This integer value sets the maximum

Name	Type	Description
		allowable test failures. A value of `0` causes the test run to stop if any failure occurs. A value of `1` causes the test run to stop on the second failure, and so on.
`packages`	string*[]	Do not use after version 10.0. For earlier, unsupported releases, the content of the package to be tested.
`skipCodeCoverage`	boolean	Indicates whether to opt out of collecting code coverage information during Apex test runs. Available in API version 43.0 and later.
`tests`	TestsNode[]	A mandatory parameter for the Tooling SOAP API call `runTests()`. Specifies individual test methods in an Apex test class. To specify classes or suites instead of a TestsNode[], set `tests` to `null`. Although this property accepts an array, the array can contain only one entry.

TestsNode

Specifies individual test methods in an Apex test class.

Name	Type	Description
`classId`	string	**Description** The ID of the Apex class that contains the test methods you want to run. `classId` or `className` is required. **Supported Methods** • `getClassId()` • `setClassId(new String "<your class ID>")`
`className`	string	**Description** The name of the Apex class that contains the test methods you want to run. To run tests from a managed package, include the package's namespace using dot notation. `classId` or `className` is required. **Supported Methods** • `getClassName()` • `setClassName(new String "YourClassName")`
`testMethods`	string*[]	**Description** The test methods you want to run. Required. **Supported Methods** • `getTestMethods()`

Name	Type	Description
		• `setTestMethods(new String[] {"testMethod1", "testMethod2"}))`

* Link goes to the *SOAP API Developer Guide*.

RunTestsResult

Contains information about the execution of unit tests, including whether unit tests were completed successfully, code coverage results, and failures.

A RunTestsResult object has the following properties:

Name	Type	Description
`apexLogId`	string	The ID of an ApexLog object that is created at the end of a test run. The ApexLog object is created if there is an active trace flag on the user running an Apex test, or on a class or trigger being executed. This field is available in API version 35.0 and later.
`codeCoverage`	CodeCoverageResult[]	An array of one or more CodeCoverageResult objects that contains the details of the code coverage for the specified unit tests.
`codeCoverageWarnings`	CodeCoverageWarning[]	An array of one or more code coverage warnings for the test run. The results include both the total number of lines that could have been executed, as well as the number, line, and column positions of code that was not executed.
`failures`	RunTestFailure[]	An array of one or more RunTestFailure objects that contain information about the unit test failures, if there are any.
`flowCoverage`	FlowCoverageResult on page 3189[]	An array of results from test runs that executed flows. This field is available in API version 44.0 and later.
`flowCoverageWarnings`	FlowCoverageWarning on page 3190[]	An array of warnings generated by test runs that executed flows. This field is available in API version 44.0 and later.
`numFailures`	int	The number of failures for the unit tests.
`numTestsRun`	int	The number of unit tests that were run.
`successes`	RunTestSuccess[]	An array of one or more RunTestSuccess objects that contain information about successes, if there are any.
`totalTime`	double	The total cumulative time spent running tests. This can be helpful for performance monitoring.

CodeCoverageResult

The RunTestsResult object contains this object. It contains information about whether or not the compile of the specified Apex and run of the unit tests was successful.

A CodeCoverageResult object has the following properties:

Name	Type	Description
`dmlInfo`	CodeLocation[]	For each class or trigger tested, for each portion of code tested, this property contains the DML statement locations, the number of times the code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.
`id`	ID	The ID of the CodeLocation. The ID is unique within an organization.
`locationsNotCovered`	CodeLocation[]	For each class or trigger tested, if any code is not covered, the line and column of the code not tested, and the number of times the code was executed.
`methodInfo`	CodeLocation[]	For each class or trigger tested, the method invocation locations, the number of times the code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.
`name`	string	The name of the class or trigger covered.
`namespace`	string	The namespace that contained the unit tests, if one is specified.
`numLocations`	int	The total number of code locations.
`soqlInfo`	CodeLocation[]	For each class or trigger tested, the location of SOQL statements in the code, the number of times this code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.
`soslInfo`	CodeLocation[]	For each class tested, the location of SOSL statements in the code, the number of times this code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.
`type`	string	Do not use. In early, unsupported releases, used to specify class or package.

CodeCoverageWarning

The RunTestsResult object contains this object. It contains information about the Apex class which generated warnings.

This object has the following properties:

Name	Type	Description
`id`	ID	The ID of the class which generated warnings.

Name	Type	Description
`message`	string	The message of the warning generated.
`name`	string	The name of the class that generated a warning. If the warning applies to the overall code coverage, this value is null.
`namespace`	string	The namespace that contains the class, if one was specified.

RunTestFailure

The RunTestsResult object returns information about failures during the unit test run.

This object has the following properties:

Name	Type	Description
`id`	ID	The ID of the class which generated failures.
`message`	string	The failure message.
`methodName`	string	The name of the method that failed.
`name`	string	The name of the class that failed.
`namespace`	string	The namespace that contained the class, if one was specified.
`seeAllData`	boolean	Indicates whether the test method has access to organization data (`true`) or not (`false`). This field is available in API version 33.0 and later.
`stackTrace`	string	The stack trace for the failure.
`time`	double	The time spent running tests for this failed operation. This can be helpful for performance monitoring.
`type`	string	Do not use. In early, unsupported releases, used to specify class or package.

FlowCoverageResult

This object contains information about the flow version and the number of elements executed by the test run. This object is available in API version 44.0 and later.

Name	Type	Description
`elementsNotCovered`	string	List of elements in the flow version that weren't executed by the test run.

Name	Type	Description
`flowId`	string	The ID of the flow version. The ID is unique within an org.
`flowName`	string	The name of the flow that was executed by the test run.
`flowNamespace`	string	The namespace that contains the flow, if one is specified.
`numElements`	int	The total number of elements in the flow version.
`numElementsNotCovered`	int	The number of elements in the flow version that weren't executed by the test run
`processType`	FlowProcessType (enumeration of type string)	The process type of the flow version.

FlowCoverageWarning

This object contains information about the flow version that generated warnings. This object is available in API version 44.0 and later.

Name	Type	Description
`flowId`	string	The ID of the flow version that generated the warning.
`flowName`	string	The name of the flow that generated the warning. If the warning applies to the overall test coverage of flows within your org, this value is null.
`flowNamespace`	string	The namespace that contains the flow, if one was specified.
`message`	string	The message of the warning that was generated.

RunTestSuccess

The RunTestsResult object returns information about successes during the unit test run.

This object has the following properties:

Name	Type	Description
`id`	ID	The ID of the class which generated the success.
`methodName`	string	The name of the method that succeeded.
`name`	string	The name of the class that succeeded.
`namespace`	string	The namespace that contained the class, if one was specified.
`seeAllData`	boolean	Indicates whether the test method has access to organization data (`true`) or not (`false`). This field is available in API version 33.0 and later.

Name	Type	Description
`time`	double	The time spent running tests for this operation. This can be helpful for performance monitoring.

CodeLocation

The RunTestsResult object contains this object in a number of fields.

This object has the following properties:

Name	Type	Description
`column`	int	The column location of the Apex tested.
`line`	int	The line location of the Apex tested.
`numExecutions`	int	The number of times the Apex was executed in the test run.
`time`	double	The total cumulative time spent at this location. This can be helpful for performance monitoring.

DebuggingHeader

Return the debug log in the output header, `DebuggingInfo`, and specify the level of detail in the debug log.

API Calls

`compileAndTest()`, `executeanonymous()`, `runTests()`

Fields

Element Name	Type	Description
`categories`	LogInfo[]	Specifies the type and amount of information to be returned in the debug log.
`debugLevel`	DebugLevel (enumeration of type string)	Deprecated. This field is provided only for backward compatibility. If you provide values for both `debugLevel` and `categories`, the `categories` value is used. The `debugLevel` field specifies the type of information returned in the debug log. The values are listed from the least amount of information returned to the most information returned. Valid values include: • `None` • `Debugonly` • `Db` • `Profiling`

Element Name	Type	Description
		• `Callout` • `Detail`

LogInfo

Specifies the type and amount of information to be returned in the debug log. The `categories` field takes a list of these objects. LogInfo is a mapping of `category` to `level`.

Fields

Element Name	Type	Description
`category`	LogCategory	Specify the type of information returned in the debug log. Valid values are: • `Db` • `Workflow` • `Validation` • `Callout` • `Apex_code` • `Apex_profiling` • `Visualforce` • `System` • `All`
`level`	LogCategoryLevel	Specifies the level of detail returned in the debug log. Valid log levels are (listed from lowest to highest): • `NONE` • `ERROR` • `WARN` • `INFO` • `DEBUG` • `FINE` • `FINER` • `FINEST`

PackageVersionHeader

Specifies the package version for each installed managed package.

A managed package can have several versions with different content and behavior. This header allows you to specify the version used for each package referenced by your API client.

If a package version is not specified, the API client uses the version of the package specified in Setup (enter *API* in the `Quick Find` box, then select **API**).

API Calls

`compileAndTest()`, `compileClasses()`, `compileTriggers()`, `executeanonymous()`

Fields

Element Name	Type	Description
`packageVersions`	PackageVersion[]	A list of package versions for installed managed packages referenced by your API client.

PackageVersion

Specifies a version of an installed managed package. A package version is *majorNumber.minorNumber*, for example `2.1`.

Fields

Field	Type	Description
`majorNumber`	int	The major version number of a package version.
`minorNumber`	int	The minor version number of a package version.
`namespace`	string	The unique namespace of the managed package.

Shipping Invoice Example

This appendix provides an example of an Apex application. This is a more complex example than the Hello World example.

- Shipping Invoice Walk-Through
- Shipping Invoice Example Code

IN THIS SECTION:

1. Shipping Invoice Example Walk-Through
2. Shipping Invoice Example Code

Shipping Invoice Example Walk-Through

The sample application in this section includes traditional Salesforce functionality blended with Apex. Many of the syntactic and semantic features of Apex, along with common idioms, are illustrated in this application.

Note: The Shipping Invoice sample requires custom objects. You can either create these on your own, or download the objects and Apex code as an unmanaged package from the Salesforce AppExchange. To obtain the sample assets in your org, install the Apex Tutorials Package. This package also contains sample code and objects for the Apex Quick Start.

Scenario

In this sample application, the user creates a new shipping invoice, or order, and then adds items to the invoice. The total amount for the order, including shipping cost, is automatically calculated and updated based on the items added or deleted from the invoice.

Data and Code Models

This sample application uses two new objects: Item and Shipping_invoice.

The following assumptions are made:

- Item A cannot be in both orders shipping_invoice1 and shipping_invoice2. Two customers cannot obtain the same (physical) product.
- The tax rate is 9.25%.
- The shipping rate is 75 cents per pound.
- Once an order is over $100, the shipping discount is applied (shipping becomes free).

The fields in the Item custom object include:

Name	Type	Description
Name	String	The name of the item
Price	Currency	The price of the item
Quantity	Number	The number of items in the order
Weight	Number	The weight of the item, used to calculate shipping costs
Shipping_invoice	Master-Detail (shipping_invoice)	The order this item is associated with

The fields in the Shipping_invoice custom object include:

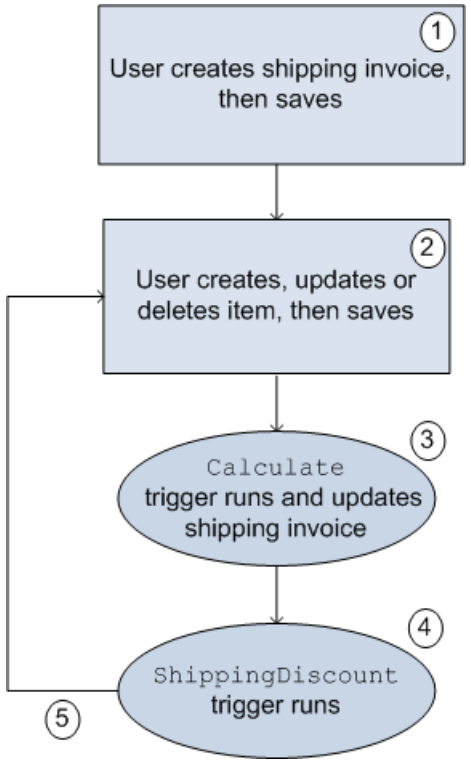
Name	Type	Description
Name	String	The name of the shipping invoice/order
Subtotal	Currency	The subtotal
GrandTotal	Currency	The total amount, including tax and shipping
Shipping	Currency	The amount charged for shipping (assumes $0.75 per pound)
ShippingDiscount	Currency	Only applied once when subtotal amount reaches $100
Tax	Currency	The amount of tax (assumes 9.25%)
TotalWeight	Number	The total weight of all items

All of the Apex for this application is contained in triggers. This application has the following triggers:

Object	Trigger Name	When Runs	Description
Item	Calculate	after insert, after update, after delete	Updates the shipping invoice, calculates the totals and shipping
Shipping_invoice	ShippingDiscount	after update	Updates the shipping invoice, calculating if there is a shipping discount

The following is the general flow of user actions and when triggers run:

Flow of user action and triggers for the shopping cart application



1. User clicks **Orders** > **New**, names the shipping invoice and clicks **Save**.
2. User clicks **New Item**, fills out information, and clicks **Save**.
3. Calculate trigger runs. Part of the Calculate trigger updates the shipping invoice.
4. ShippingDiscount trigger runs.
5. User can then add, delete or change items in the invoice.

In Shipping Invoice Example Code both of the triggers and the test class are listed. The comments in the code explain the functionality.

Testing the Shipping Invoice Application

Before an application can be included as part of a package, 75% of the code must be covered by unit tests. Therefore, one piece of the shipping invoice application is a class used for testing the triggers.

The test class verifies the following actions are completed successfully:

- Inserting items
- Updating items
- Deleting items
- Applying shipping discount
- Negative test for bad input

Shipping Invoice Example Code

The following triggers and test class make up the shipping invoice example application:

- Calculate trigger
- ShippingDiscount trigger
- Test class

Calculate Trigger

```
trigger calculate on Item__c (after insert, after update, after delete) {

// Use a map because it doesn't allow duplicate values

Map<ID, Shipping_Invoice__C> updateMap = new Map<ID, Shipping_Invoice__C>();

// Set this integer to -1 if we are deleting
Integer subtract ;

// Populate the list of items based on trigger type
List<Item__c> itemList;
    if(trigger.isInsert || trigger.isUpdate){
        itemList = Trigger.new;
        subtract = 1;
    }
    else if(trigger.isDelete)
    {
        // Note -- there is no trigger.new in delete
        itemList = trigger.old;
        subtract = -1;
    }

// Access all the information we need in a single query
// rather than querying when we need it.
// This is a best practice for bulkifying requests

set<Id> AllItems = new set<id>();

for(item__c i :itemList){
// Assert numbers are not negative.
// None of the fields would make sense with a negative value

System.assert(i.quantity__c > 0, 'Quantity must be positive');
System.assert(i.weight__c >= 0, 'Weight must be non-negative');
System.assert(i.price__c >= 0, 'Price must be non-negative');
```

```
// If there is a duplicate Id, it won't get added to a set
AllItems.add(i.Shipping_Invoice__C);
}

// Accessing all shipping invoices associated with the items in the trigger
List<Shipping_Invoice__C> AllShippingInvoices = [SELECT Id, ShippingDiscount__c,
                    SubTotal__c, TotalWeight__c, Tax__c, GrandTotal__c
                    FROM Shipping_Invoice__C WHERE Id IN :AllItems];

// Take the list we just populated and put it into a Map.
// This will make it easier to look up a shipping invoice
// because you must iterate a list, but you can use lookup for a map,
Map<ID, Shipping_Invoice__C> SIMap = new Map<ID, Shipping_Invoice__C>();

for(Shipping_Invoice__C sc : AllShippingInvoices)
{
    SIMap.put(sc.id, sc);
}

// Process the list of items
    if(Trigger.isUpdate)
    {
        // Treat updates like a removal of the old item and addition of the
        // revised item rather than figuring out the differences of each field
        // and acting accordingly.
        // Note updates have both trigger.new and trigger.old
        for(Integer x = 0; x < Trigger.old.size(); x++)
        {
            Shipping_Invoice__C myOrder;
            myOrder = SIMap.get(trigger.old[x].Shipping_Invoice__C);

            // Decrement the previous value from the subtotal and weight.
            myOrder.SubTotal__c -= (trigger.old[x].price__c *
                                    trigger.old[x].quantity__c);
            myOrder.TotalWeight__c -= (trigger.old[x].weight__c *
                                       trigger.old[x].quantity__c);

            // Increment the new subtotal and weight.
            myOrder.SubTotal__c += (trigger.new[x].price__c *
                                    trigger.new[x].quantity__c);
            myOrder.TotalWeight__c += (trigger.new[x].weight__c *
                                       trigger.new[x].quantity__c);
        }

        for(Shipping_Invoice__C myOrder : AllShippingInvoices)
        {

            // Set tax rate to 9.25%  Please note, this is a simple example.
            // Generally, you would never hard code values.
            // Leveraging Custom Settings for tax rates is a best practice.
            // See Custom Settings in the Apex Developer Guide
            // for more information.
            myOrder.Tax__c = myOrder.Subtotal__c * .0925;
```

```
            // Reset the shipping discount
            myOrder.ShippingDiscount__c = 0;

            // Set shipping rate to 75 cents per pound.
            // Generally, you would never hard code values.
            // Leveraging Custom Settings for the shipping rate is a best practice.
            // See Custom Settings in the Apex Developer Guide
            // for more information.
            myOrder.Shipping__c = (myOrder.totalWeight__c * .75);
            myOrder.GrandTotal__c = myOrder.SubTotal__c + myOrder.tax__c +
                                    myOrder.Shipping__c;
            updateMap.put(myOrder.id, myOrder);
         }
    }
    else
    {
        for(Item__c itemToProcess : itemList)
        {
            Shipping_Invoice__C myOrder;

            // Look up the correct shipping invoice from the ones we got earlier
            myOrder = SIMap.get(itemToProcess.Shipping_Invoice__C);
            myOrder.SubTotal__c += (itemToProcess.price__c *
                                    itemToProcess.quantity__c * subtract);
            myOrder.TotalWeight__c += (itemToProcess.weight__c *
                                       itemToProcess.quantity__c * subtract);
        }

        for(Shipping_Invoice__C myOrder : AllShippingInvoices)
        {

             // Set tax rate to 9.25%  Please note, this is a simple example.
             // Generally, you would never hard code values.
             // Leveraging Custom Settings for tax rates is a best practice.
             // See Custom Settings in the Apex Developer Guide
             // for more information.
             myOrder.Tax__c = myOrder.Subtotal__c * .0925;

             // Reset shipping discount

Action Links Labels

Use these labels for action link buttons.

An action link is a button on a feed element. Clicking an action link can take a user to a Web page, initiate a file download, or invoke an API call to Salesforce or to an external server. An action link includes a URL and an HTTP method, and can include a request body and

header information, such as an OAuth token for authentication. Use action links to integrate Salesforce and third-party services into the feed so that users can take action to drive productivity and accelerate innovation.

Specify the key in the `labelKey` property of the Action Link Definition Input request body. When the action link is rendered, the UI uses labels for the "New," "Pending," "Success," and "Failed" states as needed.

Tip: If none of the predefined labels work for your action link, use a custom label. To use a custom label, create an action link template and define the label in the template. See Action Link Templates.

Documentation Typographical Conventions

Apex and Visualforce documentation uses the following typographical conventions.

Convention	Description
`Courier font`	In descriptions of syntax, monospace font indicates items that you should type as shown, except for brackets. For example: `Public class HelloWorld`

Convention	Description
Italics	In descriptions of syntax, italics represent variables. You supply the actual value. In the following example, three values need to be supplied: *datatype variable_name* [= *value*]; If the syntax is bold and italic, the text represents a code element that needs a value supplied by you, such as a class name or variable value: `public static class YourClassHere { ... }`
Bold Courier font	In code samples and syntax descriptions, bold courier font emphasizes a portion of the code or syntax.

< >	In descriptions of syntax, less-than and greater-than symbols (< >) are typed exactly as shown.
	`<apex:pageBlockTable value="{!account.Contacts}" var="contact">`
	`  <apex:column value="{!contact.Name}"/>`
	`  <apex:column value="{!contact.MailingCity}"/>`
	`  <apex:column value="{!contact.Phone}"/>`
	`</apex:pageBlockTable>`

{ }	In descriptions of syntax, braces ({ }) are typed exactly as shown.
	`<apex:page>`
	`  Hello {!$User.FirstName}!`
	`</apex:page>`

[ ]	In descriptions of syntax, anything included in brackets is optional. In the following example, specifying ***value*** is optional: `data_type variable_name [ = value];`

|	In descriptions of syntax, the pipe sign means "or". You can do one of the following (not all). In the following example, you can create a new unpopulated set in one of two ways, or you can populate the set:
	`Set<data_type> set_name`
	`  [= new Set<data_type>();] |`
	`  [= new Set<data_type>{value [, value2. . .] };] |`
	`  ;`

Glossary

A | B | C | D | E | F | G | H | I | J | L | M | N | O | P | Q | R | S | T | U | V | W | X | Y | Z

A

Administrator (System Administrator)
One or more individuals in your organization who can configure and customize the application. Users assigned to the System Administrator profile have administrator privileges.

AJAX Toolkit
A JavaScript wrapper around the API that allows you to execute any API call and access any object you have permission to view from within JavaScript code. For more information, see the *AJAX Toolkit Developer's Guide*.

Anti-Join
An anti-join is a subquery on another object in a `NOT IN` clause in a SOQL query. You can use anti-joins to create advanced queries. See also Semi-Join.

Anonymous Block, Apex
Apex code that does not get stored in Salesforce, but that can be compiled and executed by using the `ExecuteAnonymousResult()` API call, or the equivalent in the AJAX Toolkit.

Apex
Apex is a strongly typed, object-oriented programming language that allows developers to execute flow and transaction control statements on the Lightning platform server in conjunction with calls to the Lightning Platform API. Using syntax that looks like Java and acts like database stored procedures, Apex enables developers to add business logic to most system events, including button clicks, related record updates, and Visualforce pages. Apex code can be initiated by Web service requests and from triggers on objects.

Apex Connector Framework
The Apex Connector Framework is a set of classes and methods in the DataSource namespace for creating a custom adapter for Salesforce Connect. Create a custom adapter to connect to data that's stored outside your Salesforce org when the other available Salesforce Connect adapters aren't suitable for your needs.

Apex-Managed Sharing
Enables developers to programmatically manipulate sharing to support their application's behavior. Apex-managed sharing is only available for custom objects.

Apex Page
See Visualforce page.

App
Short for "application." A collection of components such as tabs, reports, dashboards, and Visualforce pages that address a specific business need. Salesforce provides standard apps such as Sales and Service. You can customize the standard apps to match the way you work. In addition, you can package an app and upload it to the AppExchange along with related components such as custom fields, custom tabs, and custom objects. Then, you can make the app available to other Salesforce users from the AppExchange.

AppExchange
The AppExchange is a sharing interface from Salesforce that allows you to browse and share apps and services for the Lightning Platform.

Application Programming Interface (API)
The interface that a computer system, library, or application provides to allow other computer programs to request services from it and exchange data.

Approval Process
An approval process automates how records are approved in Salesforce. An approval process specifies each step of approval, including who to request approval from and what to do at each point of the process.

Asynchronous Calls
A call that doesn't return results immediately because the operation can take a long time. Calls in the Metadata API and Bulk API are asynchronous.

B

Batch Apex
The ability to perform long, complex operations on many records at a scheduled time using Apex.

Beta, Managed Package
In the context of managed packages, a beta managed package is an early version of a managed package distributed to a sampling of your intended audience to test it.

Bulk API
The REST-based Bulk API is optimized for processing large sets of data. It allows you to query, insert, update, upsert, or delete a large number of records asynchronously by submitting a number of batches which are processed in the background by Salesforce. See also SOAP API.

C

Callout, Apex
An Apex callout enables you to tightly integrate your Apex with an external service by making a call to an external Web service or sending a HTTP request from Apex code and then receiving the response.

Child Relationship
A relationship that has been defined on an sObject that references another sObject as the "one" side of a one-to-many relationship. For example, contacts, opportunities, and tasks have child relationships with accounts.

See also sObject.

Class, Apex
A template or blueprint from which Apex objects are created. Classes consist of other classes, user-defined methods, variables, exception types, and static initialization code. In most cases, Apex classes are modeled on their counterparts in Java.

Client App
An app that runs outside the Salesforce user interface and uses only the Lightning Platform API or Bulk API. It typically runs on a desktop or mobile device. These apps treat the platform as a data source, using the development model of whatever tool and platform for which they are designed.

Code Coverage
A way to identify which lines of code are exercised by a set of unit tests, and which are not. This helps you identify sections of code that are completely untested and therefore at greatest risk of containing a bug or introducing a regression in the future.

Component, Metadata
A component is an instance of a metadata type in the Metadata API. For example, CustomObject is a metadata type for custom objects, and the `MyCustomObject__c` component is an instance of a custom object. A component is described in an XML file and it can be deployed or retrieved using the Metadata API, or tools built on top of it, such as the Force.com IDE or the Ant Migration Tool.

Component, Visualforce
Something that can be added to a Visualforce page with a set of tags, for example, `<apex:detail>`. Visualforce includes a number of standard components, or you can create your own custom components.

Component Reference, Visualforce
A description of the standard and custom Visualforce components that are available in your organization. You can access the component library from the development footer of any Visualforce page or the *Visualforce Developer's Guide*.

Composite App
An app that combines native platform functionality with one or more external Web services, such as Yahoo! Maps. Composite apps allow for more flexibility and integration with other services, but may require running and managing external code. See also Client App and Native App.

Controller, Visualforce
An Apex class that provides a Visualforce page with the data and business logic it needs to run. Visualforce pages can use the standard controllers that come by default with every standard or custom object, or they can use custom controllers.

Controller Extension
A controller extension is an Apex class that extends the functionality of a standard or custom controller.

Cookie
Client-specific data used by some Web applications to store user and session-specific information. Salesforce issues a session "cookie" only to record encrypted authentication information for the duration of a specific session.

Custom App
See App.

Custom Controller
A custom controller is an Apex class that implements all of the logic for a page without leveraging a standard controller. Use custom controllers when you want your Visualforce page to run entirely in system mode, which does not enforce the permissions and field-level security of the current user.

Custom Field
A field that can be added in addition to the standard fields to customize Salesforce for your organization's needs.

Custom Links
Custom links are URLs defined by administrators to integrate your Salesforce data with external websites and back-office systems. Formerly known as Web links.

Custom Object
Custom records that allow you to store information unique to your organization.

Custom Settings
Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data can then be used by formula fields, validation rules, flows, Apex, and the SOAP API.

See also Hierarchy Custom Settings and List Custom Settings.

D

Database
An organized collection of information. The underlying architecture of the Lightning Platform includes a database where your data is stored.

Database Table
A list of information, presented with rows and columns, about the person, thing, or concept you want to track. See also Object.

Data Loader
A Lightning Platform tool used to import and export data from your Salesforce organization.

Data Manipulation Language (DML)
An Apex method or operation that inserts, updates, or deletes records.

Data State
The structure of data in an object at a particular point in time.

Date Literal
A keyword in a SOQL or SOSL query that represents a relative range of time such as `last month` or `next year`.

Decimal Places
Parameter for number, currency, and percent custom fields that indicates the total number of digits you can enter to the right of a decimal point, for example, 4.98 for an entry of 2. Note that the system rounds the decimal numbers you enter, if necessary. For example, if you enter 4.986 in a field with `Decimal Places` of 2, the number rounds to 4.99. Salesforce uses the round half-up rounding algorithm. Half-way values are always rounded up. For example, 1.45 is rounded to 1.5. –1.45 is rounded to –1.5.

Dependency
A relationship where one object's existence depends on that of another. There are a number of different kinds of dependencies including mandatory fields, dependent objects (parent-child), file inclusion (referenced images, for example), and ordering dependencies (when one object must be deployed before another object).

Dependent Field
Any custom picklist or multi-select picklist field that displays available values based on the value selected in its corresponding controlling field.

Deploy
To move functionality from an inactive state to active. For example, when developing new features in the Salesforce user interface, you must select the "Deployed" option to make the functionality visible to other users.

The process by which an application or other functionality is moved from development to production.

To move metadata components from a local file system to a Salesforce organization.

For installed apps, deployment makes any custom objects in the app available to users in your organization. Before a custom object is deployed, it is only available to administrators and any users with the "Customize Application" permission.

Deprecated Component
Developers can refine the functionality in a managed package over time as the requirements evolve, such as redesign some of the components in the managed package. Developers can't delete some components in a Managed - Released package, but they can deprecate a component in a later package version so that new subscribers don't receive the component, while the component continues to function for existing subscribers and API integrations.

Detail
A page that displays information about a single object record. The detail page of a record allows you to view the information, whereas the edit page allows you to modify it.

A term used in reports to distinguish between summary information and inclusion of all column data for all information in a report. You can toggle the **Show Details**/**Hide Details** button to view and hide report detail information.

Developer Edition
A free, fully-functional Salesforce organization designed for developers to extend, integrate, and develop with the Lightning Platform. Developer Edition accounts are available on developer.salesforce.com.

Salesforce Developers
The Salesforce Developers website at developer.salesforce.com provides a full range of resources for platform developers, including sample code, toolkits, an online developer community, and the ability to obtain limited Lightning Platform environments.

Development Environment
A Salesforce organization where you can make configuration changes that will not affect users on the production organization. There are two kinds of development environments, sandboxes and Developer Edition organizations.

E

Email Alert
Email alerts are actions that send emails, using a specified email template, to specified recipients.

Email Template
A form email that communicates a standard message, such as a welcome letter to new employees or an acknowledgement that a customer service request has been received. Email templates can be personalized with merge fields, and can be written in text, HTML, or custom format.

Enterprise Edition
A Salesforce edition designed for larger, more complex businesses.

Enterprise WSDL
A strongly-typed WSDL for customers who want to build an integration with their Salesforce organization only, or for partners who are using tools like Tibco or webMethods to build integrations that require strong typecasting. The downside of the Enterprise WSDL is that it only works with the schema of a single Salesforce organization because it is bound to all of the unique objects and fields that exist in that organization's data model.

Entity Relationship Diagram (ERD)
A data modeling tool that helps you organize your data into entities (or objects, as they are called in the Lightning Platform) and define the relationships between them. ERD diagrams for key Salesforce objects are published in the *SOAP API Developer's Guide*.

Enumeration Field
An enumeration is the WSDL equivalent of a picklist field. The valid values of the field are restricted to a strict set of possible values, all having the same data type.

F

Facet
A child of another Visualforce component that allows you to override an area of the rendered parent with the contents of the facet.

Field
A part of an object that holds a specific piece of information, such as a text or currency value.

Field Dependency
A filter that allows you to change the contents of a picklist based on the value of another field.

Field-Level Security
Settings that determine whether fields are hidden, visible, read only, or editable for users. Available in Professional, Enterprise, Unlimited, Performance, and Developer Editions.

Lightning Platform
The Salesforce platform for building applications in the cloud. Lightning Platform combines a powerful user interface, operating system, and database to allow you to customize and deploy applications in the cloud for your entire enterprise.

Force.com IDE
An Eclipse plug-in that allows developers to manage, author, debug and deploy Lightning Platform applications in the Eclipse development environment.

Ant Migration Tool
A toolkit that allows you to write an Apache Ant build script for migrating Lightning Platform components between a local file system and a Salesforce organization.

Foreign Key
A field whose value is the same as the primary key of another table. You can think of a foreign key as a copy of a primary key from another table. A relationship is made between two tables by matching the values of the foreign key in one table with the values of the primary key in another.

G

Getter Methods
Methods that enable developers to display database and other computed values in page markup.

Methods that return values. See also Setter Methods.

Global Variable
A special merge field that you can use to reference data in your organization.

A method access modifier for any method that needs to be referenced outside of the application, either in the SOAP API or by other Apex code.

Governor Limits
Apex execution limits that prevent developers who write inefficient code from monopolizing the resources of other Salesforce users.

Gregorian Year
A calendar based on a 12-month structure used throughout much of the world.

H

Hierarchy Custom Settings
A type of custom setting that uses a built-in hierarchical logic that lets you "personalize" settings for specific profiles or users. The hierarchy logic checks the organization, profile, and user settings for the current user and returns the most specific, or "lowest," value. In the hierarchy, settings for an organization are overridden by profile settings, which, in turn, are overridden by user settings.

HTTP Debugger
An application that can be used to identify and inspect SOAP requests that are sent from the AJAX Toolkit. They behave as proxy servers running on your local machine and allow you to inspect and author individual requests.

I

ID
See Salesforce Record ID.

IdeaExchange
A forum where Salesforce customers can suggest new product concepts, promote favorite enhancements, interact with product managers and other customers, and preview what Salesforce is planning to deliver in future releases. Visit IdeaExchange at ideas.salesforce.com.

Import Wizard
A tool for importing data into your Salesforce organization, accessible from Setup.

Instance
The cluster of software and hardware represented as a single logical server that hosts an organization's data and runs their applications. The Lightning Platform runs on multiple instances, but data for any single organization is always stored on a single instance.

Integrated Development Environment (IDE)
A software application that provides comprehensive facilities for software developers including a source code editor, testing and debugging tools, and integration with source code control systems.

Integration User
A Salesforce user defined solely for client apps or integrations. Also referred to as the logged-in user in a SOAP API context.

ISO Code
The International Organization for Standardization country code, which represents each country by two letters.

J

Junction Object
A custom object with two master-detail relationships. Using a custom junction object, you can model a "many-to-many" relationship between two objects. For example, you create a custom object called "Bug" that relates to the standard case object such that a bug could be related to multiple cases and a case could also be related to multiple bugs.

L

Length
Parameter for custom text fields that specifies the maximum number of characters (up to 255) that a user can enter in the field.

Parameter for number, currency, and percent fields that specifies the number of digits you can enter to the left of the decimal point, for example, 123.98 for an entry of 3.

Salesforce Connect
Salesforce Connect provides access to data that's stored outside the Salesforce org, such as data in an enterprise resource planning (ERP) system and records in another org. Salesforce Connect represents the data in external objects and accesses the external data in real time via Web service callouts to external data sources.

List Custom Settings
A type of custom setting that provides a reusable set of static data that can be accessed across your organization. If you use a particular set of data frequently within your application, putting that data in a list custom setting streamlines access to it. Data in list settings does not vary with profile or user, but is available organization-wide. Examples of list data include two-letter state abbreviations, international dialing prefixes, and catalog numbers for products. Because the data is cached, access is low-cost and efficient: you don't have to use SOQL queries that count against your governor limits.

List View
A list display of items (for example, accounts or contacts) based on specific criteria. Salesforce provides some predefined views.

In the Agent console, the list view is the top frame that displays a list view of records based on specific criteria. The list views you can select to display in the console are the same list views defined on the tabs of other objects. You cannot create a list view within the console.

Local Name
The value stored for the field in the user's or account's language. The local name for a field is associated with the standard name for that field.

Locale
The country or geographic region in which the user is located. The setting affects the format of date and number fields, for example, dates in the English (United States) locale display as 06/30/2000 and as 30/06/2000 in the English (United Kingdom) locale.

In Professional, Enterprise, Unlimited, Performance, and Developer Edition organizations, a user's individual `Locale` setting overrides the organization's `Default Locale` setting. In Personal and Group Editions, the organization-level locale field is called `Locale`, not `Default Locale`.

Long Text Area
Data type of custom field that allows entry of up to 32,000 characters on separate lines.

Lookup Relationship
A relationship between two records so you can associate records with each other. For example, cases have a lookup relationship with assets that lets you associate a particular asset with a case. On one side of the relationship, a lookup field allows users to click a lookup icon and select another record from a popup window. On the associated record, you can then display a related list to show all of the records that have been linked to it. If a lookup field references a record that has been deleted, by default Salesforce clears the lookup field. Alternatively, you can prevent records from being deleted if they're in a lookup relationship.

M

Managed Package
A collection of application components that is posted as a unit on the AppExchange and associated with a namespace and possibly a License Management Organization. To support upgrades, a package must be managed. An organization can create a single managed package that can be downloaded and installed by many different organizations. Managed packages differ from unmanaged packages by having some locked components, allowing the managed package to be upgraded later. Unmanaged packages do not include locked components and cannot be upgraded. In addition, managed packages obfuscate certain components (like Apex) on subscribing organizations to protect the intellectual property of the developer.

Manual Sharing
Record-level access rules that allow record owners to give read and edit permissions to other users who might not have access to the record any other way.

Many-to-Many Relationship
A relationship where each side of the relationship can have many children on the other side. Many-to-many relationships are implemented through the use of junction objects.

Master-Detail Relationship
A relationship between two different types of records that associates the records with each other. For example, accounts have a master-detail relationship with opportunities. This type of relationship affects record deletion, security, and makes the lookup relationship field required on the page layout.

Metadata
Information about the structure, appearance, and functionality of an organization and any of its parts. Lightning Platform uses XML to describe metadata.

Metadata-Driven Development
An app development model that allows apps to be defined as declarative "blueprints," with no code required. Apps built on the platform—their data models, objects, forms, workflows, and more—are defined by metadata.

Metadata WSDL
A WSDL for users who want to use the Lightning Platform Metadata API calls.

Multitenancy
An application model where all users and apps share a single, common infrastructure and code base.

MVC (Model-View-Controller)
A design paradigm that deconstructs applications into components that represent data (the model), ways of displaying that data in a user interface (the view), and ways of manipulating that data with business logic (the controller).

N

Namespace
In a packaging context, a one- to 15-character alphanumeric identifier that distinguishes your package and its contents from packages of other developers on AppExchange, similar to a domain name. Salesforce automatically prepends your namespace prefix, followed by two underscores ("__"), to all unique component names in your Salesforce organization.

Native App
An app that is built exclusively with setup (metadata) configuration on Lightning Platform. Native apps do not require any external services or infrastructure.

O

Object
An object allows you to store information in your Salesforce organization. The object is the overall definition of the type of information you are storing. For example, the case object allow you to store information regarding customer inquiries. For each object, your organization will have multiple records that store the information about specific instances of that type of data. For example, you might have a case record to store the information about Joe Smith's training inquiry and another case record to store the information about Mary Johnson's configuration issue.

Object-Level Help
Custom help text that you can provide for any custom object. It displays on custom object record home (overview), detail, and edit pages, as well as list views and related lists.

Object-Level Security
Settings that allow an administrator to hide whole objects from users so that they don't know that type of data exists. Object-level security is specified with object permissions.

One-to-Many Relationship
A relationship in which a single object is related to many other objects. For example, an account may have one or more related contacts.

Organization
A deployment of Salesforce with a defined set of licensed users. An organization is the virtual space provided to an individual customer of Salesforce. Your organization includes all of your data and applications, and is separate from all other organizations.

Organization-Wide Defaults
Settings that allow you to specify the baseline level of data access that a user has in your organization. For example, you can set organization-wide defaults so that any user can see any record of a particular object that is enabled via their object permissions, but they need extra permissions to edit one.

Outbound Call
Any call that originates from a user to a number outside of a call center in Salesforce CRM Call Center.

Outbound Message
An outbound message sends information to a designated endpoint, like an external service. Outbound messages are configured from Setup. You must configure the external endpoint and create a listener for the messages using the SOAP API.

Owner
Individual user to which a record (for example, a contact or case) is assigned.

P

PaaS
See Platform as a Service.

Package
A group of Lightning Platform components and applications that are made available to other organizations through the AppExchange. You use packages to bundle an app along with any related components so that you can upload them to AppExchange together.

Package Dependency

This is created when one component references another component, permission, or preference that is required for the component to be valid. Components can include but are not limited to:

- Standard or custom fields
- Standard or custom objects
- Visualforce pages
- Apex code

Permissions and preferences can include but are not limited to:

- Divisions
- Multicurrency
- Record types

Package Installation

Installation incorporates the contents of a package into your Salesforce organization. A package on the AppExchange can include an app, a component, or a combination of the two. After you install a package, you may need to deploy components in the package to make it generally available to the users in your organization.

Package Version

A package version is a number that identifies the set of components uploaded in a package. The version number has the format `majorNumber.minorNumber.patchNumber` (for example, 2.1.3). The major and minor numbers increase to a chosen value during every major release. The `patchNumber` is generated and updated only for a patch release.

Unmanaged packages are not upgradeable, so each package version is simply a set of components for distribution. A package version has more significance for managed packages. Packages can exhibit different behavior for different versions. Publishers can use package versions to evolve the components in their managed packages gracefully by releasing subsequent package versions without breaking existing customer integrations using the package. See also Patch and Patch Development Organization.

Partner WSDL

A loosely-typed WSDL for customers, partners, and ISVs who want to build an integration or an AppExchange app that can work across multiple Salesforce organizations. With this WSDL, the developer is responsible for marshaling data in the correct object representation, which typically involves editing the XML. However, the developer is also freed from being dependent on any particular data model or Salesforce organization. Contrast this with the Enterprise WSDL, which is strongly typed.

Patch

A patch enables a developer to change the functionality of existing components in a managed package, while ensuring subscribing organizations that there are no visible behavior changes to the package. For example, you can add new variables or change the body of an Apex class, but you may not add, deprecate, or remove any of its methods. Patches are tracked by a `patchNumber` appended to every package version. See also Patch Development Organization and Package Version.

Patch Development Organization

The organization where patch versions are developed, maintained, and uploaded. Patch development organizations are created automatically for a developer organization when they request to create a patch. See also Patch and Package Version.

Personal Edition

Product designed for individual sales representatives and single users.

Platform as a Service (PaaS)

An environment where developers use programming tools offered by a service provider to create applications and deploy them in a cloud. The application is hosted as a service and provided to customers via the Internet. The PaaS vendor provides an API for creating and extending specialized applications. The PaaS vendor also takes responsibility for the daily maintenance, operation, and support of the deployed application and each customer's data. The service alleviates the need for programmers to install, configure,

and maintain the applications on their own hardware, software, and related IT resources. Services can be delivered using the PaaS environment to any market segment.

Platform Edition
A Salesforce edition based on Enterprise, Unlimited, or Performance Edition that does not include any of the standard Salesforce apps, such as Sales or Service & Support.

Primary Key
A relational database concept. Each table in a relational database has a field in which the data value uniquely identifies the record. This field is called the primary key. The relationship is made between two tables by matching the values of the foreign key in one table with the values of the primary key in another.

Production Organization
A Salesforce organization that has live users accessing data.

Professional Edition
A Salesforce edition designed for businesses who need full-featured CRM functionality.

Prototype
The classes, methods and variables that are available to other Apex code.

Q

Query Locator
A parameter returned from the `query()` or `queryMore()` API call that specifies the index of the last result record that was returned.

Query String Parameter
A name-value pair that's included in a URL, typically after a '?' character. For example:

```
https://yourInstance.salesforce.com/001/e?name=value
```

R

Record
A single instance of a Salesforce object. For example, “John Jones” might be the name of a contact record.

Record ID
The unique identifier for each record.

Record-Level Security
A method of controlling data in which you can allow a particular user to view and edit an object, but then restrict the records that the user is allowed to see.

Record Locking
Record locking prevents users from editing a record, regardless of field-level security or sharing settings. By default, Salesforce locks records that are pending approval. Only admins can edit locked records.

Record Name
A standard field on all Salesforce objects. Whenever a record name is displayed in a Lightning Platform application, the value is represented as a link to a detail view of the record. A record name can be either free-form text or an autonumber field. `Record Name` does not have to be a unique value.

Recycle Bin
A page that lets you view and restore deleted information. Access the Recycle Bin by using the link in the sidebar.

Relationship
A connection between two objects, used to create related lists in page layouts and detail levels in reports. Matching values in a specified field in both objects are used to link related data; for example, if one object stores data about companies and another object stores data about people, a relationship allows you to find out which people work at the company.

Relationship Query
In a SOQL context, a query that traverses the relationships between objects to identify and return results. Parent-to-child and child-to-parent syntax differs in SOQL queries.

Role Hierarchy
A record-level security setting that defines different levels of users such that users at higher levels can view and edit information owned by or shared with users beneath them in the role hierarchy, regardless of the organization-wide sharing model settings.

Roll-Up Summary Field
A field type that automatically provides aggregate values from child records in a master-detail relationship.

Running User
Each dashboard has a *running user*, whose security settings determine which data to display in a dashboard. If the running user is a specific user, all dashboard viewers see data based on the security settings of that user—regardless of their own personal security settings. For dynamic dashboards, you can set the running user to be the logged-in user, so that each user sees the dashboard according to his or her own access level.

S

SaaS
See Software as a Service (SaaS).

S-Control

Note: S-controls have been superseded by Visualforce pages. After March 2010 organizations that have never created s-controls, as well as new organizations, won't be allowed to create them. Existing s-controls will remain unaffected, and can still be edited.

Custom Web content for use in custom links. Custom s-controls can contain any type of content that you can display in a browser, for example a Java applet, an Active-X control, an Excel file, or a custom HTML Web form.

Salesforce Certificate and Key Pair
Salesforce certificates and key pairs are used for signatures that verify a request is coming from your organization. They are used for authenticated SSL communications with an external web site, or when using your organization as an Identity Provider. You only need to generate a Salesforce certificate and key pair if you're working with an external website that wants verification that a request is coming from a Salesforce organization.

Salesforce Record ID
A unique 15- or 18-character alphanumeric string that identifies a single record in Salesforce.

Salesforce SOA (Service-Oriented Architecture)
A powerful capability of Lightning Platform that allows you to make calls to external Web services from within Apex.

Sandbox
A nearly identical copy of a Salesforce production organization for development, testing, and training. The content and size of a sandbox varies depending on the type of sandbox and the edition of the production organization associated with the sandbox.

Semi-Join
A semi-join is a subquery on another object in an `IN` clause in a SOQL query. You can use semi-joins to create advanced queries, such as getting all contacts for accounts that have an opportunity with a particular record type. See also Anti-Join.

Session ID
An authentication token that is returned when a user successfully logs in to Salesforce. The Session ID prevents a user from having to log in again every time they want to perform another action in Salesforce. Different from a record ID or Salesforce ID, which are terms for the unique ID of a Salesforce record.

Session Timeout
The time after login before a user is automatically logged out. Sessions expire automatically after a predetermined length of inactivity, which can be configured in Salesforce from Setup by clicking **Security Controls**. The default is 120 minutes (two hours). The inactivity timer is reset to zero if a user takes an action in the web interface or makes an API call.

Setter Methods
Methods that assign values. See also Getter Methods.

Setup
A menu where administrators can customize and define organization settings and Lightning Platform apps. Depending on your organization's user interface settings, Setup may be a link in the user interface header or in the dropdown list under your name.

Sharing
Allowing other users to view or edit information you own. There are different ways to share data:

- Sharing Model—defines the default organization-wide access levels that users have to each other's information and whether to use the hierarchies when determining access to data.
- Role Hierarchy—defines different levels of users such that users at higher levels can view and edit information owned by or shared with users beneath them in the role hierarchy, regardless of the organization-wide sharing model settings.
- Sharing Rules—allow an administrator to specify that all information created by users within a given group or role is automatically shared to the members of another group or role.
- Manual Sharing—allows individual users to share records with other users or groups.
- Apex-Managed Sharing—enables developers to programmatically manipulate sharing to support their application's behavior. See Apex-Managed Sharing.

Sharing Model
Behavior defined by your administrator that determines default access by users to different types of records.

Sharing Rule
Type of default sharing created by administrators. Allows users in a specified group or role to have access to all information created by users within a given group or role.

Sites
Salesforce Sites enables you to create public websites and applications that are directly integrated with your Salesforce organization—without requiring users to log in with a username and password.

SOAP (Simple Object Access Protocol)
A protocol that defines a uniform way of passing XML-encoded data.

SOAP API
A SOAP-based Web services application programming interface that provides access to your Salesforce organization's information.

sObject
The abstract or parent object for all objects that can be stored in the Lightning Platform.

Software as a Service (SaaS)
A delivery model where a software application is hosted as a service and provided to customers via the Internet. The SaaS vendor takes responsibility for the daily maintenance, operation, and support of the application and each customer's data. The service alleviates the need for customers to install, configure, and maintain applications with their own hardware, software, and related IT resources. Services can be delivered using the SaaS model to any market segment.

SOQL (Salesforce Object Query Language)
A query language that allows you to construct simple but powerful query strings and to specify the criteria that selects data from the Lightning Platform database.

SOSL (Salesforce Object Search Language)
A query language that allows you to perform text-based searches using the Lightning Platform API.

Standard Object
A built-in object included with the Lightning Platform. You can also build custom objects to store information that is unique to your app.

System Log
Part of the Developer Console, a separate window console that can be used for debugging code snippets. Enter the code you want to test at the bottom of the window and click Execute. The body of the System Log displays system resource information, such as how long a line took to execute or how many database calls were made. If the code did not run to completion, the console also displays debugging information.

T

Tag
In Salesforce, a word or short phrases that users can associate with most records to describe and organize their data in a personalized way. Administrators can enable tags for accounts, activities, assets, campaigns, cases, contacts, contracts, dashboards, documents, events, leads, notes, opportunities, reports, solutions, tasks, and any custom objects (except relationship group members) Tags can also be accessed through the SOAP API.

Test Case Coverage
Test cases are the expected real-world scenarios in which your code will be used. Test cases are not actual unit tests, but are documents that specify what your unit tests should do. High test case coverage means that most or all the real-world scenarios you have identified are implemented as unit tests. See also Code Coverage and Unit Test.

Test Method
An Apex class method that verifies whether a particular piece of code is working properly. Test methods take no arguments, commit no data to the database, and can be executed by the `runTests()` system method either through the command line or in an Apex IDE, such as the Force.com IDE.

Test Organization
See Sandbox.

Transaction, Apex
An *Apex transaction* represents a set of operations that are executed as a single unit. All DML operations in a transaction either complete successfully, or if an error occurs in one operation, the entire transaction is rolled back and no data is committed to the database. The boundary of a transaction can be a trigger, a class method, an anonymous block of code, a Visualforce page, or a custom Web service method.

Trigger
A piece of Apex that executes before or after records of a particular type are inserted, updated, or deleted from the database. Every trigger runs with a set of context variables that provide access to the records that caused the trigger to fire, and all triggers run in bulk mode—that is, they process several records at once, rather than just one record at a time.

Trigger Context Variable
Default variables that provide access to information about the trigger and the records that caused it to fire.

U

Unit Test
A unit is the smallest testable part of an application, usually a method. A unit test operates on that piece of code to make sure it works correctly. See also Test Method.

Unlimited Edition
Unlimited Edition is Salesforce's solution for maximizing your success and extending that success across the entire enterprise through the Lightning Platform.

Unmanaged Package
A package that cannot be upgraded or controlled by its developer.

URL (Uniform Resource Locator)
The global address of a website, document, or other resource on the Internet. For example, http://www.salesforce.com.

User Acceptance Testing (UAT)
A process used to confirm that the functionality meets the planned requirements. UAT is one of the final stages before deployment to production.

V

Validation Rule
A rule that prevents a record from being saved if it does not meet the standards that are specified.

Version
A number value that indicates the release of an item. Items that can have a version include API objects, fields, and calls; Apex classes and triggers; and Visualforce pages and components.

View
The user interface in the Model-View-Controller model, defined by Visualforce.

View State
Where the information necessary to maintain the state of the database between requests is saved.

Visualforce
A simple, tag-based markup language that allows developers to easily define custom pages and components for apps built on the platform. Each tag corresponds to a coarse or fine-grained component, such as a section of a page, a related list, or a field. The components can either be controlled by the same logic that is used in standard Salesforce pages, or developers can associate their own logic with a controller written in Apex.

Visualforce Controller
See Controller, Visualforce.

Visualforce Lifecycle
The stages of execution of a Visualforce page, including how the page is created and destroyed during a user session.

Visualforce Page
A web page created using Visualforce. Typically, Visualforce pages present information relevant to your organization, but they can also modify or capture data. They can be rendered in several ways, such as a PDF document or an email attachment, and can be associated with a CSS style.

W

Web Service
A mechanism by which two applications can easily exchange data over the Internet, even if they run on different platforms, are written in different languages, or are geographically remote from each other.

WebService Method
An Apex class method or variable that external systems can use, like a mash-up with a third-party application. Web service methods must be defined in a global class.

Web Services API
A Web services application programming interface that provides access to your Salesforce organization's information. See also SOAP PI and Bulk API.

Automated Actions
Automated actions, such as email alerts, tasks, field updates, and outbound messages, can be triggered by a process, workflow rule, approval process, or milestone.

Wrapper Class
A class that abstracts common functions such as logging in, managing sessions, and querying and batching records. A wrapper class makes an integration more straightforward to develop and maintain, keeps program logic in one place, and affords easy reuse across components. Examples of wrapper classes in Salesforce include the AJAX Toolkit, which is a JavaScript wrapper around the Salesforce SOAP API, wrapper classes such as `CCritical Section` in the CTI Adapter for Salesforce CRM Call Center, or wrapper classes created as part of a client integration application that accesses Salesforce using the SOAP API.

WSDL (Web Services Description Language) File
An XML file that describes the format of messages you send and receive from a Web service. Your development environment's SOAP client uses the Salesforce Enterprise WSDL or Partner WSDL to communicate with Salesforce using the SOAP API.

X

XML (Extensible Markup Language)
A markup language that enables the sharing and transportation of structured data. All Lightning Platform components that are retrieved or deployed through the Metadata API are represented by XML definitions.
