public Process.PluginDescribeResult.ParameterType ParameterType {get; set;}

**Property Value**
Type: Process.PluginDescribeResult.ParameterType

**PluginRequest Class**
Passes input parameters from the class that implements the Process.Plugin interface to the flow.
Tip: We recommend using the `@InvocableMethod` annotation instead of the `Process.Plugin` interface.

- The interface doesn’t support Blob, Collection, sObject, and Time data types, and it doesn’t support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

### Namespace
Process

### PluginRequest Properties
The following are properties for `PluginRequest`.

#### inputParameters
Input parameters that are passed from the class that implements the `Process.Plugin` interface to the flow.

**Signature**

```java
public MAP<String, ANY> inputParameters {get; set;}
```

**Property Value**

Type: `Map<String, Object>`

### PluginResult Class
Returns output parameters from the class that implements the `Process.Plugin` interface to the flow.

**Tip:** We recommend using the `@InvocableMethod` annotation instead of the `Process.Plugin` interface.

- The interface doesn’t support Blob, Collection, sObject, and Time data types, and it doesn’t support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

### Namespace
Process

### PluginResult Properties
The following are properties for `PluginResult`. 
IN THIS SECTION:

**outputParameters**
Output parameters returned from the class that implements the interface to the flow.

**Signature**

```java
public MAP<String, ANY> outputParameters {get; set;}
```

**Property Value**

Type: `Map<String, Object>`

---

**QuickAction Namespace**

The `QuickAction` namespace provides classes and methods for quick actions. The following are the classes in the `QuickAction` namespace.

IN THIS SECTION:

- **DescribeAvailableQuickActionResult Class**
  Contains describe metadata information for a quick action that is available for a specified parent.

- **DescribeLayoutComponent Class**
  Represents the smallest unit in a layout—a field or a separator.

- **DescribeLayoutItem Class**
  Represents an individual item in a `QuickAction.DescribeLayoutRow`.

- **DescribeLayoutRow Class**
  Represents a row in a `QuickAction.DescribeLayoutSection`.

- **DescribeLayoutSection Class**
  Represents a section of a layout and consists of one or more columns and one or more rows (an array of `QuickAction.DescribeLayoutRow`).

- **DescribeQuickActionDefaultValue Class**
  Returns a default value for a quick action.

- **DescribeQuickActionResult Class**
  Contains describe metadata information for a quick action.

- **QuickActionDefaults Class**
  Represents an abstract Apex class that provides the context for running the standard Email Action on Case Feed and the container of the Email Message fields for the action payload. You can override the target fields before the standard Email Action is rendered.
QuickAction Defaults Handler Interface
The QuickAction.QuickActionDefaultsHandler interface lets you specify the default values for the standard Email and Send Email actions in the case feed. You can use this interface to specify the From address, CC address, BCC address, subject, and email body for the Email action in the case feed. You can use the interface to pre-populate these fields based on the context where the action is displayed, such as the case origin (for example, country) and subject.

QuickAction Request Class
Use the QuickAction.QuickActionRequest class for providing action information for quick actions to be performed by QuickAction class methods. Action information includes the action name, context record ID, and record.

QuickActionResult Class
After you initiate a quick action with the QuickAction class, use the QuickActionResult class for processing action results.

SendEmailQuickActionDefaults Class
Represents an Apex class that provides: the From address list; the original email’s email message ID, provided that the reply action was invoked on the email message feed item; and methods to specify related settings on templates. You can override these fields before the standard Email Action is rendered.

DescribeAvailableQuickActionResult Class
Contains describe metadata information for a quick action that is available for a specified parent.

Namespace
QuickAction

Usage
The QuickAction describeAvailableQuickActions method returns an array of available quick action describe result objects (QuickAction.DescribeAvailableQuickActionResult).

DescribeAvailableQuickActionResult Methods
The following are methods for DescribeAvailableQuickActionResult. All are instance methods.

IN THIS SECTION:

getActionEnumOrId()
Returns the unique ID for the action. If the action doesn’t have an ID, its API name is used.

getLabel()
The quick action label.

getName()
The quick action name.

getType()
The quick action type.

getActionEnumOrId()
Returns the unique ID for the action. If the action doesn’t have an ID, its API name is used.
Signature
public String getActionEnumOrId()

Return Value
Type: String

getLabel()
The quick action label.

Signature
public String getLabel()

Return Value
Type: String

getName()
The quick action name.

Signature
public String getName()

Return Value
Type: String

getType()
The quick action type.

Signature
public String getType()

Return Value
Type: String

DescribeLayoutComponent Class
Represents the smallest unit in a layout—a field or a separator.

Namespace
QuickAction
DescribeLayoutComponent Methods

The following are methods for DescribeLayoutComponent. All are instance methods.

IN THIS SECTION:

getDisplayLines()
Returns the vertical lines displayed for a field. Applies to textarea and multi-select picklist fields.

getTabOrder()
Returns the tab order for the item in the row.

type()
Returns the name of the QuickAction.DescribeLayoutComponent type for this component.

getValue()
Returns the name of the field if the type for QuickAction.DescribeLayoutComponent is textarea.

getDisplayLines()

Returns the vertical lines displayed for a field. Applies to textarea and multi-select picklist fields.

Signature

public Integer getDisplayLines()

Return Value

Type: Integer

getTabOrder()

Returns the tab order for the item in the row.

Signature

public Integer getTabOrder()

Return Value

Type: Integer

getType()

Returns the name of the QuickAction.DescribeLayoutComponent type for this component.

Signature

public String getType()

Return Value

Type: String
getValue()  
Returns the name of the field if the type for QuickAction.DescribeLayoutComponent is textarea.

Signature

public String getValue()

Return Value

Type: String

DescribeLayoutItem Class

Represents an individual item in a QuickAction.DescribeLayoutRow.

Namespace

QuickAction

Usage

For most fields on a layout, there is only one component per layout item. However, in a display-only view, the QuickAction.DescribeLayoutItem might be a composite of the individual fields (for example, an address can consist of street, city, state, country, and postal code data). On the corresponding edit view, each component of the address field would be split up into separate QuickAction.DescribeLayoutItems.

DescribeLayoutItem Methods

The following are methods for DescribeLayoutItem. All are instance methods.

IN THIS SECTION:

getLabel()  
Returns the label text for this item.

getLayoutComponents()  
Returns a list of QuickAction.DescribeLayoutComponents for this item.

isEditableForNew()  
Indicates whether this item can be edited for new (true) or not (false).

isEditableForUpdate()  
Indicates whether this item can be edited for update (true) or not (false).

isPlaceholder()  
Indicates whether this item is a placeholder (true) or not (false). If true, then this item is blank.

isRequired()  
Indicates whether this item is required (true) or not (false).
**getLabel()**
Returns the label text for this item.

Signature
```java
public String getLabel()
```

Return Value
Type: *String*

**getLayoutComponents()**
Returns a list of `QuickAction.DescribeLayoutComponents` for this item.

Signature
```java
public List<QuickAction.DescribeLayoutComponent> getLayoutComponents()
```

Return Value
Type: `List<QuickAction.DescribeLayoutComponent>`

**isEditableForNew()**
Indicates whether this item can be edited for new (`true`) or not (`false`).

Signature
```java
public Boolean isEditableForNew()
```

Return Value
Type: *Boolean*

**isEditableForUpdate()**
Indicates whether this item can be edited for update (`true`) or not (`false`).

Signature
```java
public Boolean isEditableForUpdate()
```

Return Value
Type: *Boolean*

**isPlaceholder()**
Indicates whether this item is a placeholder (`true`) or not (`false`). If `true`, then this item is blank.
Signature

```java
public Boolean isPlaceholder()
```

Return Value
Type: Boolean

**isRequired()**
Indicates whether this item is required (**true**) or not (**false**).

Signature

```java
public Boolean isRequired()
```

Return Value
Type: Boolean

Usage
This is useful if, for example, you want to render required fields in a contrasting color.

**DescribeLayoutRow Class**

Represents a row in a `QuickAction.DescribeLayoutSection`.

**Namespace**

`QuickAction`

**Usage**

A `QuickAction.DescribeLayoutRow` consists of one or more `QuickAction.DescribeLayoutItem` objects. For each `QuickAction.DescribeLayoutRow`, a `QuickAction.DescribeLayoutItem` refers either to a specific field or to an "empty" `QuickAction.DescribeLayoutItem` (one that contains no `QuickAction.DescribeLayoutComponent` objects). An empty `QuickAction.DescribeLayoutItem` can be returned when a given `QuickAction.DescribeLayoutRow` is sparse (for example, containing more fields on the right column than on the left column).

**DescribeLayoutRow Methods**

The following are methods for `DescribeLayoutRow`. All are instance methods.

IN THIS SECTION:

- `getLayoutItems()`
  Returns either a specific field or an empty `QuickAction.DescribeLayoutItem` (one that contains no `QuickAction.DescribeLayoutComponent` objects).
getNumItems()
Returns the number of QuickAction.DescribeLayoutItem.

getLayoutItems()
Returns either a specific field or an empty QuickAction.DescribeLayoutItem (one that contains no QuickAction.DescribeLayoutComponent objects).

Signature
public List<QuickAction.DescribeLayoutItem> getLayoutItems()

Return Value
Type: List<QuickAction.DescribeLayoutItem>

getNumItems()
Returns the number of QuickAction.DescribeLayoutItem.

Signature
public Integer getNumItems()

Return Value
Type: Integer

DescribeLayoutSection Class
Represents a section of a layout and consists of one or more columns and one or more rows (an array of QuickAction.DescribeLayoutRow).

Namespace
QuickAction

DescribeLayoutSection Properties
The following are properties for DescribeLayoutSection.

collapsed
The current view of the record details section: collapsed (true) or expanded (false).

Signature
public Boolean collapsed {get; set;}

2301
Property Value
Type: Boolean

**layoutsectionid**
The unique ID of the record details section in the layout.

Signature
```csharp
public Id layoutsectionid {get; set;}
```

Property Value
Type: Id

**DescribeLayoutSection Methods**
The following are methods for DescribeLayoutSection.

**IN THIS SECTION:**
- `getColumns()`: Returns the number of columns in the QuickAction.DescribeLayoutSection.
- `getHeading()`: The heading text (label) for the QuickAction.DescribeLayoutSection.
- `getLayoutRows()`: Returns an array of one or more QuickAction.DescribeLayoutRow objects.
- `getLayoutSectionId()`: Returns the ID of the record details section in the layout.
- `getParentLayoutId()`: Returns the ID of the layout upon which this DescribeLayoutSection resides.
- `getRows()`: Returns the number of rows in the QuickAction.DescribeLayoutSection.
- `isCollapsed()`: Indicates whether the record details section is collapsed (true) or expanded (false). If you build your own app, you can use this method to see whether the current user collapsed a section, and respect that preference in your own UI.
- `isUseCollapsibleSection()`: Indicates whether the QuickAction.DescribeLayoutSection is a collapsible section (true) or not (false).
- `isUseHeading()`: Indicates whether to use the heading (true) or not (false).

**getColumns()**
Returns the number of columns in the QuickAction.DescribeLayoutSection.
getColumns()
Signature
public Integer getColumns()

Return Value
Type: Integer

getHeading()
The heading text (label) for the QuickAction.DescribeLayoutSection.

Signature
public String getHeading()

Return Value
Type: String

getLayoutRows()
Returns an array of one or more QuickAction.DescribeLayoutRow objects.

Signature
public List<QuickAction.DescribeLayoutRow> getLayoutRows()

Return Value
Type: List<QuickAction.DescribeLayoutRow>

getLayoutSectionId()
Returns the ID of the record details section in the layout.

Signature
public Id getLayoutSectionId()

Return Value
Type: Id

g getParentLayoutId()
Returns the ID of the layout upon which this DescribeLayoutSection resides.

Signature
public Id getParentLayoutId()
Return Value
Type: Id

**getRows()**
Returns the number of rows in the `QuickAction.DescribeLayoutSection`.

Signature
```
public Integer getRows()
```

Return Value
Type: Integer

**isCollapsed()**
Indicates whether the record details section is collapsed (true) or expanded (false). If you build your own app, you can use this method to see whether the current user collapsed a section, and respect that preference in your own UI.

Signature
```
public Boolean isCollapsed()
```

Return Value
Type: Boolean

**isUseCollapsibleSection()**
Indicates whether the `QuickAction.DescribeLayoutSection` is a collapsible section (true) or not (false).

Signature
```
public Boolean isUseCollapsibleSection()
```

Return Value
Type: Boolean

**isUseHeading()**
Indicates whether to use the heading (true) or not (false).

Signature
```
public Boolean isUseHeading()
```

Return Value
Type: Boolean
DescribeQuickActionDefaultValue Class

Returns a default value for a quick action.

Namespace

QuickAction

Usage

Represents the default values of fields to use in default layouts.

DescribeQuickActionDefaultValue Methods

The following are methods for DescribeQuickActionDefaultValue. All are instance methods.

IN THIS SECTION:

getDefaultValue() Returns the default value of the quick action.

getField() Returns the field name of the action.

getDefaultValue()

Returns the default value of the quick action.

Signature

public String getDefaultValue()

Return Value

Type: String

ggetField() Returns the field name of the action.

Signature

public String getField()

Return Value

Type: String

DescribeQuickActionResult Class

Contains describe metadata information for a quick action.
Namespace

QuickAction

Usage

The QuickAction describeQuickActions method returns an array of quick action describe result objects (QuickAction.DescribeQuickActionResult).

IN THIS SECTION:

   DescribeQuickActionResult Properties
   DescribeQuickActionResult Methods

DescribeQuickActionResult Properties

The following are properties for DescribeQuickActionResult.

IN THIS SECTION:

   canvasapplicationname
   The name of the Canvas application invoked by the custom action.
   colors
   Array of color information. Each color is associated with a theme.
   contextsobjecttype
   The object used for the action. Was getsourceSobjectType() in API version 29.0 and earlier.
   defaultvalues
   The action’s default values.
   flowdevname
   If the custom action invokes a flow, the fully qualified name of the flow.
   flowrecordidvar
   If the custom action invokes a flow, the input variable that the custom action passes the record’s ID to.
   height
   The height in pixels of the action pane.
   iconname
   The name of the icon used for the action. If a custom icon is not used, this value isn’t set.
   icons
   Array of icons. Each icon is associated with a theme.
   iconurl
   The URL of the icon used for the action. This icon URL corresponds to the 32x32 icon used for the current Salesforce theme, introduced in Spring ’10, or the custom icon, if there is one.
   layout
   The section of the layout where the action resides.
   lightningcomponentbundleid
   If the custom action invokes a Lightning component, the ID of the Lightning component bundle to which the component belongs.
lightningcomponentbundlename
If the custom action invokes a Lightning component, the name of the Lightning component bundle to which the component belongs.

lightningcomponentqualifiedname
The fully qualified name of the Lightning component invoked by the custom action.

miniiconurl
The icon’s URL. This icon URL corresponds to the 16x16 icon used for the current Salesforce theme, introduced in Spring ’10, or the custom icon, if there is one.

showquickactionlcheader
Indicates whether the Lightning component quick action header and footer are shown. If false, then both the header containing the quick action title and the footer containing the Save and Cancel buttons aren’t displayed.

showquickactionvfheader
Indicates whether the Visualforce quick action header and footer should be shown. If false, then both the header containing the quick action title and the footer containing the Save and Cancel buttons aren’t displayed.

targetparentfield
The parent object type of the action. Links the target object to the parent object. For example, the value is Account if the target object is Contact and the parent object is Account.

targetrecordtypeid
The record type of the target record.

targetobjecttype
The action’s target object type.

visualforcepagename
The name of the Visualforce page associated with the custom action.

visualforcepageurl
The URL of the Visualforce page associated with the action.

width
The width in pixels of the action pane, for custom actions that call Visualforce pages, Canvas apps, or Lightning components.

canvasapplicationname
The name of the Canvas application invoked by the custom action.

Signature
public String canvasapplicationname {get; set;}

Property Value
Type: String

colors
Array of color information. Each color is associated with a theme.
**Signature**

```csharp
public List<Schema.DescribeColorResult> colors {get; set;}
```

**Property Value**

Type: `List<Schema.DescribeColorResult>` on page 2459

---

**contextsobjecttype**

The object used for the action. Was `getsourceSobjectType()` in API version 29.0 and earlier.

**Signature**

```csharp
public String contextsobjecttype {get; set;}
```

**Property Value**

Type: `String`

---

**defaultvalues**

The action’s default values.

**Signature**

```csharp
public List<QuickAction.DescribeQuickActionDefaultValue> defaultvalues {get; set;}
```

**Property Value**

Type: `List<QuickAction.DescribeQuickActionDefaultValue>`

---

**flowdevname**

If the custom action invokes a flow, the fully qualified name of the flow.

**Signature**

```csharp
public String flowdevname {get; set;}
```

**Property Value**

Type: `String`

---

**flowrecordidvar**

If the custom action invokes a flow, the input variable that the custom action passes the record’s ID to.

**Signature**

```csharp
public String flowrecordidvar {get; set;}
```
Property Value
Type: String
Valid values are null or recordId.

**height**
The height in pixels of the action pane.

Signature
```
public Integer height {get; set;}
```

Property Value
Type: Integer

**iconname**
The name of the icon used for the action. If a custom icon is not used, this value isn’t set.

Signature
```
public String iconname {get; set;}
```

Property Value
Type: String

**icons**
Array of icons. Each icon is associated with a theme.

Signature
```
public List<Schema.DescribeIconResult> icons {get; set;}
```

Property Value
Type: List<Schema.DescribeIconResult> on page 2481

If no custom icon was associated with the quick action and the quick action creates a specific object, the icons will correspond to the icons used for the created object. For example, if the quick action creates an Account, the icon array will contain the icons used for Account.

If a custom icon was associated with the quick action, the array will contain that custom icon.

**iconurl**
The URL of the icon used for the action. This icon URL corresponds to the 32x32 icon used for the current Salesforce theme, introduced in Spring ’10, or the custom icon, if there is one.
Signature

```java
public String iconurl {get; set;}
```

Property Value
Type: String

**layout**
The section of the layout where the action resides.

Signature

```java
public QuickAction.DescribeLayoutSection layout {get; set;}
```

Property Value
Type: `QuickAction.DescribeLayoutSection` on page 2301

**lightningcomponentbundleid**
If the custom action invokes a Lightning component, the ID of the Lightning component bundle to which the component belongs.

Signature

```java
public String lightningcomponentbundleid {get; set;}
```

Property Value
Type: String

**lightningcomponentbundlename**
If the custom action invokes a Lightning component, the name of the Lightning component bundle to which the component belongs.

Signature

```java
public String lightningcomponentbundlename {get; set;}
```

Property Value
Type: String

**lightningcomponentqualifiedname**
The fully qualified name of the Lightning component invoked by the custom action.

Signature

```java
public String lightningcomponentqualifiedname {get; set;}
```
Property Value
Type: String

miniiconurl
The icon's URL. This icon URL corresponds to the 16x16 icon used for the current Salesforce theme, introduced in Spring '10, or the custom icon, if there is one.

Signature
public String miniiconurl {get; set;}

Property Value
Type: String

showquickactionlcheader
Indicates whether the Lightning component quick action header and footer are shown. If false, then both the header containing the quick action title and the footer containing the Save and Cancel buttons aren’t displayed.

Signature
public Boolean showquickactionlcheader {get; set;}

Property Value
Type: Boolean

showquickactionvfheader
Indicates whether the Visualforce quick action header and footer should be shown. If false, then both the header containing the quick action title and the footer containing the Save and Cancel buttons aren’t displayed.

Signature
public Boolean showquickactionvfheader {get; set;}

Property Value
Type: Boolean

targetparentfield
The parent object type of the action. Links the target object to the parent object. For example, the value is Account if the target object is Contact and the parent object is Account.

Signature
public String targetparentfield {get; set;}

Property Value
Type: String

**targetrecordtypeid**
The record type of the target record.

Signature
```java
public String targetrecordtypeid {get; set;}
```

Property Value
Type: String

**targetsobjecttype**
The action's target object type.

Signature
```java
public String targetsobjecttype {get; set;}
```

Property Value
Type: String

**visualforcepagename**
The name of the Visualforce page associated with the custom action.

Signature
```java
public String visualforcepagename {get; set;}
```

Property Value
Type: String

**visualforcepageurl**
The URL of the Visualforce page associated with the action.

Signature
```java
public String visualforcepageurl {get; set;}
```

Property Value
Type: String
width
The width in pixels of the action pane, for custom actions that call Visualforce pages, Canvas apps, or Lightning components.

Signature

```java
public Integer width {get; set;}
```

Property Value
Type: Integer

DescribeQuickActionResult Methods
The following are methods for DescribeQuickActionResult. All are instance methods.

IN THIS SECTION:
- `getActionEnumOrId()`
  Returns the unique ID for the action. If the action doesn’t have an ID, its API name is used.
- `getCanvasApplicationName()`
  Returns the name of the Canvas application, if used.
- `getColors()`
  Returns an array of color information. Each color is associated with a theme.
- `getContextSobjectType()`
  Returns the object used for the action. Replaces `getSourceSobjectType()` in API version 30.0 and later.
- `getDefaultValues()`
  Returns the default values for a action.
- `getFlowDevName()`
  If the custom action invokes a flow, returns the fully qualified name of the flow invoked by the custom action.
- `getFlowRecordIdVar()`
  If the custom action invokes a flow, returns the input variable that the custom action passes the record’s ID to.
- `getHeight()`
  Returns the height in pixels of the action pane.
- `getIconName()`
  Returns the actions’ icon name.
- `getIconUrl()`
  Returns the URL of the 32x32 icon used for the action.
- `getIcons()`
  Returns a list of `DescribeIconResult` objects that describe colors used in a tab.
- `getLabel()`
  Returns the action label.
- `getLayout()`
  Returns the layout sections that comprise an action.

2313
getLightningComponentBundleId()
If the custom action invokes a Lightning component, returns the ID of the Lightning component bundle to which the component belongs.

getLightningComponentBundleName()
If the custom action invokes a Lightning component, returns the name of the Lightning component bundle to which the component belongs.

getLightningComponentQualifiedName()
If the custom action invokes a Lightning component, returns the fully qualified name of the Lightning component invoked by the custom action.

getMiniIconUrl()
Returns the 16x16 icon URL.

getName()
Returns the action name.

getShowQuickActionLcHeader()
Returns an indication of whether the Lightning component quick action header and footer are shown.

getShowQuickActionVfHeader()
Returns an indication of whether the Visualforce quick action header and footer should be shown.

getSourceSobjectType()
Returns the object type used for the action.

getTargetParentField()
Returns the parent object's type for the action.

getTargetRecordTypeId()
Returns the record type of the targeted record.

getTargetSobjectType()
Returns the action's target object type.

getType()
Returns a create or custom Visualforce action.

getVisualforcePageName()
If Visualforce is used, returns the name of the associated page for the action.

getVisualforcePageUrl()
Returns the URL of the Visualforce page associated with the action.

getWidth()
If a custom action is created, returns the width in pixels of the action pane.

getActionEnumOrId()
Returns the unique ID for the action. If the action doesn't have an ID, its API name is used.

Signature
public String getActionEnumOrId()
Return Value
Type: String

**getCanvasApplicationName()**
Returns the name of the Canvas application, if used.

Syntax
```java
public String getCanvasApplicationName()
```

Return Value
Type: String

**getColors()**
Returns an array of color information. Each color is associated with a theme.

Signature
```java
public List<Schema.DescribeColorResult> getColors()
```

Return Value
Type: List<Schema.DescribeColorResult>

**getContextSobjectType()**
Returns the object used for the action. Replaces `getsourceSobjectType()` in API version 30.0 and later.

Signature
```java
public String getContextSobjectType()
```

Return Value
Type: String

**getDefaultValues()**
Returns the default values for a action.

Signature
```java
public List<QuickAction.DescribeQuickActionDefaultValue> getDefaultValues()
```

Return Value
Type: List<QuickAction.DescribeQuickActionDefaultValue>
**getFlowDevName()**
If the custom action invokes a flow, returns the fully qualified name of the flow invoked by the custom action.

Signature

```java
public String getFlowDevName()
```

Return Value
Type: String

**getFlowRecordIdVar()**
If the custom action invokes a flow, returns the input variable that the custom action passes the record’s ID to.

Signature

```java
public String getFlowRecordIdVar()
```

Return Value
Type: String

**getHeight()**
Returns the height in pixels of the action pane.

Signature

```java
public Integer getHeight()
```

Return Value
Type: Integer

**getIconName()**
Returns the actions’ icon name.

Signature

```java
public String getIconName()
```

Return Value
Type: String

**getIconUrl()**
Returns the URL of the 32x32 icon used for the action.
Signature
public String getIconUrl()

Return Value
Type: String

getIcons()
Returns a list of Schema.DescribeIconResult objects that describe colors used in a tab.

Signature
public List<Schema.DescribeIconResult> getIcons()

Return Value
Type: List<Schema.DescribeIconResult>

getLabel()
Returns the action label.

Signature
public String getLabel()

Return Value
Type: String

getLayout()
Returns the layout sections that comprise an action.

Signature
public QuickAction.DescribeLayoutSection getLayout()

Return Value
Type: QuickAction.DescribeLayoutSection

getLightningComponentBundleId()
If the custom action invokes a Lightning component, returns the ID of the Lightning component bundle to which the component belongs.

Signature
public String getLightningComponentBundleId()
Return Value
Type: String

getLightningComponentBundleName()
If the custom action invokes a Lightning component, returns the name of the Lightning component bundle to which the component belongs.

Signature
public String getLightningComponentBundleName()

Return Value
Type: String

getLightningComponentQualifiedName()
If the custom action invokes a Lightning component, returns the fully qualified name of the Lightning component invoked by the custom action.

Signature
public String getLightningComponentQualifiedName()

Return Value
Type: String

getMiniIconUrl()
Returns the 16x16 icon URL.

Signature
public String getMiniIconUrl()

Return Value
Type: String

getName()
Returns the action name.

Signature
public String getName()
Return Value
Type: String

**getShowQuickActionLcHeader()**

Returns an indication of whether the Lightning component quick action header and footer are shown.

Signature

```java
public Boolean getShowQuickActionLcHeader()
```

Return Value
Type: Boolean
If false, then both the header containing the quick action title and the footer containing the Save and Cancel buttons aren’t displayed.

**getShowQuickActionVfHeader()**

Returns an indication of whether the Visualforce quick action header and footer should be shown.

Signature

```java
public Boolean getShowQuickActionVfHeader()
```

Return Value
Type: Boolean
If false, then both the header containing the quick action title and the footer containing the Save and Cancel buttons aren’t displayed.

**getSourceSobjectType()**

Returns the object type used for the action.

Signature

```java
public String getSourceSobjectType()
```

Return Value
Type: String

**getTargetParentField()**

Returns the parent object’s type for the action.

Signature

```java
public String getTargetParentField()
```
Return Value
Type: String

```
getTargetRecordTypeId()
```
Returns the record type of the targeted record.

Signature
```
public String getTargetRecordTypeId()
```

Return Value
Type: String

```
getTargetSobjectType()
```
Returns the action’s target object type.

Signature
```
public String getTargetSobjectType()
```

Return Value
Type: String

```
getType()
```
Returns a create or custom Visualforce action.

Signature
```
public String getType()
```

Return Value
Type: String

```
getVisualforcePageName()
```
If Visualforce is used, returns the name of the associated page for the action.

Signature
```
public String getVisualforcePageName()
```

Return Value
Type: String
getVisualforcePageUrl()
Returns the URL of the Visualforce page associated with the action.

Signature
public String getVisualforcePageUrl()

Return Value
Type: String

getWidth()
If a custom action is created, returns the width in pixels of the action pane.

Signature
public Integer getWidth()

Return Value
Type: Integer

QuickActionDefaults Class
Represents an abstract Apex class that provides the context for running the standard Email Action on Case Feed and the container of the Email Message fields for the action payload. You can override the target fields before the standard Email Action is rendered.

Namespace
QuickAction

Usage
Note: You cannot extend this abstract class. You can use the getter methods when using it in the context of QuickActionQuickActionDefaultsHandler. Salesforce provides a class that extends this class (See QuickAction.SendEmailQuickActionDefaults.)

IN THIS SECTION:
QuickActionDefaults Methods

QuickActionDefaults Methods
The following are methods for QuickActionDefaults.

IN THIS SECTION:
getActionName() Returns the name of the standard Email Action on Case Feed (Case.Email).
getActionType()
Returns the type of the standard Email Action on Case Feed (Email).

getContextId()
The ID of the context related to the standard Email Action on Case Feed (Case ID).

getTargetSObject()
The target object of the standard Email Action on Case Feed (EmailMessage).

getActionName()
Returns the name of the standard Email Action on Case Feed (Case.Email).

Signature
public String getActionName()

Return Value
Type: String

getActionType()
Returns the type of the standard Email Action on Case Feed (Email).

Signature
public String getActionType()

Return Value
Type: String

ggetContextId()
The ID of the context related to the standard Email Action on Case Feed (Case ID).

Signature
public Id getContextId()

Return Value
Type: Id

getTargetSObject()
The target object of the standard Email Action on Case Feed (EmailMessage).

Signature
public SObject getTargetSObject()
QuickAction Defaults Handler Interface

The `QuickAction.QuickActionDefaultsHandler` interface lets you specify the default values for the standard Email and Send Email actions in the case feed. You can use this interface to specify the From address, CC address, BCC address, subject, and email body for the Email action in the case feed. You can use the interface to pre-populate these fields based on the context where the action is displayed, such as the case origin (for example, country) and subject.

Namespace

QuickAction

Usage

To specify default values for the standard Email action in the case feed, create a class that implements `QuickAction.QuickActionDefaultsHandler`.

The `QuickAction.QuickActionDefaultsHandler` interface works in Salesforce Classic and Lightning Experience.

When working in Lightning Experience, keep the following things in mind:

- The interface overrides email values set up with predefined IDs.
- The interface works with the out-of-the-box Email action provided on cases. You can also use the interface with custom Email actions for the case object.
- The interface in Lightning Experience doesn’t support:
  - Email attachments
  - Custom email fields
  - Visualforce email templates, which are a type of email template available in Salesforce Classic
- The From Address picklist isn’t customizable in Send Email action types via the `QuickActionDefaultsHandler` Interface.
- If your Apex interface adds content to the email body, merge fields display as unresolved. During preview and send, the merge fields resolve.

When you implement this interface, provide an empty parameterless constructor.

QuickAction Defaults Handler Methods

The following are methods for `QuickActionDefaultsHandler`.

IN THIS SECTION:

QuickActionDefaultsHandler Methods
QuickActionDefaultsHandler Example Implementations

onInitDefaults(actionDefaults)

Implement this method to provide default values for the standard Email action in the case feed.
**onInitDefaults(actionDefaults)**
Implement this method to provide default values for the standard Email action in the case feed.

**Signature**
```
public void onInitDefaults(QuickAction.QuickActionDefaults[] actionDefaults)
```

**Parameters**
- **actionDefaults**
  - **Type:** QuickAction.QuickActionDefaults[]
  - This array contains only one item of type QuickAction.SendEmailQuickActionDefaults.

**Return Value**
- **Type:** void

**QuickActionDefaultsHandler Example Implementations**
These examples are implementations of the QuickAction.QuickActionDefaultsHandler interface.

In this example, the `onInitDefaults` method checks whether the element passed in the array is for the standard Email action in the case feed. Then, it performs a query to retrieve the case that corresponds to the context ID. Next, it sets the value of the BCC address of the corresponding email message to a default value. The default value is based on the case reason. Finally, it sets the default values of the email template properties. The `onInitDefaults` method determines the default values based on two criteria: first, whether a reply action on an email message initiated the call to the method, and second, whether any previous emails attached to the case are associated with the call.

```apex
global class EmailPublisherLoader implements QuickAction.QuickActionDefaultsHandler {
    // Empty constructor
    global EmailPublisherLoader() {

    }

    // The main interface method
    global void onInitDefaults(QuickAction.QuickActionDefaults[] defaults) {
        QuickAction.SendEmailQuickActionDefaults sendEmailDefaults = null;

        // Check if the quick action is the standard case feed Send Email action
        for (Integer j = 0; j < defaults.size(); j++) {
            if (defaults.get(j) instanceof QuickAction.SendEmailQuickActionDefaults &&
                defaults.get(j).getTargetSObject().getSObjectType() ==
                EmailMessage.sObjectType &&
                defaults.get(j).getActionName().equals('Case.Email') &&
                defaults.get(j).getActionType().equals('Email')) {
                sendEmailDefaults =
                    (QuickAction.SendEmailQuickActionDefaults)defaults.get(j);
            } else {
                break;
            }
        }

        if (sendEmailDefaults != null) {
```

2324
Case c = [SELECT Status, Reason FROM Case WHERE Id=:sendEmailDefaults.getContextId()];

EmailMessage emailMessage = (EmailMessage)sendEmailDefaults.getTargetSObject();

// Set BCC address to make sure each email goes for audit
emailMessage.BccAddress = getBccAddress(c.Reason);

/*
Set Template related fields
when the In Reply To Id field is null we know the interface
is called on page load. Here we check if
there are any previous emails attached to the case and load
the 'New_Case_Created' or 'Automatic_Response' template.
When the In Reply To Id field is not null we know that
the interface is called on click of reply/reply all
of an email and we load the 'Default_reply_template' template */
if (sendEmailDefaults.getInReplyToId() == null) {
    Integer emailCount = [SELECT count() FROM EmailMessage WHERE ParentId=:sendEmailDefaults.getContextId()];
    if (emailCount!= null && emailCount > 0) {
        sendEmailDefaults.setTemplateId(getTemplateIdHelper('Automatic_Response'));
    } else {
        sendEmailDefaults.setTemplateId(getTemplateIdHelper('New_Case_Created'));
    }
    sendEmailDefaults.setInsertTemplateBody(false);
    sendEmailDefaults.setIgnoreTemplateSubject(false);
} else {
    sendEmailDefaults.setTemplateId(getTemplateIdHelper('Default_reply_template'));
    sendEmailDefaults.setInsertTemplateBody(false);
    sendEmailDefaults.setIgnoreTemplateSubject(true);
}

private Id getTemplateIdHelper(String templateApiName) {
    Id templateId = null;
    try {
        templateId = [select id, name from EmailTemplate where developername = : templateApiName].id;
    } catch (Exception e) {
        system.debug('Unable to locate EmailTemplate using name: ' + templateApiName + ' refer to Setup | Communications Templates ' + templateApiName);
    }
    return templateId;
}

private String getBccAddress(String reason) {
    if (reason != null && reason.equals('Technical'))
    { return 'support_technical@mycompany.com'; }
In this example, the `onInitDefaults` method checks whether the element passed in the array is for the standard Email action in the case feed. Then it performs a query to determine if the case Priority is set to High. If the Priority is set to High, the email address `managers@acme.com` is appended to the BCC field.

```apex
// Global class EmailPublisherForHighPriorityCases implements QuickAction.QuickActionDefaultsHandler {
    // Empty constructor
    global EmailPublisherForHighPriorityCases() {
    }

    // The main interface method
    global void onInitDefaults(QuickAction.QuickActionDefaults[] defaults) {
        QuickAction.SendEmailQuickActionDefaults sendEmailDefaults = (QuickAction.SendEmailQuickActionDefaults)defaults.get(0);
        EmailMessage emailMessage = (EmailMessage)sendEmailDefaults.getTargetSObject();

        Case c = [SELECT CaseNumber, Priority FROM Case WHERE Id=:sendEmailDefaults.getContextId()];

        // If case severity is "High," append "managers@acme.com" to the existing (and possibly blank) BCC field
        if (c.Priority != null && c.Priority.equals('High')) { // Priority is 'High'
            emailMessage.BccAddress = 'managers@acme.com';
        }
    }
}
```

In this example, the `onInitDefaults` method checks whether the element passed in the array is for the standard Email action in the case feed. Then it performs a query to determine if the case Type is set to Problem. If the type is set to Problem, the First Response email template is inserted into the body of the email.

```apex
// Global class EmailPublisherForCaseType implements QuickAction.QuickActionDefaultsHandler {
    // Empty constructor
    global EmailPublisherForCaseType() {
    }

    // The main interface method
    global void onInitDefaults(QuickAction.QuickActionDefaults[] defaults) {
        QuickAction.SendEmailQuickActionDefaults sendEmailDefaults = (QuickAction.SendEmailQuickActionDefaults)defaults.get(0);
        EmailMessage emailMessage = (EmailMessage)sendEmailDefaults.getTargetSObject();

        Case c = [SELECT CaseNumber, Type FROM Case WHERE Id=:sendEmailDefaults.getContextId()];

        // If case type is "Problem," insert the "First Response" email template
        if (c.Type != null && c.Type.equals('Problem')) {
            emailMessage.Body = 'First Response';
        }
    }
}
```
if (c.CaseNumber != null && c.Type.equals('Problem')) {
    sendEmailDefaults.setTemplateId('Insert Email Template ID Here'); // Set the template Id corresponding to First Response
    sendEmailDefaults.setInsertTemplateBody(true);
    sendEmailDefaults.setIgnoreTemplateSubject(false);
}

In this example, the onInitDefaults method checks whether the element passed in the array is for the standard Email action in the case feed. Then it performs a query to determine if the email is a Reply or Reply All email. If email is a Reply or Reply All email, the corresponding email templates for these emails are inserted into the body of the email.

```
global class EmailPublisherForReplyAndReplyAll implements QuickAction.QuickActionDefaultsHandler {

    // Empty constructor
    global EmailPublisherForReplyAndReplyAll() {
    }

    // The main interface method
    global void onInitDefaults(QuickAction.QuickActionDefaults[] defaults) {

        QuickAction.SendEmailQuickActionDefaults sendEmailDefaults = (QuickAction.SendEmailQuickActionDefaults)defaults.get(0);
        EmailMessage emailMessage = (EmailMessage)sendEmailDefaults.getTargetSObject();

        // If the email is a “Reply” email, insert the “Reply Email Template” to the email body
        if (sendEmailDefaults.getActionName().equals('EmailMessage._Reply')) {
            sendEmailDefaults.setTemplateId('Insert Reply Email Template ID Here');
            sendEmailDefaults.setInsertTemplateBody(true);
            sendEmailDefaults.setIgnoreTemplateSubject(false);
        }

        // If the email is a “Reply All” email, insert the “Reply All Email Template” to the email body
        } else if (sendEmailDefaults.getActionName().equals('EmailMessage._ReplyAll')) {
            sendEmailDefaults.setTemplateId('Insert Reply All Email Template ID Here');
            sendEmailDefaults.setInsertTemplateBody(true);
            sendEmailDefaults.setIgnoreTemplateSubject(false);
        }
    }
```

**QuickActionRequest Class**

Use the QuickAction.QuickActionRequest class for providing action information for quick actions to be performed by QuickAction class methods. Action information includes the action name, context record ID, and record.

**Namespace**

QuickAction
**Usage**

For Apex saved using Salesforce API version 28.0, a parent ID is associated with the QuickActionRequest instead of the context ID. The constructor of this class takes no arguments:

```java
QuickAction.QuickActionRequest qar = new QuickAction.QuickActionRequest();
```

**Example**

In this sample, a new quick action is created to create a contact and assign a record to it.

```java
QuickAction.QuickActionRequest req = new QuickAction.QuickActionRequest();
// Some quick action name
req.quickActionName = Schema.Account.QuickAction.AccountCreateContact;

// Define a record for the quick action to create
Contact c = new Contact();
c.lastname = 'last name';
req.record = c;

// Provide the context ID (or parent ID). In this case, it is an Account record.
req.contextid = '001xx000003DGcO';

QuickAction.QuickActionResult res = QuickAction.performQuickAction(req);
```

**QuickActionRequest Constructors**

The following are constructors for `QuickActionRequest`.

**QuickActionRequest()**

Creates a new instance of the `QuickAction.QuickActionRequest` class.

**QuickActionRequest()**

Creates a new instance of the `QuickAction.QuickActionRequest` class.

**Signature**

```java
public QuickActionRequest()
```
QuickActionRequest Methods
The following are methods for QuickActionRequest. All are instance methods.

IN THIS SECTION:
   - `getContextId()`: Returns this QuickAction's context record ID.
   - `getQuickActionName()`: Returns this QuickAction's name.
   - `getRecord()`: Returns the QuickAction's associated record.
   - `setContextId(contextId)`: Sets this QuickAction's context ID. Returned by `getContextId`.
   - `setQuickActionName(name)`: Sets this QuickAction's name. Returned by `getQuickActionName`.
   - `setRecord(record)`: Sets a record for this QuickAction. Returned by `getRecord`.

`getContextId()`
Returns this QuickAction's context record ID.

Signature
```
public Id getContextId()
```

Return Value
Type: ID

`getQuickActionName()`
Returns this QuickAction's name.

Signature
```
public String getQuickActionName()
```

Return Value
Type: String

`getRecord()`
Returns the QuickAction's associated record.
Signature

```java
public SObject getRecord()
```

Return Value
Type: `sObject`

**setContextId(contextId)**
Sets this QuickAction’s context ID. Returned by `getContextId`.

Signature

```java
public Void setContextId(Id contextId)
```

Parameters

`contextId`
Type: `ID`

Return Value
Type: `Void`

Usage
For Apex saved using Salesforce API version 28.0, sets this QuickAction’s parent ID and is returned by `getParentId`.

**setQuickActionName(name)**
Sets this QuickAction’s name. Returned by `getQuickActionName`.

Signature

```java
public Void setQuickActionName(String name)
```

Parameters

`name`
Type: `String`

Return Value
Type: `Void`

**setRecord(record)**
Sets a record for this QuickAction. Returned by `getRecord`.
Signature

```java
public Void setRecord(SObject record)
```

Parameters

`record`
Type: `SObject`

Return Value
Type: `Void`

**QuickActionResult Class**

After you initiate a quick action with the `QuickAction` class, use the `QuickActionResult` class for processing action results.

**Namespace**

`QuickAction`

**SEE ALSO:**
- `QuickAction Class`

**QuickActionResult Methods**

The following are methods for `QuickActionResult`. All are instance methods.

**IN THIS SECTION:**
- `getErrors()`
  If an error occurs, an array of one or more database error objects, along with error codes and descriptions, is returned.
- `getIds()`
  The IDs of the QuickActions being processed.
- `getSuccessMessage()`
  Returns the success message associated with the quick action.
- `isCreated()`
  Returns `true` if the action is created; otherwise, `false`.
- `isSuccess()`
  Returns `true` if the action completes successfully; otherwise, `false`.

**getErrors()**

If an error occurs, an array of one or more database error objects, along with error codes and descriptions, is returned.

Signature

```java
public List<Database.Error> getErrors()
```
Return Value
Type: List<Database.Error>

**getIds()**
The IDs of the QuickActions being processed.

Signature
```java
public List<Id> getIds()
```

Return Value
Type: List<Id>

**getSuccessMessage()**
Returns the success message associated with the quick action.

Signature
```java
public String getSuccessMessage()
```

Return Value
Type: String

**isCreated()**
Returns `true` if the action is created; otherwise, `false`.

Signature
```java
public Boolean isCreated()
```

Return Value
Type: Boolean

**isSuccess()**
Returns `true` if the action completes successfully; otherwise, `false`.

Signature
```java
public Boolean isSuccess()
```

Return Value
Type: Boolean
SendEmailQuickActionDefaults Class

Represents an Apex class that provides: the From address list; the original email’s email message ID, provided that the reply action was invoked on the email message feed item; and methods to specify related settings on templates. You can override these fields before the standard Email Action is rendered.

Namespace

QuickAction

Usage

Note: You cannot instantiate this class. One can use the getters/setters when using it in the context of QuickAction.QuickActionDefaultsHandler.

IN THIS SECTION:

SendEmailQuickActionDefaults Methods

SendEmailQuickActionDefaults Methods

The following are methods for SendEmailQuickActionDefaults.

IN THIS SECTION:

getFromAddressList() Returns a list of email addresses that are available in the From: address drop-down menu for the standard Email Action.

getInReplyToId() Returns the email message ID of the email to which the reply/reply all action has been invoked.

setIgnoreTemplateSubject(useOriginalSubject) Specifies whether the template subject should be ignored (true), thus using the original subject, or whether the template subject should replace the original subject (false).

setInsertTemplateBody(keepOriginalBodyContent) Specifies whether the template body should be inserted above the original body content (true) or whether it should replace the entire content with the template body (false).

setTemplateId(templateId) Sets the email template ID to load into the email body.

getFromAddressList()

Returns a list of email addresses that are available in the From: address drop-down menu for the standard Email Action.

Signature

public List<String> getFromAddressList()
getInReplyToId()

Returns the email message ID of the email to which the reply/reply all action has been invoked.

Signature
public Id getInReplyToId()

Return Value
Type: Id

setIgnoreTemplateSubject(useOriginalSubject)

Specifies whether the template subject should be ignored (true), thus using the original subject, or whether the template subject should replace the original subject (false).

Signature
public void setIgnoreTemplateSubject(Boolean useOriginalSubject)

Parameters
useOriginalSubject
Type: Boolean

Return Value
Type: void

setInsertTemplateBody(keepOriginalBodyContent)

Specifies whether the template body should be inserted above the original body content (true) or whether it should replace the entire content with the template body (false).

Signature
public void setInsertTemplateBody(Boolean keepOriginalBodyContent)

Parameters
keepOriginalBodyContent
Type: Boolean

Return Value
Type: void
**setTemplateId(templateId)**

Sets the email template ID to load into the email body.

**Signature**

```java
public void setTemplateId(Id templateId)
```

**Parameters**

`templateId`

- **Type:** `Id`
- The template ID.

**Return Value**

- **Type:** `void`

---

**Reports Namespace**

The `Reports` namespace provides classes for accessing the same data as is available in the Salesforce Reports and Dashboards REST API.

The following are the classes in the `Reports` namespace.

**IN THIS SECTION:**

- `AggregateColumn Class`
  - Contains methods for describing summary fields such as Record Count, Sum, Average, Max, Min, and custom summary formulas. Includes name, label, data type, and grouping context.
- `BucketField Class`
  - Contains methods and constructors to work with information about a bucket field, including bucket type, name, and bucketed values.
- `BucketFieldValue Class`
  - Contains information about the report values included in a bucket field.
- `BucketType Enum`
  - The types of values included in a bucket.
- `ColumnDataType Enum`
  - The `Reports.ColumnDataType` enum describes the type of data in a column. It is returned by the `getDataType` method.
- `ColumnSortOrder Enum`
  - The `Reports.ColumnSortOrder` enum describes the order that the grouping column uses to sort data.
- `CrossFilter Class`
  - Contains methods and constructors used to work with information about a cross filter.
- `CsFGroupType Enum`
  - The group level at which the custom summary format aggregate is displayed in a report.
- `DateGranularity Enum`
  - The `Reports.DateGranularity` enum describes the date interval that is used for grouping.
DetailColumn Class
Contains methods for describing fields that contain detailed data. Detailed data fields are also listed in the report metadata.

Dimension Class
Contains information for each row or column grouping.

EvaluatedCondition Class
Contains the individual components of an evaluated condition for a report notification, such as the aggregate name and label, the operator, and the value that the aggregate is compared to.

EvaluatedConditionOperator Enum
The Reports.EvaluatedConditionOperator enum describes the type of operator used to compare an aggregate to a value. It is returned by the getOperator method.

FilterOperator Class
Contains information about a filter operator, such as display name and API name.

FilterValue Class
Contains information about a filter value, such as the display name and API name.

FormulaType Enum
The format of the numbers in a custom summary formula.

GroupingColumn Class
Contains methods for describing fields that are used for column grouping.

GroupingInfo Class
Contains methods for describing fields that are used for grouping.

GroupingValue Class
Contains grouping values for a row or column, including the key, label, and value.

NotificationAction Interface
Implement this interface to trigger a custom Apex class when the conditions for a report notification are met.

NotificationActionContext Class
Contains information about the report instance and condition threshold for a report notification.

ReportCsf Class
Contains methods and constructors for working with information about a custom summary formula (CSF).

ReportCurrency Class
Contains information about a currency value, including the amount and currency code.

ReportDataCell Class
Contains the data for a cell in the report, including the display label and value.

ReportDescribeResult Class
Contains report, report type, and extended metadata for a tabular, summary, or matrix report.

ReportDetailRow Class
Contains data cells for a detail row of a report.

ReportDivisionInfo Class
Contains information about the divisions that can be used to filter a report.

ReportExtendedMetadata Class
Contains report extended metadata for a tabular, summary, or matrix report.
ReportFact Class
Contains the fact map for the report, which represents the report’s data values.

ReportFactWithDetails Class
Contains the detailed fact map for the report, which represents the report’s data values.

ReportFactWithSummaries Class
Contains the fact map for the report, which represents the report’s data values, and includes summarized fields.

ReportFilter Class
Contains information about a report filter, including column, operator, and value.

ReportFormat Enum
Contains the possible report format types.

ReportInstance Class
Returns an instance of a report that was run asynchronously. Retrieves the results for that instance.

ReportManager Class
Runs a report synchronously or asynchronously and with or without details.

ReportMetadata Class
Contains report metadata for a tabular, summary, or matrix report.

ReportResults Class
Contains the results of running a report.

ReportScopeInfo Class
Contains information about possible scope values that you can choose. Scope values depend on the report type. For example, you can set the scope for opportunity reports to All opportunities, My team’s opportunities, or My opportunities.

ReportScopeValue Class
Contains information about a possible scope value. Scope values depend on the report type. For example, you can set the scope for opportunity reports to All opportunities, My team’s opportunities, or My opportunities.

ReportType Class
Contains the unique API name and display name for the report type.

ReportTypeColumn Class
Contains detailed report type metadata about a field, including data type, display name, and filter values.

ReportTypeColumnCategory Class
Information about categories of fields in a report type.

ReportTypeMetadata Class
Contains report type metadata, which gives you information about the fields that are available in each section of the report type, plus filter information for those fields.

SortColumn Class
Contains information about the sort column used in the report.

StandardDateFilter Class
Contains information about standard date filter available in the report—for example, the API name, start date, and end date of the standard date filter duration as well as the API name of the date field on which the filter is placed.
StandardDateFilterDuration Class
Contains information about each standard date filter—also referred to as a relative date filter. It contains the API name and display label of the standard date filter duration as well as the start and end dates.

StandardDateFilterDurationGroup Class
Contains information about the standard date filter groupings, such as the grouping display label and all standard date filters that fall under the grouping. Groupings include Calendar Year, Calendar Quarter, Calendar Month, Calendar Week, Fiscal Year, Fiscal Quarter, Day, and custom values based on user-defined date ranges.

StandardFilter Class
Contains information about the standard filter defined in the report, such as the filter field API name and filter value.

StandardFilterInfo Class
Is an abstract base class for an object that provides standard filter information.

StandardFilterInfoPicklist Class
Contains information about the standard filter picklist, such as the display name and type of the filter field, the default picklist value, and a list of all possible picklist values.

StandardFilterType Enum
The StandardFilterType enum describes the type of standard filters in a report. The getType() method returns a Reports.StandardFilterType enum value.

SummaryValue Class
Contains summary data for a cell of the report.

ThresholdInformation Class
Contains a list of evaluated conditions for a report notification.

TopRows Class
Contains methods and constructors for working with information about a row limit filter.

Reports Exceptions
The Reports namespace contains exception classes.

AggregateColumn Class
Contains methods for describing summary fields such as Record Count, Sum, Average, Max, Min, and custom summary formulas. Includes name, label, data type, and grouping context.

Namespace
Reports

AggregateColumn Methods
The following are methods for AggregateColumn. All are instance methods.

IN THIS SECTION:

gSetName()
Returns the unique API name of the summary field.

gGetLabel()
Returns the localized display name for the summarized or custom summary formula field.
getDataType()
Returns the data type of the summarized or custom summary formula field.

getAcrossGroupingContext()
Returns the column grouping in the report where the summary field is displayed.

getDownGroupingContext()
Returns the row grouping in the report where the summary field is displayed.

getName()
Returns the unique API name of the summary field.

Syntax
public String getName()

Return Value
Type: String

getLabel()
Returns the localized display name for the summarized or custom summary formula field.

Syntax
public String getLabel()

Return Value
Type: String

getDataType()
Returns the data type of the summarized or custom summary formula field.

Syntax
public Reports.ColumnDataType getDataType()

Return Value
Type: Reports.ColumnDataType

getAcrossGroupingContext()
Returns the column grouping in the report where the summary field is displayed.

Syntax
public String getAcrossGroupingContext()
Return Value
Type: String

getDownGroupingContext()
Returns the row grouping in the report where the summary field is displayed.

Syntax
public String getDownGroupingContext()

Return Value
Type: String

BucketField Class
Contains methods and constructors to work with information about a bucket field, including bucket type, name, and bucketed values.

Namespace
Reports

IN THIS SECTION:
BucketField Constructors
BucketField Methods

BucketField Constructors
The following are constructors for BucketField.

IN THIS SECTION:
BucketField(bucketType, developerName, label, nullTreatedAsZero, otherBucketLabel, sourceColumnName, values)
Creates an instance of the Reports.BucketField class using the specified parameters.

BucketField()
Creates an instance of the Reports.BucketField class. You can then set values by using the class's set methods.

BucketField(bucketType, developerName, label, nullTreatedAsZero, otherBucketLabel, sourceColumnName, values)
Creates an instance of the Reports.BucketField class using the specified parameters.

Signature
public BucketField(Reports.BucketType bucketType, String developerName, String label, Boolean nullTreatedAsZero, String otherBucketLabel, String sourceColumnName, List<Reports.BucketFieldValue> values)
Parameters

**bucketType**
Type: `Reports.BucketType`
The type of bucket.

**devloperName**
Type: `String`
API name of the bucket.

**label**
Type: `String`
User-facing name of the bucket.

**nullTreatedAsZero**
Type: `Boolean`
Specifies whether null values are converted to zero (`true`) or not (`false`).

**otherBucketLabel**
Type: `String`
Name of the fields grouped as Other (in buckets of `BucketType PICKLIST`).

**sourceColumnName**
Type: `String`
Name of the bucketed field.

**values**
Type: `List<Reports.BucketType>`
Types of the values included in the bucket.

---

**BucketField()**

Creates an instance of the `Reports.BucketField` class. You can then set values by using the class’s `set` methods.

**Signature**

```
public BucketField()
```

---

**BucketField Methods**

The following are methods for `BucketField`.

**IN THIS SECTION:**

- `getBucketType()`
  Returns the bucket type.
- `getDevloperName()`
  Returns the bucket’s API name.
- `getLabel()`
  Returns the user-facing name of the bucket.
**getNullTreatedAsZero()**
Returns `true` if null values are converted to the number zero, otherwise returns `false`.

**getOtherBucketLabel()**
Returns the name of fields grouped as `Other` in buckets of type `PICKLIST`.

**getSourceColumnName()**
Returns the API name of the bucketed field.

**getValues()**
Returns the report values grouped by the bucket field.

**setBucketType(value)**
Sets the `BucketType` of the bucket.

**setBucketType(bucketType)**
Sets the `BucketType` of the bucket.

**setDevloperName(devloperName)**
Sets the API name of the bucket.

**setLabel(label)**
Sets the user-facing name of the bucket.

**setNullTreatedAsZero(nullTreatedAsZero)**
Specifies whether null values in the bucket are converted to zero (`true`) or not (`false`).

**setOtherBucketLabel(otherBucketLabel)**
Sets the name of the fields grouped as `Other` (in buckets of `BucketType PICKLIST`).

**setSourceColumnName(sourceColumnName)**
Specifies the name of the bucketed field.

**setValues(values)**
Specifies which type of values are included in the bucket.

**toString()**
Returns a string.

---

**getBucketType()**
Returns the bucket type.

**getDevloperName()**
Returns the bucket’s API name.
Signature

public String getDeveloperName()

Return Value
Type: String

**getLabel()**
Returns the user-facing name of the bucket.

Signature

public String getLabel()

Return Value
Type: String

**getNullTreatedAsZero()**
Returns `true` if null values are converted to the number zero, otherwise returns `false`.

Signature

public Boolean getNullTreatedAsZero()

Return Value
Type: Boolean

**getOtherBucketLabel()**
Returns the name of fields grouped as Other in buckets of type PICKLIST.

Signature

public String getOtherBucketLabel()

Return Value
Type: String

**getSourceColumnName()**
Returns the API name of the bucketed field.

Signature

public StringgetSourceColumnName()
Return Value
Type: String

**getValues()**
Returns the report values grouped by the bucket field.

**Signature**
```java
public List<Reports.BucketFieldValue> getValues()
```

Return Value
Type: List on page 2810<Reports.BucketFieldValue>

**setBucketType(value)**
Sets the BucketType of the bucket.

**Signature**
```java
public void setBucketType(String value)
```

Parameters

- value
  Type: String
  See the Reports.BucketType enum for valid values.

Return Value
Type: void

**setBucketType(bucketType)**
Sets the BucketType of the bucket.

**Signature**
```java
public void setBucketType(Reports.BucketType bucketType)
```

Parameters

- bucketType
  Type: Reports.BucketType

Return Value
Type: void
**setDevloperName(devloperName)**
Sets the API name of the bucket.

Signature

```
public void setDevloperName(String devloperName)
```

Parameters

*devloperName*
Type: *String*
The API name to assign to the bucket.

Return Value
Type: void

**setLabel(label)**
Sets the user-facing name of the bucket.

Signature

```
public void setLabel(String label)
```

Parameters

*label*
Type: *String*

Return Value
Type: void

**setNullTreatedAsZero(nullTreatedAsZero)**
Specifies whether null values in the bucket are converted to zero (**true**) or not (**false**).

Signature

```
public void setNullTreatedAsZero(Boolean nullTreatedAsZero)
```

Parameters

*nullTreatedAsZero*
Type: *Boolean*

Return Value
Type: void
setOtherBucketLabel(otherBucketLabel)
Sets the name of the fields grouped as Other (in buckets of BucketType PICKLIST).

Signature
public void setOtherBucketLabel(String otherBucketLabel)

Parameters
otherBucketLabel
  Type: String

Return Value
Type: void

setSourceColumnName(sourceColumnName)
Specifies the name of the bucketed field.

Signature
public void setSourceColumnName(String sourceColumnName)

Parameters
sourceColumnName
  Type: String

Return Value
Type: void

setValues(values)
Specifies which type of values are included in the bucket.

Signature
public void setValues(List<Reports.BucketFieldValue> values)

Parameters
values
  Type: List on page 2810<Reports.BucketFieldValue>

Return Value
Type: void
**toString()**

Returns a string.

Signature

```java
public String toString()
```

Return Value

Type: `String`

**BucketFieldValue Class**

Contains information about the report values included in a bucket field.

**Namespace**

Reports

**BucketFieldValue Constructors**

The following are constructors for `BucketFieldValue`.

**IN THIS SECTION:**

- BucketFieldValue(label, sourceDimensionValues, rangeUpperBound)
- BucketFieldValue()

**BucketFieldValue(label, sourceDimensionValues, rangeUpperBound)**

Creates an instance of the `Reports.BucketFieldValue` class using the specified parameters.

**BucketFieldValue()**

Creates an instance of the `Reports.BucketFieldValue` class. You can then set values by using the class’s `set` methods.

**BucketFieldValue(label, sourceDimensionValues, rangeUpperBound)**

Creates an instance of the `Reports.BucketFieldValue` class using the specified parameters.

Signature

```java
public BucketFieldValue(String label, List<String> sourceDimensionValues, Double rangeUpperBound)
```

Parameters

- `label`
  
  Type: `String`
  
  The user-facing name of the bucket.
sourceDimensionValues
Type: List on page 2810<String>
A list of the values from the source field included in this bucket category (in buckets of type PICKLIST and buckets of type TEXT).

rangeUpperBound
Type: Double
The greatest range limit under which values are included in this bucket category (in buckets of type NUMBER).

BucketFieldValue()
Creates an instance of the Reports.BucketFieldValue class. You can then set values by using the class’s set methods.

Signature
public BucketFieldValue()

BucketFieldValue Methods
The following are methods for BucketFieldValue.

IN THIS SECTION:
  getLabel()
  Returns the user-facing name of the bucket category.
  getRangeUpperBound()
  Returns the greatest range limit under which values are included in this bucket category (in buckets of type NUMBER).
  getSourceDimensionValues()
  Returns a list of the values from the source field included in this bucket category (in buckets of type PICKLIST and buckets of type TEXT).
  setLabel(label)
  Set the user-facing name of the bucket category.
  setRangeUpperBound(rangeUpperBound)
  Sets the greatest limit of a range under which values are included in this bucket category (in buckets of type NUMBER).
  setSourceDimensionValues(sourceDimensionValues)
  Specifies the values from the source field included in this bucket category (in buckets of type PICKLIST and buckets of type TEXT).
  toString()
  Returns a string.

getLabel()
Returns the user-facing name of the bucket category.

Signature
public String getLabel()
**getRangeUpperBound()**

Returns the greatest range limit under which values are included in this bucket category (in buckets of type NUMBER).

Signature

```java
public Double getRangeUpperBound()
```

**getSourceDimensionValues()**

Returns a list of the values from the source field included in this bucket category (in buckets of type PICKLIST and buckets of type TEXT).

Signature

```java
public List<String> getSourceDimensionValues()
```

**setLabel(label)**

Set the user-facing name of the bucket category.

Signature

```java
public void setLabel(String label)
```

Parameters

`label`

Type: String

**setRangeUpperBound(rangeUpperBound)**

Sets the greatest limit of a range under which values are included in this bucket category (in buckets of type NUMBER).
**BucketType Enum**

The types of values included in a bucket.

**Enum Values**

The following are the values of the `Reports.BucketType` enum.

---

Signature

```java
public void setRangeUpperBound(Double rangeUpperBound)
```

Parameters

`rangeUpperBound`

Type: `Double`

Return Value

Type: `void`

---

**setSourceDimensionValues**

Specifies the values from the source field included in this bucket category (in buckets of type `PIECLIST` and buckets of type `TEXT`).

Signature

```java
public void setSourceDimensionValues(List<String> sourceDimensionValues)
```

Parameters

`sourceDimensionValues`

Type: `List<String>`

Return Value

Type: `void`

---

**toString()**

Returns a string.

Signature

```java
public String toString()
```

Return Value

Type: `String`
### ColumnDataType Enum

The `Reports.ColumnDataType` enum describes the type of data in a column. It is returned by the `getDataType` method.

#### Namespace

**Reports**

#### Enum Values

The following are the values of the `Reports.ColumnDataType` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN_DATA</td>
<td>Boolean (<code>true</code> or <code>false</code>) values</td>
</tr>
<tr>
<td>COMBOBOX_DATA</td>
<td>Comboboxes, which provide a set of enumerated values and enable the user to specify a value that is not in the list</td>
</tr>
<tr>
<td>CURRENCY_DATA</td>
<td>Currency values</td>
</tr>
<tr>
<td>DATETIME_DATA</td>
<td>DateTime values</td>
</tr>
<tr>
<td>DATE_DATA</td>
<td>Date values</td>
</tr>
<tr>
<td>DOUBLE_DATA</td>
<td>Double values</td>
</tr>
<tr>
<td>EMAIL_DATA</td>
<td>Email addresses</td>
</tr>
<tr>
<td>ID_DATA</td>
<td>An object’s Salesforce ID</td>
</tr>
<tr>
<td>INT_DATA</td>
<td>Integer values</td>
</tr>
<tr>
<td>MULTIPICKLIST_DATA</td>
<td>Multi-select picklists, which provide a set of enumerated values from which multiple values can be selected</td>
</tr>
<tr>
<td>PERCENT_DATA</td>
<td>Percent values</td>
</tr>
<tr>
<td>PHONE_DATA</td>
<td>Phone numbers. Values can include alphabetic characters. Client applications are responsible for phone number formatting.</td>
</tr>
<tr>
<td>PICKLIST_DATA</td>
<td>Single-select picklists, which provide a set of enumerated values from which only one value can be selected</td>
</tr>
<tr>
<td>REFERENCE_DATA</td>
<td>Cross-references to another object, analogous to a foreign key field</td>
</tr>
<tr>
<td>STRING_DATA</td>
<td>String values</td>
</tr>
</tbody>
</table>
### ColumnSortOrder Enum

The `Reports.ColumnSortOrder` enum describes the order that the grouping column uses to sort data.

**Namespace**

*Reports*

**Usage**

The `GroupingInfo.getColumnSortOrder()` method returns a `Reports.ColumnSortOrder` enum value. The `GroupingInfo.setColumnSortOrder()` method takes the enum value as an argument.

**Enum Values**

The following are the values of the `Reports.ColumnSortOrder` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCENDING</td>
<td>Sort data in ascending order (A–Z)</td>
</tr>
<tr>
<td>DESCENDING</td>
<td>Sort data in descending order (Z–A)</td>
</tr>
</tbody>
</table>

### CrossFilter Class

Contains methods and constructors used to work with information about a cross filter.

**Namespace**

*Reports*

**IN THIS SECTION:**

- **CrossFilter Constructors**
- **CrossFilter Methods**

### CrossFilter Constructors

The following are constructors for `CrossFilter`. 
IN THIS SECTION:

CrossFilter(criteria, includesObject, primaryEntityField, relatedEntity, relatedEntityJoinField)
Creates an instance of the Reports.CrossFilter class using the specified parameters.

CrossFilter()
Creates an instance of the Reports.CrossFilter class. You can then set values by using the class’s set methods.

CrossFilter(criteria, includesObject, primaryEntityField, relatedEntity, relatedEntityJoinField)
Creates an instance of the Reports.CrossFilter class using the specified parameters.

Signature
public CrossFilter(List<Reports.ReportFilter> criteria, Boolean includesObject, String primaryEntityField, String relatedEntity, String relatedEntityJoinField)

Parameters
criteria
Type: List<Reports.ReportFilter>
Information about how to filter the relatedEntity. Relates the primary entity with a subset of the relatedEntity.

includesObject
Type: Boolean
Specifies whether objects returned have a relationship with the relatedEntity (true) or not (false).

primaryEntityField
Type: String
The name of the object on which the cross filter is evaluated.

relatedEntity
Type: String
The name of the object that the primaryEntityField is evaluated against—the right-hand side of the cross filter.

relatedEntityJoinField
Type: String
The name of the field used to join the primaryEntityField and relatedEntity.

CrossFilter()
Creates an instance of the Reports.CrossFilter class. You can then set values by using the class’s set methods.

Signature
public CrossFilter()
getCriteria()
Returns information about how to filter the relatedEntity. Describes the subset of the relatedEntity which the primary entity is evaluated against.

getIncludesObject()
Returns true if primary object has a relationship with the relatedEntity, otherwise returns false.

getPrimaryEntityField()
Returns the name of the object on which the cross filter is evaluated.

getRelatedEntity()
Returns name of the object that the primaryEntityField is evaluated against—the right-hand side of the cross filter.

getRelatedEntityJoinField()
Returns the name of the field used to join the primaryEntityField and relatedEntity.

setCriteria(criteria)
Specifies how to filter the relatedEntity. Relates the primary entity with a subset of the relatedEntity.

setIncludesObject(includesObject)
Specifies whether objects returned have a relationship with the relatedEntity (true) or not (false).

setPrimaryEntityField(primaryEntityField)
Specifies the name of the object on which the cross filter is evaluated.

setRelatedEntity(relatedEntity)
Specifies the name of the object that the primaryEntityField is evaluated against—the right-hand side of the cross filter.

setRelatedEntityJoinField(relatedEntityJoinField)
Specifies the name of the field used to join the primaryEntityField and relatedEntity.

toString()
Returns a string.

getCriteria()
Returns information about how to filter the relatedEntity. Describes the subset of the relatedEntity which the primary entity is evaluated against.

Signature
public List<Reports.ReportFilter> getCriteria()

Return Value
Type: List<Reports.ReportFilter>

getIncludesObject()
Returns true if primary object has a relationship with the relatedEntity, otherwise returns false.

Signature
public Boolean getIncludesObject()
Return Value
Type: Boolean

getPrimaryEntityField()
Returns the name of the object on which the cross filter is evaluated.

Signature
public String getPrimaryEntityField()

Return Value
Type: String

g RELATEDENTITY()  
Returns name of the object that the primaryEntityField is evaluated against—the right-hand side of the cross filter.

Signature
public String getRelatedEntity()

Return Value
Type: String

getRelatedEntityJoinField()
Returns the name of the field used to join the primaryEntityField and relatedEntity.

Signature
public String getRelatedEntityJoinField()

Return Value
Type: String

setCriteria(criteria)
Specifies how to filter the relatedEntity. Relates the primary entity with a subset of the relatedEntity.

Signature
public void setCriteria(List<Reports.ReportFilter> criteria)

Parameters
criteria
Type: List<Reports.ReportFilter>
setIncludesObject(includesObject)
Specifies whether objects returned have a relationship with the relatedEntity (true) or not (false).

Signature
public void setIncludesObject(Boolean includesObject)

Parameters
includesObject
Type: Boolean

Return Value
Type: void

setPrimaryEntityField(primaryEntityField)
Specifies the name of the object on which the cross filter is evaluated.

Signature
public void setPrimaryEntityField(String primaryEntityField)

Parameters
primaryEntityField
Type: String

Return Value
Type: void

setRelatedEntity(relatedEntity)
Specifies the name of the object that the primaryEntityField is evaluated against—the right-hand side of the cross filter.

Signature
public void setRelatedEntity(String relatedEntity)

Parameters
relatedEntity
Type: String
setRelatedEntityJoinField(relatedEntityJoinField)

Specifies the name of the field used to join the primaryEntityField and relatedEntity.

Signature

public void setRelatedEntityJoinField(String relatedEntityJoinField)

Parameters

relatedEntityJoinField
Type: String

Return Value
Type: void

toString()

Returns a string.

Signature

public String toString()

Return Value
Type: String

CsfGroupType Enum

The group level at which the custom summary format aggregate is displayed in a report.

Enum Values

The following are the values of the Reports.CsfGroupType enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>The aggregate is displayed at the end of every summary row.</td>
</tr>
<tr>
<td>CUSTOM</td>
<td>The aggregate is displayed at specified grouping levels.</td>
</tr>
<tr>
<td>GRAND_TOTAL</td>
<td>The aggregate is displayed only at the grand total level.</td>
</tr>
</tbody>
</table>
DateGranularity Enum

The `Reports.DateGranularity` enum describes the date interval that is used for grouping.

Namespace

Reports

Usage

The `GroupingInfo.getDateGranularity` method returns a `Reports.DateGranularity` enum value. The `GroupingInfo.setDateGranularity` method takes the enum value as an argument.

Enum Values

The following are the values of the `Reports.DateGranularity` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAY</td>
<td>The day of the week (Monday–Sunday)</td>
</tr>
<tr>
<td>DAY_IN_MONTH</td>
<td>The day of the month (1–31)</td>
</tr>
<tr>
<td>FISCAL_PERIOD</td>
<td>The fiscal period</td>
</tr>
<tr>
<td>FISCAL_QUARTER</td>
<td>The fiscal quarter</td>
</tr>
<tr>
<td>FISCAL_WEEK</td>
<td>The fiscal week</td>
</tr>
<tr>
<td>FISCAL_YEAR</td>
<td>The fiscal year</td>
</tr>
<tr>
<td>MONTH</td>
<td>The month (January–December)</td>
</tr>
<tr>
<td>MONTH_IN_YEAR</td>
<td>The month number (1–12)</td>
</tr>
<tr>
<td>NONE</td>
<td>No date grouping</td>
</tr>
<tr>
<td>QUARTER</td>
<td>The quarter number (1–4)</td>
</tr>
<tr>
<td>WEEK</td>
<td>The week number (1–52)</td>
</tr>
<tr>
<td>YEAR</td>
<td>The year number (####)</td>
</tr>
</tbody>
</table>

DetailColumn Class

Contains methods for describing fields that contain detailed data. Detailed data fields are also listed in the report metadata.

Namespace

Reports

DetailColumn Instance Methods

The following are instance methods for `DetailColumn`. All are instance methods.
IN THIS SECTION:

- **getName()**
  Returns the unique API name of the detail column field.

- **getLabel()**
  Returns the localized display name of a standard field, the ID of a custom field, or the API name of a bucket field that has detailed data.

- **getColumnDataType()**
  Returns the data type of a detail column field.

### getName()

Returns the unique API name of the detail column field.

**Syntax**

```
public String getName()
```

**Return Value**

Type: String

### getLabel()

Returns the localized display name of a standard field, the ID of a custom field, or the API name of a bucket field that has detailed data.

**Syntax**

```
public String getLabel()
```

**Return Value**

Type: String

### getDataType()

Returns the data type of a detail column field.

**Syntax**

```
public Reports.ColumnDataType getDataType()
```

**Return Value**

Type: Reports.ColumnDataType

### Dimension Class

Contains information for each row or column grouping.
Namespace
Reports

Dimension Methods
The following are methods for Dimension. All are instance methods.

IN THIS SECTION:

getGroupings()
Returns information for each row or column grouping as a list.

getGroupings()
Returns information for each row or column grouping as a list.

Syntax

public List<Reports.GroupingValue> getGroupings()

Return Value
Type: List<Reports.GroupingValue>

EvaluatedCondition Class
Contains the individual components of an evaluated condition for a report notification, such as the aggregate name and label, the operator, and the value that the aggregate is compared to.

Namespace
Reports

IN THIS SECTION:
EvaluatedCondition Constructors
EvaluatedCondition Methods

EvaluatedCondition Constructors
The following are constructors for EvaluatedCondition.

IN THIS SECTION:
EvaluatedCondition(aggregateName, aggregateLabel, compareToValue, aggregateValue, displayCompareTo, displayValue, operator)
Creates a new instance of the Reports.EvaluatedConditions class using the specified parameters.
EvaluatedCondition(aggregateName, aggregateLabel, compareToValue, aggregateValue, displayCompareTo, displayValue, operator)

Creates a new instance of the Reports.EvaluatedConditions class using the specified parameters.

Signature

public EvaluatedCondition(String aggregateName, String aggregateLabel, Double compareToValue, Double aggregateValue, String displayCompareTo, String displayValue, Reports.EvaluatedConditionOperator operator)

Parameters

aggregateName
  Type: String
  The unique API name of the aggregate.

aggregateLabel
  Type: String
  The localized display name of the aggregate.

compareToValue
  Type: Double
  The value that the aggregate is compared to in the condition.

aggregateValue
  Type: Double
  The actual value of the aggregate when the report is run.

displayCompareTo
  Type: String
  The value that the aggregate is compared to in the condition, formatted for display. For example, a display value for a currency is $20.00 or USD20.00 instead of 20.00.

displayValue
  Type: String
  The value of the aggregate when the report is run, formatted for display. For example, a display value for a currency is $20.00 or USD20.00 instead of 20.00.

operator
  Type: Reports.EvaluatedConditionOperator
  The operator used in the condition.

EvaluatedCondition Methods

The following are methods for EvaluatedCondition.

IN THIS SECTION:

  getAggregateLabel()
  Returns the localized display name of the aggregate.
getAggregateName()  
Returns the unique API name of the aggregate.

getCompareTo()  
Returns the value that the aggregate is compared to in the condition.

getDisplayCompareTo()  
Returns the value that the aggregate is compared to in the condition, formatted for display. For example, a display value for a currency is $20.00 or USD20.00 instead of 20.00.

getDisplayValue()  
Returns the value of the aggregate when the report is run, formatted for display. For example, a display value for a currency is $20.00 or USD20.00 instead of 20.00.

getOperator()  
Returns the operator used in the condition.

getValue()  
Returns the actual value of the aggregate when the report is run.

getAggregateLabel()  
Returns the localized display name of the aggregate.

Signature
public String getAggregateLabel()

Return Value
Type: String

getAggregateName()  
Returns the unique API name of the aggregate.

Signature
public String getAggregateName()

Return Value
Type: String

getCompareTo()  
Returns the value that the aggregate is compared to in the condition.

Signature
public Double getCompareTo()
Return Value
Type: Double

**getDisplayCompareTo()**
Returns the value that the aggregate is compared to in the condition, formatted for display. For example, a display value for a currency is $20.00 or USD20.00 instead of 20.00.

Signature
```java
public String getDisplayCompareTo()
```

Return Value
Type: String

**getDisplayValue()**
Returns the value of the aggregate when the report is run, formatted for display. For example, a display value for a currency is $20.00 or USD20.00 instead of 20.00.

Signature
```java
public String getDisplayValue()
```

Return Value
Type: String

**getOperator()**
Returns the operator used in the condition.

Signature
```java
public Reports.EvaluatedConditionOperator getOperator()
```

Return Value
Type: Reports.EvaluatedConditionOperator

**getValue()**
Returns the actual value of the aggregate when the report is run.

Signature
```java
public Double getValue()
```
**EvaluatedConditionOperator Enum**

The `Reports.EvaluatedConditionOperator` enum describes the type of operator used to compare an aggregate to a value. It is returned by the `getOperator` method.

### Namespace

**Reports**

### Enum Values

The following are the values of the `Reports.EvaluatedConditionOperator` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EQUAL</td>
<td>Equality operator.</td>
</tr>
<tr>
<td>GREATER_THAN</td>
<td>Greater than operator.</td>
</tr>
<tr>
<td>GREATER_THAN_EQUAL</td>
<td>Greater than or equal to operator.</td>
</tr>
<tr>
<td>LESS_THAN</td>
<td>Less than operator.</td>
</tr>
<tr>
<td>LESS_THAN_EQUAL</td>
<td>Less than or equal to operator.</td>
</tr>
<tr>
<td>NOT_EQUAL</td>
<td>Inequality operator.</td>
</tr>
</tbody>
</table>

**FilterOperator Class**

Contains information about a filter operator, such as display name and API name.

### Namespace

**Reports**

### FilterOperator Methods

The following are methods for `FilterOperator`. All are instance methods.

**IN THIS SECTION:**

- `getLabel()`
  Returns the localized display name of the filter operator. Possible values for this name are restricted based on the data type of the column being filtered.
getName()
Returns the unique API name of the filter operator. Possible values for this name are restricted based on the data type of the column being filtered. For example multipicklist fields can use the following filter operators: “equals,” “not equal to,” “includes,” and “excludes.” Bucket fields are considered to be of the String type.

getLabel()
Returns the localized display name of the filter operator. Possible values for this name are restricted based on the data type of the column being filtered.

Syntax
public String getName()
**getName()**
Returns the unique API name of the filter value. Possible values for this name are restricted based on the data type of the column being filtered.

**getLabel()**
Returns the localized display name of the filter value. Possible values for this name are restricted based on the data type of the column being filtered.

Syntax

```java
public String getLabel()
```

Return Value

Type: String

**getName()**
Returns the unique API name of the filter value. Possible values for this name are restricted based on the data type of the column being filtered.

Syntax

```java
public String getName()
```

Return Value

Type: String

### FormulaType Enum

The format of the numbers in a custom summary formula.

#### Enum Values

The following are the values of the `Reports.FormulaType` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENCY</td>
<td>Formatted as currency. For example, $100.00.</td>
</tr>
<tr>
<td>NUMBER</td>
<td>Formatted as numbers. For example, 100.</td>
</tr>
<tr>
<td>PERCENT</td>
<td>Formatted as percentages. For example, 100%.</td>
</tr>
</tbody>
</table>

### GroupingColumn Class

Contains methods for describing fields that are used for column grouping.
Namespace

Reports

The GroupingColumn class provides basic information about column grouping fields. The GroupingInfo class includes additional methods for describing and updating grouping fields.

GroupingColumn Methods

The following are methods for GroupingColumn. All are instance methods.

IN THIS SECTION:

getName()
Returns the unique API name of the field or bucket field that is used for column grouping.

getAddress()
Returns the localized display name of the field that is used for column grouping.

dataType()
Returns the data type of the field that is used for column grouping.

getName()

Returns the unique API name of the field or bucket field that is used for column grouping.

Syntax

```java
public String getName()
```

Return Value

Type: String

getAddress()

Returns the localized display name of the field that is used for column grouping.

Syntax

```java
public String getLabel()
```

Return Value

Type: String

dataType()

Returns the data type of the field that is used for column grouping.

Syntax

```java
public String getDataType()
```

Return Value

Type: String
public Reports.ColumnDataType getDataType()

Return Value
Type: Reports.ColumnDataType

g etGroupingLevel()
Returns the level of grouping for the column.

public Integer getGroupingLevel()

Return Value
Type: Integer

Usage
- In a summary report, 0, 1, or 2 indicates grouping at the first, second, or third row level.
- In a matrix report, 0 or 1 indicates grouping at the first or second row or column level.

GroupingInfo Class
Contains methods for describing fields that are used for grouping.

Namespace
Reports

GroupingInfo Methods
The following are methods for GroupingInfo. All are instance methods.

IN THIS SECTION:
  getName()  
  Returns the unique API name of the field or bucket field that is used for row or column grouping.
  getSortOrder()  
  Returns the order that is used to sort data in a row or column grouping (ASCENDING or DESCENDING).
  getDateGranularity()  
  Returns the date interval that is used for row or column grouping.
  getSortAggregate()  
  Returns the summary field that is used to sort data within a grouping in a summary report. The value is null when data within a grouping is not sorted by a summary field.
**getName()**
Returns the unique API name of the field or bucket field that is used for row or column grouping.

Syntax
```
public String getName()
```

Return Value
Type: String

**getSortOrder()**
Returns the order that is used to sort data in a row or column grouping (ASCENDING or DESCENDING).

Syntax
```
public Reports.ColumnSortOrder getSortOrder()
```

Return Value
Type: Reports.ColumnSortOrder

**getDateGranularity()**
Returns the date interval that is used for row or column grouping.

Syntax
```
public Reports.DateGranularity getDateGranularity()
```

Return Value
Type: Reports.DateGranularity

**getSortAggregate()**
Returns the summary field that is used to sort data within a grouping in a summary report. The value is null when data within a grouping is not sorted by a summary field.

Syntax
```
public String getSortAggregate()
```

Return Value
Type: String

**GroupingValue Class**
Contains grouping values for a row or column, including the key, label, and value.
Namespace

Reports

GroupingValue Methods

The following are methods for GroupingValue. All are instance methods.

IN THIS SECTION:

getGroupings()
Returns a list of second- or third-level row or column groupings. If there are none, the value is an empty array.

getKey()
Returns the unique identifier for a row or column grouping. The identifier is used by the fact map to specify data values within each grouping.

getLabel()
Returns the localized display name of a row or column grouping. For date and time fields, the label is the localized date or time.

getValue()
Returns the value of the field that is used as a row or column grouping.

getGroupings()

Returns a list of second- or third-level row or column groupings. If there are none, the value is an empty array.

Syntax

public LIST<Reports.GroupingValue> getGroupings()

Return Value
Type: List<Reports.GroupingValue>

getKey()

Returns the unique identifier for a row or column grouping. The identifier is used by the fact map to specify data values within each grouping.

Syntax

public String getKey()

Return Value
Type: String

getLabel()

Returns the localized display name of a row or column grouping. For date and time fields, the label is the localized date or time.
Syntax

public String getLabel()

Return Value
Type: String

getValue()

Returns the value of the field that is used as a row or column grouping.

Syntax

public Object getValue()

Return Value
Type: Object

Usage

The value depends on the field’s data type.

- Currency fields:
  - amount: Of type currency. A data cell’s value.
  - currency: Of type picklist. The ISO 4217 currency code, if available; for example, USD for US dollars or CNY for Chinese yuan. (If the grouping is on the converted currency, this value is the currency code for the report and not for the record.)

- Picklist fields: API name. For example, a custom picklist field—Type of Business with values 1, 2, and 3 for Consulting, Services, and Add-On Business respectively—has 1, 2, or 3 as the grouping value.

- ID fields: API name.

- Record type fields: API name.

- Date and time fields: Date or time in ISO-8601 format.

- Lookup fields: Unique API name. For example, for the Opportunity Owner lookup field, the ID of each opportunity owner’s Chatter profile page can be a grouping value.

NotificationAction Interface

Implement this interface to trigger a custom Apex class when the conditions for a report notification are met.

Namespace

Reports

Usage

Report notifications for reports that users have subscribed to can trigger a custom Apex class, which must implement the Reports.NotificationAction interface. The execute method in this interface receives a
NotificationActionContext object as a parameter, which contains information about the report instance and the conditions that must be met for a notification to be triggered.

IN THIS SECTION:

NotificationAction Methods

NotificationAction Example Implementation

NotificationAction Methods
The following are methods for NotificationAction.

IN THIS SECTION:

execute(context)
Executes the custom Apex action specified in the context parameter of the context object, NotificationActionContext. The object contains information about the report instance and the conditions that must be met for a notification to be triggered. The method executes whenever the specified conditions are met.

execute(context)
Executes the custom Apex action specified in the context parameter of the context object, NotificationActionContext. The object contains information about the report instance and the conditions that must be met for a notification to be triggered. The method executes whenever the specified conditions are met.

Signature

public void execute(Reports.NotificationActionContext context)

Parameters

costext
Type: Reports.NotificationActionContext

Return Value
Type: Void

NotificationAction Example Implementation
This is an example implementation of the Reports.NotificationAction interface.

```java
public class AlertOwners implements Reports.NotificationAction {
    public void execute(Reports.NotificationActionContext context) {
        Reports.ReportResults results = context.getReportInstance().getReportResults();
        for (Reports.GroupingValue g: results.getGroupingsDown().getGroupings()) {
            FeedItem t = new FeedItem();
            t.ParentId = (Id)g.getValue();
            t.Body = 'This record needs attention. Please view the report.';
            t.Title = 'Needs Attention: ' + results.getReportMetadata().getName();
        }
    }
}
```
NotificationActionContext Class
Contains information about the report instance and condition threshold for a report notification.

Namespace
Reports

IN THIS SECTION:
  NotificationActionContext Constructors
  NotificationActionContext Methods

NotificationActionContext Constructors
The following are constructors for NotificationActionContext.

IN THIS SECTION:
  NotificationActionContext(reportInstance, thresholdInformation)
  Creates a new instance of the Reports.NotificationActionContext class using the specified parameters.

NotificationActionContext(reportInstance, thresholdInformation)
Creates a new instance of the Reports.NotificationActionContext class using the specified parameters.

Signature
public NotificationActionContext(Reports.ReportInstance reportInstance,
  Reports.ThresholdInformation thresholdInformation)

Parameters
reportInstance
  Type: Reports.ReportInstance
  An instance of a report.
thresholdInformation
  Type: Reports.ThresholdInformation
  The evaluated conditions for the notification.

NotificationActionContext Methods
The following are methods for NotificationActionContext.

2373
IN THIS SECTION:

**getReportInstance()**
Returns the report instance associated with the notification.

**getThresholdInformation()**
Returns the threshold information associated with the notification.

---

**getReportInstance()**
Returns the report instance associated with the notification.

**Signature**

```java
public Reports.ReportInstance getReportInstance()
```

**Return Value**

Type: `Reports.ReportInstance`

---

**getThresholdInformation()**
Returns the threshold information associated with the notification.

**Signature**

```java
public Reports.ThresholdInformation getThresholdInformation()
```

**Return Value**

Type: `Reports.ThresholdInformation`

---

**ReportCsf Class**

Contains methods and constructors for working with information about a custom summary formula (CSF).

**Namespace**

`Reports`

---

IN THIS SECTION:

ReportCsf Constructors

ReportCsf Methods

---

**ReportCsf Constructors**
The following are constructors for `ReportCsf`. 
IN THIS SECTION:

ReportCsf(label, description, formulaType, decimalPlaces, downGroup, downGroupType, acrossGroup, acrossGroupType, formula)

Creates an instance of the Reports.ReportCsf class using the specified parameters.

ReportCsf()

Creates an instance of the Reports.ReportCsf class. You can then set values by using the class’s set methods.

ReportCsf(label, description, formulaType, decimalPlaces, downGroup, downGroupType, acrossGroup, acrossGroupType, formula)

Creates an instance of the Reports.ReportCsf class using the specified parameters.

Signature

```java
public ReportCsf(String label, String description, Reports.FormulaType formulaType, Integer decimalPlaces, String downGroup, Reports.CsfGroupType downGroupType, String acrossGroup, Reports.CsfGroupType acrossGroupType, String formula)
```

Parameters

- **label**
  - Type: String
  - The user-facing name of the custom summary formula.

- **description**
  - Type: String
  - The user-facing description of the custom summary formula.

- **formulaType**
  - Type: Reports.FormulaType
  - The format of the numbers in the custom summary formula.

- **decimalPlaces**
  - Type: Integer
  - The number of decimal places to include in numbers.

- **downGroup**
  - Type: String
  - The name of a row grouping when the downGroupType is CUSTOM; null otherwise.

- **downGroupType**
  - Type: Reports.CsfGroupType
  - Where to display the aggregate of the custom summary formula.

- **acrossGroup**
  - Type: String
  - The name of a column grouping when the acrossGroupType is CUSTOM; null otherwise.

- **acrossGroupType**
  - Type: Reports.CsfGroupType
  - Where to display the aggregate of the custom summary formula.
*Formula*

Type: `String`

The operations performed on values in the custom summary formula.

**ReportCsf()**

Creates an instance of the `Reports.ReportCsf` class. You can then set values by using the class’s `set` methods.

Signature

```java
public ReportCsf()
```

**ReportCsf Methods**

The following are methods for `ReportCsf`.

**IN THIS SECTION:**

- `getAcrossGroup()`: Returns the name of a column grouping when the `acrossGroupType` is `CUSTOM`. Otherwise, returns `null`.
- `getAcrossGroupType()`: Returns where to display the aggregate.
- `getDecimalPlaces()`: Returns the number of decimal places that numbers in the custom summary formula have.
- `getDescription()`: Returns the user-facing description of a custom summary formula.
- `getDownGroup()`: Returns the name of a row grouping when the `downGroupType` is `CUSTOM`. Otherwise, returns `null`.
- `getDownGroupType()`: Returns where to display the aggregate of the custom summary formula.
- `getFormula()`: Returns the operations performed on values in the custom summary formula.
- `getFormulaType()`: Returns the formula type.
- `getLabel()`: Returns the user-facing name of the custom summary formula.
- `setAcrossGroup(acrossGroup)`: Specifies the column for the across grouping.
- `setAcrossGroupType(value)`: Sets where to display the aggregate.
- `setAcrossGroupType(acrossGroupType)`: Sets where to display the aggregate.
- `setDecimalPlaces(decimalPlaces)`: Sets the number of decimal places in numbers.
setDescription(description)
Sets the user-facing description of the custom summary formula.

downGroup(downGroup)
Sets the name of a row grouping when the downGroupType is CUSTOM.

downGroupType(value)
Sets where to display the aggregate.

downGroupType(downGroupType)
Sets where to display the aggregate.

setFormula(formula)
Sets the operations to perform on values in the custom summary formula.

setFormulaType(value)
Sets the format of the numbers in the custom summary formula.

setFormulaType(formulaType)
Sets the format of numbers used in the custom summary formula.

setLabel(label)
Sets the user-facing name of the custom summary formula.

toString()
Returns a string.

getAcrossGroup()
Returns the name of a column grouping when the acrossGroupType is CUSTOM. Otherwise, returns null.

Signature
public String getAcrossGroup()

Return Value
Type: String

getAcrossGroupType()
Returns where to display the aggregate.

Signature
public Reports.CsfGroupType getAcrossGroupType()

Return Value
Type: Reports.CsfGroupType

getDecimalPlaces()
Returns the number of decimal places that numbers in the custom summary formula have.
public Integer getDecimalPlaces()

Return Value
Type: Integer

ggetDescription()
Returns the user-facing description of a custom summary formula.

public String getDescription()

Return Value
Type: String

ggetDownGroup()
Returns the name of a row grouping when the downGroupType is CUSTOM. Otherwise, returns null.

public String getDownGroup()

Return Value
Type: String

ggetDownGroupType()
Returns where to display the aggregate of the custom summary formula.

public Reports.CsfGroupType getDownGroupType()

Return Value
Type: Reports.CsfGroupType

ggetFormula()
Returns the operations performed on values in the custom summary formula.

public String getFormula()
getFormulaType()
Returns the formula type.

Signature
public Reports.FormulaType getFormulaType()

Return Value
Type: Reports.FormulaType

g.getLabel()
Returns the user-facing name of the custom summary formula.

Signature
public String getLabel()

Return Value
Type: String

setAcrossGroup(acrossGroup)
Specifies the column for the across grouping.

Signature
public void setAcrossGroup(String acrossGroup)

Parameters
acrossGroup
Type: String

Return Value
Type: void

setAcrossGroupType(value)
Sets where to display the aggregate.

Signature
public void setAcrossGroupType(String value)
setAcrossGroupType(acrossGroupType)
Sets where to display the aggregate.

Signature
public void setAcrossGroupType(Reports.CsfGroupType acrossGroupType)

Parameters
acrossGroupType
Type: Reports.CsfGroupType

Return Value
Type: void

setDecimalPlaces(decimalPlaces)
Sets the number of decimal places in numbers.

Signature
public void setDecimalPlaces(Integer decimalPlaces)

Parameters
decimalPlaces
Type: Integer

Return Value
Type: void

setDescription(description)
Sets the user-facing description of the custom summary formula.

Signature
public void setDescription(String description)
Parameters

description
Type: String

Return Value
Type: void

**setDownGroup**(downGroup)
Sets the name of a row grouping when the downGroupType is CUSTOM.

Signature

```java
public void setDownGroup(String downGroup)
```

Parameters

downGroup
Type: String

Return Value
Type: void

**setDownGroupType**(value)
Sets where to display the aggregate.

Signature

```java
public void setDownGroupType(String value)
```

Parameters

value
Type: String

For valid values, see Reports.CsfGroupType.

Return Value
Type: void

**setDownGroupType**(downGroupType)
Sets where to display the aggregate.

Signature

```java
public void setDownGroupType(Reports.CsfGroupType downGroupType)
```
Parameters

\textit{downGroupType}

Type: \texttt{Reports.CsfGroupType}

Return Value
Type: \texttt{void}

\textbf{setFormula(formula)}
Sets the operations to perform on values in the custom summary formula.

Signature

\texttt{public void setFormula(String formula)}

Parameters

\textit{formula}

Type: \texttt{String}

Return Value
Type: \texttt{void}

\textbf{setFormulaType(value)}
Sets the format of the numbers in the custom summary formula.

Signature

\texttt{public void setFormulaType(String value)}

Parameters

\textit{value}

Type: \texttt{String}

For valid values, see \texttt{Reports.FormulaType}.

Return Value
Type: \texttt{void}

\textbf{setFormulaType(formulaType)}
Sets the format of numbers used in the custom summary formula.

Signature

\texttt{public void setFormulaType(Reports.FormulaType formulaType)}
Parameters

*formulaType*

Type: `Reports.FormulaType`

Return Value

Type: `void`

**setLabel(label)**

Sets the user-facing name of the custom summary formula.

Signature

```java
public void setLabel(String label)
```

Parameters

*label*

Type: `String`

Return Value

Type: `void`

**toString()**

Returns a string.

Signature

```java
public String toString()
```

Return Value

Type: `String`

---

**ReportCurrency Class**

Contains information about a currency value, including the amount and currency code.

**Namespace**

`Reports`

**ReportCurrency Methods**

The following are methods for `ReportCurrency`. All are instance methods.
getAmount()  
Returns the amount of the currency value.

getCurrencyCode() 
Returns the report currency code, such as USD, EUR, or GBP, for an organization that has multicurrency enabled. The value is \texttt{null} if the organization does not have multicurrency enabled.

getAmount() 
Returns the amount of the currency value.

Syntax  
\begin{verbatim}
public Decimal getAmount()
\end{verbatim}

Return Value  
Type: Decimal

gCurrencyCode() 
Returns the report currency code, such as USD, EUR, or GBP, for an organization that has multicurrency enabled. The value is \texttt{null} if the organization does not have multicurrency enabled.

Syntax  
\begin{verbatim}
public String getCurrencyCode()
\end{verbatim}

Return Value  
Type: String

ReportDataCell Class
Contains the data for a cell in the report, including the display label and value.

Namespace
Reports

ReportDataCell Methods
The following are methods for ReportDataCell. All are instance methods.

IN THIS SECTION:

gLabel()  
Returns the localized display name of the value of a specified cell in the report.
getValue()  
Returns the value of a specified cell of a detail row of a report.

getLabel()  
Returns the localized display name of the value of a specified cell in the report.

Syntax
public String getLabel()

Return Value
Type: String

getValue()  
Returns the value of a specified cell of a detail row of a report.

Syntax
public Object getValue()

Return Value
Type: Object

ReportDescribeResult Class  
Contains report, report type, and extended metadata for a tabular, summary, or matrix report.

Namespace  
Reports

ReportDescribeResult Methods  
The following are methods for ReportDescribeResult. All are instance methods.

IN THIS SECTION:
  - getReportExtendedMetadata()  
    Returns additional information about grouping and summaries.
  - getReportMetadata()  
    Returns unique identifiers for groupings and summaries.
  - getReportTypeMetadata()  
    Returns the fields in each section of a report type, plus filtering information for those fields.
**getReportExtendedMetadata()**
Returns additional information about grouping and summaries.

Syntax
```
public Reports.ReportExtendedMetadata getReportExtendedMetadata()
```

Return Value
Type: `Reports.ReportExtendedMetadata`

**getReportMetadata()**
Returns unique identifiers for groupings and summaries.

Syntax
```
public Reports.ReportMetadata getReportMetadata()
```

Return Value
Type: `Reports.ReportMetadata`

**getReportTypeMetadata()**
Returns the fields in each section of a report type, plus filtering information for those fields.

Syntax
```
public Reports.ReportTypeMetadata getReportTypeMetadata()
```

Return Value
Type: `Reports.ReportTypeMetadata`

**ReportDetailRow Class**
Contains data cells for a detail row of a report.

**Namespace**
*Reports*

**ReportDetailRow Methods**
The following are methods for `ReportDetailRow`. All are instance methods.
IN THIS SECTION:

**getDataCells()**

Returns a list of data cells for a detail row.

**getDataCells()**

Returns a list of data cells for a detail row.

Syntax

```java
public LIST<Reports.ReportDataCell> getDataCells()
```

Return Value

Type: `List<Reports.ReportDataCell>`

---

**ReportDivisionInfo Class**

Contains information about the divisions that can be used to filter a report.

Available only if your organization uses divisions to segment data and you have the “Affected by Divisions” permission. If you do not have the “Affected by Divisions” permission, your reports include records in all divisions.

**Namespace**

`Reports`

**Usage**

Use to filter records in the report based on a division, like West Coast and East Coast.

**ReportDivisionInfo Methods**

The following are methods for `ReportDivisionInfo`.

**getDefaultValue()**

Returns the default division for the report.

**Signature**

```java
public String getDefaultValue()
```

**Return Value**

Type: `String`

**getValues()**

Returns a list of all possible divisions for the report.
Signature

```java
public List<Reports.FilterValue> getValues()
```

Return Value

Type: `List<Reports.FilterValue>`

**ReportExtendedMetadata Class**

Contains report extended metadata for a tabular, summary, or matrix report.

**Namespace**

**Reports**

Report extended metadata provides additional, detailed metadata about summary and grouping fields, including data type and label information.

**ReportExtendedMetadata Methods**

The following are methods for `ReportExtendedMetadata`. All are instance methods.

**IN THIS SECTION:**

- `getAggregateColumnInfo()`
  - Returns all report summaries such as `Record Count`, `Sum`, `Average`, `Max`, `Min`, and custom summary formulas. Contains values for each summary that is listed in the report metadata.

- `getDetailColumnInfo()`
  - Returns a map of two properties for each field that has detailed data identified by its unique API name. The detailed data fields are also listed in the report metadata.

- `getGroupingColumnInfo()`
  - Returns a map of each row or column grouping to its metadata. Contains values for each grouping that is identified in the `groupingsDown` and `groupingsAcross` lists.

**getAggregateColumnInfo()**

Returns all report summaries such as `Record Count`, `Sum`, `Average`, `Max`, `Min`, and custom summary formulas. Contains values for each summary that is listed in the report metadata.

**Syntax**

```java
public MAP<String,Reports.AggregateColumn> getAggregateColumnInfo()
```

Return Value

Type: `Map<String,Reports.AggregateColumn>`
getDetailColumnInfo()
Returns a map of two properties for each field that has detailed data identified by its unique API name. The detailed data fields are also listed in the report metadata.

Syntax
public MAP<String,Reports.DetailColumn> getDetailColumnInfo()

Return Value
Type: Map<String,Reports.DetailColumn>

getGroupingColumnInfo()
Returns a map of each row or column grouping to its metadata. Contains values for each grouping that is identified in the groupingsDown and groupingsAcross lists.

Syntax
public MAP<String,Reports.GroupingColumn> getGroupingColumnInfo()

Return Value
Type: Map<String,Reports.GroupingColumn>

ReportFact Class
Contains the fact map for the report, which represents the report’s data values.

Namespace
Reports

Usage
ReportFact is the parent class of ReportFactWithDetails and ReportFactWithSummaries. If includeDetails is true when the report is run, the fact map is a ReportFactWithDetails object. If includeDetails is false when the report is run, the fact map is a ReportFactWithSummaries object.

ReportFact Methods
The following are methods for ReportFact. All are instance methods.

IN THIS SECTION:
  getAggregates()
  Returns summary-level data for a report, including the record count.
getKey()
Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

getAggregates()
Returns summary-level data for a report, including the record count.

Syntax
public LIST<Reports.SummaryValue> getAggregates()

Return Value
Type: List<Reports.SummaryValue>

ggetKey()
Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

Syntax
public String getKey()

Return Value
Type: String

ReportFactWithDetails Class
Contains the detailed fact map for the report, which represents the report’s data values.

Namespace
Reports

Usage
The ReportFactWithDetails class extends the ReportFact class. A ReportFactWithDetails object is returned if includeDetails is set to true when the report is run. To access the detail values, you’ll need to cast the return value of the ReportResults.getFactMap method to a ReportFactWithDetails object.

ReportFactWithDetails Methods
The following are methods for ReportFactWithDetails. All are instance methods.

IN THIS SECTION:
  getAggregates()
  Returns summary-level data for a report, including the record count.
getKey()
Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

getRows()
Returns a list of detailed report data in the order of the detail columns that are provided by the report metadata.

getAggregates()
Returns summary-level data for a report, including the record count.

Syntax

```java
public LIST<Reports.SummaryValue> getAggregates()
```

Return Value

Type: List<Reports.SummaryValue>

getKey()
Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

Syntax

```java
public String getKey()
```

Return Value

Type: String

getRows()
Returns a list of detailed report data in the order of the detail columns that are provided by the report metadata.

Syntax

```java
public LIST<Reports.ReportDetailRow> getRows()
```

Return Value

Type: List<Reports.ReportDetailRow>

ReportFactWithSummaries Class
Contains the fact map for the report, which represents the report’s data values, and includes summarized fields.

Namespace

Reports
Usage
The `ReportFactWithSummaries` class extends the `ReportFact` class. A `ReportFactWithSummaries` object is returned if `includeDetails` is set to `false` when the report is run.

ReportFactWithSummaries Methods
The following are methods for `ReportFactWithSummaries`. All are instance methods.

IN THIS SECTION:
- `getAggregates()`
  - Returns summary-level data for a report, including the record count.
- `getKey()`
  - Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.
- `toString()`
  - Returns a string.

**getAggregates()**
Returns summary-level data for a report, including the record count.

Syntax
```java
public LIST<Reports.SummaryValue> getAggregates()
```

Return Value
Type: `List<Reports.SummaryValue>`

**getKey()**
Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

Syntax
```java
public String getKey()
```

Return Value
Type: `String`

**toString()**
Returns a string.

Signature
```java
public String toString()
```
Return Value
Type: String

ReportFilter Class
Contains information about a report filter, including column, operator, and value.

Namespace
Reports

IN THIS SECTION:
ReportFilter Constructors
ReportFilter Methods

ReportFilter Constructors
The following are constructors for ReportFilter.

IN THIS SECTION:
ReportFilter()
ReportFilter(column, operator, value)

ReportFilter()
Creates a new instance of the Reports.ReportFilter class. You can then set values by using the “set” methods.

Signature
public ReportFilter()

ReportFilter(column, operator, value)
Creates a new instance of the Reports.ReportFilter class by using the specified parameters.

Signature
public ReportFilter(String column, String operator, String value)

Parameters

<table>
<thead>
<tr>
<th>column</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type: String</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>operator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type: String</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type: String</td>
</tr>
</tbody>
</table>

2393
value
Type: String

ReportFilter Methods
The following are methods for ReportFilter. All are instance methods.

IN THIS SECTION:
getColumn()
Returns the unique API name for the field that’s being filtered.

getOperator()
Returns the unique API name for the condition that is used to filter a field, such as “greater than” or “not equal to.” Filter conditions depend on the data type of the field.

getValue()
Returns the value by which a field can be filtered. For example, the field Age can be filtered by a numeric value.

setColumn(column)
Sets the unique API name for the field that’s being filtered.

setOperator(operator)
Sets the unique API name for the condition that is used to filter a field, such as “greater than” or “not equal to.” Filter conditions depend on the data type of the field.

setValue(value)
Sets the value by which a field can be filtered. For example, the field Age can be filtered by a numeric value.

getColumn()
Returns the unique API name for the field that’s being filtered.

Syntax
public String getColumn()  

Return Value
Type: String

getOperator()
Returns the unique API name for the condition that is used to filter a field, such as “greater than” or “not equal to.” Filter conditions depend on the data type of the field.

Syntax
public String getOperator()  

Return Value
Type: String
getValue()  
Returns the value by which a field can be filtered. For example, the field Age can be filtered by a numeric value.

Syntax
public String getValue()

Return Value
Type: String

setColumn(column)  
Sets the unique API name for the field that’s being filtered.

Syntax
public Void setColumn(String column)

Parameters
column
  Type: String

Return Value
Type: Void

setOperator(operator)  
Sets the unique API name for the condition that is used to filter a field, such as “greater than” or “not equal to.” Filter conditions depend on the data type of the field.

Syntax
public Void setOperator(String operator)

Parameters
operator
  Type: String

Return Value
Type: Void

setValue(value)  
Sets the value by which a field can be filtered. For example, the field Age can be filtered by a numeric value.
Syntax

```
public Void setValue(String value)
```

Parameters

`value`

Type: String

Return Value

Type: Void

**ReportFormat Enum**

Contains the possible report format types.

**Namespace**

Reports

**Enum Values**

The following are the values of the `Reports.ReportFormat` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MATRIX</td>
<td>Matrix report format</td>
</tr>
<tr>
<td>SUMMARY</td>
<td>Summary report format</td>
</tr>
<tr>
<td>TABULAR</td>
<td>Tabular report format</td>
</tr>
</tbody>
</table>

**ReportInstance Class**

Returns an instance of a report that was run asynchronously. Retrieves the results for that instance.

**Namespace**

Reports

**ReportInstance Methods**

The following are methods for `ReportInstance`. All are instance methods.

**IN THIS SECTION:**

`getCompletionDate()`

Returns the date and time when the instance of the report finished running. The completion date is available only if the report instance ran successfully or couldn’t be run because of an error. Date and time information is in ISO-8601 format.
getId()  
Returns the unique ID for an instance of a report that was run asynchronously.

getOwnerId()  
Returns the ID of the user who created the report instance.

getReportId()  
Returns the unique ID of the report this instance is based on.

getReportResults()  
Retrieves results for an instance of an asynchronous report. When you request your report, you can specify whether to summarize data or include details.

getRequestDate()  
Returns the date and time when an instance of the report was run. Date and time information is in ISO-8601 format.

getStatus()  
Returns the status of a report.

getCompletionDate()  
Returns the date and time when the instance of the report finished running. The completion date is available only if the report instance ran successfully or couldn’t be run because of an error. Date and time information is in ISO-8601 format.

Syntax
public Datetime getCompletionDate()

Return Value
Type: Datetime

getId()  
Returns the unique ID for an instance of a report that was run asynchronously.

Syntax
public Id getId()

Return Value
Type: Id

getOwnerId()  
Returns the ID of the user who created the report instance.

Syntax
public Id getOwnerId()
Return Value
Type: Id

getReportId()
Returns the unique ID of the report this instance is based on.

Syntax
public Id getReportId()

Return Value
Type: Id

getReportResults()
Retrieves results for an instance of an asynchronous report. When you request your report, you can specify whether to summarize data or include details.

Syntax
public Reports.ReportResults getReportResults()

Return Value
Type: Reports.ReportResults

getRequestDate()
Returns the date and time when an instance of the report was run. Date and time information is in ISO-8601 format.

Syntax
public Datetime getRequestDate()

Return Value
Type: Datetime

getStatus()
Returns the status of a report.

Syntax
public String getStatus()

Return Value
Type: String
Usage

- **New** if the report run was recently triggered through a request.
- **Success** if the report ran.
- **Running** if the report is being run.
- **Error** if the report run failed. The instance of a report run can return an error if, for example, your permission to access the report was removed after you requested the run.

ReportManager Class

Runs a report synchronously or asynchronously and with or without details.

Namespace

*Reports*

Usage

Gets instances of reports and describes the metadata of Reports.

ReportManager Methods

The following are methods for `ReportManager`. All methods are static.

**IN THIS SECTION:**

- `describeReport(reportId)`
  Retrieves report, report type, and extended metadata for a tabular, summary, or matrix report.
- `getDatatypeFilterOperatorMap()`
  Lists the field data types that you can use to filter the report.
- `getReportInstanceOfananceld)`
  Retrieves results for an instance of a report that has been run asynchronously. The settings you use when you run your asynchronous report determine whether you can retrieve summary data or detailed data.
- `getReportInstances(reportId)`
  Returns a list of instances for a report that was run asynchronously. Each item in the list represents a separate instance of the report, with metadata for the time at which the report was run.
- `runAsyncReport(reportId, reportMetadata, includeDetails)`
  Runs a report asynchronously with the report ID. Includes details if `includeDetails` is set to `true`. Filters the report based on the report metadata in `reportMetadata`.
- `runAsyncReport(reportId, includeDetails)`
  Runs a report asynchronously with the report ID. Includes details if `includeDetails` is set to `true`.
- `runAsyncReport(reportId, reportMetadata)`
  Runs a report asynchronously with the report ID. Filters the results based on the report metadata in `reportMetadata`.
- `runAsyncReport(reportId)`
  Runs a report asynchronously with the report ID.
runReport(reportId, reportMetadata, includeDetails)
Runs a report immediately with the report ID. Includes details if includeDetails is set to true. Filters the results based on the report metadata in reportMetadata.

runReport(reportId, includeDetails)
Runs a report immediately with the report ID. Includes details if includeDetails is set to true.

runReport(reportId, reportMetadata)
Runs a report immediately with the report ID. Filters the results based on the report metadata in reportMetadata.

runReport(reportId)
Runs a report immediately with the report ID.

descrbeReport(reportId)
Retrieves report, report type, and extended metadata for a tabular, summary, or matrix report.

Syntax
public static Reports.ReportDescribeResult describeReport(Id reportId)

Parameters
reportId
Type: Id

Return Value
Type: Reports.ReportDescribeResult

getDatatypeFilterOperatorMap ()
Lists the field data types that you can use to filter the report.

Syntax
public static MAP<String,LIST<Reports.FilterOperator>> getDatatypeFilterOperatorMap()

Return Value
Type: Map<String, List<Reports.FilterOperator>>

getReportInstance(instanceId)
Retrieves results for an instance of a report that has been run asynchronously. The settings you use when you run your asynchronous report determine whether you can retrieve summary data or detailed data.

Syntax
public static Reports.ReportInstance getReportInstance(Id instanceId)
Arguments

instanceId
Type: Id

Return Value
Type: Reports.ReportInstance

getReportInstances(reportId)
Returns a list of instances for a report that was run asynchronously. Each item in the list represents a separate instance of the report, with metadata for the time at which the report was run.

Syntax
public static LIST<Reports.ReportInstance> getReportInstances(Id reportId)

Parameters
reportId
Type: Id

Return Value
Type: List<Reports.ReportInstance>

runAsyncReport(reportId, reportMetadata, includeDetails)
Runs a report asynchronously with the report ID. Includes details if includeDetails is set to true. Filters the report based on the report metadata in reportMetadata.

Syntax
public static Reports.ReportInstance runAsyncReport(Id reportId, Reports.ReportMetadata reportMetadata, Boolean includeDetails)

Parameters
reportId
Type: Id
reportMetadata
Type: Reports.ReportMetadata
includeDetails
Type: Boolean

Return Value
Type: Reports.ReportInstance
runAsyncReport(reportId, includeDetails)
Runs a report asynchronously with the report ID. Includes details if includeDetails is set to true.

Syntax
public static Reports.ReportInstance runAsyncReport(Id reportId, Boolean includeDetails)

Parameters
reportId
Type: Id
includeDetails
Type: Boolean

Return Value
Type: Reports.ReportInstance

runAsyncReport(reportId, reportMetadata)
Runs a report asynchronously with the report ID. Filters the results based on the report metadata in reportMetadata.

Syntax
public static Reports.ReportInstance runAsyncReport(Id reportId, Reports.ReportMetadata reportMetadata)

Parameters
reportId
Type: Id
reportMetadata
Type: Reports.ReportMetadata

Return Value
Type: Reports.ReportInstance

runAsyncReport(reportId)
Runs a report asynchronously with the report ID.

Syntax
public static Reports.ReportInstance runAsyncReport(Id reportId)
runReport(reportId, reportMetadata, includeDetails)

Runs a report immediately with the report ID. Includes details if includeDetails is set to true. Filters the results based on the report metadata in reportMetadata.

Syntax

public static Reports.ReportResults runReport(Id reportId, Reports.ReportMetadata reportMetadata, Boolean includeDetails)

Parameters

- reportId
  Type: Id
- reportMetadata
  Type: Reports.ReportMetadata
- includeDetails
  Type: Boolean

Return Value

Type: Reports.ReportResults

runReport(reportId, includeDetails)

Runs a report immediately with the report ID. Includes details if includeDetails is set to true.

Syntax

public static Reports.ReportResults runReport(Id reportId, Boolean includeDetails)

Parameters

- reportId
  Type: Id
- includeDetails
  Type: Boolean

Return Value

Type: Reports.ReportResults

runReport(reportId, reportMetadata)

Runs a report immediately with the report ID. Filters the results based on the report metadata in reportMetadata.
Syntax

```
public static Reports.ReportResults runReport(Id reportId, Reports.ReportMetadata reportMetadata)
```

Parameters

- `reportId`
  - Type: Id

- `reportMetadata`
  - Type: Reports.ReportMetadata

Return Value

Type: Reports.ReportResults

```
runReport(reportId)
```

Runs a report immediately with the report ID.

Syntax

```
public static Reports.ReportResults runReport(Id reportId)
```

Parameters

- `reportId`
  - Type: Id

Return Value

Type: Reports.ReportResults

ReportMetadata Class

Contains report metadata for a tabular, summary, or matrix report.

Namespace

Reports

Usage

Report metadata gives information about the report as a whole, such as the report type, format, summary fields, row or column groupings, and filters that are saved to the report. You can use the `ReportMetadata` class to retrieve report metadata and to set metadata that can be used to filter a report.

ReportMetadata Methods

The following are methods for `ReportMetadata`. All are instance methods.
getAggregates()
Returns unique identifiers for summary or custom summary formula fields in the report.

getBuckets()
Returns a list of bucket fields in the report.

getCrossFilters()
Returns information about cross filters applied to a report.

getCurrencyCode()
Returns report currency, such as USD, EUR, or GBP, for an organization that has multicurrency enabled. The value is null if the organization does not have multicurrency enabled.

getCustomSummaryFormula()
Returns information about custom summary formulas in a report.

description()
Returns the description of the report.

detailColumns()
Returns unique API names (column names) for the fields that contain detailed data. For example, the method might return the following values: “OPPORTUNITY_NAME, TYPE, LEAD_SOURCE, AMOUNT.”

developerName()
Returns the report API name. For example, the method might return the following value: “Closed_Sales_This_Quarter.”

division()
Returns the division specified in the report.

groupingsAcross()
Returns column groupings in a report.

groupingsDown()
Returns row groupings for a report.

hasDetailRows()
Indicates whether the report has detail rows.

hasRecordCount()
Indicates whether the report shows the total number of records.

historicalSnapshotDates()
Returns a list of historical snapshot dates.

id()
Returns the unique report ID.

name()
Returns the report name.

reportBooleanFilter()
Returns logic to parse custom field filters. The value is null when filter logic is not specified.

reportFilters()
Returns a list of each custom filter in the report along with the field name, filter operator, and filter value.

reportFormat()
Returns the format of the report.
getReportType()  
Retruns the unique API name and display name for the report type.

getScope()  
Retruns the API name for the scope defined for the report. Scope values depend on the report type.

getShowGrandTotal()  
Indicates whether the report shows the grand total.

getShowSubtotals()  
Indicates whether the report shows subtotals, such as column or row totals.

getSortBy()  
Retruns the list of columns on which the report is sorted. Currently, you can sort on only one column.

getStandardDateFilter()  
Retruns information about the standard date filter for the report, such as the start date, end date, date range, and date field API name.

getStandardFilters()  
Retruns a list of standard filters for the report.

getTopRows()  
Retruns information about a row limit filter, including the number of rows returned and the sort order.

setAggregates(aggregates)  
Sets unique identifiers for standard or custom summary formula fields in the report.

setBuckets(buckets)  
Creates bucket fields in a report.

setCrossFilters(crossFilters)  
Applies cross filters to a report.

setCurrencyCode(currencyCode)  
Sets the currency, such as USD, EUR, or GBP, for report summary fields in an organization that has multicurrency enabled.

setCustomSummaryFormula(customSummaryFormula)  
Adds a custom summary formula to a report.

setDescription(description)  
Sets the description of the report.

setDetailColumns(detailColumns)  
Sets the unique API names for the fields that contain detailed data—for example, OPPORTUNITY_NAME, TYPE, LEAD_SOURCE, or AMOUNT.

setDeveloperName(developerName)  
Sets the report API name—for example, Closed_Sales_This_Quarter.

setDivision(division)  
Sets the division of the report.

setGroupingsAcross(groupingInfo)  
Sets column groupings in a report.

setGroupingsDown(groupingInfo)  
Sets row groupings for a report.
setHasDetailRows(hasDetailRows)
Specifies whether the report has detail rows.

setHasRecordCount(hasRecordCount)
Specifies whether the report is configured to show the total number of records.

setHistoricalSnapshotDates(historicalSnapshot)
Sets a list of historical snapshot dates.

setId(id)
Sets the unique report ID.

setName(name)
Sets the report name.

setReportBooleanFilter(reportBooleanFilter)
Sets logic to parse custom field filters.

setReportFilters(reportFilters)
Sets a list of each custom filter in the report along with the field name, filter operator, and filter value.

setReportFormat(format)
Sets the format of the report.

setReportType(reportType)
Sets the unique API name and display name for the report type.

setScope(scopeName)
Sets the API name for the scope defined for the report. Scope values depend on the report type.

setShowGrandTotal(showGrandTotal)
Specifies whether the report shows the grand total.

setShowSubtotals(showSubtotals)
Specifies whether the report shows subtotals, such as column or row totals.

setSortBy(column)
Sets the list of columns on which the report is sorted. Currently, you can only sort on one column.

setStandardDateFilter(dateFilter)
Sets the standard date filter—which includes the start date, end date, date range, and date field API name—for the report.

setStandardFilters(filters)
Sets one or more standard filters on the report.

setTopRows(topRows)
Applies a row limit filter to a report.

getAggregates()
Returns unique identifiers for summary or custom summary formula fields in the report.

Syntax

public LIST<String> getAggregates()
Return Value
Type: List<String>

Usage
For example:
- $a!Amount$ represents the average for the $Amount$ column.
- $s!Amount$ represents the sum of the $Amount$ column.
- $m!Amount$ represents the minimum value of the $Amount$ column.
- $x!Amount$ represents the maximum value of the $Amount$ column.
- $s!<customfieldID>$ represents the sum of a custom field column. For custom fields and custom report types, the identifier is a combination of the summary type and the field ID.

getBuckets()
Returns a list of bucket fields in the report.

Signature
public List<Reports.BucketField> getBuckets()

Return Value
Type: List<Reports.BucketField>

getcrossFilters()
Returns information about cross filters applied to a report.

Signature
public Reports.CrossFilter getCrossFilters()

Return Value
Type: List<Reports.CrossFilter>

getCurrencyCode()
Returns report currency, such as USD, EUR, or GBP, for an organization that has multicurrency enabled. The value is $null$ if the organization does not have multicurrency enabled.

Syntax
public String getCurrencyCode()
**getCustomSummaryFormula()**

Returns information about custom summary formulas in a report.

**Signature**

```java
public Map<String,Reports.ReportCsf> getCustomSummaryFormula()
```

**Return Value**

Type: `Map<String,Reports.ReportCsf>`

**getDescription()**

Returns the description of the report.

**Signature**

```java
public String getDescription()
```

**Return Value**

Type: `String`

**getDetailColumns()**

Returns unique API names (column names) for the fields that contain detailed data. For example, the method might return the following values: “OPPORTUNITY_NAME, TYPE, LEAD_SOURCE, AMOUNT.”

**Syntax**

```java
public List<String> getDetailColumns()
```

**Return Value**

Type: `List<String>`

**getDeveloperName()**

Returns the report API name. For example, the method might return the following value: “Closed_Sales_This_Quarter.”

**Syntax**

```java
public String getDeveloperName()
```

**Return Value**

Type: `String`

**getDivision()**

Returns the division specified in the report.
Note: Reports that use standard filters (such as My Cases or My Team's Accounts) show records in all divisions. These reports can't be further limited to a specific division.

**Signature**

```java
public String getDivision()
```

**Return Value**

Type: `String`

### getGroupingsAcross()

Returns column groupings in a report.

**Syntax**

```java
public LIST<Reports.GroupingInfo> getGroupingsAcross()
```

**Return Value**

Type: `List<Reports.GroupingInfo>`

**Usage**

The identifier is:

- An empty array for reports in summary format, because summary reports don't include column groupings
- `BucketField_(ID)` for bucket fields
- The ID of a custom field when the custom field is used for a column grouping

### getGroupingsDown()

Returns row groupings for a report.

**Syntax**

```java
public LIST<Reports.GroupingInfo> getGroupingsDown()
```

**Return Value**

Type: `List<Reports.GroupingInfo>`

**Usage**

The identifier is:

- `BucketField_(ID)` for bucket fields
- The ID of a custom field when the custom field is used for grouping
getHasDetailRows()
Indicates whether the report has detail rows.

Signature
public Boolean getHasDetailRows()

Return Value
Type: Boolean

getHasRecordCount()
Indicates whether the report shows the total number of records.

Signature
public Boolean getHasRecordCount()

Return Value
Type: Boolean

getHistoricalSnapshotDates()
Returns a list of historical snapshot dates.

Syntax
public LIST<String> getHistoricalSnapshotDates()

Return Value
Type: List<String>

getId()
Returns the unique report ID.

Syntax
public Id getId()

Return Value
Type: Id

getName()
Returns the report name.
**public String getName()**

Return Value
Type: String

**getReportBooleanFilter()**
Returns logic to parse custom field filters. The value is `null` when filter logic is not specified.

**Syntax**

public String getReportBooleanFilter()

**getReportFilters()**
Returns a list of each custom filter in the report along with the field name, filter operator, and filter value.

**Syntax**

public List<Reports.ReportFilter> getReportFilters()

**getReportFormat()**
Returns the format of the report.

**Syntax**

public Reports.ReportFormat getReportFormat()

**Usage**
This value can be:

- TABULAR
- SUMMARY
- MATRIX
**getReportType()**
Returns the unique API name and display name for the report type.

Syntax
```java
public Reports.ReportType getReportType()
```

Return Value
Type: `Reports.ReportType`

**getScope()**
Returns the API name for the scope defined for the report. Scope values depend on the report type.

Signature
```java
public String getScope()
```

Return Value
Type: `String`

**getShowGrandTotal()**
Indicates whether the report shows the grand total.

Signature
```java
public Boolean getShowGrandTotal()
```

Return Value
Type: `Boolean`

**getShowSubtotals()**
Indicates whether the report shows subtotals, such as column or row totals.

Signature
```java
public Boolean getShowSubtotals()
```

Return Value
Type: `Boolean`

**getSortBy()**
Returns the list of columns on which the report is sorted. Currently, you can sort on only one column.
getSortBy()

Signature
public List<Reports.SortColumn> getSortBy()

Return Value
Type: List<Reports.SortColumn>

getStandardDateFilter()

Returns information about the standard date filter for the report, such as the start date, end date, date range, and date field API name.

Signature
public Reports.StandardDateFilter getStandardDateFilter()

Return Value
Type: Reports.StandardDateFilter

getStandardFilters()

Returns a list of standard filters for the report.

Signature
public List<Reports.StandardFilter> getStandardFilters()

Return Value
Type: List<Reports.StandardFilter>

getTopRows()

Returns information about a row limit filter, including the number of rows returned and the sort order.

Signature
public Reports.TopRows getTopRows()

Return Value
Type: Reports.TopRows

setAggregates( aggregates)

Sets unique identifiers for standard or custom summary formula fields in the report.

Signature
public void setAggregates(List<String> aggregates)
Parameters

`aggregates`
Type: List<String>

Return Value
Type: void

**setBuckets(buckets)**
Creates bucket fields in a report.

Signature
```
public void setBuckets(List<Reports.BucketField> buckets)
```

Parameters

`buckets`
Type: List<Reports.BucketField>

Return Value
Type: void

**setCrossFilters(crossFilters)**
Applies cross filters to a report.

Signature
```
public void setCrossFilters(List<Reports.CrossFilter> crossFilters)
```

Parameters

`crossFilter`
Type: List<Reports.CrossFilter>

Return Value
Type: void

**setCurrencyCode(currencyCode)**
Sets the currency, such as USD, EUR, or GBP, for report summary fields in an organization that has multicurrency enabled.

Signature
```
public void setCurrencyCode(String currencyCode)
```
Parameters

currencyCode
Type: String

Return Value
Type: void

setCustomSummaryFormula(customSummaryFormula)
Adds a custom summary formula to a report.

Signature
public void setCustomSummaryFormula(Map<String, Reports.ReportCsf> customSummaryFormula)

Parameters

customSummaryFormula
Type: Map<String, Reports.ReportCsf>

Return Value
Type: void

description
Sets the description of the report.

Signature
public void setDescription(String description)

Parameters

description
Type: String

Return Value
Type: void

setDetailColumns(detailColumns)
Sets the unique API names for the fields that contain detailed data—for example, OPPORTUNITY_NAME, TYPE, LEAD_SOURCE, or AMOUNT.

Signature
public void setDetailColumns(List<String> detailColumns)
Parameters
detailColumns
   Type: List<String>

Return Value
Type: void

**setDeveloperName(String developerName)**
Sets the report API name—for example, Closed_Sales_This_Quarter.

Signature
```
public void setDeveloperName(String developerName)
```

Parameters
devveloperName
   Type: String

Return Value
Type: void

**setDivision(String division)**
Sets the division of the report.

Note: Reports that use standard filters (such as My Cases or My Team’s Accounts) show records in all divisions. These reports can’t be further limited to a specific division.

Signature
```
public void setDivision(String division)
```

Parameters
division
   Type: String

Return Value
Type: void

**setGroupingsAcross(String groupingInfo)**
Sets column groupings in a report.
public void setGroupingsAcross(List<Reports.GroupingInfo> groupingInfo)

Parameters

groupingInfo
   Type: List<Reports.GroupingInfo>

Return Value

Type: void

setGroupingsDown(groupingInfo)
Sets row groupings for a report.

Signature

public void setGroupingsDown(List<Reports.GroupingInfo> groupingInfo)

Parameters

groupingInfo
   Type: List<Reports.GroupingInfo>

Return Value

Type: void

setHasDetailRows(hasDetailRows)
Specifies whether the report has detail rows.

Signature

public void setHasDetailRows(Boolean hasDetailRows)

Parameters

hasDetailRows
   Type: Boolean

Return Value

Type: Boolean

setHasRecordCount(hasRecordCount)
Specifies whether the report is configured to show the total number of records.

Signature

public void setHasRecordCount(Boolean hasRecordCount)
Signature

public void setHasRecordCount(Boolean hasRecordCount)

Parameters

hasRecordCount
  Type: Boolean

Return Value

Type: void

**setHistoricalSnapshotDates (historicalSnapshot)**

Sets a list of historical snapshot dates.

Syntax

public Void setHistoricalSnapshotDates(LIST<String> historicalSnapshot)

Parameters

historicalSnapshot
  Type: List<String>

Return Value

Type: Void

**setId(id)**

Sets the unique report ID.

Signature

public void setId(Id id)

Parameters

id
  Type: Id

Return Value

Type: void

**setName(name)**

Sets the report name.
**setName(String name)**

Parameters

- name
  - Type: String

Return Value

- Type: void

**setReportBooleanFilter(String reportBooleanFilter)**

Sets logic to parse custom field filters.

Syntax

```java
public Void setReportBooleanFilter(String reportBooleanFilter)
```

Parameters

- reportBooleanFilter
  - Type: String

Return Value

- Type: Void

**setReportFilters(List<Reports.ReportFilter> reportFilters)**

Sets a list of each custom filter in the report along with the field name, filter operator, and filter value.

Syntax

```java
public Void setReportFilters(List<Reports.ReportFilter> reportFilters)
```

Parameters

- reportFilters
  - Type: List<Reports.ReportFilter>

Return Value

- Type: Void

**setReportFormat(String format)**

Sets the format of the report.
public void setReportFormat(Reports.ReportFormat format)

Parameters
format
Type: Reports.ReportFormat

Return Value
Type: void

setReportType(reportType)
Sets the unique API name and display name for the report type.

Signature
public void setReportType(Reports.ReportType reportType)

Parameters
reportType
Type: Reports.ReportType

Return Value
Type: void

setScope(scopeName)
Sets the API name for the scope defined for the report. Scope values depend on the report type.

Signature
public void setScope(String scopeName)

Parameters
scopeName
Type: String

Return Value
Type: void

setShowGrandTotal(showGrandTotal)
Specifies whether the report shows the grand total.
public void setShowGrandTotal(Boolean showGrandTotal)

Parameters
showGrandTotal
  Type: Boolean

Return Value
Type: void

setShowSubtotals(showSubtotals)
Specifies whether the report shows subtotals, such as column or row totals.

Signature
public void setShowSubtotals(Boolean showSubtotals)

Parameters
showSubtotals
  Type: Boolean

Return Value
Type: void

setSortBy(column)
Sets the list of columns on which the report is sorted. Currently, you can only sort on one column.

Signature
public void setSortBy(List<Reports.SortColumn> column)

Parameters
column
  Type: List<Reports.SortColumn>

Return Value
Type: void

setStandardDateFilter(dateFilter)
Sets the standard date filter—which includes the start date, end date, date range, and date field API name—for the report.
public void setStandardDateFilter(Reports.StandardDateFilter dateFilter)

Parameters

dateFilter
Type: Reports.StandardDateFilter

Return Value
Type: void

setStandardFilters(filters)
Sets one or more standard filters on the report.

Signature

class void setStandardFilters(List<Reports.StandardFilter> filters)

Parameters

filters
Type: List<Reports.StandardFilter>

Return Value
Type: void

setTopRows(topRows)
Applies a row limit filter to a report.

Signature

public Reports.TopRows setTopRows(Reports.TopRows topRows)

Parameters

topRows
Type: Reports.TopRows

Return Value
Type: void

ReportResults Class
Contains the results of running a report.
Namespace

Reports

ReportResults Methods

The following are methods for ReportResults. All are instance methods.

IN THIS SECTION:

- **getAllData()**
  Returns all report data.

- **getFactMap()**
  Returns summary-level data or summary and detailed data for each row or column grouping. Detailed data is available if the includeDetails parameter is set to true when the report is run.

- **getGroupingsAcross()**
  Returns a collection of column groupings, keys, and values.

- **getGroupingsDown()**
  Returns a collection of row groupings, keys, and values.

- **getHasDetailRows()**
  Returns information about whether the fact map has detail rows.

- **getReportExtendedMetadata()**
  Returns additional, detailed metadata about the report, including data type and label information for groupings and summaries.

- **getReportMetadata()**
  Returns metadata about the report, including grouping and summary information.

getAllData()

Returns all report data.

Syntax

```java
public Boolean getAllData()
```

Return Value

Type: Boolean

Usage

When `true`, indicates that all report results are returned.

When `false`, indicates that results are returned for the same number of rows as in a report run in Salesforce.

Note: For reports that contain too many records, use filters to refine results.
getFactMap()  
Returns summary-level data or summary and detailed data for each row or column grouping. Detailed data is available if the includeDetails parameter is set to true when the report is run.

Syntax

```
public MAP<String,Reports.ReportFact> getFactMap()
```

Return Value

Type: Map<String,Reports.ReportFact>

getGroupingsAcross()  
Returns a collection of column groupings, keys, and values.

Syntax

```
public Reports.Dimension getGroupingsAcross()
```

Return Value

Type: Reports.Dimension

getGroupingsDown()  
Returns a collection of row groupings, keys, and values.

Syntax

```
public Reports.Dimension getGroupingsDown()
```

Return Value

Type: Reports.Dimension

getHasDetailRows()  
Returns information about whether the fact map has detail rows.

Syntax

```
public Boolean getHasDetailRows()
```

Return Value

Type: Boolean

Usage

- When true, indicates that the fact map returns values for summary-level and record-level data.
• When `false`, indicates that the fact map returns summary values.

**getReportExtendedMetadata()**

Returns additional, detailed metadata about the report, including data type and label information for groupings and summaries.

Syntax

```java
public Reports.ReportExtendedMetadata getReportExtendedMetadata()
```

Return Value

Type: `Reports.ReportExtendedMetadata`

**getReportMetadata()**

Returns metadata about the report, including grouping and summary information.

Syntax

```java
public Reports.ReportMetadata getReportMetadata()
```

Return Value

Type: `Reports.ReportMetadata`

**ReportScopeInfo Class**

Contains information about possible scope values that you can choose. Scope values depend on the report type. For example, you can set the scope for opportunity reports to `All opportunities`, `My team’s opportunities`, or `My opportunities`.

**Namespace**

`Reports`

**IN THIS SECTION:**

- `ReportScopeInfo Methods`

**ReportScopeInfo Methods**

The following are methods for `ReportScopeInfo`.

**IN THIS SECTION:**

- `getDefaultValue()`
  *Returns the default scope of the data to display in the report.*

- `getValues()`
  *Returns a list of scope values specified for the report.*
**getDefaultValue()**

Returns the default scope of the data to display in the report.

Signature

```java
public String getDefaultValue()
```

Return Value

Type: String

**getValues()**

Returns a list of scope values specified for the report.

Signature

```java
public List<Reports.ReportScopeValue> getValues()
```

Return Value

Type: List<Reports.ReportScopeValue>

---

**ReportScopeValue Class**

Contains information about a possible scope value. Scope values depend on the report type. For example, you can set the scope for opportunity reports to All opportunities, My team’s opportunities, or My opportunities.

**Namespace**

Reports

**IN THIS SECTION:**

ReportScopeValue Methods

**ReportScopeValue Methods**

The following are methods for ReportScopeValue.

**IN THIS SECTION:**

- `getAllowsDivision()`
  Returns a boolean value that indicates whether you can segment the report by this scope.
- `getLabel()`
  Returns the display name of the scope of the report.
- `getValue()`
  Returns the scope value for the report.
getAllowsDivision()  
Returns a boolean value that indicates whether you can segment the report by this scope.

Signature

public Boolean getAllowsDivision()

Return Value
Type: Boolean

getLabel()  
Returns the display name of the scope of the report.

Signature

public String getLabel()

Return Value
Type: String

getValue()  
Returns the scope value for the report.

Signature

public String getValue()

Return Value
Type: String

ReportType Class  
Contains the unique API name and display name for the report type.

Namespace

Reports

ReportType Methods  
The following are methods for ReportType. All are instance methods.
IN THIS SECTION:

getLabel()
Returns the localized display name of the report type.

getType()
Returns the unique identifier of the report type.

getLabel()  
Returns the localized display name of the report type.

Syntax

public String getLabel()

Return Value

Type: String

getType()  
Returns the unique identifier of the report type.

Syntax

public String getType()

Return Value

Type: String

ReportTypeColumn Class
Contains detailed report type metadata about a field, including data type, display name, and filter values.

Namespace

Reports

ReportTypeColumn Methods
The following are methods for ReportTypeColumn. All are instance methods.

IN THIS SECTION:

dataType()  
Returns the data type of the field.
getFilterValues()
If the field data type is picklist, multi-select picklist, boolean, or checkbox, returns all filter values for a field. For example, checkbox fields always have a value of true or false. For fields of other data types, the filter value is an empty array, because their values can’t be determined.

gerFilterable()
If the field is of a type that can’t be filtered, returns false. For example, fields of the type Encrypted Text can’t be filtered.

getLabel()
Returns the localized display name of the field.

getName()
Returns the unique API name of the field.

getDataType()
Returns the data type of the field.

Syntax
public Reports.ColumnDataType getDataType()

Return Value
Type: Reports.ColumnDataType

getFilterValues()
If the field data type is picklist, multi-select picklist, boolean, or checkbox, returns all filter values for a field. For example, checkbox fields always have a value of true or false. For fields of other data types, the filter value is an empty array, because their values can’t be determined.

Syntax
public LIST<Reports.FilterValue> getFilterValues()

Return Value
Type: List<Reports.FilterValue>

getFilterable()
If the field is of a type that can’t be filtered, returns false. For example, fields of the type Encrypted Text can’t be filtered.

Syntax
public Boolean getFilterable()

Return Value
Type: Boolean
**getLabel()**

Returns the localized display name of the field.

Syntax

```java
public String getLabel()
```

Return Value

Type: String

**getName()**

Returns the unique API name of the field.

Syntax

```java
public String getName()
```

Return Value

Type: String

---

**ReportTypeColumnCategory Class**

Information about categories of fields in a report type.

**Namespace**

Reports

**Usage**

A report type column category is a set of fields that the report type grants access to. For example, an opportunity report has categories like *Opportunity Information* and *Primary Contact*. The Opportunity Information category has fields like *Amount*, *Probability*, and *Close Date*.

Get category information about a report by first getting the report metadata:

```java
// Get the report ID
List<Report> reportList = [SELECT Id,DeveloperName FROM Report where DeveloperName = 'Q1_Opportunities2'];

String reportId = (String)reportList.get(0).get('Id');

// Describe the report
Reports.ReportDescribeResult describeResults = Reports.ReportManager.describeReport(reportId);

// Get report type metadata
Reports.ReportTypeMetadata reportTypeMetadata = describeResults.getReportTypeMetadata();
```
// Get report type column categories
List<Reports.ReportTypeColumnCategory> reportTypeColumnCategories = reportTypeMetadata.getCategories();
System.debug('reportTypeColumnCategories: ' + reportTypeColumnCategories);

**ReportTypeColumnCategory Methods**

The following are methods for `ReportTypeColumnCategory`. All are instance methods.

**IN THIS SECTION:**
- `getColumns()`
  Returns information for all fields in the report type. The information is organized by each section’s unique API name.
- `getLabel()`
  Returns the localized display name of a section in the report type under which fields are organized. For example, in an Accounts with Contacts custom report type, **Account General** is the display name of the section that contains fields on general account information.

**getColumns()**

Returns information for all fields in the report type. The information is organized by each section’s unique API name.

**Syntax**

```
public MAP<String,Reports.ReportTypeColumn> getColumns()
```

**Return Value**

Type: `Map<String,Reports.ReportTypeColumn>`

**getLabel()**

Returns the localized display name of a section in the report type under which fields are organized. For example, in an Accounts with Contacts custom report type, **Account General** is the display name of the section that contains fields on general account information.

**Syntax**

```
public String getLabel()
```

**Return Value**

Type: `String`

**ReportTypeMetadata Class**

Contains report type metadata, which gives you information about the fields that are available in each section of the report type, plus filter information for those fields.
Namespace

Reports

IN THIS SECTION:

ReportTypeMetadata Methods

ReportTypeMetadata Methods

The following are methods for ReportTypeMetadata. All are instance methods.

IN THIS SECTION:

getCategories()
Returns all fields in the report type. The fields are organized by section.

categorizes() is public.

getDivisionInfo()
Returns the default division and a list of all possible divisions that can be applied to this type of report.

categorizes() is public.

getScopeInfo()
Returns information about the scopes that can be applied to this type of report.

categorizes() is public.

getStandardDateFilterDurationGroups()
Returns information about the standard date filter groupings that can be applied to this type of report. Standard date filter groupings include Calendar Year, Calendar Quarter, Calendar Month, Calendar Week, Fiscal Year, Fiscal Quarter, Day and a custom value based on a user-defined date range.

categorizes() is public.

getStandardFilterInfos()
Returns information about standard date filters that can be applied to this type of report.

categorizes() is public.

gcategories() is public.

getCategories()

Returns all fields in the report type. The fields are organized by section.

Syntax

public LIST<Reports.ReportTypeColumnCategory> getCategories()

Return Value

Type: List<Reports.ReportTypeColumnCategory>

ggetDivisionInfo()

Returns the default division and a list of all possible divisions that can be applied to this type of report.

Signature

public Reports.ReportDivisionInfo getDivisionInfo()
getScopeInfo()
Returns information about the scopes that can be applied to this type of report.

Signature
public Reports.ReportScopeInfo getScopeInfo()

getStandardDateFilterDurationGroups()
Returns information about the standard date filter groupings that can be applied to this type of report. Standard date filter groupings include Calendar Year, Calendar Quarter, Calendar Month, Calendar Week, Fiscal Year, Fiscal Quarter, Day and a custom value based on a user-defined date range.

Signature
public List<Reports.StandardDateFilterDurationGroup> getStandardDateFilterDurationGroups()

getStandardFilterInfos()
Returns information about standard date filters that can be applied to this type of report.

Signature
public Map<String,Reports.StandardFilterInfo> getStandardFilterInfos()

SortColumn Class
Contains information about the sort column used in the report.

Namespace
Reports
SortColumn Methods

IN THIS SECTION:
getSortColumn()
Returns the column used to sort the records in the report.
getSortOrder()
Returns the the sort order—ascending or descending—for the sort column.
setSortColumn(sortColumn)
Sets the column used to sort the records in the report.
setSortOrder(SortOrder)
Sets the sort order—ascending or descending—for the sort column.

getSortColumn()
Returns the column used to sort the records in the report.

Signature
public String getSortColumn()

Return Value
Type: String

getSortOrder()
Returns the the sort order—ascending or descending—for the sort column.

Signature
public Reports.ColumnSortOrder getSortOrder()

Return Value
Type: Reports.ColumnSortOrder

setSortColumn(sortColumn)
Sets the column used to sort the records in the report.

Signature
public void setSortColumn(String sortColumn)
Parameters

sortColumn
Type: String

Return Value
Type: void

setSortOrder(SortOrder)
Sets the sort order—ascending or descending—for the sort column.

Signature
public void setSortOrder(Reports.ColumnSortOrder sortOrder)

Parameters

sortOrder
Type: Reports.ColumnSortOrder

Return Value
Type: void

StandardDateFilter Class
Contains information about standard date filter available in the report—for example, the API name, start date, and end date of the standard date filter duration as well as the API name of the date field on which the filter is placed.

Namespace
Reports

IN THIS SECTION:
StandardDateFilter Methods

StandardDateFilter Methods
The following are methods for StandardDateFilter.

IN THIS SECTION:
getColumn()
Returns the API name of the standard date filter column.

getDurationValue()
Returns duration information about a standard date filter, such as start date, end date, and display name and API name of the date filter.
getEndDate()
Returns the end date of the standard date filter.

getStartDate()
Returns the start date for the standard date filter.

setColumn(standardDateFilterColumnName)
Sets the API name of the standard date filter column.

setDurationValue(durationName)
Sets the API name of the standard date filter.

setEndDate(endDate)
Sets the end date for the standard date filter.

setStartDate(startDate)
Sets the start date for the standard date filter.

getColumn()
Returns the API name of the standard date filter column.

Signature
public String getColumn()

Return Value
Type: String

ggetDurationValue()
Returns duration information about a standard date filter, such as start date, end date, and display name and API name of the date filter.

Signature
public String getDurationValue()

Return Value
Type: String

getEndDate()
Returns the end date of the standard date filter.

Signature
public String getEndeDate()

Return Value
Type: String
**getStartDate()**
Returns the start date for the standard date filter.

Signature
```
public String getStartDate()
```

Return Value
Type: String

**setColumn(standardDateFilterColumnName)**
Sets the API name of the standard date filter column.

Signature
```
public void setColumn(String standardDateFilterColumnName)
```

Parameters

- `standardDateFilterColumnName`
  Type: String

Return Value
Type: void

**setDurationValue(durationName)**
Sets the API name of the standard date filter.

Signature
```
public void setDurationValue(String durationName)
```

Parameters

- `durationName`
  Type: String

Return Value
Type: void

**setEndDate(endDate)**
Sets the end date for the standard date filter.

Report Namespace
Apex Developer Guide
Signature
public void setEndDate(String endDate)

Parameters
endDate
Type: String

Return Value
Type: void

setStartDate(startDate)
Sets the start date for the standard date filter.

Signature
public void setStartDate(String startDate)

Parameters
startDate
Type: String

Return Value
Type: void

StandardDateFilterDuration Class
Contains information about each standard date filter—also referred to as a relative date filter. It contains the API name and display label of the standard date filter duration as well as the start and end dates.

Namespace
Reports

IN THIS SECTION:
StandardDateFilterDuration Methods

StandardDateFilterDuration Methods
The following are methods for StandardDateFilterDuration.

IN THIS SECTION:
getEndDate()
Returns the end date of the date filter.
getLabel()
Returns the display name of the date filter. Possible values are relative date filters—like Current FY and Current FQ—and custom date filters.

getStartDate()
Returns the start date of the date filter.

getValue()
Returns the API name of the date filter. Possible values are relative date filters—like THIS_FISCAL_YEAR and NEXT_FISCAL_QUARTER—and custom date filters.

getEndDate()
Returns the end date of the date filter.

Signature
public String getEndDate()

Return Value
Type: String

getLabel()
Returns the display name of the date filter. Possible values are relative date filters—like Current FY and Current FQ—and custom date filters.

Signature
public String getLabel()

Return Value
Type: String

getStartDate()
Returns the start date of the date filter.

Signature
public String getStartDate()

Return Value
Type: String

getValue()
Returns the API name of the date filter. Possible values are relative date filters—like THIS_FISCAL_YEAR and NEXT_FISCAL_QUARTER—and custom date filters.
public String getValue()

Return Value
Type: String

StandardDateFilterDurationGroup Class

Contains information about the standard date filter groupings, such as the grouping display label and all standard date filters that fall under the grouping. Groupings include Calendar Year, Calendar Quarter, Calendar Month, Calendar Week, Fiscal Year, Fiscal Quarter, Day, and custom values based on user-defined date ranges.

Namespace
Reports

IN THIS SECTION:
StandardDateFilterDurationGroup Methods

StandardDateFilterDurationGroup Methods

The following are methods for StandardDateFilterDurationGroup.

IN THIS SECTION:

getLabel()
Returns the display label for the standard date filter grouping.

getStandardDateFilterDurations()
Returns the standard date filter groupings.

getLabel()
Returns the display label for the standard date filter grouping.

Signature
public String getLabel()

Return Value
Type: String

getStandardDateFilterDurations()
Returns the standard date filter groupings.
Signature

```
public List<Reports.StandardDateFilterDuration> getStandardDateFilterDurations()
```

Return Value

Type: List<Reports.StandardDateFilterDuration>

For example, a standard filter date grouping might look like this:

```
Report.StandardDateFilterDuration[endDate=2015-12-31, label=Current FY, startDate=2015-01-01, value=THIS_FISCAL_YEAR],
Report.StandardDateFilterDuration[endDate=2014-12-31, label=Previous FY, startDate=2014-01-01, value=LAST_FISCAL_YEAR],
Report.StandardDateFilterDuration[endDate=2014-12-31, label=Previous 2 FY, startDate=2013-01-01, value=LAST_N_FISCAL_YEARS:2]
```

**StandardFilter Class**

Contains information about the standard filter defined in the report, such as the filter field API name and filter value.

**Namespace**

*Reports*

**Usage**

Use to get or set standard filters on a report. Standard filters vary by report type. For example, standard filters for reports on the Opportunity object are Show, Opportunity Status, and Probability.

**IN THIS SECTION:**

*StandardFilter Methods*

**StandardFilter Methods**

The following are methods for StandardFilter.

**IN THIS SECTION:**

*getName()*

Return the API name of the standard filter.

*getValue()*

Returns the standard filter value.

*setName(name)*

Sets the API name of the standard filter.

*setValue(value)*

Sets the standard filter value.
**getName()**
Return the API name of the standard filter.

Signature
```
public String getName()
```

Return Value
Type: String

**getValue()**
Returns the standard filter value.

Signature
```
public String getValue()
```

Return Value
Type: String

**setName(name)**
Sets the API name of the standard filter.

Signature
```
public void setName(String name)
```

Parameters
- **name**
  Type: String

Return Value
Type: void

**setValue(value)**
Sets the standard filter value.

Signature
```
public void setValue(String value)
```
Parameters

d value
type: String

Return Value

type: void

**StandardFilterInfo Class**

Is an abstract base class for an object that provides standard filter information.

**Namespace**

Reports

**IN THIS SECTION:**

- StandardFilterInfo Methods

**StandardFilterInfo Methods**

The following are methods for `StandardFilterInfo`.

**getLabel()**

Returns the display label of the standard filter.

**Signature**

```java
public String getLabel()
```

**Return Value**

type: String

**getType()**

Returns the type of standard filter.

**Signature**

```java
public Reports.StandardFilterType getType()
```
Return Value
Type: Reports.StandardFilterType

StandardFilterInfoPicklist Class
Contains information about the standard filter picklist, such as the display name and type of the filter field, the default picklist value, and a list of all possible picklist values.

Namespace
Reports

IN THIS SECTION:
StandardFilterInfoPicklist Methods

StandardFilterInfoPicklist Methods
The following are methods for StandardFilterInfoPicklist.

IN THIS SECTION:
- getDefaultValue()
- getFilterValues()
- getLabel()
- getType()

getDefaultValue()
Returns the default value for the standard filter picklist.

Signature
public String getDefaultValue()
public List<Reports.FilterValue> getFilterValues()

ReturnType
Type: List<Reports.FilterValue>

getLabel()
Returns the display name of the standard filter picklist.

Signature
public String getLabel()

ReturnType
Type: String

ggetType()
Returns the type of the standard filter picklist.

Signature
public Reports.StandardFilterType getType()

ReturnType
Type: Reports.StandardFilterType

StandardFilterType Enum
The StandardFilterType enum describes the type of standard filters in a report. The getType() method returns a Reports.StandardFilterType enum value.

Namespace
Reports

Enum Values
The following are the values of the Reports.StandardFilterType enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PICKLIST</td>
<td>Values for the standard filter type.</td>
</tr>
<tr>
<td>STRING</td>
<td>String values.</td>
</tr>
</tbody>
</table>
SummaryValue Class
Contains summary data for a cell of the report.

Namespace
Reports

SummaryValue Methods
The following are methods for SummaryValue. All are instance methods.

IN THIS SECTION:

getLabel()
Returns the formatted summary data for a specified cell.

g getValue() Returns the numeric value of the summary data for a specified cell.

getLabel()
Returns the formatted summary data for a specified cell.

Syntax
public String getLabel()

Return Value
Type: String

g getValue()
Returns the numeric value of the summary data for a specified cell.

Syntax
public Object getValue()

Return Value
Type: Object

ThresholdInformation Class
Contains a list of evaluated conditions for a report notification.

Namespace
Reports
IN THIS SECTION:

ThresholdInformation Constructors

ThresholdInformation Methods

ThresholdInformation Constructors

The following are constructors for ThresholdInformation.

IN THIS SECTION:

ThresholdInformation(evaluatedConditions)

Creates a new instance of the Reports.EvaluatedCondition class.

ThresholdInformation(evaluatedConditions)

Creates a new instance of the Reports.EvaluatedCondition class.

Signature

public ThresholdInformation(List<Reports.EvaluatedCondition> evaluatedConditions)

Parameters

evaluatedConditions

Type: List<Reports.EvaluatedCondition>

A list of Reports.EvaluatedCondition objects.

ThresholdInformation Methods

The following are methods for ThresholdInformation.

IN THIS SECTION:

getEvaluatedConditions()

Returns a list of evaluated conditions for a report notification.

getEvaluatedConditions()

Returns a list of evaluated conditions for a report notification.

Signature

public List<Reports.EvaluatedCondition> getEvaluatedConditions()
TopRows Class
Contains methods and constructors for working with information about a row limit filter.

Namespace
Reports

IN THIS SECTION:
TopRows Constructors
TopRows Methods

TopRows Constructors
The following are constructors for TopRows.

IN THIS SECTION:
TopRows(rowLimit, direction)
Creates an instance of the Reports.TopRows class using the specified parameters.

TopRows()
Creates an instance of the Reports.TopRows class. You can then set values by using the class’s set methods.

TopRows (rowLimit, direction)
Creates an instance of the Reports.TopRows class using the specified parameters.

Signature
public TopRows(Integer rowLimit, Reports.ColumnSortOrder direction)

Parameters
rowLimit
Type: Integer
The number of rows returned in the report.
direction
Type: Reports.ColumnSortOrder
The sort order of the report rows.

TopRows ()
Creates an instance of the Reports.TopRows class. You can then set values by using the class’s set methods.

Signature
public TopRows ()
TopRows Methods

The following are methods for TopRows.

IN THIS SECTION:

getDirection()
Returns the sort order of the report rows.
getRowLimit()
Returns the maximum number of rows shown in the report.
setDirection(value)
Sets the sort order of the report’s rows.
setDirection(direction)
Sets the sort order of the report’s rows.
setRowLimit(rowLimit)
Sets the maximum number of rows included in the report.
toString()
Returns a string.

getDirection()
Returns the sort order of the report rows.

Signature

public Reports.ColumnSortOrder getDirection()

Return Value
Type: Reports.ColumnSortOrder

ggetRowLimit()
Returns the maximum number of rows shown in the report.

Signature

public Integer getRowLimit()

Return Value
Type: Integer

setDirection(value)
Sets the sort order of the report’s rows.
setDirection(String value)

Parameters
value
  Type: String
  For possible values, see Reports.ColumnSortOrder.

Return Value
Type: void

setDirection(Reports.ColumnSortOrder direction)

Parameters
direction
  Type: Reports.ColumnSortOrder

Return Value
Type: void

setRowLimit(Integer rowLimit)

Sets the maximum number of rows included in the report.

Signature
public void setRowLimit(Integer rowLimit)

Parameters
rowLimit
  Type: Integer

Return Value
Type: void

toString()

Returns a string.
public String toString()

Return Value
Type: String

Reports Exceptions

The Reports namespace contains exception classes.
All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions on page 2715.

The Reports namespace contains these exceptions:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reports.FeatureNotSupportedException</td>
<td>Invalid report format</td>
<td></td>
</tr>
<tr>
<td>Reports.InstanceAccessException</td>
<td>Unable to access report instance</td>
<td></td>
</tr>
<tr>
<td>Reports.InvalidFilterException</td>
<td>Filter validation error</td>
<td>List&lt;String&gt; getFilterErrors() returns a list of filter errors</td>
</tr>
<tr>
<td>Reports.InvalidReportMetadataException</td>
<td>Missing metadata for filters</td>
<td>List&lt;String&gt; getReportMetadataErrors() returns a list of metadata errors</td>
</tr>
<tr>
<td>Reports.InvalidSnapshotDateException</td>
<td>Invalid historical report format</td>
<td>List&lt;String&gt; getSnapshotDateErrors() returns a list of snapshot date errors</td>
</tr>
<tr>
<td>Reports.MetadataException</td>
<td>No selected report columns</td>
<td></td>
</tr>
<tr>
<td>Reports.ReportRunException</td>
<td>Error running report</td>
<td></td>
</tr>
<tr>
<td>Reports.UnsupportedOperationException</td>
<td>Missing permissions for running reports</td>
<td></td>
</tr>
</tbody>
</table>

Schema Namespace

The Schema namespace provides classes and methods for schema metadata information.
The following are the classes in the Schema namespace.

IN THIS SECTION:

ChildRelationship Class
Contains methods for accessing the child relationship as well as the child sObject for a parent sObject.

DataCategory Class
Represents the categories within a category group.
DataCategoryGroupSobjectTypePair Class
Specifies a category group and an associated object.

DescribeColorResult Class
Contains color metadata information for a tab.

DescribeDataCategoryGroupResult Class
Contains the list of the category groups associated with KnowledgeArticleVersion and Question.

DescribeDataCategoryGroupStructureResult Class
Contains the category groups and categories associated with KnowledgeArticleVersion and Question.

DescribeFieldResult Class
Contains methods for describing sObject fields.

DescribeIconResult Class
Contains icon metadata information for a tab.

DescribeSObjectResult Class
Contains methods for describing sObjects.

DescribeTabResult Class
Contains tab metadata information for a tab in a standard or custom app available in the Salesforce user interface.

DescribeTabSetResult Class
Contains metadata information about a standard or custom app available in the Salesforce user interface.

DisplayTypeEnum
A Schema.DisplayType enum value is returned by the field describe result’s getType method.

FieldSet Class
Contains methods for discovering and retrieving the details of field sets created on sObjects.

FieldSetMember Class
Contains methods for accessing the metadata for field set member fields.

PicklistEntry Class
Represents a picklist entry.

RecordTypeInfo Class
Contains methods for accessing record type information for an sObject with associated record types.

SOAPTypeEnum
A Schema.SOAPType enum value is returned by the field describe result getSoapType method.

SObjectField Class
A Schema.sObjectField object is returned from the field describe result using the getController and getSObjectField methods.

SObjectType Class
A Schema.sObjectType object is returned from the field describe result using the getReferenceTo method, or from the sObject describe result using the getSObjectType method.

ChildRelationship Class
Contains methods for accessing the child relationship as well as the child sObject for a parent sObject.
Namespace

Schema

Example

A ChildRelationship object is returned from the sObject describe result using the `getChildRelationship` method. For example:

```java
Schema.DescribeSObjectResult R = Account.SObjectType.getDescribe();
```

ChildRelationship Methods

The following are methods for `ChildRelationship`. All are instance methods.

IN THIS SECTION:

- `getChildSObject()`
  - Returns the token of the child sObject on which there is a foreign key back to the parent sObject.

- `getField()`
  - Returns the token of the field that has a foreign key back to the parent sObject.

- `getRelationshipName()`
  - Returns the name of the relationship.

- `isCascadeDelete()`
  - Returns `true` if the child object is deleted when the parent object is deleted, `false` otherwise.

- `isDeprecatedAndHidden()`
  - Reserved for future use.

- `isRestrictedDelete()`
  - Returns `true` if the parent object can't be deleted because it is referenced by a child object, `false` otherwise.

**getChildSObject()**

Returns the token of the child sObject on which there is a foreign key back to the parent sObject.

Signature

```java
public Schema.SObjectType getChildSObject()
```

Return Value

Type: `Schema.SObjectType`

**getField()**

Returns the token of the field that has a foreign key back to the parent sObject.

Signature

```java
public Schema.SObjectField getField()
```
Return Value
Type: Schema.SObjectField

**getRelationshipName()**
Returns the name of the relationship.

Signature
```java
public String getRelationshipName()
```

Return Value
Type: String

**isCascadeDelete()**
Returns **true** if the child object is deleted when the parent object is deleted, **false** otherwise.

Signature
```java
public Boolean isCascadeDelete()
```

Return Value
Type: Boolean

**isDeprecatedAndHidden()**
Reserved for future use.

Signature
```java
public Boolean isDeprecatedAndHidden()
```

Return Value
Type: Boolean

**isRestrictedDelete()**
Returns **true** if the parent object can’t be deleted because it is referenced by a child object, **false** otherwise.

Signature
```java
public Boolean isRestrictedDelete()
```

Return Value
Type: Boolean
DataCategory Class

Represents the categories within a category group.

Namespace

Schema

Usage

The Schema.DataCategory object is returned by the getTopCategories method.

DataCategory Methods

The following are methods for DataCategory. All are instance methods.

IN THIS SECTION:

   getChildCategories()
   Returns a recursive object that contains the visible sub categories in the data category.

   getLabel()
   Returns the label for the data category used in the Salesforce user interface.

   getName()
   Returns the unique name used by the API to access to the data category.

   getChildCategories()

Returns a recursive object that contains the visible sub categories in the data category.

Signature

public Schema.DataCategory getChildCategories()

Return Value

Type: List<Schema.DataCategory>

getLabel()

Returns the label for the data category used in the Salesforce user interface.

Signature

public String getLabel()

Return Value

Type: String
getName()

Returns the unique name used by the API to access to the data category.

Signature

```
public String getName()
```

Return Value

Type: `String`

DataCategoryGroupSobjectTypePair Class

Specifies a category group and an associated object.

Namespace

`Schema`

Usage

`Schema.DataCategoryGroupSobjectTypePair` is used by the `describeDataCategoryGroupStructures` method to return the categories available to this object.

IN THIS SECTION:

- DataCategoryGroupSobjectTypePair Constructors
- DataCategoryGroupSobjectTypePair Methods

DataCategoryGroupSobjectTypePair Constructors

The following are constructors for `DataCategoryGroupSobjectTypePair`.

IN THIS SECTION:

- `DataCategoryGroupSobjectTypePair()`

  Creates a new instance of the `Schema.DataCategoryGroupSobjectTypePair` class.

DataCategoryGroupSobjectTypePair() (public)

```
public DataCategoryGroupSobjectTypePair()
```

DataCategoryGroupSobjectTypePair Methods

The following are methods for `DataCategoryGroupSobjectTypePair`. All are instance methods.
IN THIS SECTION:
- `getDataCategoryGroupName()`
  Returns the unique name used by the API to access the data category group.
- `getSobject()`
  Returns the object name associated with the data category group.
- `setDataCategoryGroupName(name)`
  Specifies the unique name used by the API to access the data category group.
- `setSobject(sObjectName)`
  Sets the sObject associated with the data category group.

`getDataCategoryGroupName()`
Returns the unique name used by the API to access the data category group.

Signature

```
public String getDataCategoryGroupName()
```

Return Value
Type: `String`

`getSobject()`
Returns the object name associated with the data category group.

Signature

```
public String getSobject()
```

Return Value
Type: `String`

`setDataCategoryGroupName(name)`
Specifies the unique name used by the API to access the data category group.

Signature

```
public String setDataCategoryGroupName(String name)
```

Parameters

- `name`
  Type: `String`
Return Value
Type: Void

**setSobject(sObjectName)**
Sets the sObject associated with the data category group.

Signature

```java
public Void setSobject(String sObjectName)
```

Parameters

- **sObjectName**
  Type: String
  The sObjectName is the object name associated with the data category group. Valid values are:
  - KnowledgeArticleVersion—for article types.
  - Question—for questions from Answers.

Return Value
Type: Void

**DescribeColorResult Class**
Contains color metadata information for a tab.

**Namespace**

Schema

**Usage**
The `getColors` method of the `Schema.DescribeTabResult` class returns a list of `Schema.DescribeColorResult` objects that describe colors used in a tab.

The methods in the `Schema.DescribeColorResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses () to call the property counterpart. For example, `colorResultObj.color` is equivalent to `colorResultObj.getColor()`.

**Example**
This sample shows how to get the color information in the Sales app for the first tab's first color.

```java
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.DescribeTabs();

// Iterate through each tab set describe for each app and display the info
for(Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Display tab info for the Sales app
    // ...
if (tsr.getLabel() == 'Sales') {
   // Get color information for the first tab
   List<Schema.DescribeColorResult> colorDesc = tsr.getTabs()[0].getColors();
   // Display the icon color, theme, and context of the first color returned
   System.debug('Color: ' + colorDesc[0].getColor());
   System.debug('Theme: ' + colorDesc[0].getTheme());
   System.debug('Context: ' + colorDesc[0].getContext());
}

// Example debug statement output
// DEBUG|Color: 1797C0
// DEBUG|Theme: theme4
// DEBUG|Context: primary

DescribeColorResult Methods

The following are methods for DescribeColorResult. All are instance methods.

IN THIS SECTION:

getColor()
Returns the Web RGB color code, such as 00FF00.

getContext()
Returns the color context. The context determines whether the color is the main color for the tab or not.

getTheme()
Returns the color theme.

**getColor()**
Returns the Web RGB color code, such as 00FF00.

Signature

public String getColor()

Return Value

Type: String

**getContext()**
Returns the color context. The context determines whether the color is the main color for the tab or not.

Signature

public String getContext()
Return Value
Type: String

`getTheme()`
Returns the color theme.

Signature
`public String getTheme()`

Return Value
Type: String
Possible theme values include `theme3`, `theme4`, and `custom`.
- `theme3` is the Salesforce theme introduced during Spring '10.
- `theme4` is the Salesforce theme introduced in Winter '14 for the mobile touchscreen version of Salesforce.
- `custom` is the theme name associated with a custom icon.

DescribeDataCategoryGroupResult Class
Contains the list of the category groups associated with KnowledgeArticleVersion and Question.

Namespace
Schema

Usage
The `describeDataCategoryGroups` method returns a `Schema.DescribeDataCategoryGroupResult` object containing the list of the category groups associated with the specified object.

For additional information and code examples using `describeDataCategoryGroups`, see Accessing All Data Categories Associated with an sObject.

Example
The following is an example of how to instantiate a data category group describe result object:

```java
List<String> objType = new List<String>(){
    objType.add('KnowledgeArticleVersion');
    objType.add('Question');
};

List<Schema.DescribeDataCategoryGroupResult> describeCategoryResult =
    Schema.describeDataCategoryGroups(objType);
```

DescribeDataCategoryGroupResult Methods
The following are methods for `DescribeDataCategoryGroupResult`. All are instance methods.
IN THIS SECTION:

getCategoryCount()  
Returns the number of visible data categories in the data category group.

description()  
Returns the description of the data category group.

getLabel()  
Returns the label for the data category group used in the Salesforce user interface.

getName()  
Returns the unique name used by the API to access to the data category group.

getSobject()  
Returns the object name associated with the data category group.

getCategoryCount()  
Returns the number of visible data categories in the data category group.

Signature  
public Integer getCategoryCount()  

Return Value  
Type: Integer

description()  
Returns the description of the data category group.

Signature  
public String getDescription()  

Return Value  
Type: String

getLabel()  
Returns the label for the data category group used in the Salesforce user interface.

Signature  
public String getLabel()  

Return Value  
Type: String
getName ()
Returns the unique name used by the API to access to the data category group.

Signature
public String getName ()

Return Value
Type: String

getSobject ()
Returns the object name associated with the data category group.

Signature
public String getSobject ()

Return Value
Type: String

DescribeDataCategoryGroupStructureResult Class
Contains the category groups and categories associated with KnowledgeArticleVersion and Question.

Namespace
Schema

Usage
The describeDataCategoryGroupStructures method returns a list of Schema.Describe
DataCategoryGroupStructureResult objects containing the category groups and categories associated with the specified
object.
For additional information and code examples, see Accessing All Data Categories Associated with an sObject.

Example
The following is an example of how to instantiate a data category group structure describe result object:

```java
List<DataCategoryGroupObjectSobjectTypePair> pairs =
    new List<DataCategoryGroupObjectSobjectTypePair>();

DataCategoryGroupObjectSobjectTypePair pair1 =
    new DataCategoryGroupObjectSobjectTypePair();
pair1.setSobject('KnowledgeArticleVersion');
pair1.setDataCategoryGroupName('Regions');
```
DataCategoryGroupSobjectTypePair pair2 =
new DataCategoryGroupSobjectTypePair();
pair2.setSobject('Questions');
pair2.setDataCategoryGroupName('Regions');

pairs.add(pair1);
pairs.add(pair2);

List<Schema.DescribeDataCategoryGroupStructureResult> results =
    Schema.describeDataCategoryGroupStructures(pairs, true);

DescribeDataCategoryGroupStructureResult Methods

The following are methods for DescribeDataCategoryGroupStructureResult. All are instance methods.

IN THIS SECTION:

getDescription()  
Returns the description of the data category group.

getLabel()   
Returns the label for the data category group used in the Salesforce user interface.

getName()   
Returns the unique name used by the API to access to the data category group.

getSobject()   
Returns the name of object associated with the data category group.

getTopCategories()   
Returns a Schema.DataCategory object, that contains the top categories visible depending on the user’s data category group visibility settings.

getDescription()   
Returns the description of the data category group.

Signature

public String getDescription()

Return Value

Type: String

getLabel()   
Returns the label for the data category group used in the Salesforce user interface.

Signature

public String getLabel()
Return Value
Type: String

getName()
Returns the unique name used by the API to access to the data category group.

Signature
public String getName()

Return Value
Type: String

g getSobject()
Returns the name of object associated with the data category group.

Signature
public String getSobject()

Return Value
Type: String

getTopCategories()
Returns a Schema.DataCategory object, that contains the top categories visible depending on the user's data category group visibility settings.

Signature
public List<Schema.DataCategory> getTopCategories()

Return Value
Type: List<Schema.DataCategory>

Usage
For more information on data category group visibility, see “Data Category Visibility” in the Salesforce online help.

DescribeFieldResult Class
Contains methods for describing sObject fields.
Namespace

Schema

Example

The following is an example of how to instantiate a field describe result object:

```java
Schema.DescribeFieldResult dfr = Account.Description.getDescribe();
```

DescribeFieldResult Methods

The following are methods for `DescribeFieldResult`. All are instance methods.

IN THIS SECTION:

- `getBytesLength()`  
  For variable-length fields (including binary fields), returns the maximum size of the field, in bytes.
- `getCalculatedFormula()`  
  Returns the formula specified for this field.
- `getController()`  
  Returns the token of the controlling field.
- `getDefaultValue()`  
  Returns the default value for this field.
- `getDefaultValueFormula()`  
  Returns the default value specified for this field if a formula is not used.
- `getDigits()`  
  Returns the maximum number of digits specified for the field. This method is only valid with Integer fields.
- `getInlineHelpText()`  
  Returns the content of the field-level help.
- `getLabel()`  
  Returns the text label that is displayed next to the field in the Salesforce user interface. This label can be localized.
- `getLength()`  
  Returns the maximum size of the field for the DescribeFieldResult object in Unicode characters (not bytes).
- `getLocalName()`  
  Returns the name of the field, similar to the `getName` method. However, if the field is part of the current namespace, the namespace portion of the name is omitted.
- `getName()`  
  Returns the field name used in Apex.
- `getPicklistValues()`  
  Returns a list of PicklistEntry objects. A runtime error is returned if the field is not a picklist.
- `getPrecision()`  
  For fields of type Double, returns the maximum number of digits that can be stored, including all numbers to the left and to the right of the decimal point (but excluding the decimal point character).  

getReferenceTargetField()
Returns the name of the custom field on the parent standard or custom object whose values are matched against the values of the child external object’s indirect lookup relationship field. The match is done to determine which records are related to each other.

getReferenceTo()
Returns a list of Schema.sObjectType objects for the parent objects of this field. If the isNamePointing method returns true, there is more than one entry in the list, otherwise there is only one.

getReferenceTo()
Returns the name of the relationship.

getRelationshipName()
Returns the name of the relationship.

getRelationshipOrder()
Returns 1 if the field is a child, 0 otherwise.

getScale()
For fields of type Double, returns the number of digits to the right of the decimal point. Any extra digits to the right of the decimal point are truncated.

getSOAPType()
Returns one of the SoapType enum values, depending on the type of field.

getSObjectField()
Returns the token for this field.

getType()
Returns one of the DisplayType enum values, depending on the type of field.

isAccessible()
Returns true if the current user can see this field, false otherwise.

isAiPredictionField() (Beta)
Returns true if the current field is enabled to display Einstein prediction data, false otherwise.

isAutoNumber()
Returns true if the field is an Auto Number field, false otherwise.

isCalculated()
Returns true if the field is a custom formula field, false otherwise. Note that custom formula fields are always read-only.

isCascadeDelete()
Returns true if the child object is deleted when the parent object is deleted, false otherwise.

isCaseSensitive()
Returns true if the field is case sensitive, false otherwise.

isCreateable()
Returns true if the field can be created by the current user, false otherwise.

isCustom()
Returns true if the field is a custom field, false if it is a standard field, such as Name.

isDefaultedOnCreate()
Returns true if the field receives a default value when created, false otherwise.

isDependentPicklist()
Returns true if the picklist is a dependent picklist, false otherwise.

isDeprecatedAndHidden()
Reserved for future use.
isExternalID()
Returns true if the field is used as an external ID, false otherwise.

isFilterable()
Returns true if the field can be used as part of the filter criteria of a WHERE statement, false otherwise.

isFormulaTreatNullNumberAsZero()
Returns true if null is treated as zero in a formula field, false otherwise.

isGroupable()
Returns true if the field can be included in the GROUP BY clause of a SOQL query, false otherwise. This method is only available for Apex classes and triggers saved using API version 18.0 and higher.

isHtmlFormatted()
Returns true if the field has been formatted for HTML and should be encoded for display in HTML, false otherwise. One example of a field that returns true for this method is a hyperlink custom formula field. Another example is a custom formula field that has an IMAGE text function.

isIdLookup()
Returns true if the field can be used to specify a record in an upsert method, false otherwise.

isNameField()
Returns true if the field is a name field, false otherwise.

isNamePointing()
Returns true if the field can have multiple types of objects as parents. For example, a task can have both the Contact/Lead ID (WhoId) field and the Opportunity/Account ID (WhatId) field return true for this method. because either of those objects can be the parent of a particular task record. This method returns false otherwise.

isNillable()
Returns true if the field is nillable, false otherwise. A nillable field can have empty content. A non-nillable field must have a value for the object to be created or saved.

isPermissionable()
Returns true if field permissions can be specified for the field, false otherwise.

isRestrictedDelete()
Returns true if the parent object can't be deleted because it is referenced by a child object, false otherwise.

isRestrictedPicklist()
Returns true if the field is a restricted picklist, false otherwise

isSearchPrefilterable()
Returns true if a foreign key can be included in prefiltering when used in a SOSL WHERE clause, false otherwise.

isSortable()
Returns true if a query can sort on the field, false otherwise.

isUnique()
Returns true if the value for the field must be unique, false otherwise

isUpdateable()
Returns true if the field can be edited by the current user, or child records in a master-detail relationship field on a custom object can be re-parented to different parent records; false otherwise.

isWriteRequiresMasterRead()
Returns true if writing to the detail object requires read sharing instead of read/write sharing of the parent.
**getByteLength()**
For variable-length fields (including binary fields), returns the maximum size of the field, in bytes.

Signature
```java
public Integer getByteLength()
```

Return Value
Type: `Integer`

**getCalculatedFormula()**
Returns the formula specified for this field.

Signature
```java
public String getCalculatedFormula()
```

Return Value
Type: `String`

**getController()**
Returns the token of the controlling field.

Signature
```java
public Schema.sObjectField getController()
```

Return Value
Type: `Schema.SObjectField`

**getDefaultValue()**
Returns the default value for this field.

Signature
```java
public Object getDefaultValue()
```

Return Value
Type: `Object`

**getDefaultValueFormula()**
Returns the default value specified for this field if a formula is not used.
public String getDefaultValueFormula()

Return Value
Type: String

getDigits()
Returns the maximum number of digits specified for the field. This method is only valid with Integer fields.

Signature
public Integer getDigits()

Return Value
Type: Integer

getInlineHelpText()
Returns the content of the field-level help.

Signature
public String getInlineHelpText()

Return Value
Type: String

Usage
For more information, see “Define Field-Level Help” in the Salesforce online help.

g.getLabel()
Returns the text label that is displayed next to the field in the Salesforce user interface. This label can be localized.

Signature
public String getLabel()

Return Value
Type: String

Usage
Note: For the Type field on standard objects, getLabel returns a label different from the default label. It returns a label of the form Object Type, where Object is the standard object label. For example, for the Type field on Account, getLabel returns
getLength()
Returns the maximum size of the field for the DescribeFieldResult object in Unicode characters (not bytes).

Signature
public Integer getLength()

Return Value
Type: Integer

getLocalName()
Returns the name of the field, similar to the getName method. However, if the field is part of the current namespace, the namespace portion of the name is omitted.

Signature
public String getLocalName()

Return Value
Type: String

getName()
Returns the field name used in Apex.

Signature
public String getName()

Return Value
Type: String

getPicklistValues()
Returns a list of PicklistEntry objects. A runtime error is returned if the field is not a picklist.

Signature
public List<Schema.PicklistEntry> getPicklistValues()
getPrecision()
For fields of type Double, returns the maximum number of digits that can be stored, including all numbers to the left and to the right of the decimal point (but excluding the decimal point character).

**Signature**
```
public Integer getPrecision()
```

getReferenceTargetField()
Returns the name of the custom field on the parent standard or custom object whose values are matched against the values of the child external object's indirect lookup relationship field. The match is done to determine which records are related to each other.

**Signature**
```
public String getReferenceTargetField()
```

getReferenceTo()
Returns a list of Schema.sObjectType objects for the parent objects of this field. If the `isNamePointing` method returns `true`, there is more than one entry in the list, otherwise there is only one.

**Signature**
```
public List<Schema.sObjectType> getReferenceTo()
```

getRelationshipName()
Returns the name of the relationship.
Signature
public String getRelationshipName()

Return Value
Type: String

Usage
For more information about relationships and relationship names, see Understanding Relationship Names in the SOQL and SOSL Reference.

getRelationshipOrder()
Returns 1 if the field is a child, 0 otherwise.

Signature
public Integer getRelationshipOrder()

Return Value
Type: Integer

Usage
For more information about relationships and relationship names, see Understanding Relationship Names in the SOQL and SOSL Reference.

setScale()
For fields of type Double, returns the number of digits to the right of the decimal point. Any extra digits to the right of the decimal point are truncated.

Signature
public Integer getScale()

Return Value
Type: Integer

Usage
This method returns a fault response if the number has too many digits to the left of the decimal point.

getSOAPType()
Returns one of the SoapType enum values, depending on the type of field.

Signature
public Schema.SOAPType getSOAPType()
Return Value
Type: Schema.SOAPType

**getSObjectField()**
Returns the token for this field.

Signature
```
public Schema.sObjectField getSObjectField()
```

Return Value
Type: Schema.SObjectField

**getType()**
Returns one of the DisplayType enum values, depending on the type of field.

Signature
```
public Schema.DisplayType getType()
```

Return Value
Type: Schema.DisplayType

**isAccessible()**
Returns `true` if the current user can see this field, `false` otherwise.

Signature
```
public Boolean isAccessible()
```

Return Value
Type: Boolean

**isAiPredictionField()** *(Beta)*
Returns `true` if the current field is enabled to display Einstein prediction data, `false` otherwise.

Signature
```
public Boolean isAiPredictionField()
```

Return Value
Type: Boolean
Usage

Custom number fields can be set to display Einstein prediction values. If you are participating in the Einstein Prediction Builder Beta program, use Einstein Prediction Builder to set up the value to display. Use this method to find out if a field is enabled to display an Einstein prediction value.

**isAutoNumber()**

Returns true if the field is an Auto Number field, false otherwise.

Signature

```java
public Boolean isAutoNumber()
```

Return Value

Type: Boolean

Usage

Analogous to a SQL IDENTITY type, Auto Number fields are read-only, non-createable text fields with a maximum length of 30 characters. Auto Number fields are used to provide a unique ID that is independent of the internal object ID (such as a purchase order number or invoice number). Auto Number fields are configured entirely in the Salesforce user interface.

**isCalculated()**

Returns true if the field is a custom formula field, false otherwise. Note that custom formula fields are always read-only.

Signature

```java
public Boolean isCalculated()
```

Return Value

Type: Boolean

**isCascadeDelete()**

Returns true if the child object is deleted when the parent object is deleted, false otherwise.

Signature

```java
public Boolean isCascadeDelete()
```

Return Value

Type: Boolean

**isCaseSensitive()**

Returns true if the field is case sensitive, false otherwise.
Signature
public Boolean isCaseSensitive()

Return Value
Type: Boolean

**isCreateable()**
Returns **true** if the field can be created by the current user, **false** otherwise.

Signature
public Boolean isCreateable()

Return Value
Type: Boolean

**isCustom()**
Returns **true** if the field is a custom field, **false** if it is a standard field, such as Name.

Signature
public Boolean isCustom()

Return Value
Type: Boolean

**isDefaultedOnCreate()**
Returns **true** if the field receives a default value when created, **false** otherwise.

Signature
public Boolean isDefaultedOnCreate()

Return Value
Type: Boolean

Usage
If this method returns **true**, Salesforce implicitly assigns a value for this field when the object is created, even if a value for this field is not passed in on the create call. For example, in the Opportunity object, the Probability field has this attribute because its value is derived from the Stage field. Similarly, the Owner has this attribute on most objects because its value is derived from the current user (if the Owner field is not specified).
isDependentPicklist()
Returns true if the picklist is a dependent picklist, false otherwise.

Signature
public Boolean isDependentPicklist()

Return Value
Type: Boolean

isDeprecatedAndHidden()
Reserved for future use.

Signature
public Boolean isDeprecatedAndHidden()

Return Value
Type: Boolean

isExternalID()
Returns true if the field is used as an external ID, false otherwise.

Signature
public Boolean isExternalID()

Return Value
Type: Boolean

isFilterable()
Returns true if the field can be used as part of the filter criteria of a WHERE statement, false otherwise.

Signature
public Boolean isFilterable()

Return Value
Type: Boolean

isFormulaTreatNullNumberAsZero()
Returns true if null is treated as zero in a formula field, false otherwise.
public Boolean isFormulaTreatNullNumberAsZero()

Return Value
Type: Boolean

isGroupable()
Returns true if the field can be included in the GROUP BY clause of a SOQL query, false otherwise. This method is only available for Apex classes and triggers saved using API version 18.0 and higher.

public Boolean isGroupable()

Return Value
Type: Boolean

isHtmlFormatted()
Returns true if the field has been formatted for HTML and should be encoded for display in HTML, false otherwise. One example of a field that returns true for this method is a hyperlink custom formula field. Another example is a custom formula field that has an IMAGE text function.

public Boolean isHtmlFormatted()

Return Value
Type: Boolean

isIdLookup()
Returns true if the field can be used to specify a record in an upsert method, false otherwise.

public Boolean isIdLookup()

Return Value
Type: Boolean

isNameField()
Returns true if the field is a name field, false otherwise.
Signature

public Boolean isNameField()

Return Value
Type: Boolean

Usage
This method is used to identify the name field for standard objects (such as `AccountName` for an Account object) and custom objects. Objects can only have one name field, except where the `FirstName` and `LastName` fields are used instead (such as on the Contact object).

If a compound name is present, for example, the `Name` field on a person account, `isNameField` is set to `true` for that record.

`isNamePointing()`

Returns `true` if the field can have multiple types of objects as parents. For example, a task can have both the `Contact/Lead ID (WhoId)` field and the `Opportunity/Account ID (WhatId)` field return `true` for this method because either of those objects can be the parent of a particular task record. This method returns `false` otherwise.

Signature

public Boolean isNamePointing()

Return Value
Type: Boolean

`isNillable()`

Returns `true` if the field is nillable, `false` otherwise. A nillable field can have empty content. A non-nillable field must have a value for the object to be created or saved.

Signature

public Boolean isNillable()

Return Value
Type: Boolean

`isPermissionable()`

Returns `true` if field permissions can be specified for the field, `false` otherwise.

Signature

public Boolean isPermissionable()
Return Value
Type: Boolean

**isRestrictedDelete()**
Returns `true` if the parent object can’t be deleted because it is referenced by a child object, `false` otherwise.

Signature
```java
public Boolean isRestrictedDelete()
```

Return Value
Type: Boolean

**isRestrictedPicklist()**
Returns `true` if the field is a restricted picklist, `false` otherwise

Signature
```java
public Boolean isRestrictedPicklist()
```

Return Value
Type: Boolean

**isSearchPrefilterable()**
Returns `true` if a foreign key can be included in prefiltering when used in a SOSL WHERE clause, `false` otherwise.

Signature
```java
public Boolean isSearchPrefilterable()
```

Return Value
Type: Boolean

Usage
Prefiltering means to filter by a specific field value before executing the full search query. Prefiltering is supported only in WHERE clauses with the equals (=) operator.

**isSortable()**
Returns `true` if a query can sort on the field, `false` otherwise

Signature
```java
public Boolean isSortable()
```
Return Value
Type: Boolean

**isUnique()**
Returns `true` if the value for the field must be unique, `false` otherwise.

Signature
`public Boolean isUnique()`

Return Value
Type: Boolean

**isUpdateable()**
Returns `true` if the field can be edited by the current user, or child records in a master-detail relationship field on a custom object can be reparented to different parent records; `false` otherwise.

Signature
`public Boolean isUpdateable()`

Return Value
Type: Boolean

**isWriteRequiresMasterRead()**
Returns `true` if writing to the detail object requires read sharing instead of read/write sharing of the parent.

Signature
`public Boolean isWriteRequiresMasterRead()`

Return Value
Type: Boolean

**DescribeIconResult Class**
Contains icon metadata information for a tab.

**Namespace**
Schema
Usage

The getIcons method of the Schema.DescribeTabResult class returns a list of Schema.DescribeIconResult objects that describe colors used in a tab.

The methods in the Schema.DescribeIconResult class can be called using their property counterparts. For each method starting with get, you can omit the get prefix and the ending parentheses () to call the property counterpart. For example, iconResultObj.url is equivalent to iconResultObj.getUrl().

Example

This sample shows how to get the icon information in the Sales app for the first tab's first icon.

```java
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set
for (Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Get tab info for the Sales app
    if (tsr.getLabel() == 'Sales') {
        // Get icon information for the first tab
        List<Schema.DescribeIconResult> iconDesc = tsr.getTabs()[0].getIcons();
        // Display the icon height and width of the first icon
        System.debug('Height: ' + iconDesc[0].getHeight());
        System.debug('Width: ' + iconDesc[0].getWidth());
    }
}

// Example debug statement output
// DEBUG|Height: 32
// DEBUG|Width: 32
```

DescribeIconResult Methods

The following are methods for DescribeIconResult. All are instance methods.

IN THIS SECTION:

- **getContentType()**
  Returns the tab icon’s content type, such as image/png.

- **getHeight()**
  Returns the tab icon’s height in pixels.

- **getTheme()**
  Returns the tab’s icon theme.

- **getUrl()**
  Returns the tab’s icon fully qualified URL.

- **getWidth()**
  Returns the tab’s icon width in pixels.
**getContentType()**

Returns the tab icon's content type, such as `image/png`.

Signature

```java
public String getContentType()
```

Return Value

Type: `String`

**getHeight()**

Returns the tab icon's height in pixels.

Signature

```java
public Integer getHeight()
```

Return Value

Type: `Integer`

**Usage**

⚠️ **Note:** If the icon content type is SVG, the icon won't have a size and its height is zero.

**getTheme()**

Returns the tab's icon theme.

Signature

```java
public String getTheme()
```

Return Value

Type: `String`

Possible theme values include `theme3`, `theme4`, and `custom`.

- `theme3` is the Salesforce theme introduced during Spring '10.
- `theme4` is the Salesforce theme introduced in Winter '14 for the mobile touchscreen version of Salesforce.
- `custom` is the theme name associated with a custom icon.

**getUrl()**

Returns the tab's icon fully qualified URL.
Signature

```java
public String getUrl()
```

Return Value
Type: String

### `getWidth()`

Returns the tab's icon width in pixels.

Signature

```java
public Integer getWidth()
```

Return Value
Type: Integer

#### Usage

**Note:** If the icon content type is SVG, the icon won't have a size and its width is zero.

---

### DescribeSObjectResult Class

Contains methods for describing sObjects.

#### Namespace

**Schema**

#### Usage

None of the methods take an argument.

#### DescribeSObjectResult Methods

The following are methods for `DescribeSObjectResult`. All are instance methods.

#### IN THIS SECTION:

- **fields**
  - Follow `fields` with a field member variable name or with the `getMap` method.

- **fieldSets**
  - Follow `fieldSets` with a field set name or with the `getMap` method.

- **getChildRelationships()**
  - Returns a list of child relationships, which are the names of the sObjects that have a foreign key to the sObject being described.
getDefaultImplementation()
Reserved for future use.

getHasSubtypes()
Indicates whether the object has subtypes. The Account object, which has subtype PersonAccount, is the only object that will return true.

getImplementedBy()
Reserved for future use.

getImplementsInterfaces()
Reserved for future use.

getIsInterface()
Reserved for future use.

getKeyPrefix()
Returns the three-character prefix code for the object. Record IDs are prefixed with three-character codes that specify the type of the object (for example, accounts have a prefix of 001 and opportunities have a prefix of 006).

getLabel()
Returns the object’s label, which may or may not match the object name.

getLabelPlural()
Returns the object’s plural label, which may or may not match the object name.

getLocalName()
Returns the name of the object, similar to the getName method. However, if the object is part of the current namespace, the namespace portion of the name is omitted.

getName()
Returns the name of the object.

getRecordTypeInfos()
Returns a list of the record types supported by this object. The current user is not required to have access to a record type to see it in this list.

getRecordTypeInfosByDeveloperName()
Returns a map that matches developer names to their associated record type. The current user is not required to have access to a record type to see it in this map.

getRecordTypeInfosById()
Returns a map that matches record IDs to their associated record types. The current user is not required to have access to a record type to see it in this map.

getRecordTypeInfosByName()
Returns a map that matches record labels to their associated record type. The current user is not required to have access to a record type to see it in this map.

getSobjectType()
Returns the Schema.SObjectType object for the sObject. You can use this to create a similar sObject.

isAccessible()
Returns true if the current user can see this object, false otherwise.

isCreateable()
Returns true if the object can be created by the current user, false otherwise.
isCustom()  
Returns `true` if the object is a custom object, `false` if it is a standard object.

isCustomSetting()  
Returns `true` if the object is a custom setting, `false` otherwise.

isDeletable()  
Returns `true` if the object can be deleted by the current user, `false` otherwise.

isDeprecatedAndHidden()  
Reserved for future use.

isFeedEnabled()  
Returns `true` if Chatter feeds are enabled for the object, `false` otherwise. This method is only available for Apex classes and triggers saved using SalesforceAPI version 19.0 and later.

isMergeable()  
Returns `true` if the object can be merged with other objects of its type by the current user, `false` otherwise. `true` is returned for leads, contacts, and accounts.

isMruEnabled()  
Returns `true` if Most Recently Used (MRU) list functionality is enabled for the object, `false` otherwise.

isQueryable()  
Returns `true` if the object can be queried by the current user, `false` otherwise.

isSearchable()  
Returns `true` if the object can be searched by the current user, `false` otherwise.

isUndeletable()  
Returns `true` if the object can be undeleted by the current user, `false` otherwise.

isUpdateable()  
Returns `true` if the object can be updated by the current user, `false` otherwise.

**fields**  
Follow `fields` with a field member variable name or with the `getMap` method.

**Signature**

```java
public Schema.SObjectTypeFields fields()
```

**Return Value**

Type: The return value is a special data type. See the example to learn how to use `fields`.

**Usage**

**Note:** When you describe sObjects and their fields from within an Apex class, custom fields of new field types are returned regardless of the API version that the class is saved in. If a field type, such as the geolocation field type, is available only in a recent API version, components of a geolocation field are returned even if the class is saved in an earlier API version.
Example

```java
```

To get a custom field name, specify the custom field name.

SEE ALSO:
- Using Field Tokens
- Describing sObjects Using Schema Method
- Understanding Apex Describe Information

**fieldSets**

Follow `fieldSets` with a field set name or with the `getMap` method.

Signature

```java
public Schema.SObjectTypeFields fieldSets()
```

Return Value

Type: The return value is a special data type. See the example to learn how to use `fieldSets`.

Example

```java
Schema.DescribeSObjectResult d = Account.sObjectType.getDescribe();
Map<String, Schema.FieldSet> FsMap = d.fieldSets.getMap();
```

SEE ALSO:
- Using Field Tokens
- Describing sObjects Using Schema Method
- Understanding Apex Describe Information

**getChildRelationships()**

Returns a list of child relationships, which are the names of the sObjects that have a foreign key to the sObject being described.

Signature

```java
public Schema.ChildRelationship getChildRelationships()
```

Return Value

Type: `List<Schema.ChildRelationship>`
Example
For example, the Account object includes Contacts and Opportunities as child relationships.

`getDefaultImplementation()`
Reserved for future use.

Signature
`public String getDefaultImplementation()`

Return Value
Type: String

`getHasSubtypes()`
Indicates whether the object has subtypes. The Account object, which has subtype PersonAccount, is the only object that will return true.

Signature
`public Boolean getHasSubtypes()`

Return Value
Type: Boolean

`getImplementedBy()`
Reserved for future use.

Signature
`public String getImplementedBy()`

Return Value
Type: String

`getImplementsInterfaces()`
Reserved for future use.

Signature
`public String getImplementsInterfaces()`

Return Value
Type: String
**getIsInterface()**
Reserved for future use.

Signature
```
public Boolean getIsInterface()
```

Return Value
Type: Boolean

**getKeyPrefix()**
Returns the three-character prefix code for the object. Record IDs are prefixed with three-character codes that specify the type of the object (for example, accounts have a prefix of 001 and opportunities have a prefix of 006).

Signature
```
public String getKeyPrefix()
```

Return Value
Type: String

Usage
The DescribeSobjectResult object returns a value for objects that have a stable prefix. For object types that do not have a stable or predictable prefix, this field is blank. Client applications that rely on these codes can use this way of determining object type to ensure forward compatibility.

**getLabel()**
Returns the object’s label, which may or may not match the object name.

Signature
```
public String getLabel()
```

Return Value
Type: String

Usage
The object’s label might not always match the object name. For example, an organization in the medical industry might change the label for Account to Patient. This label is then used in the Salesforce user interface. See the Salesforce online help for more information.

**getLabelPlural()**
Returns the object’s plural label, which may or may not match the object name.
public String getLabelPlural()

Return Value
Type: String

Usage
The object’s plural label might not always match the object name. For example, an organization in the medical industry might change the plural label for Account to Patients. This label is then used in the Salesforce user interface. See the Salesforce online help for more information.

getLocalName()
Returns the name of the object, similar to the getName method. However, if the object is part of the current namespace, the namespace portion of the name is omitted.

Signature
public String getLocalName()

Return Value
Type: String

getName()
Returns the name of the object.

Signature
public String getName()

Return Value
Type: String

getRecordTypeInfos()
Returns a list of the record types supported by this object. The current user is not required to have access to a record type to see it in this list.

Signature
public List<Schema.RecordTypeInfo> getRecordTypeInfos()

Return Value
Type: List<Schema.RecordTypeInfo>
**getRecordTypeInfosByDeveloperName()**

Returns a map that matches developer names to their associated record type. The current user is not required to have access to a record type to see it in this map.

Signature

```java
public Map<String, Schema.RecordTypeInfo> getRecordTypeInfosByDeveloperName()
```

Return Value

Type: `Map<String, Schema.RecordTypeInfo>`

**getRecordTypeInfosById()**

Returns a map that matches record IDs to their associated record types. The current user is not required to have access to a record type to see it in this map.

Signature

```java
public Schema.RecordTypeInfo getRecordTypeInfosById()
```

Return Value

Type: `Map<ID, Schema.RecordTypeInfo>`

**getRecordTypeInfosByName()**

Returns a map that matches record labels to their associated record type. The current user is not required to have access to a record type to see it in this map.

Signature

```java
public Schema.RecordTypeInfo getRecordTypeInfosByName()
```

Return Value

Type: `Map<String, Schema.RecordTypeInfo>`

**getSobjectType()**

Returns the Schema.SObjectType object for the sObject. You can use this to create a similar sObject.

Signature

```java
public Schema.SObjectType getSobjectType()
```

Return Value

Type: `Schema.SObjectType`
isAccessible()
Returns true if the current user can see this object, false otherwise.

Signature
public Boolean isAccessible()

Return Value
Type: Boolean

isCreateable()
Returns true if the object can be created by the current user, false otherwise.

Signature
public Boolean isCreateable()

Return Value
Type: Boolean

isCustom()
Returns true if the object is a custom object, false if it is a standard object.

Signature
public Boolean isCustom()

Return Value
Type: Boolean

isCustomSetting()
Returns true if the object is a custom setting, false otherwise.

Signature
public Boolean isCustomSetting()

Return Value
Type: Boolean

isDeletable()
Returns true if the object can be deleted by the current user, false otherwise.
Signature
public Boolean isDeletable()

Return Value
Type: Boolean

**isDeprecatedAndHidden()**
Reserved for future use.

Signature
public Boolean isDeprecatedAndHidden()

Return Value
Type: Boolean

**isFeedEnabled()**
Returns true if Chatter feeds are enabled for the object, false otherwise. This method is only available for Apex classes and triggers saved using SalesforceAPI version 19.0 and later.

Signature
public Boolean isFeedEnabled()

Return Value
Type: Boolean

**isMergeable()**
Returns true if the object can be merged with other objects of its type by the current user, false otherwise. true is returned for leads, contacts, and accounts.

Signature
public Boolean isMergeable()

Return Value
Type: Boolean

**isMruEnabled()**
Returns true if Most Recently Used (MRU) list functionality is enabled for the object, false otherwise.
Signature
public Boolean isMruEnabled()

Return Value
Type: Boolean

**isQueryable()**
Returns `true` if the object can be queried by the current user, `false` otherwise.

Signature
public Boolean isQueryable()

Return Value
Type: Boolean

**isSearchable()**
Returns `true` if the object can be searched by the current user, `false` otherwise.

Signature
public Boolean isSearchable()

Return Value
Type: Boolean

**isUndeletable()**
Returns `true` if the object can be undeleted by the current user, `false` otherwise.

Signature
public Boolean isUndeletable()

Return Value
Type: Boolean

**isUpdateable()**
Returns `true` if the object can be updated by the current user, `false` otherwise.

Signature
public Boolean isUpdateable()
Return Value

Type: Boolean

**DescribeTabResult Class**

Contains tab metadata information for a tab in a standard or custom app available in the Salesforce user interface.

**Namespace**

*Schema*

**Usage**

The `getTabs` method of the `Schema.DescribeTabSetResult` returns a list of `Schema.DescribeTabResult` objects that describe the tabs of one app.

The methods in the `Schema.DescribeTabResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses `()` to call the property counterpart. For example, `tabResultObj.label` is equivalent to `tabResultObj.getLabel()`. Similarly, for each method starting with `is`, omit the `is` prefix and the ending parentheses `()`. For example, `tabResultObj.isCustom` is equivalent to `tabResultObj.custom`.

**DescribeTabResult Methods**

The following are methods for `DescribeTabResult`. All are instance methods.

IN THIS SECTION:

- `getColors()`: Returns a list of color metadata information for all colors associated with this tab. Each color is associated with a theme and context.
- `getIconUrl()`: Returns the URL for the main 32 x 32-pixel icon for a tab. This icon corresponds to the current theme (theme3) and appears next to the heading at the top of most pages.
- `getIcons()`: Returns a list of icon metadata information for all icons associated with this tab. Each icon is associated with a theme and context.
- `getLabel()`: Returns the display label of this tab.
- `getMiniIconUrl()`: Returns the URL for the 16 x 16-pixel icon that represents a tab. This icon corresponds to the current theme (theme3) and appears in related lists and other locations.
- `getSobjectName()`: Returns the name of the sObject that is primarily displayed on this tab (for tabs that display a particular SObject).
- `getUrl()`: Returns a fully qualified URL for viewing this tab.
- `isCustom()`: Returns `true` if this is a custom tab, or `false` if this is a standard tab.
**getColors()**
Returns a list of color metadata information for all colors associated with this tab. Each color is associated with a theme and context.

**Signature**
```
public List<Schema.DescribeColorResult> getColors()
```

**Return Value**
Type: `List<Schema.DescribeColorResult>`

**getIconUrl()**
Returns the URL for the main 32 x 32-pixel icon for a tab. This icon corresponds to the current theme (theme3) and appears next to the heading at the top of most pages.

**Signature**
```
public String getIconUrl()
```

**Return Value**
Type: `String`

**getIcons()**
Returns a list of icon metadata information for all icons associated with this tab. Each icon is associated with a theme and context.

**Signature**
```
public List<Schema.DescribeIconResult> getIcons()
```

**Return Value**
Type: `List<Schema.DescribeIconResult>`

**getLabel()**
Returns the display label of this tab.

**Signature**
```
public String getLabel()
```

**Return Value**
Type: `String`
**getMiniIconUrl()**
Returns the URL for the 16 x 16-pixel icon that represents a tab. This icon corresponds to the current theme (theme3) and appears in related lists and other locations.

Signature
```
public String getMiniIconUrl()
```

Return Value
Type: String

**getSobjectName()**
Returns the name of the sObject that is primarily displayed on this tab (for tabs that display a particular SObject).

Signature
```
public String getSobjectName()
```

Return Value
Type: String

**getUrl()**
Returns a fully qualified URL for viewing this tab.

Signature
```
public String getUrl()
```

Return Value
Type: String

**isCustom()**
Returns true if this is a custom tab, or false if this is a standard tab.

Signature
```
public Boolean isCustom()
```

Return Value
Type: Boolean

**DescribeTabSetResult Class**
Contains metadata information about a standard or custom app available in the Salesforce user interface.
Namespace

Schema

Usage

The `Schema.describeTabs` method returns a list of `Schema.DescribeTabSetResult` objects that describe standard and custom apps.

The methods in the `Schema.DescribeTabSetResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses () to call the property counterpart. For example, `tabSetResultObj.label` is equivalent to `tabSetResultObj.getLabel()`. Similarly, for each method starting with `is`, omit the `is` prefix and the ending parentheses (). For example, `tabSetResultObj.isSelected` is equivalent to `tabSetResultObj.selected`.

Example

This example shows how to call the `Schema.describeTabs` method to get describe information for all available apps. This example iterates through each describe result and gets more metadata information for the Sales app.

```java
// App we're interested to get more info about
String appName = 'Sales';

// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set describe for each app and display the info
for (Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Get more information for the Sales app
    if (tsr.getLabel() == appName) {
        // Find out if the app is selected
        if (tsr.isSelected()) {
            System.debug('The ' + appName + ' app is selected.');
        }
        // Get the app's Logo URL and namespace
        String logo = tsr.getLogoUrl();
        System.debug('Logo URL: ' + logo);
        String ns = tsr.getNamespace();
        if (ns == '') {
            System.debug('The ' + appName + ' app has no namespace defined.');
        } else {
            System.debug('Namespace: ' + ns);
        }
        // Get the number of tabs
        System.debug('The ' + appName + ' app has ' + tsr.getTabs().size() + ' tabs.');
    }
}
```

// Example debug statement output
// DEBUG|The Sales app is selected.
// DEBUG|Logo URL: https://yourInstance.salesforce.com/img/seasonLogos/2014_winter_aloha.png
DescribeTabSetResult Methods

The following are methods for DescribeTabSetResult. All are instance methods.

IN THIS SECTION:

- **getDescription()**: Returns the display description for the standard or custom app.
- **getLabel()**: Returns the display label for the standard or custom app.
- **getLogoUrl()**: Returns a fully qualified URL to the logo image associated with the standard or custom app.
- **getNamespace()**: Returns the developer namespace prefix of a Salesforce AppExchange managed package.
- **getTabs()**: Returns metadata information about the standard or custom app's displayed tabs.
- **isSelected()**: Returns true if this standard or custom app is the user's currently selected app. Otherwise, returns false.

### getDescription()

Returns the display description for the standard or custom app.

**Signature**

```java
public String getDescription()
```

**Return Value**

Type: String

### getLabel()

Returns the display label for the standard or custom app.

**Signature**

```java
public String getLabel()
```

**Return Value**

Type: String
Usage
The display label changes when tabs are renamed in the Salesforce user interface. See the Salesforce online help for more information.

**getLogoUrl()**
Returns a fully qualified URL to the logo image associated with the standard or custom app.

**Signature**
public String getLogoUrl()

**Return Value**
Type: String

**getNamespace()**
Returns the developer namespace prefix of a Salesforce AppExchange managed package.

**Signature**
public String getNamespace()

**Return Value**
Type: String

**Usage**
This namespace prefix corresponds to the namespace prefix of the Developer Edition organization that was enabled to allow publishing a managed package. This method applies to a custom app containing a set of tabs and installed as part of a managed package.

**getTabs()**
Returns metadata information about the standard or custom app’s displayed tabs.

**Signature**
public List<Schema.DescribeTabResult> getTabs()

**Return Value**
Type: List<Schema.DescribeTabResult>

**isSelected()**
Returns true if this standard or custom app is the user’s currently selected app. Otherwise, returns false.

**Signature**
public Boolean isSelected()
Return Value
Type: Boolean

DisplayType Enum
A Schema.DisplayType enum value is returned by the field describe result's getType method.

Namespace
Schema

<table>
<thead>
<tr>
<th>Type Field Value</th>
<th>What the Field Object Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>Address values</td>
</tr>
<tr>
<td>anytype</td>
<td>Any value of the following types: String, Picklist, Boolean, Integer, Double, Percent, ID, Date, DateTime, URL, or Email.</td>
</tr>
<tr>
<td>base64</td>
<td>Base64-encoded arbitrary binary data (of type base64Binary)</td>
</tr>
<tr>
<td>Boolean</td>
<td>Boolean (true or false) values</td>
</tr>
<tr>
<td>Combobox</td>
<td>Comboboxes, which provide a set of enumerated values and allow the user to specify a value not in the list</td>
</tr>
<tr>
<td>Currency</td>
<td>Currency values</td>
</tr>
<tr>
<td>DataCategoryGroupReference</td>
<td>Reference to a data category group or a category unique name</td>

<td>Percent values</td>
</tr>
<tr>
<td>Phone</td>
<td>Phone numbers. Values can include alphabetic characters. Client applications are responsible for phone number formatting.</td>
</tr>
<tr>
<td>Picklist</td>
<td>Single-select picklists, which provide a set of enumerated values from which only one value can be selected</td>
</tr>
<tr>
<td>Reference</td>
<td>Cross-references to a different object, analogous to a foreign key field</td>
</tr>
</tbody>
</table>
### Type Field Value | What the Field Object Contains
--- | ---
String | String values
Textarea | String values that are displayed as multiline text fields
Time | Time values
URL | URL values that are displayed as hyperlinks

### Usage
For more information, see Field Types in the Object Reference for Salesforce. For more information about the methods shared by all enums, see Enum Methods.

### FieldSet Class
Contains methods for discovering and retrieving the details of field sets created on sObjects.

### Namespace
Schema

### Usage
Use the methods in the Schema.FieldSet class to discover the fields contained within a field set, and get details about the field set itself, such as the name, namespace, label, and so on. The following example shows how to get a collection of field set describe result objects for an sObject. The key of the returned Map is the field set name, and the value is the corresponding field set describe result.

```java
Map<String, Schema.FieldSet> FsMap = Schema.SObjectType.Account.fieldSets.getMap();
```

Field sets are also available from sObject describe results. The following lines of code are equivalent to the prior sample:

```java
Schema.DescribeSObjectResult d = Account.sObjectType.getDescribe();
Map<String, Schema.FieldSet> FsMap = d.fieldSets.getMap();
```

To work with an individual field set, you can access it via the map of field sets on an sObject or, when you know the name of the field set in advance, using an explicit reference to the field set. The following two lines of code retrieve the same field set:

```java
Schema.FieldSet fs1 = Schema.SObjectType.Account.fieldSets.getMap().get('field_set_name');
Schema.FieldSet fs2 = Schema.SObjectType.Account.fieldSets.field_set_name;
```

### Example: Displaying a Field Set on a Visualforce Page
This sample uses Schema.FieldSet and Schema.FieldSetMember methods to dynamically get all the fields in the Dimensions field set for the Merchandise custom object. The list of fields is then used to construct a SOQL query that ensures those fields are available for display. The Visualforce page uses the MerchandiseDetails class as its controller.

```java
public class MerchandiseDetails {

```
public Merchandise__c merch { get; set; }

public MerchandiseDetails() {
    this.merch = getMerchandise();
}

public List<Schema.FieldSetMember> getFields() {
    return SObjectType.Merchandise__c.FieldSets.Dimensions.getFields();
}

private Merchandise__c getMerchandise() {
    String query = 'SELECT ';
    for(Schema.FieldSetMember f : this.getFields()) {
        query += f.getFieldPath() + ', ';
    }
    query += 'Id, Name FROM Merchandise__c LIMIT 1';
    return Database.query(query);
}

The Visualforce page using the above controller is simple:

    <apex:page controller="MerchandiseDetails">
        <apex:form >

            <apex:pageBlock title="Product Details">
                <apex:pageBlockSection title="Product">
                    <apex:inputField value="{!merch.Name}"/>
                </apex:pageBlockSection>

                <apex:pageBlockSection title="Dimensions">
                    <apex:repeat value="{!fields}" var="f">
                        <apex:inputField value="{!merch[f.fieldPath]}"
                                          required="{!OR(f.required, f.dbrequired)}"/>
                    </apex:repeat>
                </apex:pageBlockSection>

            </apex:pageBlock>

        </apex:form>
    </apex:page>

One thing to note about the above markup is the expression used to determine if a field on the form should be indicated as being a required field. A field in a field set can be required by either the field set definition, or the field's own definition. The expression handles both cases.

FieldSet Methods

The following are methods for FieldSet. All are instance methods.

IN THIS SECTION:
    getDescription()  
        Returns the field set's description.
getFields()
Returns a list of Schema.FieldSetMember objects for the fields making up the field set.

getLabel()
Returns the translation of the text label that is displayed next to the field in the Salesforce user interface.

getName()
Returns the field set's name.

getNamespace()
Returns the field set's namespace.

getSObjectType()
Returns the Schema.sObjectType of the sObject containing the field set definition.

description()
Returns the field set's description.

Signature
public String getDescription()

Return Value
Type: String

Usage
Description is a required field for a field set, intended to describe the context and content of the field set. It's often intended for administrators who might be configuring a field set defined in a managed package, rather than for end users.

gfields()
Returns a list of Schema.FieldSetMember objects for the fields making up the field set.

Signature
public List<FieldSetMember> getFields()

Return Value
Type: List<Schema.FieldSetMember>

glabel()
Returns the translation of the text label that is displayed next to the field in the Salesforce user interface.

Signature
public String getLabel()
Return Value
Type: String

**getName()**
Returns the field set's name.

Signature
public String getName()

Return Value
Type: String

**getNamespace()**
Returns the field set's namespace.

Signature
public String getNamespace()

Return Value
Type: String

**Usage**
The returned namespace is an empty string if your organization hasn't set a namespace, and the field set is defined in your organization. Otherwise, it's the namespace of your organization, or the namespace of the managed package containing the field set.

**getSObjectType()**
Returns the `Schema.SObjectType` of the sObject containing the field set definition.

Signature
public Schema.SObjectType getSObjectType()

Return Value
Type: Schema.SObjectType

**FieldSetMember Class**
Contains methods for accessing the metadata for field set member fields.
Namespace

Schema

Usage

Use the methods in the `Schema.FieldSetMember` class to get details about fields contained within a field set, such as the field label, type, a dynamic SOQL-ready field path, and so on. The following example shows how to get a collection of field set member describe result objects for a specific field set on an sObject:

```java
List<Schema.FieldSetMember> fields =
    Schema.SObjectType.Account.fieldSets.getMap().get('field_set_name').getFields();
```

If you know the name of the field set in advance, you can access its fields more directly using an explicit reference to the field set:

```java
List<Schema.FieldSetMember> fields =
    Schema.SObjectType.Account.fieldSets.field_set_name.getFields();
```

SEE ALSO:
FieldSet Class

FieldSetMember Methods

The following are methods for `FieldSetMember`. All are instance methods.

IN THIS SECTION:

- `getDBRequired()`
  - Returns `true` if the field is required by the field's definition in its sObject, otherwise, `false`.
- `getFieldPath()`
  - Returns a field path string in a format ready to be used in a dynamic SOQL query.
- `getLabel()`
  - Returns the text label that's displayed next to the field in the Salesforce user interface.
- `getRequired()`
  - Returns `true` if the field is required by the field set, otherwise, `false`.
- `getType()`
  - Returns the field's Apex data type.
- `getSObjectField()`
  - Returns the token for this field.

**getDBRequired()**

Returns `true` if the field is required by the field's definition in its sObject, otherwise, `false`.

Signature

```java
public Boolean getDBRequired()
```
Return Value
Type: `Boolean`

`getFieldPath()`
Returns a field path string in a format ready to be used in a dynamic SOQL query.

Signature
```java
public String getFieldPath()
```

Return Value
Type: `String`

Example
See [Displaying a Field Set on a Visualforce Page](#) for an example of how to use this method.

`getLabel()`
Returns the text label that’s displayed next to the field in the Salesforce user interface.

Signature
```java
public String getLabel()
```

Return Value
Type: `String`

`isRequired()`
Returns `true` if the field is required by the field set, otherwise, `false`.

Signature
```java
public Boolean getRequired()
```

Return Value
Type: `Boolean`

`getType()`
Returns the field’s Apex data type.

Signature
```java
public Schema.DisplayType getType()
```
Return Value
Type: Schema.DisplayType

**getSObjectField()**
Returns the token for this field.

**Signature**
```java
public Schema.sObjectField getSObjectField()
```

Return Value
Type: Schema.SObjectField

**PicklistEntry Class**
Represents a picklist entry.

**Namespace**
Schema

**Usage**
Picklist fields contain a list of one or more items from which a user chooses a single item. They display as drop-down lists in the Salesforce user interface. One of the items can be configured as the default item.

A `Schema.PicklistEntry` object is returned from the field describe result using the `getPicklistValues` method. For example:

```java
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
List<Schema.PicklistEntry> P = F.getPicklistValues();
```

**PicklistEntry Methods**
The following are methods for PicklistEntry. All are instance methods.

**IN THIS SECTION:**
- `getLabel()`
  Returns the display name of this item in the picklist.
- `getValue()`
  Returns the value of this item in the picklist.
- `isActive()`
  Returns `true` if this item must be displayed in the drop-down list for the picklist field in the user interface, `false` otherwise.
- `isDefaultValue()`
  Returns `true` if this item is the default value for the picklist, `false` otherwise. Only one item in a picklist can be designated as the default.
**getLabel()**
Returns the display name of this item in the picklist.

**Signature**
```java
public String getLabel()
```

**Return Value**
Type: **String**

**getValue()**
Returns the value of this item in the picklist.

**Signature**
```java
public String getValue()
```

**Return Value**
Type: **String**

**isActive()**
Returns `true` if this item must be displayed in the drop-down list for the picklist field in the user interface, `false` otherwise.

**Signature**
```java
public Boolean isActive()
```

**Return Value**
Type: **Boolean**

**isDefaultValue()**
Returns `true` if this item is the default value for the picklist, `false` otherwise. Only one item in a picklist can be designated as the default.

**Signature**
```java
public Boolean isDefaultValue()
```

**Return Value**
Type: **Boolean**

**RecordTypeInfo Class**
Contains methods for accessing record type information for an sObject with associated record types.
Namespace

Schema

Usage

A RecordTypeInfo object is returned from the sObject describe result using the `getRecordTypeInfos` method. For example:

```java
Schema.DescribeSObjectResult R = Account.SObjectType.getDescribe();
List<Schema.RecordTypeInfo> RT = R.getRecordTypeInfos();
```

In addition to the `getRecordTypeInfos` method, you can use the `getRecordTypeInfosById` and the `getRecordTypeInfosByName` methods. These methods return maps that associate RecordTypeInfo with record IDs and record labels, respectively.

Example

The following example assumes at least one record type has been created for the Account object:

```java
RecordType rt = [SELECT Id,Name FROM RecordType WHERE SobjectType='Account' LIMIT 1];
Map<Id,Schema.RecordTypeInfo> rtMapById = d.getRecordTypeInfosById();
Schema.RecordTypeInfo rtById = rtMapById.get(rt.id);
Map<String,Schema.RecordTypeInfo> rtMapByName = d.getRecordTypeInfosByName();
Schema.RecordTypeInfo rtByName = rtMapByName.get(rt.name);
System.assertEquals(rtById,rtByName);
```

RecordTypeInfo Methods

The following are methods for RecordTypeInfo. All are instance methods.

IN THIS SECTION:

- `getDeveloperName()`: Returns the developer name for this record type.
- `getName()`: Returns the UI label of this record type. The label can be translated into any language that Salesforce supports.
- `getRecordTypeId()`: Returns the ID of this record type.
- `isActive()`: Returns `true` if this record type is active, `false` otherwise.
- `isAvailable()`: Returns `true` if this record type is available to the current user, `false` otherwise. Use this method to display a list of available record types to the user when he or she is creating a new record.
- `isDefaultRecordTypeMapping()`: Returns `true` if this is the default record type for the user, `false` otherwise.
- `isMaster()`: Returns `true` if this is the master record type and `false` otherwise. The master record type is the default record type that’s used when a record has no custom record type associated with it.
**getDeveloperName()**

Returns the developer name for this record type.

**Signature**

```java
public String getDeveloperName()
```

**Return Value**

Type: `String`

---

**getName()**

Returns the UI label of this record type. The label can be translated into any language that Salesforce supports.

**Signature**

```java
public String getName()
```

**Return Value**

Type: `String`

---

**getRecordTypeId()**

Returns the ID of this record type.

**Signature**

```java
public ID getRecordTypeId()
```

**Return Value**

Type: `ID`

---

**isActive()**

Returns `true` if this record type is active, `false` otherwise.

**Signature**

```java
public Boolean isActive()
```

**Return Value**

Type: `Boolean`

---

**isAvailable()**

Returns `true` if this record type is available to the current user, `false` otherwise. Use this method to display a list of available record types to the user when he or she is creating a new record.
Signature

public Boolean isAvailable()

Return Value
Type: Boolean

isDefaultRecordTypeMapping()
Returns true if this is the default record type for the user, false otherwise.

Signature

public Boolean isDefaultRecordTypeMapping()

Return Value
Type: Boolean

isMaster()
Returns true if this is the master record type and false otherwise. The master record type is the default record type that’s used when a record has no custom record type associated with it.

Signature

public Boolean isMaster()

Return Value
Type: Boolean

SOAPType Enum
A Schema.SOAPType enum value is returned by the field describe result getSoapType method.

Namespace
Schema

<table>
<thead>
<tr>
<th>Type Field Value</th>
<th>What the Field Object Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>anytype</td>
<td>Any value of the following types: String, Boolean, Integer, Double, ID, Date or DateTime.</td>
</tr>
<tr>
<td>base64binary</td>
<td>Base64-encoded arbitrary binary data (of type base64Binary)</td>
</tr>
<tr>
<td>Boolean</td>
<td>Boolean (true or false) values</td>
</tr>
<tr>
<td>Date</td>
<td>Date values</td>
</tr>
<tr>
<td>DateTime</td>
<td>DateTime values</td>
</tr>
<tr>
<td>Type Field Value</td>
<td>What the Field Object Contains</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------</td>

<tr>
<td>Double</td>
<td>Double values</td>
</tr>
<tr>
<td>ID</td>
<td>Primary key field for an object</td>
</tr>
<tr>
<td>Integer</td>
<td>Integer values</td>
</tr>
<tr>
<td>String</td>
<td>String values</td>
</tr>
<tr>
<td>Time</td>
<td>Time values</td>
</tr>
</tbody>
</table>

**Usage**

For more information, see SOAPTypes in the SOAP API Developer Guide. For more information about the methods shared by all enums, see Enum Methods.

**SObjectField Class**

A Schema.sObjectField object is returned from the field describe result using the getController and getSObjectField methods.

**Namespace**

Schema

**Example**

```java
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
Schema.sObjectField T = F.getSObjectField();
```

**sObjectField Methods**

The following are instance methods for sObjectField.

**IN THIS SECTION:**

- `getDescribe()`
  - Returns the describe field result for this field.

- `getDescribe(options)`
  - Returns the describe field result for this field. This method also provides an option to get all the describe field results for an object.

**getDescribe()**

Returns the describe field result for this field.

**Signature**

```java
public Schema.DescribeFieldResult getDescribe()
```
Return Value
Type: Schema.DescribeFieldResult

**getDescribe**(options)
Returns the describe field result for this field. This method also provides an option to get all the describe field results for an object.

Signature
```
public Schema.DescribeFieldResult getDescribe(Object options)
```

Parameters

**options**
Type: Object
Use this parameter to pass FieldDescribeOptions.FULL_DESCRIBE when a subset of system objects could have different results for picklist values based on the context they're invoked in. This parameter computes all aspects of describe field results.

For example, `AIConversationContext.PersonType` field is a picklist that contains a list of accessible object types.

Return Value
Type: Schema.DescribeFieldResult

### SObjectType Class

A Schema.sObjectType object is returned from the field describe result using the `getReferenceTo` method, or from the sObject describe result using the `getSObjectType` method.

### Namespace

**Schema**

### Usage

```
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
List<Schema.sObjectType> P = F.getReferenceTo();
```

### SObjectType Methods

The following are methods for SObjectType. All are instance methods.

IN THIS SECTION:
- `getDescription()`
  Returns the describe sObject result for this field.
- `newSObject()`
  Constructs a new sObject of this type.
newSObject(id)
Constructs a new sObject of this type, with the specified ID.

newSObject(recordTypeId, loadDefaults)
Constructs a new sObject of this type, and optionally, of the specified record type ID and with default custom field values.

gDescribe()  
Returns the describe sObject result for this field.

Signature
public Schema.DescribeSObjectResult getDescribe()

Return Value
Type: Schema.DescribeSObjectResult

ewSObject()
Constructs a new sObject of this type.

Signature
public sObject newSObject()

Return Value
Type: sObject

Example
For an example, see Dynamic sObject Creation Example.

newSObject(id)
Constructs a new sObject of this type, with the specified ID.

Signature
public sObject newSObject(ID id)

Parameters
id
  Type: ID

Return Value
Type: sObject
Usage

For the argument, pass the ID of an existing record in the database.

After you create a new sObject, the sObject returned has all fields set to null. You can set any updateable field to desired values and then update the record in the database. Only the fields you set new values for are updated and all other fields which are not system fields are preserved.

newSObject(recordTypeId, loadDefaults)

Constructs a new sObject of this type, and optionally, of the specified record type ID and with default custom field values.

Signature

public sObject newSObject(ID recordTypeId, Boolean loadDefaults)

Parameters

recordTypeId
Type: ID
Specifies the record type ID of the sObject to create. If no record type exists for this sObject, use null. If the sObject has record types and you specify null, the default record type is used.

loadDefaults
Type: Boolean
Specifies whether to populate custom fields with their predefined default values (true) or not (false).

Return Value

Type: sObject

Usage

• For required fields that have no default values, make sure to provide a value before inserting the new sObject. Otherwise, the insertion results in an error. An example is the Account Name field or a master-detail relationship field.

• Since picklists and multi-select picklists can have default values specified per record type, this method populates the default value corresponding to the record type specified.

• If fields have no predefined default values and the loadDefaults argument is true, this method creates the sObject with field values of null.

• If the loadDefaults argument is false, this method creates the sObject with field values of null.

• This method populates read-only custom fields of the new sObject with default values. You can then insert the new sObject with the read-only fields, even though these fields cannot be edited after they’re inserted.

• If a custom field is marked as unique and also provides a default value, inserting more than one new sObject will cause a run-time exception because of duplicate field values.

To learn more about default field values, see “Default Field Values” in the Salesforce online help.
Example: Creating New sObject with Default Values

This sample creates an account with any default values populated for its custom fields, if any, using the newSObject method. It also creates a second account for a specific record type. For both accounts, the sample sets the Name field, which is a required field that doesn't have a default value, before inserting the new accounts.

```apex
// Create an account with predefined default values
Account acct = (Account)Account.sObjectType.newSObject(null, true);
// Provide a value for Name
acct.Name = 'Acme';
// Insert new account
insert acct;

// This is for record type RT1 of Account
ID rtId = [SELECT Id FROM RecordType WHERE sObjectType='Account' AND Name='RT1'].Id;
Account acct2 = (Account)Account.sObjectType.newSObject(rtId, true);
// Provide a value for Name
acct2.Name = 'Acme2';
// Insert new account
insert acct2;
```

Search Namespace

The Search namespace provides classes for getting search results and suggestion results.

The following are the classes in the Search namespace.

IN THIS SECTION:

- **KnowledgeSuggestionFilter Class**
  Filter settings that narrow the results from a call to System.Search.suggest(searchQuery, sObjectType, options) when the SOSL search query contains a KnowledgeArticleVersion object.

- **QuestionSuggestionFilter Class**
  The Search.QuestionSuggestionFilter class filters results from a call to System.Search.suggest(searchQuery, sObjectType, options) when the SOSL searchQuery contains a FeedItem object.

- **SearchResult Class**
  A wrapper object that contains an sObject and search metadata.

- **SearchResults Class**
  Wraps the results returned by the Search.find(String) method.

- **SuggestionOption Class**
  Options that narrow record and article suggestion results returned from a call to System.Search.suggest(String, String, Search.SuggestionOption).

- **SuggestionResult Class**
  A wrapper object that contains an sObject.
SuggestionResults Class
Wraps the results returned by the `Search.suggest(String, String, Search.SuggestionOption)` method.

SEE ALSO:
find(searchQuery)
suggest(searchQuery, sObjectType, suggestions)

KnowledgeSuggestionFilter Class
Filter settings that narrow the results from a call to `System.Search.suggest(searchQuery, sObjectType, options)` when the SOSL search query contains a KnowledgeArticleVersion object.

Namespace
Search

KnowledgeSuggestionFilter Methods
The following are methods for `KnowledgeSuggestionFilter`.

IN THIS SECTION:
addArticleType(articleType)
Adds a filter that narrows suggestion results to display the specified article type. This filter is optional.
addDataCategory(dataCategoryGroupName, dataCategoryName)
Adds a filter that narrows suggestion results to display articles in the specified data category. This filter is optional.
addTopic(topic)
Specifies the article topic to return. This filter is optional.
setChannel(channelName)
Sets a channel to narrow the suggestion results to articles in the specified channel. This filter is optional.
setDataCategories(dataCategoryFilters)
Adds filters that narrow suggestion results to display articles in the specified data categories. Use this method to set multiple data category group and name pairs in one call. This filter is optional.
setLanguage(localeCode)
Sets a language to narrow the suggestion results to display articles in that language. This filter value is required in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`.
setPublishStatus(publishStatus)
Sets a publish status to narrow the suggestion results to display articles with that status. This filter value is required in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`.
setValidationStatus(validationStatus)
Sets a validation status to narrow the suggestion results to display articles with that status. This filter is optional.

addArticleType(articleType)
Adds a filter that narrows suggestion results to display the specified article type. This filter is optional.
**addArticleType(String articleType)**

**Parameters**

*articleType*

Type: `String`

A three-character ID prefix indicating the desired article type.

**Return Value**

Type: `void`

**Usage**

To add more than 1 article type, call the method multiple times.

**addDataCategory(String dataCategoryGroupName, String dataCategoryName)**

Adds a filter that narrows suggestion results to display articles in the specified data category. This filter is optional.

**Signature**

`public void addDataCategory(String dataCategoryGroupName, String dataCategoryName)`

**Parameters**

*dataCategoryGroupName*

Type: `String`

The name of the data category group

*dataCategoryName*

Type: `String`

The name of the data category.

**Return Value**

Type: `void`

**Usage**

To set multiple data categories, call the method multiple times. The name of the data category group and name of the data category for desired articles, expressed as a mapping, for example,

`Search.KnowledgeSuggestionFilter.addDataCategory('Regions', 'Asia')`.

**addTopic(String topic)**

Specifies the article topic to return. This filter is optional.
Signature

```java
public void addTopic(String topic)
```

Parameters

- `addTopic`
  - Type: `String`
  - The name of the article topic.

Return Value

Type: void

Usage

To add more than 1 article topic, call the method multiple times.

**setChannel(channelName)**

Sets a channel to narrow the suggestion results to articles in the specified channel. This filter is optional.

Signature

```java
public void setChannel(String channelName)
```

Parameters

- `channelName`
  - Type: `String`
  - The name of a channel. Valid values are:
    - `AllChannels`—Visible in all channels the user has access to
    - `App`—Visible in the internal Salesforce Knowledge application
    - `Pkb`—Visible in the public knowledge base
    - `Csp`—Visible in the Customer Portal
    - `Prm`—Visible in the Partner Portal

If `channel` isn’t specified, the default value is determined by the type of user.

- `Pkb` for a guest user
- `Csp` for a Customer Portal user
- `Prm` for a Partner Portal user
- `App` for any other type of user

If `channel` is specified, the specified value may not be the actual value requested, because of certain requirements.

- For guest, Customer Portal, and Partner Portal users, the specified value must match the default value for each user type. If the values don’t match or `AllChannels` is specified, then `App` replaces the specified value.
- For all users other than guest, Customer Portal, and Partner Portal users:
  - If `Pkb`, `Csp`, `Prm`, or `App` are specified, then the specified value is used.
If AllChannels is specified, then App replaces the specified value.

Return Value
Type: void

**setDataCategories(dataCategoryFilters)**
Adds filters that narrow suggestion results to display articles in the specified data categories. Use this method to set multiple data category group and name pairs in one call. This filter is optional.

Signature

```java
public void setDataCategories(Map dataCategoryFilters)
```

Parameters

- **dataCategoryFilters**
  Type: Map
  A map of data category group and data category name pairs.

Return Value
Type: void

**setLanguage(localeCode)**
Sets a language to narrow the suggestion results to display articles in that language. This filter value is required in calls to System.Search.suggest(String, String, Search.SuggestionOption).

Signature

```java
public void setLanguage(String localeCode)
```

Parameters

- **localeCode**
  Type: String
  A locale code. For example, 'en_US' (English–United States), or 'es' (Spanish).

Return Value
Type: void

SEE ALSO:
  - Supported Locales

2521
**setPublishStatus(publishStatus)**
Sets a publish status to narrow the suggestion results to display articles with that status. This filter value is required in calls to System.Search.suggest(String, String, Search.SuggestionOption).

Signature

```java
public void setPublishStatus(String publishStatus)
```

Parameters

**publishStatus**
Type: String
A publish status. Valid values are:
- Draft–Articles aren’t published in Salesforce Knowledge.
- Online–Articles are published in Salesforce Knowledge.
- Archived–Articles aren’t published and are available in Archived Articles view.

**setValidationStatus(validationStatus)**
Sets a validation status to narrow the suggestion results to display articles with that status. This filter is optional.

Signature

```java
public void setValidationStatus(String validationStatus)
```

Parameters

**validationStatus**
Type: String
An article validation status. These values are available in the ValidationStatus field on the KnowledgeArticleVersion object.

Return Value
Type: void

**QuestionSuggestionFilter Class**
The Search.QuestionSuggestionFilter class filters results from a call to System.Search.suggest(searchQuery, sObjectType, options) when the SOSL searchQuery contains a FeedItem object.

**Namespace**

Search

IN THIS SECTION:

QuestionSuggestionFilter Methods
QuestionSuggestionFilter Methods

The following are methods for QuestionSuggestionFilter.

IN THIS SECTION:

- **addGroupId(groupId)**
  Adds a filter to display questions associated with the single specified group whose ID is passed in as an argument. This filter is optional.

- **addNetworkId(networkId)**
  Adds a filter to display questions associated with the single specified network whose ID is passed in as an argument. This filter is optional.

- **addUserId(userId)**
  Adds a filter to display questions belonging to the single specified user whose ID is passed in as an argument. This filter is optional.

- **setGroupIds(groupIds)**
  Sets a new list of groups to replace the current list of groups where the group IDs are passed in as an argument. This filter is optional.

- **setNetworkIds(networkIds)**
  Sets a new list of networks to replace the current list of networks where the network IDs are passed in as an argument. This filter is optional.

- **setTopicId(topicId)**
  Sets a filter to display questions associated with the single specified topic whose ID is passed in as an argument. This filter is optional.

- **setUserIds(userIds)**
  Sets a new list of users to replace the current list of users where the users IDs are passed in as an argument. This filter is optional.

### addGroupId(groupId)

Adds a filter to display questions associated with the single specified group whose ID is passed in as an argument. This filter is optional.

**Signature**

```java
public void addGroupId(String groupId)
```

**Parameters**

- **groupId**
  Type: String
  The ID for a group.

**Return Value**

Type: void

**Usage**

To add more than one group, call the method multiple times.
**addNetworkId(networkId)**

Adds a filter to display questions associated with the single specified network whose ID is passed in as an argument. This filter is optional.

Signature

```java
public void addNetworkId(String networkId)
```

Parameters

`networkId`

Type: `String`

The ID of the community about which you're retrieving this information.

Return Value

Type: `void`

Usage

To add more than one network, call the method multiple times.

**addUserId(userId)**

Adds a filter to display questions belonging to the single specified user whose ID is passed in as an argument. This filter is optional.

Signature

```java
public void addUserId(String userId)
```

Parameters

`userId`

Type: `String`

The ID for the user.

Return Value

Type: `void`

Usage

To add more than one user, call the method multiple times.

**setGroupIds(groupIds)**

Sets a new list of groups to replace the current list of groups where the group IDs are passed in as an argument. This filter is optional.

Signature

```java
public void setGroupIds(List<String> groupIds)
```
Parameters

**groupId**
Type: *List<String>*
A list of group IDs.

Return Value
Type: *void*

**setNetworkIds** *(networkIds)*
Sets a new list of networks to replace the current list of networks where the network IDs are passed in as an argument. This filter is optional.

Signature

`public void setNetworkIds(List<String> networkIds)`

Parameters

**networkIds**
Type: *List<String>*
A list of network IDs.

Return Value
Type: *void*

**setTopicId** *(topicId)*
Sets a filter to display questions associated with the single specified topic whose ID is passed in as an argument. This filter is optional.

Signature

`public void setTopicId(String topicId)`

Parameters

**topicId**
Type: *String*
The ID for a topic.

Return Value
Type: *void*

**setUserIds** *(userIds)*
Sets a new list of users to replace the current list of users where the users IDs are passed in as an argument. This filter is optional.
Signature

```java
public void setUserIds(List<String> userIds)
```

Parameters

- `userIds`
  
  Type: `List<String>`
  
  A list of user IDs.

Return Value

Type: `void`

**SearchResult Class**

A wrapper object that contains an sObject and search metadata.

**Namespace**

`Search`

**SearchResult Methods**

The following are methods for `SearchResult`.

**IN THIS SECTION:**

- `getSObject()`
  Returns an sObject from a SearchResult object.

- `getSnippet(fieldName)`
  Returns a snippet from a Case, Feed, or Knowledge Article SearchResult object based on the specified field name.

- `getSnippet()`
  Returns a snippet from a SearchResult object based on the default field.

**`getSObject()`**

Returns an sObject from a SearchResult object.

Signature

```java
public SObject getSObject()
```
Return Value
Type: SObject

SEE ALSO:
    find(searchQuery)
    Dynamic SOSL

**getSnippet**(fieldName)
Returns a snippet from a Case, Feed, or Knowledge Article SearchResult object based on the specified field name.

Signature

```java
public String getSnippet(String fieldName)
```

Parameters

**fieldName**
Type: String
The field name to use for creating the snippet.
Valid values: Case.Casenumber, FeedPost.Title, KnowledgeArticleVersion.Title

Return Value
Type: String

SEE ALSO:
    find(searchQuery)
    Dynamic SOSL

**getSnippet()**
Returns a snippet from a SearchResult object based on the default field.

Signature

```java
public String getSnippet()
```

Return Value
Type: String

SEE ALSO:
    find(searchQuery)
    Dynamic SOSL
SearchResults Class

Wraps the results returned by the Search\:find\(\text{String}\) method.

Namespace

Search

SearchResults Methods

The following are methods for SearchResults.

IN THIS SECTION:

get\(\text{String} \)\n
Returns a list of Search\:SearchResult objects that contain an sObject of the specified type.

get\(\text{String} \)\n
Returns a list of Search\:SearchResult objects that contain an sObject of the specified type.

**Signature**

```java
public List<Search.SearchResult> get(String sObjectType)
```

**Parameters**

sObjectType
Type: String

The name of an sObject in the dynamic SOSL query passed to the Search\:find\(\text{String}\) method.

**Return Value**

Type: List<Search\:SearchResult>

**Usage**

SOSL queries passed to the Search\:find\(\text{String}\) method can return results for multiple objects. For example, the query

```java
Search\:find('FIND \'map\' IN ALL FIELDS RETURNING Account, Contact, Opportunity')
```

includes results for 3 objects. You can call get\(\text{String}\) to retrieve search results for 1 object at a time. For example, to get results for the Account object, call Search\:SearchResults\:get\('Account'\).

SEE ALSO:

find\(\text{String}\)

SearchResult Methods

Dynamic SOSL
SuggestionOption Class

Options that narrow record and article suggestion results returned from a call to System.Search.suggest(String, String, Search.SuggestionOption).

Namespace

Search

SuggestionOption Methods

The following are methods for SuggestionOption.

IN THIS SECTION:

- setFilter(knowledgeSuggestionFilter)
  Set filters that narrow Salesforce Knowledge article results in a call to System.Search.suggest(String, String, Search.SuggestionOption).
- setLimit(limit)
  The maximum number of record or article suggestions to retrieve.

**setFilter (knowledgeSuggestionFilter)**

Set filters that narrow Salesforce Knowledge article results in a call to System.Search.suggest(String, String, Search.SuggestionOption).

**Signature**

public void setFilter(Search.KnowledgeSuggestionFilter knowledgeSuggestionFilter)

**Parameters**

- knowledgeSuggestionFilter
  Type: KnowledgeSuggestionFilter
  An object containing filters that narrow the search results.

**Return Value**

Type: void

**Usage**

```java
Search.KnowledgeSuggestionFilter filters = new Search.KnowledgeSuggestionFilter();
filters.setLanguage('en_US');
filters.setPublishStatus('Online');
filters.setChannel('app');

Search.SuggestionOption options = new Search.SuggestionOption();
options.setFilter(filters);
```
Search.SuggestionResults suggestionResults = Search.suggest('all', 'KnowledgeArticleVersion', options);

for (Search.SuggestionResult searchResult : suggestionResults.getSuggestionResults()) {
    KnowledgeArticleVersion article = (KnowledgeArticleVersion)result.getSObject();
    System.debug(article.title);
}

`setLimit(limit)`
The maximum number of record or article suggestions to retrieve.

**Signature**

```
public void setLimit(Integer limit)
```

**Parameters**

`limit`

Type: `Integer`

The maximum number of record or article suggestions to retrieve.

**Return Value**

Type: `void`

**Usage**

By default, the `System.Search.suggest(String, String, Search.SuggestionOption)` method returns the 5 most relevant results. However, if your query is broad, it could match more than 5 results. If `Search.SuggestionResults.hasMoreResults()` returns `true`, there are more than 5 results. To retrieve them, call `setLimit(Integer)` to increase the number of suggestions results.

```
Search.SuggestionOption option = new Search.SuggestionOption();
option.setLimit(10);
Search.suggest('my query', 'mySObjectType', option);
```

**SuggestionResult Class**

A wrapper object that contains an `sObject`.

**Namespace**

`Search`

**SuggestionResult Methods**

The following are methods for `SuggestionResult`. 

2530
getSObject()  
Returns the sObject from a SuggestionResult object.

**Signature**

```java
public SObject getSObject()
```

**Return Value**

Type: SObject

---

**SuggestionResults Class**

Wraps the results returned by the `Search.suggest(String, String, Search.SuggestionOption)` method.

**Namespace**

`Search`

**SuggestionResults Methods**

The following are methods for `SuggestionResults`.

---

getSuggestionResults()  
Returns a list of SuggestionResult objects from the response to a call to `Search.suggest(String, String, Search.SuggestionOption)`.

**Signature**

```java
public List<Search.SuggestionResult> getSuggestionResults()
```

**Return Value**

Type: List<SuggestionResult>
**hasMoreResults()**

Indicates whether a call to `System.Search.suggest(String, String, Search.SuggestionOption)` has more results available than were returned.

**Signature**

```java
public Boolean hasMoreResults()
```

**Return Value**

Type: Boolean

**Usage**

If a limit isn’t specified, 5 records are returned in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`. If there are more suggested records than the limit specified, a call to `hasMoreResults()` returns `true`.

## Sfc Namespace

The `Sfc` namespace contains classes used in Salesforce Files.

The following are the classes in the `Sfc` namespace.

**IN THIS SECTION:**

- `ContentDownloadContext Enum`
  
  This enum specifies the download context.

- `ContentDownloadHandler Class`
  
  Use `ContentDownloadHandler` to define a custom download handler that controls how content is downloaded.

- `ContentDownloadHandlerFactory Interface`
  
  Use this interface to provide a class factory that Salesforce can call to create instances of your custom `ContentDownloadHandler`.

### ContentDownloadContext Enum

This enum specifies the download context.

**Enum Values**

The following are the values of the `Sfc.ContentDownloadContext` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHATTER</td>
<td>Download from Chatter.</td>
</tr>
<tr>
<td>CONTENT</td>
<td>Default value. Downloads from the Salesforce CRM Content product.</td>
</tr>
<tr>
<td>DELIVERY</td>
<td>Download of a content delivery.</td>
</tr>
<tr>
<td>MOBILE</td>
<td>Download from a mobile device.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>

</tbody>
</table>

**ContentDownloadHandler Class**

Use `ContentDownloadHandler` to define a custom download handler that controls how content is downloaded.

**Namespace**

*Sfc* on page 2532

**IN THIS SECTION:**

*ContentDownloadHandler Properties*

**ContentDownloadHandler Properties**

The following are properties for `ContentDownloadHandler`.

**IN THIS SECTION:**

*downloadErrorMessage*

A customized error message explaining why the download isn’t allowed.

*isDownloadAllowed*

Indicates whether or not download is allowed.

*redirectUrl*

The URL the user should be redirected to, for applying Information Rights Management (IRM) control, virus scanning, or other behavior.

**downloadErrorMessage**

A customized error message explaining why the download isn’t allowed.

**Signature**

```
public String downloadErrorMessage {get; set;}
```

**Property Value**

Type: *String*
This message is used if a redirectUrl is not provided. If the download is not allowed, Salesforce will throw a ContentCustomizedDownloadException exception that contains the downloadErrorMessage.

**isDownloadAllowed**
Indicates whether or not download is allowed.

Signature
```
public Boolean isDownloadAllowed {get; set;}
```

Property Value
Type: Boolean

**redirectUrl**
The URL the user should be redirected to, for applying Information Rights Management (IRM) control, virus scanning, or other behavior.

Signature
```
public String redirectUrl {get; set;}
```

Property Value
Type: String
The URL must be a valid relative URL. For example, the redirect can be a custom Visualforce page such as “/apex/IRMControl”. URLs with no path, such as “www.domain.com”, will result in an InvalidParameterValueException.

**ContentDownloadHandlerFactory Interface**
Use this interface to provide a class factory that Salesforce can call to create instances of your custom ContentDownloadHandler.

**Namespace**
Sfc on page 2532

**Usage**
ContentDownloadHandler getContentDownloadHandler(List<ID> ids, ContentDownloadContext context);

IN THIS SECTION:
- ContentDownloadHandlerFactory Methods
- ContentDownloadHandlerFactory Example Implementation

**ContentDownloadHandlerFactory Methods**
The following are methods for ContentDownloadHandlerFactory.
getContentDownloadHandler(var1, var2)
Returns a ContentDownloadHandler for a given list of content IDs and a download context.

**Signature**

```java
public Sfc.ContentDownloadHandler getContentDownloadHandler(List<Id> var1, Sfc.ContentDownloadContext var2)
```

**Parameters**

- **var1**
  - Type: `List<Id>`
- **var2**
  - Type: `Sfc.ContentDownloadContext` on page 2532

**Return Value**

Type: `Sfc.ContentDownloadHandler` on page 2533

**ContentDownloadHandlerFactory Example Implementation**

This example creates a class that implements the `Sfc.ContentDownloadHandlerFactory` interface and returns a download handler that blocks downloading content to mobile devices.

```java
// Allow customization of the content download experience
public class ContentDownloadHandlerFactoryImpl implements Sfc.ContentDownloadHandlerFactory {

    public Sfc.ContentDownloadHandler getContentDownloadHandler(Id id, Sfc.ContentDownloadContext context) {
        Sfc.ContentDownloadHandler contentDownloadHandler = new Sfc.ContentDownloadHandler();

        if (context == Sfc.ContentDownloadContext.MOBILE) {
            contentDownloadHandler.isDownloadAllowed = false;
            contentDownloadHandler.downloadErrorMessage = 'Downloading a file from a mobile device isn't allowed.';
        }
        return contentDownloadHandler;
    }
}
```
Site Namespace

The Site namespace provides an interface for rewriting Sites URLs.

The following is the interface in the Site namespace.

IN THIS SECTION:

UrlRewriter Interface
Enables rewriting Sites URLs.

Site Exceptions
The Site namespace contains an exception class.

UrlRewriter Interface
Enables rewriting Sites URLs.

Namespace
Site

Usage
Sites provides built-in logic that helps you display user-friendly URLs and links to site visitors. Create rules to rewrite URL requests typed into the address bar, launched from bookmarks, or linked from external websites. You can also create rules to rewrite the URLs for links within site pages. URL rewriting not only makes URLs more descriptive and intuitive for users, it allows search engines to better index your site pages.

For example, let's say that you have a blog site. Without URL rewriting, a blog entry's URL might look like this:
http://myblog.force.com/posts?id=003D000000Q0PcN

To rewrite URLs for a site, create an Apex class that maps the original URLs to user-friendly URLs, and then add the Apex class to your site.

UrlRewriter Methods
The following are methods for UrlRewriter. All are instance methods.

IN THIS SECTION:

generateUrlFor(salesforceUrls)
Maps a list of Salesforce URLs to a list of user-friendly URLs.

mapRequestUrl(userFriendlyUrl)
Maps a user-friendly URL to a Salesforce URL.

generateUrlFor(salesforceUrls)
Maps a list of Salesforce URLs to a list of user-friendly URLs.
Signature

```java
public System.PageReference[] generateUrlFor(System.PageReference[] salesforceUrls)
```

Parameters

- `salesforceUrls`
  - Type: `System.PageReference[]`

Return Value

- Type: `System.PageReference[]`

Usage

You can use `List<PageReference>` instead of `PageReference[]`, if you prefer.

**Important:** The size and order of the input list of Salesforce URLs must exactly correspond to the size and order of the generated list of user-friendly URLs. The `generateUrlFor` method maps input URLs to output URLs based on the order in the lists.

`mapRequestUrl(userFriendlyUrl)`

Maps a user-friendly URL to a Salesforce URL.

Signature

```java
public System.PageReference mapRequestUrl(System.PageReference userFriendlyUrl)
```

Parameters

- `userFriendlyUrl`
  - Type: `System.PageReference`

Return Value

- Type: `System.PageReference`

Site Exceptions

The `Site` namespace contains an exception class.

All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions.

The `Site` namespace contains this exception:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Site.ExternalUserCreateException</code></td>
<td>Unable to create external user</td>
<td>Use the <code>String getMessage()</code> to get the error message and write it to debug log.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Use <code>List&lt;String&gt; getDisplayMessages()</code> to get a list of errors displayed to the end user.</td>
</tr>
</tbody>
</table>

2537
Support Namespace

The Support namespace provides an interface used for Case Feed.

The following is the interface in the Support namespace.

IN THIS SECTION:

EmailTemplateSelector Interface
The Support.EmailTemplateSelector interface enables providing default email templates in Case Feed. With default email templates, specified email templates are preloaded for cases based on criteria such as case origin or subject.

MilestoneTriggerTimeCalculator Interface
The Support.MilestoneTriggerTimeCalculator interface calculates the time trigger for a milestone.

EmailTemplateSelector Interface

The Support.EmailTemplateSelector interface enables providing default email templates in Case Feed. With default email templates, specified email templates are preloaded for cases based on criteria such as case origin or subject.

Namespace
Support
To specify default templates, you must create a class that implements Support.EmailTemplateSelector.
When you implement this interface, provide an empty parameterless constructor.

IN THIS SECTION:

EmailTemplateSelector Methods
EmailTemplateSelector Example Implementation

EmailTemplateSelector Methods

The following are methods for EmailTemplateSelector.

IN THIS SECTION:

getDefaultTemplateId(caseId)
Returns the ID of the email template to preload for the case currently being viewed in the case feed using the specified case ID.

defaultGetTemplateId(caseId)
Returns the ID of the email template to preload for the case currently being viewed in the case feed using the specified case ID.
Signature

public ID getDefaultTemplateId(ID caseId)

Parameters

caseId
Type: ID

Return Value
Type: ID

EmailTemplateSelector Example Implementation

This is an example implementation of the Support.EmailTemplateSelector interface.

The getDefaultEmailTemplateId method implementation retrieves the subject and description of the case corresponding to the specified case ID. Next, it selects an email template based on the case subject and returns the email template ID.

```apex
global class MyCaseTemplateChooser implements Support.EmailTemplateSelector {

    // Empty constructor
    global MyCaseTemplateChooser() {

        // The main interface method
        global ID getDefaultEmailTemplateId(ID caseId) {
            // Select the case we're interested in, choosing any fields that are relevant to our decision
            Case c = [SELECT Subject, Description FROM Case WHERE Id=:caseId];

            EmailTemplate et;

            if (c.subject.contains('LX-1150')) {
                et = [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1150_template'];
            } else if (c.subject.contains('LX-1220')) {
                et = [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1220_template'];
            }

            // Return the ID of the template selected
            return et.id;
        }
    }
}
```

The following example tests the above code:

```apex
@isTest
private class MyCaseTemplateChooserTest {

    static testMethod void testChooseTemplate() {

        MyCaseTemplateChooser chooser = new MyCaseTemplateChooser();

        // Create a simulated case to test with
        Case c = new Case();
        c.Subject = 'I\'m having trouble with my LX-1150';
```
Database.insert(c);

// Make sure the proper template is chosen for this subject
Id actualTemplateId = chooser.getDefaultEmailTemplateId(c.Id);
EmailTemplate expectedTemplate =
   [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1150_template'];
Id expectedTemplateId = expectedTemplate.Id;
System.assertEquals(actualTemplateId, expectedTemplateId);

// Change the case properties to match a different template
    c.Subject = 'My LX1220 is overheating';
Database.update(c);

// Make sure the correct template is chosen in this case
    actualTemplateId = chooser.getDefaultEmailTemplateId(c.Id);
    expectedTemplate =
        [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1220_template'];
    expectedTemplateId = expectedTemplate.Id;
    System.assertEquals(actualTemplateId, expectedTemplateId);

MilestoneTriggerTimeCalculator Interface

The Support.MilestoneTriggerTimeCalculator interface calculates the time trigger for a milestone.

Namespace

Support

Implement the Support.MilestoneTriggerTimeCalculator interface to calculate a dynamic time trigger for a milestone based on the milestone type, the properties of the case, and case-related objects. To implement the Support.MilestoneTriggerTimeCalculator interface, you must first declare a class with the implements keyword as follows:

goal class Employee implements Support.MilestoneTriggerTimeCalculator {

Next, your class must provide an implementation for the following method:

goal Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId)

The implemented method must be declared as global or public.

IN THIS SECTION:
   MilestoneTriggerTimeCalculator Methods
   MilestoneTriggerTimeCalculator Example Implementation

MilestoneTriggerTimeCalculator Methods

The following are instance methods for MilestoneTriggerTimeCalculator.
IN THIS SECTION:

**calculateMilestoneTriggerTime(caseId, milestoneTypeId)**

Calculates the milestone trigger time based on the specified case and milestone type and returns the time in minutes.

**calculateMilestoneTriggerTime(caseId, milestoneTypeId)**

Calculates the milestone trigger time based on the specified case and milestone type and returns the time in minutes.

**Syntax**

```java
public Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId)
```

**Parameters**

*caseId*

Type: String

ID of the case the milestone is applied to.

*milestoneTypeId*

Type: String

ID of the milestone type.

**Return Value**

Type: Integer

The calculated trigger time in minutes.

**MilestoneTriggerTimeCalculator Example Implementation**

This sample class demonstrates the implementation of the `Support.MilestoneTriggerTimeCalculator` interface. In this sample, the case’s priority and the milestone `m1` determine that the time trigger is 18 minutes.

```java
global class myMilestoneTimeCalculator implements Support.MilestoneTriggerTimeCalculator {
    global Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId) {
        Case c = [SELECT Priority FROM Case WHERE Id=:caseId];
        MilestoneType mt = [SELECT Name FROM MilestoneType WHERE Id=:milestoneTypeId];
        if (c.Priority != null && c.Priority.equals('High')){
            if (mt.Name != null && mt.Name.equals('m1')) { return 7; }
            else { return 5; }
        } else { return 18; }
    }
}
```

This test class can be used to test the implementation of `Support.MilestoneTriggerTimeCalculator`.

```java
@isTest
private class MilestoneTimeCalculatorTest {
```
static testMethod void testMilestoneTimeCalculator() {

    // Select an existing milestone type to test with
    MilestoneType[] mtLst = [SELECT Id, Name FROM MilestoneType LIMIT 1];
    if(mtLst.size() == 0) { return; }
    MilestoneType mt = mtLst[0];

    // Create case data.
    // Typically, the milestone type is related to the case,
    // but for simplicity, the case is created separately for this test.
    Case c = new Case(priority = 'High');
    insert c;

    myMilestoneTimeCalculator calculator = new myMilestoneTimeCalculator();
    Integer actualTriggerTime = calculator.calculateMilestoneTriggerTime(c.Id, mt.Id);

    if(mt.name != null && mt.Name.equals('m1')) {
        System.assertEquals(actualTriggerTime, 7);
    } else {
        System.assertEquals(actualTriggerTime, 5);
    }
    c.priority = 'Low';
    update c;
    actualTriggerTime = calculator.calculateMilestoneTriggerTime(c.Id, mt.Id);
    System.assertEquals(actualTriggerTime, 18);
}

System Namespace

The System namespace provides classes and methods for core Apex functionality. The following are the classes in the System namespace.

IN THIS SECTION:

AccessType Enum
Specifies the access check type for the fields of an sObject.

Address Class
Contains methods for accessing the component fields of address compound fields.

Answers Class
Represents zone answers.

ApexPages Class
Use ApexPages to add and check for messages associated with the current page, as well as to reference the current page.

Approval Class
Contains methods for processing approval requests and setting approval-process locks and unlocks on records.
Blob Class
Contains methods for the Blob primitive data type.

Boolean Class
Contains methods for the Boolean primitive data type.

BusinessHours Class
Use the BusinessHours methods to set the business hours at which your customer support team operates.

Callable Interface
Enables developers to use a common interface to build loosely coupled integrations between Apex classes or triggers, even for code in separate packages. Agreeing upon a common interface enables developers from different companies or different departments to build upon one another’s solutions. Implement this interface to enable the broader community, which might have different solutions than the ones you had in mind, to extend your code’s functionality.

Cases Class
Use the Cases class to interact with case records.

Comparable Interface
Adds sorting support for Lists that contain non-primitive types, that is, Lists of user-defined types.

Continuation Class
Use the Continuation class to make callouts asynchronously to a SOAP or REST Web service.

Cookie Class
The Cookie class lets you access cookies for your Salesforce site using Apex.

Crypto Class
Provides methods for creating digests, message authentication codes, and signatures, as well as encrypting and decrypting information.

Custom Settings Methods
Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data can then be used by formula fields, validation rules, flows, Apex, and the SOAP API.

Database Class
Contains methods for creating and manipulating data.

Date Class
Contains methods for the Date primitive data type.

Datetime Class
Contains methods for the Datetime primitive data type.

Decimal Class
Contains methods for the Decimal primitive data type.

Double Class
Contains methods for the Double primitive data type.

EncodingUtil Class
Use the methods in the EncodingUtil class to encode and decode URL strings, and convert strings to hexadecimal format.

Enum Methods
An enum is an abstract data type with values that each take on exactly one of a finite set of identifiers that you specify. Apex provides built-in enums, such as LoggingLevel, and you can define your own enum.
EventBus Class
Contains methods for publishing platform events.

Exception Class and Built-In Exceptions
An exception denotes an error that disrupts the normal flow of code execution. You can use Apex built-in exceptions or create custom exceptions. All exceptions have common methods.

FlexQueue Class
Contains methods that reorder batch jobs in the Apex flex queue.

FeatureManagement Class
Use the methods in the System.FeatureManagement class to check and modify the values of feature parameters, and to show or hide custom objects and custom permissions in your subscribers’ orgs.

Formula Class
Contains the recalculateFormulas method that updates (recalculates) all formula fields on the input SObjects.

FormulaRecalcFieldError Class
The return type of the FormulaRecalcResult.getErrors method.

FormulaRecalcResult Class
The return type of the Formula.recalculateFormulas method.

Http Class
Use the Http class to initiate an HTTP request and response.

HttpServletRequest Mock Interface
Enables sending fake responses when testing HTTP callouts.

HttpRequest Class
Use the HttpRequest class to programmatically create HTTP requests like GET, POST, PUT, and DELETE.

HttpResponse Class
Use the HttpResponse class to handle the HTTP response returned by the Http class.

Id Class
Contains methods for the ID primitive data type.

I ideas Class
Represents zone ideas.

InstallHandler Interface
Enables custom code to run after a managed package installation or upgrade.

Integer Class
Contains methods for the Integer primitive data type.

JSON Class
Contains methods for serializing Apex objects into JSON format and deserializing JSON content that was serialized using the serialize method in this class.

JSONGenerator Class
Contains methods used to serialize objects into JSON content using the standard JSON encoding.

JSONParser Class
Represents a parser for JSON-encoded content.

JSONToken Enum
Contains all token values used for parsing JSON content.
Limits Class
Contains methods that return limit information for specific resources.

List Class
Contains methods for the List collection type.

Location Class
Contains methods for accessing the component fields of geolocation compound fields.

Long Class
Contains methods for the Long primitive data type.

Map Class
Contains methods for the Map collection type.

Matcher Class
Matchers use Patterns to perform match operations on a character string.

Math Class
Contains methods for mathematical operations.

Messaging Class
Contains messaging methods used when sending a single or mass email.

MultiStaticResourceCalloutMock Class
Utility class used to specify a fake response using multiple resources for testing HTTP callouts.

Network Class
Represents a community.

OrgLimit Class
Contains methods that provide the name, maximum value, and current value of an org limit.

OrgLimits Class
Contains methods that provide a list or map of all OrgLimit instances for Salesforce your org, such as SOAP API requests, Bulk API requests, and Streaming API limits.

PageReference Class
A PageReference is a reference to an instantiation of a page. Among other attributes, PageReferences consist of a URL and a set of query parameter names and values.

Packaging Class
Contains a method for obtaining information about managed and unlocked packages.

getCurrentPackageId()
Returns the context packageID in managed and unlocked packages.

Pattern Class
Represents a compiled representation of a regular expression.

Queueable Interface
Enables the asynchronous execution of Apex jobs that can be monitored.

QueueableContext Interface
Represents the parameter type of the execute() method in a class that implements the Queueable interface and contains the job ID. This interface is implemented internally by Apex.
QuickAction Class
Use Apex to request and process actions on objects that allow custom fields, on objects that appear in a Chatter feed, or on objects that are available globally.

RemoteObjectController
Use RemoteObjectController to access the standard Visualforce Remote Objects operations in your Remote Objects override methods.

ResetPasswordResult Class
Represents the result of a password reset.

RestContext Class
Contains the RestRequest and RestResponse objects.

RestRequest Class
Represents an object used to pass data from an HTTP request to an Apex RESTful Web service method.

RestResponse Class
Represents an object used to pass data from an Apex RESTful Web service method to an HTTP response.

SandboxPostCopy Interface
To make your sandbox environment business ready, automate data manipulation or business logic tasks. Extend this interface and add methods to perform post-copy tasks, then specify the class during sandbox creation.

Schedulable Interface
The class that implements this interface can be scheduled to run at different intervals.

SchedulableContext Interface
Represents the parameter type of a method in a class that implements the Schedulable interface and contains the scheduled job ID. This interface is implemented internally by Apex.

Schema Class
Contains methods for obtaining schema describe information.

Search Class
Use the methods of the Search class to perform dynamic SOSL queries.

Security Class (Beta)
Contains methods to securely implement Apex applications.

SelectOption Class
A SelectOption object specifies one of the possible values for a Visualforce selectCheckboxes, selectList, or selectRadio component.

Set Class
Represents a collection of unique elements with no duplicate values.

Site Class
Use the Site Class to manage your Lightning Platform sites.

SObject Class
Contains methods for the sObject data type.

SObjectAccessDecision Class
Contains the results of a call to the Security.stripInaccessible method and methods to retrieve those results.

StaticResourceCalloutMock Class
Utility class used to specify a fake response for testing HTTP callouts.
String Class
Contains methods for the String primitive data type.

StubProvider Interface
StubProvider is a callback interface that you can use as part of the Apex stub API to implement a mocking framework. Use this interface with the Test.createStub() method to create stubbed Apex objects for testing.

System Class
Contains methods for system operations, such as writing debug messages and scheduling jobs.

Test Class
Contains methods related to Apex tests.

Time Class
Contains methods for the Time primitive data type.

TimeZone Class
Represents a time zone. Contains methods for creating a new time zone and obtaining time zone properties, such as the time zone ID, offset, and display name.

Trigger Class
Use the Trigger class to access run-time context information in a trigger, such as the type of trigger or the list of sObject records that the trigger operates on.

TriggerOperation Enum
System.TriggerOperation enum values are associated with trigger events.

Type Class
Contains methods for getting the Apex type that corresponds to an Apex class and for instantiating new types.

UninstallHandler Interface
Enables custom code to run after a managed package is uninstalled.

URL Class
Represents a uniform resource locator (URL) and provides access to parts of the URL. Enables access to the Salesforce instance URL.

UserInfo Class
Contains methods for obtaining information about the context user.

UserManagement Class
Contains methods to manage end users, for example, to register their verification methods, verify their identity, or remove their personal information.

Version Class
Use the Version methods to get the version of a managed package of a subscriber and to compare package versions.

WebServiceCallout Class
Enables making callouts to SOAP operations on an external Web service. This class is used in the Apex stub class that is auto-generated from a WSDL.

WebServiceMock Interface
Enables sending fake responses when testing Web service callouts of a class auto-generated from a WSDL.

XmlStreamReader Class
The XmlStreamReader class provides methods for forward, read-only access to XML data. You can pull data from XML or skip unwanted events. You can parse nested XML content that’s up to 50 nodes deep.
XmlStreamWriter Class

The XmlStreamWriter class provides methods for writing XML data.

AccessType Enum

Specifies the access check type for the fields of an sObject.

Usage

Use these enum values for the accessCheckType parameter of the stripInaccessible method.

Enum Values

The following are the values of the System.AccessType enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATABLE</td>
<td>Check the fields of an sObject for create access.</td>
</tr>
<tr>
<td>READABLE</td>
<td>Check the fields of an sObject for read access.</td>
</tr>
<tr>
<td>UPDATABLE</td>
<td>Check the fields of an sObject for update access.</td>
</tr>
<tr>
<td>UPSERTABLE</td>
<td>Check the fields of an sObject for insert and update access.</td>
</tr>
</tbody>
</table>

Address Class

Contains methods for accessing the component fields of address compound fields.

Namespace

System

Usage

Each of these methods is also equivalent to a read-only property. For each getter method, you can access the property using dot notation. For example, myAddress.getCity() is equivalent to myAddress.city.

You can’t use dot notation to access compound fields’ subfields directly on the parent field. Instead, assign the parent field to a variable of type Address, and then access its components. For example, to access the City field in myAccount.BillingAddress, do the following:

```java
Address addr = myAccount.BillingAddress;
String acctCity = addr.City;
```

Important: “Address” in Salesforce can also refer to the Address standard object. When referencing the Address object in your Apex code, always use Schema.Address instead of Address to prevent confusion with the standard Address compound field. If referencing both the Address object and the Address standard field in the same snippet, you can differentiate between the two by using System.Address for the field and Schema.Address for the object.

Example

// Select and access Address fields.
// Call the getDistance() method in different ways.
Account[] records = [SELECT id, BillingAddress FROM Account LIMIT 10];
for (Account acct : records) {
    Address addr = acct.BillingAddress;
    Double lat = addr.latitude;
    Double lon = addr.longitude;
    Location loc1 = Location.newInstance(30.1944,-97.6682);
    Double apexDist1 = addr.getDistance(loc1, 'mi');
    Double apexDist2 = loc1.getDistance(addr, 'mi');
    System.assertEquals(apexDist1, apexDist2);
    Double apexDist3 = Location.getDistance(addr, loc1, 'mi');
    System.assertEquals(apexDist2, apexDist3);
}

IN THIS SECTION:

Address Methods

The following are methods for Address.

IN THIS SECTION:

getCity()
Returns the city field of this address.

getCountry()
Returns the text-only country name component of this address.

getCountryCode()
Returns the country code of this address if state and country picklists are enabled in your organization. Otherwise, returns null.

getDistance(toLocation, unit)
Returns the distance from this location to the specified location using the specified unit.

getGeocodeAccuracy()
When using geolocation data for a given address, this method gives you relative location information based on latitude and longitude values. For example, you can find out if the latitude and longitude values point to the middle of the street, instead of the exact address.

gGetLatitude()
Returns the latitude field of this address.

gGetLongitude()
Returns the longitude field of this address.

gGetPostalCode()
Returns the postal code of this address.

gGetState()
Returns the text-only state name component of this address.
getStateCode()
Returns the state code of this address if state and country picklists are enabled in your organization. Otherwise, returns null.

getStreet()
Returns the street field of this address.

getCity()
Returns the city field of this address.

Signature
public String getCity()

Return Value
Type: String

gCountry()()
Returns the text-only country name component of this address.

Signature
public String getCountry()

Return Value
Type: String

gCountryCode()()
Returns the country code of this address if state and country picklists are enabled in your organization. Otherwise, returns null.

Signature
public String getCountryCode()

Return Value
Type: String

gDistance(toLocation, unit)
Returns the distance from this location to the specified location using the specified unit.

Signature
public Double getDistance(Location toLocation, String unit)
Parameters

toLocation
  Type: Location
  The Location to which you want to calculate the distance from the current Location.

unit
  Type: String
  The distance unit you want to use: mi or km.

Return Value
Type: Double

getGeocodeAccuracy()
When using geolocation data for a given address, this method gives you relative location information based on latitude and longitude values. For example, you can find out if the latitude and longitude values point to the middle of the street, instead of the exact address.

Signature
public String getGeocodeAccuracy()

Return Value
Type: String
The getGeocodeAccuracy() return value tells you more about the location at a latitude and longitude for a given address. For example, Zip means the latitude and longitude point to the center of the zip code area, in case a match for an exact street address can’t be found.

<table>
<thead>
<tr>
<th>Accuracy Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address</td>
<td>In the same building</td>
</tr>
<tr>
<td>NearAddress</td>
<td>Near the address</td>
</tr>
<tr>
<td>Block</td>
<td>Midway point of the block</td>
</tr>
<tr>
<td>Street</td>
<td>Midway point of the street</td>
</tr>
<tr>
<td>ExtendedZip</td>
<td>Center of the extended zip code area</td>
</tr>
<tr>
<td>Zip</td>
<td>Center of the zip code area</td>
</tr>
<tr>
<td>Neighborhood</td>
<td>Center of the neighborhood</td>
</tr>
<tr>
<td>City</td>
<td>Center of the city</td>
</tr>
<tr>
<td>County</td>
<td>Center of the county</td>
</tr>
<tr>
<td>State</td>
<td>Center of the state</td>
</tr>
<tr>
<td>Unknown</td>
<td>No match for the address was found</td>
</tr>
</tbody>
</table>
Geocodes are added only for some standard addresses.

- Billing Address on accounts
- Shipping Address on accounts
- Mailing Address on contacts
- Address on leads

Person accounts are not supported.

**Note:** For `getGeocodeAccuracy()` to work, set up and activate the geocode data integration rules for the related address fields.

### getLatitude()

Returns the latitude field of this address.

**Signature**

```java
public Double getLatitude()
```

**Return Value**

Type: `Double`

### getLongitude()

Returns the longitude field of this address.

**Signature**

```java
public Double getLongitude()
```

**Return Value**

Type: `Double`

### getPostalCode()

Returns the postal code of this address.

**Signature**

```java
public String getPostalCode()
```

**Return Value**

Type: `String`

### getState()

Returns the text-only state name component of this address.
Signature
public String getState()

Return Value
Type: String

gStateCode()
Returns the state code of this address if state and country picklists are enabled in your organization. Otherwise, returns null.

Signature
public String getStateCode()

Return Value
Type: String

gStreet()
Returns the street field of this address.

Signature
public String getStreet()

Return Value
Type: String

Answers Class
Represents zone answers.

Namespace
System

Usage
Answers is a feature of the Community application that enables users to ask questions and have community members post replies. Community members can then vote on the helpfulness of each reply, and the person who asked the question can mark one reply as the best answer.
For more information on answers, see “Answers Overview” in the Salesforce online help.
Example
The following example finds questions in an internal zone that have similar titles as a new question:

```java
public class FindSimilarQuestionController {

    public static void test() {
        // Instantiate a new question
        Question question = new Question ();

        // Specify a title for the new question
        question.title = 'How much vacation time do full-time employees get?';

        // Specify the communityID (INTERNAL_COMMUNITY) in which to find similar questions.
        Community community = [ SELECT Id FROM Community WHERE Name = 'INTERNAL_COMMUNITY' ];

        question.communityId = community.id;

        ID[] results = Answers.findSimilar(question);
    }
}
```

The following example marks a reply as the best reply:

```java
ID questionId = [SELECT Id FROM Question WHERE Title = 'Testing setBestReplyId' LIMIT 1].Id;
ID replyID = [SELECT Id FROM Reply WHERE QuestionId = :questionId LIMIT 1].Id;
Answers.setBestReply(questionId, replyId);
```

Answers Methods
The following are methods for `Answers`. All methods are static.

IN THIS SECTION:

- **findSimilar(yourQuestion)**
  Returns a list of similar questions based on the title of the specified question.
- **setBestReply(questionId, replyId)**
  Sets the specified reply for the specified question as the best reply. Because a question can have multiple replies, setting the best reply helps users quickly identify the reply that contains the most helpful information.

**findSimilar(yourQuestion)**
Returns a list of similar questions based on the title of the specified question.

Signature

```java
public static ID[] findSimilar(Question yourQuestion)
```

Parameters

- **yourQuestion**
  Type: Question
Return Value
Type: ID[]

Usage
Each findSimilar call counts against the SOSL statements governor limit allowed for the process.

**setBestReply(questionId, replyId)**

Sets the specified reply for the specified question as the best reply. Because a question can have multiple replies, setting the best reply helps users quickly identify the reply that contains the most helpful information.

**Signature**

```java
public static Void setBestReply(String questionId, String replyId)
```

**Parameters**

- `questionId`
  Type: String
- `replyId`
  Type: String

**Return Value**
Type: Void

**ApexPages Class**

Use ApexPages to add and check for messages associated with the current page, as well as to reference the current page.

**Namespace**

System

**Usage**

In addition, ApexPages is used as a namespace for the PageReference Class and the Message Class.

**ApexPages Methods**

The following are methods for ApexPages. All are instance methods.

**IN THIS SECTION:**

- `addMessage(message)`
  Add a message to the current page context.
- `addMessages(exceptionThrown)`
  Adds a list of messages to the current page context based on a thrown exception.
currentPage()
Returns the current page's PageReference.

getMessages()
Returns a list of the messages associated with the current context.

hasMessages()
Returns true if there are messages associated with the current context, false otherwise.

hasMessages(severity)
Returns true if messages of the specified severity exist, false otherwise.

addMessage (message)
Add a message to the current page context.

Signature
public Void addMessage(ApexPages.Message message)

Parameters
message
Type: ApexPages.Message

Return Value
Type: Void

addMessages (exceptionThrown)
Adds a list of messages to the current page context based on a thrown exception.

Signature
public Void addMessages(Exception exceptionThrown)

Parameters
exceptionThrown
Type: Exception

Return Value
Type: Void

currentPage()
Returns the current page's PageReference.
**currentPage()**

**Signature**

public System.PageReference currentPage()

**Return Value**

Type: System.PageReference

**Example**

This code segment returns the id parameter of the current page.

```java
public MyController() {
    account = [
        SELECT Id, Name, Site
        FROM Account
        WHERE Id = :ApexPages.currentPage().getParameters().get('id')
    ];
}
```

**getMessages()**

Returns a list of the messages associated with the current context.

**Signature**

public ApexPages.Message[] getMessages()

**Return Value**

Type: ApexPages.Message[]

**hasMessages()**

Returns true if there are messages associated with the current context, false otherwise.

**Signature**

public Boolean hasMessages()

**Return Value**

Type: Boolean

**hasMessages(severity)**

Returns true if messages of the specified severity exist, false otherwise.
Signature

```public Boolean hasMessages(ApexPages.Severity severity)```

Parameters

`sev`

Type: `ApexPages.Severity`

Return Value

Type: `Boolean`

Approval Class

Contains methods for processing approval requests and setting approval-process locks and unlocks on records.

Namespace

`System`

Usage

Salesforce admins can edit locked records. Depending on your approval process configuration settings, an assigned approver can also edit locked records. Locks and unlocks that are set programmatically use the same record editability settings as other approval-process locks and unlocks.

Record locks and unlocks are treated as DML. They're blocked before a callout, they count toward your DML limits, and if a failure occurs, they're rolled back along with the rest of your transaction. To change this rollback behavior, use an `allOrNone` parameter.

Approval is also used as a namespace for the `ProcessRequest` and `ProcessResult` classes.

SEE ALSO:

`Approval Process Considerations`

Approval Methods

The following are methods for `Approval`. All methods are static.

IN THIS SECTION:

`isLocked(id)`

Returns `true` if the record with the ID `id` is locked, or `false` if it's not.

`isLocked(ids)`

Returns a map of record IDs and their lock statuses. If the record is locked the status is `true`. If the record is not locked the status is `false`.

`isLocked(sobject)`

Returns `true` if the `sobject` record is locked, or `false` if it's not.

`isLocked(sobjects)`

Returns a map of record IDs to lock statuses. If the record is locked the status is `true`. If the record is not locked the status is `false`. 
lock(recordId)
Locks an object, and returns the lock results.

lock(recordIds)
Locks a set of objects, and returns the lock results, including failures.

lock(recordToLock)
Locks an object, and returns the lock results.

lock(recordsToLock)
Locks a set of objects, and returns the lock results, including failures.

lock(recordId, allOrNothing)
Locks an object, with the option for partial success, and returns the lock result.

lock(recordIds, allOrNothing)
Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

lock(recordToLock, allOrNothing)
Locks an object, with the option for partial success, and returns the lock result.

lock(recordsToLock, allOrNothing)
Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

process(approvalRequest)
Submits a new approval request and approves or rejects existing approval requests.

process(approvalRequest, allOrNone)
Submits a new approval request and approves or rejects existing approval requests.

process(approvalRequests)
Submits a list of new approval requests, and approves or rejects existing approval requests.

process(approvalRequests, allOrNone)
Submits a list of new approval requests, and approves or rejects existing approval requests.

unlock(recordId)
Unlocks an object, and returns the unlock results.

unlock(recordIds)
Unlocks a set of objects, and returns the unlock results, including failures.

unlock(recordToUnlock)
Unlocks an object, and returns the unlock results.

unlock(recordsToUnlock)
Unlocks a set of objects, and returns the unlock results, including failures.

unlock(recordId, allOrNothing)
Unlocks an object, with the option for partial success, and returns the unlock result.

unlock(recordIds, allOrNothing)
Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

unlock(recordToUnlock, allOrNothing)
Unlocks an object, with the option for partial success, and returns the unlock result.

unlock(recordsToUnlock, allOrNothing)
Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.
**isLocked(id)**

Returns `true` if the record with the ID `id` is locked, or `false` if it's not.

Signature

```java
public static Boolean isLocked(Id id)
```

Parameters

`id`

Type: `Id`

The ID of the record whose lock or unlock status is in question.

Return Value

Type: `Boolean`

**isLocked(ids)**

Returns a map of record IDs and their lock statuses. If the record is locked the status is `true`. If the record is not locked the status is `false`.

Signature

```java
public static Map<Id,Boolean> isLocked(List<Id> ids)
```

Parameters

`ids`

Type: `List<Id>`

The IDs of the records whose lock or unlock statuses are in question.

Return Value

Type: `Map<Id,Boolean>`

**isLocked(sobject)**

Returns `true` if the `sobject` record is locked, or `false` if it's not.

Signature

```java
public static Boolean isLocked(SObject sobject)
```

Parameters

`sobject`

Type: `SObject`

The record whose lock or unlock status is in question.
Return Value
Type: Boolean

**isLocked(sobjects)**
Returns a map of record IDs to lock statuses. If the record is locked the status is true. If the record is not locked the status is false.

Signature
```
public static Map<Id,Boolean> isLocked(List<SObject> sobjects)
```

Parameters
sobjects
  Type: List<SObject>
  The records whose lock or unlock statuses are in question.

Return Value
Type: Map<Id,Boolean>

**lock(recordId)**
Locks an object, and returns the lock results.

Signature
```
public static Approval.LockResult lock(Id recordId)
```

Parameters
recordId
  Type: Id
  ID of the object to lock.

Return Value
Type: Approval.LockResult

**lock(recordIds)**
Locks a set of objects, and returns the lock results, including failures.

Signature
```
public static List<Approval.LockResult> lock(List<Id> ids)
```
Parameters

.ids
  Type: List<Id>
  IDs of the objects to lock.

Return Value
Type: List<Approval.LockResult>

lock(recordToLock)
Locks an object, and returns the lock results.

Signature
public static Approval.LockResult lock(SObject recordToLock)

Parameters

recordToLock
  Type: SObject

Return Value
Type: Approval.LockResult

lock(recordsToLock)
Locks a set of objects, and returns the lock results, including failures.

Signature
public static List<Approval.LockResult> lock(List<SObject> recordsToLock)

Parameters

recordsToLock
  Type: List<SObject>

Return Value
Type: List<Approval.LockResult>

lock(recordId, allOrNothing)
Locks an object, with the option for partial success, and returns the lock result.

Signature
public static Approval.LockResult lock(Id recordId, Boolean allOrNothing)
Parameters

`recordId`
- **Type:** Id
  - ID of the object to lock.

`allOrNothing`
- **Type:** Boolean
  - Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
- **Type:** Approval.LockResult

**lock(recordIds, allOrNothing)**
Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

**Signature**

```
public static List<Approval.LockResult> lock(List<Id> recordIds, Boolean allOrNothing)
```

Parameters

`recordIds`
- **Type:** List<Id>
  - IDs of the objects to lock.

`allOrNothing`
- **Type:** Boolean
  - Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
- **Type:** List<Approval.LockResult>

**lock(recordToLock, allOrNothing)**
Locks an object, with the option for partial success, and returns the lock result.

**Signature**

```
public static Approval.LockResult lock(SObject recordToLock, Boolean allOrNothing)
```

Parameters

`recordToLock`
- **Type:** SObject
**allOrNothing**

Type: `Boolean`

Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

**Return Value**

Type: `Approval.LockResult`

**lock(recordsToLock, allOrNothing)**

Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

**Signature**

```java
public static List<Approval.LockResult> lock(List<SObject> recordsToLock, Boolean allOrNothing)
```

**Parameters**

- `recordsToLock`
  Type: `List<SObject>`

- `allOrNothing`
  Type: `Boolean`  

  Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

**Return Value**

Type: `List<Approval.LockResult>`

**process(approvalRequest)**

Submits a new approval request and approves or rejects existing approval requests.

**Signature**

```java
public static Approval.ProcessResult process(Approval.ProcessRequest approvalRequest)
```

**Parameters**

- `approvalRequest`
  Type: `Approval.ProcessRequest`

**Return Value**

Type: `Approval.ProcessResult`
Example

```java
// Insert an account
Account a = new Account(Name='Test',
    annualRevenue=100.0);

insert a;

// Create an approval request for the account
Approval.ProcessSubmitRequest req1 =
    new Approval.ProcessSubmitRequest();
req1.setObjectId(a.id);

// Submit the approval request for the account
Approval.ProcessResult result =
    Approval.process(req1);
```

**process(approvalRequest, allOrNone)**

Submits a new approval request and approves or rejects existing approval requests.

**Signature**

```java
public static Approval.ProcessResult process(Approval.ProcessRequest approvalRequest,
    Boolean allOrNone)
```

**Parameters**

- **approvalRequest**
  - Type: Approval.ProcessRequest

- **allOrNone**
  - Type: Boolean

  The optional `allOrNone` parameter specifies whether the operation allows for partial success. If you specify `false` for this parameter and an approval fails, the remainder of the approval processes can still succeed.

**Return Value**

Approval.ProcessResult

**process(approvalRequests)**

Submits a list of new approval requests, and approves or rejects existing approval requests.

**Signature**

```java
public static Approval.ProcessResult [] process(Approval.ProcessRequest[]
    approvalRequests)
```
Parameters

approvalRequests
  Approval.ProcessRequest []

Return Value

Approval.ProcessResult []

**process(approvalRequests, allOrNone)**

Submits a list of new approval requests, and approves or rejects existing approval requests.

Signature

```java
public static Approval.ProcessResult [] process(Approval.ProcessRequest[] approvalRequests, Boolean allOrNone)
```

Parameters

approvalRequests
  Approval.ProcessRequest []

allOrNone
  Type: Boolean
  The optional *allOrNone* parameter specifies whether the operation allows for partial success. If you specify *false* for this parameter and an approval fails, the remainder of the approval processes can still succeed.

Return Value

Approval.ProcessResult []

**unlock(recordId)**

Unlocks an object, and returns the unlock results.

Signature

```java
public static Approval.UnlockResult unlock(Id recordId)
```

Parameters

recordId
  Type: Id
  ID of the object to unlock.

Return Value

Type: Approval.UnlockResult
unlock(recordIds)
Unlocks a set of objects, and returns the unlock results, including failures.

Signature
public static List<Approval.UnlockResult> unlock(List<Id> recordIds)

Parameters
recordIds
Type: List<Id>
IDs of the objects to unlock.

Return Value
Type: List<Approval.UnlockResult>

unlock(recordToUnlock)
Unlocks an object, and returns the unlock results.

Signature
public static Approval.UnlockResult unlock(SObject recordToUnlock)

Parameters
recordToUnlock
Type: SObject

Return Value
Type: Approval.UnlockResult

unlock(recordsToUnlock)
Unlocks a set of objects, and returns the unlock results, including failures.

Signature
public static List<Approval.UnlockResult> unlock(List<SObject> recordsToUnlock)

Parameters
recordsToUnlock
Type: List<SObject>

Return Value
Type: List<Approval.UnlockResult>
**unlock(recordId, allOrNothing)**

Unlocks an object, with the option for partial success, and returns the unlock result.

**Signature**

```java
public static Approval.UnlockResult unlock(Id recordId, Boolean allOrNothing)
```

**Parameters**

- **recordId**
  - Type: Id
  - ID of the object to lock.

- **allOrNothing**
  - Type: Boolean
  - Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

**Return Value**

- Type: Approval.UnlockResult

**unlock(recordIds, allOrNothing)**

Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

**Signature**

```java
public static List<Approval.UnlockResult> unlock(List<Id> recordIds, Boolean allOrNothing)
```

**Parameters**

- **recordIds**
  - Type: List<Id>
  - IDs of the objects to unlock.

- **allOrNothing**
  - Type: Boolean
  - Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

**Return Value**

- Type: List<Approval.UnlockResult>

**unlock(recordToUnlock, allOrNothing)**

Unlocks an object, with the option for partial success, and returns the unlock result.
Signature

```
public static Approval.UnlockResult unlock(SObject recordToUnlock, Boolean allOrNothing)
```

Parameters

- `recordToUnlock`
  Type: `SObject`
- `allOrNothing`
  Type: `Boolean`

  Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value

Type: `Approval.UnlockResult`

```
unlock(recordsToUnlock, allOrNothing)
```

Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

Signature

```
public static List<Approval.UnlockResult> unlock(List<SObject> recordsToUnlock, Boolean allOrNothing)
```

Parameters

- `recordsToUnlock`
  Type: `List<SObject>`
- `allOrNothing`
  Type: `Boolean`

  Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value

Type: `List<Approval.UnlockResult>`

**Blob Class**

Contains methods for the Blob primitive data type.

**Namespace**

`System`
Usage
For more information on Blobs, see Primitive Data Types on page 26.

Blob Methods
The following are methods for Blob.

IN THIS SECTION:

size()
Returns the number of characters in the Blob.

toPdf(stringToConvert)
Creates a binary object out of the given string, encoding it as a PDF file.

toString()
Casts the Blob into a String.

valueOf(stringToBlob)
Casts the specified String to a Blob.

size()
Returns the number of characters in the Blob.

Signature
public Integer size()

Return Value
Type: Integer

Example

```java
String myString = 'StringToBlob';
Blob myBlob = Blob.valueOf(myString);
Integer size = myBlob.size();
```

toPdf(stringToConvert)
Creates a binary object out of the given string, encoding it as a PDF file.

Signature
public static Blob toPdf(String stringToConvert)

Parameters

stringToConvert
Type: String
Return Value
Type: Blob

Example

```java
String pdfContent = 'This is a test string';
Account a = new account(name = 'test');
insert a;
Attachment attachmentPDF = new Attachment();
attachmentPdf.parentId = a.id;
attachmentPdf.name = a.name + '.pdf';
attachmentPdf.body = blob.toPDF(pdfContent);
insert attachmentPDF;
```

**toString()**
Casts the Blob into a String.

**Signature**

```java
public String toString()
```

**Return Value**
Type: String

**Example**

```java
String myString = 'StringToBlob';
Blob myBlob = Blob.valueOf(myString);
System.assertEquals('StringToBlob', myBlob.toString());
```

**valueOf(stringToBlob)**
Casts the specified String to a Blob.

**Signature**

```java
public static Blob valueOf(String stringToBlob)
```

**Parameters**

`stringToBlob`
Type: String

**Return Value**
Type: Blob
Example

```java
String myString = 'StringToBlob';
Blob myBlob = Blob.valueOf(myString);
```

**Boolean Class**

Contains methods for the Boolean primitive data type.

**Namespace**

`System`

**Boolean Methods**

The following are methods for `Boolean`. All methods are static.

IN THIS SECTION:

- `valueOf(stringToBoolean)`: Converts the specified string to a Boolean value and returns `true` if the specified string value is `true`. Otherwise, returns `false`.
- `valueOf(fieldValue)`: Converts the specified object to a Boolean value. Use this method to convert a history tracking field value or an object that represents a Boolean value.

### `valueOf(stringToBoolean)`

Converts the specified string to a Boolean value and returns `true` if the specified string value is `true`. Otherwise, returns `false`.

**Signature**

```java
public static Boolean valueOf(String stringToBoolean)
```

**Parameters**

- `stringToBoolean`  
  Type: `String`

**Return Value**

Type: `Boolean`

**Usage**

If the specified argument is null, this method throws an exception.

**Example**

```java
Boolean b = Boolean.valueOf('true');
System.assertEquals(true, b);
```
**valueOf(fieldValue)**

Converts the specified object to a Boolean value. Use this method to convert a history tracking field value or an object that represents a Boolean value.

**Signature**

```java
public static Boolean valueOf(Object fieldValue)
```

**Parameters**

- **fieldValue**
  - **Type:** Object

**Return Value**

- **Type:** Boolean

**Usage**

Use this method with the `OldValue` or `NewValue` fields of history sObjects, such as `AccountHistory`, when the field type corresponds to a Boolean type, like a checkbox field.

**Example**

```java
List<AccountHistory> ahlist =
    [SELECT Field, OldValue, NewValue
     FROM AccountHistory];
for(AccountHistory ah : ahlist) {
System.debug('Field: ' + ah.Field);
if (ah.field == 'IsPlatinum__c') {
    Boolean oldValue =
        Boolean.valueOf(ah.OldValue);
    Boolean newValue =
        Boolean.valueOf(ah.NewValue);
}
```

---

**BusinessHours Class**

Use the `BusinessHours` methods to set the business hours at which your customer support team operates.

**Namespace**

- **System**

**BusinessHours Methods**

The following are methods for `BusinessHours`. All methods are static.
IN THIS SECTION:

- `add(businessHoursId, startDate, intervalMilliseconds)`
  Adds an interval of time from a start Datetime traversing business hours only. Returns the result Datetime in the local time zone.

- `addGmt(businessHoursId, startDate, intervalMilliseconds)`
  Adds an interval of milliseconds from a start Datetime traversing business hours only. Returns the result Datetime in GMT.

- `diff(businessHoursId, startDate, endDate)`
  Returns the difference in milliseconds between a start and end Datetime based on a specific set of business hours.

- `isWithin(businessHoursId, targetDate)`
  Returns `true` if the specified target date occurs within business hours. Holidays are included in the calculation.

- `nextStartDate(businessHoursId, targetDate)`
  Starting from the specified target date, returns the next date when business hours are open. If the specified target date falls within business hours, this target date is returned.

`add(businessHoursId, startDate, intervalMilliseconds)`

Adds an interval of time from a start Datetime traversing business hours only. Returns the result Datetime in the local time zone.

**Signature**

```java
public static Datetime add(String businessHoursId, Datetime startDate, Long intervalMilliseconds)
```

**Parameters**

- `businessHoursId`  
  **Type:** `String`

- `startDate`  
  **Type:** `Datetime`

- `intervalMilliseconds`  
  **Type:** `Long`

  Interval value should be provided in milliseconds, however time precision smaller than one minute is ignored.

**Return Value**

**Type:** `Datetime`

`addGmt(businessHoursId, startDate, intervalMilliseconds)`

Adds an interval of milliseconds from a start Datetime traversing business hours only. Returns the result Datetime in GMT.

**Signature**

```java
public static Datetime addGmt(String businessHoursId, Datetime startDate, Long intervalMilliseconds)
```
Parameters

- **businessHoursId**
  - Type: String
- **startDate**
  - Type: Datetime
- **intervalMilliseconds**
  - Type: Long

Return Value

- Type: Datetime

**diff** (*businessHoursId*, *startDate*, *endDate*)

Returns the difference in milliseconds between a start and end Datetime based on a specific set of business hours.

Signature

```
public static Long diff(String businessHoursId, Datetime startDate, Datetime endDate)
```

Parameters

- **businessHoursId**
  - Type: String
- **startDate**
  - Type: Datetime
- **endDate**
  - Type: Datetime

Return Value

- Type: Long

**isWithin** (*businessHoursId*, *targetDate*)

Returns true if the specified target date occurs within business hours. Holidays are included in the calculation.

Signature

```
public static Boolean isWithin(String businessHoursId, Datetime targetDate)
```

Parameters

- **businessHoursId**
  - Type: String
  - The business hours ID.
- **targetDate**
  - Type: Datetime
The date to verify.

Return Value
Type: Boolean

Example
The following example finds whether a given time is within the default business hours.

```java
// Get the default business hours
BusinessHours bh = [SELECT Id FROM BusinessHours WHERE IsDefault=true];

// Create Datetime on May 28, 2013 at 1:06:08 AM in the local timezone.
Datetime targetTime = Datetime.newInstance(2013, 5, 28, 1, 6, 8);

// Find whether the time is within the default business hours
Boolean isWithin= BusinessHours.isWithin(bh.id, targetTime);
```

**nextStartDate**(businessHoursId, targetDate)

Starting from the specified target date, returns the next date when business hours are open. If the specified target date falls within business hours, this target date is returned.

Signature

```java
public static Datetime nextStartDate(String businessHoursId, Datetime targetDate)
```

Parameters

- **businessHoursId**
  Type: String
  The business hours ID.

- **targetDate**
  Type: Datetime
  The date used as a start date to obtain the next date.

Return Value
Type: Datetime

Example
The following example finds the next date starting from the target date when business hours reopens. If the target date is within the given business hours, the target date is returned. The returned time is in the local time zone.

```java
// Get the default business hours
BusinessHours bh = [SELECT Id FROM BusinessHours WHERE IsDefault=true];

// Create Datetime on May 28, 2013 at 1:06:08 AM in the local timezone.
Datetime targetTime = Datetime.newInstance(2013, 5, 28, 1, 6, 8);
```
// Starting from the targetTime, find the next date when business hours reopens. Return the target time.

// if it is within the business hours. The returned time will be in the local time zone
Datetime nextStart = BusinessHours.nextStartDate(bh.id, targetTime);

Callable Interface

Enables developers to use a common interface to build loosely coupled integrations between Apex classes or triggers, even for code in separate packages. Agreeing upon a common interface enables developers from different companies or different departments to build upon one another's solutions. Implement this interface to enable the broader community, which might have different solutions than the ones you had in mind, to extend your code's functionality.

Note: This interface is not an analog of the Java Callable interface, which is used for asynchronous invocation. Don't confuse the two.

Namespace

System

Usage

To implement the Callable interface, you need to write only one method: call(String action, Map<String, Object> args).

In code that utilizes or tests an implementation of Callable, cast an instance of your type to Callable.

This interface is not intended to replace defining more specific interfaces. Rather, the Callable interface allows integrations in which code from different classes or packages can use common base types.

IN THIS SECTION:

Callable Methods

Callable Example Implementation

Callable Methods

The following are methods for Callable.

IN THIS SECTION:

call(action, args)
Provides functionality that other classes or packages can utilize and build upon.

call(action, args)

Provides functionality that other classes or packages can utilize and build upon.

Signature

public Object call(String action, Map<String, Object> args)
Parameters

**action**
Type: String
The behavior for the method to exhibit.

**args**
Type: Map on page 2829<String, Object>
Arguments to be used by the specified action.

Return Value
Type: Object
The result of the method invocation.

Callable Example Implementation

This class is an example implementation of the System.Callable interface.

```java
public class Extension implements Callable {

    // Actual method
    String concatStrings(String stringValue) {
        return stringValue + stringValue;
    }

    // Actual method
    Decimal multiplyNumbers(Decimal decimalValue) {
        return decimalValue * decimalValue;
    }

    // Dispatch actual methods
    public Object call(String action, Map<String, Object> args) {
        switch on action {
            when 'concatStrings' {
                return this.concatStrings((String)args.get('stringValue'));
            }
            when 'multiplyNumbers' {
                return this.multiplyNumbers((Decimal)args.get('decimalValue'));
            }
            when else {
                throw new ExtensionMalformedCallException('Method not implemented');
            }
        }
    }

    public class ExtensionMalformedCallException extends Exception {}}
```

The following test code illustrates how calling code utilizes the interface to call a method.

```java
@IsTest
private with sharing class ExtensionCaller {

```
@IsTest
private static void givenConfiguredExtensionWhenCalledThenValidResult() {

    // Given
    String extensionClass = 'Extension'; // Typically set via configuration
    Decimal decimalTestValue = 10;

    // When
    Callable extension =
        (Callable) Type.forName(extensionClass).newInstance();
    Decimal result = (Decimal)
        extension.call('multiplyNumbers', new Map<String, Object> {
            'decimalValue' => decimalTestValue
        });

    // Then
    System.assertEquals(100, result);
}

SEE ALSO:
Classes and Casting

Cases Class

Use the Cases class to interact with case records.

Namespace
System

Cases Methods

The following are static methods for Cases.

IN THIS SECTION:
getCaseIdFromEmailThreadId(emailThreadId)
Returns the case ID corresponding to the specified email thread ID.

getCaseIdFromEmailThreadId(emailThreadId)

Returns the case ID corresponding to the specified email thread ID.

Signature
public static ID getCaseIdFromEmailThreadId(String emailThreadId)
Parameters

**emailThreadId**

Type: String

Return Value

Type: ID

Usage

The `emailThreadId` argument should have the following format: `_00Dxx1gEW._500xxYktg`. Other formats, such as `ref:_00Dxx1gEW._500xxYktl:ref` and `[ref:_00Dxx1gEW._500xxYktl:ref]`, are invalid.

**Comparable Interface**

Adds sorting support for Lists that contain non-primitive types, that is, Lists of user-defined types.

**Namespace**

System

**Usage**

To add List sorting support for your Apex class, you must implement the `Comparable` interface with its `compareTo` method in your class.

To implement the `Comparable` interface, you must first declare a class with the `implements` keyword as follows:

```
global class Employee implements Comparable {
```

Next, your class must provide an implementation for the following method:

```
global Integer compareTo(Object compareTo) {
    // Your code here
}
```

The implemented method must be declared as `global` or `public`.

IN THIS SECTION:

- Comparable Methods
- Comparable Example Implementation

SEE ALSO:

- List Class

**Comparable Methods**

The following are methods for `Comparable`. 
IN THIS SECTION:

`compareTo(objectToCompareTo)`

Returns an Integer value that is the result of the comparison.

`compareTo(objectToCompareTo)`

Returns an Integer value that is the result of the comparison.

**Signature**

```
public Integer compareTo(Object objectToCompareTo)
```

**Parameters**

`objectToCompareTo`

Type: Object

**Return Value**

Type: Integer

**Usage**

The implementation of this method returns the following values:

- 0 if this instance and `objectToCompareTo` are equal
- > 0 if this instance is greater than `objectToCompareTo`
- < 0 if this instance is less than `objectToCompareTo`

If this object instance and `objectToCompareTo` are incompatible, a `System.TypeException` is thrown.

**Comparable Example Implementation**

This is an example implementation of the `Comparable` interface. The `compareTo` method in this example compares the employee of this class instance with the employee passed in the argument. The method returns an Integer value based on the comparison of the employee IDs.

```java
global class Employee implements Comparable {

    public Long id;
    public String name;
    public String phone;

    // Constructor
    public Employee(Long i, String n, String p) {
        id = i;
        name = n;
        phone = p;
    }

    // Implement the compareTo() method
    global Integer compareTo(Object compareTo) {
```
Employee compareToEmp = (Employee)compareTo;
if (id == compareToEmp.id) return 0;
if (id > compareToEmp.id) return 1;
return -1;
}

This example tests the sort order of a list of Employee objects.

@isTest
private class EmployeeSortingTest {
    static testmethod void test1() {
        List<Employee> empList = new List<Employee>();
        empList.add(new Employee(101, 'Joe Smith', '4155551212'));
        empList.add(new Employee(101, 'J. Smith', '4155551212'));
        empList.add(new Employee(25 , 'Caragh Smith', '4155551000'));
        empList.add(new Employee(105, 'Mario Ruiz', '4155551099'));

        // Sort using the custom compareTo() method
        empList.sort();

        // Write list contents to the debug log
        System.debug(empList);

        // Verify list sort order.
        System.assertEquals('Caragh Smith', empList[0].Name);
        System.assertEquals('Joe Smith', empList[1].Name);
        System.assertEquals('J. Smith', empList[2].Name);
        System.assertEquals('Mario Ruiz', empList[3].Name);
    }
}

Continuation Class

Use the Continuation class to make callouts asynchronously to a SOAP or REST Web service.

Namespace

System

Example

For a code example, see Make Long-Running Callouts from a Visualforce Page.

IN THIS SECTION:

Continuation Constructors
Continuation Properties
Continuation Methods
Continuation Constructors
The following are constructors for Continuation.

IN THIS SECTION:
- Continuation(timeout)
  Creates an instance of the Continuation class by using the specified timeout in seconds. The timeout maximum is 120 seconds.

Continuation(timeout)
Creates an instance of the Continuation class by using the specified timeout in seconds. The timeout maximum is 120 seconds.

Signature
public Continuation(Integer timeout)

Parameters
- timeout
  Type: Integer
  The timeout for this continuation in seconds.

Continuation Properties
The following are properties for Continuation.

IN THIS SECTION:
- continuationMethod
  The name of the callback method that is called after the callout response returns.
- timeout
  The timeout of the continuation in seconds. Maximum: 120 seconds seconds.
- state
  Data that is stored in this continuation and that can be retrieved after the callout is finished and the callback method is invoked.

continuationMethod
The name of the callback method that is called after the callout response returns.

Signature
public String continuationMethod {get; set;}

Property Value
Type: String
Usage

**Note:** If the `continuationMethod` property is not set for a Continuation, the same action method that made the asynchronous callout is called again when the callout response returns.

**timeout**
The timeout of the continuation in seconds. Maximum: 120 seconds.

Signature

```java
public Integer timeout {get; set;}
```

Property Value

Type: *Integer*

**state**

Data that is stored in this continuation and that can be retrieved after the callout is finished and the callback method is invoked.

Signature

```java
public Object state {get; set;}
```

Property Value

Type: *Object*

Example

This example shows how to save state information for a continuation in a controller.

```java
// Declare inner class to hold state info
private class StateInfo {
    String msg { get; set; }
    List<String> urls { get; set; }
    StateInfo(String msg, List<String> urls) {
        this.msg = msg;
        this.urls = urls;
    }
}

// Then in the action method, set state for the continuation
continuationInstance.state = new StateInfo('Some state data', urls);
```

**Continuation Methods**
The following are methods for `Continuation`. 

2584
IN THIS SECTION:

- **addHttpRequest(request)**
  Adds the HTTP request for the callout that is associated with this continuation.

- **getRequests()**
  Returns all labels and requests that are associated with this continuation as key-value pairs.

- **getResponse(requestLabel)**
  Returns the response for the request that corresponds to the specified label.

---

### addHttpRequest(request)

**Description**

Adds the HTTP request for the callout that is associated with this continuation.

**Signature**

```java
public String addHttpRequest(System.HttpRequest request)
```

**Parameters**

- `request`
  Type: `HttpRequest`
  The HTTP request to be sent to the external service by this continuation.

**Return Value**

- Type: `String`
  A unique label that identifies the HTTP request that is associated with this continuation. This label is used in the map that `getRequests()` returns to identify individual requests in a continuation.

**Usage**

You can add up to three requests to a continuation.

**Note:** The timeout that is set in each passed-in request is ignored. Only the global timeout maximum of 120 seconds applies for a continuation.

---

### getRequests()

**Description**

Returns all labels and requests that are associated with this continuation as key-value pairs.

**Signature**

```java
public Map<String, System.HttpRequest> getRequests()
```

**Return Value**

- Type: `Map<String, HttpRequest>`
  A map of all requests that are associated with this continuation. The map key is the request label, and the map value is the corresponding HTTP request.
getResponse (requestLabel)
Returns the response for the request that corresponds to the specified label.

Signature
public static HttpResponse getResponse(String requestLabel)

Parameters
requestLabel
  Type: String
  The request label to get the response for.

Return Value
Type: HttpResponse

Usage
The status code is returned in the HttpResponse object and can be obtained by calling getStatusCode() on the response. A status code of 200 indicates that the request was successful. Other status code values indicate the type of problem that was encountered.

Sample of Error Status Codes
When a problem occurs with the response, some possible status code values are:
• 2000: The timeout was reached, and the server didn’t get a chance to respond.
• 2001: There was a connection failure.
• 2002: Exceptions occurred.
• 2003: The response hasn’t arrived (which also means that the Apex asynchronous callout framework hasn’t resumed).
• 2004: The response size is too large (greater than 1 MB).

Cookie Class
The Cookie class lets you access cookies for your Salesforce site using Apex.

Namespace
System

Usage
Use the setCookies method of the PageReference Class to attach cookies to a page.

⚠ Important:
• Cookie names and values set in Apex are URL encoded, that is, characters such as @ are replaced with a percent sign and their hexadecimal representation.
• The setCookies method adds the prefix “apex__” to the cookie names.
• Setting a cookie’s value to null sends a cookie with an empty string value instead of setting an expired attribute.
After you create a cookie, the properties of the cookie can't be changed.

Be careful when storing sensitive information in cookies. Pages are cached regardless of a cookie value. If you use a cookie value to generate dynamic content, you should disable page caching. For more information, see “Cache Salesforce Sites Pages” in the Salesforce online help.

Consider the following limitations when using the `Cookie` class:

- The `Cookie` class can only be accessed using Apex that is saved using the Salesforce API version 19 and above.
- The maximum number of cookies that can be set per Salesforce Sites domain depends on your browser. Newer browsers have higher limits than older ones.
- Cookies must be less than 4K, including name and attributes.

For more information on sites, see “Salesforce Sites” in the Salesforce online help.

Example

The following example creates a class, `CookieController`, which is used with a Visualforce page (see markup below) to update a counter each time a user displays a page. The number of times a user goes to the page is stored in a cookie.

```java
// A Visualforce controller class that creates a cookie
// used to keep track of how often a user displays a page
public class CookieController {
    public CookieController() {
        Cookie counter = ApexPages.currentPage().getCookies().get('counter');

        // If this is the first time the user is accessing the page,
        // create a new cookie with name 'counter', an initial value of '1',
        // path 'null', maxAge '-1', and isSecure 'false'.
        if (counter == null) {
            counter = new Cookie('counter','1',null,-1,false);
        } else {
            // If this isn't the first time the user is accessing the page
            // create a new cookie, incrementing the value of the original count by 1
            Integer count = Integer.valueOf(counter.getValue());
            counter = new Cookie('counter', String.valueOf(count+1),null,-1,false);
        }

        // Set the new cookie for the page
        ApexPages.currentPage().setCookies(new Cookie[]{counter});
    }

    // This method is used by the Visualforce action {!count} to display the current
    // value of the number of times a user had displayed a page.
    // This value is stored in the cookie.
    public String getCount() {
        Cookie counter = ApexPages.currentPage().getCookies().get('counter');
        if(counter == null) {
            return '0';
        }
        return counter.getValue();
    }
}
```
// Test class for the Visualforce controller
@isTest
private class CookieControllerTest {
    // Test method for verifying the positive test case
    static testMethod void testCounter() {
        // first page view
        CookieController controller = new CookieController();
        System.assert(controller.getCount() == '1');

        // second page view
        controller = new CookieController();
        System.assert(controller.getCount() == '2');
    }
}

The following is the Visualforce page that uses the CookieController Apex controller above. The action {!count} calls the getCount method in the controller above.

<apex:page controller="CookieController">
    You have seen this page {!count} times
</apex:page>

IN THIS SECTION:

Cookie Constructors

Cookie Methods

Cookie Constructors

The following are constructors for Cookie.

IN THIS SECTION:

Cookie(name, value, path, maxAge, isSecure)

Creates a new instance of the Cookie class using the specified name, value, path, age, and the secure setting.

**Cookie(name, value, path, maxAge, isSecure)**

Creates a new instance of the Cookie class using the specified name, value, path, age, and the secure setting.

Signature

public Cookie(String name, String value, String path, Integer maxAge, Boolean isSecure)

Parameters

**name**

Type: String

The cookie name. It can't be null.
**value**
Type: **String**
The cookie data, such as session ID.

**path**
Type: **String**
The path from where you can retrieve the cookie.

**maxAge**
Type: **Integer**
A number representing how long a cookie is valid for in seconds. If set to less than zero, a session cookie is issued. If set to zero, the cookie is deleted.

**isSecure**
Type: **Boolean**
A value indicating whether the cookie can only be accessed through HTTPS (`true`) or not (`false`).

**Cookie Methods**
The following are methods for `Cookie`. All are instance methods.

**IN THIS SECTION:**
- `getDomain()`
  Returns the name of the server making the request.
- `getMaxAge()`
  Returns a number representing how long the cookie is valid for, in seconds. If set to less than zero, a session cookie is issued. If set to zero, the cookie is deleted.
- `getName()`
  Returns the name of the cookie. Can't be `null`.
- `getPath()`
  Returns the path from which you can retrieve the cookie. If `null` or blank, the location is set to root, or `/`.
- `getValue()`
  Returns the data captured in the cookie, such as Session ID.
- `isSecure()`
  Returns `true` if the cookie can only be accessed through HTTPS, otherwise returns `false`.

**getDomain()**
Returns the name of the server making the request.

**Signature**

```
public String getDomain()
```

**Return Value**

Type: **String**
**getMaxAge()**

Returns a number representing how long the cookie is valid for, in seconds. If set to < 0, a session cookie is issued. If set to 0, the cookie is deleted.

Signature

```
public Integer getMaxAge()
```

Return Value

Type: Integer

**getName()**

Returns the name of the cookie. Can't be null.

Signature

```
public String getName()
```

Return Value

Type: String

**getPath()**

Returns the path from which you can retrieve the cookie. If null or blank, the location is set to root, or “/”.

Signature

```
public String getPath()
```

Return Value

Type: String

**getValue()**

Returns the data captured in the cookie, such as Session ID.

Signature

```
public String getValue()
```

Return Value

Type: String

**isSecure()**

Returns true if the cookie can only be accessed through HTTPS, otherwise returns false.
Signature

public Boolean isSecure()

Return Value
Type: Boolean

Crypto Class
Provides methods for creating digests, message authentication codes, and signatures, as well as encrypting and decrypting information.

Namespace
System

Usage
The methods in the Crypto class can be used for securing content in Lightning Platform, or for integrating with external services such as Google or Amazon WebServices (AWS).

Encrypt and Decrypt Exceptions
The following exceptions can be thrown for these methods:

- decrypt
- encrypt
- decryptWithManagedIV
- encryptWithManagedIV

<table>
<thead>
<tr>
<th>Exception</th>
<th>Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>InvalidParameterValue</td>
<td>Unable to parse initialization vector from encrypted data.</td>
<td>Thrown if you’re using managed initialization vectors, and the cipher text is less than 16 bytes.</td>
</tr>
<tr>
<td>InvalidParameterValue</td>
<td>Invalid algorithm algoName. Must be AES128, AES192, or AES256.</td>
<td>Thrown if the algorithm name isn’t one of the valid values.</td>
</tr>
<tr>
<td>InvalidParameterValue</td>
<td>Invalid private key. Must be size bytes.</td>
<td>Thrown if size of the private key doesn’t match the specified algorithm.</td>
</tr>
<tr>
<td>InvalidParameterValue</td>
<td>Invalid initialization vector. Must be 16 bytes.</td>
<td>Thrown if the initialization vector isn’t 16 bytes.</td>
</tr>
<tr>
<td>InvalidParameterValue</td>
<td>Invalid data. Input data is size bytes, which exceeds the limit of 1048576 bytes.</td>
<td>Thrown if the data is greater than 1 MB. For decryption, 1048608 bytes are allowed for the initialization vector header, plus any additional padding the encryption added to align to block size.</td>
</tr>
</tbody>
</table>
**Exception** | **Message** | **Description**
--- | --- | ---
NullPointerException | Argument cannot be null. | Thrown if one of the required method arguments is null.

**SecurityException** | Given final block not properly padded. | Thrown if the data isn’t properly block-aligned or similar issues occur during encryption or decryption.

**SecurityException** | Message Varies | Thrown if something goes wrong during either encryption or decryption.

---

**Crypto Methods**

The following are methods for Crypto. All methods are static.

**IN THIS SECTION:**

- `decrypt(algorithmName, privateKey, initializationVector, cipherText)`: Decrypts the Blob `cipherText` using the specified algorithm, private key, and initialization vector. Use this method to decrypt blobs encrypted using a third party application or the `encrypt` method.

- `decryptWithManagedIV(algorithmName, privateKey, IVAndCipherText)`: Decrypts the Blob `IVAndCipherText` using the specified algorithm and private key. Use this method to decrypt blobs encrypted using a third party application or the `encryptWithManagedIV` method.

- `encrypt(algorithmName, privateKey, initializationVector, clearText)`: Encrypts the Blob `clearText` using the specified algorithm, private key and initialization vector. Use this method when you want to specify your own initialization vector.

- `encryptWithManagedIV(algorithmName, privateKey, clearText)`: Encrypts the Blob `clearText` using the specified algorithm and private key. Use this method when you want Salesforce to generate the initialization vector for you.

- `generateAesKey(size)`: Generates an Advanced Encryption Standard (AES) key.

- `generateDigest(algorithmName, input)`: Computes a secure, one-way hash digest based on the supplied input string and algorithm name.

- `generateMac(algorithmName, input, privateKey)`: Computes a message authentication code (MAC) for the input string, using the private key and the specified algorithm.

- `getRandomInteger()`: Returns a random Integer.

- `sign(algorithmName, input, privateKey)`: Computes a unique digital signature for the input string, using the specified algorithm and the supplied private key.

- `signWithCertificate(algorithmName, input, certDevName)`: Computes a unique digital signature for the input string, using the specified algorithm and the supplied certificate and key pair.
signXML(algorithmName, node, idAttributeName, certDevName)
Envelops the signature into an XML document.

signXML(algorithmName, node, idAttributeName, certDevName, refChild)
Inserts the signature envelope before the specified child node.

verify(String algorithmName, Blob data, Blob signature, Blob publicKey)
Verifies the digital signature for the Blob data using the specified algorithm and the supplied public key. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

verify(String algorithmName, Blob data, Blob signature, String certDevName)
Verifies the digital signature for the Blob data using the specified algorithm and the public key associated with the certDevName. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

verifyHMac(String algorithmName, Blob input, Blob privateKey, Blob macToVerify)
Verifies the HMAC signature for Blob data using the specified algorithm, input data, privateKey, and the mac. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

decrypt(algorithmName, privateKey, initializationVector, cipherText)
Decrypts the Blob cipherText using the specified algorithm, private key, and initialization vector. Use this method to decrypt blobs encrypted using a third party application or the encrypt method.

Signature

public static Blob decrypt(String algorithmName, Blob privateKey, Blob initializationVector, Blob cipherText)

Parameters

algorithmName
Type: String

privateKey
Type: Blob

initializationVector
Type: Blob

cipherText
Type: Blob

Return Value
Type: Blob

Usage

Valid values for algorithmName are:

- AES128
- AES192
- AES256
These algorithms are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS5 padding.

The length of `privateKey` must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16 bytes, 24 bytes, or 32 bytes, respectively. You can use a third-party application or the `generateAesKey` method to generate this key for you.

The initialization vector must be 128 bits (16 bytes.)

Example

```java
Blob exampleIv = Blob.valueOf('Example of IV123');
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encrypt('AES128', key, exampleIv, data);

Blob decrypted = Crypto.decrypt('AES128', key, exampleIv, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

decryptWithManagedIV(algorithmName, privateKey, IVAndCipherText)

Decrypts the Blob `IVAndCipherText` using the specified algorithm and private key. Use this method to decrypt blobs encrypted using a third party application or the `encryptWithManagedIV` method.

Signature

```java
public static Blob decryptWithManagedIV(String algorithmName, Blob privateKey, Blob IVAndCipherText)
```

Parameters

- `algorithmName`
  Type: `String`
- `privateKey`
  Type: `Blob`
- `IVAndCipherText`
  Type: `Blob`

The first 128 bits (16 bytes) of `IVAndCipherText` must contain the initialization vector.

Return Value

Type: `Blob`

Usage

Valid values for `algorithmName` are:

- AES128
- AES192
- AES256
These algorithms are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS5 padding.

The length of `privateKey` must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16 bytes, 24 bytes, or 32 bytes, respectively. You can use a third-party application or the `generateAesKey` method to generate this key for you.

Example

```java
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encryptWithManagedIV('AES128', key, data);

Blob decrypted = Crypto.decryptWithManagedIV('AES128', key, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

**encrypt(algorithmName, privateKey, initializationVector, clearText)**

Encrypts the Blob `clearText` using the specified algorithm, private key and initialization vector. Use this method when you want to specify your own initialization vector.

**Signature**

```java
public static Blob encrypt(String algorithmName, Blob privateKey, Blob initializationVector, Blob clearText)
```

**Parameters**

- `algorithmName`
  - Type: `String`
- `privateKey`
  - Type: `Blob`
- `initializationVector`
  - Type: `Blob`
- `clearText`
  - Type: `Blob`

**Return Value**

Type: `Blob`

**Usage**

The initialization vector must be 128 bits (16 bytes.) Use either a third-party application or the `decrypt` method to decrypt blobs encrypted using this method. Use the `encryptWithManagedIV` method if you want Salesforce to generate the initialization vector for you. It is stored as the first 128 bits (16 bytes) of the encrypted Blob.

Valid values for `algorithmName` are:

- AES128
- AES192
• AES256

These algorithms are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS5 padding.

The length of `privateKey` must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16 bytes, 24 bytes, or 32 bytes, respectively. You can use a third-party application or the `generateAesKey` method to generate this key for you.

Example

```java
Blob exampleIv = Blob.valueOf('Example of IV123');
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encrypt('AES128', key, exampleIv, data);

Blob decrypted = Crypto.decrypt('AES128', key, exampleIv, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

`encryptWithManagedIV(algorithmName, privateKey, clearText)`

Encrypts the Blob `clearText` using the specified algorithm and private key. Use this method when you want Salesforce to generate the initialization vector for you.

Signature

```java
public static Blob encryptWithManagedIV(String algorithmName, Blob privateKey, Blob clearText)
```

Parameters

`algorithmName`

Type: `String`

`privateKey`

Type: `Blob`

`clearText`

Type: `Blob`

Return Value

Type: `Blob`

Usage

The initialization vector is stored as the first 128 bits (16 bytes) of the encrypted Blob. Use either third-party applications or the `decryptWithManagedIV` method to decrypt blobs encrypted with this method. Use the `encrypt` method if you want to generate your own initialization vector.

Valid values for `algorithmName` are:

• AES128
• AES192

2596
• AES256

These algorithms are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS5 padding.

The length of privateKey must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16 bytes, 24 bytes, or 32 bytes, respectively. You can use a third-party application or the generateAesKey method to generate this key for you.

Example

```java
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encryptWithManagedIV('AES128', key, data);

Blob decrypted = Crypto.decryptWithManagedIV('AES128', key, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

**generateAesKey(size)**

Generates an Advanced Encryption Standard (AES) key.

Signature

```
public static Blob generateAesKey(Integer size)
```

Parameters

- `size` Type: `Integer`
  
The key’s size in bits. Valid values are:
  
  - 128
  - 192
  - 256

Return Value

Type: `Blob`

Example

```
Blob key = Crypto.generateAesKey(128);
```

**generateDigest(algorithmName, input)**

Computes a secure, one-way hash digest based on the supplied input string and algorithm name.

Signature

```
public static Blob generateDigest(String algorithmName, Blob input)
```
Parameters

algorithmName
Type: String

Valid values for algorithmName are:

- MD5
- SHA1
- SHA-256
- SHA-512

input
Type: Blob

Return Value
Type: Blob

Example

```java
Blob targetBlob = Blob.valueOf('ExampleMD5String');
Blob hash = Crypto.generateDigest('MD5', targetBlob);
```

generateMac(algorithmName, input, privateKey)

Computes a message authentication code (MAC) for the input string, using the private key and the specified algorithm.

Signature

```java
public static Blob generateMac(String algorithmName, Blob input, Blob privateKey)
```

Parameters

algorithmName
Type: String

The valid values for algorithmName are:

- hmacMD5
- hmacSHA1
- hmacSHA256
- hmacSHA512

input
Type: Blob

privateKey
Type: Blob

The value of privateKey does not need to be in decoded form. The value cannot exceed 4 KB.
Return Value
Type: Blob

Example
```
String salt = String.valueOf(Crypto.getRandomInteger());
String key = 'key';
Blob data = crypto.generateMac('HmacSHA256',
    Blob.valueOf(salt), Blob.valueOf(key));
```

getRandomInteger()
Returns a random Integer.

Signature
```
public static Integer getRandomInteger()
```

Return Value
Type: Integer

Example
```
Integer randomInt = Crypto.getRandomInteger();
```

getRandomLong()
Returns a random Long.

Signature
```
public static Long getRandomLong()
```

Return Value
Type: Long

Example
```
Long randomLong = Crypto.getRandomLong();
```

sign(algorithmName, input, privateKey)
Computes a unique digital signature for the input string, using the specified algorithm and the supplied private key.

Signature
```
public static Blob sign(String algorithmName, Blob input, Blob privateKey)
```
Parameters

`algorithmName`

Type: String

The algorithm name. The valid values for `algorithmName` are RSA-SHA1, RSA-SHA256, or RSA.

- RSA-SHA1 is an RSA signature (with an asymmetric key pair) of a SHA1 hash.
- RSA-SHA256 is an RSA signature of a SHA256 hash.
- RSA is the same as RSA-SHA1.

`input`

Type: Blob

The data to sign.

`privateKey`

Type: Blob

The value of `privateKey` must be decoded using the `EncodingUtil.base64Decode` method, and should be in RSA's PKCS #8 (1.2) Private-Key Information Syntax Standard form. The value cannot exceed 4 KB.

Return Value

Type: Blob

Example

The following snippet shows how to call the `sign` method.

```java
String algorithmName = 'RSA';
String key = '';
Blob privateKey = EncodingUtil.base64Decode(key);
Blob input = Blob.valueOf('12345qwerty');
Crypto.sign(algorithmName, input, privateKey);
```

`signWithCertificate(algorithmName, input, certDevName)`

Computes a unique digital signature for the input string, using the specified algorithm and the supplied certificate and key pair.

Signature

```java
public static Blob signWithCertificate(String algorithmName, Blob input, String certDevName)
```

Parameters

`algorithmName`

Type: String

The algorithm name. The valid values for `algorithmName` are RSA-SHA1, RSA-SHA256, or RSA.

- RSA-SHA1 is an RSA signature (with an asymmetric key pair) of a SHA1 hash.
- RSA-SHA256 is an RSA signature of a SHA256 hash.
- RSA is the same as RSA-SHA1.
**input**

Type: **Blob**

The data to sign.

**certDevName**

Type: **String**

The *Unique Name* for a certificate stored in the Salesforce organization’s Certificate and Key Management page to use for signing. To access the Certificate and Key Management page from Setup, enter *Certificate and Key Management* in the Quick Find box, then select *Certificate and Key Management*.

**Return Value**

Type: **Blob**

**Example**

The following snippet is an example of the method for signing the content referenced by `data`.

```java
Blob data = Blob.valueOf('12345qwerty');
System.Crypto.signWithCertificate('RSA-SHA256', data, 'signingCert');
```

**signXML(algorithmName, node, idAttributeName, certDevName)**

Envelops the signature into an XML document.

**Signature**

```
public Void signXML(String algorithmName, Dom.XmlNode node, String idAttributeName, String certDevName)
```

**Parameters**

**algorithmName**

Type: **String**

The algorithm name. Valid names are RSA-SHA1, RSA-SHA256, or RSA.

- RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.
- RSA-SHA256 is an RSA signature of an SHA256 hash.
- RSA is the same as RSA-SHA1.

**node**

Type: **Dom.XmlNode**

The XML node to sign and insert the signature into.

**idAttributeName**

Type: **String**

The full name (including the namespace) of the attribute on the node (XmlNode) to use as the reference ID. If `null`, this method uses the ID attribute on the node. If there is no ID attribute, Salesforce generates a new ID and adds it to the node.
certDevName
Type: String
The unique name for a certificate stored in the Salesforce org’s Certificate and Key Management page to use for signing.
To access the Certificate and Key Management page from Setup, enter Certificate and Key Management in the Quick Find box, then select Certificate and Key Management.

Return Value
Type: void

Example
The following is an example declaration and initialization.

```java
doc.load(...);
System.Crypto.signXml('RSA-SHA256', doc.getRootElement(), null, 'signingCert');
return doc.toXmlString();
```

`signXML(algorithmName, node, idAttributeName, certDevName, refChild)`
Inserts the signature envelope before the specified child node.

Signature
```
public static void signXml(String algorithmName, Dom.XmlNode node, String idAttributeName, String certDevName, Dom.XmlNode refChild)
```

Parameters
```
algorithmName
Type: String
The RSA encryption algorithm name. Valid names are RSA-SHA1, RSA-SHA256, or RSA.
RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.
RSA-SHA256 is an RSA signature of an SHA256 hash.
RSA is the same as RSA-SHA1.

node
Type: Dom.XmlNode
The XML node to sign and insert the signature into.

idAttributeName
Type: String
The full name (including the namespace) of the attribute on the node (XmlNode) to use as the reference ID. If null, this method uses the ID attribute on the node. If there is no ID attribute, Salesforce generates a new ID and adds it to the node.

certDevName
Type: String
The unique name for a certificate stored in the Salesforce org’s Certificate and Key Management page to use for signing.
```
To access the Certificate and Key Management page from Setup, enter Certificate and Key Management in the Quick Find box, then select Certificate and Key Management.

-refChild

The XML node before which to insert the signature. If refChild is null, the signature is added at the end.

Return Value
Type: Void

verify(String algorithmName, Blob data, Blob signature, Blob publicKey)
Verifies the digital signature for the Blob data using the specified algorithm and the supplied public key. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

Signature

public static Blob verify(String algorithmName, Blob data, Blob signature, Blob publicKey)

Parameters

algorithmName
Type: String
The algorithm name. The valid values for algorithmName are RSA-SHA1, RSA-SHA256, or RSA.

RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.

RSA-SHA256 is an RSA signature of an SHA256 hash.

RSA is the same as RSA-SHA1.

data
Type: Blob
The data to sign.

signature
Type:
Blob
The RSA signature.

publicKey
Type: Blob
The value of publicKey must be decoded using the EncodingUtil.base64Decode method, and be in X.509 standard.

Return Value
Type: Blob
Example

```java
String algorithmName = 'RSA';
String privateKey = '';
String publicKey = '';
Blob privateKey = EncodingUtil.base64Decode(privateKey);
Blob publicKey = EncodingUtil.base64Decode(publicKey);
Blob input = Blob.valueOf('12345qwerty');
Blob signature = Crypto.sign(algorithmName, input, privateKey);
Boolean verified = Crypto.verify(algorithmName, input, signature, publicKey);
```

`verify(String algorithmName, Blob data, Blob signature, String certDevName)`

Verifies the digital signature for the Blob `data` using the specified algorithm and the public key associated with the `certDevName`. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

Signature

```java
public static Blob verify(String algorithmName, Blob data, Blob signature, String certDevName)
```

Parameters

- **algorithmName**
  - Type: `String`
  - The algorithm name. The valid values for `algorithmName` are RSA-SHA1, RSA-SHA256, or RSA.
  - RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.
  - RSA-SHA256 is an RSA signature of an SHA256 hash.
  - RSA is the same as RSA-SHA1.

- **data**
  - Type: `Blob`
  - The data to sign.

- **signature**
  - Type: `Blob`
  - The RSA signature.

- **certDevName**
  - Type: `String`
  - The Unique Name for a certificate stored in the Salesforce organization’s Certificate and Key Management page to use for signing. To access the Certificate and Key Management page from Setup, enter Certificate and Key Management in the Quick Find box, then select Certificate and Key Management.

Return Value

- Type: `Blob`
Example

```java
Blob data = Blob.valueOf('12345qwerty');
Blob signature = Crypto.signWithCertificate('RSA-SHA256', data, 'signingCert');
Boolean verified = Crypto.verify('RSA-SHA256', data, signature, 'signingCert');
```

verifyHMac(String algorithmName, Blob input, Blob privateKey, Blob macToVerify)

Verifies the HMAC signature for Blob `data` using the specified algorithm, input data, privateKey, and the mac. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

Signature

```java
public static Blob verifyHMac(String algorithmName, Blob input, Blob privateKey, Blob macToVerify)
```

Parameters

- `algorithmName`  
  Type: String  
  The valid values for `algorithmName` are:  
  - hmacMD5  
  - hmacSHA1  
  - hmacSHA256  
  - hmacSHA512

- `data`  
  Type: Blob  
  The data to sign.

- `privateKey`  
  Type: Blob  
  The value of `privateKey` does not need to be in decoded form. The value cannot exceed 4 KB.

- `macToVerify`  
  Type: Blob  
  The value of the `mac` must be verified against the provided `privateKey`, `data`, and algorithm.

Return Value

Type: Boolean

Example

```java
String salt = String.valueOf(Crypto.getRandomInteger());
String key = 'key';
Blob mac = Crypto.generateMac('HmacSHA256', Blob.valueOf(salt), Blob.valueOf(key));
Boolean verified = Crypto.verifyHMac('HmacSHA256', Blob.valueOf(salt), Blob.valueOf(key), mac);
```
Custom Settings Methods

Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data can then be used by formula fields, validation rules, flows, Apex, and the SOAP API.

Usage

Custom settings methods are all instance methods, that is, they are called by and operate on a particular instance of a custom setting. There are two types of custom settings: hierarchy and list. The methods are divided into those that work with list custom settings, and those that work with hierarchy custom settings.

Note: All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. However, querying custom settings data using Standard Object Query Language (SOQL) doesn’t make use of the application cache and is similar to querying a custom object. To benefit from caching, use other methods for accessing custom settings data such as the Apex Custom Settings methods.

For more information on creating custom settings in the Salesforce user interface, see “Create Custom Settings” in the Salesforce online help.

Custom Setting Examples

The following example uses a list custom setting called Games. Games has a field called GameType. This example determines if the value of the first data set is equal to the string PC.

```java
List<Games__C> mcs = Games__c.getAll().values();
boolean textField = null;
if (mcs[0].GameType__c == 'PC') {
    textField = true;
}
System.assertEquals(textField, true);
```

The following example uses a custom setting from Country and State Code Custom Settings Example. This example demonstrates that the getValues and getInstance methods list custom setting return identical values.

```java
Foundation_Countries__c myCS1 = Foundation_Countries__c.getValues('United States');
String myCCVal = myCS1.Country_code__c;
Foundation_Countries__c myCS2 = Foundation_Countries__c.getInstance('United States');
String myCCInst = myCS2.Country_code__c;
System.assertEquals(myCCInst, myCCVal);
```

Hierarchy Custom Setting Examples

In the following example, the hierarchy custom setting GamesSupport has a field called Corporate_number. The code returns the value for the profile specified with pid.

```java
GamesSupport__c mhc = GamesSupport__c.getInstance(pid);
string mPhone = mhc.Corporate_number__c;
```

The example is identical if you choose to use the getValues method.
The following example shows how to use hierarchy custom settings methods. For `getInstance`, the example shows how field values that aren’t set for a specific user or profile are returned from fields defined at the next lowest level in the hierarchy. The example also shows how to use `getOrgDefaults`.

Finally, the example demonstrates how `getValues` returns fields in the custom setting record only for the specific user or profile, and doesn’t merge values from other levels of the hierarchy. Instead, `getValues` returns null for any fields that aren’t set. This example uses a hierarchy custom setting called `Hierarchy`. `Hierarchy` has two fields: `OverrideMe` and `DontOverrideMe`. In addition, a user named Robert has a System Administrator profile. The organization, profile, and user settings for this example are as follows:

**Organization settings**
- `OverrideMe`: Hello
- `DontOverrideMe`: World

**Profile settings**
- `OverrideMe`: Goodbye
- `DontOverrideMe` is not set.

**User settings**
- `OverrideMe`: Fluffy
- `DontOverrideMe` is not set.

The following example demonstrates the result of the `getInstance` method if Robert calls it in his organization:

```java
Hierarchy__c CS = Hierarchy__c.getInstance();
System.Assert(CS.OverrideMe__c == 'Fluffy');
System.assert(CS.DontOverrideMe__c == 'World');
```

If Robert passes his user ID specified by `RobertId` to `getInstance`, the results are the same. This is because the lowest level of data in the custom setting is specified at the user level.

```java
Hierarchy__c CS = Hierarchy__c.getInstance(RobertId);
System.Assert(CS.OverrideMe__c == 'Fluffy');
System.assert(CS.DontOverrideMe__c == 'World');
```

If Robert passes the System Administrator profile ID specified by `SysAdminID` to `getInstance`, the result is different. The data specified for the profile is returned:

```java
Hierarchy__c CS = Hierarchy__c.getInstance(SysAdminID);
System.Assert(CS.OverrideMe__c == 'Goodbye');
System.assert(CS.DontOverrideMe__c == 'World');
```

When Robert tries to return the data set for the organization using `getOrgDefaults`, the result is:

```java
Hierarchy__c CS = Hierarchy__c.getOrgDefaults();
System.Assert(CS.OverrideMe__c == 'Hello');
System.assert(CS.DontOverrideMe__c == 'World');
```

By using the `getValues` method, Robert can get the hierarchy custom setting values specific to his user and profile settings. For example, if Robert passes his user ID `RobertId` to `getValues`, the result is:

```java
Hierarchy__c CS = Hierarchy__c.getValues(RobertId);
System.Assert(CS.OverrideMe__c == 'Fluffy');
// Note how this value is null, because you are returning
// data specific for the user
System.assert(CS.DontOverrideMe__c == null);
```
If Robert passes his System Administrator profile ID `SysAdminID` to `getValues`, the result is:

```java
Hierarchy__c CS = Hierarchy__c.getValues(SysAdminID);
System.Assert(CS.OverrideMe__c == 'Goodbye');
// Note how this value is null, because you are returning
// data specific for the profile
System.assert(CS.DontOverrideMe__c == null);
```

**Country and State Code Custom Settings Example**

This example illustrates using two custom setting objects for storing related information, and a Visualforce page to display the data in a set of related picklists.

In the following example, country and state codes are stored in two different custom settings: Foundation_Countries and Foundation_States.

The Foundation_Countries custom setting is a list type custom setting and has a single field, `Country_Code`.

The Foundation_States custom setting is also a List type of custom setting and has the following fields:

- Country Code
- State Code
- State Name
The Visualforce page shows two picklists: one for country and one for state.

<apex:page controller="CountryStatePicker">
  <apex:actionFunction name="rerenderStates" rerender="statesSelectList">
    <apex:param name="firstParam" assignTo="!country" value="" />
  </apex:actionFunction>
  <table>
    <tr>
      <th>Country</th>
      <td>
        <apex:selectList id="country" styleclass="std" size="1"
          value="!country" onChange="rerenderStates(this.value)"
        >
          <apex:selectOptions value="!countriesSelectList"/>
        </apex:selectList>
      </td>
    </tr>
    <tr id="state_input">
      <th>State/Province</th>
      <td>
        <apex:selectList id="statesSelectList" styleclass="std" size="1"
          value="!state"
        >
          <apex:selectOptions value="!statesSelectList"/>
        </apex:selectList>
      </td>
    </tr>
  </table>
</apex:page>
The Apex controller CountryStatePicker finds the values entered into the custom settings, then returns them to the Visualforce page.

```apex
public with sharing class CountryStatePicker {

    // Variables to store country and state selected by user
    public String state { get; set; }
    public String country {get; set;}

    // Generates country dropdown from country settings
    public List<SelectOption> getCountriesSelectList() {
        List<SelectOption> options = new List<SelectOption>();
        options.add(new SelectOption('', '-- Select One --'));

        // Find all the countries in the custom setting
        Map<String, Foundation_Countries__c> countries = Foundation_Countries__c.getAll();

        // Sort them by name
        List<String> countryNames = new List<String>();
        countryNames.addAll(countries.keySet());
        countryNames.sort();

        // Create the Select Options.
        for (String countryName : countryNames) {
            Foundation_Countries__c country = countries.get(countryName);
            options.add(new SelectOption(country.country_code__c, country.Name));
        }
        return options;
    }

    // To generate the states picklist based on the country selected by user.
    public List<SelectOption> getStatesSelectList() {
        List<Foundation_States__c> allstates = Foundation_States__c.getAll();

        // Filter states that belong to the selected country
        Map<String, Foundation_States__c> states = new Map<String, Foundation_States__c>();
        for (Foundation_States__c state : allstates.values()) {
            if (state.country_code__c == this.country) {
                states.put(state.name, state);
            }
        }

        // Sort the states based on their names
        List<String> stateNames = new List<String>();
        stateNames.addAll(states.keySet());
        stateNames.sort();

        // Generate the Select Options based on the final sorted list
        for (String stateName : stateNames) {
            Foundation_States__c state = states.get(stateName);
            options.add(new SelectOption(state.state_code__c, state.state_name__c));
        }
    }
}
```
// If no states are found, just say not required in the dropdown.
if (options.size() > 0) {
    options.add(0, new SelectOption('', '"Select One --'"));
} else {
    options.add(new SelectOption('"', '"Not Required'"));
}
return options;
}

List Custom Setting Methods
Hierarchy Custom Setting Methods

SEE ALSO:
Custom Settings

List Custom Setting Methods
The following are instance methods for list custom settings.

IN THIS SECTION:
getAll()
Returns a map of the data sets defined for the custom setting.
getInstance(dataSetName)
Returns the custom setting data set record for the specified data set name. This method returns the exact same object as
getValues(dataSetName).
getValues(dataSetName)
Returns the custom setting data set record for the specified data set name. This method returns the exact same object as
getInstance(dataSetName).

getAll()
Returns a map of the data sets defined for the custom setting.

Signature
public Map<String, CustomSetting__c> getAll()

Return Value
Type: Map<String, CustomSetting__c>
Usage

If no data set is defined, this method returns an empty map.

Note: For Apex saved using Salesforce API version 20.0 or earlier, the data set names, which are the keys in the returned map, are converted to lower case. For Apex saved using Salesforce API version 21.0 and later, the case of the data set names in the returned map keys is not changed and the original case is preserved.

**getInstance(dataSetName)**

Returns the custom setting data set record for the specified data set name. This method returns the exact same object as `getValues(dataSetName)`.

Signature

```java
public CustomSetting__c getInstance(String dataSetName)
```

Parameters

*dataSetName*

Type: String

Return Value

Type: CustomSetting__c

Usage

If no data is defined for the specified data set, this method returns `null`.

**getValues(dataSetName)**

Returns the custom setting data set record for the specified data set name. This method returns the exact same object as `getInstance(dataSetName)`.

Signature

```java
public CustomSetting__c getValues(String dataSetName)
```

Parameters

*dataSetName*

Type: String

Return Value

Type: CustomSetting__c

Usage

If no data is defined for the specified data set, this method returns `null`.
Hierarchy Custom Setting Methods

The following are instance methods for hierarchy custom settings.

Note:

- In API version 41.0 and below, each method in an Apex test class, including testSetup methods, are able to insert hierarchy custom setting values. This behavior is true even when the methods have the same SetupOwnerId value as a hierarchy custom setting record inserted in a different test method.
- In API version 42.0 and later, if a hierarchy custom setting is inserted in a testSetup method, inserting a hierarchy custom setting record with the same SetupOwnerId in a test method throws a DUPLICATE_VALUE exception.

IN THIS SECTION:

getInstance()
Returns a custom setting data set record for the current user. The fields returned in the custom setting record are merged based on the lowest level fields that are defined in the hierarchy.

getInstance(userId)
Returns the custom setting data set record for the specified user ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the user level.

getInstance(profileId)
Returns the custom setting data set record for the specified profile ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the profile level.

getOrgDefaults()
Returns the custom setting data set record for the organization.

getValues(userId)
Returns the custom setting data set record for the specified user ID.

getValues(profileId)
Returns the custom setting data set record for the specified profile ID.

getInstance()

Returns a custom setting data set record for the current user. The fields returned in the custom setting record are merged based on the lowest level fields that are defined in the hierarchy.

Signature

public CustomSetting__c getInstance()

Return Value

Type: CustomSetting__c

Usage

If no custom setting data is defined for the user, this method returns a new custom setting object. The new custom setting object contains an ID set to null and merged fields from higher in the hierarchy. You can add this new custom setting record for the user by using insert or upsert. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the SetupOwnerId field which contains the user ID.
Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the user. Also, if no custom setting data is defined in the hierarchy, this method returns `null`.

This method is equivalent to a method call to `getInstance(User_Id)` for the current user.

Example

- Custom setting data set defined for the user: If you have a custom setting data set defined for the user “Uriel Jones,” for the profile “System Administrator,” and for the organization as a whole, and the user running the code is Uriel Jones, this method returns the custom setting record defined for Uriel Jones.
- Merged fields: If you have a custom setting data set with fields A and B for the user “Uriel Jones” and for the profile “System Administrator,” and field A is defined for Uriel Jones, field B is `null` but is defined for the System Administrator profile, this method returns the custom setting record for Uriel Jones with field A for Uriel Jones and field B from the System Administrator profile.
- No custom setting data set record defined for the user: If the current user is “Barbara Mahonie,” who also shares the “System Administrator” profile, but no data is defined for Barbara as a user, this method returns a new custom setting record with the ID set to `null` and with fields merged based on the fields defined in the lowest level in the hierarchy.

`getInstance(userId)`

Returns the custom setting data set record for the specified user ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the user level.

Signature

```plaintext```
public CustomSetting__c getInstance(ID userId)
```

Parameters

- `userId`
  Type: ID

Return Value

Type: CustomSetting__c

Usage

If no custom setting data is defined for the user, this method returns a new custom setting object. The new custom setting object contains an ID set to `null` and merged fields from higher in the hierarchy. You can add this new custom setting record for the user by using `insert` or `upsert`. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the `SetupOwnerId` field which contains the user ID.

Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the user. Also, if no custom setting data is defined in the hierarchy, this method returns `null`.

`getInstance(profileId)`

Returns the custom setting data set record for the specified profile ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the profile level.
Signature

public CustomSetting__c getInstance(ID profileId)

Parameters

profileId
  Type: ID

Return Value

Type: CustomSetting__c

Usage

If no custom setting data is defined for the profile, this method returns a new custom setting record. The new custom setting object contains an ID set to null and with merged fields from your organization’s default values. You can add this new custom setting for the profile by using insert or upsert. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the SetupOwnerId field which contains the profile ID.

Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the profile. Also, if no custom setting data is defined in the hierarchy, this method returns null.

getOrgDefaults()

Returns the custom setting data set record for the organization.

Signature

public CustomSetting__c getOrgDefaults()

Return Value

Type: CustomSetting__c

Usage

If no custom setting data is defined for the organization, this method returns an empty custom setting object.

Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns null if no custom setting data is defined for the organization.

getValues(userId)

Returns the custom setting data set record for the specified user ID.

Signature

public CustomSetting__c getValues(ID userId)
Parameters

userId
   Type: ID

Return Value

Type: CustomSetting__c

Usage

Use this if you only want the subset of custom setting data that has been defined at the user level. For example, suppose you have a custom setting field that has been assigned a value of “alpha” at the organizational level, but has no value assigned at the user or profile level. Using `getValues(userId)` returns `null` for this custom setting field.

`getValues(profileId)`

Returns the custom setting data set for the specified profile ID.

Signature

```java
public CustomSetting__c getValues(ID profileId)
```

Parameters

profileId
  Type: ID

Return Value

Type: CustomSetting__c

Usage

Use this if you only want the subset of custom setting data that has been defined at the profile level. For example, suppose you have a custom setting field that has been assigned a value of “alpha” at the organizational level, but has no value assigned at the user or profile level. Using `getValues(ProfileId)` returns `null` for this custom setting field.

Database Class

Contains methods for creating and manipulating data.

Namespace

System
Usage
Some Database methods also exist as DML statements.

SEE ALSO:
Apex DML Operations

Database Methods
The following are methods for Database. All methods are static.

IN THIS SECTION:
convertLead(leadToConvert, allOrNone)
Converts a lead into an account and contact, as well as (optionally) an opportunity.
convertLead(leadToConvert, allOrNone)
Converts a list of LeadConvert objects into accounts and contacts, as well as (optionally) opportunities.
countQuery(query)
Returns the number of records that a dynamic SOQL query would return when executed.
delete(recordToDelete, allOrNone)
Deletes an existing sObject record, such as an individual account or contact, from your organization's data.
delete(recordsToDelete, allOrNone)
Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization's data.
delete(recordID, allOrNone)
Deletes existing sObject records, such as individual accounts or contacts, from your organization's data.
delete(recordIDs, allOrNone)
Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization's data.
deleteAsync(sobjects, callback)
Initiates requests to delete the external data that corresponds to the specified external object records. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose processDelete method is called for each record after deletion.
deleteAsync(sobject, callback)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose processDelete method is called after deletion.
deleteAsync(sobjects)
Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.
deleteAsync(sobject)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.
deleteImmediate(sobjects)
Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

deleteImmediate(sobject)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

eemptyRecycleBin(recordIds)
Permanently deletes the specified records from the Recycle Bin.

eemptyRecycleBin(obj)
Permanently deletes the specified sObject from the Recycle Bin.

eemptyRecycleBin(listOfSObjects)
Permanently deletes the specified sObjects from the Recycle Bin.

eexecuteBatch(batchClassObject)
Submits a batch Apex job for execution corresponding to the specified class.

eexecuteBatch(batchClassObject, scope)
Submits a batch Apex job for execution using the specified class and scope.

egetAsyncDeleteResult(deleteResult)
Retrieves the status of an asynchronous delete operation that’s identified by a Database.DeleteResult object.

egetAsyncDeleteResult(asyncLocator)
Retrieves the result of an asynchronous delete operation based on the result’s unique identifier.

egetAsyncLocator(result)
Returns the asyncLocator associated with the result of a specified asynchronous insert, update, or delete operation.

egetAsyncSaveResult(saveResult)
Returns the status of an asynchronous insert or update operation that’s identified by a Database.SaveResult object.

egetAsyncSaveResult(asyncLocator)
Returns the status of an asynchronous insert or update operation based on the unique identifier associated with each modification.

egetDeleted(sObjectType, startDate, endDate)
Returns the list of individual records that have been deleted for an sObject type within the specified start and end dates and times and that are still in the Recycle Bin.

egetQueryLocator(listofQueries)
Creates a QueryLocator object used in batch Apex or Visualforce.

egetQueryLocator(query)
Creates a QueryLocator object used in batch Apex or Visualforce.

egetUpdated(sobjectType, startDate, endDate)
Returns the list of individual records that have been updated for an sObject type within the specified start and end dates and times.

insert(recordToInsert, allOrNone)
Add an sObject, such as an individual account or contact, to your organization’s data.

insert(recordsToInsert, allOrNone)
Add one or more sObjects, such as individual accounts or contacts, to your organization’s data.
insert(recordToInsert, dmlOptions)
Adds an sObject, such as an individual account or contact, to your organization’s data.

insert(recordsToInsert, dmlOptions)
Adds one or more sObjects, such as individual accounts or contacts, to your organization’s data.

insertAsync(sobjects, callback)
Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose processSave method is called for each record after the remote operations are completed.

insertAsync(object, callback)
Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processSave method is called after the remote operation is completed.

insertAsync(sobjects)
Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

insertAsync(object)
Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

insertImmediate(sobjects)
Initiates requests to add external object data to the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

insertImmediate(object)
Initiates a request to add external object data to the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

merge(masterRecord, duplicateId)
Merges the specified duplicate record into the master sObject record of the same type, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

merge(masterRecord, duplicateRecord)
Merges the specified duplicate sObject record into the master sObject of the same type, deleting the duplicate, and reparenting any related records.

merge(masterRecord, duplicateIds)
Merges up to two records of the same sObject type into the master sObject record, deleting the others, and reparenting any related records.

merge(masterRecord, duplicateRecords)
Merges up to two records of the same object type into the master sObject record, deleting the others, and reparenting any related records.

merge(masterRecord, duplicateId, allOrNone)
Merges the specified duplicate record into the master sObject record of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.
merge(masterRecord, duplicateRecord, allOrNone)
Merges the specified duplicate sObject record into the master sObject of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records.

merge(masterRecord, duplicateIds, allOrNone)
Merges up to two records of the same sObject type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

merge(masterRecord, duplicateRecords, allOrNone)
Merges up to two records of the same object type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

query(queryString)
Creates a dynamic SOQL query at runtime.

rollback(databaseSavepoint)
Restores the database to the state specified by the savepoint variable. Any emails submitted since the last savepoint are also rolled back and not sent.

setSavepoint()
Returns a savepoint variable that can be stored as a local variable, then used with the rollback method to restore the database to that point.

undelete(recordToUndelete, allOrNone)
Restores an existing sObject record, such as an individual account or contact, from your organization’s Recycle Bin.

undelete(recordsToUndelete, allOrNone)
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

undelete(recordID, allOrNone)
Restores an existing sObject record, such as an individual account or contact, from your organization’s Recycle Bin.

undelete(recordIDs, allOrNone)
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

update(recordToUpdate, allOrNone)
Modifies an existing sObject record, such as an individual account or contact, in your organization’s data.

update(recordsToUpdate, allOrNone)
Modifies one or more existing sObject records, such as individual accounts or contacts, in your organization’s data.

update(recordToUpdate, dmlOptions)
Modifies an existing sObject record, such as an individual account or contact, in your organization’s data.

update(recordsToUpdate, dmlOptions)
Modifies one or more existing sObject records, such as individual accounts or contacts, in your organization’s data.

upsert(recordToUpsert, externalIdField, allOrNone)
Creates a new sObject record or updates an existing sObject record within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

upsert(recordsToUpsert, externalIdField, allOrNone)
Creates new sObject records or updates existing sObject records within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.
updateAsync(sobject, callback)
Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processSave method is called after the remote operation is completed.

updateAsync(sobjects)
Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

updateImmediate(sobjects)
Initiates requests to update external object data on the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

updateImmediate(sobject)
Initiates a request to update external object data on the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

convertLead(leadToConvert, allOrNone)
Converts a lead into an account and contact, as well as (optionally) an opportunity.

Signature

public static Database.LeadConvertResult convertLead(Database.LeadConvert leadToConvert, Boolean allOrNone)

Parameters

leadToConvert
Type: Database.LeadConvert

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value

Type: Database.LeadConvertResult
Usage
The convertLead method accepts up to 100 LeadConvert objects. Each executed convertLead method counts against the governor limit for DML statements.

**convertLead(leadsToConvert, allOrNone)**

Converts a list of LeadConvert objects into accounts and contacts, as well as (optionally) opportunities.

**Signature**

```
public static Database.LeadConvertResult[] convertLead(Database.LeadConvert[] leadsToConvert, Boolean allOrNone)
```

**Parameters**

- **leadsToConvert**
  - Type: `Database.LeadConvert[]`

- **allOrNone**
  - Type: `Boolean`

  The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

**Return Value**

Type: `Database.LeadConvertResult[]`

Usage
The convertLead method accepts up to 100 LeadConvert objects. Each executed convertLead method counts against the governor limit for DML statements.

**countQuery(query)**

Returns the number of records that a dynamic SOQL query would return when executed.

**Signature**

```
public static Integer countQuery(String query)
```

**Parameters**

- **query**
  - Type: `String`

**Return Value**

Type: `Integer`
Usage

For more information, see Dynamic SOQL on page 184.

Each executed `countQuery` method counts against the governor limit for SOQL queries.

Example

```java
String QueryString = 'SELECT count() FROM Account';
Integer i = Database.countQuery(QueryString);
```

**delete** *(recordToDelete, allOrNone)*

Deletes an existing sObject record, such as an individual account or contact, from your organization’s data.

Signature

```java
public static Database.DeleteResult delete(SObject recordToDelete, Boolean allOrNone)
```

Parameters

- **recordToDelete**
  - Type: `sObject`

- **allOrNone**
  - Type: `Boolean`

  The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

- Type: `Database.DeleteResult`

Usage

`delete` is analogous to the `delete()` statement in the SOAP API.

Each executed `delete` method counts against the governor limit for DML statements.

**delete** *(recordsToDelete, allOrNone)*

Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.

Signature

```java
public static Database.DeleteResult[] delete(SObject[] recordsToDelete, Boolean allOrNone)
```
Parameters

`recordsToDelete`
Type: `sObject[]`

`allOrNone`
Type: `Boolean`

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value
Type: `Database.DeleteResult[]`

Usage
`delete` is analogous to the `delete()` statement in the SOAP API.

Each executed `delete` method counts against the governor limit for DML statements.

Example
The following example deletes an account named 'DotCom':

```java
Account[] doomedAccts = [SELECT Id, Name FROM Account WHERE Name = 'DotCom'];
Database.DeleteResult[] DR_Dels = Database.delete(doomedAccts);
```

`delete(recordID, allOrNone)`
Deletes existing sObject records, such as individual accounts or contacts, from your organization’s data.

Signature
`public static Database.DeleteResult delete(ID recordID, Boolean allOrNone)`

Parameters
`recordID`
Type: `ID`

`allOrNone`
Type: `Boolean`

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value
Type: `Database.DeleteResult`
Usage

delete is analogous to the delete() statement in the SOAP API.
Each executed delete method counts against the governor limit for DML statements.

**delete(recordIDs, allOrNone)**

Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.

**Signature**

```java
public static Database.DeleteResult[] delete(ID[] recordIDs, Boolean allOrNone)
```

**Parameters**

- `recordIDs`
  Type: ID[]
- `allOrNone`
  Type: Boolean

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

**Return Value**

Type: Database.DeleteResult[]

Usage

delete is analogous to the delete() statement in the SOAP API.
Each executed delete method counts against the governor limit for DML statements.

**deleteAsync(sobjects, callback)**

Initiates requests to delete the external data that corresponds to the specified external object records. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose `processDelete` method is called for each record after deletion.

**Signature**

```java
public static List<Database.DeleteResult> deleteAsync(List<SObject> sobjects, DataSource.AsyncDeleteCallback callback)
```

**Parameters**

- `sobjects`
  Type: List<SObject>
    List of external object records to delete.
callback

Type: DataSource.AsyncDeleteCallback

The callback that contains the state in the originating context and an action (the processDelete method) that is executed after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend DataSource.AsyncDeleteCallback.

Return Value

Type: List<Database.DeleteResult>

Status results for the delete operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncDeleteResult().

deleteAsync(object, callback)

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose processDelete method is called after deletion.

Signature

public static Database.DeleteResult deleteAsync(SObject object, DataSource.AsyncDeleteCallback callback)

Parameters

object

Type: SObject

The external object record to delete.

callback

Type: DataSource.AsyncDeleteCallback

The callback that contains the state in the originating context and an action (the processDelete method) that is executed after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend DataSource.AsyncDeleteCallback.

Return Value

Type: Database.DeleteResult

Status result for the delete operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncDeleteResult().

deleteAsync(objects)

Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.
Signature

```java
public static List<Database.DeleteResult> deleteAsync(List<SObject> sobjects)
```

Parameters

- `sobjects`
  - Type: `List<SObject>`
  - List of external object records to delete.

Return Value

- Type: `List<Database.DeleteResult>`
  - Status results for the delete operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. To retrieve the final result, use `Database.getAsyncDeleteResult()`.

`deleteAsync(sobject)`

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object’s associated external data source.

Signature

```java
public static Database.DeleteResult deleteAsync(SObject sobject)
```

Parameters

- `sobject`
  - Type: `SObject`
  - The external object record to delete.

Return Value

- Type: `Database.DeleteResult`
  - Status result for the delete operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. To retrieve the final result, use `Database.getAsyncDeleteResult()`.

`deleteImmediate(sobjects)`

Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

Signature

```java
public static List<Database.DeleteResult> deleteImmediate(List<SObject> sobjects)
```
Parameters

sobjects
Type: List<SObject>
List of external object records to delete.

Return Value

Type: List<Database.DeleteResult>
Status results for the delete operation.

deleteImmediate(sobject)

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

Signature

public static Database.DeleteResult deleteImmediate(SObject sobject)

Parameters

sobject
Type: SObject
The external object record to delete.

Return Value

Type: Database.DeleteResult
Status result for the delete operation.

emptyRecycleBin(recordIds)

Permanently deletes the specified records from the Recycle Bin.

Signature

public static Database.EmptyRecycleBinResult[] emptyRecycleBin(ID [] recordIds)

Parameters

recordIds
Type: ID[]

Return Value

Type: Database.EmptyRecycleBinResult[]
Usage

Note the following:

• After records are deleted using this method, they cannot be undeleted.
• Only 10,000 records can be specified for deletion.
• Logged in users can delete any record that they can query in their Recycle Bin, or the recycle bins of any subordinates. If logged in users have “Modify All Data” permission, they can query and delete records from any Recycle Bin in the organization.
• Cascade delete record IDs should not be included in the list of IDs; otherwise an error occurs. For example, if an account record is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include the Id of the top-level account. All related records are automatically removed.
• Deleted items are added to the number of items processed by a DML statement, and the method call is added to the total number of DML statements issued. Each executed emptyRecycleBin method counts against the governor limit for DML statements.

emptyRecycleBin(obj)
Permanently deletes the specified sObject from the Recycle Bin.

Signature

public static Database.EmptyRecycleBinResult emptyRecycleBin(sObject obj)

Parameters

obj
Type: sObject

Return Value

Type: Database.EmptyRecycleBinResult

Usage

Note the following:

• After an sObject is deleted using this method, it cannot be undeleted.
• Only 10,000 sObjects can be specified for deletion.
• The logged-in user can delete any sObject (that can be queried) in their Recycle Bin, or the recycle bins of any subordinates. If the logged-in user has “Modify All Data” permission, he or she can query and delete sObjects from any Recycle Bin in the organization.
• Do not include an sObject that was deleted due to a cascade delete; otherwise an error occurs. For example, if an account is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include sObjects of the top-level account. All related sObjects are automatically removed.
• Deleted items are added to the number of items processed by a DML statement, and the method call is added to the total number of DML statements issued. Each executed emptyRecycleBin method counts against the governor limit for DML statements.

emptyRecycleBin(listOfSObjects)
Permanently deletes the specified sObjects from the Recycle Bin.
**emptyRecycleBin**

**Signature**

```java
public static Database.EmptyRecycleBinResult[] emptyRecycleBin(sObject[] listOfSObjects)
```

**Parameters**

`listOfSObjects`

Type: `sObject[]`

**Return Value**

Type: `Database.EmptyRecycleBinResult[]`

**Usage**

Note the following:

- After an sObject is deleted using this method, it cannot be undeleted.
- Only 10,000 sObjects can be specified for deletion.
- The logged-in user can delete any sObject (that can be queried) in their Recycle Bin, or the recycle bins of any subordinates. If the logged-in user has "Modify All Data" permission, he or she can query and delete sObjects from any Recycle Bin in the organization.
- Do not include an sObject that was deleted due to a cascade delete; otherwise an error occurs. For example, if an account is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include sObjects of the top-level account. All related sObjects are automatically removed.
- Deleted items are added to the number of items processed by a DML statement, and the method call is added to the total number of DML statements issued. Each executed emptyRecycleBin method counts against the governor limit for DML statements.

**executeBatch**

**executeBatch(batchClassObject)**

Submits a batch Apex job for execution corresponding to the specified class.

**Signature**

```java
public static ID executeBatch(Object batchClassObject)
```

**Parameters**

`batchClassObject`

Type: `Object`

An instance of a class that implements the `Database.Batchable` interface.

**Return Value**

Type: `ID`

The ID of the new batch job (AsyncApexJob).

If the `executeBatch` call fails to acquire an Apex flex queue lock, the call returns an empty ID, "000000000000000", instead of throwing an exception.
Usage
When calling this method, Salesforce chunks the records returned by the `start` method of the batch class into batches of 200, and then passes each batch to the `execute` method. Apex governor limits are reset for each execution of `execute`.
For more information, see Using Batch Apex on page 251.

`executeBatch(batchClassObject, scope)`
Submits a batch Apex job for execution using the specified class and scope.

Signature

```
public static ID executeBatch(Object batchClassObject, Integer scope)
```

Parameters

- `batchClassObject`
  Type: Object
  An instance of a class that implements the `Database.Batchable` interface.

- `scope`
  Type: Integer
  Number of records to be passed into the `execute` method for batch processing.

Return Value
Type: ID
The ID of the new batch job (AsyncApexJob).

If the `executeBatch` call fails to acquire an Apex flex queue lock, the call returns an empty ID, "000000000000000", instead of throwing an exception.

Usage
The value for `scope` must be greater than 0.
If the `start` method of the batch class returns a `Database.QueryLocator`, the scope parameter of `Database.executeBatch` can have a maximum value of 2,000. If set to a higher value, Salesforce chunks the records returned by the QueryLocator into smaller batches of up to 200 records. If the `start` method of the batch class returns an iterable, the scope parameter value has no upper limit; however, if you use a very high number, you could run into other limits.
Apex governor limits are reset for each execution of `execute`.
For more information, see Using Batch Apex on page 251.

`getAsyncDeleteResult(deleteResult)`
Retrieves the status of an asynchronous delete operation that's identified by a `Database.DeleteResult` object.

Signature

```
public static Database.DeleteResult getAsyncDeleteResult(Database.DeleteResult deleteResult)
```
Parameters

databaseDeleteResult
  Type: Database.DeleteResult
  The result record for the delete operation being retrieved.

Return Value

Type: Database.DeleteResult
The result of a completed asynchronous delete of a record or records.

getAsyncDeleteResult (asyncLocator)
Retrieves the result of an asynchronous delete operation based on the result’s unique identifier.

Signature

public static Database.DeleteResult getAsyncDeleteResult (String asyncLocator)

Parameters

asyncLocator
  Type: String
  The unique identifier associated with the result of an asynchronous operation.

Return Value

Type: Database.DeleteResult
The result of a completed asynchronous delete of a record or records.

getAsyncLocator (result)
Returns the asyncLocator associated with the result of a specified asynchronous insert, update, or delete operation.

Signature

public static String getAsyncLocator (Object result)

Parameters

result
  Type: Object
  The saved result of an asynchronous insert, update, or delete operation. The result object can be of type Database.SaveResult or Database.DeleteResult.

Return Value

Type: String
The unique identifier associated with the result of the specified operation.
getAsyncSaveResult (saveResult)
Returns the status of an asynchronous insert or update operation that's identified by a Database.SaveResult object.

Signature
public static Database.SaveResult getAsyncSaveResult(Database.SaveResult saveResult)

Parameters
saveResult
Type: Database.SaveResult
The result record for the insert or update operation being retrieved.

Return Value
Database.SaveResult
The result of a completed asynchronous operation on a record or records.

getAsyncSaveResult (asyncLocator)
Returns the status of an asynchronous insert or update operation based on the unique identifier associated with each modification.

Signature
public static Database.SaveResult getAsyncSaveResult(String asyncLocator)

Parameters
asyncLocator
Type: String
The unique identifier associated with the result of an asynchronous operation.

Return Value
Database.SaveResult
The result of a completed asynchronous operation on a record or records.

getDeleted(sObjectType, startDate, endDate)
Returns the list of individual records that have been deleted for an sObject type within the specified start and end dates and times and that are still in the Recycle Bin.

Signature
public static Database.GetDeletedResult getDeleted(String sObjectType, Datetime startDate, Datetime endDate)
Parameters

**sObjectType**
Type: String

The `sObjectType` argument is the sObject type name for which to get the deleted records, such as account or merchandise__c.

**startDate**
Type: Datetime

Start date and time of the deleted records time window.

**endDate**
Type: Datetime

End date and time of the deleted records time window.

Return Value

Type: `Database.GetDeletedResult`

Usage

Because the Recycle Bin holds records up to 15 days, results are returned for no more than 15 days previous to the day the call is executed (or earlier if an administrator has purged the Recycle Bin).

Example

```java
Database.GetDeletedResult r =
    Database.getDeleted('Merchandise__c',
                        Datetime.now().addHours(-1),
                        Datetime.now());
```

### getQueryLocator(listOfQueries)

Creates a QueryLocator object used in batch Apex or Visualforce.

Signature

```java
public static Database.QueryLocator getQueryLocator(sObject [] listOfQueries)
```

Parameters

**listOfQueries**
Type: `sObject []`

Return Value

Type: `Database.QueryLocator`

Usage

You can’t use `getQueryLocator` with any query that contains an **aggregate function**.
Each executed `getQueryLocator` method counts against the governor limit of 10,000 total records retrieved and the total number of SOQL queries issued.

For more information, see Understanding Apex Managed Sharing, and IdeaStandardSetController Class.

**getQueryLocator(query)**

Creates a QueryLocator object used in batch Apex or Visualforce.

**Signature**

```java
public static Database.QueryLocator getQueryLocator(String query)
```

**Parameters**

- `query`
  - Type: `String`

**Return Value**

Type: `Database.QueryLocator`

**Usage**

You can’t use `getQueryLocator` with any query that contains an aggregate function.

Each executed `getQueryLocator` method counts against the governor limit of 10,000 total records retrieved and the total number of SOQL queries issued.

For more information, see Understanding Apex Managed Sharing, and StandardSetController Class.

**getUpdated(sobjectType, startDate, endDate)**

Returns the list of individual records that have been updated for an sObject type within the specified start and end dates and times.

**Signature**

```java
public static Database.GetUpdatedResult getUpdated(String sobjectType, Datetime startDate, Datetime endDate)
```

**Parameters**

- `sobjectType`
  - Type: `String`

  The `sobjectType` argument is the sObject type name for which to get the updated records, such as account or merchandise__c.

- `startDate`
  - Type: `Datetime`

  The `startDate` argument is the start date and time of the updated records time window.

- `endDate`
  - Type: `Datetime`

  The `endDate` argument is the end date and time of the updated records time window.
Return Value
Type: Database.GetUpdatedResult

Usage
The date range for the returned results is no more than 30 days previous to the day the call is executed.

Example

```java
Database.GetUpdatedResult r =
    Database.getUpdated(
        'Merchandise__c',
        Datetime.now().addHours(-1),
        Datetime.now());
```

**insert**(recordToInsert, allOrNone)

Adds an sObject, such as an individual account or contact, to your organization’s data.

Signature

```java
public static Database.SaveResult insert(sObject recordToInsert, Boolean allOrNone)
```

Parameters

- **recordToInsert**
  Type: sObject
- **allOrNone**
  Type: Boolean
  The optional **allOrNone** parameter specifies whether the operation allows partial success. If you specify **false** for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set **true**, an exception is thrown if the method is not successful.

Return Value
Type: Database.SaveResult

Usage

**insert** is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed **insert** method counts against the governor limit for DML statements.

**insert**(recordsToInsert, allOrNone)

Adds one or more sObjects, such as individual accounts or contacts, to your organization’s data.
public static Database.SaveResult[] insert(sObject[] recordsToInsert, Boolean allOrNone)

Parameters
recordsToInsert
Type: sObject []

allOrNone
Type: Boolean
The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value
Type: Database.SaveResult[]

Usage
insert is analogous to the INSERT statement in SQL.
Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.
Each executed insert method counts against the governor limit for DML statements.

Example
The following example inserts two accounts:

```java
Account a = new Account(name = 'Acme1');
Database.SaveResult[] lsr = Database.insert(
    new Account[] {a, new Account(Name = 'Acme2')},
    false);
```

insert(recordToInsert, dmlOptions)
Adds an sObject, such as an individual account or contact, to your organization's data.

Signature
public static Database.SaveResult insert(sObject recordToInsert, Database.DMLOptions dmlOptions)

Parameters
recordToInsert
Type: sObject
**dmlOptions**

*Type: Database.DMLOptions*

The optional *dmlOptions* parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value

*Type: Database.SaveResult*

Usage

*insert* is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed *insert* method counts against the governor limit for DML statements.

**insert(recordsToInsert, dmlOptions)**

Adds one or more sObjects, such as individual accounts or contacts, to your organization's data.

Signature

```java
public static Database.SaveResult insert(sObject[] recordsToInsert, Database.DMLOptions dmlOptions)
```

Parameters

- `recordsToInsert`
  *Type: sObject[]*

- `dmlOptions`
  *Type: Database.DMLOptions*

  The optional *dmlOptions* parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value

*Type: Database.SaveResult[]*

Usage

*insert* is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed *insert* method counts against the governor limit for DML statements.
**insertAsync(sobjects, callback)**

Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose `processSave` method is called for each record after the remote operations are completed.

**Signature**

```java
public static List<Database.SaveResult> insertAsync(List<SObject> sobjects, DataSource.AsyncSaveCallback callback)
```

**Parameters**

- **sobjects**
  - Type: `List<SObject>`
  - List of external object records to insert.

- **callback**
  - Type: `DataSource.AsyncSaveCallback`
  - The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation’s results. The callback object must extend `DataSource.AsyncSaveCallback`.

**Return Value**

- **Type**: `List<Database.SaveResult>`
  - Status results for the insert operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

**Usage**

`Database.insertAsync()` methods can’t be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use `Database.insertImmediate()` methods.

**insertAsync(object, callback)**

Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose `processSave` method is called after the remote operation is completed.

**Signature**

```java
public static Database.SaveResult insertAsync(SObject object, DataSource.AsyncSaveCallback callback)
```

**Parameters**

- **object**
  - Type: `SObject`
The external object record to insert.

```java
callback
Type: DataSource.AsyncSaveCallback

The callback object that contains the state in the originating context and an action (the processSave method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend DataSource.AsyncSaveCallback.
```

Return Value
Type: Database.SaveResult

Status result for the insert operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

Usage
Database.insertAsync() methods can't be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use Database.insertImmediate() methods.

`insertAsync(sobjects)`

Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.

Signature

```java
public static List<Database.SaveResult> insertAsync(List<SObject> sobjects)
```

Parameters

- `sobjects`
  Type: List<SObject>
  List of external object records to insert.

Return Value
Type: List<Database.SaveResult>

Status results for the insert operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

Usage

Database.insertAsync() methods can't be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use Database.insertImmediate() methods.
**insertAsync(object)**

Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.

**Signature**

```java
public static Database.SaveResult insertAsync(SObject object)
```

**Parameters**

- `object`
  - Type: `SObject`
  - The external object record to insert.

**Return Value**

- Type: `Database.SaveResult`
  - Status result for the insert operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

**Usage**

`Database.insertAsync()` methods can’t be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use `Database.insertImmediate()` methods.

**insertImmediate(objects)**

Initiates requests to add external object data to the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

**Signature**

```java
public static List<Database.SaveResult> insertImmediate(List<SObject> objects)
```

**Parameters**

- `objects`
  - Type: `List<SObject>`
  - List of external object records to insert.

**Return Value**

- Type: `List<Database.SaveResult>`
  - Status results for the insert operation.
**insertImmediate(sobject)**

Initiates a request to add external object data to the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

**Signature**

```java
public static Database.SaveResult insertImmediate(SObject sobject)
```

**Parameters**

- `sobject`
  - Type: `SObject`
  - The external object record to insert.

**Return Value**

Type: `Database.SaveResult`

Status result for the insert operation.

**merge(masterRecord, duplicateId)**

Merges the specified duplicate record into the master sObject record of the same type, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

**Signature**

```java
public static Database.MergeResult merge(sObject masterRecord, Id duplicateId)
```

**Parameters**

- `masterRecord`
  - Type: `sObject`
  - The master sObject record the duplicate record is merged into.

- `duplicateId`
  - Type: `ID`
  - The ID of the record to merge with the master. This record must be of the same sObject type as the master.

**Return Value**

Type: `Database.MergeResult`

**Usage**

Each executed `merge` method counts against the governor limit for DML statements.
**merge(masterRecord, duplicateRecord)**

Merges the specified duplicate sObject record into the master sObject of the same type, deleting the duplicate, and reparenting any related records.

**Signature**

```java
public static Database.MergeResult merge(sObject masterRecord, sObject duplicateRecord)
```

**Parameters**

- **masterRecord**
  - Type: sObject
  - The master sObject record the duplicate record is merged into.

- **duplicateRecord**
  - Type: sObject
  - The sObject record to merge with the master. This sObject must be of the same type as the master.

**Return Value**

- Type: Database.MergeResult

**Usage**

Each executed `merge` method counts against the governor limit for DML statements.

**merge(masterRecord, duplicateIds)**

Merges up to two records of the same sObject type into the master sObject record, deleting the others, and reparenting any related records.

**Signature**

```java
public static List<Database.MergeResult> merge(sObject masterRecord, List<Id> duplicateIds)
```

**Parameters**

- **masterRecord**
  - Type: sObject
  - The master sObject record the other records are merged into.

- **duplicateIds**
  - Type: List<Id>
  - A list of IDs of up to two records to merge with the master. These records must be of the same sObject type as the master.

**Return Value**

- Type: List<Database.MergeResult>
Usage
Each executed `merge` method counts against the governor limit for DML statements.

`merge(masterRecord, duplicateRecords)`
Merges up to two records of the same object type into the master sObject record, deleting the others, and reparenting any related records.

Signature
`public static List<Database.MergeResult> merge(sObject masterRecord, List<SObject> duplicateRecords)`

Parameters
- `masterRecord`  
  Type: `sObject`  
  The master sObject record the other sObjects are merged into.
- `duplicateRecords`  
  Type: `List<SObject>`  
  A list of up to two sObject records to merge with the master. These sObjects must be of the same type as the master.

Return Value
Type: `List<Database.MergeResult>`

Usage
Each executed `merge` method counts against the governor limit for DML statements.

`merge(masterRecord, duplicateId, allOrNone)`
Merges the specified duplicate record into the master sObject record of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

Signature
`public static Database.MergeResult merge(sObject masterRecord, Id duplicateId, Boolean allOrNone)`

Parameters
- `masterRecord`  
  Type: `sObject`  
  The master sObject record the duplicate record is merged into.
- `duplicateId`  
  Type: `Id`  
  The ID of the record to merge with the master. This record must be of the same sObject type as the master.
**allOrNone**
Type: Boolean
Set to false to return any errors encountered in this operation as part of the returned result. If set to true, this method throws an exception if the operation fails. The default is true.

Return Value
Type: Database.MergeResult

Usage
Each executed merge method counts against the governor limit for DML statements.

**merge(masterRecord, duplicateRecord, allOrNone)**
Merges the specified duplicate sObject record into the master sObject of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records.

Signature
public static Database.MergeResult merge(sObject masterRecord, sObject duplicateRecord, Boolean allOrNone)

Parameters
**masterRecord**
Type: sObject
The master sObject record the duplicate record is merged into.

**duplicateRecord**
Type: sObject
The sObject record to merge with the master. This sObject must be of the same type as the master.

**allOrNone**
Type: Boolean
Set to false to return any errors encountered in this operation as part of the returned result. If set to true, this method throws an exception if the operation fails. The default is true.

Return Value
Type: Database.MergeResult

Usage
Each executed merge method counts against the governor limit for DML statements.

**merge(masterRecord, duplicateIds, allOrNone)**
Merges up to two records of the same sObject type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.
Signature

```java
public static List<Database.MergeResult> merge(sObject masterRecord, List<Id> duplicateIds, Boolean allOrNone)
```

Parameters

**masterRecord**
- Type: `sObject`
  - The master `sObject` record the other records are merged into.

**duplicateIds**
- Type: `List<Id>`
  - A list of IDs of up to two records to merge with the master. These records must be of the same `sObject` type as the master.

**allOrNone**
- Type: `Boolean`
  - Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

Return Value

Type: `List<Database.MergeResult>`

Usage

Each executed `merge` method counts against the governor limit for DML statements.

### `merge(masterRecord, duplicateRecords, allOrNone)`

Merges up to two records of the same object type into the master `sObject` record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

Signature

```java
public static List<Database.MergeResult> merge(sObject masterRecord, List<sObject> duplicateRecords, Boolean allOrNone)
```

Parameters

**masterRecord**
- Type: `sObject`
  - The master `sObject` record the other `sObjects` are merged into.

**duplicateRecords**
- Type: `List<sObject>`
  - A list of up to two `sObject` records to merge with the master. These `sObjects` must be of the same type as the master.

**allOrNone**
- Type: `Boolean`
Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

Return Value
Type: `List<Database.MergeResult>`

Usage
Each executed `merge` method counts against the governor limit for DML statements.

`query(queryString)`
Creates a dynamic SOQL query at runtime.

Signature
```
public static sObject[] query(String queryString)
```

Parameters
`queryString`
Type: `String`

Return Value
Type: `sObject[]`

Usage
This method can be used wherever a static SOQL query can be used, such as in regular assignment statements and `for` loops. Unlike inline SOQL, fields in bind variables are not supported. For more information, see Dynamic SOQL on page 184. Each executed `query` method counts against the governor limit for SOQL queries.

`rollback(databaseSavepoint)`
Restores the database to the state specified by the savepoint variable. Any emails submitted since the last savepoint are also rolled back and not sent.

Signature
```
public static Void rollback(System.Savepoint databaseSavepoint)
```

Parameters
`databaseSavepoint`
Type: `System.Savepoint`
Return Value
Type: Void

Usage
Note the following:

- Static variables are not reverted during a rollback. If you try to run the trigger again, the static variables retain the values from the first run.
- Each rollback counts against the governor limit for DML statements. You will receive a runtime error if you try to rollback the database additional times.
- The ID on an sObject inserted after setting a savepoint is not cleared after a rollback. Create an sObject to insert after a rollback. Attempting to insert the sObject using the variable created before the rollback fails because the sObject variable has an ID. Updating or upserting the sObject using the same variable also fails because the sObject is not in the database and, thus, cannot be updated.

For an example, see Transaction Control.

**setSavepoint()**

Returns a savepoint variable that can be stored as a local variable, then used with the rollback method to restore the database to that point.

**Signature**

```
public static System.Savepoint setSavepoint()
```

**Return Value**
Type: System.Savepoint

**Usage**
Note the following:

- If you set more than one savepoint, then roll back to a savepoint that is not the last savepoint you generated, the later savepoint variables become invalid. For example, if you generated savepoint SP1 first, savepoint SP2 after that, and then you rolled back to SP1, the variable SP2 would no longer be valid. You will receive a runtime error if you try to use it.
- References to savepoints cannot cross trigger invocations because each trigger invocation is a new trigger context. If you declare a savepoint as a static variable then try to use it across trigger contexts, you will receive a run-time error.
- Each savepoint you set counts against the governor limit for DML statements.

For an example, see Transaction Control.

**undelete(recordToUndelete, allOrNone)**

Restores an existing sObject record, such as an individual account or contact, from your organization’s Recycle Bin.

**Signature**

```
public static Database.UndeleteResult undelete(sObject recordToUndelete, Boolean allOrNone)
```
Parameters

**recordToUndelete**
Type: sObject

**allOrNone**
Type: Boolean

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value
Type: Database.UndeleteResult

Usage

`undelete` is analogous to the UNDELETE statement in SQL.

Each executed `undelete` method counts against the governor limit for DML statements.

**undelete(recordsToUndelete, allOrNone)**

Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

Signature

```java
public static Database.UndeleteResult[] undelete(sObject[] recordsToUndelete, Boolean allOrNone)
```

Parameters

**recordsToUndelete**
Type: sObject[]

**allOrNone**
Type: Boolean

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value
Type: Database.UndeleteResult[]

Usage

`undelete` is analogous to the UNDELETE statement in SQL.

Each executed `undelete` method counts against the governor limit for DML statements.
Example

The following example restores all accounts named 'Universal Containers'. The **ALL ROWS** keyword queries all rows for both top-level and aggregate relationships, including deleted records and archived activities.

```java
Account[] savedAccts = [SELECT Id, Name FROM Account WHERE Name = 'Universal Containers' ALL ROWS];
Database.UndeleteResult[] UDR_Dels = Database.undelete(savedAccts);
```

**undelete(recordID, allOrNone)**

Restores an existing sObject record, such as an individual account or contact, from your organization's Recycle Bin.

Signature

```java
public static Database.UndeleteResult undelete(ID recordID, Boolean allOrNone)
```

Parameters

- `recordID`
  - Type: `ID`
  - `allOrNone`
  - Type: `Boolean`

  The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

- Type: `Database.UndeleteResult`

Usage

`undelete` is analogous to the UNDELETE statement in SQL.

Each executed `undelete` method counts against the governor limit for DML statements.

**undelete(recordIDs, allOrNone)**

Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

Signature

```java
public static Database.UndeleteResult[] undelete(ID[] recordIDs, Boolean allOrNone)
```

Parameters

- `RecordIDs`
  - Type: `ID[]`
The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

**Return Value**

Type: `Database.UndeleteResult[]`

**Usage**

`undelete` is analogous to the UNDELETE statement in SQL.

Each executed `undelete` method counts against the governor limit for DML statements.

### `update(recordToUpdate, allOrNone)`

Modifies an existing sObject record, such as an individual account or contact, in your organization’s data.

**Signature**

```java
public static Database.SaveResult update(sObject recordToUpdate, Boolean allOrNone)
```

**Parameters**

- `recordToUpdate`
  
  Type: `sObject`

- `allOrNone`
  
  Type: `Boolean`

  The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

**Return Value**

Type: `Database.SaveResult`

**Usage**

`update` is analogous to the UPDATE statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `update` method counts against the governor limit for DML statements.
Example

The following example updates the BillingCity field on a single account.

```java
Account a = new Account(Name='SFDC');
insert(a);

Account myAcct =
    {SELECT Id, Name, BillingCity
     FROM Account WHERE Id = :a.Id};
myAcct.BillingCity = 'San Francisco';

Database.SaveResult SR =
    Database.update(myAcct);
```

**update**(recordsToUpdate, allOrNone)

Modifies one or more existing sObject records, such as individual accounts or contacts, statement, in your organization’s data.

Signature

```java
public static Database.SaveResult[] update(sObject[] recordsToUpdate, Boolean allOrNone)
```

Parameters

- `recordsToUpdate`
  - Type: `sObject[]`
- `allOrNone`
  - Type: `Boolean`

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: `Database.SaveResult[]`

Usage

`update` is analogous to the UPDATE statement in SQL.

Each executed `update` method counts against the governor limit for DML statements.

**update**(recordToUpdate, dmlOptions)

Modifies an existing sObject record, such as an individual account or contact, in your organization’s data.

Signature

```java
public static Database.SaveResult update(sObject recordToUpdate, Database.DmlOptions dmlOptions)
```
Parameters

`recordToUpdate`
- Type: `sObject`

`dmlOptions`
- Type: `Database.DMLOptions`

The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value

Type: `Database.SaveResult`

Usage

`update` is analogous to the UPDATE statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `update` method counts against the governor limit for DML statements.

`update(recordsToUpdate, dmlOptions)`

Modifies one or more existing sObject records, such as individual accounts or contacts in invoice statements, in your organization’s data.

Signature

```java
public static Database.SaveResult[] update(sObject[] recordsToUpdate, Database.DMLOptions dmlOptions)
```

Parameters

`recordsToUpdate`
- Type: `sObject[]`

`dmlOptions`
- Type: `Database.DMLOptions`

The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value

Type: `Database.SaveResult[]`

Usage

`update` is analogous to the UPDATE statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `update` method counts against the governor limit for DML statements.
**upsert**(recordToUpsert, externalIdField, allOrNone)

Creates a new sObject record or updates an existing sObject record within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

**Signature**

```java
public static Database.UpsertResult upsert(sObject recordToUpsert, Schema.SObjectField externalIdField, Boolean allOrNone)
```

**Parameters**

- **recordToUpsert**
  - Type: `sObject`

- **externalIdField**
  - Type: `Schema.SObjectField`

  The `externalIdField` is of type `Schema.SObjectField`, that is, a field token. Find the token for the field by using the `fields` special method. For example, `Schema.SObjectField f = Account.Fields.MyExternalId`. The `externalIdField` parameter is the field that `upsert()` uses to match sObjects with existing records. This field can be a custom field marked as external ID, or a standard field with the `idLookup` attribute.

- **allOrNone**
  - Type: `Boolean`

  The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

**Return Value**

- Type: `Database.UpsertResult`

**Usage**

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `upsert` method counts against the governor limit for DML statements.

For more information on how the upsert operation works, see the `upsert()` statement.

**upsert**(recordsToUpsert, externalIdField, allOrNone)

Creates new sObject records or updates existing sObject records within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

**Signature**

```java
public static Database.UpsertResult[] upsert(sObject[] recordsToUpsert, Schema.SObjectField externalIdField, Boolean allOrNone)
```
**Parameters**

*recordsToUpsert*
  
  Type: *sObject []*

*externalIdField*
  
  Type: *Schema.SObjectField*

  The *externalIdField* is of type *Schema.SObjectField*, that is, a field token. Find the token for the field by using the *fields* special method. For example, `Schema.SObjectField f = Account.Fields.MyExternalId`. The *externalIdField* parameter is the field that *upsert()* uses to match sObjects with existing records. This field can be a custom field marked as external ID, or a standard field with the *idLookup* attribute.

*allOrNone*
  
  Type: *Boolean*

  The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify *false* for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set *true*, an exception is thrown if the method is not successful.

**Return Value**

Type: *Database.UpsertResult[]*

**Usage**

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed *upsert* method counts against the governor limit for DML statements.

For more information on how the upsert operation works, see the *upsert()* statement.

### `updateAsync(sobjects, callback)`

Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose *processSave* method is called for each record after the remote operations are completed.

**Signature**

Public static List<Database.SaveResult> updateAsync(List<SObject> sobjects, DataSource.AsyncSaveCallback callback)

**Parameters**

*sobjects*
  
  Type: *List<SObject>*

  List of external object records to modify.

*callback*
  
  Type: *DataSource.AsyncSaveCallback*
The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncSaveCallback`.

Return Value
Type: `List<Database.SaveResult>`
Status results for the update operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

**updateAsync(sobject, callback)**
Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processSave` method is called after the remote operation is completed.

**Signature**
```java
public static Database.SaveResult updateAsync(SObject sobject,
                                           DataSource.AsyncSaveCallback callback)
```

**Parameters**
- `sobject`
  Type: `SObject`
  External object record to modify.
- `callback`
  Type: `DataSource.AsyncSaveCallback`
  The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncSaveCallback`.

**Return Value**
Type: `Database.SaveResult`
Status result for the insert operation. The result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

**updateAsync(sobjects)**
Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.

**Signature**
```java
public static List<Database.SaveResult> updateAsync(List<SObject> sobjects)
```
Parameters

\textit{sobject}

Type: List\langle SObject\rangle

List of external object records to modify.

Return Value

Type: List\langle Database.SaveResult\rangle

Status results for the update operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The \textit{asyncLocator} value is included in the errors array of the result. You can retrieve this identifier with \textit{Database.getAsyncLocator()} and retrieve the final result with \textit{Database.getAsyncSaveResult()}.

\textbf{updateAsync(sobject)}

Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.

Signature

\textbf{public static Database.SaveResult updateAsync(SObject sobject)}

Parameters

\textit{sobject}

Type: SObject

External object record to modify.

Return Value

Type: Database.SaveResult

Status result for the insert operation. The result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The \textit{asyncLocator} value is included in the errors array of the result. You can retrieve this identifier with \textit{Database.getAsyncLocator()} and retrieve the final result with \textit{Database.getAsyncSaveResult()}.

\textbf{updateImmediate(sobjects)}

Initiates requests to update external object data on the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can't be completed and throw exceptions.

Signature

\textbf{public static List\langle Database.SaveResult\rangle updateImmediate(List\langle SObject\rangle sobjects)}

Parameters

\textit{sobjects}

Type: List\langle SObject\rangle
List of external object records to modify.

Return Value
Type: List<Database.SaveResult>
Status results for the update operation.

**updateImmediate** (sobject)
Initiates a request to update external object data on the relevant external system. The request is executed synchronously and is sent to the external system that's defined by the external object's associated external data source. If the Apex transaction contains pending changes, the synchronous operation can't be completed and throws an exception.

Signature
```
public static Database.SaveResult updateImmediate(SObject object)
```

Parameters
`sobject`
Type: SObject
External object record to modify.

Return Value
Type: Database.SaveResult
Status result for the update operation.

**Date Class**
Contains methods for the Date primitive data type.

**Namespace**
System

**Usage**
For more information on Dates, see Primitive Data Types on page 26.

**Date Methods**
The following are methods for Date.

IN THIS SECTION:
```
addDays(additionalDays)
```
Adds the specified number of additional days to a Date.
addMonths(additionalMonths)
Adds the specified number of additional months to a Date

addYears(additionalYears)
Adds the specified number of additional years to a Date

day()
Returns the day-of-month component of a Date.

dayOfYear()
Returns the day-of-year component of a Date.

daysBetween(secondDate)
Returns the number of days between the Date that called the method and the specified date.

daysInMonth(year, month)
Returns the number of days in the month for the specified \textit{year} and \textit{month} (1=Jan).

format()
Returns the Date as a string using the locale of the context user

isLeapYear(year)
Returns \textit{true} if the specified year is a leap year.

isSameDay(dateToCompare)
Returns \textit{true} if the Date that called the method is the same as the specified date.

month()
Returns the month component of a Date (1=Jan).

monthsBetween(secondDate)
Returns the number of months between the Date that called the method and the specified date, ignoring the difference in days.

newInstance(year, month, day)
Constructs a Date from Integer representations of the \textit{year}, \textit{month} (1=Jan), and \textit{day}.

parse(stringDate)
Constructs a Date from a String. The format of the String depends on the local date format.

today()
Returns the current date in the current user's time zone.

toStartOfMonth()
Returns the first of the month for the Date that called the method.

toStartOfWeek()
Returns the start of the week for the Date that called the method, depending on the context user's locale.

valueOf(stringDate)
Returns a Date that contains the value of the specified String.

valueOf(fieldValue)
Converts the specified object to a Date. Use this method to convert a history tracking field value or an object that represents a Date value.

year()
Returns the year component of a Date
**addDays (additionalDays)**
Add the specified number of additional days to a Date.

**Signature**
public Date addDays(Integer additionalDays)

**Parameters**
additionalDays
Type: Integer

**Return Value**
Type: Date

**Example**
```java
Date myDate = Date.newInstance(1960, 2, 17);
Date newDate = myDate.addDays(2);
```

**addMonths (additionalMonths)**
Add the specified number of additional months to a Date.

**Signature**
public Date addMonths(Integer additionalMonths)

**Parameters**
additionalMonths
Type: Integer

**Return Value**
Type: Date

**Example**
```java
date myDate = date.newInstance(1990, 11, 21);
date newDate = myDate.addMonths(3);
date expectedDate = date.newInstance(1991, 2, 21);
system.assertEquals(expectedDate, newDate);
```

**addYears (additionalYears)**
Add the specified number of additional years to a Date.
Signature
```
public Date addYears(Integer additionalYears)
```

Parameters
- `additionalYears`
  - Type: `Integer`

Return Value
- Type: `Date`

Example
```
date myDate = date.newInstance(1983, 7, 15);
date newDate = myDate.addYears(2);
date expectedDate = date.newInstance(1985, 7, 15);
system.assertEquals(expectedDate, newDate);
```

`day()`
Returns the day-of-month component of a Date.

Signature
```
public Integer day()
```

Return Value
- Type: `Integer`

Example
```
date myDate = date.newInstance(1989, 4, 21);
Integer day = myDate.day();
system.assertEquals(21, day);
```

`dayOfYear()`
Returns the day-of-year component of a Date.

Signature
```
public Integer dayOfYear()
```

Return Value
- Type: `Integer`
Example

date myDate = date.newInstance(1998, 10, 21);
Integer day = myDate.dayOfYear();
system.assertEquals(294, day);

daysBetween (secondDate)
Returns the number of days between the Date that called the method and the specified date.

Signature

public Integer daysBetween(Date secondDate)

Parameters

secondDate
Type: Date

Return Value

Type: Integer

Usage

If the Date that calls the method occurs after the secondDate, the return value is negative.

Example

Date startDate = Date.newInstance(2008, 1, 1);
Date dueDate = Date.newInstance(2008, 1, 30);
Integer numberDaysDue = startDate.daysBetween(dueDate);

daysInMonth (year, month)
Returns the number of days in the month for the specified year and month (1=Jan).

Signature

public static Integer daysInMonth(Integer year, Integer month)

Parameters

year
Type: Integer

month
Type: Integer

Return Value

Type: Integer
Example

The following example finds the number of days in the month of February in the year 1960.

```java
Integer numberDays = date.daysInMonth(1960, 2);
```

**format()**

Returns the Date as a string using the locale of the context user

Signature

```java
public String format()
```

Return Value

Type: String

Example

```java
// In American-English locale
date myDate = date.newInstance(2001, 3, 21);
String dayString = myDate.format();

system.assertEquals('3/21/2001', dayString);
```

**isLeapYear(year)**

Returns true if the specified year is a leap year.

Signature

```java
public static Boolean isLeapYear(Integer year)
```

Parameters

`year`

Type: Integer

Return Value

Type: Boolean

Example

```java
system.assert(Date.isLeapYear(2004));
```

**isSameDay(dateToCompare)**

Returns true if the Date that called the method is the same as the specified date.
Signature
public Boolean isSameDay(Date dateToCompare)

Parameters
dateToCompare
Type: Date

Return Value
Type: Boolean

Example

date myDate = date.today();
date dueDate = date.newInstance(2008, 1, 30);
boolean dueNow = myDate.isSameDay(dueDate);

month()
Returns the month component of a Date (1=Jan).

Signature
public Integer month()

Return Value
Type: Integer

Example

date myDate = date.newInstance(2004, 11, 21);
Integer month = myDate.month();
system.assertEquals(11, month);

monthsBetween(secondDate)
Returns the number of months between the Date that called the method and the specified date, ignoring the difference in days.

Signature
public Integer monthsBetween(Date secondDate)

Parameters
secondDate
Type: Date
Return Value
Type: Integer

Example

```java
Date firstDate = Date.newInstance(2006, 12, 2);
Date secondDate = Date.newInstance(2012, 12, 8);
Integer monthsBetween = firstDate.monthsBetween(secondDate);
System.assertEquals(72, monthsBetween);
```

**newInstance**(year, month, day)

Constructs a Date from Integer representations of the year, month (1=Jan), and day.

Signature

```java
public static Date newInstance(Integer year, Integer month, Integer day)
```

Parameters

- **year**
  Type: Integer
- **month**
  Type: Integer
- **day**
  Type: Integer

Return Value
Type: Date

Example

The following example creates the date February 17th, 1960:

```java
Date myDate = date.newInstance(1960, 2, 17);
```

**parse**(stringDate)

Constructs a Date from a String. The format of the String depends on the local date format.

Signature

```java
public static Date parse(String stringDate)
```

Parameters

- **stringDate**
  Type: String
Return Value
Type: Date

Example
The following example works in some locales.

```java
date mydate = date.parse('12/27/2009');
```

today()

Returns the current date in the current user's time zone.

Signature
```java
public static Date today()
```

Return Value
Type: Date

toStartOfMonth()

Returns the first of the month for the Date that called the method.

Signature
```java
public Date toStartOfMonth()
```

Return Value
Type: Date

Example
```java
date myDate = date.newInstance(1987, 12, 17);
date firstDate = myDate.toStartOfMonth();
date expectedDate = date.newInstance(1987, 12, 1);
system.assertEquals(expectedDate, firstDate);
```

toStartOfWeek()

Returns the start of the week for the Date that called the method, depending on the context user's locale.

Signature
```java
public Date toStartOfWeek()
```

Return Value
Type: Date
Example
For example, the start of a week is Sunday in the United States locale, and Monday in European locales. For example:

```java
Date myDate = Date.today();
Date weekStart = myDate.toStartOfWeek();
```

**valueOf(stringDate)**
Returns a Date that contains the value of the specified String.

Signature

```java
public static Date valueOf(String stringDate)
```

Parameters

`stringDate`
Type: String

Return Value

Type: Date

Usage

The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the local time zone.

Example

```java
string year = '2008';
string month = '10';
string day = '5';
string hour = '12';
string minute = '20';
string second = '20';
string stringDate = year + '-' + month + '-' + day + ' ' + hour + ':' + minute + ':' + second;
Date myDate = date.valueOf(stringDate);
```

**valueOf(fieldValue)**
Converts the specified object to a Date. Use this method to convert a history tracking field value or an object that represents a Date value.

Signature

```java
public static Date valueOf(Object fieldValue)
```
Parameters

*fieldValue*

Type: Object

Return Value

Type: Date

Usage

Use this method with the `OldValue` or `NewValue` fields of history sObjects, such as `AccountHistory`, when the field is a Date field.

**Note:** In API version 33.0 or earlier, if you call `Date.valueOf` with an object that represents a `Datetime`, the method returns a `Date` value that contains the hours, minutes, and seconds. In version 34.0 and later, `Date.valueOf` converts the object to a valid `Date` without the time information. To convert a variable of type `Datetime` to a `Date`, use the `Datetime.date` method.

Example

This example converts history tracking fields to `Date` values.

```cpp
List<AccountHistory> ahlist = [SELECT Field, OldValue, NewValue FROM AccountHistory];
for (AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'MyDate__c') {
        Date oldValue = Date.valueOf(ah.OldValue);
        Date newValue = Date.valueOf(ah.NewValue);
    }
}
```

**year()**

Returns the year component of a Date

Signature

`public Integer year()`

Return Value

Type: Integer

Example

```cpp
date myDate = date.newInstance(1988, 12, 17);
system.assertEquals(1988, myDate.year());
```

**Datetime Class**

Contains methods for the Datetime primitive data type.
Namespace
System

Usage
For more information about the Datetime, see Primitive Data Types on page 26.

Datetime Methods
The following are methods for Datetime.

IN THIS SECTION:
addDays(additionalDays)
Adds the specified number of days to a Datetime.
addHours(additionalHours)
Adds the specified number of hours to a Datetime.
addMinutes(additionalMinutes)
Adds the specified number of minutes to a Datetime.
addMonths(additionalMonths)
Adds the specified number of months to a Datetime.
addSeconds(additionalSeconds)
Adds the specified number of seconds to a Datetime.
addYears(additionalYears)
Adds the specified number of years to a Datetime.
date()
Returns the Date component of a Datetime in the local time zone of the context user.
dateGMT()
Return the Date component of a Datetime in the GMT time zone.
day()
Returns the day-of-month component of a Datetime in the local time zone of the context user.
dayGmt()
Returns the day-of-month component of a Datetime in the GMT time zone.
dayOfYear()
Returns the day-of-year component of a Datetime in the local time zone of the context user.
dayOfYearGmt()
Returns the day-of-year component of a Datetime in the GMT time zone.
format()
Converts the date to the local time zone and returns the converted date as a formatted string using the locale of the context user. If the time zone cannot be determined, GMT is used.
format(dateFormatString)
Converts the date to the local time zone and returns the converted date as a string using the supplied Java simple date format. If the time zone cannot be determined, GMT is used.
format(dateFormatString, timezone)
Converts the date to the specified time zone and returns the converted date as a string using the supplied Java simple date format. If the supplied time zone is not in the correct format, GMT is used.

formatGmt(dateFormatString)
Returns a Datetime as a string using the supplied Java simple date format and the GMT time zone.

formatLong()
Converts the date to the local time zone and returns the converted date in long date format.

getTime()
Returns the number of milliseconds since January 1, 1970, 00:00:00 GMT represented by this DateTime object.

hour()
Returns the hour component of a Datetime in the local time zone of the context user.

hourGmt()
Returns the hour component of a Datetime in the GMT time zone.

isSameDay(dateToCompare)
Returns true if the Datetime that called the method is the same as the specified Datetime in the local time zone of the context user.

millisecond()
Returns the millisecond component of a Datetime in the local time zone of the context user.

millisecondGmt()
Returns the millisecond component of a Datetime in the GMT time zone.

minute()
Returns the minute component of a Datetime in the local time zone of the context user.

minuteGmt()
Returns the minute component of a Datetime in the GMT time zone.

month()
Returns the month component of a Datetime in the local time zone of the context user (1=Jan).

monthGmt()
Returns the month component of a Datetime in the GMT time zone (1=Jan).

newInstance(milliseconds)
Constructs a Datetime and initializes it to represent the specified number of milliseconds since January 1, 1970, 00:00:00 GMT.

newInstance(date, time)
Constructs a DateTime from the specified date and time in the local time zone.

newInstance(year, month, day)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the local time zone.

newInstance(year, month, day, hour, minute, second)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the local time zone.

newInstanceGmt(date, time)
Constructs a DateTime from the specified date and time in the GMT time zone.

newInstanceGmt(year, month, date)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the GMT time zone.
newInstanceGmt(year, month, date, hour, minute, second)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the GMT time zone.

now()
Returns the current Datetime based on a GMT calendar.

parse(datetimeString)
Constructs a Datetime from the given String in the local time zone and in the format of the user locale.

second()
Returns the second component of a Datetime in the local time zone of the context user.

secondGmt()
Returns the second component of a Datetime in the GMT time zone.

time()
Returns the time component of a Datetime in the local time zone of the context user.

timeGmt()
Returns the time component of a Datetime in the GMT time zone.

valueOf(dateTimeString)
Returns a Datetime that contains the value of the specified string.

valueOf(fieldValue)
Converts the specified object to a Datetime. Use this method to convert a history tracking field value or an object that represents a Datetime value.

valueOfGmt(dateTimeString)
Returns a Datetime that contains the value of the specified String.

year()
Returns the year component of a Datetime in the local time zone of the context user.

yearGmt()
Returns the year component of a Datetime in the GMT time zone.

addDays(additionalDays)
Adds the specified number of days to a Datetime.

Signature
public Datetime addDays(Integer additionalDays)

Parameters

additionalDays
Type: Integer

Return Value
Type: Datetime
addHours(additionalHours)

Adds the specified number of hours to a Datetime.

Signature

public Datetime addHours(Integer additionalHours)

Parameters

additionalHours
Type: Integer

Return Value

Type: Datetime

Example

DateTime myDateTime = DateTime.newInstance(1997, 1, 31, 7, 8, 16);
DateTime newDateTime = myDateTime.addHours(3);
DateTime expected = DateTime.newInstance(1997, 1, 31, 10, 8, 16);
System.assertEquals(expected, newDateTime);

addMinutes(additionalMinutes)

Adds the specified number of minutes to a Datetime.

Signature

public Datetime addMinutes(Integer additionalMinutes)

Parameters

additionalMinutes
Type: Integer

Return Value

Type: Datetime

Example

DateTime myDateTime = DateTime.newInstance(1997, 1, 31, 7, 8, 16);
DateTime newDateTime = myDateTime.addMinutes(3);
DateTime expected = DateTime.newInstance(1997, 1, 31, 7, 11, 16);
System.assertEquals(expected, newDateTime);
Example

```java
datetime myDateTime = datetime.newInstance(1999, 2, 11, 8, 6, 16);
datetime newDateTime = myDateTime.addMinutes(7);
datetime expected = datetime.newInstance(1999, 2, 11, 8, 13, 16);
System.assertEquals(expected, newDateTime);
```

addMonths(additionalMonths)

Adds the specified number of months to a Date time.

Signature

```java
public datetime addMonths(int additionalMonths)
```

Parameters

- `additionalMonths`
  - Type: `Integer`

Return Value

Type: `datetime`

Example

```java
datetime myDateTime = datetime.newInstance(2000, 7, 7, 7, 8, 12);
datetime newDateTime = myDateTime.addMonths(1);
datetime expected = datetime.newInstance(2000, 8, 7, 7, 8, 12);
System.assertEquals(expected, newDateTime);
```

addSeconds(additionalSeconds)

Adds the specified number of seconds to a Date time.

Signature

```java
public datetime addSeconds(int additionalSeconds)
```

Parameters

- `additionalSeconds`
  - Type: `Integer`

Return Value

Type: `datetime`
**addYears(additionalYears)**

Adds the specified number of years to a Datetime.

**Signature**

```java
public Datetime addYears(Integer additionalYears)
```

**Parameters**

- **additionalYears**
  - Type: `Integer`

**Return Value**

- Type: `Datetime`

**Example**

```java
DateTime myDateTime = DateTime.newInstance(2009, 12, 17, 13, 6, 6);
DateTime newDateTime = myDateTime.addYears(1);
DateTime expected = DateTime.newInstance(2010, 12, 17, 13, 6, 6);
System.assertEquals(expected, newDateTime);
```

**date()**

Returns the Date component of a Datetime in the local time zone of the context user.

**Signature**

```java
public Date date()
```

**Return Value**

- Type: `Date`

**Example**

```java
DateTime myDateTime = DateTime.newInstance(2006, 3, 16, 12, 6, 13);
Date myDate = myDateTime.date();
Date expected = Date.newInstance(2006, 3, 16);
System.assertEquals(expected, myDate);
```
**dateGMT()**

Return the Date component of a Datetime in the GMT time zone.

**Signature**

```java
public Date dateGMT()
```

**Return Value**

Type: Date

**Example**

```java
// California local time, PST
DateTime myDateTime = DateTime.newInstance(2006, 3, 16, 23, 0, 0);
Date myDate = myDateTime.dateGMT();
Date expected = Date.newInstance(2006, 3, 17);
System.assertEquals(expected, myDate);
```

**day()**

Returns the day-of-month component of a Datetime in the local time zone of the context user.

**Signature**

```java
public Integer day()
```

**Return Value**

Type: Integer

**Example**

```java
DateTime myDateTime = DateTime.newInstance(1986, 2, 21, 23, 0, 0);
System.assertEquals(21, myDateTime.day());
```

**dayGmt()**

Returns the day-of-month component of a Datetime in the GMT time zone.

**Signature**

```java
public Integer dayGmt()
```

**Return Value**

Type: Integer
Example

// California local time, PST
DateTime myDateTime = DateTime.newInstance(1987, 1, 14, 23, 0, 3);
System.assertEquals(15, myDateTime.dayGMT());

dayOfYear()
Returns the day-of-year component of a Datetime in the local time zone of the context user.

Signature
public Integer dayOfYear()

Return Value
Type: Integer

Example
For example, February 5, 2008 08:30:12 would be day 36.

Datetime myDate = Datetime.newInstance(2008, 2, 5, 8, 30, 12);
System.assertEquals(myDate.dayOfYear(), 36);

dayOfYearGmt()
Returns the day-of-year component of a Datetime in the GMT time zone.

Signature
public Integer dayOfYearGmt()

Return Value
Type: Integer

Example
// This sample assumes we are in the PST timezone
DateTime myDateTime = DateTime.newInstance(1999, 2, 5, 23, 0, 3);
// January has 31 days + 5 days in February = 36 days
// dayOfYearGmt() adjusts the time zone from the current time zone to GMT
// by adding 8 hours to the PST time zone, so it's 37 days and not 36 days
System.assertEquals(37, myDateTime.dayOfYearGmt());

format()
Converts the date to the local time zone and returns the converted date as a formatted string using the locale of the context user. If the time zone cannot be determined, GMT is used.
public String format()

Return Value
Type: String

Example:

```java
DateTime myDateTime = DateTime.newInstance(1993, 6, 6, 3, 3, 3);
system.assertEquals('6/6/1993 3:03 AM', mydatetime.format());
```

**format(dateFormatString)**
Converts the date to the local time zone and returns the converted date as a string using the supplied Java simple date format. If the time zone cannot be determined, GMT is used.

Signature

```java
public String format(String dateFormatString)
```

Parameters

dateFormatString
Type: String

Return Value
Type: String

Usage
For more information on the Java simple date format, see Java SimpleDateFormat.

Example:

```java
Datetime myDT = Datetime.now();
String myDate = myDT.format('h:mm a');
```

**format(dateFormatString, timezone)**
Converts the date to the specified time zone and returns the converted date as a string using the supplied Java simple date format. If the supplied time zone is not in the correct format, GMT is used.

Signature

```java
public String format(String dateFormatString, String timezone)
```
Parameters

dateFormatString
  Type: String

timezone
  Type: String

Valid time zone values for the timezone argument are the time zones of the Java TimeZone class that correspond to the time zones returned by the TimeZone.getAvailableIDs method in Java. We recommend you use full time zone names, not the three-letter abbreviations.

Return Value
Type: String

Usage
For more information on the Java simple date format, see Java SimpleDateFormat.

Example
This example uses format to convert a GMT date to the America/New_York time zone and formats the date using the specified date format.

```java
Datetime GMTDate =
  Datetime.newInstanceGmt(2011,6,1,12,1,5);
String strConvertedDate =
  GMTDate.format('MM/dd/yyyy HH:mm:ss',
                 'America/New_York');
// Date is converted to
// the new time zone and is adjusted
// for daylight saving time.
System.assertEquals(   '06/01/2011 08:01:05', strConvertedDate);
```

formatGmt(dateFormatString)
Returns a Datetime as a string using the supplied Java simple date format and the GMT time zone.

Signature
public String formatGmt(String dateFormatString)
Usage
For more information on the Java simple date format, see Java SimpleDateFormat.

Example
```
DateTime myDateTime = DateTime.newInstance(1993, 6, 6, 3, 3, 3);
String formatted = myDateTime.formatGMT('EEE, MMM d yyyy HH:mm:ss');
String expected = 'Sun, Jun 6 1993 10:03:03';
System.assertEquals(expected, formatted);
```

**formatLong()**
Converts the date to the local time zone and returns the converted date in long date format.

Signature
```
public String formatLong()
```

Return Value
Type: **String**

Example
```
// Passing local date based on the PST time zone
Datetime dt = DateTime.newInstance(2012,12,28,10,0,0);
// Writes 12/28/2012 10:00:00 AM PST
System.debug('dt.formatLong()=' + dt.formatLong());
```

**getTime()**
Returns the number of milliseconds since January 1, 1970, 00:00:00 GMT represented by this DateTime object.

Signature
```
public Long getTime()
```

Return Value
Type: **Long**

Example
```
DateTime dt = DateTime.newInstance(2007, 6, 23, 3, 3, 3);
Long gettime = dt.getTime();
Long expected = 1182592983000L;
System.assertEquals(expected, gettime);
```
hour()
Returns the hour component of a Datetime in the local time zone of the context user.

Signature
public Integer hour()

Return Value
Type: Integer

Example
DateTime myDateTime = DateTime.newInstance(1998, 11, 21, 3, 3, 3);
System.assertEquals(3, myDateTime.hour());

hourGmt()
Returns the hour component of a Datetime in the GMT time zone.

Signature
public Integer hourGmt()

Return Value
Type: Integer

Example
// California local time
DateTime myDateTime = DateTime.newInstance(2000, 4, 27, 3, 3, 3);
System.assertEquals(10, myDateTime.hourGmt());

isSameDay(dateToCompare)
Returns true if the Datetime that called the method is the same as the specified Datetime in the local time zone of the context user.

Signature
public Boolean isSameDay(Datetime dateToCompare)

Parameters
dateToCompare
Type: Datetime

Return Value
Type: Boolean
datetime myDate = datetime.now();
datetime dueDate =
    datetime.newInstance(2008, 1, 30);
boolean dueNow = myDate.isSameDay(dueDate);

milliseconds

Return the millisecond component of a Datetime in the local time zone of the context user.

Signature

public Integer millisecond()

Return Value
Type: Integer

Example

DateTime myDateTime = DateTime.now();
system.debug(myDateTime.millisecond());

millisecondsGmt

Return the millisecond component of a Datetime in the GMT time zone.

Signature

public Integer millisecondGmt()

Return Value
Type: Integer

Example

DateTime myDateTime = DateTime.now();
system.debug(myDateTime.millisecondGMT());

minute

Returns the minute component of a Datetime in the local time zone of the context user.

Signature

public Integer minute()
Return Value
Type: Integer

Example
```java
DateTime myDateTime = DateTime.newInstance(2001, 2, 27, 3, 3, 3);
system.assertEquals(3, myDateTime.minute());
```

`minuteGmt()`
Returns the minute component of a Datetime in the GMT time zone.

Signature
```java
public Integer minuteGmt()
```

Return Value
Type: Integer

Example
```java
DateTime myDateTime = DateTime.newInstance(2002, 12, 3, 3, 3, 3);
system.assertEquals(3, myDateTime.minuteGMT());
```

`month()`
Returns the month component of a Datetime in the local time zone of the context user (1=Jan).

Signature
```java
public Integer month()
```

Return Value
Type: Integer

Example
```java
DateTime myDateTime = DateTime.newInstance(2004, 11, 4, 3, 3, 3);
system.assertEquals(11, myDateTime.month());
```

`monthGmt()`
Returns the month component of a Datetime in the GMT time zone (1=Jan).

Signature
```java
public Integer monthGmt()
```
Return Value
Type: Integer

Example
```
DateTime myDateTime = DateTime.newInstance(2006, 11, 19, 3, 3, 3);
system.assertEquals(11, myDateTime.monthGMT());
```

**newInstance(milliseconds)**
Constructs a Datetime and initializes it to represent the specified number of milliseconds since January 1, 1970, 00:00:00 GMT.

Signature
```
public static Datetime newInstance(Long milliseconds)
```

Parameters
- milliseconds
  Type: Long

Return Value
Type: Datetime
The returned date is in the GMT time zone.

Example
```
Long longtime = 1341828183000L;
DateTime dt = DateTime.newInstance(longtime);
DateTime expected = DateTime.newInstance(2012, 7, 09, 3, 3, 3);
System.assertEquals(expected, dt);
```

**newInstance(date, time)**
Constructs a DateTime from the specified date and time in the local time zone.

Signature
```
public static Datetime newInstance(Date date, Time time)
```

Parameters
- date
  Type: Date
- time
  Type: Time
Return Value

Type: Datetime

The returned date is in the GMT time zone.

Example

```java
Date myDate = Date.newInstance(2011, 11, 18);
Time myTime = Time.newInstance(3, 3, 3, 0);
DateTime dt = DateTime.newInstance(myDate, myTime);
DateTime expected = DateTime.newInstance(2011, 11, 18, 3, 3, 3);
System.assertEquals(expected, dt);
```

**newInstance(year, month, day)**

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the local time zone.

Signature

```java
public static Datetime newInstance(Integer year, Integer month, Integer day)
```

Parameters

- `year` Type: Integer
- `month` Type: Integer
- `day` Type: Integer

Return Value

Type: Datetime

The returned date is in the GMT time zone.

Example

```java
datetime myDate = datetime.newInstance(2008, 12, 1);
```

**newInstance(year, month, day, hour, minute, second)**

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the local time zone.

Signature

```java
public static Datetime newInstance(Integer year, Integer month, Integer day, Integer hour, Integer minute, Integer second)
```
Parameters

- **year**
  Type: Integer
- **month**
  Type: Integer
- **day**
  Type: Integer
- **hour**
  Type: Integer
- **minute**
  Type: Integer
- **second**
  Type: Integer

Return Value

Type: Datetime

The returned date is in the GMT time zone.

Example

```
Datetime myDate = Datetime.newInstance(2008, 12, 1, 12, 30, 2);
```

**newInstanceGmt(date, time)**

Constructs a DateTime from the specified date and time in the GMT time zone.

Signature

```
public static Datetime newInstanceGmt(Date date, Time time)
```

Parameters

- **date**
  Type: Date
- **time**
  Type: Time

Return Value

Type: Datetime

Example

```
Date myDate = Date.newInstance(2013, 11, 12);
Time myTime = Time.newInstance(3, 3, 3, 0);
DateTime dt = DateTime.newInstanceGMT(myDate, myTime);
```
newInstanceGmt(year, month, date)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the GMT time zone

Signature
public static Datetime newInstanceGmt(Integer year, Integer month, Integer date)

Parameters
year
  Type: Integer
month
  Type: Integer
date
  Type: Integer

Return Value
Type: Datetime

Example
DateTime dt = DateTime.newInstanceGMT(1996, 3, 22);

newInstanceGmt(year, month, date, hour, minute, second)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the GMT time zone

Signature
public static Datetime newInstanceGmt(Integer year, Integer month, Integer date, Integer hour, Integer minute, Integer second)

Parameters
year
  Type: Integer
month
  Type: Integer
date
  Type: Integer
hour
  Type: Integer

minute
  Type: Integer

second
  Type: Integer

Return Value
Type: Datetime

Example

//California local time
DateTime dt = DateTime.newInstanceGMT(1998, 1, 29, 2, 2, 3);
DateTime expected = DateTime.newInstance(1998, 1, 28, 18, 2, 3);
System.assertEquals(expected, dt);

now()
Returns the current Datetime based on a GMT calendar.

Signature
public static Datetime now()

Return Value
Type: Datetime
The format of the returned datetime is: 'MM/DD/YYYY HH:MM PERIOD'

Example

datetime myDateTime = datetime.now();

parse(datetimeString)
Constructs a Datetime from the given String in the local time zone and in the format of the user locale.

Signature
public static Datetime parse(String datetimeString)

Parameters
datetimeString
  Type: String

Return Value
Type: Datetime
The returned date is in the GMT time zone.

Example
This example uses `parse` to create a Datetime from a date passed in as a string and that is formatted for the English (United States) locale. You may need to change the format of the date string if you have a different locale.

```java
Datetime dt = DateTime.parse('10/14/2011 11:46 AM');
String myDtString = dt.format();
system.assertEquals(myDtString, '10/14/2011 11:46 AM');
```

**second()**

Returns the second component of a Datetime in the local time zone of the context user.

**Signature**

```java
public Integer second()
```

**Return Value**

Type: Integer

**Example**

```java
DateTime dt = DateTime.newInstanceGMT(1999, 9, 22, 3, 1, 2);
System.assertEquals(2, dt.second());
```

**secondGMT()**

Returns the second component of a Datetime in the GMT time zone.

**Signature**

```java
public Integer secondGMT()
```

**Return Value**

Type: Integer

**Example**

```java
DateTime dt = DateTime.newInstance(2000, 2, 3, 3, 1, 5);
System.assertEquals(5, dt.secondGMT());
```

**time()**

Returns the time component of a Datetime in the local time zone of the context user.
Signature

```java
public Time time()
```

Return Value

Type: Time

Example

```java
DateTime dt = DateTime.newInstance(2002, 11, 21, 0, 2, 2);
Time expected = Time.newInstance(0, 2, 2, 0);
System.assertEquals(expected, dt.time());
```

**timeGmt()**

Returns the time component of a Datetime in the GMT time zone.

Signature

```java
public Time timeGmt()
```

Return Value

Type: Time

Example

```java
// This sample is based on the PST time zone
DateTime dt = DateTime.newInstance(2004, 1, 27, 4, 1, 2);
Time expected = Time.newInstance(12, 1, 2, 0);
// 8 hours are added to the time to convert it from
// PST to GMT
System.assertEquals(expected, dt.timeGMT());
```

**valueOf(dateTimeString)**

Returns a Datetime that contains the value of the specified string.

Signature

```java
public static Datetime valueOf(String dateTimeString)
```

Parameters

- `dateTimeString`  
  Type: String

Return Value

Type: Datetime
The returned date is in the GMT time zone.

Usage

The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the local time zone.

Example

```java
string year = '2008';
string month = '10';
string day = '5';
string hour = '12';
string minute = '20';
string second = '20';
string stringDate = year + '-' + month + '-' + day + ' ' + hour + ':'
    + minute + ':' + second;

Datetime myDate = Datetime.valueOf(stringDate);
```

**valueOf(fieldValue)**

Converts the specified object to a Datetime. Use this method to convert a history tracking field value or an object that represents a Datetime value.

Signature

```java
public static Datetime valueOf(Object fieldValue)
```

Parameters

- **fieldValue**
  - Type: Object

Return Value

- Type: Datetime

Usage

Use this method with the **OldValue** or **NewValue** fields of history sObjects, such as **AccountHistory**, when the field is a Date/Time field.

Example

```java
List<AccountHistory> ahlist = [SELECT Field, OldValue, NewValue FROM AccountHistory];
for(AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'MyDatetime__c') {
        Datetime oldValue = Datetime.valueOf(ah.OldValue);
        Datetime newValue = Datetime.valueOf(ah.NewValue);
    }
}
```
valueOfGmt(String dateTimeString)
Returns a Datetime that contains the value of the specified String.

Signature
public static Datetime valueOfGmt(String dateTimeString)

Parameters
dateTimeString
Type: String

Return Value
Type: Datetime

Usage
The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the GMT time zone.

Example

```java
// California locale time
string year = '2009';
string month = '3';
string day = '5';
string hour = '5';
string minute = '2';
string second = '2';
string stringDate = year + '-' + month + '-' + day + ' ' + hour + ':'
    + minute + ':' + second;

Datetime myDate = Datetime.valueOfGMT(stringDate);

DateTime expected = DateTime.newInstance(2009, 3, 4, 21, 2, 2);
System.assertEquals(expected, myDate);
```

year()
Returns the year component of a Datetime in the local time zone of the context user.

Signature
public Integer year()
Return Value
Type: Integer

Example
```
DateTime dt = DateTime.newInstance(2012, 1, 26, 5, 2, 4);
System.assertEquals(2012, dt.year());
```

`yearGmt()`
Returns the year component of a Datetime in the GMT time zone.

Signature
```
public Integer yearGmt()
```

Example
```
DateTime dt = DateTime.newInstance(2012, 10, 4, 6, 4, 6);
System.assertEquals(2012, dt.yearGMT());
```

Decimal Class
Contains methods for the Decimal primitive data type.

Namespace
```
System
```

Usage
For more information on Decimal, see Primitive Data Types on page 26.

IN THIS SECTION:
  - Rounding Mode
  - Decimal Methods

Rounding Mode
Rounding mode specifies the rounding behavior for numerical operations capable of discarding precision.

Each rounding mode indicates how the least significant returned digit of a rounded result is to be calculated. The following are the valid values for `roundingMode`. 

2692
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEILING</td>
<td>Rounds towards positive infinity. That is, if the result is positive, this mode behaves the same as the UP rounding mode; if the result is negative, it behaves the same as the DOWN rounding mode. Note that this rounding mode never decreases the calculated value. For example:</td>
</tr>
<tr>
<td></td>
<td>• Input number 5.5: CEILING round mode result: 6</td>
</tr>
<tr>
<td></td>
<td>• Input number 1.1: CEILING round mode result: 2</td>
</tr>
<tr>
<td></td>
<td>• Input number -1.1: CEILING round mode result: -1</td>
</tr>
<tr>
<td></td>
<td>• Input number -2.7: CEILING round mode result: -2</td>
</tr>
<tr>
<td></td>
<td>Decimal[] example = new Decimal[](5.5, 1.1, -1.1, -2.7);</td>
</tr>
<tr>
<td></td>
<td>Long[] expected = new Long[](6, 2, -1, -2);</td>
</tr>
<tr>
<td></td>
<td>for(integer x = 0; x &lt; example.size(); x++){</td>
</tr>
<tr>
<td></td>
<td>System.assertEquals(expected[x],</td>
</tr>
<tr>
<td></td>
<td>example[x].round(System.RoundingMode.CEILING));</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>DOWN</td>
<td>Rounds towards zero. This rounding mode always discards any fractions (decimal points) prior to executing. Note that this rounding mode never increases the magnitude of the calculated value. For example:</td>
</tr>
<tr>
<td></td>
<td>• Input number 5.5: DOWN round mode result: 5</td>
</tr>
<tr>
<td></td>
<td>• Input number 1.1: DOWN round mode result: 1</td>
</tr>
<tr>
<td></td>
<td>• Input number -1.1: DOWN round mode result: -1</td>
</tr>
<tr>
<td></td>
<td>• Input number -2.7: DOWN round mode result: -2</td>
</tr>
<tr>
<td></td>
<td>Decimal[] example = new Decimal[](5.5, 1.1, -1.1, -2.7);</td>
</tr>
<tr>
<td></td>
<td>Long[] expected = new Long[](5, 1, -1, -2);</td>
</tr>
<tr>
<td></td>
<td>for(integer x = 0; x &lt; example.size(); x++){</td>
</tr>
<tr>
<td></td>
<td>System.assertEquals(expected[x],</td>
</tr>
<tr>
<td></td>
<td>example[x].round(System.RoundingMode.DOWN));</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>FLOOR</td>
<td>Rounds towards negative infinity. That is, if the result is positive, this mode behaves the same as the DOWN rounding mode; if negative, this mode behaves the same as the UP rounding mode. Note that this rounding mode never increases the calculated value. For example:</td>
</tr>
<tr>
<td></td>
<td>• Input number 5.5: FLOOR round mode result: 5</td>
</tr>
<tr>
<td></td>
<td>• Input number 1.1: FLOOR round mode result: 1</td>
</tr>
<tr>
<td></td>
<td>• Input number -1.1: FLOOR round mode result: -2</td>
</tr>
<tr>
<td></td>
<td>• Input number -2.7: FLOOR round mode result: -3</td>
</tr>
<tr>
<td></td>
<td>Decimal[] example = new Decimal[](5.5, 1.1, -1.1, -2.7);</td>
</tr>
<tr>
<td></td>
<td>Long[] expected = new Long[](5, 1, -2, -3);</td>
</tr>
<tr>
<td></td>
<td>for(integer x = 0; x &lt; example.size(); x++){</td>
</tr>
<tr>
<td></td>
<td>System.assertEquals(expected[x],</td>
</tr>
<tr>
<td></td>
<td>example[x].round(System.RoundingMode.FLOOR));</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>HALF_DOWN</td>
<td>Rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case this mode rounds down. This rounding mode behaves the same as the UP rounding mode if the discarded fraction (decimal point) is &gt; 0.5; otherwise, it behaves the same as DOWN rounding mode. For example:</td>
</tr>
<tr>
<td></td>
<td>- Input number 5.5: HALF_DOWN round mode result: 5</td>
</tr>
<tr>
<td></td>
<td>- Input number 1.1: HALF_DOWN round mode result: 1</td>
</tr>
<tr>
<td></td>
<td>- Input number -1.1: HALF_DOWN round mode result: -1</td>
</tr>
<tr>
<td></td>
<td>- Input number -2.7: HALF_DOWN round mode result: -3</td>
</tr>
<tr>
<td></td>
<td><code>Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};</code></td>
</tr>
<tr>
<td></td>
<td><code>Long[] expected = new Long[]{5, 1, -1, -3};</code></td>
</tr>
<tr>
<td></td>
<td><code>for(integer x = 0; x &lt; example.size(); x++){</code></td>
</tr>
<tr>
<td></td>
<td>System.assertEquals(expected[x], example[x].round(System.RoundingMode.HALF_DOWN));</td>
</tr>
<tr>
<td></td>
<td><code>}</code></td>

| HALF_EVEN        | Rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor. This rounding mode behaves the same as the HALF_UP rounding mode if the digit to the left of the discarded fraction (decimal point) is odd. It behaves the same as the HALF_DOWN rounding method if it is even. For example: |
|                  | - Input number 5.5: HALF_EVEN round mode result: 6                                                                                                                                  |
|                  | - Input number 1.1: HALF_EVEN round mode result: 1                                                                                                                                      |
|                  | - Input number -1.1: HALF_EVEN round mode result: -1                                                                                                                                   |
|                  | - Input number -2.7: HALF_EVEN round mode result: -3                                                                                                                                   |
|                  | `Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};`                                                                                                                               |
|                  | `Long[] expected = new Long[]{6, 1, -1, -3};`                                                                                                                                             |
|                  | `for(integer x = 0; x < example.size(); x++){`                                                                                                                                            |
|                  |     System.assertEquals(expected[x], example[x].round(System.RoundingMode.HALF_EVEN));                                                                                           |
|                  | `}`                                                                                                                                                                                          |

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

| HALF_UP          | Rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds up. This rounding method behaves the same as the UP rounding method if the discarded fraction (decimal point) is >= 0.5; otherwise, this rounding method behaves the same as the DOWN rounding method. For example: |
|                  | - Input number 5.5: HALF_UP round mode result: 6                                                                                                                                  |
|                  | - Input number 1.1: HALF_UP round mode result: 1                                                                                                                                      |
|                  | - Input number -1.1: HALF_UP round mode result: -1                                                                                                                                   |
|                  | - Input number -2.7: HALF_UP round mode result: -3                                                                                                                                   |
|                  | `Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};`                                                                                                                               |
|                  | `Long[] expected = new Long[]{6, 1, -1, -3};`                                                                                                                                             |
|                  | `for(integer x = 0; x < example.size(); x++){`                                                                                                                                            |
|                  |     System.assertEquals(expected[x], example[x].round(System.RoundingMode.HALF_UP));                                                                                           |
|                  | `}`                                                                                                                                                                                          |
### UNNECESSARY

Asserts that the requested operation has an exact result, which means that no rounding is necessary. If this rounding mode is specified on an operation that yields an inexact result, a `MathException` is thrown. For example:

- Input number 5.5: `UNNECESSARY` round mode result: `MathException`
- Input number 1.1: `UNNECESSARY` round mode result: `MathException`
- Input number 1.0: `UNNECESSARY` round mode result: 1
- Input number -1.0: `UNNECESSARY` round mode result: -1
- Input number -2.2: `UNNECESSARY` round mode result: `MathException`

```java
Decimal example1 = 5.5;
Decimal example2 = 1.0;
system.assertEquals(1,
    example2.round(System.RoundingMode.UNNECESSARY));
try{
    example1.round(System.RoundingMode.UNNECESSARY);
} catch(Exception E) {
    system.assertEquals('System.MathException', E.getTypeName());
}
```

### UP

Rounds away from zero. This rounding mode always truncates any fractions (decimal points) prior to executing. Note that this rounding mode never decreases the magnitude of the calculated value. For example:

- Input number 5.5: `UP` round mode result: 6
- Input number 1.1: `UP` round mode result: 2
- Input number -1.1: `UP` round mode result: -2
- Input number -2.7: `UP` round mode result: -3

```java
Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
Long[] expected = new Long[]{6, 2, -2, -3};
for(integer x = 0; x < example.size(); x++){
    System.assertEquals(expected[x],
        example[x].round(System.RoundingMode.UP));
}
```

### Decimal Methods

The following are methods for `Decimal`.

**IN THIS SECTION:**

- `abs()`
  
Rounds away from zero. This rounding mode always truncates any fractions (decimal points) prior to executing. Note that this rounding mode never decreases the magnitude of the calculated value. For example:

- Input number 5.5: `UP` round mode result: 6
- Input number 1.1: `UP` round mode result: 2
- Input number -1.1: `UP` round mode result: -2
- Input number -2.7: `UP` round mode result: -3

```java
Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
Long[] expected = new Long[]{6, 2, -2, -3};
for(integer x = 0; x < example.size(); x++){
    System.assertEquals(expected[x],
        example[x].round(System.RoundingMode.UP));
}
```
divide(divisor, scale)
Divides this Decimal by the specified divisor, and sets the scale, that is, the number of decimal places, of the result using the specified scale.

divide(divisor, scale, roundingMode)
Divides this Decimal by the specified divisor, sets the scale, that is, the number of decimal places, of the result using the specified scale, and if necessary, rounds the value using the rounding mode.

doubleValue()
Returns the Double value of this Decimal.

format()
Returns the String value of this Decimal using the locale of the context user.

intValue()
Returns the Integer value of this Decimal.

longValue()
Returns the Long value of this Decimal.

pow(exponent)
Returns the value of this decimal raised to the power of the specified exponent.

precision()
Returns the total number of digits for the Decimal.

round()
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

round(roundingMode)
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using the rounding mode specified by the rounding mode.

scale()
Returns the scale of the Decimal, that is, the number of decimal places.

setScale(scale)
Returns the Decimal scaled to the specified number of decimal places, using half-even rounding, if necessary. Half-even rounding mode rounds toward the “nearest neighbor.” If both neighbors are equidistant, the number is rounded toward the even neighbor.

setScale(scale, roundingMode)
Returns the Decimal scaled to the specified number of decimal places, using the specified rounding mode, if necessary.

stripTrailingZeros()
Returns the Decimal with any trailing zeros removed.

toPlainString()
Returns the String value of this Decimal, without using scientific notation.

valueOf(doubleToDecimal)
Returns a Decimal that contains the value of the specified Double.

valueOf(longToDecimal)
Returns a Decimal that contains the value of the specified Long.
valueOf(stringToDecimal)
Returns a Decimal that contains the value of the specified String. As in Java, the string is interpreted as representing a signed Decimal.

abs()
Returns the absolute value of the Decimal.

Signature
public Decimal abs()

Return Value
Type: Decimal

Example
Decimal myDecimal = -6.02214129;
System.assertEquals(6.02214129, myDecimal.abs());

divide(divisor, scale)
Divides this Decimal by the specified divisor, and sets the scale, that is, the number of decimal places, of the result using the specified scale.

Signature
public Decimal divide(Decimal divisor, Integer scale)

Parameters
divisor
  Type: Decimal
scale
  Type: Integer

Return Value
Type: Decimal

Example
Decimal decimalNumber = 19;
Decimal result = decimalNumber.divide(100, 3);
System.assertEquals(0.190, result);

divide(divisor, scale, roundingMode)
Divides this Decimal by the specified divisor, sets the scale, that is, the number of decimal places, of the result using the specified scale, and if necessary, rounds the value using the rounding mode.
Signature

```java
public Decimal divide(Decimal divisor, Integer scale, System.RoundingMode roundingMode)
```

Parameters

divisor
Type: Decimal

scale
Type: Integer

roundingMode
Type: System.RoundingMode

Return Value
Type: Decimal

Example

```java
Decimal myDecimal = 12.4567;
Decimal divDec = myDecimal.divide(7, 2, System.RoundingMode.UP);
System.assertEquals(divDec, 1.78);
```

doubleValue()

Returns the Double value of this Decimal.

Signature

```java
public Double doubleValue()
```

Return Value
Type: Double

Example

```java
Decimal myDecimal = 6.62606957;
Double value = myDecimal.doubleValue();
System.assertEquals(6.62606957, value);
```

format()

Returns the String value of this Decimal using the locale of the context user.

Signature

```java
public String format()
```
Return Value
Type: String

Usage
Scientific notation will be used if an exponent is needed.

Example

```java
// U.S. locale
Decimal myDecimal = 12345.6789;
system.assertEquals('12,345.679', myDecimal.format());
```

**intValue()**

Returns the Integer value of this Decimal.

Signature

```java
public Integer intValue()
```

Return Value
Type: Integer

Example

```java
Decimal myDecimal = 1.602176565;
system.assertEquals(1, myDecimal.intValue());
```

**longValue()**

Returns the Long value of this Decimal.

Signature

```java
public Long longValue()
```

Return Value
Type: Long

Example

```java
Decimal myDecimal = 376.730313461;
system.assertEquals(376, myDecimal.longValue());
```

**pow(exponent)**

Returns the value of this decimal raised to the power of the specified exponent.
Signature

```java
public Decimal pow(Integer exponent)
```

Parameters

- `exponent`
  
  Type: Integer
  
  The value of `exponent` must be between 0 and 32,767.

Return Value

Type: Decimal

Usage

If you use `MyDecimal.pow(0), 1` is returned.

The `Math.pow` method does accept negative values.

Example

```java
Decimal myDecimal = 4.12;
Decimal powDec = myDecimal.pow(2);
System.assertEquals(powDec, 16.9744);
```

`precision()`

Returns the total number of digits for the Decimal.

Signature

```java
public Integer precision()
```

Return Value

Type: Integer

Example

For example, if the Decimal value was 123.45, `precision` returns 5. If the Decimal value is 123.123, `precision` returns 6.

```java
Decimal D1 = 123.45;
Integer precision1 = D1.precision();
System.assertEquals(precision1, 5);
Decimal D2 = 123.123;
Integer precision2 = D2.precision();
System.assertEquals(precision2, 6);
```
round()

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

Signature

```
public Long round()
```

Return Value

Type: Long

Usage

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

Example

```
Decimal D = 4.5;
Long L = D.round();
System.assertEquals(4, L);

Decimal D1 = 5.5;
Long L1 = D1.round();
System.assertEquals(6, L1);

Decimal D2 = 5.2;
Long L2 = D2.round();
System.assertEquals(5, L2);

Decimal D3 = -5.7;
Long L3 = D3.round();
System.assertEquals(-6, L3);
```

round(roundingMode)

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using the rounding mode specified by the rounding mode.

Signature

```
public Long round(System.RoundingMode roundingMode)
```

Parameters

roundingMode

Type: System.RoundingMode
Return Value
Type: Long

scale()
Returns the scale of the Decimal, that is, the number of decimal places.

Signature
public Integer scale()

Example
Decimal myDecimal = 9.27400968;
system.assertEquals(8, myDecimal.scale());

setScale(scale)
Returns the Decimal scaled to the specified number of decimal places, using half-even rounding, if necessary. Half-even rounding mode rounds toward the "nearest neighbor." If both neighbors are equidistant, the number is rounded toward the even neighbor.

Signature
public Decimal setScale(Integer scale)

Parameters
scale
Type: Integer
The value of scale must be between –33 and 33. If the value of scale is negative, your unscaled value is multiplied by 10 to the power of the negation of scale. For example, after this operation, the value of d is 4*10^-3.

Decimal d = 4000;
d = d.setScale(-3);

Usage
If you do not explicitly set the scale for a Decimal, the item from which the Decimal is created determines the scale.
• If the Decimal is created as part of a query, the scale is based on the scale of the field returned from the query.
• If the Decimal is created from a String, the scale is the number of characters after the decimal point of the String.
If the Decimal is created from a non-decimal number, the number is first converted to a String. Scale is then set using the number of characters after the decimal point.

Example

```java
Decimal myDecimal = 8.987551787;
Decimal setScaled = myDecimal.setScale(3);
System.assertEquals(8.988, setScaled);
```

**setScale(scale, roundingMode)**

Returns the Decimal scaled to the specified number of decimal places, using the specified rounding mode, if necessary.

**Signature**

```java
public Decimal setScale(Integer scale, System.RoundingMode roundingMode)
```

**Parameters**

- **scale**
  - Type: `Integer`
  - The value of `scale` must be between -33 and 33. If the value of `scale` is negative, your unscaled value is multiplied by 10 to the power of the negation of `scale`. For example, after this operation, the value of `d` is $4 \times 10^3$.

```java
Decimal d = 4000;
d = d.setScale(-3);
```

- **roundingMode**
  - Type: `System.RoundingMode`

**Return Value**

Type: `Decimal`

**Usage**

If you do not explicitly set the scale for a Decimal, the item from which the Decimal is created determines the scale.

- If the Decimal is created as part of a query, the scale is based on the scale of the field returned from the query.
- If the Decimal is created from a String, the scale is the number of characters after the decimal point of the String.
- If the Decimal is created from a non-decimal number, the number is first converted to a String. Scale is then set using the number of characters after the decimal point.

**stripTrailingZeros()**

Returns the Decimal with any trailing zeros removed.

**Signature**

```java
public Decimal stripTrailingZeros()
```
### toPlainString()

Returns the String value of this Decimal, without using scientific notation.

**Signature**

```java
public String toPlainString()
```

**Return Value**

Type: **String**

**Example**

```java
Decimal myDecimal = 12345.6789;
System.assertEquals('12345.6789', myDecimal.toPlainString());
```

### valueOf(doubleToDecimal)

Returns a Decimal that contains the value of the specified Double.

**Signature**

```java
public static Decimal valueOf(Double doubleToDecimal)
```

**Parameters**

`doubleValueToDecimal`  
Type: **Double**

**Return Value**

Type: **Decimal**

**Example**

```java
Double myDouble = 2.718281828459045;
Decimal myDecimal = Decimal.valueOf(myDouble);
System.assertEquals(2.718281828459045, myDecimal);
```
**valueOf(longToDecimal)**

Returns a Decimal that contains the value of the specified Long.

**Signature**

```java
public static Decimal valueOf(Long longToDecimal)
```

**Parameters**

- `longToDecimal`
  - Type: `Long`

**Return Value**

- Type: `Decimal`

**Example**

```java
Long myLong = 299792458;
Decimal myDecimal = Decimal.valueOf(myLong);
System.assertEquals(299792458, myDecimal);
```

**valueOf(stringToDecimal)**

Returns a Decimal that contains the value of the specified String. As in Java, the string is interpreted as representing a signed Decimal.

**Signature**

```java
public static Decimal valueOf(String stringToDecimal)
```

**Parameters**

- `stringToDecimal`
  - Type: `String`

**Return Value**

- Type: `Decimal`

**Example**

```java
String temp = '12.4567';
Decimal myDecimal = Decimal.valueOf(temp);
```

**Double Class**

Contains methods for the Double primitive data type.
Namespace
System

Usage
For more information on Double, see Primitive Data Types on page 26.

Double Methods
The following are methods for Double.

IN THIS SECTION:
- format()
  Returns the String value for this Double using the locale of the context user
- intValue()
  Returns the Integer value of this Double by casting it to an Integer.
- longValue()
  Returns the Long value of this Double.
- round()
  Returns the closest Long to this Double value.
- valueOf(stringToDouble)
  Returns a Double that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal.
- valueOf(fieldValue)
  Converts the specified object to a Double value. Use this method to convert a history tracking field value or an object that represents a Double value.

format()
Returns the String value for this Double using the locale of the context user

Signature
public String format()

Return Value
Type: String

Example
```java
Double myDouble = 1261992;
system.assertEquals('1,261,992', myDouble.format());
```

intValue()
Returns the Integer value of this Double by casting it to an Integer.
Signature

public Integer intValue()

Return Value
Type: Integer

Example

```java
Double DD1 = Double.valueOf('3.14159');
Integer value = DD1.intValue();
System.assertEquals(value, 3);
```

`longValue()`
Returns the Long value of this Double.

Signature

public Long longValue()

Return Value
Type: Long

Example

```java
Double myDouble = 421994;
Long value = myDouble.longValue();
System.assertEquals(421949, value);
```

`round()`
Returns the closest Long to this Double value.

Signature

public Long round()

Return Value
Type: Long

Example

```java
Double D1 = 4.5;
Long L1 = D1.round();
System.assertEquals(5, L1);
Double D2 = 4.2;
```
```java
Long L2 = D2.round();
System.assertEquals(4, L2);

Double D3 = -4.7;
Long L3 = D3.round();
System.assertEquals(-5, L3);
```

### `valueOf` (String to Double)

Returns a `Double` that contains the value of the specified `String`. As in Java, the `String` is interpreted as representing a signed decimal.

**Signature**

```java
public static Double valueOf(String stringToDouble)
```

**Parameters**

- `stringToDouble`  
  Type: `String`

**Return Value**

Type: `Double`

**Example**

```java
Double DD1 = double.valueOf('3.14159');
```

### `valueOf` (fieldValue)

Converts the specified object to a `Double` value. Use this method to convert a history tracking field value or an object that represents a `Double` value.

**Signature**

```java
public static Double valueOf(Object fieldValue)
```

**Parameters**

- `fieldValue`  
  Type: `Object`

**Return Value**

Type: `Double`

**Usage**

Use this method with the `OldValue` or `NewValue` fields of history `sObjects`, such as `AccountHistory`, when the field type corresponds to a `Double` type, like a number field.
List<AccountHistory> ahlist =
(SELECT Field, OldValue, NewValue
FROM AccountHistory);
for (AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'NumberOfEmployees') {
        Double oldValue =
            Double.valueOf(ah.OldValue);
        Double newValue =
            Double.valueOf(ah.NewValue);
    }
}

EncodingUtil Class
Use the methods in the EncodingUtil class to encode and decode URL strings, and convert strings to hexadecimal format.

Namespace
System

Usage
Note: You cannot use the EncodingUtil methods to move documents with non-ASCII characters to Salesforce. You can, however, download a document from Salesforce. To do so, query the ID of the document using the API query call, then request it by ID.

EncodingUtil Methods
The following are methods for EncodingUtil. All methods are static.

IN THIS SECTION:

base64Decode(inputString)
Converts a Base64-encoded String to a Blob representing its normal form.

base64Encode(inputBlob)
Converts a Blob to an unencoded String representing its normal form.

convertFromHex(inputString)
Converts the specified hexadecimal (base 16) string to a Blob value and returns this Blob value.

convertToHex(inputBlob)
Returns a hexadecimal (base 16) representation of the inputBlob. This method can be used to compute the client response (for example, HA1 or HA2) for HTTP Digest Authentication (RFC2617).

urlDecode(inputString, encodingScheme)
Decodes a string in application/x-www-form-urlencoded format using a specific encoding scheme, for example "UTF-8."

urlEncode(inputString, encodingScheme)
Encodes a string into the application/x-www-form-urlencoded format using a specific encoding scheme, for example "UTF-8."
`base64Decode(inputString)`  
Converts a Base64-encoded String to a Blob representing its normal form.

Signature
```
public static Blob base64Decode(String inputString)
```

Parameters

`inputString`
Type: `String`

Return Value
Type: `Blob`

`base64Encode(inputBlob)`  
Converts a Blob to an unencoded String representing its normal form.

Signature
```
public static String base64Encode(Blob inputBlob)
```

Parameters

`inputBlob`
Type: `Blob`

Return Value
Type: `String`

`convertFromHex(inputString)`  
Converts the specified hexadecimal (base 16) string to a Blob value and returns this Blob value.

Signature
```
public static Blob convertFromHex(String inputString)
```

Parameters

`inputString`
Type: `String`

The hexadecimal string to convert. The string can contain only valid hexadecimal characters (0-9, a-f, A-F) and must have an even number of characters.
Return Value
Type: Blob

Usage
Each byte in the Blob is constructed from two hexadecimal characters in the input string.

The `convertFromHex` method throws the following exceptions.

- `NullPointerException` — the `inputString` is `null`.
- `InvalidParameterValueException` — the `inputString` contains invalid hexadecimal characters or doesn’t contain an even number of characters.

Example

```java
Blob blobValue = EncodingUtil.convertFromHex('4A4B4C');
System.assertEquals('JKL', blobValue.toString());
```

`convertToHex(inputBlob)`
Returns a hexadecimal (base 16) representation of the `inputBlob`. This method can be used to compute the client response (for example, HA1 or HA2) for HTTP Digest Authentication (RFC2617).

Signature
```
public static String convertToHex(Blob inputBlob)
```

Parameters
`inputBlob` Type: Blob

Return Value
Type: String

`urlDecode(inputString, encodingScheme)`
Decodes a string in `application/x-www-form-urlencoded` format using a specific encoding scheme, for example “UTF-8.”

Signature
```
public static String urlDecode(String inputString, String encodingScheme)
```

Parameters
`inputString` Type: String
```
encodingScheme` Type: String
Return Value
Type: String

Usage
This method uses the supplied encoding scheme to determine which characters are represented by any consecutive sequence of the from "%xy". For more information about the format, see The form-urlencoded Media Type in Hypertext Markup Language - 2.0.

**urlEncode(inputString, encodingScheme)**
Encodes a string into the application/x-www-form-urlencoded format using a specific encoding scheme, for example “UTF-8.”

Signature
```java
public static String urlEncode(String inputString, String encodingScheme)
```

Parameters
- `inputString`  
  Type: String
- `encodingScheme`  
  Type: String

Return Value
Type: String

Usage
This method uses the supplied encoding scheme to obtain the bytes for unsafe characters. For more information about the format, see The form-urlencoded Media Type in Hypertext Markup Language - 2.0.

Example
```java
String encoded = EncodingUtil.urlEncode(url, 'UTF-8');
```

**Enum Methods**
An enum is an abstract data type with values that each take on exactly one of a finite set of identifiers that you specify. Apex provides built-in enums, such as `LoggingLevel`, and you can define your own enum.

All Apex enums, whether user-defined enums or built-in enums, have the following common method that takes no arguments.

```java
values
```
This method returns the values of the Enum as a list of the same Enum type.

Each Enum value has the following methods that take no arguments.

```java
name
```
Returns the name of the Enum item as a String.
ordinal
Returns the position of the item, as an Integer, in the list of Enum values starting with zero.

Enum values cannot have user-defined methods added to them.
For more information about Enum, see Enums on page 35.

Example

```java
Integer i = StatusCode.DELETE_FAILED.ordinal();
String s = StatusCode.DELETE_FAILED.name();
List<StatusCode> values = StatusCode.values();
```

EventBus Class
Contains methods for publishing platform events.

Namespace
System

IN THIS SECTION:
EventBus Methods

SEE ALSO:
Platform Events Developer Guide: Publishing Platform Events

EventBus Methods
The following are methods for EventBus. All methods are static.

IN THIS SECTION:
getOperationId(result)
Returns the ID of the asynchronous event publishing operation based on the passed-in SaveResult. Use this ID to correlate the asynchronous publishing result sent on the /event/AsyncOperationEvent channel.

publish(event)
Publishes the given platform event.

publish(events)
Publishes the given list of platform events.

getOperationId(result)
Returns the ID of the asynchronous event publishing operation based on the passed-in SaveResult. Use this ID to correlate the asynchronous publishing result sent on the /event/AsyncOperationEvent channel.
public static String getOperationId(Object result)

Parameters
result
Type: Object
The SaveResult that is returned by the EventBus.publish call.

Return Value
Type: String

publish(event)
Publishes the given platform event.

public static Database.SaveResult publish(SObject event)

Parameters
event
Type: SObject
An instance of a platform event. For example, an instance of MyEvent__e. You must first define your platform event object in your org.

Return Value
Type: Database.SaveResult
The result of publishing the given event. Database.SaveResult contains information about whether the operation was successful and the errors encountered. If the isSuccess() method returns true, the event was published for a standard-volume event. For a high-volume event, the publish request is queued in Salesforce and the event message might not be published immediately. For more information, see High-Volume Platform Event Persistence. If isSuccess() returns false, the event publish operation resulted in errors, which are returned in the Database.Error object. This method doesn't throw an exception due to an unsuccessful publish operation.

Database.SaveResult also contains the Id system field. The Id field value is not included in the event message delivered to subscribers. It is not used to identify an event message, and is not always unique.

Usage
- The platform event message is published either immediately or after a transaction is committed, depending on the publish behavior you set in the platform event definition. For more information, see Platform Event Fields in the Platform Events Developer Guide.
- Apex governor limits apply, including DML limits. Each method execution is counted as one DML statement.
**publish(events)**

Publishes the given list of platform events.

**Signature**

```java
public static List<Database.SaveResult> publish(List<SObject> events)
```

**Parameters**

**events**

Type: List<SObject>

A list of platform event instances. For example, a list of `MyEvent__e` objects. You must first define your platform event object in your org.

**Return Value**

Type: List<Database.SaveResult>

A list of results, each corresponding to the result of publishing one event. For each event, `Database.SaveResult` contains information about whether the operation was successful and the errors encountered. If the `isSuccess()` method returns `true`, the event was published for a standard-volume event. For a high-volume event, the publish request is queued in Salesforce and the event message might not be published immediately. For more information, see High-Volume Platform Event Persistence. If `isSuccess()` returns `false`, the event publish operation resulted in errors which are returned in the `Database.Error` object. `EventBus.publish()` can publish some passed-in events, even when other events can't be published due to errors. The `EventBus.publish()` method doesn't throw exceptions caused by an unsuccessful publish operation. It is similar in behavior to the Apex `Database.insert` method when called with the partial success option. `Database.SaveResult` also contains the `Id` system field. The `Id` field value is not included in the event message delivered to subscribers. It is not used to identify an event message, and is not always unique.

**Usage**

- The platform event message is published either immediately or after a transaction is committed, depending on the publish behavior you set in the platform event definition. For more information, see Platform Event Fields in the Platform Events Developer Guide.
- Apex governor limits apply, including DML limits. Each method execution is counted as one DML statement.

**Exception Class and Built-In Exceptions**

An exception denotes an error that disrupts the normal flow of code execution. You can use Apex built-in exceptions or create custom exceptions. All exceptions have common methods.

All exceptions support built-in methods for returning the error message and exception type. In addition to the standard exception class, there are several different types of exceptions:

The following are exceptions in the `System` namespace.

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AsyncException</td>
<td>Any problem with an asynchronous operation, such as failing to enqueue an asynchronous call.</td>
</tr>
<tr>
<td>Exception</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>BigObjectException</td>
<td>Any problem with big object records, such as connection timeouts during attempts to access or insert big object records.</td>
</tr>
<tr>
<td>CalloutException</td>
<td>Any problem with a Web service operation, such as failing to make a callout to an external system.</td>
</tr>
<tr>
<td>DmlException</td>
<td>Any problem with a DML statement, such as an insert statement missing a required field on a record.</td>
</tr>
<tr>
<td>EmailException</td>
<td>Any problem with email, such as failure to deliver. For more information, see Outbound Email.</td>
</tr>
<tr>
<td>ExternalObjectException</td>
<td>Any problem with external object records, such as connection timeouts during attempts to access the data that's stored on external systems.</td>
</tr>
<tr>
<td>IllegalArgumentException</td>
<td>An illegal argument was provided to a method call. For example, a method that requires a non-null argument throws this exception if a null value is passed into the method.</td>
</tr>
<tr>
<td>InvalidParameterValueException</td>
<td>An invalid parameter was supplied for a method or any problem with a URL used with Visualforce pages. For more information on Visualforce, see the Visualforce Developer's Guide.</td>
</tr>
<tr>
<td>LimitException</td>
<td>A governor limit has been exceeded. This exception can't be caught.</td>
</tr>
<tr>
<td>JSONException</td>
<td>Any problem with JSON serialization and deserialization operations. For more information, see the methods of System.JSON, System.JSONParser, and System.JSONGenerator.</td>
</tr>
<tr>
<td>ListException</td>
<td>Any problem with a list, such as attempting to access an index that is out of bounds.</td>
</tr>
<tr>
<td>MathException</td>
<td>Any problem with a mathematical operation, such as dividing by zero.</td>
</tr>
<tr>
<td>NoAccessException</td>
<td>Any problem with unauthorized access, such as trying to access an sObject that the current user does not have access to. This exception is used with Visualforce pages. For more information on Visualforce, see the Visualforce Developer's Guide.</td>
</tr>
<tr>
<td>NoDataFoundException</td>
<td>Any problem with data that does not exist, such as trying to access an sObject that has been deleted. This exception is used with Visualforce pages. For more information on Visualforce, see the Visualforce Developer's Guide.</td>
</tr>
<tr>
<td>NoSuchElementException</td>
<td>This exception is thrown if you try to access items that are outside the bounds of a list. This exception is used by the Iterator next method. For example, if iterator.hasNext() == false and you call iterator.next(), this exception is thrown. This exception is also used by the Apex Flex Queue methods and is thrown if you attempt to access a job at an invalid position in the flex queue.</td>
</tr>
<tr>
<td>NullPointerException</td>
<td>Any problem with dereferencing null, such as in the following code:</td>
</tr>
<tr>
<td></td>
<td>String s;                                                                                                                                  // Since s is null, this call causes</td>
</tr>
<tr>
<td></td>
<td>// a NullPointerException</td>
</tr>
<tr>
<td>QueryException</td>
<td>Any problem with SOQL queries, such as assigning a query that returns no records or more than one record to a singleton sObject variable.</td>
</tr>
</tbody>
</table>
### Exception Description

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RequiredFeatureMissing</td>
<td>A Chatter feature is required for code that has been deployed to an organization that does not have Chatter enabled.</td>
</tr>
<tr>
<td>SearchException</td>
<td>Any problem with SOSL queries executed with SOAP API <code>search()</code> call, for example, when the <code>searchString</code> parameter contains fewer than two characters. For more information, see the <a href="https://developer.salesforce.com/docs/atlas.en-us.soapapi.meta/soapapi/soapapi_search.htm">SOAP API Developer Guide</a>.</td>
</tr>
<tr>
<td>SecurityException</td>
<td>Any problem with static methods in the Crypto utility class. For more information, see <a href="https://developer.salesforce.com/docs/atlas.en-us.soapapi.meta/soapapi/apex_classes_crypto.htm">Crypto Class</a>.</td>
</tr>
<tr>
<td>SerializationException</td>
<td>Any problem with the serialization of data. This exception is used with Visualforce pages. For more information on Visualforce, see the <a href="https://developer.salesforce.com/docs/atlas.en-us.visualforce.meta/visualforce/visualforce_dev_guide.htm">Visualforce Developer’s Guide</a>.</td>
</tr>
<tr>
<td>SObjectException</td>
<td>Any problem with sObject records, such as attempting to change a field in an <code>update</code> statement that can only be changed during <code>insert</code>.</td>
</tr>
<tr>
<td>StringException</td>
<td>Any problem with Strings, such as a String that is exceeding your heap size.</td>
</tr>
<tr>
<td>TypeException</td>
<td>Any problem with type conversions, such as attempting to convert the String ‘a’ to an Integer using the <code>valueOf</code> method.</td>
</tr>
<tr>
<td>VisualforceException</td>
<td>Any problem with a Visualforce page. For more information on Visualforce, see the <a href="https://developer.salesforce.com/docs/atlas.en-us.visualforce.meta/visualforce/visualforce_dev_guide.htm">Visualforce Developer’s Guide</a>.</td>
</tr>
<tr>
<td>XmlException</td>
<td>Any problem with the XmlStream classes, such as failing to read or write XML.</td>
</tr>
</tbody>
</table>

The following is an example using the DmlException exception:

```java
Account[] accts = new Account[] {new Account(billingcity = 'San Jose')};
try {
  insert accts;
} catch (System.DmlException e) {
  for (Integer i = 0; i < e.getNumDml(); i++) {
    // Process exception here
    System.debug(e.getDmlMessage(i));
  }
}
```

For exceptions in other namespaces, see:

- [Canvas Exceptions](https://developer.salesforce.com/docs/atlas.en-us.canvas.meta/canvas/apex_sdk_canvas.htm)
- [ConnectApi Exceptions](https://developer.salesforce.com/docs/atlas.en-us.c2s_api.meta/c2s_api/apex_sdk_connectapi.htm)
- [DataSource Exceptions](https://developer.salesforce.com/docs/atlas.en-us.datasource.meta/datasource/apex_sdk_datasource.htm)
- [Reports Exceptions](https://developer.salesforce.com/docs/atlas.en-us.apex_developer.meta/apex_developer/apex_sdk_apexreports.htm)
- [Site Exceptions](https://developer.salesforce.com/docs/atlas.en-us.apex_developer.meta/apex_developer/apex_sdk_sites.htm)

### Common Exception Methods

Exception methods are all called by and operate on a instance of an exception. The table below describes all instance exception methods. All types of exceptions have the following methods in common:
### Description Return Type Arguments Name

Returns the cause of the exception as an exception object. Exception

getCause

Returns the line number from where the exception was thrown. Integer

getLineNumber

Returns the error message that displays for the user. String

getMessage

Returns the stack trace as a string. String

getStackTraceString

Returns the type of exception, such as DmlException, ListException, MathException, and so on. String

getTypeName

Sets the cause for this exception, if one has not already been set. Void

initCause

Sets the error message that displays for the user. Void

setMessage

### DMLException and EmailException Methods

In addition to the common exception methods, DMLExceptions and EmailExceptions have these methods:

### Description Return Type Arguments Name

Returns the names of the field or fields that caused the error described by the \(i\)th failed row. String []

Integer i

getDmlFieldNames

Returns the field token or tokens for the field or fields that caused the error described by the \(i\)th failed row. For more information on field tokens, see Dynamic Apex. Schema.sObjectField []

Integer i

getDmlFields

Returns the ID of the failed record that caused the error described by the \(i\)th failed row. String

Integer i

getDmlId

Returns the original row position of the \(i\)th failed row. Integer

getDmlIndex

Returns the user message for the \(i\)th failed row. String

getDmlMessage

Deprecated. Use getDmlType instead. Returns the Apex failure code for the \(i\)th failed row. String

Integer i

getDmlStatusCode

Returns the value of the System.StatusCode enum. For example:

```java
try {
    insert new Account();
} catch (System.DmlException ex) {
    System.assertEquals(
        StatusCode.REQUIRED_FIELD_MISSING,
        ex.getDmlType(0));
}
```

For more information about System.StatusCode, see Enums.
**FlexQueue Class**

Contains methods that reorder batch jobs in the Apex flex queue.

**Namespace**

System

**Usage**

You can place up to 100 batch jobs in a holding status for future execution. When system resources become available, the jobs are taken from the top of the Apex flex queue and moved to the batch job queue. Up to five queued or active jobs can be processed simultaneously for each org. When a job is moved out of the flex queue for processing, its status changes from Holding to Queued. Queued jobs are executed when the system is ready to process new jobs.

Use this class’s methods to reorder your Holding jobs in the flex queue.

**Example**

This example moves a job in the flex queue so that it is executed immediately before the specified job in the queue. Ensure that you have jobs in the flex queue before execution. To move the job, call the `System.FlexQueue.moveBeforeJob()` method and pass it both jobs' IDs.

```java
ID jobToMoveId = System.enqueueJob(new MyQueueableClass());
AsyncApexJob a = [SELECT Id FROM AsyncApexJob WHERE ApexClassId IN (SELECT Id from ApexClass WHERE NamespacePrefix = null AND Name = 'MyBatchClass')];
ID jobInQueueId = a.ID;
Boolean isSuccess = FlexQueue.moveBeforeJob(jobToMoveId, jobInQueueId);
```

**IN THIS SECTION:**

- FlexQueue Methods

**SEE ALSO:**

- Monitoring the Apex Flex Queue
- Using Batch Apex

**FlexQueue Methods**

The following are methods for FlexQueue.
IN THIS SECTION:

`moveAfterJob(jobToMoveId, jobInQueueId)`  
Moves the job with the ID `jobToMoveId` immediately after the job with the ID `jobInQueueId` in the flex queue. You can move `jobToMoveId` forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if `jobToMoveId` is already immediately after `jobInQueueId`, so no change is made.

`moveBeforeJob(jobToMoveId, jobInQueueId)`  
Moves the job with the ID `jobToMoveId` immediately before the job with the ID `jobInQueueId` in the flex queue. You can move `jobToMoveId` forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if `jobToMoveId` is already immediately before `jobInQueueId`, so no change is made.

`moveJobToEnd(jobId)`  
Moves the specified job the end of the flex queue, to index position `(size - 1)`. All jobs after the job’s starting position move one spot forward. If the job isn’t in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if the job is already at the end of the queue, so no change is made.

`moveJobToFront(jobId)`  
Moves the specified job to the front of the flex queue, to index position 0. All other jobs move back one spot. If the job isn’t in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if the job is already at the front of the queue, so no change is made.

`moveAfterJob (jobToMoveId, jobInQueueId)`  
Moves the job with the ID `jobToMoveId` immediately after the job with the ID `jobInQueueId` in the flex queue. You can move `jobToMoveId` forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if `jobToMoveId` is already immediately after `jobInQueueId`, so no change is made.

Signature  
```
public static Boolean moveAfterJob(Id jobToMoveId, Id jobInQueueId)
```

Parameters  

`jobToMoveId`  
Type: `Id`  
The ID of the job to move.

`jobInQueueId`  
Type: `Id`  
The ID of the job to move after.

Return Value  
Type: `Boolean`
**moveBeforeJob**(jobToMoveId, jobInQueueId)

Moves the job with the ID `jobToMoveId` immediately before the job with the ID `jobInQueueId` in the flex queue. You can move `jobToMoveId` forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns **true** if the job is moved, or **false** if `jobToMoveId` is already immediately before `jobInQueueId`, so no change is made.

Signature

```java
public static Boolean moveBeforeJob(Id jobToMoveId, Id jobInQueueId)
```

Parameters

- **jobToMoveId**
  - Type: **Id**
  - The ID of the job to move.
- **jobInQueueId**
  - Type: **Id**
  - The ID of the job to use as a reference point.

Return Value

Type: **Boolean**

**moveJobToEnd**(jobId)

Moves the specified job to the end of the flex queue, to index position `(size - 1)`. All jobs after the job’s starting position move one spot forward. If the job isn’t in the queue, it throws an element-not-found exception. Returns **true** if the job is moved, or **false** if the job is already at the end of the queue, so no change is made.

Signature

```java
public static Boolean moveJobToEnd(Id jobId)
```

Parameters

- **jobId**
  - Type: **Id**
  - The ID of the job to move.

Return Value

Type: **Boolean**

**moveJobToFront**(jobId)

Moves the specified job to the front of the flex queue, to index position 0. All other jobs move back one spot. If the job isn’t in the queue, it throws an element-not-found exception. Returns **true** if the job is moved, or **false** if the job is already at the front of the queue, so no change is made.
Signature

public static Boolean moveJobToFront(Id jobId)

Parameters

jobId
Type: Id
The ID of the job to move.

Return Value
Type: Boolean

FeatureManagement Class
Use the methods in the System.FeatureManagement class to check and modify the values of feature parameters, and to show or hide custom objects and custom permissions in your subscribers' orgs.

Namespace
System

Usage
For information about feature parameters, see “Get Started with the Feature Management App” in the ISVforce Guide.

IN THIS SECTION:
FeatureManagement Methods

FeatureManagement Methods
The following are methods for FeatureManagement.

IN THIS SECTION:
changeProtection(apiName, typeApiName, protection)
Hides or reveals custom permissions, or reveals custom objects, in your subscriber’s org.

checkPackageBooleanValue(apiName)
Checks the value__c value of the FeatureParameterBoolean__c record for a feature parameter in your subscriber’s org. You set the record’s value using setPackageBooleanValue(apiName, value).

checkPackageDateValue(apiName)
Checks the value__c value of the FeatureParameterDate__c record for a feature parameter in your subscriber’s org. You can set the record’s value using setPackageDateValue(apiName, value).

checkPackageIntegerValue(apiName)
Checks the value__c value of the FeatureParameterInteger__c record for a feature parameter in your subscriber’s org. You can set the record’s value using setPackageIntegerValue(apiName, value).
checkPermission(apiName)
Checks whether a custom permission is enabled.

setPackageBooleanValue(apiName, value)
Sets the value__c value of the FeatureParameterBoolean__c record for a subscriber-to-LMO feature parameter in your subscriber’s org. You can check the record’s value using checkPackageBooleanValue(apiName).

setPackageDateValue(apiName, value)
Sets the value__c value of the FeatureParameterDate__c record for a subscriber-to-LMO feature parameter in your subscriber’s org. You can check the record’s value using checkPackageDateValue(apiName).

setPackageIntegerValue(apiName, value)
Sets the value__c value of the FeatureParameterInteger__c record for a subscriber-to-LMO feature parameter in your subscriber’s org. You can check the record’s value using checkPackageIntegerValue(apiName).

changeProtection(apiName, typeApiName, protection)
Hides or reveals custom permissions, or reveals custom objects, in your subscriber’s org.

Signature

public static void changeProtection(String apiName, String typeApiName, String protection)

Parameters

apiName
Type: String
The API name of the custom object or custom permission to show or hide—for example, 'MyCustomObject__c' or 'MyCustomPermission'.

typeApiName
Type: String
The API name of the type that you want to show or hide: 'CustomObject' or 'CustomPermission'.

protection
Type: String
To show a custom object or custom permission, 'Unprotected'.
To hide a custom permission, 'Protected'.

Return Value
Type: void

Usage

⚠️ Warning: For custom permissions, you can toggle the protected value indefinitely. However, after you’ve released unprotected objects to subscribers, you can’t set visibility to Protected. Be sure to protect any custom objects that you want to hide before you release the first package version that contains them.
To hide custom permissions in released packages:

```javascript
FeatureManagement.changeProtection('YourCustomPermissionName', 'CustomPermission', 'Protected');
```

To unhide custom permissions and custom objects in released packages:

```javascript
FeatureManagement.changeProtection('YourCustomPermissionName', 'CustomPermission', 'Unprotected');
FeatureManagement.changeProtection('YourCustomObjectName__c', 'CustomObject', 'Unprotected');
```

**checkPackageBooleanValue(apiName)**

Checks the value__c value of the FeatureParameterBoolean__c record for a feature parameter in your subscriber’s org. You set the record's value using `setPackageBooleanValue(apiName, value)`.

**Signature**

```
public static Boolean checkPackageBooleanValue(String apiName)
```

**Parameters**

- `apiName`
  - **Type**: String
  - The fullName__c value of the feature parameter whose value you want to check—for example, 'SpecialAccessAvailable'.

**Return Value**

- **Type**: Boolean
  - The value that's currently assigned to the value__c field on the FeatureParameterBoolean__c record that associates the feature parameter with its related license.

**checkPackageDateValue(apiName)**

Checks the value__c value of the FeatureParameterDate__c record for a feature parameter in your subscriber’s org. You can set the record's value using `setPackageDateValue(apiName, value)`.

**Signature**

```
public static Date checkPackageDateValue(String apiName)
```

**Parameters**

- `apiName`
  - **Type**: String
  - The fullName__c value of the feature parameter whose value you want to check—for example, 'TrialExpirationDate'.

2724
Return Value
Type: Date
The value that’s currently assigned to the value__c field on the FeatureParameterDate__c record that associates the feature parameter with its related license.

**checkPackageIntegerValue(apiName)**
Checks the value__c value of the FeatureParameterInteger__c record for a feature parameter in your subscriber’s org. You can set the record’s value using setPackageIntegerValue(apiName, value).

Signature
```java
public static Integer checkPackageIntegerValue(String apiName)
```

Parameters
- **apiName**
  Type: String
  The fullName__c value of the feature parameter whose value you want to check—for example, 'NumberOfLicenses'.

Return Value
Type: Integer
The value that’s currently assigned to the value__c field on the FeatureParameterInteger__c record that associates the feature parameter with its related license.

**checkPermission(apiName)**
Checks whether a custom permission is enabled.

Signature
```java
public static Boolean checkPermission(String apiName)
```

Parameters
- **apiName**
  Type: String
  The API name of the custom permission to check the value of—for example, 'MyCustomPermission'.

Return Value
Type: Boolean
Shows whether the permission is enabled (true) or disabled (false).

**setPackageBooleanValue(apiName, value)**
Sets the value__c value of the FeatureParameterBoolean__c record for a subscriber-to-LMO feature parameter in your subscriber’s org. You can check the record’s value using checkPackageBooleanValue(apiName).
Signature

public static void setPackageBooleanValue(String apiName, Boolean value)

Parameters

apiName
  Type: String
  The fullName__c value of the feature parameter whose value you want to set—for example, 'SpecialAccessAvailable'.

value
  Type: Boolean
  The value to assign to the value__c field on the FeatureParameterBoolean__c record that associates the feature parameter with its related license.

Return Value

Type: void

setPackageBooleanValue(apiName, value)

Sets the value__c value of the FeatureParameterBoolean__c record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using checkPackageBooleanValue(apiName).

Signature

public static void setPackageBooleanValue(String apiName, Date value)

Parameters

apiName
  Type: String
  The fullName__c value of the feature parameter whose value you want to set—for example, 'TrialExpirationDate'.

value
  Type: Date
  The value to assign to the value__c field on the FeatureParameterDate__c record that associates the feature parameter with its related license.

Return Value

Type: void

setPackageDateValue(apiName, value)

Sets the value__c value of the FeatureParameterDate__c record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using checkPackageDateValue(apiName).

Signature

public static void setPackageIntegerValue(String apiName, Integer value)

Parameters

apiName
  Type: String
  The fullName__c value of the feature parameter whose value you want to set—for example, 'TrialExpirationDate'.

value
  Type: Integer
  The value to assign to the value__c field on the FeatureParameterInteger__c record that associates the feature parameter with its related license.

Return Value

Type: void

setPackageIntegerValue(apiName, value)

Sets the value__c value of the FeatureParameterInteger__c record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using checkPackageIntegerValue(apiName).
Signature

```java
public static void setPackageIntegerValue(String apiName, Integer value)
```

Parameters

- **apiName**
  - Type: `String`
  - The `fullName__c` value of the feature parameter whose value you want to set—for example, 'NumberOfLicenses'.

- **value**
  - Type: `Integer`
  - The value to assign to the `value__c` field on the `FeatureParameterInteger__c` record that associates the feature parameter with its related license.

Return Value

Type: `void`

**Formula Class**

Contains the `recalculateFormulas` method that updates (recalculates) all formula fields on the input SObjects.

**Namespace**

`System`

**Usage**

Recalculate formula fields on new or queried SObjects. If all data is present on the SObjects, SOQL limits are not affected. If the data required to evaluate a formula field is missing, that data is loaded and limits are changed accordingly.

The new formula values are stored in the SObjects themselves and overwrite previous values of formula fields.

**Example**

```java
Account a = new Account();
a.Name = 'Salesforce';
a.BillingCity = 'San Francisco';
List<Account> accounts = new List<Account>{a};

List<FormulaRecalcResult> results = Formula.recalculateFormulas(accounts);
System.assert(results[0].isSuccess());
// Option 1
System.debug('New value: ' + accounts[0].get('My_Formula_Field__c'));
// Option 2
System.debug('New value: ' + results[0].getSObject().get('My_Formula_Field__c'));
```

**IN THIS SECTION:**

- Formula Methods
Formula Methods
The following are methods for Formula.

IN THIS SECTION:

  recalculateFormulas(sobjects)
  Updates (recalculates) all formula fields on the input SObjects.

recalculateFormulas(sobjects)
Updates (recalculates) all formula fields on the input SObjects.

Signature
public static List<System.FormulaRecalcResult> recalculateFormulas(List<SObject> sobjects)

Parameters
sobjects
  Type: List<SObject>
  List of sObjects whose formula fields are to be recalculated.

Return Value
Type: List<FormulaRecalcResult Class>

FormulaRecalcFieldError Class
The return type of the FormulaRecalcResult.getErrors method.

Namespace
System

IN THIS SECTION:
  FormulaRecalcFieldError Methods

FormulaRecalcFieldError Methods
The following are methods for FormulaRecalcFieldError.

IN THIS SECTION:
  getFieldName()
  Returns the name of the formula recalculation error field.

  getFieldName()
getFieldError()
Returns a message describing the errors encountered during formula recalculation.

Signature
public String getFieldError()

Return Value
Type: String

getFieldName()
Returns the name of the formula recalculation error field.

Signature
public String getFieldName()

Return Value
Type: String

**FormulaRecalcResult Class**
The return type of the `Formula.recalculateFormulas` method.

**Namespace**
System

**Usage**
Indicates the result and status of recalculating formulas on a single sObject. Holds a reference to the sObject and a list of all the fields that were recalculated.

**Example**
This example assumes that you have a formula field called divide__c with formula “1 / LEN(Name).

```java
List<Account> accounts = [SELECT Name FROM Account WHERE Name='Acme'];
accounts[0].Name = '';
List<FormulaRecalcResult> results = Formula.recalculateFormulas(accounts);
FormulaRecalcResult result0 = results[0];
FormulaRecalcFieldError fieldError = result0.getErrors()[0];
System.debug(fieldError.getFieldName()); // 'divide'
System.debug(fieldError.getFieldError()); // 'Division by zero'
```

IN THIS SECTION:
FormulaRecalcResult Methods
**FormulaRecalcResult Methods**

The following are methods for `FormulaRecalcResult`.

**IN THIS SECTION:**

- `getErrors()`
  - If an error occurs during formula recalculation, an array of one or more database error objects, along with error codes and descriptions, is returned.

- `getSObject()`
  - Returns the sObject with formulas recalculated.

- `isSuccess()`
  - Returns a Boolean value that is set to `true` if the formula recalculation process completed successfully; otherwise, it is set to `false`.

---

**getErrors()**

If an error occurs during formula recalculation, an array of one or more database error objects, along with error codes and descriptions, is returned.

**Signature**

```java
public List<System.FormulaRecalcFieldError> getErrors()
```

**Return Value**

Type: `List<FormulaRecalcFieldError Class>`

---

**getSObject()**

Returns the sObject with formulas recalculated.

**Signature**

```java
public SObject getSObject()
```

**Return Value**

Type: `SObject`

---

**isSuccess()**

Returns a Boolean value that is set to `true` if the formula recalculation process completed successfully; otherwise, it is set to `false`.

**Signature**

```java
public Boolean isSuccess()
```

**Return Value**

Type: `Boolean`
Http Class

Use the Http class to initiate an HTTP request and response.

Namespace

System

Http Methods

The following are methods for Http. All are instance methods.

IN THIS SECTION:

send(request)

Sends an HttpRequest and returns the response.

toString()

Returns a string that displays and identifies the object’s properties.

send(request)

Sends an HttpRequest and returns the response.

Signature

public HttpResponse send(HttpRequest request)

Parameters

request

Type: System.HttpRequest

Return Value

Type: System.HttpResponse

toString() 

Returns a string that displays and identifies the object’s properties.

Signature

public String toString()

Return Value

Type: String
HttpCalloutMock Interface
Enables sending fake responses when testing HTTP callouts.

Namespace
System

Usage
For an implementation example, see Testing HTTP Callouts by Implementing the HttpCalloutMock Interface.

HttpCalloutMock Methods
The following are methods for HttpCalloutMock.

IN THIS SECTION:
respond(request)
Returns an HTTP response for the given request. The implementation of this method is called by the Apex runtime to send a fake response when an HTTP callout is made after Test.setMock has been called.

respond(request)
Returns an HTTP response for the given request. The implementation of this method is called by the Apex runtime to send a fake response when an HTTP callout is made after Test.setMock has been called.

Signature
public HttpResponse respond(HttpRequest request)

Parameters
request
Type: System.HttpRequest

Return Value
Type: System.HttpResponse

HttpRequest Class
Use the HttpRequest class to programmatically create HTTP requests like GET, POST, PUT, and DELETE.

Namespace
System
Usage

Use the XML classes or JSON classes to parse XML or JSON content in the body of a request created by HttpRequest.

Example

The following example illustrates how you can use an authorization header with a request and handle the response.

```java
public class AuthCallout {

    public void basicAuthCallout(){
        HttpRequest req = new HttpRequest();
        req.setEndpoint('http://www.yahoo.com');
        req.setMethod('GET');

        // Specify the required user name and password to access the endpoint
        // As well as the header and header information
        String username = 'myname';
        String password = 'mypwd';

        Blob headerValue = Blob.valueOf(username + ':' + password); // String 'Basic ' + EncodingUtil.base64Encode(headerValue);
        req.setHeader('Authorization', 'Basic ' + EncodingUtil.base64Encode(headerValue));

        // Create a new http object to send the request object
        // A response object is generated as a result of the request
        Http http = new Http();
        HTTPResponse res = http.send(req);
        System.debug(res.getBody());
    }  
}
```

Note: You can set the endpoint as a named credential URL. A named credential URL contains the scheme callout:, the name of the named credential, and an optional path. For example: callout:My_Named_Credential/some_path. A named credential specifies the URL of a callout endpoint and its required authentication parameters in one definition. Salesforce manages all authentication for Apex callouts that specify a named credential as the callout endpoint so that your code doesn't have to. See Named Credentials as Callout Endpoints on page 491.

Compression

To compress the data you send, use setCompressed.

```java
HttpRequest req = new HttpRequest();
req.setEndPoint('my_endpoint');
req.setCompressed(true);
req.setBody('some post body');
```

If a response comes back in compressed format, getBody recognizes the format, uncompresses it, and returns the uncompressed value.
HttpRequest Constructors

The following are constructors for HttpRequest.

HttpRequest()

Creates a new instance of the HttpRequest class.

HttpRequest()

Creates a new instance of the HttpRequest class.

HttpRequest()

IN THIS SECTION:

HttpRequest Constructor

HttpRequest Methods

SEE ALSO:

JSON Support
XML Support

HttpRequest Constructors

IN THIS SECTION:

HttpRequest()

HttpRequest()

HttpRequest()

HttpRequest() Creates a new instance of the HttpRequest class.

Signature

public HttpRequest()

HttpRequest Methods

The following are methods for HttpRequest. All are instance methods.

IN THIS SECTION:

getBody()

Retrieves the body of this request.

getBodyAsBlob()

Retrieves the body of this request as a Blob.

getBodyDocument()

Retrieves the body of this request as a DOM document.

getCompressed()

If true, the request body is compressed, false otherwise.

getEndpoint()

Retrieves the URL for the endpoint of the external server for this request.

getHeader(key)

Retrieves the contents of the request header.

getMethod()

Returns the type of method used by HttpRequest.
**setBody(body)**
Sets the contents of the body for this request.

**setBodyAsBlob(body)**
Sets the contents of the body for this request using a Blob.

**setBodyDocument(document)**
Sets the contents of the body for this request. The contents represent a DOM document.

**setClientCertificate(clientCert, password)**
This method is deprecated. Use `setClientCertificateName` instead.

**setClientCertificateName(certDevName)**
If the external service requires a client certificate for authentication, set the certificate name.

**setCompressed(flag)**
If `true`, the data in the body is delivered to the endpoint in the gzip compressed format. If `false`, no compression format is used.

**setEndpoint(endpoint)**
Specifies the endpoint for this request.

**setHeader(key, value)**
Sets the contents of the request header.

**setMethod(method)**
Sets the type of method to be used for the HTTP request.

**setTimeout(timeout)**
Sets the timeout in milliseconds for the request.

**toString()**
Returns a string containing the URL for the endpoint of the external server for this request and the method used, for example, `Endpoint=http://YourServer, Method=POST`.

---

**getBody()**
Retrieves the body of this request.

**Signature**

```java
public String getBody()
```

**Return Value**

Type: **String**

**getBodyAsBlob()**
Retrieves the body of this request as a Blob.

**Signature**

```java
public Blob getBodyAsBlob()
```
Return Value
Type: Blob

**getBodyDocument()**
Retrieves the body of this request as a DOM document.

Signature

```java
public Dom.Document getBodyDocument()
```

Return Value
Type: Dom.Document

Example
Use this method as a shortcut for:

```java
String xml = httpRequest.getBody();
Dom.Document domDoc = new Dom.Document(xml);
```

**getCompressed()**
If true, the request body is compressed, false otherwise.

Signature

```java
public Boolean getCompressed()
```

Return Value
Type: Boolean

**getEndpoint()**
Retrieves the URL for the endpoint of the external server for this request.

Signature

```java
public String getEndpoint()
```

Return Value
Type: String

**getHeader(key)**
Retrieves the contents of the request header.
Signature

public String getHeader(String key)

Parameters

key
  Type: String

Return Value

Type: String

getMethod()

Returns the type of method used by HttpRequest.

Signature

public String getMethod()

Return Value

Type: String

Usage

Examples of return values:

- DELETE
- GET
- HEAD
- POST
- PUT
- TRACE

setBody (body)

Sets the contents of the body for this request.

Signature

public Void setBody(String body)

Parameters

body
  Type: String
Return Value
Type: Void

Usage
Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.
The HTTP request and response sizes count towards the total heap size.

**setBodyAsBlob** *(body)*
Sets the contents of the body for this request using a Blob.

Signature
```
public Void setBodyAsBlob(Blob body)
```

Parameters
```
body
  Type: Blob
```

Return Value
Type: Void

Usage
Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.
The HTTP request and response sizes count towards the total heap size.

**setBodyDocument** *(document)*
Sets the contents of the body for this request. The contents represent a DOM document.

Signature
```
```

Parameters
```
document
  Type: Dom.Document
```

Return Value
Type: Void

Usage
Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.
**setClientCertificate(clientCert, password)**

This method is deprecated. Use `setClientCertificateName` instead.

**Signature**

```java
public Void setClientCertificate(String clientCert, String password)
```

**Parameters**

- `clientCert`
  - Type: String
- `password`
  - Type: String

**Return Value**

Type: Void

**Usage**

If the server requires a client certificate for authentication, set the client certificate PKCS12 key store and password.

**setClientCertificateName(certDevName)**

If the external service requires a client certificate for authentication, set the certificate name.

**Signature**

```java
public Void setClientCertificateName(String certDevName)
```

**Parameters**

- `certDevName`
  - Type: String

**Return Value**

Type: Void

**Usage**

See Using Certificates with HTTP Requests.

**setCompressed(flag)**

If `true`, the data in the body is delivered to the endpoint in the gzip compressed format. If `false`, no compression format is used.

**Signature**

```java
public Void setCompressed(Boolean flag)
```
Parameters

flag
   Type: Boolean

Return Value
Type: Void

**setEndpoint(endpoint)**
Specifies the endpoint for this request.

Signature
```
public Void setEndpoint(String endpoint)
```

Parameters

endpoint
   Type: String

Possible values for the endpoint:
- Endpoint URL
  ```
  https://my_endpoint.example.com/some_path
  ```
- Named credential URL, which contains the scheme callout, the name of the named credential, and, optionally, an appended path
  ```
  callout:My_Named_Credential/some_path
  ```

Return Value
Type: Void

SEE ALSO:
- Named Credentials as Callout Endpoints

**setHeader(key, value)**
Sets the contents of the request header.

Signature
```
public Void setHeader(String key, String value)
```

Parameters

key
   Type: String
value
Type: String

Return Value
Type: Void

Usage
Limit 100 KB.

**setMethod(method)**
Sets the type of method to be used for the HTTP request.

Signature
```
public Void setMethod(String method)
```

Parameters

*method*
Type: String

Possible values for the method type include:
- DELETE
- GET
- HEAD
- POST
- PUT
- TRACE

Return Value
Type: Void

Usage
You can also use this method to set any required options.

**setTimeout(timeout)**
Sets the timeout in milliseconds for the request.

Signature
```
public Void setTimeout(Integer timeout)
```
Parameters

timeout
  Type: Integer

Return Value
Type: Void

Usage
The timeout can be any value between 1 and 120,000 milliseconds.

**toString()**

Returns a string containing the URL for the endpoint of the external server for this request and the method used, for example, Endpoint=http://YourServer, Method=POST

Signature

```java
public String toString()
```

Return Value
Type: String

**HttpResponse Class**

Use the `HttpResponse` class to handle the HTTP response returned by the `Http` class.

**Namespace**

`System`

**Usage**

Use the XML classes or JSON Classes to parse XML or JSON content in the body of a response accessed by `HttpResponse`.

**Example**

In the following `getXmlStreamReader` example, content is retrieved from an external Web server, then the XML is parsed using the `XmlStreamReader` class.

```java
public class ReaderFromCalloutSample {

    public void getAndParse() {

        // Get the XML document from the external server
        Http http = new Http();
        HttpRequest req = new HttpRequest();
        req.setEndpoint('https://docsample.herokuapp.com/xmlSample');
        req.setMethod('GET');
```
HttpResponse res = http.send(req);

// Log the XML content
System.debug(res.getBody());

// Generate the HTTP response as an XML stream
XmlStreamReader reader = res.getInputStream();

// Read through the XML
while(reader.hasNext()) {
    System.debug('Event Type:' + reader.getEventType());
    if (reader.getEventType() == XmlTag.START_ELEMENT) {
        System.debug(reader.getLocalName());
    }
    reader.next();
}

SEE ALSO:
- JSON Support
- XML Support

HttpResponse Methods

The following are methods for HttpResponse. All are instance methods.

IN THIS SECTION:
- getBody()
  Retrieves the body returned in the response.
- getBodyAsBlob()
  Retrieves the body returned in the response as a Blob.
- getBodyDocument()
  Retrieves the body returned in the response as a DOM document.
- getHeader(key)
  Retrieves the contents of the response header.
- getHeaderKeys()
  Retrieves an array of header keys returned in the response.
- getStatus()
  Retrieves the status message returned for the response.
- getStatusCode()
  Retrieves the value of the status code returned in the response.
- getXmlStreamReader()
  Returns an XmlStreamReader that parses the body of the callout response.
setBody(body)
Specifies the body returned in the response.

setBodyAsBlob(body)
Specifies the body returned in the response using a Blob.

setHeader(key, value)
Specifies the contents of the response header.

setStatus(status)
Specifies the status message returned in the response.

setStatusCode(statusCode)
Specifies the value of the status code returned in the response.

toString()
Returns the status message and status code returned in the response, for example:

getBody()
Retrieves the body returned in the response.

Signature

public String getBody()

Return Value
Type: String

Usage
Limit 6 MB for synchronous Apex or 12 MB for asynchronous Apex. The HTTP request and response sizes count towards the total heap size.

getBodyAsBlob()
Retrieves the body returned in the response as a Blob.

Signature

public Blob getBodyAsBlob()

Return Value
Type: Blob

Usage
Limit 6 MB for synchronous Apex or 12 MB for asynchronous Apex. The HTTP request and response sizes count towards the total heap size.
**getBodyDocument()**
Retrieves the body returned in the response as a DOM document.

Signature
```
public Dom.Document getBodyDocument()
```

Return Value
Type: Dom.Document

Example
Use it as a shortcut for:
```
String xml = httpResponse.getBody();
Dom.Document domDoc = new Dom.Document(xml);
```

**getHeader(key)**
Retrieves the contents of the response header.

Signature
```
public String getHeader(String key)
```

Parameters
```
key
  Type: String
```

Return Value
Type: String

**getHeaderKeys()**
Retrieves an array of header keys returned in the response.

Signature
```
public String[] getHeaderKeys()
```

Return Value
Type: String[]

**getStatus()**
Retrieves the status message returned for the response.
Signature

```
public String getStatus()
```

Return Value
Type: String

### getStatusCode()
Retrieves the value of the status code returned in the response.

Signature

```
public Integer getStatusCode()
```

Return Value
Type: Integer

### getXmlStreamReader()
Returns an `XmlStreamReader` that parses the body of the callout response.

Signature

```
public XmlStreamReader getXmlStreamReader()
```

Return Value
Type: `System.XmlStreamReader`

#### Usage
Use it as a shortcut for:

```java
String xml = httpResponse.getBody();
XmlStreamReader xsr = new XmlStreamReader(xml);
```

### setBody(body)
Specifies the body returned in the response.

Signature

```
public Void setBody(String body)
```

Parameters

- `body`
  Type: String
Return Value
Type: Void

**setBodyAsBlob** *(body)*
Specifies the body returned in the response using a Blob.

**Signature**
```
public Void setBodyAsBlob(Blob body)
```

**Parameters**
- **body**
  Type: Blob

Return Value
Type: Void

**setStatus** *(status)*
Specifies the status message returned in the response.

**Signature**
```
public Void setStatus(String status)
```

**Parameters**
- **status**
  Type: String

Return Value
Type: Void
Parameters

status
Type: String

Return Value
Type: Void

setStatusCode(statusCode)
Specifies the value of the status code returned in the response.

Signature
public Void setStatusCode(Integer statusCode)

Parameters

statusCode
Type: Integer

Return Value
Type: Void

toString()
Returns the status message and status code returned in the response, for example:

Signature
public String toString()

Return Value
Type: String

Example
Status=OK, StatusCode=200

Id Class
Contains methods for the ID primitive data type.

Namespace
System
Apex Developer Guide

System Namespace

Example: Getting an sObject Token From an ID
This sample shows how to use the getSObjectType method to obtain an sObject token from an ID. The updateOwner method
in this sample accepts a list of IDs of the sObjects to update the ownerId field of. This list contains IDs of sObjects of the same type. The
second parameter is the new owner ID. Note that since it is a future method, it doesn’t accept sObject types as parameters; this is why
it accepts IDs of sObjects. This method gets the sObject token from the first ID in the list, then does a describe to obtain the object name
and constructs a query dynamicallly. It then queries for all sObjects and updates their owner ID fields to the new owner ID.
public class MyDynamicSolution {
@future
public static void updateOwner(List<ID> objIds, ID newOwnerId) {
// Validate input
System.assert(objIds != null);
System.assert(objIds.size() > 0);
System.assert(newOwnerId != null);
// Get the sObject token from the first ID
// (the List contains IDs of sObjects of the same type).
Schema.SObjectType token = objIds[0].getSObjectType();
// Using the token, do a describe
// and construct a query dynamically.
Schema.DescribeSObjectResult dr = token.getDescribe();
String queryString = 'SELECT ownerId FROM ' + dr.getName() +
' WHERE ';
for(ID objId : objIds) {
queryString += 'Id=\'' + objId + '\' OR ';
}
// Remove the last ' OR'
queryString = queryString.subString(0, queryString.length() - 4);
sObject[] objDBList = Database.query(queryString);
System.assert(objDBList.size() > 0);
// Update the owner ID on the sObjects
for(Integer i=0;i<objDBList.size();i++) {
objDBList[i].put('ownerId', newOwnerId);
}
Database.SaveResult[] srList = Database.update(objDBList, false);
for(Database.SaveResult sr : srList) {
if (sr.isSuccess()) {
System.debug('Updated owner ID successfully for ' +
dr.getName() + ' ID ' + sr.getId());
}
else {
System.debug('Updating ' + dr.getName() + ' returned the following errors.');
for(Database.Error e : sr.getErrors()) {
System.debug(e.getMessage());
}
}
}
}
}

2749


Id Methods

The following are methods for Id.

IN THIS SECTION:

addError(errorMsg)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

addError(errorMsg, escape)
Marks a trigger record with a custom error message, specifies if the error message should be escaped, and prevents any DML operation from occurring.

addError(exceptionError)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

addError(exceptionError, escape)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

g getSObjectType()
Returns the token for the sObject corresponding to this ID. This method is primarily used with describe information.

valueOf(toID)
Converts the specified String into an ID and returns the ID.

addError(errorMsg)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature

public Void addError(String errorMsg)

Parameters

errorMsg
Type: String
The error message to mark the record with.

Return Value

Type: Void

Usage

This method is similar to the addError (errorMsg) sObject method.

Note: This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &", \, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.
Example

Trigger.new[0].IdaddError('bad');

**addError(errorMsg, escape)**

Marks a trigger record with a custom error message, specifies if the error message should be escaped, and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(String errorMsg, Boolean escape)
```

**Parameters**

- **errorMsg**
  - Type: String
  - The error message to mark the record with.

- **escape**
  - Type: Boolean
  - Indicates whether any HTML markup in the custom error message should be escaped (`true`) or not (`false`). This parameter is ignored in Lightning Experience and the Salesforce app and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

**Return Value**

- Type: Void

**Usage**

The escaped characters are: `\n`, `<`, `>`, `&`, `"`, `\`, `\u2028`, `\u2029`, and `\u00a9`. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

⚠️ **Warning**: Be cautious if you specify `false` for the `escape` argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false` `escape` argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify `true` for the `escape` argument or call `addError(String errorMsg)` instead.

Example

```
Trigger.new[0].Id.addError('Fix & resubmit', false);
```

**addError(exceptionError)**

Marks a trigger record with a custom error message and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(Exception exceptionError)
```
Parameters

_exceptionError_
Type: System.Exception
An Exception object or a custom exception object that contains the error message to mark the record with.

Return Value
Type: Void

Usage
This method is similar to the `addError(exceptionError)` sObject method.

Note: This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &, " and \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

Example
```
public class MyException extends Exception{}

Trigger.new[0].Id.addError(new myException('Invalid Id'));
```

addError(exceptionError, escape)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature
```
public Void addError(Exception exceptionError, Boolean escape)
```

Parameters

_exceptionError_
Type: System.Exception
An Exception object or a custom exception object that contains the error message to mark the record with.

_escape_
Type: Boolean
Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false). This parameter is ignored in Lightning Experience and the Salesforce app and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value
Type: Void
Usage

The escaped characters are: \n, <, >, &", \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

⚠️ Warning: Be cautious if you specify false for the escape argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a false escape argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify true for the escape argument or call addError(Exception e) instead.

Example

```java
public class MyException extends Exception{}

account a = new account();
aaddError(new MyException('Invalid Id & other issues'), false);
```

**getSObjectType()**

Returns the token for the sObject corresponding to this ID. This method is primarily used with describe information.

**Signature**

```java
public Schema.SObjectType getSObjectType()
```

**Return Value**

Type: Schema.SObjectType

**Usage**

For more information about describes, see Understanding Apex Describe Information.

Example

```java
account a = new account(name = 'account');
insert a;
Id myId = a.id;
system.assertEquals(Schema.Account.SObjectType, myId.getSobjectType());
```

**valueOf(toID)**

Converts the specified String into an ID and returns the ID.

**Signature**

```java
public static ID valueOf(String toID)
```
Parameters

toID
    Type: String

Return Value

Type: ID

Example

Id myId = Id.valueOf('001xa000003DIlo');

Ideas Class

Represents zone ideas.

Namespace

System

Usage

Ideas is a community of users who post, vote for, and comment on ideas. An Ideas community provides an online, transparent way for you to attract, manage, and showcase innovation.

A set of recent replies (returned by methods, see below) includes ideas that a user has posted or commented on that already have comments posted by another user. The returned ideas are listed based on the time of the last comment made by another user, with the most recent ideas appearing first.

The userID argument is a required argument that filters the results so only the ideas that the specified user has posted or commented on are returned.

The communityID argument filters the results so only the ideas within the specified zone are returned. If this argument is the empty string, then all recent replies for the specified user are returned regardless of the zone.

For more information on ideas, see “Using Ideas” in the Salesforce online help.

Example

The following example finds ideas in a specific zone that have similar titles as a new idea:

```apex
public class FindSimilarIdeasController {

    public static void test() {
        // Instantiate a new idea
        Idea idea = new Idea();

        // Specify a title for the new idea
        idea.Title = 'Increase Vacation Time for Employees';

        // Specify the communityID (INTERNAL_IDEAS) in which to find similar ideas.
        Community community = [ SELECT Id FROM Community WHERE Name = 'INTERNAL_IDEAS' ];
```
The following example uses a Visualforce page in conjunction with a custom controller, that is, a special Apex class. For more information on Visualforce, see the Visualforce Developer’s Guide.

This example creates an Apex method in the controller that returns unread recent replies. You can leverage this same example for the getAllRecentReplies and getReadRecentReplies methods. For this example to work, there must be ideas posted to the zone. In addition, at least one zone member must have posted a comment to another zone member’s idea or comment.

```apex
// Create an Apex method to retrieve the recent replies marked as unread in all communities
public class IdeasController {

    public Idea[] getUnreadRecentReplies() {
        Idea[] recentReplies;
        if (recentReplies == null) {
            Id[] recentRepliesIds = Ideas.getUnreadRecentReplies(UserInfo.getUserId(), '');
            recentReplies = [SELECT Id, Title FROM Idea WHERE Id IN :recentRepliesIds];
        }
        return recentReplies;
    }
}
```

The following is the markup for a Visualforce page that uses the above custom controller to list unread recent replies.

```apex
<apex:page controller="IdeasController" showHeader="false">
    <apex:dataList value="{!unreadRecentReplies}" var="recentReplyIdea">
        <a href="/apex/viewIdea?id={!recentReplyIdea.Id}"
           var="recentReplyIdea">
            <apex:outputText value="{!recentReplyIdea.Title}" escape="true"/>
        </a>
    </apex:dataList>
</apex:page>
```

The following example uses a Visualforce page in conjunction with a custom controller to list ideas. Then, a second Visualforce page and custom controller is used to display a specific idea and mark it as read. For this example to work, there must be ideas posted to the zone.

```apex
// Create a controller to use on a Visualforce page to list ideas
public class IdeaListController {

    public final Idea[] ideas {get; private set;}

    public IdeaListController() {
        Integer i = 0;
        ideas = new Idea[10];
        for (Idea tmp : Database.query ('SELECT Id, Title FROM Idea WHERE Id != null AND parentIdeaId = null LIMIT 10')) {
            i++;
            ideas.add(tmp);
        }
    }
}
```
The following is the markup for a Visualforce page that uses the above custom controller to list ideas:

```xml
<apex:page controller="IdeaListController" tabStyle="Idea" showHeader="false">
    <apex:dataList value="{!ideas}" var="idea" id="ideaList">
        <a href="/apex/viewIdea?id={!idea.id}"
            <apex:outputText value="{!idea.title}" escape="true"/>
    </apex:dataList>
</apex:page>
```

The following example also uses a Visualforce page and custom controller, this time, to display the idea that is selected on the above idea list page. In this example, the `markRead` method marks the selected idea and associated comments as read by the user that is currently logged in. Note that the `markRead` method is in the constructor so that the idea is marked read immediately when the user goes to a page that uses this controller. For this example to work, there must be ideas posted to the zone. In addition, at least one zone member must have posted a comment to another zone member's idea or comment.

```xml
// Create an Apex method in the controller that marks all comments as read for the selected idea
public class ViewIdeaController {

    private final String id = System.currentPage().getParameters().get('id');

    public ViewIdeaController(ApexPages.StandardController controller) {
        Ideas.markRead(id);
    }
}
```

The following is the markup for a Visualforce page that uses the above custom controller to display the idea as read.

```xml
<apex:page standardController="Idea" extensions="ViewIdeaController" showHeader="false">

    <h2><apex:outputText value="{!idea.title}" /></h2>
    <apex:outputText value="{!idea.body}" />

</apex:page>
```

### Ideas Methods

The following are methods for `Ideas`. All methods are static.

**IN THIS SECTION:**

- `findSimilar(idea)`
  Returns a list of similar ideas based on the title of the specified idea.

- `getAllRecentReplies(userId, communityID)`
  Returns ideas that have recent replies for the specified user or zone. This includes all read and unread replies.
getReadRecentReplies(userID, communityID)
Returns ideas that have recent replies marked as read.

getUnreadRecentReplies(userID, communityID)
Returns ideas that have recent replies marked as unread.

markRead(ideaID)
Marks all comments as read for the user that is currently logged in.

**findSimilar(idea)**

Returns a list of similar ideas based on the title of the specified idea.

**Signature**

```java
public static ID[] findSimilar(Idea idea)
```

**Parameters**

- `idea`
  Type: Idea

**Return Value**

Type: ID[]

**Usage**

Each `findSimilar` call counts against the SOSL query limits. See Execution Governors and Limits.

getAllRecentReplies(userID, communityID)
Returns ideas that have recent replies for the specified user or zone. This includes all read and unread replies.

**Signature**

```java
public static ID[] getAllRecentReplies(String userID, String communityID)
```

**Parameters**

- `userID`
  Type: String
- `communityID`
  Type: String

**Return Value**

Type: ID[]
Usage
Each `getAllRecentReplies` call counts against the SOQL query limits. See Execution Governors and Limits.

`getReadRecentReplies(userID, communityID)`
Returns ideas that have recent replies marked as read.

Signature
```java
public static ID[] getReadRecentReplies(String userID, String communityID)
```

Parameters
- `userID`  
  Type: `String`
- `communityID`  
  Type: `String`

Return Value
Type: `ID[]`

Usage
Each `getReadRecentReplies` call counts against the SOQL query limits. See Execution Governors and Limits.

`getUnreadRecentReplies(userID, communityID)`
Returns ideas that have recent replies marked as unread.

Signature
```java
public static ID[] getUnreadRecentReplies(String userID, String communityID)
```

Parameters
- `userID`  
  Type: `String`
- `communityID`  
  Type: `String`

Return Value
Type: `ID[]`

Usage
Each `getUnreadRecentReplies` call counts against the SOQL query limits. See Execution Governors and Limits.
markRead(ideaID)
Marks all comments as read for the user that is currently logged in.

Signature

```java
public static Void markRead(String ideaID)
```

Parameters

- `ideaID`
  Type: String

Return Value

Type: Void

InstallHandler Interface

Enables custom code to run after a managed package installation or upgrade.

Namespace

System

Usage

App developers can implement this interface to specify Apex code that runs automatically after a subscriber installs or upgrades a managed package. This makes it possible to customize the package install or upgrade, based on details of the subscriber’s organization. For instance, you can use the script to populate custom settings, create sample data, send an email to the installer, notify an external system, or kick off a batch operation to populate a new field across a large set of data.

The post install script is invoked after tests have been run, and is subject to default governor limits. It runs as a special system user that represents your package, so all operations performed by the script appear to be done by your package. You can access this user by using UserInfo. You will only see this user at runtime, not while running tests.

If the script fails, the install/upgrade is aborted. Any errors in the script are emailed to the user specified in the Notify on Apex Error field of the package. If no user is specified, the install/upgrade details will be unavailable.

The post install script has the following additional properties.

- It can initiate batch, scheduled, and future jobs.
- It can't access Session IDs.
- It can only perform callouts using an async operation. The callout occurs after the script is run and the install is complete and committed.
- It can't call another Apex class in the package if that Apex class uses the `with sharing` keyword. This keyword can prevent the package from successfully installing. See the Apex Developer Guide to learn more.
The `InstallHandler` interface has a single method called `onInstall`, which specifies the actions to be performed on install/upgrade.

```java
global interface InstallHandler {
    void onInstall(InstallContext context);
};
```

The `onInstall` method takes a context object as its argument, which provides the following information.

- The org ID of the organization in which the installation takes place.
- The user ID of the user who initiated the installation.
- The version number of the previously installed package (specified using the `Version` class). This is always a three-part number, such as 1.2.0.
- Whether the installation is an upgrade.
- Whether the installation is a push.

The context argument is an object whose type is the `InstallContext` interface. This interface is automatically implemented by the system. The following definition of the `InstallContext` interface shows the methods you can call on the context argument.

```java
global interface InstallContext {
    ID organizationId();
    ID installerId();
    Boolean isUpgrade();
    Boolean isPush();
    Version previousVersion();
};
```

### IN THIS SECTION:

- InstallHandler Methods
- InstallHandler Example Implementation

### InstallHandler Methods

The following are methods for `InstallHandler`.

#### onInstall(context)

Specifies the actions to be performed on install/upgrade.

**Signature**

```java
public Void onInstall(InstallContext context)
```
InstallHandler Example Implementation

The following sample post install script performs these actions on package install/upgrade.

- If the previous version is null, that is, the package is being installed for the first time, the script:
  - Creates a new Account called “Newco” and verifies that it was created.
  - Creates a new instance of the custom object Survey, called "Client Satisfaction Survey”.
  - Sends an email message to the subscriber confirming installation of the package.

- If the previous version is 1.0, the script creates a new instance of Survey called "Upgrading from Version 1.0”.

- If the package is an upgrade, the script creates a new instance of Survey called "Sample Survey during Upgrade”.

- If the upgrade is being pushed, the script creates a new instance of Survey called "Sample Survey during Push”.

```apex
global class PostInstallClass implements InstallHandler {
    global void onInstall(InstallContext context) {
        if(context.previousVersion() == null) {
            Account a = new Account(name='Newco');
            insert(a);

            Survey__c obj = new Survey__c(name='Client Satisfaction Survey');
            insert obj;

            User u = [Select Id, Email from User where Id =:context.installerID()];
            String toAddress= u.Email;
            String[] toAddresses = new String[]{toAddress};
            Messaging.SingleEmailMessage mail =
                new Messaging.SingleEmailMessage();
            mail.setToAddresses(toAddresses);
            mail.setReplyTo('support@package.dev');
            mail.setSenderDisplayName('My Package Support');
            mail.setSubject('Package install successful');
            mail.setPlainTextBody('Thanks for installing the package.');
            Messaging.sendEmail(new Messaging.Email[] { mail });
        } else
            if(context.previousVersion().compareTo(new Version(1,0)) == 0) {
                Survey__c obj = new Survey__c(name='Upgrading from Version 1.0');
                insert(obj);
            }
        if(context.isUpgrade()) {
            Survey__c obj = new Survey__c(name='Sample Survey during Upgrade');
            insert obj;
        } else
            if(context.isPush()) {
```

```
```
Survey__c obj = new Survey__c(name='Sample Survey during Push');
insert obj;
}
}
}

You can test a post install script using the new testInstall method of the Test class. This method takes the following arguments.

- A class that implements the InstallHandler interface.
- A Version object that specifies the version number of the existing package.
- An optional Boolean value that is true if the installation is a push. The default is false.

This sample shows how to test a post install script implemented in the PostInstallClass Apex class.

```apex
@isTest
static void testInstallScript() {
    PostInstallClass postinstall = new PostInstallClass();
    Test.testInstall(postinstall, null);
    Test.testInstall(postinstall, new Version(1,0), true);
    List<Account> a = [Select id, name from Account where name = 'Newco'];
    System.assertEquals(a.size(), 1, 'Account not found');
}
```

**Integer Class**

Contains methods for the Integer primitive data type.

**Namespace**

*System*

**Usage**

For more information on integers, see Primitive Data Types on page 26.

**Integer Methods**

The following are methods for Integer.

**IN THIS SECTION:**

- **format()**
  Returns the integer as a string using the locale of the context user.

- **valueOf(stringToInt)***
  Returns an Integer that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal integer.

- **valueOf(fieldValue)**
  Converts the specified object to an Integer. Use this method to convert a history tracking field value or an object that represents an Integer value.
**format()**

Returns the integer as a string using the locale of the context user.

Signature

```java
public String format()
```

Return Value

Type: `String`

Example

```java
integer myInt = 22;
system.assertEquals('22', myInt.format());
```

**valueOf(stringToInteger)**

Returns an `Integer` that contains the value of the specified `String`. As in Java, the `String` is interpreted as representing a signed decimal integer.

Signature

```java
public static Integer valueOf(String stringToInteger)
```

Parameters

`stringToInteger`  
Type: `String`

Return Value

Type: `Integer`

Example

```java
Integer myInt = Integer.valueOf('123');
```

**valueOf(fieldValue)**

Converts the specified `Object` to an `Integer`. Use this method to convert a history tracking field value or an object that represents an `Integer` value.

Signature

```java
public static Integer valueOf(Object fieldValue)
```
Parameters

**fieldValue**
Type: Object

Return Value
Type: Integer

Usage
Use this method with the OldValue or NewValue fields of history sObjects, such as AccountHistory, when the field type corresponds to an Integer type, like a number field.

Example:

```java
List<AccountHistory> ahlist =
    [SELECT Field, OldValue, NewValue
     FROM AccountHistory];
for (AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'NumberOfEmployees') {
        Integer oldValue =
            Integer.valueOf(ah.OldValue);
        Integer newValue =
            Integer.valueOf(ah.NewValue);
    }
}
```

JSON Class
Contains methods for serializing Apex objects into JSON format and deserializing JSON content that was serialized using the `serialize` method in this class.

Namespace
**System**

Usage
Use the methods in the **System.JSON** class to perform round-trip JSON serialization and deserialization of Apex objects.

SEE ALSO:
    - **Roundtrip Serialization and Deserialization**

JSON Methods
The following are methods for **JSON**. All methods are static.
IN THIS SECTION:

createGenerator(prettyPrint)
Returns a new JSON generator.
createParser(jsonString)
Returns a new JSON parser.
deserialize(jsonString, apexType)
Deserializes the specified JSON string into an Apex object of the specified type.
deserializeStrict(jsonString, apexType)
Deserializes the specified JSON string into an Apex object of the specified type.
deserializeUntyped(jsonString)
Deserializes the specified JSON string into collections of primitive data types.
serialize(objectToSerialize)
Serializes Apex objects into JSON content.
serialize(objectToSerialize, suppressApexObjectNulls)
Suppresses null values when serializing Apex objects into JSON content.
serializePretty(objectToSerialize)
Serializes Apex objects into JSON content and generates indented content using the pretty-print format.
serializePretty(objectToSerialize, suppressApexObjectNulls)
Suppresses null values when serializing Apex objects into JSON content and generates indented content using the pretty-print format.

createGenerator(prettyPrint)
Returns a new JSON generator.

Signature

public static System.JSONGenerator createGenerator(Boolean prettyPrint)

Parameters

prettyPrint
  Type: Boolean
  Determines whether the JSON generator creates JSON content in pretty-print format with the content indented. Set to true to create indented content.

Return Value

Type: System.JSONGenerator

createParser(jsonString)
Returns a new JSON parser.
Signature

```java
public static System.JSONParser createParser(String jsonString)
```

Parameters

`jsonString`
Type: String
The JSON content to parse.

Return Value

Type: System.JSONParser

**deserialize(jsonString, apexType)**

Deserializes the specified JSON string into an Apex object of the specified type.

Signature

```java
public static Object deserialize(String jsonString, System.Type apexType)
```

Parameters

`jsonString`
Type: String
The JSON content to deserialize.

`apexType`
Type: System.Type
The Apex type of the object that this method creates after deserializing the JSON content.

Return Value

Type: Object

Usage

If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content into a custom object or an sObject using Salesforce API version 34.0 or earlier, this method throws a runtime exception when passed extraneous attributes. When deserializing JSON content into an Apex class in any API version, or into an object in API version 35.0 or later, no exception is thrown. When no exception is thrown, this method ignores extraneous attributes and parses the rest of the JSON content.

Example

The following example deserializes a `Decimal` value.

```java
Decimal n = (Decimal)JSON.deserialize('100.1', Decimal.class);
System.assertEquals(n, 100.1);
```
**deserializeStrict(jsonString, apexType)**

Deserializes the specified JSON string into an Apex object of the specified type.

**Signature**

```java
public static Object deserializeStrict(String jsonString, System.Type apexType)
```

**Parameters**

- `jsonString`
  - **Type:** String
  - The JSON content to deserialize.

- `apexType`
  - **Type:** System.Type
  - The Apex type of the object that this method creates after deserializing the JSON content.

**Return Value**

- **Type:** Object

**Usage**

All attributes in the JSON string must be present in the specified type. If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content with extraneous attributes into an Apex class, this method throws an exception in all API versions. However, no exception is thrown when you use this method to deserialize JSON content into a custom object or an sObject.

**Example**

The following example deserializes a JSON string into an object of a user-defined type represented by the `Car` class, which this example also defines.

```java
public class Car {
    public String make;
    public String year;
}

public void parse() {
    Car c = (Car)JSON.deserializeStrict(
        '{"make":"SFDC","year":"2020"}',
        Car.class);
    System.assertEquals(c.make, 'SFDC');
    System.assertEquals(c.year, '2020');
}
```

**deserializeUntyped(jsonString)**

Deserializes the specified JSON string into collections of primitive data types.
Signature

```java
public static Object deserializeUntyped(String jsonString)
```

Parameters

`jsonString`
Type: `String`
The JSON content to deserialize.

Return Value
Type: `Object`

Example

The following example deserializes a JSON representation of an appliance object into a map that contains primitive data types and further collections of primitive types. It then verifies the deserialized values.

```java
String jsonInput = '{
  "description": "An appliance",
  "accessories": [
    "powerCord",
    {
      "right": "door handle1",
      "left": "door handle2"
    }
  ],
  "dimensions": {
    "height": 5.5,
    "width": 3.0,
    "depth": 2.2
  },
  "type": null,
  "inventory": 2000,
  "price": 1023.45,
  "isShipped": true,
  "modelNumber": "123"
};
Map<String, Object> m = (Map<String, Object>) JSON.deserializeUntyped(jsonInput);
System.assertEquals("An appliance", m.get("description"));
List<Object> a = (List<Object>)m.get("accessories");
System.assertEquals("powerCord", a[0]);
Map<String, Object> a2 = (Map<String, Object>)a[1];
System.assertEquals("door handle1", a2.get("right"));
System.assertEquals("door handle2", a2.get("left"));
Map<String, Object> dim = (Map<String, Object>)m.get("dimensions");
```
serialize(objectToSerialize)

Serializes Apex objects into JSON content.

Signature

```java
public static String serialize(Object objectToSerialize)
```

Parameters

**objectToSerialize**

Type: `Object`

The Apex object to serialize.

Return Value

Type: `String`

Example

The following example serializes a new `Datetime` value.

```java
Datetime dt = Datetime.newInstance(
  Date.newInstance(
    2011, 3, 22),
  Time.newInstance(
    1, 15, 18, 0));
String str = JSON.serialize(dt);
System.assertEquals(
  "2011-03-22T08:15:18.000Z",
  str);
```

serialize(objectToSerialize, suppress ApexObjectNulls)

Suppresses `null` values when serializing Apex objects into JSON content.
public static String serialize(Object objectToSerialize, Boolean suppressApexObjectNulls)

Parameters

objectToSerialize
  Type: Object
  The Apex object to serialize.

suppressApexObjectNulls
  Type: Boolean
  If true, remove null values before serializing the JSON object.

Return Value

Type: String

Usage

This method allows you to specify whether to suppress null values when serializing Apex objects into JSON content.

serializePretty(objectToSerialize)

Serializes Apex objects into JSON content and generates indented content using the pretty-print format.

public static String serializePretty(Object objectToSerialize)

Parameters

objectToSerialize
  Type: Object
  The Apex object to serialize.

Return Value

Type: String

serializePretty(objectToSerialize, suppressApexObjectNulls)

Suppresses null values when serializing Apex objects into JSON content and generates indented content using the pretty-print format.

public static String serializePretty(Object objectToSerialize, Boolean suppressApexObjectNulls)
Parameters

objectToSerialize
  Type: Object
  The Apex object to serialize.

suppressApexObjectNulls
  Type: Boolean
  If true, remove null values before serializing the JSON object.

Return Value
Type: String

JSONGenerator Class
Contains methods used to serialize objects into JSON content using the standard JSON encoding.

Namespace
System

Usage
The System.JSONGenerator class is provided to enable the generation of standard JSON-encoded content and gives you more control on the structure of the JSON output.

SEE ALSO:
  JSON Generator

JSONGenerator Methods
The following are methods for JSONGenerator. All are instance methods.

IN THIS SECTION:
  close()
  Closes the JSON generator.
  getAsString()
  Returns the generated JSON content.
  isClosed()
  Returns true if the JSON generator is closed; otherwise, returns false.
  writeBlob(blobValue)
  Writes the specified Blob value as a base64-encoded string.
  writeBlobField(fieldName, blobValue)
  Writes a field name and value pair using the specified field name and BLOB value.
writeBoolean(blobValue)
Writes the specified Boolean value.
writeBooleanField(fieldName, booleanValue)
Writes a field name and value pair using the specified field name and Boolean value.
writeDate(dateValue)
Writes the specified date value in the ISO-8601 format.
writeDateField(fieldName, dateValue)
Writes a field name and value pair using the specified field name and date value. The date value is written in the ISO-8601 format.
writeDateTime(datetimeValue)
Writes the specified date and time value in the ISO-8601 format.
writeDateTimeField(fieldName, datetimeValue)
Writes a field name and value pair using the specified field name and date and time value. The date and time value is written in the ISO-8601 format.
writeEndArray()
Writes the ending marker of a JSON array (').
writeEndObject()
Writes the ending marker of a JSON object ('}').
writeFieldName(fieldName)
Writes a field name.
writeId(identifier)
Writes the specified ID value.
writeIdField(fieldName, identifier)
Writes a field name and value pair using the specified field name and identifier value.
writeNull()
Writes the JSON null literal value.
writeNullField(fieldName)
Writes a field name and value pair using the specified field name and the JSON null literal value.
writeNumber(number)
Writes the specified decimal value.
writeNumber(number)
Writes the specified double value.
writeNumber(number)
Writes the specified integer value.
writeNumber(number)
Writes the specified long value.
writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and decimal value.
writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and double value.
writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and integer value.
writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and long value.

writeObject(anyObject)
Writes the specified Apex object in JSON format.

writeObjectField(fieldName, value)
Writes a field name and value pair using the specified field name and Apex object.

writeStartArray()
Writes the starting marker of a JSON array ('[').

writeStartObject()
Writes the starting marker of a JSON object ('{').

writeString(stringValue)
Writes the specified string value.

writeStringField(fieldName, stringValue)
Writes a field name and value pair using the specified field name and string value.

writeTime(timeValue)
Writes the specified time value in the ISO-8601 format.

writeTimeField(fieldName, timeValue)
Writes a field name and value pair using the specified field name and time value in the ISO-8601 format.

close()
Closes the JSON generator.

Signature
public Void close()

Return Value
Type: Void

Usage
No more content can be written after the JSON generator is closed.

getAsString()
Returns the generated JSON content.

Signature
public String getAsString()

Return Value
Type: String
Usage
This method closes the JSON generator if it isn't closed already.

**isClosed()**
Returns `true` if the JSON generator is closed; otherwise, returns `false`.

Signature
```java
public Boolean isClosed()
```

Return Value
Type: `Boolean`

**writeBlob(blobValue)**
Writes the specified `Blob` value as a base64-encoded string.

Signature
```java
public Void writeBlob(Blob blobValue)
```

Parameters
- `blobValue`  
  Type: `Blob`

Return Value
Type: `Void`

**writeBlobField(fieldName, blobValue)**
Writes a field name and value pair using the specified field name and BLOB value.

Signature
```java
public Void writeBlobField(String fieldName, Blob blobValue)
```

Parameters
- `fieldName`  
  Type: `String`
- `blobValue`  
  Type: `Blob`

Return Value
Type: `Void`
**writeBoolean(blobValue)**

Writes the specified Boolean value.

**Signature**

```java
public Void writeBoolean(Boolean blobValue)
```

**Parameters**

- **blobValue**
  - Type: `Boolean`

**Return Value**

Type: `Void`

**writeBooleanField(fieldName, booleanValue)**

Writes a field name and value pair using the specified field name and Boolean value.

**Signature**

```java
public Void writeBooleanField(String fieldName, Boolean booleanValue)
```

**Parameters**

- **fieldName**
  - Type: `String`
- **booleanValue**
  - Type: `Boolean`

**Return Value**

Type: `Void`

**writeDate(dateValue)**

Writes the specified date value in the ISO-8601 format.

**Signature**

```java
public Void writeDate(Date dateValue)
```

**Parameters**

- **dateValue**
  - Type: `Date`
writeDateField(fieldName, dateValue)
Writes a field name and value pair using the specified field name and date value. The date value is written in the ISO-8601 format.

Signature
public Void writeDateField(String fieldName, Date dateValue)

Parameters
fieldName
Type: String
dateValue
Type: Date

Return Value
Type: Void

writeDateTime(datetimeValue)
Writes the specified date and time value in the ISO-8601 format.

Signature
public Void writeDateTime(Datetime datetimeValue)

Parameters
datetimeValue
Type: Datetime

Return Value
Type: Void

writeDateTimeField(fieldName, datetimeValue)
Writes a field name and value pair using the specified field name and date and time value. The date and time value is written in the ISO-8601 format.

Signature
public Void writeDateTimeField(String fieldName, Datetime datetimeValue)
Parameters

fieldName
  Type: String
datetimeValue
  Type: Datetime

Return Value
Type: Void

**writeEndArray()**
 Writes the ending marker of a JSON array (').

Signature
public Void writeEndArray()

Return Value
Type: Void

**writeEndObject()**
 Writes the ending marker of a JSON object (').

Signature
public Void writeEndObject()

Return Value
Type: Void

**writeFieldName(String fieldName)**
 Writes a field name.

Signature
public Void writeFieldName(String fieldName)

Parameters

fieldName
  Type: String

Return Value
Type: Void
**writeId(identifier)**
Writes the specified ID value.

Signature

```java
public Void writeId(ID identifier)
```

Parameters

- `identifier`
  Type: ID

Return Value

Type: Void

**writeIdField(fieldName, identifier)**
Writes a field name and value pair using the specified field name and identifier value.

Signature

```java
public Void writeIdField(String fieldName, Id identifier)
```

Parameters

- `fieldName`
  Type: String
- `identifier`
  Type: ID

Return Value

Type: Void

**writeNull()**
Writes the JSON null literal value.

Signature

```java
public Void writeNull()
```

Return Value

Type: Void

**writeNullField(fieldName)**
Writes a field name and value pair using the specified field name and the JSON null literal value.
**Signature**

```java
public Void writeNullField(String fieldName)
```

**Parameters**

- `fieldName`
  - Type: `String`

**Return Value**

- Type: `Void`

**writeNumber(number)**

Writes the specified decimal value.

**Signature**

```java
public Void writeNumber(Decimal number)
```

**Parameters**

- `number`
  - Type: `Decimal`

**Return Value**

- Type: `Void`

**writeNumber(number)**

Writes the specified double value.

**Signature**

```java
public Void writeNumber(Double number)
```

**Parameters**

- `number`
  - Type: `Double`

**Return Value**

- Type: `Void`

**writeNumber(number)**

Writes the specified integer value.
### writeNumber(Integer number)

**Signature**

```java
public Void writeNumber(Integer number)
```

**Parameters**

- `number`
  
  **Type:** Integer

**Return Value**

- **Type:** Void

**writeNumber(number)**

Writes the specified long value.

### writeNumber(Long number)

**Signature**

```java
public Void writeNumber(Long number)
```

**Parameters**

- `number`
  
  **Type:** Long

**Return Value**

- **Type:** Void

### writeNumberField(String fieldName, Decimal number)

**Signature**

```java
public Void writeNumberField(String fieldName, Decimal number)
```

**Parameters**

- `fieldName`
  
  **Type:** String

- `number`
  
  **Type:** Decimal

**Return Value**

- **Type:** Void
writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and double value.

Signature
public Void writeNumberField(String fieldName, Double number)

Parameters
fieldName
  Type: String
number
  Type: Double

Return Value
Type: Void

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and integer value.

Signature
public Void writeNumberField(String fieldName, Integer number)

Parameters
fieldName
  Type: String
number
  Type: Integer

Return Value
Type: Void

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and long value.

Signature
public Void writeNumberField(String fieldName, Long number)

Parameters
fieldName
  Type: String
**number**
  Type: Long

Return Value
Type: Void

**writeObject(anyObject)**
Writes the specified Apex object in JSON format.

Signature
public Void writeObject(Object anyObject)

Parameters
anyObject
  Type: Object

Return Value
Type: Void

**writeObjectField(fieldName, value)**
Writes a field name and value pair using the specified field name and Apex object.

Signature
public Void writeObjectField(String fieldName, Object value)

Parameters
fieldName
  Type: String
value
  Type: Object

Return Value
Type: Void

**writeStartArray()**
Writes the starting marker of a JSON array ('[').

Signature
public Void writeStartArray()
Return Value
Type: Void

writeStartObject()
Writes the starting marker of a JSON object ('{').

Signature
public Void writeStartObject()

Return Value
Type: Void

writeString(stringValue)
Writes the specified string value.

Signature
public Void writeString(String stringValue)

Parameters
stringValue
Type: String

Return Value
Type: Void

writeStringField(fieldName, stringValue)
Writes a field name and value pair using the specified field name and string value.

Signature
public Void writeStringField(String fieldName, String stringValue)

Parameters
fieldName
Type: String
stringValue
Type: String

Return Value
Type: Void
**writeTime(timeValue)**

Writes the specified time value in the ISO-8601 format.

**Signature**

```java
public Void writeTime(Time timeValue)
```

**Parameters**

- **timeValue**
  - Type: `Time`

**Return Value**

Type: `Void`

**writeTimeField(fieldName, timeValue)**

Writes a field name and value pair using the specified field name and time value in the ISO-8601 format.

**Signature**

```java
public Void writeTimeField(String fieldName, Time timeValue)
```

**Parameters**

- **fieldName**
  - Type: `String`
- **timeValue**
  - Type: `Time`

**Return Value**

Type: `Void`

**JSONParser Class**

Represents a parser for JSON-encoded content.

**Namespace**

`System`
Usage

Use the System.JSONParser methods to parse a response that’s returned from a call to an external service that is in JSON format, such as a JSON-encoded response of a Web service callout.

SEE ALSO:
  JSON Parsing

JSONParser Methods

The following are methods for JSONParser. All are instance methods.

IN THIS SECTION:
  clearCurrentToken()
  gets current token.
  getBlobValue()
  Returns the current token as a BLOB value.
  getBooleanValue()
  Returns the current token as a Boolean value.
  getCurrentName()
  Returns the name associated with the current token.
  getCurrentToken()
  Returns the token that the parser currently points to or null if there’s no current token.
  getDatetimeValue()
  Returns the current token as a date and time value.
  getDateValue()
  Returns the current token as a date value.
  getDecimalValue()
  Returns the current token as a decimal value.
  getDoubleValue()
  Returns the current token as a double value.
  getIdValue()
  Returns the current token as an ID value.
  getIntegerValue()
  Returns the current token as an integer value.
  getLastClearedToken()
  Returns the last token that was cleared by the clearCurrentToken method.
  getLongValue()
  Returns the current token as a long value.
  getText()
  Returns the textual representation of the current token or null if there’s no current token.
getTimeValue() - Returns the current token as a time value.

hasCurrentToken() - Returns `true` if the parser currently points to a token; otherwise, returns `false`.

nextToken() - Returns the next token or `null` if the parser has reached the end of the input stream.

nextValue() - Returns the next token that is a value type or `null` if the parser has reached the end of the input stream.

readValueAs(apexType) - Deserializes JSON content into an object of the specified Apex type and returns the deserialized object.

readValueAsStrict(apexType) - Deserializes JSON content into an object of the specified Apex type and returns the deserialized object. All attributes in the JSON content must be present in the specified type.

skipChildren() - Skips all child tokens of type `JSONToken.START_ARRAY` and `JSONToken.START_OBJECT` that the parser currently points to.

clearCurrentToken() - Removes the current token.

**Signature**

`public Void clearCurrentToken()`

**Return Value**

Type: Void

**Usage**

After this method is called, a call to `hasCurrentToken` returns `false` and a call to `getCurrentToken` returns `null`. You can retrieve the cleared token by calling `getLastClearedToken`.

getBlobValue() - Returns the current token as a BLOB value.

**Signature**

`public Blob getBlobValue()`

**Return Value**

Type: Blob
Usage
The current token must be of type JSONToken.VALUE_STRING and must be Base64-encoded.

**getBooleanValue()**
Returns the current token as a Boolean value.

**Signature**
```
public Boolean getBooleanValue()
```

**Return Value**
Type: Boolean

Usage
The current token must be of type JSONToken.VALUE_TRUE or JSONToken.VALUE_FALSE.

The following example parses a sample JSON string and retrieves a Boolean value.

```java
String JSONContent = "{"isActive":true}";
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the Boolean value.
Boolean isActive = parser.getBooleanValue();
```

**getCurrentName()**
Returns the name associated with the current token.

**Signature**
```
public String getCurrentName()
```

**Return Value**
Type: String

Usage
If the current token is of type JSONToken.FIELD_NAME, this method returns the same value as getText. If the current token is a value, this method returns the field name that precedes this token. For other values such as array values or root-level values, this method returns null.

The following example parses a sample JSON string. It advances to the field value and retrieves its corresponding field name.
Example

```java
String JSONContent = '{"firstName":"John"}';
JSONParser parser =
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the field name for the current value.
String fieldName = parser.getCurrentName();
// Get the textual representation
// of the value.
String fieldValue = parser.getText();
```

**getCurrentToken()**

Returns the token that the parser currently points to or `null` if there's no current token.

**Signature**

```java
public System.JSONToken getCurrentToken()
```

**Return Value**

Type: `System.JSONToken`

**Usage**

The following example iterates through all the tokens in a sample JSON string.

```java
String JSONContent = '{"firstName":"John"}';
JSONParser parser =
    JSON.createParser(JSONContent);
// Advance to the next token.
while (parser.nextToken() != null) {  
    System.debug('Current token: ' +  
                   parser.getCurrentToken());
}
```

**getDatetimeValue()**

Returns the current token as a date and time value.

**Signature**

```java
public Datetime getDatetimeValue()
```

**Return Value**

Type: `Datetime`
Usage

The current token must be of type `JSONToken.VALUE_STRING` and must represent a `Datetime` value in the ISO-8601 format. The following example parses a sample JSON string and retrieves a Datetime value.

```java
String JSONContent = '
{"transactionDate":"2011-03-22T13:01:23"}';
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the transaction date.
Datetime transactionDate = parser.getDatetimeValue();
```

`getDateTimeValue()`

Returns the current token as a date value.

Signature

```java
public Date getDateTimeValue()
```

Return Value

Type: `Date`

Usage

The current token must be of type `JSONToken.VALUE_STRING` and must represent a `Date` value in the ISO-8601 format.

The following example parses a sample JSON string and retrieves a Date value.

```java
String JSONContent = '
{"dateOfBirth":"2011-03-22"}';
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parsed.nextValue();
// Get the transaction date.
Date dob = parser.getDateValue();
```

`getDecimalValue()`

Returns the current token as a decimal value.

Signature

```java
public Decimal getDecimalValue()
```
Return Value
Type: **Decimal**

Usage
The current token must be of type `JSONToken.VALUE_NUMBER_FLOAT` or `JSONToken.VALUE_NUMBER_INT` and is a numerical value that can be converted to a value of type `Decimal`.

The following example parses a sample JSON string and retrieves a Decimal value.

```java
String JSONContent = 
  '{"GPA":3.8}';
JSONParser parser = 
  JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the GPA score.
Decimal gpa = parser.getDecimalValue();
```

**getDoubleValue()**

Returns the current token as a double value.

Signature

```java
public Double getDoubleValue()
```

Return Value
Type: **Double**

Usage
The current token must be of type `JSONToken.VALUE_NUMBER_FLOAT` and is a numerical value that can be converted to a value of type `Double`.

The following example parses a sample JSON string and retrieves a Double value.

```java
String JSONContent = 
  '{"GPA":3.8}';
JSONParser parser = 
  JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the GPA score.
Double gpa = parser.getDoubleValue();
```
**getIdValue()**

Returns the current token as an ID value.

Signature

```java
public ID getIdValue()
```

Return Value

Type: ID

Usage

The current token must be of type `JSONToken.VALUE_STRING` and must be a valid ID.

The following example parses a sample JSON string and retrieves an ID value.

```java
String JSONContent = 
    '{"recordId":"001R0000002nO6H"}';
JSONParser parser = 
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parsed.nextToken();
// Advance to the next value.
parsed.readValue();
// Get the record ID.
ID recordID = parser.getIdValue();
```
parser.nextValue();
    // Get the record count.
    Integer count = parser.getIntegerValue();

**getLastClearedToken()**

Returns the last token that was cleared by the `clearCurrentToken` method.

**Signature**

```java
public System.JSONToken getLastClearedToken()
```

**Return Value**

Type: `System.JSONToken`

**getLongValue()**

Returns the current token as a long value.

**Signature**

```java
public Long getLongValue()
```

**Return Value**

Type: `Long`

**Usage**

The current token must be of type `JSONToken.VALUE_NUMBER_INT` and is a numerical value that can be converted to a value of type `Long`.

The following example parses a sample JSON string and retrieves a `Long` value.

```java
String JSONContent =
    '{"recordCount":2097531021}';
JSONParser parser = JSON.createParser(JSONContent);
    // Advance to the start object marker.
    parser.nextToken();
    // Advance to the next value.
    parser.nextValue();
    // Get the record count.
    Long count = parser.getLongValue();
```

**getText()**

Returns the textual representation of the current token or `null` if there's no current token.
Signature

public String getText()

Return Value
Type: String

Usage
No current token exists, and therefore this method returns null, if nextToken has not been called yet for the first time or if the parser has reached the end of the input stream.

getTimeValue()

Returns the current token as a time value.

Signature

public Time getTimeValue()

Return Value
Type: Time

Usage
The current token must be of type JSONToken.VALUE_STRING and must represent a Time value in the ISO-8601 format.
The following example parses a sample JSON string and retrieves a Datetime value.

```java
String JSONContent =
   '{"arrivalTime":"18:05"}';
JSONParser parser =
   JSON.createParser(JSONContent);
   // Advance to the start object marker.
parser.nextToken();
   // Advance to the next value.
parser.nextValue();
   // Get the arrival time.
Time arrivalTime = parser.getTimeValue();
```

hasCurrentToken()

Returns true if the parser currently points to a token; otherwise, returns false.

Signature

public Boolean hasCurrentToken()

Return Value
Type: Boolean
**nextToken()**
Returns the next token or `null` if the parser has reached the end of the input stream.

Signature
```
public System.JSONToken nextToken()
```

Return Value
Type: `System.JSONToken`

Usage
Advances the stream enough to determine the type of the next token, if any.

**nextValue()**
Returns the next token that is a value type or `null` if the parser has reached the end of the input stream.

Signature
```
public System.JSONToken nextValue()
```

Return Value
Type: `System.JSONToken`

Usage
Advances the stream enough to determine the type of the next token that is of a value type, if any, including a JSON array and object start and end markers.

**readValueAs(apexType)**
Deserializes JSON content into an object of the specified Apex type and returns the deserialized object.

Signature
```
public Object readValueAs(System.Type apexType)
```

Parameters
`apexType`
Type: `System.Type`

The `apexType` argument specifies the type of the object that this method returns after deserializing the current value.

Return Value
Type: `Object`
Usage

If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content into a custom object or an sObject using Salesforce API version 34.0 or earlier, this method throws a runtime exception when passed extraneous attributes. When deserializing JSON content into an Apex class in any API version, or into an object in API version 35.0 or later, no exception is thrown. When no exception is thrown, this method ignores extraneous attributes and parses the rest of the JSON content.

Example

The following example parses a sample JSON string and retrieves a Datetime value. Before being able to run this sample, you must create a new Apex class as follows:

```java
public class Person {
    public String name;
    public String phone;
}
```

Next, insert the following sample in a class method:

```java
// JSON string that contains a Person object.
String JSONContent =
    '{"person":{
    "name":"John Smith"," +
    "phone":"555-1212"}}';
JSONParser parser =
    JSON.createParser(JSONContent);
// Make calls to nextToken()
// to point to the second
// start object marker.
parser.nextToken();
parser.nextToken();
parser.nextToken();
// Retrieve the Person object
// from the JSON string.
Person obj =
    (Person)parser.readValueAs(
    Person.class);
System.assertEquals(
    obj.name, 'John Smith');
System.assertEquals(
    obj.phone, '555-1212');
```

`readValueAsStrict(apexType)`

Deserializes JSON content into an object of the specified Apex type and returns the deserialized object. All attributes in the JSON content must be present in the specified type.

Signature

```java
public Object readValueAsStrict(System.Type apexType)
```
Parameters

**apexType**
Type: System.Type

The **apexType** argument specifies the type of the object that this method returns after deserializing the current value.

Return Value

Type: Object

Usage

If the JSON content contains attributes not present in the System.Type argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content with extraneous attributes into an Apex class, this method throws an exception in all API versions. However, no exception is thrown when you use this method to deserialize JSON content into a custom object or an sObject.

The following example parses a sample JSON string and retrieves a Datetime value. Before being able to run this sample, you must create a new Apex class as follows:

```java
public class Person {
    public String name;
    public String phone;
}
```

Next, insert the following sample in a class method:

```java
// JSON string that contains a Person object.
String JSONContent = '{"person":{
    "name":"John Smith",
    "phone":"555-1212"}}';
JSONParser parser = JSON.createParser(JSONContent);
// Make calls to nextToken()
// to point to the second
// start object marker.
parser.nextToken();
parser.nextToken();
parser.nextToken();
// Retrieve the Person object
// from the JSON string.
Person obj = (Person)parser.readValueAsStrict(
    Person.class);
System.assertEquals(
    obj.name, 'John Smith');
System.assertEquals(
    obj.phone, '555-1212');
```

**skipChildren()**

Skips all child tokens of type JSONToken.START_ARRAY and JSONToken.START_OBJECT that the parser currently points to.
Signature

public Void skipChildren()

Return Value
Type: Void

JSONToken Enum
Contains all token values used for parsing JSON content.

Namespace
System

<table>
<thead>
<tr>
<th>Enum Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>END_ARRAY</td>
<td>The ending of an array value. This token is returned when ']' is encountered.</td>
</tr>
<tr>
<td>END_OBJECT</td>
<td>The ending of an object value. This token is returned when '}' is encountered.</td>
</tr>
<tr>
<td>FIELD_NAME</td>
<td>A string token that is a field name.</td>
</tr>
<tr>
<td>NOT_AVAILABLE</td>
<td>The requested token isn't available.</td>
</tr>
<tr>
<td>START_ARRAY</td>
<td>The start of an array value. This token is returned when '[' is encountered.</td>
</tr>
<tr>
<td>START_OBJECT</td>
<td>The start of an object value. This token is returned when '{' is encountered.</td>
</tr>
<tr>
<td>VALUE_EMBEDDED_OBJECT</td>
<td>An embedded object that isn't accessible as a typical object structure that includes the start and end object tokens START_OBJECT and END_OBJECT but is represented as a raw object.</td>
</tr>
<tr>
<td>VALUE_FALSE</td>
<td>The literal &quot;false&quot; value.</td>
</tr>
<tr>
<td>VALUE_NULL</td>
<td>The literal &quot;null&quot; value.</td>
</tr>
<tr>
<td>VALUE_NUMBER_FLOAT</td>
<td>A float value.</td>
</tr>
<tr>
<td>VALUE_NUMBER_INT</td>
<td>An integer value.</td>
</tr>
<tr>
<td>VALUE_STRING</td>
<td>A string value.</td>
</tr>
<tr>
<td>VALUE_TRUE</td>
<td>A value that corresponds to the &quot;true&quot; string literal.</td>
</tr>
</tbody>
</table>

Limits Class
Contains methods that return limit information for specific resources.
Namespace

System

Usage

The Limits methods return the specific limit for the particular governor, such as the number of calls of a method or the amount of heap size remaining.

Because Apex runs in a multitenant environment, the Apex runtime engine strictly enforces a number of limits to ensure that runaway Apex doesn’t monopolize shared resources.

None of the Limits methods require an argument. The format of the limits methods is as follows:

```java
myDMLLimit = Limits.getDMLStatements();
```

There are two versions of every method: the first returns the amount of the resource that has been used while the second version contains the word limit and returns the total amount of the resource that is available.

See Execution Governors and Limits on page 288.

Limits Methods

The following are methods for Limits. All methods are static.

IN THIS SECTION:

- `getAggregateQueries()`
  Returns the number of aggregate queries that have been processed with any SOQL query statement.

- `getLimitAggregateQueries()`
  Returns the total number of aggregate queries that can be processed with SOQL query statements.

- `getAsycCalls()`
  Reserved for future use.

- `getLimitAsyncCalls()`
  Reserved for future use.

- `getCallouts()`
  Returns the number of Web service statements that have been processed.

- `getChildRelationshipsDescribes()`
  Deprecated. Returns the number of child relationship objects that have been returned.

- `getLimitCallouts()`
  Returns the total number of Web service statements that can be processed.

- `getCpuTime()`
  Returns the CPU time (in milliseconds) that has been used in the current transaction.

- `getLimitCpuTime()`
  Returns the maximum CPU time (in milliseconds) that can be used in a transaction.

- `getDMLRows()`
  Returns the number of records that have been processed with any statement that counts against DML limits, such as DML statements, the `Database.emptyRecycleBin` method, and other methods.
getLimitDMLRows()
Returns the total number of records that can be processed with any statement that counts against DML limits, such as DML statements, the database.EmptyRecycleBin method, and other methods.

def DMLStatements()
Returns the number of DML statements (such as insert, update or the database.EmptyRecycleBin method) that have been called.

defLimitDMLStatements()
Returns the total number of DML statements or the database.EmptyRecycleBin methods that can be called.

defEmailInvocations()
Returns the number of email invocations (such as sendEmail) that have been called.

defLimitEmailInvocations()
Returns the total number of email invocation (such as sendEmail) that can be called.

defFindSimilarCalls()
Deprecated. Returns the same value as getSoslQueries. The number of findSimilar methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

defLimitFindSimilarCalls()
Deprecated. Returns the same value as getLimitSoslQueries. The number of findSimilar methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

defFutureCalls()
Returns the number of methods with the future annotation that have been executed (not necessarily completed).

defLimitFutureCalls()
Returns the total number of methods with the future annotation that can be executed (not necessarily completed).

defHeapSize()
Returns the approximate amount of memory (in bytes) that has been used for the heap.

defLimitHeapSize()
Returns the total amount of memory (in bytes) that can be used for the heap.

defMobilePushApexCalls()
Returns the number of Apex calls that have been used by mobile push notifications during the current metering interval.

defLimitMobilePushApexCalls()
Returns the total number of Apex calls that are allowed per transaction for mobile push notifications.

defQueries()
Returns the number of SOQL queries that have been issued.

defLimitQueries()
Returns the total number of SOQL queries that can be issued.

defQueryLocatorRows()
Returns the number of records that have been returned by the Database.getQueryLocator method.

defLimitQueryLocatorRows()
Returns the total number of records that can be returned by the Database.getQueryLocator method.

defQueryRows()
Returns the number of records that have been returned by issuing SOQL queries.
getLimitQueryRows()
Returns the total number of records that can be returned by issuing SOQL queries.

getQueueableJobs()
Returns the number of queueable jobs that have been added to the queue per transaction. A queueable job corresponds to a class that implements the Queueable interface.

getLimitQueueableJobs()
Returns the maximum number of queueable jobs that can be added to the queue per transaction. A queueable job corresponds to a class that implements the Queueable interface.

getRunAs()
Deprecated. Returns the same value as getDMLStatements.

gGetLimitRunAs()
Deprecated. Returns the same value as getLimitDMLStatements.

gGetSavepointRollbacks()
Deprecated. Returns the same value as getDMLStatements.

gGetLimitSavepointRollbacks()
Deprecated. Returns the same value as getLimitDMLStatements.

gGetSavepoints()
Deprecated. Returns the same value as getDMLStatements.

gGetLimitSavepoints()
Deprecated. Returns the same value as getLimitDMLStatements.

gSoslQueries()
Returns the number of SOSL queries that have been issued.

gGetLimitSoslQueries()
Returns the total number of SOSL queries that can be issued.

gGetAggregateQueries()
Returns the number of aggregate queries that have been processed with any SOQL query statement.

Signature

public static Integer getAggregateQueries()

Return Value

Type: Integer

gGetLimitAggregateQueries()
Returns the total number of aggregate queries that can be processed with SOQL query statements.

Signature

public static Integer getLimitAggregateQueries()
Return Value
Type: Integer

**getAsyncCalls()**
Reserved for future use.

Signature
```java
public static Integer getAsyncCalls()
```

Return Value
Type: Integer

**getLimitAsyncCalls()**
Reserved for future use.

Signature
```java
public static Integer getLimitAsyncCalls()
```

Return Value
Type: Integer

**getCallouts()**
Returns the number of Web service statements that have been processed.

Signature
```java
public static Integer getCallouts()
```

Return Value
Type: Integer

**getChildRelationshipsDescribes()**
Deprecated. Returns the number of child relationship objects that have been returned.

Signature
```java
public static Integer getChildRelationshipsDescribes()
```

Return Value
Type: Integer
Usage

Note: Because describe limits are no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is available but is deprecated.

**getLimitCallouts()**

Returns the total number of Web service statements that can be processed.

Signature

```
public static Integer getLimitCallouts()
```

Return Value

Type: `Integer`

**getCpuTime()**

Returns the CPU time (in milliseconds) that has been used in the current transaction.

Signature

```
public static Integer getCpuTime()
```

Return Value

Type: `Integer`

**getLimitCpuTime()**

Returns the maximum CPU time (in milliseconds) that can be used in a transaction.

Signature

```
public static Integer getLimitCpuTime()
```

Return Value

Type: `Integer`

**getDMLRows()**

Returns the number of records that have been processed with any statement that counts against DML limits, such as DML statements, the `Database.emptyRecycleBin` method, and other methods.

Signature

```
public static Integer getDMLRows()
```
Return Value
Type: Integer

**getLimitDMLRows()**
Returns the total number of records that can be processed with any statement that counts against DML limits, such as DML statements, the `database.EmptyRecycleBin` method, and other methods.

Signature

```
public static Integer getLimitDMLRows()
```

Return Value
Type: Integer

**getDMLStatements()**
Returns the number of DML statements (such as `insert`, `update` or the `database.EmptyRecycleBin` method) that have been called.

Signature

```
public static Integer getDMLStatements()
```

Return Value
Type: Integer

**getLimitDMLStatements()**
Returns the total number of DML statements or the `database.EmptyRecycleBin` methods that can be called.

Signature

```
public static Integer getLimitDMLStatements()
```

Return Value
Type: Integer

**getEmailInvocations()**
Returns the number of email invocations (such as `sendEmail`) that have been called.

Signature

```
public static Integer getEmailInvocations()
```
Return Value
Type: `Integer`

**getLimitEmailInvocations()**
Returns the total number of email invocation (such as `sendEmail`) that can be called.

Signature
```
public static Integer getLimitEmailInvocations()
```

Return Value
Type: `Integer`

**getFindSimilarCalls()**
Deprecated. Returns the same value as `getSoslQueries`. The number of `findSimilar` methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

Signature
```
public static Integer getFindSimilarCalls()
```

Return Value
Type: `Integer`

**getLimitFindSimilarCalls()**
Deprecated. Returns the same value as `getLimitSoslQueries`. The number of `findSimilar` methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

Signature
```
public static Integer getLimitFindSimilarCalls()
```

Return Value
Type: `Integer`

**getFutureCalls()**
Returns the number of methods with the `future` annotation that have been executed (not necessarily completed).

Signature
```
public static Integer getFutureCalls()
```
Return Value
Type: Integer

**getLimitFutureCalls()**
Returns the total number of methods with the `future` annotation that can be executed (not necessarily completed).

Signature
`public static Integer getLimitFutureCalls()`

Return Value
Type: Integer

**getHeapSize()**
Returns the approximate amount of memory (in bytes) that has been used for the heap.

Signature
`public static Integer getHeapSize()`

Return Value
Type: Integer

**getLimitHeapSize()**
Returns the total amount of memory (in bytes) that can be used for the heap.

Signature
`public static Integer getLimitHeapSize()`

Return Value
Type: Integer

**getMobilePushApexCalls()**
Returns the number of Apex calls that have been used by mobile push notifications during the current metering interval.

Signature
`public static Integer getMobilePushApexCalls()`

Return Value
Type: Integer
getLimitMobilePushApexCalls()
Returns the total number of Apex calls that are allowed per transaction for mobile push notifications.

Signature
public static Integer getLimitMobilePushApexCalls()

Return Value
Type: Integer

getQueries()
Returns the number of SOQL queries that have been issued.

Signature
public static Integer getQueries()

Return Value
Type: Integer

getLimitQueries()
Returns the total number of SOQL queries that can be issued.

Signature
public static Integer getLimitQueries()

Return Value
Type: Integer

getQueryLocatorRows()
Returns the number of records that have been returned by the Database.getQueryLocator method.

Signature
public static Integer getQueryLocatorRows()

Return Value
Type: Integer

getLimitQueryLocatorRows()
Returns the total number of records that can be returned by the Database.getQueryLocator method.
**getLimitQueryLocatorRows()**

Returns the total number of records that can be returned by issuing SOQL queries.

**Signature**

```java
public static Integer getLimitQueryLocatorRows()
```

**Return Value**

Type: Integer

**getQueryRows()**

Returns the number of records that have been returned by issuing SOQL queries.

**Signature**

```java
public static Integer getQueryRows()
```

**Return Value**

Type: Integer

**getLimitQueryRows()**

Returns the total number of records that can be returned by issuing SOQL queries.

**Signature**

```java
public static Integer getLimitQueryRows()
```

**Return Value**

Type: Integer

**getQueueableJobs()**

Returns the number of queueable jobs that have been added to the queue per transaction. A queueable job corresponds to a class that implements the `Queueable` interface.

**Signature**

```java
public static Integer getQueueableJobs()
```

**Return Value**

Type: Integer

**getLimitQueueableJobs()**

Returns the maximum number of queueable jobs that can be added to the queue per transaction. A queueable job corresponds to a class that implements the `Queueable` interface.

**Signature**

```java
public static Integer getLimitQueueableJobs()
```
Signature

```java
public static Integer getLimitQueueableJobs()
```

Return Value
Type: Integer

**getRunAs()**
Deprecated. Returns the same value as `getDMLStatements`.

Signature

```java
public static Integer getRunAs()
```

Return Value
Type: Integer

Usage
The number of RunAs methods is no longer a separate limit, but is tracked as the number of DML statements issued.

**getLimitRunAs()**
Deprecated. Returns the same value as `getLimitDMLStatements`.

Signature

```java
public static Integer getLimitRunAs()
```

Return Value
Type: Integer

Usage
The number of RunAs methods is no longer a separate limit, but is tracked as the number of DML statements issued.

**getSavepointRollbacks()**
Deprecated. Returns the same value as `getDMLStatements`.

Signature

```java
public static Integer getSavepointRollbacks()
```

Return Value
Type: Integer
Usage
The number of Rollback methods is no longer a separate limit, but is tracked as the number of DML statements issued.

`getLimitSavepointRollbacks()`
Deprecated. Returns the same value as `getLimitDMLStatements`.

Signature
```
public static Integer getLimitSavepointRollbacks()
```

Return Value
Type: **Integer**

Usage
The number of Rollback methods is no longer a separate limit, but is tracked as the number of DML statements issued.

`getSavepoints()`
Deprecated. Returns the same value as `getDMLStatements`.

Signature
```
public static Integer getSavepoints()
```

Return Value
Type: **Integer**

Usage
The number of `setSavepoint` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

`getLimitSavepoints()`
Deprecated. Returns the same value as `getLimitDMLStatements`.

Signature
```
public static Integer getLimitSavepoints()
```

Return Value
Type: **Integer**

Usage
The number of `setSavepoint` methods is no longer a separate limit, but is tracked as the number of DML statements issued.
**getSoslQueries()**
Returns the number of SOSL queries that have been issued.

Signature
```
public static Integer getSoslQueries()
```

Return Value
Type: Integer

**getLimitSoslQueries()**
Returns the total number of SOSL queries that can be issued.

Signature
```
public static Integer getLimitSoslQueries()
```

Return Value
Type: Integer

**List Class**
Contains methods for the List collection type.

**Namespace**
System

**Usage**
The list methods are all instance methods, that is, they operate on a particular instance of a list. For example, the following removes all elements from `myList`:
```
myList.clear();
```

Even though the `clear` method does not include any parameters, the list that calls it is its implicit parameter.

**Note:**
- When using a custom type for the list elements, provide an `equals` method in your class. Apex uses this method to determine equality and uniqueness for your objects. For more information on providing an `equals` method, see Using Custom Types in Map Keys and Sets.
- If the list contains String elements, the elements are case-sensitive. Two list elements that differ only by case are considered distinct.

For more information on lists, see Lists on page 30.
List Constructors

The following are constructors for List.

List<T>()

Creates a new instance of the List class. A list can hold elements of any data type T.

Signature

public List<T>()

Example

// Create a list
List<Integer> ls1 = new List<Integer>();
// Add two integers to the list
ls1.add(1);
ls1.add(2);

List<T>(listToCopy)

Creates a new instance of the List class by copying the elements from the specified list. T is the data type of the elements in both lists and can be any data type.

Signature

public List<T>(List<T> listToCopy)

Parameters

listToCopy
  Type: List<T>
The list containing the elements to initialize this list from. T is the data type of the list elements.

Example

```java
List<Integer> ls1 = new List<Integer>(){
    ls1.add(1);
    ls1.add(2);
    // Create a list based on an existing one
    List<Integer> ls2 = new List<Integer>(ls1);
    // ls2 elements are copied from ls1
    System.debug(ls2);// DEBUG|(1, 2)
```

**List<T>(setToCopy)**

Creates a new instance of the List class by copying the elements from the specified set. T is the data type of the elements in the set and list and can be any data type.

Signature

```
public List<T>(Set<T> setToCopy)
```

Parameters

**setToCopy**

Type: Set<T>

The set containing the elements to initialize this list with. T is the data type of the set elements.

Example

```java
Set<Integer> s1 = new Set<Integer>(){
    s1.add(1);
    s1.add(2);
    // Create a list based on a set
    List<Integer> ls = new List<Integer>(s1);
    // ls elements are copied from s1
    System.debug(ls);// DEBUG|(1, 2)
```

**List Methods**

The following are methods for List. All are instance methods.

**IN THIS SECTION:**

- `add(listElement)`
  Adds an element to the end of the list.

- `add(index, listElement)`
  Inserts an element into the list at the specified index position.

- `addAll(fromList)`
  Adds all of the elements in the specified list to the list that calls the method. Both lists must be of the same type.
addAll(fromSet)
Add all of the elements in specified set to the list that calls the method. The set and the list must be of the same type.

clear()
Removes all elements from a list, consequently setting the list's length to zero.

clone()
Makes a duplicate copy of a list.

contains(listElement)
Returns true if the list contains the specified element.

deepClone(preserveld, preserveReadOnlyTimestamps, preserveAutonumber)
Makes a duplicate copy of a list of sObject records, including the sObject records themselves.

equals(list2)
Compares this list with the specified list and returns true if both lists are equal; otherwise, returns false.

get(index)
Returns the list element stored at the specified index.

getSObjectType()
Returns the token of the sObject type that makes up a list of sObjects.

hashCode()
Returns the hashcode corresponding to this list and its contents.

indexOf(listElement)
Returns the index of the first occurrence of the specified element in this list. If this list does not contain the element, returns -1.

isEmpty()
Returns true if the list has zero elements.

iterator()
Returns an instance of an iterator for this list.

remove(index)
Removes the list element stored at the specified index, returning the element that was removed.

set(index, listElement)
Sets the specified value for the element at the given index.

size()
Returns the number of elements in the list.

sort()
Sorts the items in the list in ascending order.

### add(listElement)
Adds an element to the end of the list.

**Signature**

```java
public Void add(Object listElement)
```
**Parameters**

`listElement`

Type: Object

**Return Value**

Type: Void

**Example**

```java
List<Integer> myList = new List<Integer>();
myList.add(47);
Integer myNumber = myList.get(0);
System.assertEquals(47, myNumber);
```

**add(index, listElement)**

Inserts an element into the list at the specified index position.

**Signature**

```java
public Void add(Integer index, Object listElement)
```

**Parameters**

`index`

Type: Integer

`listElement`

Type: Object

**Return Value**

Type: Void

**Example**

In the following example, a list with six elements is created, and integers are added to the first and second index positions.

```java
List<Integer> myList = new Integer[6];
myList.add(0, 47);
Integer myNumber = myList.get(0);
System.assertEquals(52, myList.get(1));
```

**addAll(fromList)**

Adds all of the elements in the specified list to the list that calls the method. Both lists must be of the same type.

**Signature**

```java
public Void addAll(List fromList)
```
Parameters

fromList
Type: List

Return Value
Type: Void

**addAll(fromSet)**
Add all of the elements in specified set to the list that calls the method. The set and the list must be of the same type.

Signature

```
public Void addAll(Set fromSet)
```

Parameters

fromSet
Type: Set

Return Value
Type: Void

**clear()**
Removes all elements from a list, consequently setting the list's length to zero.

Signature

```
public Void clear()
```

Return Value
Type: Void

**clone()**
Makes a duplicate copy of a list.

Signature

```
public List<Object> clone()
```

Return Value
Type: List<Object>
Usage

The cloned list is of the same type as the current list.

Note that if this is a list of sObject records, the duplicate list will only be a shallow copy of the list. That is, the duplicate will have references to each object, but the sObject records themselves will not be duplicated. For example:

To also copy the sObject records, you must use the `deepClone` method.

Example

```java
Account a = new Account(Name='Acme', BillingCity='New York');
Account b = new Account();
Account[] q1 = new Account[]{a,b};
Account[] q2 = q1.clone();
q1[0].BillingCity = 'San Francisco';
System.assertEquals('San Francisco', q1[0].BillingCity);
System.assertEquals('San Francisco', q2[0].BillingCity);
```

`contains(listElement)`

Returns `true` if the list contains the specified element.

Signature

```java
public Boolean contains(Object listElement)
```

Parameters

`listElement`

Type: `Object`

Return Value

Type: `Boolean`

Example

```java
List<String> myStrings = new List<String>{'a', 'b'};
Boolean result = myStrings.contains('z');
System.assertEquals(false, result);
```

depthClone(preserveId, preserveReadonlyTimestamps, preserveAutonumber)

Makes a duplicate copy of a list of sObject records, including the sObject records themselves.
Signature

```java
public List<Object> deepClone(Boolean preserveId, Boolean preserveReadonlyTimestamps, Boolean preserveAutonumber)
```

Parameters

`preserveId`
Type: Boolean
The optional `preserveId` argument determines whether the IDs of the original objects are preserved or cleared in the duplicates. If set to `true`, the IDs are copied to the cloned objects. The default is `false`, that is, the IDs are cleared.

`preserveReadonlyTimestamps`
Type: Boolean
The optional `preserveReadonlyTimestamps` argument determines whether the read-only timestamp and user ID fields are preserved or cleared in the duplicates. If set to `true`, the read-only fields `CreatedBy`, `CreatedDate`, `LastModifiedBy`, and `LastModifiedDate` are copied to the cloned objects. The default is `false`, that is, the values are cleared.

`preserveAutonumber`
Type: Boolean
The optional `preserveAutonumber` argument determines whether the autonumber fields of the original objects are preserved or cleared in the duplicates. If set to `true`, auto number fields are copied to the cloned objects. The default is `false`, that is, auto number fields are cleared.

Return Value
Type: `List<Object>`

Usage
The returned list is of the same type as the current list.

Note:
- `deepClone` only works with lists of sObjects, not with lists of primitives.
- For Apex saved using Salesforce API version 22.0 or earlier, the default value for the `preserve_id` argument is `true`, that is, the IDs are preserved.

To make a shallow copy of a list without duplicating the sObject records it contains, use the `clone` method.

Example
This example performs a deep clone for a list with two accounts.

```java
Account a = new Account(Name='Acme', BillingCity='New York');
Account b = new Account(Name='Salesforce');
Account[] q1 = new Account[] {a,b};
Account[] q2 = q1.deepClone();
q1[0].BillingCity = 'San Francisco';
```
This example is based on the previous example and shows how to clone a list with preserved read-only timestamp and user ID fields.

```apex
insert q1;

List<Account> accts = [SELECT CreatedById, CreatedDate, LastModifiedById,
                         LastModifiedDate, BillingCity
                         FROM Account
                         WHERE Name='Acme' OR Name='Salesforce';

// Clone list while preserving timestamp and user ID fields.
Account[] q3 = accts.deepClone(false,true,false);

// Verify timestamp fields are preserved for the first list element.
System.assertEquals(accts[0].CreatedById, q3[0].CreatedById);
System.assertEquals(accts[0].CreatedDate, q3[0].CreatedDate);
System.assertEquals(accts[0].LastModifiedById, q3[0].LastModifiedById);
System.assertEquals(accts[0].LastModifiedDate, q3[0].LastModifiedDate);
```

### equals(list2)

Compared this list with the specified list and returns **true** if both lists are equal; otherwise, returns **false**.

**Signature**

```apex
public Boolean equals(List list2)
```

**Parameters**

- **list2**
  - Type: `List`
  - The list to compare this list with.

**Return Value**

- Type: `Boolean`
Usage
Two lists are equal if their elements are equal and are in the same order. The == operator is used to compare the elements of the lists. The == operator is equivalent to calling the equals method, so you can call list1.equals(list2); instead of list1 == list2;.

get(index)
Returns the list element stored at the specified index.

Signature
public Object get(Integer index)

Parameters
index
Type: Integer

Return Value
Type: Object

Usage
To reference an element of a one-dimensional list of primitives or sObjects, you can also follow the name of the list with the element's index position in square brackets as shown in the example.

Example
```java
List<Integer> myList = new List<Integer>();
myList.add(47);
Integer myNumber = myList.get(0);
system.assertEquals(47, myNumber);

List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
```

getSObjectType()
Returns the token of the sObject type that makes up a list of sObjects.

Signature
public Schema.SObjectType getSObjectType()

Return Value
Type: Schema.SObjectType
Usage

Use this method with describe information to determine if a list contains sObjects of a particular type. Note that this method can only be used with lists that are composed of sObjects.

For more information, see Understanding Apex Describe Information on page 172.

Example

```java
// Create a generic sObject variable.
SObject sObj = Database.query('SELECT Id FROM Account LIMIT 1');

// Verify if that sObject variable is an Account token.
System.assertEquals(Account.sObjectType, sObj.getSObjectType());

// Create a list of generic sObjects.
List<sObject> q = new Account[]{};

// Verify if the list of sObjects contains Account tokens.
System.assertEquals(Account.sObjectType, q.getSObjectType());
```

hashCode()

Returns the hashcode corresponding to this list and its contents.

Signature

```java
public Integer hashCode()
```

Return Value

Type: Integer

indexOf(listElement)

Returns the index of the first occurrence of the specified element in this list. If this list does not contain the element, returns -1.

Signature

```java
public Integer indexOf(Object listElement)
```

Parameters

listElement

Type: Object
Return Value
Type: Integer

Example

```java
List<String> myStrings = new List<String>{'a', 'b', 'a'};
Integer result = myStrings.indexOf('a');
System.assertEquals(0, result);
```

**isEmpty()**

Returns true if the list has zero elements.

Signature

```java
public Boolean isEmpty()
```

Return Value
Type: Boolean

**iterator()**

Returns an instance of an iterator for this list.

Signature

```java
public Iterator iterator()
```

Return Value
Type: Iterator

Usage

From the returned iterator, you can use the iterable methods `hasNext` and `next` to iterate through the list.

Note: You do not have to implement the `iterable` interface to use the `iterable` methods with a list.

See Custom Iterators.

Example

```java
class CustomIterable implements Iterator<Account>{
    List<Account> accs {get; set;}
    Integer i {get; set;}

    public CustomIterable()
    accs =
```

```java
2821
```
[SELECT Id, Name,
NumberOfEmployees
FROM Account
WHERE Name = 'false'];
i = 0;
}

global boolean hasNext(){
  if(i >= accs.size()) {
    return false;
  } else {
    return true;
  }
}

global Account next(){
  // 8 is an arbitrary
  // constant in this example
  // that represents the
  // maximum size of the list.
  if(i == 8){return null;}
i++;
  return accs[i-1];
}

remove(index)
Removes the list element stored at the specified index, returning the element that was removed.

Signature
public Object remove(Integer index)

Parameters
index
  Type: Integer

Return Value
Type: Object

Example
List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
String s1 = colors.remove(2);
system.assertEquals('Green', s1);
**set(index, listElement)**
Sets the specified value for the element at the given index.

**Signature**
```
public Void set(Integer index, Object listElement)
```

**Parameters**
- **index**
  Type: Integer
  The index of the list element to set.
- **listElement**
  Type: Object
  The value of the list element to set.

**Return Value**
Type: Void

**Usage**
To set an element of a one-dimensional list of primitives or sObjects, you can also follow the name of the list with the element's index position in square brackets.

**Example**
```
List<Integer> myList = new Integer[6];
myList.set(0, 47);
myList.set(1, 52);
system.assertEquals(52, myList.get(1));

List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
```

**size()**
Returns the number of elements in the list.

**Signature**
```
public Integer size()
```

**Return Value**
Type: Integer
Example

```
List<Integer> myList = new List<Integer>();
Integer size = myList.size();
system.assertEquals(0, size);

List<Integer> myList2 = new Integer[6];
Integer size2 = myList2.size();
system.assertEquals(6, size2);
```

** sort()**

Sorts the items in the list in ascending order.

**Signature**

```
public Void sort()
```

**Return Value**

Type: Void

**Usage**

Using this method, you can sort primitive types, SelectOption elements, and sObjects (standard objects and custom objects). For more information on the sort order used for sObjects, see Sorting Lists of sObjects. You can also sort custom types (your Apex classes) if they implement the Comparable Interface interface.

When you use sort() methods on List<Id>s that contain both 15-character and 18-character IDs, IDs for the same record sort together in API version 35.0 and later.

**Example**

In the following example, the list has three elements. When the list is sorted, the first element is null because it has no value assigned while the second element has the value of 5.

```
List<Integer> q1 = new Integer[3];

// Assign values to the first two elements.
q1[0] = 10;
q1[1] = 5;

q1.sort();
// First element is null, second is 5.
system.assertEquals(5, q1.get(1));
```

**Location Class**

Contains methods for accessing the component fields of geolocation compound fields.
Namespace

system

Usage

Each of these methods is also equivalent to a read-only property. For each getter method you can access the property using dot notation. For example, `myLocation.getLatitude()` is equivalent to `myLocation.latitude`.

You can’t use dot notation to access compound fields’ subfields directly on the parent field. Instead, assign the parent field to a variable of type `Location`, and then access its components.

```java
Location loc = myAccount.MyLocation__c;
Double lat = loc.latitude;
```

**Important:** “Location” in Salesforce can also refer to the Location standard object. When referencing the Location object in your Apex code, always use `Schema.Location` instead of `Location` to prevent confusion with the standard Location compound field. If referencing both the location object and the Location field in the same snippet, you can differentiate between the two by using `System.Location` for the field and `Schema.Location` for the object.

Example

```java
// Select and access the Location field. MyLocation__c is the name of a geolocation field on Account.
Account[] records = [SELECT id, MyLocation__c FROM Account LIMIT 10];
for(Account acct : records) {
    Location loc = acct.MyLocation__c;
    Double lat = loc.latitude;
    Double lon = loc.longitude;
}

// Instantiate new Location objects and compute the distance between them in different ways.
Location loc1 = Location.newInstance(28.635308,77.22496);
Location loc2 = Location.newInstance(37.7749295,-122.4194155);
Double dist = Location.getDistance(loc1, loc2, 'mi');
Double dist2 = loc1.getDistance(loc2, 'mi');
```

IN THIS SECTION:

Location Methods

The following are methods for `Location`.

IN THIS SECTION:

getDistance(toLocation, unit)

Calculates the distance between this location and the specified location, using an approximation of the haversine formula and the specified unit.
getDistance(firstLocation, secondLocation, unit)
Calculates the distance between the two specified locations, using an approximation of the haversine formula and the specified unit.

getLatitude()
Returns the latitude field of this location.

g Longitude()
Returns the longitude field of this location.

newInstance(latitude, longitude)
Creates an instance of the Location class, with the specified latitude and longitude.

getDistance(toLocation, unit)
Calculates the distance between this location and the specified location, using an approximation of the haversine formula and the specified unit.

Signature
public Double getDistance(Location toLocation, String unit)

Parameters

\textbf{toLocation}
Type: Location
The Location to which you want to calculate the distance from the current Location.

\textbf{unit}
Type: String
The distance unit you want to use: mi or km.

Return Value
Type: Double

getDistance(firstLocation, secondLocation, unit)
Calculates the distance between the two specified locations, using an approximation of the haversine formula and the specified unit.

Signature
public static Double getDistance(Location firstLocation, Location secondLocation, String unit)

Parameters

\textbf{firstLocation}
Type: Location
The first of two locations used to calculate distance.
secondLocation
  Type: Location
  The second of two locations used to calculate distance.

unit
  Type: String
  The distance unit you want to use: mi or km.

Return Value
Type: Double

getLatitude()
Returns the latitude field of this location.

Signature
public Double getLatitude()

Return Value
Type: Double

getLongitude()
Returns the longitude field of this location.

Signature
public Double getLongitude()

Return Value
Type: Double

newInstance(latitude, longitude)
Creates an instance of the Location class, with the specified latitude and longitude.

Signature
public static Location newInstance(Decimal latitude, Decimal longitude)

Parameters
latitude
  Type: Decimal
longitude
  Type: Decimal
Long Class
Contains methods for the Long primitive data type.

Namespace
System

Usage
For more information on Long, see Primitive Data Types on page 26.

Long Methods
The following are methods for Long.

IN THIS SECTION:
- format()
  Returns the String format for this Long using the locale of the context user.
- intValue()
  Returns the Integer value for this Long.
- valueOf(stringToLong)
  Returns a Long that contains the value of the specified String. As in Java, the string is interpreted as representing a signed decimal Long.

format()
Returns the String format for this Long using the locale of the context user.

Signature
public String format()

Return Value
Type: String

Example
Long myLong = 4271990;
system.assertEquals('4,271,990', myLong.format());

intValue()
Returns the Integer value for this Long.
Signature

`public Integer intValue()`

Return Value

Type: `Integer`

Example

```java
Long myLong = 7191991;
Integer value = myLong.intValue();
system.assertEquals(7191991, myLong.intValue());
```

`valueOf(stringToLong)`

Returns a `Long` that contains the value of the specified `String`. As in Java, the string is interpreted as representing a signed decimal `Long`.

**Signature**

```
public static Long valueOf(String stringToLong)
```

**Parameters**

`stringToLong`

Type: `String`

**Return Value**

Type: `Long`

Example

```java
Long L1 = long.valueOf('123456789');
```

**Map Class**

Contains methods for the Map collection type.

**Namespace**

`System`

**Usage**

The Map methods are all instance methods, that is, they operate on a particular instance of a map. The following are the instance methods for maps.
Note:

- Map keys and values can be of any data type—primitive types, collections, sObjects, user-defined types, and built-in Apex types.
- Uniqueness of map keys of user-defined types is determined by the equals and hashCode methods, which you provide in your classes. Uniqueness of keys of all other non-primitive types, such as sObject keys, is determined by comparing the objects' field values.
- Map keys of type String are case-sensitive. Two keys that differ only by the case are considered unique and have corresponding distinct Map entries. Subsequently, the Map methods, including put, get, containsKey, and remove treat these keys as distinct.

For more information on maps, see Maps on page 33.

IN THIS SECTION:
- Map Constructors
- Map Methods

Map Constructors

The following are constructors for Map.

IN THIS SECTION:
- Map<T1,T2>()
- Map<T1,T2>(mapToCopy)
- Map<ID,sObject>(recordList)

Map<T1,T2>()

Creates a new instance of the Map class. T1 is the data type of the keys and T2 is the data type of the values.

Signature

public Map<T1,T2>()

Example

```java
Map<Integer, String> m1 = new Map<Integer, String>();
m1.put(1, 'First item');
m1.put(2, 'Second item');
```
**Map<T1,T2>(mapToCopy)**

Creates a new instance of the `Map` class and initializes it by copying the entries from the specified map. T1 is the data type of the keys and T2 is the data type of the values.

**Signature**

```java
public Map<T1,T2>(Map<T1,T2> mapToCopy)
```

**Parameters**

`mapToCopy`

Type: `Map<T1, T2>`

The map to initialize this map with. T1 is the data type of the keys and T2 is the data type of the values. All map keys and values are copied to this map.

**Example**

```java
Map<Integer, String> m1 = new Map<Integer, String>();
m1.put(1, 'First item');
m1.put(2, 'Second item');
Map<Integer, String> m2 = new Map<Integer, String>(m1);
// The map elements of m2 are copied from m1
System.debug(m2);
```

**Map<ID,sObject>(recordList)**

Creates a new instance of the `Map` class and populates it with the passed-in list of `sObject` records. The keys are populated with the `sObject` IDs and the values are the `sObjects`.

**Signature**

```java
public Map<ID,sObject>(List<sObject> recordList)
```

**Parameters**

`recordList`

Type: `List<sObject>`

The list of `sObjects` to populate the map with.

**Example**

```java
List<Account> ls = [select Id,Name from Account];
Map<ID, Account> m = new Map<ID, Account>(ls);
```

**Map Methods**

The following are methods for `Map`. All are instance methods.
clear()  
Removes all of the key-value mappings from the map.

Signature  
public Void clear()
Return Value
Type: Void

`clone()`
Makes a duplicate copy of the map.

Signature

```java
public Map<Object, Object> clone()
```

Usage
If this is a map with sObject record values, the duplicate map will only be a shallow copy of the map. That is, the duplicate will have references to each sObject record, but the records themselves are not duplicated. For example:
To also copy the sObject records, you must use the `deepClone` method.

Example

```java
Account a = new Account(
    Name='Acme',
    BillingCity='New York');

Map<Integer, Account> map1 = new Map<Integer, Account> {};
map1.put(1, a);

Map<Integer, Account> map2 = map1.clone();
map1.get(1).BillingCity = 'San Francisco';

System.assertEquals('San Francisco', map1.get(1).BillingCity);
System.assertEquals('San Francisco', map2.get(1).BillingCity);
```

`containsKey(key)`
Returns `true` if the map contains a mapping for the specified key.

Signature

```java
public Boolean containsKey(Object key)
```
Parameters

key
Type: Object

Return Value
Type: Boolean

Usage
If the key is a string, the key value is case-sensitive.

Example

```java
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

Boolean contains = colorCodes.containsKey('Blue');
System.assertEquals(true, contains);
```

deepClone()

Makes a duplicate copy of a map, including sObject records if this is a map with sObject record values.

Signature

```java
public Map<Object, Object> deepClone()
```

Return Value
Type: Map (of the same type)

Usage
To make a shallow copy of a map without duplicating the sObject records it contains, use the clone() method.

Example

```java
Account a = new Account(
    Name='Acme',
    BillingCity='New York');

Map<Integer, Account> map1 = new Map<Integer, Account>{};
map1.put(1, a);

Map<Integer, Account> map2 = map1.deepClone();
// Update the first entry of map1
```
map1.get(1).BillingCity = 'San Francisco';
// Verify that the BillingCity is updated in map1 but not in map2
System.assertEquals('San Francisco', map1.get(1).BillingCity);
System.assertEquals('New York', map2.get(1).BillingCity);

**equals(map2)**

Compares this map with the specified map and returns `true` if both maps are equal; otherwise, returns `false`.

**Signature**

```
public Boolean equals(Map map2)
```

**Parameters**

`map2`

Type: `Map`

The `map2` argument is the map to compare this map with.

**Return Value**

Type: `Boolean`

**Usage**

Two maps are equal if their key/value pairs are identical, regardless of the order of those pairs. The `==` operator is used to compare the map keys and values.

The `==` operator is equivalent to calling the `equals` method, so you can call `map1.equals(map2);` instead of `map1 == map2;`.

**get(key)**

Returns the value to which the specified key is mapped, or `null` if the map contains no value for this key.

**Signature**

```
public Object get(Object key)
```

**Parameters**

`key`

Type: `Object`

**Return Value**

Type: `Object`

**Usage**

If the key is a string, the key value is case-sensitive.
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

String code = colorCodes.get('Blue');
System.assertEquals('0000A0', code);

// The following is not a color in the map
String code2 = colorCodes.get('Magenta');
System.assertEquals(null, code2);

getSObjectType()
Returns the token of the sObject type that makes up the map values.

Signature
public Schema.SObjectType getSObjectType()

Return Value
Type: Schema.SObjectType

Usage
Use this method with describe information, to determine if a map contains sObjects of a particular type.
Note that this method can only be used with maps that have sObject values.
For more information, see Understanding Apex Describe Information on page 172.

Example

// Create a generic sObject variable.
SObject sObj = Database.query('SELECT Id FROM Account LIMIT 1');

// Verify if that sObject variable is an Account token.
System.assertEquals(
    Account.sObjectType,
    sObj.getSObjectType());

// Create a map of generic sObjects
Map<Integer, Account> m = new Map<Integer, Account>();

// Verify if the map contains Account tokens.
System.assertEquals(
    Account.sObjectType,
    m.getSObjectType());
hashCode()
Returns the hashcode corresponding to this map.

Signature
public Integer hashCode()

Return Value
Type: Integer

isEmpty()
Returns true if the map has zero key-value pairs.

Signature
public Boolean isEmpty()

Return Value
Type: Boolean

Example
Map<String, String> colorCodes = new Map<String, String>();
Boolean empty = colorCodes.isEmpty();
System.assertEquals(true, empty);

keySet()
Returns a set that contains all of the keys in the map.

Signature
public Set<Object> keySet()

Return Value
Type: Set (of key type)

Example
Map<String, String> colorCodes = new Map<String, String>();

  colorCodes.put('Red', 'FF0000');
  colorCodes.put('Blue', '0000A0');

Set <String> colorSet = new Set<String>();
  colorSet = colorCodes.keySet();
**put(key, value)**

Associates the specified value with the specified key in the map.

**Signature**

```java
public Object put(Object key, Object value)
```

**Parameters**

- `key`  
  Type: `Object`

- `value`  
  Type: `Object`

**Return Value**

Type: `Object`

**Usage**

If the map previously contained a mapping for this key, the old value is returned by the method and then replaced.

If the key is a string, the key value is case-sensitive.

**Example**

```java
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'ff0000');
colorCodes.put('Red', '#FF0000');
// Red is now #FF0000
```

**putAll(fromMap)**

Copies all of the mappings from the specified map to the original map.

**Signature**

```java
public Void putAll(Map fromMap)
```

**Parameters**

- `fromMap`  
  Type: `Map`

**Return Value**

Type: `Void`
Usage

The new mappings from `fromMap` replace any mappings that the original map had.

Example

```java
Map<String, String> map1 = new Map<String, String>(){
    map1.put('Red','FF0000');
};
Map<String, String> map2 = new Map<String, String>(){
    map2.put('Blue','0000FF');
    // Add map1 entries to map2
    map2.putAll(map1);
    System.assertEquals(2, map2.size());
}
```

`putAll(sObjectArray)`

Adds the list of sObject records to a map declared as `Map<ID, sObject>` or `Map<String, sObject>`.

Signature

```java
public Void putAll(sObject[] sobjectArray)
```

Parameters

`sobjectArray`

Type: `sObject[]`

Return Value

Type: `Void`

Usage

This method is similar to calling the Map constructor with the same input.

Example

```java
List<Account> accts = new List<Account>(){
    accts.add(new Account(Name='Account1'));
    accts.add(new Account(Name='Account2'));
    // Insert accounts so their IDs are populated.
    insert accts;
    Map<Id, Account> m = new Map<Id, Account>(){
        // Add all the records to the map.
        m.putAll(accts);
        System.assertEquals(2, m.size());
    }
```

`remove(key)`

Removes the mapping for the specified key from the map, if present, and returns the corresponding value.
Signature

public Object remove(Key key)

Parameters

key
   Type: Key

Return Value

Type: Object

Usage

If the key is a string, the key value is case-sensitive.

Example

```java
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

String myColor = colorCodes.remove('Blue');
String code2 = colorCodes.get('Blue');

System.assertEquals(null, code2);
```

size()

Returns the number of key-value pairs in the map.

Signature

public Integer size()

Return Value

Type: Integer

Example

```java
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

Integer mSize = colorCodes.size();
System.assertEquals(2, mSize);
```
values()
Returns a list that contains all the values in the map.

Signature
public List<Object> values()

Return Value
Type: List<Object>

Usage
The order of map elements is deterministic. You can rely on the order being the same in each subsequent execution of the same code. For example, suppose the values() method returns a list containing value1 and index 0 and value2 and index 1. Subsequent runs of the same code result in those values being returned in the same order.

Example
```java
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');
List<String> colors = new List<String>();
colors = colorCodes.values();
```

Matcher Class
Matchers use Patterns to perform match operations on a character string.

Namespace
System

Matcher Methods
The following are methods for Matcher.

IN THIS SECTION:
```
end()
Returns the position after the last matched character.
end(groupIndex)
Returns the position after the last character of the subsequence captured by the group index during the previous match operation. If the match was successful but the group itself did not match anything, this method returns -1.
find()
Attempts to find the next subsequence of the input sequence that matches the pattern. This method returns true if a subsequence of the input sequence matches this Matcher object’s pattern.
```
find(group)
Resets the Matcher object and then tries to find the next subsequence of the input sequence that matches the pattern. This method returns `true` if a subsequence of the input sequence matches this Matcher object’s pattern.

group()
Returns the input subsequence returned by the previous match.

group(groupIndex)
Returns the input subsequence captured by the specified group index during the previous match operation. If the match was successful but the specified group failed to match any part of the input sequence, `null` is returned.

groupCount()
Returns the number of capturing groups in this Matcher object’s pattern. Group zero denotes the entire pattern and is not included in this count.

hasAnchoringBounds()
Returns true if the Matcher object has anchoring bounds, false otherwise. By default, a Matcher object uses anchoring bounds regions.

hasTransparentBounds()
Returns true if the Matcher object has transparent bounds, false if it uses opaque bounds. By default, a Matcher object uses opaque region boundaries.

hitEnd()
Returns true if the end of input was found by the search engine in the last match operation performed by this Matcher object. When this method returns true, it is possible that more input would have changed the result of the last search.

lookingAt()
Attempts to match the input sequence, starting at the beginning of the region, against the pattern.

matches()
Attempts to match the entire region against the pattern.

pattern()
Returns the Pattern object from which this Matcher object was created.

quoteReplacement(inputString)
Returns a literal replacement string for the specified string `inputString`. The characters in the returned string match the sequence of characters in `inputString`.

region(start, end)
Sets the limits of this Matcher object’s region. The region is the part of the input sequence that is searched to find a match.

regionEnd()
Returns the end index (exclusive) of this Matcher object’s region.

regionStart()
Returns the start index (inclusive) of this Matcher object’s region.

replaceAll(replacementString)
Replaces every subsequence of the input sequence that matches the pattern with the replacement string.

replaceFirst(replacementString)
Replaces the first subsequence of the input sequence that matches the pattern with the replacement string.

requireEnd()
Returns true if more input could change a positive match into a negative one.
reset()
Resets this Matcher object. Resetting a Matcher object discards all of its explicit state information.

reset(inputSequence)
Resets this Matcher object with the new input sequence. Resetting a Matcher object discards all of its explicit state information.

start()
Returns the start index of the first character of the previous match.

start(groupIndex)
Returns the start index of the subsequence captured by the group specified by the group index during the previous match operation. Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression m.start(0) is equivalent to m.start().

useAnchoringBounds(anchoringBounds)
Sets the anchoring bounds of the region for the Matcher object. By default, a Matcher object uses anchoring bounds regions.

usePattern(pattern)
Changes the Pattern object that the Matcher object uses to find matches. This method causes the Matcher object to lose information about the groups of the last match that occurred. The Matcher object’s position in the input is maintained.

useTransparentBounds(transparentBounds)
Sets the transparency bounds for this Matcher object. By default, a Matcher object uses anchoring bounds regions.

de()()
Returns the position after the last matched character.

Signature
public Integer end()

Return Value
Type: Integer

de(groupIndex)
Returns the position after the last character of the subsequence captured by the group index during the previous match operation. If the match was successful but the group itself did not match anything, this method returns -1.

Signature
public Integer end(Integer groupIndex)

Parameters

groupIndex
Type: Integer

Return Value
Type: Integer
Usage
Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression `m.end(0)` is equivalent to `m.end()`.
See Understanding Capturing Groups.

**find()**
Attempts to find the next subsequence of the input sequence that matches the pattern. This method returns true if a subsequence of the input sequence matches this Matcher object’s pattern.

Signature
```
public Boolean find()
```

Return Value
Type: Boolean

Usage
This method starts at the beginning of this Matcher object’s region, or, if a previous invocation of the method was successful and the Matcher object has not since been reset, at the first character not matched by the previous match.
If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.
For more information, see Using Regions.

**find(group)**
Resets the Matcher object and then tries to find the next subsequence of the input sequence that matches the pattern. This method returns `true` if a subsequence of the input sequence matches this Matcher object’s pattern.

Signature
```
public Boolean find(Integer group)
```

Parameters

**group**
Type: Integer

Return Value
Type: Boolean

Usage
If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.
group() 
Returns the input subsequence returned by the previous match.

Signature

```java
public String group()
```

Return Value
Type: String

Usage
Note that some groups, such as \( (a^+) \), match the empty string. This method returns the empty string when such a group successfully matches the empty string in the input.

group(groupIndex)

Returns the input subsequence captured by the specified group index during the previous match operation. If the match was successful but the specified group failed to match any part of the input sequence, null is returned.

Signature

```java
public String group(Integer groupIndex)
```

Parameters
groupIndex
  Type: Integer

Return Value
Type: String

Usage
Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression \( m \cdot group(0) \) is equivalent to \( m \cdot group() \).

Note that some groups, such as \( (a^+) \), match the empty string. This method returns the empty string when such a group successfully matches the empty string in the input.

See Understanding Capturing Groups.

groupCount()

Returns the number of capturing groups in this Matching object's pattern. Group zero denotes the entire pattern and is not included in this count.

Signature

```java
public Integer groupCount()
```
Return Value
Type: Integer

Usage
See Understanding Capturing Groups.

**hasAnchoringBounds()**

Returns true if the Matcher object has anchoring bounds, false otherwise. By default, a Matcher object uses anchoring bounds regions.

Signature

```java
public Boolean hasAnchoringBounds()
```

Return Value
Type: Boolean

Usage
If a Matcher object uses anchoring bounds, the boundaries of this Matcher object’s region match start and end of line anchors such as ^ and $.
For more information, see Using Bounds.

**hasTransparentBounds()**

Returns true if the Matcher object has transparent bounds, false if it uses opaque bounds. By default, a Matcher object uses opaque region boundaries.

Signature

```java
public Boolean hasTransparentBounds()
```

Return Value
Type: Boolean

Usage
For more information, see Using Bounds.

**hitEnd()**

Returns true if the end of input was found by the search engine in the last match operation performed by this Matcher object. When this method returns true, it is possible that more input would have changed the result of the last search.

Signature

```java
public Boolean hitEnd()
```
Return Value
Type: Boolean

lookingAt()
Attempts to match the input sequence, starting at the beginning of the region, against the pattern.

Signature
public Boolean lookingAt()

Return Value
Type: Boolean

Usage
Like the matches method, this method always starts at the beginning of the region; unlike that method, it does not require the entire region be matched.
If the match succeeds, more information can be obtained using the start, end, and group methods.
See Using Regions.

matches()
Attempts to match the entire region against the pattern.

Signature
public Boolean matches()

Return Value
Type: Boolean

Usage
If the match succeeds, more information can be obtained using the start, end, and group methods.
See Using Regions.

pattern()
Returns the Pattern object from which this Matcher object was created.

Signature
public Pattern object pattern()

Return Value
Type: System.Pattern
quoteReplacement(inputString)

Returns a literal replacement string for the specified string inputString. The characters in the returned string match the sequence of characters in inputString.

Signature

public static String quoteReplacement(String inputString)

Parameters

inputString

Type: String

Return Value

Type: String

Usage

Metacharacters (such as $ or ^) and escape sequences in the input string are treated as literal characters with no special meaning.

region(start, end)

Sets the limits of this Matcher object’s region. The region is the part of the input sequence that is searched to find a match.

Signature

public Matcher object region(Integer start, Integer end)

Parameters

start

Type: Integer

dend

Type: Integer

Return Value

Type: Matcher

Usage

This method first resets the Matcher object, then sets the region to start at the index specified by start and end at the index specified by end. Depending on the transparency boundaries being used, certain constructs such as anchors may behave differently at or around the boundaries of the region. See Using Regions and Using Bounds.
regionEnd()
Returns the end index (exclusive) of this Matcher object’s region.

Signature
public Integer regionEnd()

Return Value
Type: Integer

Usage
See Using Regions.

regionStart()
Returns the start index (inclusive) of this Matcher object’s region.

Signature
public Integer regionStart()

Return Value
Type: Integer

Usage
See Using Regions.

replaceAll(replacementString)
Replaces every subsequence of the input sequence that matches the pattern with the replacement string.

Signature
public StringreplaceAll(String replacementString)

Parameters
replacementString
Type: String

Return Value
Type: String
Usage

This method first resets the Matcher object, then scans the input sequence looking for matches of the pattern. Characters that are not part of any match are appended directly to the result string; each match is replaced in the result by the replacement string. The replacement string may contain references to captured subsequences.

Note that backslashes (\) and dollar signs ($) in the replacement string may cause the results to be different than if the string was treated as a literal replacement string. Dollar signs may be treated as references to captured subsequences, and backslashes are used to escape literal characters in the replacement string.

Invoking this method changes this Matcher object’s state. If the Matcher object is to be used in further matching operations it should first be reset.

Given the regular expression a*b, the input "aabxyzaabxyzabxyzb", and the replacement string "-", an invocation of this method on a Matcher object for that expression would yield the string "-xyz-xyz-xyz-".

**replaceFirst(replacementString)**

Replaces the first subsequence of the input sequence that matches the pattern with the replacement string.

Signature

```java
public String replaceFirst(String replacementString)
```

Parameters

- **replacementString**
  - Type: String

Return Value

- Type: String

Usage

Note that backslashes (\) and dollar signs ($) in the replacement string may cause the results to be different than if the string was treated as a literal replacement string. Dollar signs may be treated as references to captured subsequences, and backslashes are used to escape literal characters in the replacement string.

Invoking this method changes this Matcher object’s state. If the Matcher object is to be used in further matching operations it should first be reset.

Given the regular expression dog, the input "zzzdogzzzdogzzz", and the replacement string "cat", an invocation of this method on a Matcher object for that expression would return the string "zzzcatzzzdogzzz".

**requireEnd()**

Returns true if more input could change a positive match into a negative one.

Signature

```java
public Boolean requireEnd()
```
Return Value
Type: Boolean

Usage
If this method returns true, and a match was found, then more input could cause the match to be lost.
If this method returns false and a match was found, then more input might change the match but the match won’t be lost.
If a match was not found, then requireEnd has no meaning.

reset()
Resets this Matcher object. Resetting a Matcher object discards all of its explicit state information.

Signature
public Matcher object reset()

Return Value
Type: Matcher

Usage
This method does not change whether the Matcher object uses anchoring bounds. You must explicitly use the useAnchoringBounds method to change the anchoring bounds.
For more information, see Using Bounds.

reset(inputSequence)
Resets this Matcher object with the new input sequence. Resetting a Matcher object discards all of its explicit state information.

Signature
public Matcher reset(String inputSequence)

Parameters
inputSequence
  Type: String

Return Value
Type: Matcher

start()
Returns the start index of the first character of the previous match.
Signature

```java
public Integer start()
```

Return Value
Type: Integer

**start(groupIndex)**

Returns the start index of the subsequence captured by the group specified by the group index during the previous match operation. Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression `m.start(0)` is equivalent to `m.start()`.

Signature

```java
public Integer start(Integer groupIndex)
```

Parameters

- **groupIndex**
  Type: Integer

Return Value
Type: Integer

Usage

See Understanding Capturing Groups on page 553.

**useAnchoringBounds(anchoringBounds)**

Sets the anchoring bounds of the region for the Matcher object. By default, a Matcher object uses anchoring bounds regions.

Signature

```java
public Matcher object useAnchoringBounds(Boolean anchoringBounds)
```

Parameters

- **anchoringBounds**
  Type: Boolean

  If you specify `true`, the Matcher object uses anchoring bounds. If you specify `false`, non-anchoring bounds are used.

Return Value
Type: Matcher
Usage

If a Matcher object uses anchoring bounds, the boundaries of this Matcher object's region match start and end of line anchors such as ^ and $.

For more information, see Using Bounds on page 552.

**usePattern(pattern)**

Changes the Pattern object that the Matcher object uses to find matches. This method causes the Matcher object to lose information about the groups of the last match that occurred. The Matcher object's position in the input is maintained.

Signature

```java
public Matcher object usePattern(Pattern pattern)
```

Parameters

`pattern`

Type: `System.Pattern`

Return Value

Type: `Matcher`

**useTransparentBounds(transparentBounds)**

Sets the transparency bounds for this Matcher object. By default, a Matcher object uses anchoring bounds regions.

Signature

```java
public Matcher object useTransparentBounds(Boolean transparentBounds)
```

Parameters

`transparentBounds`

Type: `Boolean`

If you specify `true`, the Matcher object uses transparent bounds. If you specify `false`, opaque bounds are used.

Return Value

Type: `Matcher`

Usage

For more information, see Using Bounds.

**Math Class**

Contains methods for mathematical operations.
Namespace
System

Math Fields
The following are fields for Math.

IN THIS SECTION:

E
Returns the mathematical constant e, which is the base of natural logarithms.

PI
Returns the mathematical constant pi, which is the ratio of the circumference of a circle to its diameter.

E
Returns the mathematical constant e, which is the base of natural logarithms.

Signature
public static final Double E

Property Value
Type: Double

PI
Returns the mathematical constant pi, which is the ratio of the circumference of a circle to its diameter.

Signature
public static final Double PI

Property Value
Type: Double

Math Methods
The following are methods for Math. All methods are static.

IN THIS SECTION:

abs(decimalValue)
Returns the absolute value of the specified Decimal.

abs(doubleValue)
Returns the absolute value of the specified Double.
abs(integerValue)
Returns the absolute value of the specified Integer.

abs(longValue)
Returns the absolute value of the specified Long.

acos(decimalAngle)
Returns the arc cosine of an angle, in the range of 0.0 through \(\pi\).

acos(doubleAngle)
Returns the arc cosine of an angle, in the range of 0.0 through \(\pi\).

asin(decimalAngle)
Returns the arc sine of an angle, in the range of \(-\pi/2\) through \(\pi/2\).

asin(doubleAngle)
Returns the arc sine of an angle, in the range of \(-\pi/2\) through \(\pi/2\).

atan(decimalAngle)
Returns the arc tangent of an angle, in the range of \(-\pi/2\) through \(\pi/2\).

atan(doubleAngle)
Returns the arc tangent of an angle, in the range of \(-\pi/2\) through \(\pi/2\).

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates \((xCoordinate, yCoordinate)\) to polar \((r, \theta)\). This method computes the phase \(\theta\) by computing an arc tangent of \(xCoordinate/yCoordinate\) in the range of \(-\pi To \(\pi\).

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates \((xCoordinate, yCoordinate)\) to polar \((r, \theta)\). This method computes the phase \(\theta\) by computing an arc tangent of \(xCoordinate/yCoordinate\) in the range of \(-\pi To \(\pi\).

cbrt(decimalValue)
Returns the cube root of the specified Decimal. The cube root of a negative value is the negative of the cube root of that value's magnitude.

cbrt(doubleValue)
Returns the cube root of the specified Double. The cube root of a negative value is the negative of the cube root of that value's magnitude.

ceil(decimalValue)
Returns the smallest (closest to negative infinity) Decimal that is not less than the argument and is equal to a mathematical integer.

ceil(doubleValue)
Returns the smallest (closest to negative infinity) Double that is not less than the argument and is equal to a mathematical integer.

cos(decimalAngle)
Returns the trigonometric cosine of the angle specified by \(decimalAngle\).

cos(doubleAngle)
Returns the trigonometric cosine of the angle specified by \(doubleAngle\).

cosh(decimalAngle)
Returns the hyperbolic cosine of \(decimalAngle\). The hyperbolic cosine of \(d\) is defined to be \((e^d + e^{-d})/2\) where \(e\) is Euler's number.

cosh(doubleAngle)
Returns the hyperbolic cosine of \(doubleAngle\). The hyperbolic cosine of \(d\) is defined to be \((e^d + e^{-d})/2\) where \(e\) is Euler's number.
exp(exponentDecimal)
Returns Euler's number e raised to the power of the specified Decimal.

exp(exponentDouble)
Returns Euler's number e raised to the power of the specified Double.

floor(decimalValue)
Returns the largest (closest to positive infinity) Decimal that is not greater than the argument and is equal to a mathematical integer.

floor(doubleValue)
Returns the largest (closest to positive infinity) Double that is not greater than the argument and is equal to a mathematical integer.

log(decimalValue)
Returns the natural logarithm (base e) of the specified Decimal.

log(doubleValue)
Returns the natural logarithm (base e) of the specified Double.

log10(decimalValue)
Returns the logarithm (base 10) of the specified Decimal.

log10(doubleValue)
Returns the logarithm (base 10) of the specified Double.

max(decimalValue1, decimalValue2)
Returns the larger of the two specified Decimals.

max(doubleValue1, doubleValue2)
Returns the larger of the two specified Doubles.

max(integerValue1, integerValue2)
Returns the larger of the two specified Integers.

max(longValue1, longValue2)
Returns the larger of the two specified Longs.

min(decimalValue1, decimalValue2)
Returns the smaller of the two specified Decimals.

min(doubleValue1, doubleValue2)
Returns the smaller of the two specified Doubles.

min(integerValue1, integerValue2)
Returns the smaller of the two specified Integers.

min(longValue1, longValue2)
Returns the smaller of the two specified Longs.

mod(integerValue1, integerValue2)
Returns the remainder of integerValue1 divided by integerValue2.

mod(longValue1, longValue2)
Returns the remainder of longValue1 divided by longValue2.

pow(doubleValue, exponent)
Returns the value of the first Double raised to the power of exponent.

random()
Returns a positive Double that is greater than or equal to 0.0 and less than 1.0.
rint(decimalValue)
Returns the value that is closest in value to decimalValue and is equal to a mathematical integer.

rint(doubleValue)
Returns the value that is closest in value to doubleValue and is equal to a mathematical integer.

round(doubleValue)
Do not use. This method is deprecated as of the Winter '08 release. Instead, use Math.roundToLong. Returns the closest Integer to the specified Double. If the result is less than -2,147,483,648 or greater than 2,147,483,647, Apex generates an error.

round(decimalValue)
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

roundToLong(decimalValue)
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

roundToLong(doubleValue)
Returns the closest Long to the specified Double.

signum(decimalValue)
Returns the signum function of the specified Decimal, which is 0 if decimalValue is 0, 1.0 if decimalValue is greater than 0, -1.0 if decimalValue is less than 0.

signum(doubleValue)
Returns the signum function of the specified Double, which is 0 if doubleValue is 0, 1.0 if doubleValue is greater than 0, -1.0 if doubleValue is less than 0.

sin(decimalAngle)
Returns the trigonometric sine of the angle specified by decimalAngle.

sin(doubleAngle)
Returns the trigonometric sine of the angle specified by doubleAngle.

sinh(decimalAngle)
Returns the hyperbolic sine of decimalAngle. The hyperbolic sine of decimalAngle is defined to be \( \frac{e^x - e^{-x}}{2} \) where \( e \) is Euler’s number.

sinh(doubleAngle)
Returns the hyperbolic sine of doubleAngle. The hyperbolic sine of doubleAngle is defined to be \( \frac{e^x - e^{-x}}{2} \) where \( e \) is Euler’s number.

sqrt(decimalValue)
Returns the correctly rounded positive square root of decimalValue.

sqrt(doubleValue)
Returns the correctly rounded positive square root of doubleValue.

tan(decimalAngle)
Returns the trigonometric tangent of the angle specified by decimalAngle.

tan(doubleAngle)
Returns the trigonometric tangent of the angle specified by doubleAngle.
tanh(decimalAngle)
Returns the hyperbolic tangent of decimalAngle. The hyperbolic tangent of decimalAngle is defined to be \((e^x - e^{-x})/(e^x + e^{-x})\) where \(e\) is Euler's number. In other words, it is equivalent to \(\sinh(x)/\cosh(x)\). The absolute value of the exact \(\tanh\) is always less than 1.

tanh(doubleAngle)
Returns the hyperbolic tangent of doubleAngle. The hyperbolic tangent of doubleAngle is defined to be \((e^x - e^{-x})/(e^x + e^{-x})\) where \(e\) is Euler's number. In other words, it is equivalent to \(\sinh(x)/\cosh(x)\). The absolute value of the exact \(\tanh\) is always less than 1.

abs(decimalValue)
Returns the absolute value of the specified Decimal.

Signature

public static Decimal abs(Decimal decimalValue)

Parameters

decimalValue
Type: Decimal

Return Value
Type: Decimal

abs(doubleValue)
Returns the absolute value of the specified Double.

Signature

public static Double abs(Double doubleValue)

Parameters

doubleValue
Type: Double

Return Value
Type: Double

abs(integerValue)
Returns the absolute value of the specified Integer.

Signature

public static Integer abs(Integer integerValue)
Parameters

\texttt{integerValue}

Type: \texttt{Integer}

Return Value

Type: \texttt{Integer}

Example

\begin{verbatim}
Integer i = -42;
Integer i2 = \texttt{math.abs}(i);
\texttt{system.assertEquals}(i2, 42);
\end{verbatim}

\texttt{abs(longValue)}

Returns the absolute value of the specified \texttt{Long}.

Signature

\texttt{public static Long abs(Long longValue)}

Parameters

\texttt{longValue}

Type: \texttt{Long}

Return Value

Type: \texttt{Long}

\texttt{acos(decimalAngle)}

Returns the arc cosine of an angle, in the range of 0.0 through \texttt{pi}.

Signature

\texttt{public static Decimal acos(Decimal decimalAngle)}

Parameters

\texttt{decimalAngle}

Type: \texttt{Decimal}

Return Value

Type: \texttt{Decimal}
**acos(doubleAngle)**
Returns the arc cosine of an angle, in the range of 0.0 through \( \pi \).

**Signature**
```java
public static Double acos(Double doubleAngle)
```

**Parameters**
- `doubleAngle`
  Type: `Double`

**Return Value**
Type: `Double`

**asin(decimalAngle)**
Returns the arc sine of an angle, in the range of \(-\pi/2\) through \(\pi/2\).

**Signature**
```java
public static Decimal asin(Decimal decimalAngle)
```

**Parameters**
- `decimalAngle`
  Type: `Decimal`

**Return Value**
Type: `Decimal`

**asin(doubleAngle)**
Returns the arc sine of an angle, in the range of \(-\pi/2\) through \(\pi/2\).

**Signature**
```java
public static Double asin(Double doubleAngle)
```

**Parameters**
- `doubleAngle`
  Type: `Double`

**Return Value**
Type: `Double`
atan(decimalAngle)
Returns the arc tangent of an angle, in the range of -pi/2 through pi/2.

Signature
public static Decimal atan(Decimal decimalAngle)

Parameters
decimalAngle
Type: Decimal

Return Value
Type: Decimal

atan(doubleAngle)
Returns the arc tangent of an angle, in the range of -pi/2 through pi/2.

Signature
public static Double atan(Double doubleAngle)

Parameters
doubleAngle
Type: Double

Return Value
Type: Double

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates (xCoordinate and yCoordinate) to polar (r and theta). This method computes the phase theta by computing an arc tangent of xCoordinate/yCoordinate in the range of -pi to pi.

Signature
public static Decimal atan2(Decimal xCoordinate, Decimal yCoordinate)

Parameters
xCoordinate
Type: Decimal
yCoordinate
Type: Decimal
Return Value
Type: Decimal

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates (xCoordinate and yCoordinate) to polar (r and theta). This method computes the phase theta by computing an arc tangent of xCoordinate/yCoordinate in the range of -pi to pi.

Signature
public static Double atan2(Double xCoordinate, Double yCoordinate)

Parameters
xCoordinate
Type: Double
yCoordinate
Type: Double

Return Value
Type: Double

cbrt(decimalValue)
Returns the cube root of the specified Decimal. The cube root of a negative value is the negative of the cube root of that value’s magnitude.

Signature
public static Decimal cbrt(Decimal decimalValue)

Parameters
decimalValue
Type: Decimal

Return Value
Type: Decimal

cbrt(doubleValue)
Returns the cube root of the specified Double. The cube root of a negative value is the negative of the cube root of that value’s magnitude.

Signature
public static Double cbrt(Double doubleValue)
Parameters

doubleValue
  Type: Double

Return Value
Type: Double

**ceil(decimalValue)**

Returns the smallest (closest to negative infinity) Decimal that is not less than the argument and is equal to a mathematical integer.

Signature

```java
public static Decimal ceil(Decimal decimalValue)
```

Parameters

decimalValue
  Type: Decimal

Return Value
Type: Decimal

**ceil(doubleValue)**

Returns the smallest (closest to negative infinity) Double that is not less than the argument and is equal to a mathematical integer.

Signature

```java
public static Double ceil(Double doubleValue)
```

Parameters

doubleValue
  Type: Double

Return Value
Type: Double

**cos(decimalAngle)**

Returns the trigonometric cosine of the angle specified by `decimalAngle`.

Signature

```java
public static Decimal cos(Decimal decimalAngle)
```
Parameters

decimalAngle
  Type: Decimal

Return Value
Type: Decimal

\texttt{cos(doubleAngle)}

Returns the trigonometric cosine of the angle specified by \texttt{doubleAngle}.

Signature

\texttt{public static Double cos(Double doubleAngle)}

Parameters

doubleAngle
  Type: Double

Return Value
Type: Double

\texttt{cosh(decimalAngle)}

Returns the hyperbolic cosine of \texttt{decimalAngle}. The hyperbolic cosine of \texttt{d} is defined to be \((e^x + e^{-x})/2\) where \(e\) is Euler's number.

Signature

\texttt{public static Decimal cosh(Decimal decimalAngle)}

Parameters

decimalAngle
  Type: Decimal

Return Value
Type: Decimal

\texttt{cosh(doubleAngle)}

Returns the hyperbolic cosine of \texttt{doubleAngle}. The hyperbolic cosine of \texttt{d} is defined to be \((e^x + e^{-x})/2\) where \(e\) is Euler's number.

Signature

\texttt{public static Double cosh(Double doubleAngle)}
Parameters

doubleAngle
   Type: Double

Return Value
Type: Double

**exp(exponentDecimal)**

Returns Euler's number $e$ raised to the power of the specified Decimal.

Signature

```
public static Decimal exp(Decimal exponentDecimal)
```

Parameters

exponentDecimal
   Type: Decimal

Return Value
Type: Decimal

**exp(exponentDouble)**

Returns Euler's number $e$ raised to the power of the specified Double.

Signature

```
public static Double exp(Double exponentDouble)
```

Parameters

exponentDouble
   Type: Double

Return Value
Type: Double

**floor(decimalValue)**

Returns the largest (closest to positive infinity) Decimal that is not greater than the argument and is equal to a mathematical integer.

Signature

```
public static Decimal floor(Decimal decimalValue)
```
floor(doubleValue)
Returns the largest (closest to positive infinity) Double that is not greater than the argument and is equal to a mathematical integer.

Signature
public static Double floor(Double doubleValue)

Parameters
doubleValue
Type: Double

Return Value
Type: Double

log(decimalValue)
Returns the natural logarithm (base e) of the specified Decimal.

Signature
public static Decimal log(Decimal decimalValue)

Parameters
decimalValue
Type: Decimal

Return Value
Type: Decimal

log(doubleValue)
Returns the natural logarithm (base e) of the specified Double.

Signature
public static Double log(Double doubleValue)
Parameters

doubleValue
  Type: Double

Return Value
  Type: Double

log10(decimalValue)
Returns the logarithm (base 10) of the specified Decimal.

Signature
public static Decimal log10(Decimal decimalValue)

Parameters

decimalValue
  Type: Decimal

Return Value
  Type: Decimal

log10(doubleValue)
Returns the logarithm (base 10) of the specified Double.

Signature
public static Double log10(Double doubleValue)

Parameters

doubleValue
  Type: Double

Return Value
  Type: Double

max(decimalValue1, decimalValue2)
Returns the larger of the two specified Decimals.

Signature
public static Decimal max(Decimal decimalValue1, Decimal decimalValue2)
Parameters

decimalValue1
Type: Decimal

decimalValue2
Type: Decimal

Return Value
Type: Decimal

Example

```java
Decimal larger = math.max(12.3, 156.6);
system.assertEquals(larger, 156.6);
```

**max(doubleValue1, doubleValue2)**

Returns the larger of the two specified Doubles.

Signature

```java
public static Double max(Double doubleValue1, Double doubleValue2)
```

Parameters

doubleValue1
Type: Double
doubleValue2
Type: Double

Return Value
Type: Double

**max(integerValue1, integerValue2)**

Returns the larger of the two specified Integers.

Signature

```java
public static Integer max(Integer integerValue1, Integer integerValue2)
```

Parameters

integerValue1
Type: Integer
integerValue2
Type: Integer
Return Value
Type: Integer

max(longValue1, longValue2)
Returns the larger of the two specified Longs.

Signature
public static Long max(Long longValue1, Long longValue2)

Parameters
longValue1
Type: Long
longValue2
Type: Long

Return Value
Type: Long

min(decimalValue1, decimalValue2)
Returns the smaller of the two specified Decimals.

Signature
public static Decimal min(Decimal decimalValue1, Decimal decimalValue2)

Parameters
decimalValue1
Type: Decimal
decimalValue2
Type: Decimal

Return Value
Type: Decimal

Example
Decimal smaller = math.min(12.3, 156.6);
system.assertEquals(smaller, 12.3);

min(doubleValue1, doubleValue2)
Returns the smaller of the two specified Doubles.
Signature

public static Double min(Double doubleValue1, Double doubleValue2)

Parameters

doubleValue1
  Type: Double
doubleValue2
  Type: Double

Return Value
Type: Double

\textbf{min(integerValue1, integerValue2)}

Returns the smaller of the two specified Integers.

Signature

public static Integer min(Integer integerValue1, Integer integerValue2)

Parameters

integerValue1
  Type: Integer
integerValue2
  Type: Integer

Return Value
Type: Integer

\textbf{min(longValue1, longValue2)}

Returns the smaller of the two specified Longs.

Signature

public static Long min(Long longValue1, Long longValue2)

Parameters

longValue1
  Type: Long
longValue2
  Type: Long
Return Value
Type: Long

mod(integerValue1, integerValue2)
Returns the remainder of integerValue1 divided by integerValue2.

Signature
public static Integer mod(Integer integerValue1, Integer integerValue2)

Parameters
integerValue1
Type: Integer
integerValue2
Type: Integer

Return Value
Type: Integer

Example
```java
Integer remainder = math.mod(12, 2);
system.assertEquals(remainder, 0);

Integer remainder2 = math.mod(8, 3);
system.assertEquals(remainder2, 2);
```

mod(longValue1, longValue2)
Returns the remainder of longValue1 divided by longValue2.

Signature
public static Long mod(Long longValue1, Long longValue2)

Parameters
longValue1
Type: Long
longValue2
Type: Long

Return Value
Type: Long
**pow(doubleValue, exponent)**
Returns the value of the first Double raised to the power of *exponent*.

Signature
```
public static Double pow(Double doubleValue, Double exponent)
```

Parameters
- `doubleValue`  
  Type: `Double`
- `exponent`  
  Type: `Double`

Return Value  
Type: `Double`

**random()**
Returns a positive Double that is greater than or equal to 0.0 and less than 1.0.

Signature
```
public static Double random()
```

Return Value  
Type: `Double`

**rint(decimalValue)**
Returns the value that is closest in value to *decimalValue* and is equal to a mathematical integer.

Signature
```
public static Decimal rint(Decimal decimalValue)
```

Parameters
- `decimalValue`  
  Type: `Decimal`

Return Value  
Type: `Decimal`

**rint(doubleValue)**
Returns the value that is closest in value to *doubleValue* and is equal to a mathematical integer.
public static Double rint(Double doubleValue)

Parameters
doubleValue
  Type: Double

Return Value
Type: Double

round(doubleValue)
Do not use. This method is deprecated as of the Winter '08 release. Instead, use Math.roundToLong. Returns the closest Integer to the specified Double. If the result is less than -2,147,483,648 or greater than 2,147,483,647, Apex generates an error.

public static Integer round(Double doubleValue)

Parameters
doubleValue
  Type: Double

Return Value
Type: Integer

round(decimalValue)
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

public static Integer round(Decimal decimalValue)

Parameters
decimalValue
  Type: Decimal

Return Value
Type: Integer
Usage

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

Example

```java
Decimal d1 = 4.5;
Integer i1 = Math.round(d1);
System.assertEquals(4, i1);

Decimal d2 = 5.5;
Integer i2 = Math.round(d2);
System.assertEquals(6, i2);
```

`roundToLong(decimalValue)`

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

Signature

```
public static Long roundToLong(Decimal decimalValue)
```

Parameters

decimalValue
  Type: Decimal

Return Value

Type: Long

Usage

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

Example

```java
Decimal d1 = 4.5;
Long i1 = Math.roundToLong(d1);
System.assertEquals(4, i1);

Decimal d2 = 5.5;
Long i2 = Math.roundToLong(d2);
System.assertEquals(6, i2);
```

`roundToLong(doubleValue)`

Returns the closest Long to the specified Double.
Signature

public static Long roundToLong(Double doubleValue)

Parameters

doubleValue
   Type: Double

Return Value

Type: Long

**signum(decimalValue)**

Returns the signum function of the specified Decimal, which is 0 if `decimalValue` is 0, 1.0 if `decimalValue` is greater than 0, -1.0 if `decimalValue` is less than 0.

Signature

public static Decimal signum(Decimal decimalValue)

Parameters

decimalValue
   Type: Decimal

Return Value

Type: Decimal

**signum(doubleValue)**

Returns the signum function of the specified Double, which is 0 if `doubleValue` is 0, 1.0 if `doubleValue` is greater than 0, -1.0 if `doubleValue` is less than 0.

Signature

public static Double signum(Double doubleValue)

Parameters

doubleValue
   Type: Double

Return Value

Type: Double

**sin(decimalAngle)**

Returns the trigonometric sine of the angle specified by `decimalAngle`. 
Signature

public static Decimal sin(Decimal decimalAngle)

Parameters

decimalAngle
Type: Decimal

Return Value
Type: Decimal

\textbf{sin(\textit{doubleValue})}

Returns the trigonometric sine of the angle specified by \textit{doubleValue}.

Signature

public static Double sin(Double doubleAngle)

Parameters

doubleAngle
Type: Double

Return Value
Type: Double

\textbf{sinh(\textit{decimalAngle})}

Returns the hyperbolic sine of \textit{decimalAngle}. The hyperbolic sine of \textit{decimalAngle} is defined to be \((e^x - e^{-x})/2\) where \(e\) is Euler's number.

Signature

public static Decimal sinh(Decimal decimalAngle)

Parameters

decimalAngle
Type: Decimal

Return Value
Type: Decimal

\textbf{sinh(\textit{doubleValue})}

Returns the hyperbolic sine of \textit{doubleValue}. The hyperbolic sine of \textit{doubleValue} is defined to be \((e^x - e^{-x})/2\) where \(e\) is Euler's number.
Signature

public static Double sinh(Double doubleAngle)

Parameters

doubleAngle
   Type: Double

Return Value
Type: Double

**sqrt(decimalValue)**

Returns the correctly rounded positive square root of `decimalValue`.

Signature

public static Decimal sqrt(Decimal decimalValue)

Parameters

decimalValue
   Type: Decimal

Return Value
Type: Decimal

**sqrt(doubleValue)**

Returns the correctly rounded positive square root of `doubleValue`.

Signature

public static Double sqrt(Double doubleValue)

Parameters

doubleValue
   Type: Double

Return Value
Type: Double

**tan(decimalAngle)**

Returns the trigonometric tangent of the angle specified by `decimalAngle`. 
Signature

```java
public static Decimal tan(Decimal decimalAngle)
```

Parameters

decimalAngle
  Type: Decimal

Return Value
Type: Decimal

**tan(doubleAngle)**

Returns the trigonometric tangent of the angle specified by `doubleAngle`.

Signature

```java
public static Double tan(Double doubleAngle)
```

Parameters

doubleAngle
  Type: Double

Return Value
Type: Double

**tanh(decimalAngle)**

Returns the hyperbolic tangent of `decimalAngle`. The hyperbolic tangent of `decimalAngle` is defined to be \((e^x - e^{-x})/(e^x + e^{-x})\) where \(e\) is Euler's number. In other words, it is equivalent to \(\sinh(x)/\cosh(x)\). The absolute value of the exact \(\tanh\) is always less than 1.

Signature

```java
public static Decimal tanh(Decimal decimalAngle)
```

Parameters

decimalAngle
  Type: Decimal

Return Value
Type: Decimal
**tanh (doubleAngle)**

Returns the hyperbolic tangent of `doubleAngle`. The hyperbolic tangent of `doubleAngle` is defined to be \((e^x - e^{-x})/(e^x + e^{-x})\) where \(e\) is Euler's number. In other words, it is equivalent to \(\sinh(x)/\cosh(x)\). The absolute value of the exact \(\tanh\) is always less than 1.

**Signature**

```java
public static Double tanh(Double doubleAngle)
```

**Parameters**

- `doubleAngle`
  - Type: `Double`

**Return Value**

- Type: `Double`

**Messaging Class**

Contains messaging methods used when sending a single or mass email.

**Namespace**

`System`

**Messaging Methods**

The following are methods for `Messaging`. All are instance methods.

**IN THIS SECTION:**

- `extractInboundEmail(source, includeForwardedAttachments)`
  Use this method in your email service code to control how to parse and process forwarded or attached emails. Returns an instance of `Messaging.InboundEmail` from a stream of data that is in RFC822 format. The data stream can be a forwarded email in an attachment to an existing `InboundEmail`, or a stream from another source.

- `reserveMassEmailCapacity(amountReserved)`
  Reserves email capacity to send mass email to the specified number of email addresses, after the current transaction commits.

- `reserveSingleEmailCapacity(amountReserved)`
  Reserves email capacity to send single email to the specified number of email addresses, after the current transaction commits.

- `sendEmail(emails, allOrNothing)`
  Sends the list of up to 10 emails instantiated with either `SingleEmailMessage` or `MassEmailMessage` and returns a list of `SendEmailResult` objects. When org preferences are set to save `EmailMessage` objects and a trigger is defined for `EmailMessage` objects, the trigger is fired for each `SingleEmailMessage` individually.

- `sendEmailMessage(emailMessageIds, allOrNothing)`
  Sends up to 10 draft email messages as defined by the specified email message IDs and returns a list of `SendEmailResult` objects.
renderEmailTemplate(whoid, whatld, bodies)
Replaces merge fields in text bodies of email templates with values from Salesforce records. Returns an array of RenderEmailTemplateBodyResult objects, each of which corresponds to an element in the supplied array of text bodies. Each RenderEmailTemplateBodyResult provides a success or failure indication, along with either an error code or the rendered text.

renderStoredEmailTemplate(templateId, whoid, whatld)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of Messaging.SingleEmailMessage. Includes all attachment content in the returned email message.

renderStoredEmailTemplate(templateId, whoid, whatld, attachmentRetrievalOption)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of Messaging.SingleEmailMessage. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

renderStoredEmailTemplate(templateId, whoid, whatld, attachmentRetrievalOption, updateEmailTemplateUsage)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of Messaging.SingleEmailMessage. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

extractInboundEmail(source, includeForwardedAttachments)
Use this method in your email service code to control how to parse and process forwarded or attached emails. Returns an instance of Messaging.InboundEmail from a stream of data that is in RFC822 format. The data stream can be a forwarded email in an attachment to an existing InboundEmail, or a stream from another source.

Signature
public static Messaging.InboundEmail extractInboundEmail(Object source, Boolean includeForwardedAttachments)

Parameters
source
Type: Object
An instance of Messaging.InboundEmail.BinaryAttachment whose MimeTypeSubtype is message/rfc822 or a Blob. If source is a Blob, then supply a byte array in RFC822 format.

includeForwardedAttachments
Type: Boolean
This parameter controls how attachments to embedded or forwarded emails are handled. Set to true to provide all attachments, even attachments in embedded emails in the binaryAttachments and textAttachments properties of the returned value. Set to false to provide only the attachments that are at the top level of the source email.

Return Value
Type: Messaging.InboundEmail

reserveMassEmailCapacity(amountReserved)
Reserves email capacity to send mass email to the specified number of email addresses, after the current transaction commits.
Signature

```java
public Void reserveMassEmailCapacity(Integer amountReserved)
```

Parameters

```java
amountReserved
    Type: Integer
```

Return Value

Type: Void

Usage

This method can be called when you know in advance how many addresses emails will be sent to as a result of the transaction. If the transaction would cause the organization to exceed its daily email limit, using this method results in the following error:
System.HandledException: The daily limit for the org would be exceeded by this request.
If the organization doesn’t have permission to send API or mass email, using this method results in the following error:
System.NoAccessException: The organization is not permitted to send email.

```java
reserveSingleEmailCapacity(amountReserved)
```

Reserves email capacity to send single email to the specified number of email addresses, after the current transaction commits.

Signature

```java
public Void reserveSingleEmailCapacity(Integer amountReserved)
```

Parameters

```java
amountReserved
    Type: Integer
```

Return Value

Type: Void

Usage

This method can be called when you know in advance how many addresses emails will be sent to as a result of the transaction. If the transaction would cause the organization to exceed its daily email limit, using this method results in the following error:
System.HandledException: The daily limit for the org would be exceeded by this request.
If the organization doesn’t have permission to send API or mass email, using this method results in the following error:
System.NoAccessException: The organization is not permitted to send email.

```java
sendEmail(emails, allOrNothing)
```

Sends the list of up to 10 emails instantiated with either `SingleEmailMessage` or `MassEmailMessage` and returns a list of `SendEmailResult` objects. When org preferences are set to save `EmailMessage` objects and a trigger is defined for `EmailMessage` objects, the trigger is fired for each `SingleEmailMessage` individually.
Signature

```java
public Messaging.SendEmailResult[] sendEmail(Messaging.Email[] emails, Boolean allOrNothing)
```

Parameters

- `emails`  
  Type: Messaging.Email[]
- `allOrNothing`  
  Type: Boolean

The optional `opt_allOrNone` parameter specifies whether `sendEmail` prevents delivery of all other messages when any of the messages fail due to an error (`true`), or whether it allows delivery of the messages that don’t have errors (`false`). The default is `true`.

Return Value

Type: Messaging.SendEmailResult[]

**sendEmailMessage(emailMessageIds, allOrNothing)**

Sends up to 10 draft email messages as defined by the specified email message IDs and returns a list of SendEmailResult objects.

Signature

```java
public Messaging.SendEmailResult[] sendEmailMessage(List<ID> emailMessageIds, Boolean allOrNothing)
```

Parameters

- `emailMessageIds`  
  Type: List<ID>
- `allOrNothing`  
  Type: Boolean

Return Value

Type: Messaging.SendEmailResult[]

Usage

The `sendEmailMessage` method assumes that the optional `opt_allOrNone` parameter is always `false` and ignores the value you set. This optional parameter specifies whether `sendEmailMessage` prevents delivery of all other messages when any of the messages fail due to an error (`true`), or whether it allows delivery of the messages that don’t have errors (`false`).
Example

This example shows how to send a draft email message. It creates a case and a new email message associated with the case. Next, the example sends a draft email message and checks the results. Before running this example, make sure to replace the email address with a valid address.

```apex
Case c = new Case();
insert c;

EmailMessage e = new EmailMessage();
e.parentid = c.id;
// Set to draft status.
// This status is required
// for sendEmailMessage().
e.Status = '5';
e.TextBody = 'Sample email message.';
e.Subject = 'Apex sample';
e.ToAddress = 'customer@email.com';
insert e;

List<Messaging.SendEmailResult> results =
    Messaging.sendEmailMessage(new ID[]
    { e.id });

System.assertEquals(1, results.size());
System.assertEquals(true,
    results[0].success);
```

renderEmailTemplate(whoId, whatId, bodies)

Replaces merge fields in text bodies of email templates with values from Salesforce records. Returns an array of RenderEmailTemplateBodyResult objects, each of which corresponds to an element in the supplied array of text bodies. Each RenderEmailTemplateBodyResult provides a success or failure indication, along with either an error code or the rendered text.

Signature

```apex
public static List<Messaging.RenderEmailTemplateBodyResult> renderEmailTemplate(String whoId, String whatId, List<String> bodies)
```

Parameters

whoId
Type: String
The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

whatId
Type: String
Identifies an object in the database like an account or opportunity. The record for that object is read and used in merge field processing.
bodies
Type: List<String>
An array of strings that are examined for merge field references. The corresponding data from the object referenced by the whoId or whatId replaces the merge field reference.

Return Value
Type: List<Messaging.RenderEmailTemplateBodyResult>

Usage
Use this method in situations in which you want to dynamically compose blocks of text that are enriched with data from the database. You can then use the rendered blocks of text to compose and send an email or update a text value in another database record.

Executing the renderEmailTemplate method counts toward the SOQL governor limit. The number of SOQL queries that this method consumes is the number of elements in the list of strings passed in the bodies parameter.

SEE ALSO:
Execution Governors and Limits

renderStoredEmailTemplate(templatedId, whoId, whatId)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of Messaging.SingleEmailMessage. Includes all attachment content in the returned email message.

Signature
public static Messaging.SingleEmailMessage renderStoredEmailTemplate(String templateId, String whoId, String whatId)

Parameters

templateId
Type: String
An email template that exists in the database, such as text, HTML, custom, and Visualforce templates.

whoId
Type: String
The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

whatId
Type: String
Identifies an object in the database, like an account or opportunity. The record for that object is read and used in merge field processing.

Return Value
Type: Messaging.SingleEmailMessage
Usage

Executing the `renderStoredEmailTemplate` method counts toward the SOQL governor limit as one query.

SEE ALSO:

   Execution Governors and Limits

`renderStoredEmailTemplate(templateId, whoId, whatId, attachmentRetrievalOption)`

Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of `Messaging.SingleEmailMessage`. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

Signature

```java
public static Messaging.SingleEmailMessage renderStoredEmailTemplate(String templateId, String whoId, String whatId, Messaging.AttachmentRetrievalOption attachmentRetrievalOption)
```

Parameters

`templateId`

Type: `String`

An email template that exists in the database, such as text, HTML, custom, and Visualforce templates.

`whoId`

Type: `String`

The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

`whatId`

Type: `String`

Identifies an object in the database, like an account or opportunity. The record for that object is read and used in merge field processing.

`attachmentRetrievalOption`

Type: `Messaging.AttachmentRetrievalOption`

Specifies options for including attachments in the `fileAttachments` property of the returned `Messaging.SingleEmailMessage`. Set to one of the `Messaging.AttachmentRetrievalOption` values to include attachment metadata only, attachment metadata and content, or to exclude attachments.

**Note:** When the `attachmentRetrievalOption` parameter is not set to `NONE`, the `entityAttachments` property of `Messaging.SingleEmailMessage` contains the ID of the Salesforce content objects to attach (ContentVersion or Document). The `fileAttachments` property contains the IDs of attachments, in addition to all the IDs in the `entityAttachments` property. As a result, the ID values in `entityAttachments` are duplicates of the IDs in the `fileAttachments` property. If you call `renderStoredEmailTemplate()` by passing the `METADATA_WITH_BODY` option, and send the rendered email message, the email will contain duplicate attachments. Before using the returned email message with `sendEmail(emails, allOrNothing)`, you can remove attachments from `fileAttachments` that are duplicated in `entityAttachments`.  

2885
Return Value
Type: Messaging.SingleEmailMessage

Usage
Executing the `renderStoredEmailTemplate` method counts toward the SOQL governor limit as one query.

```java
renderStoredEmailTemplate(templateId, whoId, whatId, attachmentRetrievalOption, updateEmailTemplateUsage)
```

Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of `Messaging.SingleEmailMessage`. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

Signature
```
public static Messaging.SingleEmailMessage renderStoredEmailTemplate(String templateId, String whoId, String whatId, Messaging.AttachmentRetrievalOption attachmentRetrievalOption, Boolean updateEmailTemplateUsage)
```

Parameters
`templateId`
Type: String
An email template that exists in the database, such as text, HTML, custom, and Visualforce templates.

`whoId`
Type: String
The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

`whatId`
Type: String
Identifies an object in the database, like an account or opportunity. The record for that object is read and used in merge field processing.

`attachmentRetrievalOption`
Type: Messaging.AttachmentRetrievalOption
Specifies options for including attachments in the `fileAttachments` property of the returned `Messaging.SingleEmailMessage`. Set to one of the `Messaging.AttachmentRetrievalOption` values to include attachment metadata only, attachment metadata and content, or to exclude attachments.

**Note:** When the `attachmentRetrievalOption` parameter is not set to NONE, the `entityAttachments` property of `Messaging.SingleEmailMessage` contains the ID of the Salesforce content objects to attach (ContentVersion or Document). The `fileAttachments` property contains the IDs of attachments, in addition to all the IDs in the `entityAttachments` property. As a result, the ID values in `entityAttachments` are duplicates of the IDs in the `fileAttachments` property. If you call `renderStoredEmailTemplate()` by passing the `METADATA_WITH_BODY` option, and send the rendered email message, the email will contain duplicate attachments. Before using the returned email message with `sendEmail(emails, allOrNothing)`, you can remove attachments from `fileAttachments` that are duplicated in `entityAttachments`.

2886
updateEmailTemplateUsage
Type: Boolean
Specifies whether the usage field in the EmailTemplate record is updated upon successful rendering.

Return Value
Type: Messaging.SingleEmailMessage

Usage
Executing the renderStoredEmailTemplate method counts toward the SOQL governor limit as one query.

MultiStaticResourceCalloutMock Class
Utility class used to specify a fake response using multiple resources for testing HTTP callouts.

Namespace
System

Usage
Use the methods in this class to set the response properties for testing HTTP callouts. You can specify a resource for each endpoint.

IN THIS SECTION:
- MultiStaticResourceCalloutMock Constructors
- MultiStaticResourceCalloutMock Methods

MultiStaticResourceCalloutMock Constructors
The following are constructors for MultiStaticResourceCalloutMock.

IN THIS SECTION:
- MultiStaticResourceCalloutMock()
  Creates a new instance of the System.MultiStaticResourceCalloutMock class.

MultiStaticResourceCalloutMock()
Creates a new instance of the System.MultiStaticResourceCalloutMock class.

Signature
public MultiStaticResourceCalloutMock()

MultiStaticResourceCalloutMock Methods
The following are methods for MultiStaticResourceCalloutMock. All are instance methods.
IN THIS SECTION:

  - **setHeader(headerName, headerValue)**
    Sets the specified header name and value for the fake response.

  - **setStaticResource(endpoint, resourceName)**
    Sets the specified static resource corresponding to the endpoint. The static resource contains the response body.

  - **setStatus(httpStatus)**
    Sets the specified HTTP status for the response.

  - **setStatusCode(httpStatusCode)**
    Sets the specified HTTP status code for the response.

**setHeader(headerName, headerValue)**
Sets the specified header name and value for the fake response.

**Signature**

```java
public Void setHeader(String headerName, String headerValue)
```

**Parameters**

- **headerName**
  Type: String
- **headerValue**
  Type: String

**Return Value**

Type: Void

**setStaticResource(endpoint, resourceName)**
Sets the specified static resource corresponding to the endpoint. The static resource contains the response body.

**Signature**

```java
public Void setStaticResource(String endpoint, String resourceName)
```

**Parameters**

- **endpoint**
  Type: String
- **resourceName**
  Type: String

**Return Value**

Type: Void
setStatus(httpStatus)
Sets the specified HTTP status for the response.

Signature
public Void setStatus(String httpStatus)

Parameters
httpStatus
  Type: String

Return Value
Type: Void

setStatusCode(httpStatusCode)
Sets the specified HTTP status code for the response.

Signature
public Void setStatusCode(Integer httpStatusCode)

Parameters
httpStatusCode
  Type: Integer

Return Value
Type: Void

Network Class
Represents a community.

Namespace
System

Usage
Use the method in the Network class to determine which community a user is currently logged into.

IN THIS SECTION:
  Network Constructors
  Network Methods
Network Constructors

The following are constructors for Network.

IN THIS SECTION:

Network()

Creates a new instance of the System.Network class.

Network()

Creates a new instance of the System.Network class.

Signature

public Network()

Network Methods

The following are methods for Network. All methods are static.

IN THIS SECTION:

communitiesLanding()

Returns a Page Reference to the default landing page for the community. This is the first tab of the community.

forwardToAuthPage(startURL)

Returns a Page Reference to the default login page. StartURL is included as a query parameter for where to redirect after a successful login.

getLoginUrl(networkId)

Returns the absolute URL of the login page used by the community.

getLogoutUrl(networkId)

Returns the absolute URL of the logout page used by the community.

getNetworkId()

Returns the user’s current community.

getSelfRegUrl(networkId)

Returns the absolute URL of the self-registration page used by the community.

loadAllPackageDefaultNetworkDashboardSettings()

Maps the dashboards from the Salesforce Communities Management package onto each community’s unconfigured dashboard settings. Returns the number of settings it configures.

loadAllPackageDefaultNetworkPulseSettings()

Maps the Insights reports from the Salesforce Communities Management package onto each community’s unconfigured Insights settings. Returns the number of settings it configures.

communitiesLanding()

Returns a Page Reference to the default landing page for the community. This is the first tab of the community.
Signature

`public static String communitiesLanding()`

Return Value
Type: PageReference

Usage
If Communities isn’t enabled for the user’s organization or the user is currently in the internal organization, returns `null`.

`forwardToAuthPage(startURL)`

Returns a Page Reference to the default login page. StartURL is included as a query parameter for where to redirect after a successful login.

Signature

`public static PageReference forwardToAuthPage(String startURL)`

Parameters
`startURL`  
Type: String

Return Value
Type: PageReference

Usage
If Communities isn’t enabled for the user’s organization or the user is currently in the internal organization, returns `null`.

`getLoginUrl(networkId)`

Returns the absolute URL of the login page used by the community.

Signature

`public static String getLoginUrl(String networkId)`

Parameters
`networkId`  
Type: String
  
  The ID of the community you’re retrieving this information for.

Return Value
Type: String
Usage
Returns the full URL for the Lightning Platform or Community Builder page used as the login page in the community.

**getLogoutUrl(networkId)**

Returns the absolute URL of the logout page used by the community.

Signature
```
public static String getLogoutUrl(String networkId)
```

Parameters

**networkId**
Type: String
The ID of the community you’re retrieving this information for.

Return Value
Type: String

Usage
Returns the full URL for the Lightning Platform page, Community Builder page, or Web page used as the logout page in the community.

**getNetworkId()**

Returns the user’s current community.

Signature
```
public static String getNetworkId()
```

Return Value
Type: String

Usage
If Communities isn’t enabled for the user’s organization or the user is currently in the internal organization, returns null.

**getSelfRegUrl(networkId)**

Returns the absolute URL of the self-registration page used by the community.

Signature
```
public static String getSelfRegUrl(String networkId)
```
Parameters

networkId
Type: String

The ID of the community you're retrieving this information for.

Return Value
Type: String

Usage
Returns the full URL for the Lightning Platform or Community Builder page used as the self-registration page in the community.

loadAllPackageDefaultNetworkDashboardSettings()
Maps the dashboards from the Salesforce Communities Management package onto each community's unconfigured dashboard settings. Returns the number of settings it configures.

Signature
public static Integer loadAllPackageDefaultNetworkDashboardSettings()

Return Value
Type: Integer

Usage
If Communities is enabled, and the Salesforce Communities Management package is installed, maps the dashboards provided in the package onto each community's unconfigured dashboard settings. Returns the number of settings it configures. This method is invoked automatically during community creation and package installation, but isn't typically invoked manually.

If Communities isn't enabled for the user's organization or the user is in the internal organization, returns 0.

loadAllPackageDefaultNetworkPulseSettings()
Maps the Insights reports from the Salesforce Communities Management package onto each community's unconfigured Insights settings. Returns the number of settings it configures.

Signature
public static Integer loadAllPackageDefaultNetworkPulseSettings()

Return Value
Type: Integer
Usage

If Communities is enabled, and the Salesforce Communities Management package is installed, maps the Insights reports provided in the package onto each community’s unconfigured Insights settings. Returns the number of settings it configures. This method is invoked automatically during community creation and package installation, but isn’t typically invoked manually.

If Communities isn’t enabled for the user’s organization or the user is in the internal organization, returns 0.

OrgLimit Class
Contains methods that provide the name, maximum value, and current value of an org limit.

Namespace
System

Usage
Use the System.OrgLimits getAll and getMap methods to obtain either a list or a map of all your org limits. To get details on each limit, use instance methods from System.OrgLimit.

For comparison, the Limits Class System.Limits class returns Apex governor limits and not Salesforce API limits.

IN THIS SECTION:
  OrgLimit Methods

OrgLimit Methods
The following are methods for OrgLimit.

IN THIS SECTION:
  getLimit()
    Returns the maximum allowed limit value.
  getName()
    Returns the limit’s name.
  getValue()
    Returns the limit usage value.

getLimit()
Returns the maximum allowed limit value.

Signature
public Integer getLimit()

Return Value
Type: Integer
Example

```java
List<System.OrgLimit> limits = OrgLimits.getAll();
for (System.OrgLimit aLimit: limits) {
    System.debug('Limit: ' + aLimit.getName());
    System.debug('Max Limit is: ' + aLimit.getLimit());
}
```

**getName()**

Returns the limit’s name.

**Signature**

```java
public String getName()
```

**Return Value**

Type: `String`

Example

```java
List<System.OrgLimit> limits = OrgLimits.getAll();
for (System.OrgLimit aLimit: limits) {
    System.debug('Limit: ' + aLimit.getName());
    System.debug('Max Limit is: ' + aLimit.getLimit());
}
```

**getValue()**

Returns the limit usage value.

**Signature**

```java
public Integer getValue()
```

**Return Value**

Type: `Integer`

Example

```java
List<System.OrgLimit> limits = OrgLimits.getAll();
for (System.OrgLimit aLimit: limits) {
    System.debug('Limit: ' + aLimit.getName());
    System.debug('Max Limit is: ' + aLimit.getLimit());
}
```
OrgLimits Class

Contains methods that provide a list or map of all OrgLimit instances for Salesforce your org, such as SOAP API requests, Bulk API requests, and Streaming API limits.

Namespace

System

Usage

Use the System.OrgLimits getAll and getMap methods to obtain either a list or a map of all your org limits. To get details on each limit, use instance methods from System.OrgLimit.

For comparison, the Limits Class System.Limits class returns Apex governor limits and not Salesforce API limits.

IN THIS SECTION:

OrgLimits Methods

OrgLimits Methods

The following are methods for OrgLimits.

IN THIS SECTION:

getAll()

Returns a list of OrgLimit instances.

getMap()

Returns a map of all OrgLimit instances with the limit name as key.

getAll()

Returns a list of OrgLimit instances.

Signature

public static List<System.OrgLimit> getAll()

Return Value

Type: List<System.OrgLimit>

getMap()

Returns a map of all OrgLimit instances with the limit name as key.

Signature

public static Map<String,System.OrgLimit> getMap()
Return Value

Type: Map<String, System.OrgLimit>

Example

```java
Map<String, System.OrgLimit> limitsMap = OrgLimits.getMap();
System.OrgLimit apiRequestsLimit = limitsMap.get('DailyApiRequests');
System.debug('Limit Name: ' + apiRequestsLimit.getName());
System.debug('Usage Value: ' + apiRequestsLimit.getValue());
System.debug('Maximum Limit: ' + apiRequestsLimit.getLimit());
```

PageReference Class

A PageReference is a reference to an instantiation of a page. Among other attributes, PageReferences consist of a URL and a set of query parameter names and values.

Namespace

System

Use a PageReference object:

- To view or set query string parameters and values for a page
- To navigate the user to a different page as the result of an action method

Instantiation

In a custom controller or controller extension, you can refer to or instantiate a PageReference in one of the following ways:
• **Page**.existsPageName

Refers to a PageReference for a Visualforce page that has already been saved in your organization. By referring to a page in this way, the platform recognizes that this controller or controller extension is dependent on the existence of the specified page and will prevent the page from being deleted while the controller or extension exists.

```java
PageReference pageRef = new PageReference('partialURL');
```

Creates a PageReference to any page that is hosted on the Lightning platform. For example, setting 'partialURL' to '/apex/HelloWorld' refers to the Visualforce page located at http://mySalesforceInstance/apex/HelloWorld. Likewise, setting 'partialURL' to '/' + 'recordID' refers to the detail page for the specified record.

This syntax is less preferable for referencing other Visualforce pages than Page EXISTSPageName because the PageReference is constructed at runtime, rather than referenced at compile time. Runtime references are not available to the referential integrity system. Consequently, the platform doesn’t recognize that this controller or controller extension is dependent on the existence of the specified page and won’t issue an error message to prevent user deletion of the page.

```java
PageReference pageRef = new PageReference('fullURL');
```

Creates a PageReference for an external URL. For example:

```java
PageReference pageRef = new PageReference('http://www.google.com');
```

You can also instantiate a PageReference object for the current page with the currentPage ApexPages method. For example:

```java
PageReference pageRef = ApexPages.currentPage();
```

**Request Headers**

The following table is a non-exhaustive list of headers that are set on requests.

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>The host name requested in the request URL. This header is always set on Lightning Platform Site requests and My Domain requests. This header is optional on other requests when HTTP/1.0 is used instead of HTTP/1.1.</td>
</tr>
<tr>
<td>Referer</td>
<td>The URL that is either included or linked to the current request's URL. This header is optional.</td>
</tr>
<tr>
<td>User-Agent</td>
<td>The name, version, and extension support of the program that initiated this request, such as a Web browser. This header is optional and can be overridden in most browsers to be a different value. Therefore, this header should not be relied upon.</td>
</tr>
<tr>
<td>CipherSuite</td>
<td>If this header exists and has a non-blank value, this means that the request is using HTTPS. Otherwise, the request is using HTTP. The contents of a non-blank value are not defined by this API, and can be changed without notice.</td>
</tr>
<tr>
<td>X-Salesforce-SIP</td>
<td>The source IP address of the request. This header is always set on HTTP and HTTPS requests that are initiated outside of Salesforce's data centers.</td>
</tr>
</tbody>
</table>

**Note:** If a request passes through a content delivery network (CDN) or proxy server, the source IP address might be altered, and no longer the original client IP address.
X-Salesforce-Forwarded-To

The fully qualified domain name of the Salesforce instance that is handling this request. This header is always set on HTTP and HTTPS requests that are initiated outside of Salesforce’s data centers.

Example: Retrieving Query String Parameters

The following example shows how to use a PageReference object to retrieve a query string parameter in the current page URL. In this example, the getAccount method references the id query string parameter:

```java
public class MyController {
    public Account getAccount() {
        return [SELECT Id, Name FROM Account
        WHERE Id = :ApexPages.currentPage().getParameters().get('Id')];
    }
}
```

The following page markup calls the getAccount method from the controller above:

```xml
<apex:page controller="MyController">
    <apex:pageBlock title="Retrieving Query String Parameters">
        You are viewing the {!account.name} account.
    </apex:pageBlock>
</apex:page>
```

Note: For this example to render properly, you must associate the Visualforce page with a valid account record in the URL. For example, if 001D000000IRt53 is the account ID, the resulting URL should be:

https://Salesforce_instance/apex/MyFirstPage?id=001D000000IRt53

The getAccount method uses an embedded SOQL query to return the account specified by the id parameter in the URL of the page. To access id, the getAccount method uses the ApexPages namespace:

- First the currentPage method returns the PageReference instance for the current page. PageReference returns a reference to a Visualforce page, including its query string parameters.
- Using the page reference, use the getParameters method to return a map of the specified query string parameter names and values.
- Then a call to the get method specifying id returns the value of the id parameter itself.

Example: Navigating to a New Page as the Result of an Action Method

Any action method in a custom controller or controller extension can return a PageReference object as the result of the method. If the redirect attribute on the PageReference is set to true, the user navigates to the URL specified by the PageReference.

The following example shows how this can be implemented with a save method. In this example, the PageReference returned by the save method redirects the user to the detail page for the account record that was just saved:

```java
public class mySecondController {
    Account account;

    public Account getAccount() {
        if(account == null) account = new Account();
        return account;
    }
}
```
public PageReference save() {
    // Add the account to the database.
    insert account;
    // Send the user to the detail page for the new account.
    acctPage.setRedirect(true);
    return acctPage;
}

The following page markup calls the save method from the controller above. When a user clicks Save, he or she is redirected to the detail page for the account just created:

```apex
<apex:page controller="mySecondController" tabStyle="Account">
    <apex:sectionHeader title="New Account Edit Page" />
    <apex:form>
        <apex:pageBlock title="Create a New Account">
            <apex:pageBlockButtons location="bottom">
                <apex:commandButton action="!save" value="Save"/>
            </apex:pageBlockButtons>
            <apex:pageBlockSection title="Account Information">
                <apex:inputField id="accountName" value="!account.name"/>
                <apex:inputField id="accountSite" value="!account.site"/>
            </apex:pageBlockSection>
        </apex:pageBlock>
    </apex:form>
</apex:page>
```

IN THIS SECTION:

PageReference Constructors
PageReference Methods

PageReference Constructors

The following are constructors for PageReference.

IN THIS SECTION:

PageReference(partialURL)
Creates a new instance of the PageReference class using the specified URL.

PageReference(record)
Generate a new instance of the PageReference class for the specified sObject record.

PageReference (partialURL)
Creates a new instance of the PageReference class using the specified URL.
Signature

public PageReference(String partialURL)

Parameters

partialURL
  Type: String
  The partial URL of a page hosted on the Lightning platform or a full external URL. The following are some examples of the partialURL parameter values:
  • /apex/HelloWorld: refers to the Visualforce page located at http://mySalesforceInstance/apex/HelloWorld.
  • /recordID: refers to the detail page of a specified record.
  • http://www.google.com: refers to an external URL.

PageReference (record)

Generate a new instance of the PageReference class for the specified sObject record.

Signature

public PageReference(SObject record)

Parameters

record
  Type: SObject
  The sObject record that references the ApexPage. The reference must be an ApexPage.

SEE ALSO:
  Visualforce Developer Guide: apex:page
  SOAP API Developer Guide: ApexPage

PageReference Methods

The following are methods for PageReference. All are instance methods.

IN THIS SECTION:
  forResource(resourceName, path)
  Create a PageReference for nested content inside a zip static resource, by name and path.
  forResource(resourceName)
  Create a PageReference for a static resource, by name.
  getAnchor()
  Returns the name of the anchor referenced in the page’s URL. That is, the part of the URL after the hashtag (#).
  getContent()
  Returns the output of the page, as displayed to a user in a web browser.
getContentViewAsPDF()
Returns the page in PDF, regardless of the `<apex:page>` component’s `renderAs` attribute.

getCookies()
Returns a map of cookie names and cookie objects, where the key is a String of the cookie name and the value contains the cookie object with that name.

getHeaders()
Returns a map of the request headers, where the key string contains the name of the header, and the value string contains the value of the header.

getParameters()
Returns a map of the query string parameters for the PageReference; both POST and GET parameters are included. The key string contains the name of the parameter, while the value string contains the value of the parameter.

getRedirect()
Returns the current value of the PageReference object’s `redirect` attribute.

getUrl()
Returns the relative URL associated with the PageReference when it was originally defined, including any query string parameters and anchors.

setAnchor(ANCHOR)
Sets the URL’s anchor reference to the specified string.

setCookies(cookies)
Creates a list of cookie objects. Used in conjunction with the Cookie class.

setRedirect(redirect)
Sets the value of the PageReference object’s `redirect` attribute. If set to `true`, a redirect is performed through a client-side redirect.

forResource(resourceName, path)
Create a PageReference for nested content inside a zip static resource, by name and path.

Signature
public static System.PageReference forResource(String resourceName, String path)

Parameters
resourceName
Type: String
The resource name

path
Type: String
The resource path

Return Value
Type: System.PageReference
forResource(resourceName)
Create a PageReference for a static resource, by name.

Signature
public static System.PageReference forResource(String resourceName)

Parameters
resourceName
Type: String
The resource name

Return Value
Type: System.PageReference

getAnchor()
Returns the name of the anchor referenced in the page's URL. That is, the part of the URL after the hashtag (#).

Signature
public String getAnchor()

Return Value
Type: String

Note: Instances of PageReference returned by ApexPages.currentPage() have a null anchor attribute, because URL fragments are not sent to the Salesforce server during a request.

getContent()
Returns the output of the page, as displayed to a user in a web browser.

Signature
public Blob getContent()

Return Value
Type: Blob

Usage
The content of the returned Blob depends on how the page is rendered. If the page is rendered as a PDF file, it returns the PDF document. If the page is not rendered as PDF, it returns HTML. To access the content of the returned HTML as a string, use the toString Blob method.
Note: If you use `getContent` in a test method, the test method fails. `getContent` is treated as a callout in API version 34.0 and later.

This method can't be used in:
- Triggers
- Test methods
- Apex email services

If the Visualforce page has an error, an `ExecutionException` is thrown.

`getContentAsPDF()`

Returns the page in PDF, regardless of the `<apex:page>` component's `renderAs` attribute.

Signature

```
public Blob getContentAsPDF()
```

Return Value

Type: `Blob`

Usage

Note: If you use `getContentAsPDF` in a test method, the test method fails. `getContentAsPDF` is treated as a callout in API version 34.0 and later.

This method can't be used in:
- Triggers
- Test methods
- Apex email services

`getCookies()`

Returns a map of cookie names and cookie objects, where the key is a `String` of the cookie name and the the value contains the cookie object with that name.

Signature

```
public Map<String, System.Cookie> get_cookies()
```

Return Value

Type: `Map<String, System.Cookie>`

Usage

Used in conjunction with the `Cookie` class. Only returns cookies with the “apex__” prefix set by the `setCookies` method.
**getHeaders()**

Returns a map of the request headers, where the key string contains the name of the header, and the value string contains the value of the header.

**Signature**

```java
public Map<String, String> getHeaders()
```

**Return Value**

Type: `Map<String, String>`

**Usage**

This map can be modified and remains in scope for the PageReference object. For instance, you could do:

```java
PageReference.getHeaders().put('Date', '9/9/99');
```

For a description of request headers, see Request Headers.

**getParameters()**

Returns a map of the query string parameters for the PageReference; both POST and GET parameters are included. The key string contains the name of the parameter, while the value string contains the value of the parameter.

**Signature**

```java
public Map<String, String> getParameters()
```

**Return Value**

Type: `Map<String, String>`

**Usage**

This map can be modified and remains in scope for the PageReference object. For instance, you could do:

```java
PageReference.getParameters().put('id', myID);
```

Parameter keys are case-insensitive. For example:

```java
System.assert(
    ApexPages.currentPage().getParameters().get('myParamName') ==
    ApexPages.currentPage().getParameters().get('myparamname'));
```

**getRedirect()**

Returns the current value of the PageReference object’s `redirect` attribute.

**Signature**

```java
public Boolean getRedirect()
```
Return Value
Type: Boolean

Usage
Note that if the URL of the PageReference object is set to a website outside of the salesforce.com domain, the redirect always occurs, regardless of whether the redirect attribute is set to true or false.

getUrl()
Returns the relative URL associated with the PageReference when it was originally defined, including any query string parameters and anchors.

Signature
public String getUrl()

Return Value
Type: String

setAnchor(anchor)
Sets the URL's anchor reference to the specified string.

Signature
public System.PageReference setAnchor(String anchor)

Parameters
anchor
Type: String

Return Value
Type: System.PageReference

setCookies(cookies)
Creates a list of cookie objects. Used in conjunction with the Cookie class.

Signature
public Void setCookies(Cookie[] cookies)

Parameters
cookies
Type: System.Cookie[]
Return Value
Type: Void

Usage

Important:
- Cookie names and values set in Apex are URL encoded, that is, characters such as @ are replaced with a percent sign and their hexadecimal representation.
- The setCookies method adds the prefix “apex__” to the cookie names.
- Setting a cookie’s value to null sends a cookie with an empty string value instead of setting an expired attribute.
- After you create a cookie, the properties of the cookie can’t be changed.
- Be careful when storing sensitive information in cookies. Pages are cached regardless of a cookie value. If you use a cookie value to generate dynamic content, you should disable page caching. For more information, see “Cache Salesforce Sites Pages” in the Salesforce online help.

**setRedirect(redirect)**
Sets the value of the PageReference object’s redirect attribute. If set to true, a redirect is performed through a client side redirect.

Signature
```
public System.PageReference setRedirect(Boolean redirect)
```

Parameters
- `redirect`
  Type: Boolean

Return Value
Type: System.PageReference

Usage
This type of redirect performs an HTTP GET request, and flushes the view state, which uses POST. If set to false, the redirect is a server-side forward that preserves the view state if and only if the target page uses the same controller and contains the proper subset of extensions used by the source page.

Note that if the URL of the PageReference object is set to a website outside of the salesforce.com domain, or to a page with a different controller or controller extension, the redirect always occurs, regardless of whether the redirect attribute is set to true or false.

**Packaging Class**
Contains a method for obtaining information about managed and unlocked packages.

**Namespace**
System
Usage
In the context of a package, use the getCurrentPackageId method to retrieve the packageID.

getCurrentPackageId()
Returns the context packageID in managed and unlocked packages.

Signature
public String getCurrentPackageId()

Return Value
Type: String

Usage
For managed packages, this method can be combined with isCurrentUserLicensedForPackage(packageId) to retrieve the packageId at runtime. Then, use packageId to confirm that the contextual user is licensed to use that managed package.

Pattern Class
Represents a compiled representation of a regular expression.

Namespace
System

Pattern Methods
The following are methods for Pattern.

IN THIS SECTION:
    compile(regExp)
    Compiles the regular expression into a Pattern object.
    matcher(regExp)
    Creates a Matcher object that matches the input string regExp against this Pattern object.
    matches(regExp, stringToMatch)
    Compiles the regular expression regExp and tries to match it against the specified string. This method returns true if the specified string matches the regular expression, false otherwise.
    pattern()
    Returns the regular expression from which this Pattern object was compiled.
    quote(yourString)
    Returns a string that can be used to create a pattern that matches the string yourString as if it were a literal pattern.
    split(regExp)
    Returns a list that contains each substring of the String that matches this pattern.
split(regExp, limit)
Returns a list that contains each substring of the String that is terminated either by the regular expression \textit{regExp} that matches this pattern, or by the end of the String.

\textbf{compile(regExp)}
Compiles the regular expression into a Pattern object.

Signature
\begin{verbatim}
public static Pattern compile(String regExp)
\end{verbatim}

Parameters
\begin{itemize}
\item \texttt{regExp}
  \hspace{1cm} Type: String
\end{itemize}

Return Value
Type: System.Pattern

\textbf{matcher(regExp)}
Creates a Matcher object that matches the input string \texttt{regExp} against this Pattern object.

Signature
\begin{verbatim}
public Matcher matcher(String regExp)
\end{verbatim}

Parameters
\begin{itemize}
\item \texttt{regExp}
  \hspace{1cm} Type: String
\end{itemize}

Return Value
Type: Matcher

\textbf{matches(regExp, stringtoMatch)}
Compiles the regular expression \texttt{regExp} and tries to match it against the specified string. This method returns \texttt{true} if the specified string matches the regular expression, \texttt{false} otherwise.

Signature
\begin{verbatim}
public static Boolean matches(String regExp, String stringtoMatch)
\end{verbatim}

Parameters
\begin{itemize}
\item \texttt{regExp}
  \hspace{1cm} Type: String
\end{itemize}
stringToMatch
Type: String

Return Value
Type: Boolean

Usage
If a pattern is to be used multiple times, compiling it once and reusing it is more efficient than invoking this method each time.

Example
Note that the following code example:

```
Pattern.matches(regExp, input);
```
produces the same result as this code example:

```
Pattern.compile(regex).matcher(input).matches();
```

`pattern()`
Returs the regular expression from which this Pattern object was compiled.

Signature
```
public String pattern()
```

Return Value
Type: String

`quote(yourString)`
Returns a string that can be used to create a pattern that matches the string `yourString` as if it were a literal pattern.

Signature
```
public static String quote(String yourString)
```

Parameters
`yourString`
Type: String

Return Value
Type: String
Usage
Metacharacters (such as $ or ^) and escape sequences in the input string are treated as literal characters with no special meaning.

**split(regExp)**
Returns a list that contains each substring of the String that matches this pattern.

Signature
```java
public String[] split(String regExp)
```

Parameters
- `regExp`
  Type: `String`

Return Value
Type: `String[]`

Note: In API version 34.0 and earlier, a zero-width `regExp` value produces an empty list item at the beginning of the method's output.

Usage
The substrings are placed in the list in the order in which they occur in the String. If `regExp` does not match the pattern, the resulting list has just one element containing the original String.

**split(regExp, limit)**
Returns a list that contains each substring of the String that is terminated either by the regular expression `regExp` that matches this pattern, or by the end of the String.

Signature
```java
public String[] split(String regExp, Integer limit)
```

Parameters
- `regExp`
  Type: `String`
- `limit`
  Type: `Integer`

(Optional) Controls the number of times the pattern is applied and therefore affects the length of the list.

- If `limit` is greater than zero:
  - The pattern is applied a maximum of `(limit - 1)` times.
  - The list's length is no greater than `limit`.
  - The list's last entry contains all input beyond the last matched delimiter.
If \( limit \) is non-positive, the pattern is applied as many times as possible, and the list can have any length.

If \( limit \) is zero, the pattern is applied as many times as possible, the list can have any length, and trailing empty strings are discarded.

**Return Value**

**Type:** String[]

**Note:** In API version 34.0 and earlier, a zero-width \( \text{RegExp} \) value produces an empty list item at the beginning of the method’s output.

**Queueable Interface**

Enables the asynchronous execution of Apex jobs that can be monitored.

**Namespace**

System

**Usage**

To execute Apex as an asynchronous job, implement the `Queueable` interface and add the processing logic in your implementation of the `execute` method.

To implement the `Queueable` interface, you must first declare a class with the `implements` keyword as follows:

```java
public class MyQueueableClass implements Queueable {
}
```

Next, your class must provide an implementation for the following method:

```java
public void execute(QueueableContext context) {
    // Your code here
}
```

Your class and method implementation must be declared as `public` or `global`.

To submit your class for asynchronous execution, call the `System.enqueueJob` by passing it an instance of your class implementation of the `Queueable` interface as follows:

```java
ID jobID = System.enqueueJob(new MyQueueableClass());
```

**IN THIS SECTION:**

- Queueable Methods
- Queueable Example Implementation

**SEE ALSO:**

- Queueable Apex

**Queueable Methods**

The following are methods for `Queueable`. 
IN THIS SECTION:

execute(context)
Executes the queueable job.

**execute(context)**
Executes the queueable job.

**Signature**

```java
public void execute(QueueableContext context)
```

**Parameters**

*context*
Type: QueueableContext
Contains the job ID.

**Return Value**

Type: Void

**Queueable Example Implementation**

This example is an implementation of the Queueable interface. The `execute` method in this example inserts a new account.

```java
public class AsyncExecutionExample implements Queueable {
    public void execute(QueueableContext context) {
        Account a = new Account(Name='Acme',Phone='(415) 555-1212');
        insert a;
    }
}
```

To add this class as a job on the queue, call this method:

```java
ID jobID = System.enqueueJob(new AsyncExecutionExample());
```

After you submit your queueable class for execution, the job is added to the queue and will be processed when system resources become available. You can monitor the status of your job programatically by querying AsyncApexJob or through the user interface in Setup by entering Apex Jobs in the Quick Find box, then selecting Apex Jobs.

To query information about your submitted job, perform a SOQL query on AsyncApexJob by filtering on the job ID that the System.enqueueJob method returns. This example uses the jobID variable that was obtained in the previous example.

```sql
AsyncApexJob jobInfo = [SELECT Status,NumberOfErrors FROM AsyncApexJob WHERE Id=:jobID];
```

Similar to future jobs, queueable jobs don’t process batches, and so the number of processed batches and the number of total batches are always zero.

**Testing Queueable Jobs**

This example shows how to test the execution of a queueable job in a test method. A queueable job is an asynchronous process. To ensure that this process runs within the test method, the job is submitted to the queue between the `Test.startTest` and
Test.stopTest block. The system executes all asynchronous processes started in a test method synchronously after the Test.stopTest statement. Next, the test method verifies the results of the queueable job by querying the account that the job created.

```java
@isTest
class AsyncExecutionExampleTest {
    static testmethod void test1() {
        // startTest/stopTest block to force async processes to run in the test.
        Test.startTest();
        System.enqueueJob(new AsyncExecutionExample());
        Test.stopTest();

        // Validate that the job has run
        // by verifying that the record was created.
        // This query returns only the account created in test context by the Queueable class method.
        Account acct = [SELECT Name,Phone FROM Account WHERE Name='Acme' LIMIT 1];
        System.assertNotEquals(null, acct);
        System.assertEquals('(415) 555-1212', acct.Phone);
    }
}
```

**Note:** The ID of a queueable Apex job isn’t returned in test context—System.enqueueJob returns null in a running test.

QueueableContext Interface

Represents the parameter type of the `execute()` method in a class that implements the `Queueable` interface and contains the job ID. This interface is implemented internally by Apex.

**Namespace**

System

**QueueableContext Methods**

The following are methods for QueueableContext.

**IN THIS SECTION:**

- `getJobId()`
  Returns the ID of the submitted job that uses the `Queueable` interface.

- `getJobId()`
  Returns the ID of the submitted job that uses the `Queueable` interface.

**Signature**

```java
public ID getJobId()
```
Return Value
Type: ID
The ID of the submitted job.

QuickAction Class

Use Apex to request and process actions on objects that allow custom fields, on objects that appear in a Chatter feed, or on objects that are available globally.

Namespace
System

Example

In this sample, the trigger determines if the new contacts to be inserted are created by a quick action. If so, it sets the WhereFrom__c custom field to a value that depends on whether the quick action is global or local to the contact. Otherwise, if the inserted contacts don’t originate from a quick action, the WhereFrom__c field is set to 'NoAction'.

```
trigger accTrig2 on Contact (before insert) {
    for (Contact c : Trigger.new) {
        if (c.getQuickActionName() == QuickAction.CreateContact) {
            c.WhereFrom__c = 'GlobaAction1';
        } else if (c.getQuickActionName() == Schema.Account.QuickAction.CreateContact) {
            c.WhereFrom__c = 'AccountAction';
        } else if (c.getQuickActionName() == null) {
            c.WhereFrom__c = 'NoAction';
        } else {
            System.assert(false);
        }
    }
}
```

This sample performs a global action—QuickAction.CreateContact—on the passed-in contact object.

```
public Id globalCreate(Contact c) {
    QuickAction.QuickActionRequest req = new QuickAction.QuickActionRequest();
    req.quickActionName = QuickAction.CreateContact;
    req.record = c;
    QuickAction.QuickActionResult res = QuickAction.performQuickAction(req);
    return c.id;
}
```

SEE ALSO:
- QuickActionRequest Class
- QuickActionResult Class

QuickAction Methods

The following are methods for QuickAction. All methods are static.
IN THIS SECTION:

- `describeAvailableQuickActions(parentType)`
  Returns metadata information for the available quick actions of the provided parent object.

- `describeAvailableQuickActions(sObjectNames)`
  Returns the metadata information for the provided quick actions.

- `performQuickAction(quickActionRequest)`
  Performs the quick action specified in the quick action request and returns the action result.

- `performQuickAction(quickActionRequest, allOrNothing)`
  Performs the quick action specified in the quick action request with the option for partial success, and returns the result.

- `performQuickActions(quickActionRequests)`
  Performs the quick actions specified in the quick action request list and returns action results.

- `performQuickActions(quickActionRequests, allOrNothing)`
  Performs the quick actions specified in the quick action request list with the option for partial success, and returns action results.

### `describeAvailableQuickActions(parentType)`

Returns metadata information for the available quick actions of the provided parent object.

**Signature**

```java
public static List<QuickAction.DescribeAvailableQuickActionResult> describeAvailableQuickActions(String parentType)
```

**Parameters**

- `parentType`
  - Type: `String`
  - The parent object type. This can be an object type name ('Account') or 'Global' (meaning that this method is called at a global level and not an entity level).

**Return Value**

- Type: `List<QuickAction.DescribeAvailableQuickActionResult>`
  - The metadata information for the available quick actions of the parent object.

**Example**

```java
// Called for Account entity.
List<QuickAction.DescribeAvailableQuickActionResult> result1 =
    QuickAction.DescribeAvailableQuickActions('Account');

// Called at global level, not entity level.
List<QuickAction.DescribeAvailableQuickActionResult> result2 =
    QuickAction.DescribeAvailableQuickActions('Global');
```
**describeAvailableQuickActions(sObjectNames)**

Returns the metadata information for the provided quick actions.

**Signature**

```java
public static List<QuickAction.DescribeQuickActionResult>
describeAvailableQuickActions(List<String> sObjectNames)
```

**Parameters**

- `sObjectNames`  
  Type: `List<String>`  
  The names of the quick actions. The quick action name can contain the entity name if it is at the entity level (`'Account.QuickCreateContact'`), or 'Global' if used for the action at the global level (`'Global.CreateNewContact'`).

**Return Value**

Type: `List<QuickAction.DescribeQuickActionResult>`  
The metadata information for the provided quick actions.

**Example**

```java
// First 3 parameter values are for actions at the entity level.
// Last parameter is for an action at the global level.
List<QuickAction.DescribeQuickActionResult> result =
    QuickAction.DescribeQuickActions(new List<String> {
        'Account.QuickCreateContact', 'Opportunity.Update1',
        'Contact.Create1', 'Global.CreateNewContact' });
```

**performQuickAction(quickActionRequest)**

Performs the quick action specified in the quick action request and returns the action result.

**Signature**

```java
public static QuickAction.QuickActionResult
performQuickAction(QuickAction.QuickActionRequest quickActionRequest)
```

**Parameters**

- `quickActionRequest`  
  Type: `QuickAction.QuickActionRequest`

**Return Value**

Type: `QuickAction.QuickActionResult`

**performQuickAction(quickActionRequest, allOrNothing)**

Performs the quick action specified in the quick action request with the option for partial success, and returns the result.
Signature

```java
public static QuickAction.QuickActionResult performQuickAction(QuickAction.QuickActionRequest quickActionRequest, Boolean allOrNothing)
```

Parameters

- `quickActionRequest`  
  Type: `QuickAction.QuickActionRequest`

- `allOrNothing`  
  Type: `Boolean`

Specifies whether this operation allows partial success. If you specify `false` for this argument and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value

Type: `QuickAction.QuickActionResult`

**performQuickActions(quickActionRequests)**

Performs the quick actions specified in the quick action request list and returns action results.

Signature

```java
public static List<QuickAction.QuickActionResult> performQuickActions(List<QuickAction.QuickActionRequest> quickActionRequests)
```

Parameters

- `quickActionRequests`  
  Type: `List<QuickAction.QuickActionRequest>`

Return Value

Type: `List<QuickAction.QuickActionResult>`

**performQuickActions(quickActionRequests, allOrNothing)**

Performs the quick actions specified in the quick action request list with the option for partial success, and returns action results.

Signature

```java
public static List<QuickAction.QuickActionResult> performQuickActions(List<QuickAction.QuickActionRequest> quickActionRequests, Boolean allOrNothing)
```
Parameters

*quickActionRequests*
Type: List<QuickAction.QuickActionRequest>

*allOrNothing*
Type: Boolean

Specifies whether this operation allows partial success. If you specify `false` for this argument and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value
Type: List<QuickAction.QuickActionResult>

**RemoteObjectController**

Use `RemoteObjectController` to access the standard Visualforce Remote Objects operations in your Remote Objects override methods.

**Namespace**

*System*

**Usage**

`RemoteObjectController` is supported only for use within Remote Objects methods. See “Overriding Default Remote Objects Operations” in the Visualforce Developer’s Guide for examples of how to use `RemoteObjectController` with your Visualforce pages.

**RemoteObjectController Methods**

The following are methods for `RemoteObjectController`. All methods are static.

**IN THIS SECTION:**

- `create(type, fields)`
  Create a record in the database.
- `del(type, recordIds)`
  Delete records from the database.
- `retrieve(type, fields, criteria)`
  Retrieve records from the database.
- `updat(type, recordIds, fields)`
  Update records in the database.

**create(type, fields)**
Create a record in the database.
Signature

```java
public static Map<String, Object> create(String type, Map<String, Object> fields)
```

Parameters

type
  Type: String
  The sObject type on which create is being called.

fields
  Type: Map<String, Object>
  The fields and values to set on the new record.

Return Value
  Type: Map<String, Object>
  The return value is a map that represents the result of the Remote Objects operation. What is returned depends on the results of the call.

  **Success**
  A map that contains a single element with the ID of the record created. For example, `{ id: 'recordId' }`.

  **Failure**
  A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

---

del(type, recordIds)
Delete records from the database.

Signature

```java
public static Map<String, Object> del(String type, List<String> recordIds)
```

Parameters

type
  Type: String
  The sObject type on which delete is being called.

recordIds
  Type: List<String>
  The IDs of the records to be deleted.

Return Value
  Type: Map<String, Object>
  The return value is a map that represents the result of the Remote Objects operation. What is returned depends on how the method was called and the results of the call.
Single Delete—Success
A map that contains a single element with the ID of the record that was deleted. For example, `{ id: 'recordId' }`.

Batch Delete—Success
A map that contains a single element, an array of Map<String,Object> elements. Each element contains the ID of a record that was deleted and an array of errors, if there were any, for that record’s individual delete. For example, `{ results: [ { id: 'recordId', errors: ['errorMessage', ...] }, ... ] }`.

Single and Batch Delete—Failure
A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

`retrieve(type, fields, criteria)`
Retrieves records from the database.

**Signature**

```java
public static Map<String,Object> retrieve(String type, List<String> fields,
Map<String,Object> criteria)
```

**Parameters**

- `type`
  - Type: `String`
  - The sObject type on which `retrieve` is being called.

- `fields`
  - Type: `List<String>`
  - The fields to retrieve for each record.

- `criteria`
  - Type: `Map<String,Object>`
  - The criteria to use when performing the query.

**Return Value**

- Type: `Map<String,Object>`

The return value is a map that represents the result of the Remote Objects operation. What is returned depends on the results of the call.

**Success**

A map that contains the following elements.

- `records`: An array of records that match the query conditions.
- `type`: A string that indicates the type of the sObject that was retrieved.
- `size`: The number of records in the response.

**Failure**

A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.
**updat(type, recordIds, fields)**
Update records in the database.

**Signature**

```java
public static Map<String,Object> updat(String type, List<String> recordIds,
Map<String,Object> fields)
```

**Parameters**

- **type**
  - Type: String
  - The sObject type on which update is being called.

- **recordIds**
  - Type: List<String>
  - The IDs of the records to be updated.

- **fields**
  - Type: Map<String,Object>
  - The fields to update, and the value to update each field with.

**Return Value**

Type: Map<String,Object>

The return value is a map that represents the result of the Remote Objects operation. What is returned depends on how the method was called and the results of the call.

**Single Update—Success**

A map that contains a single element with the ID of the record that was updated. For example, `{ id: 'recordId' }`.

**Batch Update—Success**

A map that contains a single element, an array of Map<String,Object> elements. Each element contains the ID of the record updated and an array of errors, if there were any, for that record's individual update. For example, `{ results: [ { id: 'recordId', errors: ['errorMessage', ...]}, ...] }`.

**Single and Batch Update—Failure**

A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

**ResetPasswordResult Class**

Represents the result of a password reset.

**Namespace**

*System*

**ResetPasswordResult Methods**

The following are instance methods for ResetPasswordResult.
getPassword() Returns the password generated by the System.resetPassword method call.

**Signature**

```java
public String getPassword()
```

**Return Value**

Type: String

**RestContext Class**

Contains the RestRequest and RestResponse objects.

**Namespace**

System

**Usage**

Use the System.RestContext class to access the RestRequest and RestResponse objects in your Apex REST methods.

**Sample**

The following example shows how to use RestContext to access the RestRequest and RestResponse objects in an Apex REST method.

```java
@RestResource(urlMapping='/MyRestContextExample/*')
global with sharing class MyRestContextExample {

    @HttpGet
    global static Account doGet() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
        String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
        Account result = [SELECT Id, Name, Phone, Website FROM Account WHERE Id = :accountId];
        return result;
    }

}
```

**RestContext Properties**

The following are properties for RestContext.
IN THIS SECTION:

- request
  Returns the RestRequest for your Apex REST method.

- response
  Returns the RestResponse for your Apex REST method.

**request**

Returns the RestRequest for your Apex REST method.

**Signature**

```java
public RestRequest request {get; set;}
```

**Property Value**

Type: System.RestRequest

**response**

Returns the RestResponse for your Apex REST method.

**Signature**

```java
public RestResponse response {get; set;}
```

**Property Value**

Type: System.RestResponse

**RestRequest Class**

Represents an object used to pass data from an HTTP request to an Apex RESTful Web service method.

**Namespace**

System

**Usage**

Use the System.RestRequest class to pass request data into an Apex RESTful Web service method that is defined using one of the REST annotations.

**Example: An Apex Class with REST Annotated Methods**

The following example shows you how to implement the Apex REST API in Apex. This class exposes three methods that each handle a different HTTP request: GET, DELETE, and POST. You can call these annotated methods from a client by issuing HTTP requests.

```java
@RestResource(urlMapping='/Account/*')
global with sharing class MyRestResource {
```
@HttpDelete
global static void doDelete() {
    RestRequest req = RestContext.request;
    RestResponse res = RestContext.response;
    String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
    Account account = 
        [SELECT Id FROM Account WHERE Id = :accountId];
    delete account;
}

@HttpGet
global static Account doGet() {
    RestRequest req = RestContext.request;
    RestResponse res = RestContext.response;
    String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
    Account result = 
        [SELECT Id, Name, Phone, Website FROM Account WHERE Id = :accountId];
    return result;
}

@HttpPost
global static String doPost(String name,
    String phone, String website) {
    Account account = new Account();
    account.Name = name;
    account.phone = phone;
    account.website = website;
    insert account;
    return account.Id;
}

IN THIS SECTION:
RestRequest Constructors
RestRequest Properties
RestRequest Methods

RestRequest Constructors
The following are constructors for RestRequest.

IN THIS SECTION:
RestRequest()
Creates a new instance of the System.RestRequest class.

RestRequest()
Creates a new instance of the System.RestRequest class.
RestRequest Properties
The following are properties for RestRequest.

Note: While the RestRequest List and Map properties are read-only, their contents are read-write. You can modify them by calling the collection methods directly or you can use the associated RestRequest methods shown in the previous table.

IN THIS SECTION:

headers
Returns the headers that are received by the request.

httpMethod
Returns one of the supported HTTP request methods.

params
Returns the parameters that are received by the request.

remoteAddress
Returns the IP address of the client making the request.

requestBody
Returns or sets the body of the request.

requestURI
Returns or sets everything after the host in the HTTP request string.

resourcePath
Returns the REST resource path for the request.

headers
Returns the headers that are received by the request.

Signature

public Map<String, String> headers {get; set;}

Property Value

Type: Map<String, String>

httpMethod
Returns one of the supported HTTP request methods.

Signature

public String httpMethod {get; set;}

Property Value
Type: String
Possible values returned:
• DELETE
• GET
• HEAD
• PATCH
• POST
• PUT

**params**
Returns the parameters that are received by the request.

Signature
public Map <String, String> params {get; set;}

Property Value
Type: Map<String, String>

**remoteAddress**
Returns the IP address of the client making the request.

Signature
public String remoteAddress {get; set;}

Property Value
Type: String

**requestBody**
Returns or sets the body of the request.

Signature
public Blob requestBody {get; set;}

Property Value
Type: Blob
Usage

If the Apex method has no parameters, then Apex REST copies the HTTP request body into the RestRequest.requestBody property. If there are parameters, then Apex REST attempts to deserialize the data into those parameters and the data won't be deserialized into the RestRequest.requestBody property.

requestURI

Returns or sets everything after the host in the HTTP request string.

Signature

public String requestURI {get; set;}

Property Value

Type: String

Example

For example, if the request string is https://instance.salesforce.com/services/apexrest/Account/ then the requestURI is /Account/.

resourcePath

Returns the REST resource path for the request.

Signature

public String resourcePath {get; set;}

Property Value

Type: String

Example

For example, if the Apex REST class defines a urlMapping of /MyResource/*, the resourcePath property returns /services/apexrest/MyResource/*.

RestRequest Methods

The following are methods for RestRequest. All are instance methods.

Note: At runtime, you typically don't need to add a header or parameter to the RestRequest object because they are automatically deserialized into the corresponding properties. The following methods are intended for unit testing Apex REST classes. You can use them to add header or parameter values to the RestRequest object without having to recreate the REST method call.
addHeader(name, value)
Adds a header to the request header map.

addParameter(name, value)
Adds a parameter to the request params map.

addHeader(name, value)

Signature

public Void addHeader(String name, String value)

Parameters

name
Type: String

value
Type: String

Return Value
Type: Void

Usage
This method is intended for unit testing of Apex REST classes.
The following headers aren’t allowed:

- cookie
- set-cookie
- set-cookie2
- content-length
- authorization

If any of these headers are used, an Apex exception is thrown.

addParameter(name, value)

Signature

public Void addParameter(String name, String value)
Parameters

- **name**
  - Type: String
- **value**
  - Type: String

Return Value

Type: Void

Usage

This method is intended for unit testing of Apex REST classes.

**RestResponse Class**

Represents an object used to pass data from an Apex RESTful Web service method to an HTTP response.

**Namespace**

`System`

Usage

Use the `System.RestResponse` class to pass response data from an Apex RESTful web service method that is defined using one of the REST annotations on page 98.

IN THIS SECTION:

- RestResponse Constructors
- RestResponse Properties
- RestResponse Methods

**RestResponse Constructors**

The following are constructors for `RestResponse`.

IN THIS SECTION:

- `RestResponse()`
  - Creates a new instance of the `System.RestResponse` class.

**`RestResponse()`**

Creates a new instance of the `System.RestResponse` class.

Signature

`public RestResponse()`
RestResponse Properties

The following are properties for RestResponse.

Note: While the RestResponse List and Map properties are read-only, their contents are read-write. You can modify them by calling the collection methods directly or you can use of the associated RestResponse methods shown in the previous table.

IN THIS SECTION:

responseBody
Returns or sets the body of the response.

headers
Returns the headers to be sent to the response.

statusCode
Returns or sets the response status code.

responseBody

Returns or sets the body of the response.

Signature

public Blob responseBody {get; set;}

Property Value
Type: Blob

Usage
The response is either the serialized form of the method return value or it's the value of the responseBody property based on the following rules:

• If the method returns void, then Apex REST returns the response in the responseBody property.
• If the method returns a value, then Apex REST serializes the return value as the response.

headers

Returns the headers to be sent to the response.

Signature

public Map<String, String> headers {get; set;}

Property Value
Type: Map<String, String>
**statusCode**

Returns or sets the response status code.

**Signature**

```java
public Integer statuscode {get; set;}
```

**Property Value**

*Type: Integer*

**Status Codes**

The following are valid response status codes. The status code is returned by the `RestResponse.statusCode` property.

Note: If you set the `RestResponse.statusCode` property to a value that's not listed in the table, then an HTTP status of 500 is returned with the error message "Invalid status code for HTTP response: nnn" where nnn is the invalid status code value.

<table>

</table>

**RestResponse Methods**

The following are instance methods for `RestResponse`.

**Note:** At runtime, you typically don’t need to add a header to the `RestResponse` object because it’s automatically deserialized into the corresponding properties. The following methods are intended for unit testing Apex REST classes. You can use them to add header or parameter values to the `RestRequest` object without having to recreate the REST method call.

**IN THIS SECTION:**

- `addHeader(name, value)`
  Adds a header to the response header map.

**addHeader(name, value)**

Add a header to the response header map.

**Signature**

```
public Void addHeader(String name, String value)
```

**Parameters**

- `name`
  Type: `String`

- `value`
  Type: `String`

**Return Value**

Type: `Void`

**Usage**

The following headers aren’t allowed:

- `cookie`
- `set-cookie`
- `set-cookie2`
If any of these headers are used, an Apex exception is thrown.

**SandboxPostCopy Interface**

To make your sandbox environment business ready, automate data manipulation or business logic tasks. Extend this interface and add methods to perform post-copy tasks, then specify the class during sandbox creation.

**Namespace**

System

**Usage**

Create an Apex class that implements this interface. Specify your class during sandbox creation. After your sandbox is created, the `runApexClass(context)` method in your class runs using the automated process user's permissions.

**Important:** The SandboxPostCopy Apex class is executed at the end of the sandbox copy using a special Automated Process user that isn’t visible within the org. This user doesn’t have access to all object and features; therefore, the Apex script cannot access all objects and features. If the script fails, run the script after sandbox activation as a user with appropriate permissions.

IN THIS SECTION:

- **SandboxPostCopy Methods**
- **SandboxPostCopy Example Implementation**

These examples show a simple implementation of the SandboxPostCopy interface and a test for that implementation. To test your SandboxPostCopy implementation, use the `System.Test.testSandboxPostCopyScript()` method.

SEE ALSO:

- Tooling API: SandboxInfo
- Tooling API: SandboxProcess

**SandboxPostCopy Methods**

The following method is for `SandboxPostCopy`.

IN THIS SECTION:

- `runApexClass(context)`
  
  Executes actions in a new sandbox to prepare it for use. For example, add logic to this method to create users, run sanitizing code on records, and perform other setup tasks.

**runApexClass(context)**

Executes actions in a new sandbox to prepare it for use. For example, add logic to this method to create users, run sanitizing code on records, and perform other setup tasks.
Signature

public void runApexClass(System.SandboxContext context)

Parameters

context
    Type: System.SandboxContext
    The org ID, sandbox ID, and sandbox name for your sandbox. To work with these values, reference context.organizationId(), context.sandboxId(), and context.sandboxName() in your code.

Return Value

Type: void

SandboxPostCopy Example Implementation

These examples show a simple implementation of the SandboxPostCopy interface and a test for that implementation. To test your SandboxPostCopy implementation, use the System.Test.testSandboxPostCopyScript() method.

Important: The SandboxPostCopy Apex class is executed at the end of the sandbox copy using a special Automated Process user that isn't visible within the org. This user doesn't have access to all object and features; therefore, the Apex script cannot access all objects and features. If the script fails, run the script after sandbox activation as a user with appropriate permissions.

This is an example implementation of the System.SandboxPostCopy interface.

global class PrepareMySandbox implements SandboxPostCopy {
    global void runApexClass(SandboxContext context) {
        System.debug('Org ID: ' + context.organizationId());
        System.debug('Sandbox ID: ' + context.sandboxId());
        System.debug('Sandbox Name: ' + context.sandboxName());

        // Insert logic here to prepare the sandbox for use.
    }
}

The following example tests the implementation using the System.Test.testSandboxPostCopyScript() method. This method takes four parameters: a reference to a class that implements the SandboxPostCopy interface, and the three fields on the context object that you pass to the runApexClass(context) method.

@isTest
class PrepareMySandboxTest {

    @isTest
    static void testMySandboxPrep() {
        // Insert logic here to create records of the objects that the class you’re testing
        // manipulates.
        Test.startTest();

        Test.testSandboxPostCopyScript{
            new PrepareMySandbox(), UserInfo.getOrganizationId(),
            UserInfo.getOrganizationId(), UserInfo.getOrganizationName());
    }
Test.stopTest();

// Insert assert statements here to check that the records you created above have
// the values you expect.
}

For more information on testing, see Testing Apex.

**Scheduled Interface**

The class that implements this interface can be scheduled to run at different intervals.

**Namespace**

System

SEE ALSO:

Apex Scheduler

**Scheduled Methods**

The following are methods for `Schedulable`.

IN THIS SECTION:

- **execute(context)**
  
  Executes the scheduled Apex job.

**execute(context)**

Executes the scheduled Apex job.

**Signature**

```
public Void execute(SchedulableContext context)
```

**Parameters**

- **context**
  
  Type: `System.SchedulableContext`
  
  Contains the job ID.

**Return Value**

Type: Void
SchedulableContext Interface

Represents the parameter type of a method in a class that implements the Schedulable interface and contains the scheduled job ID. This interface is implemented internally by Apex.

Namespace
System

SEE ALSO:
  Schedulable Interface

SchedulableContext Methods

The following are methods for SchedulableContext.

IN THIS SECTION:
  getId()
  Returns the ID of the CronTrigger scheduled job.

getId()

Returns the ID of the CronTrigger scheduled job.

Signature

public Id getId()

Return Value

Type: ID

Schema Class

Contains methods for obtaining schema describe information.

Namespace
System

Schema Methods

The following are methods for Schema. All methods are static.

IN THIS SECTION:
  getGlobalDescribe()
  Returns a map of all sObject names (keys) to sObject tokens (values) for the standard and custom objects defined in your organization.
describeDataCategoryGroups(sObjectNames)
Returns a list of the category groups associated with the specified objects.

describeSObjects(sObjectTypes)
Describes metadata (field list and object properties) for the specified sObject or array of sObjects.

describeTabs()
Returns information about the standard and custom apps available to the running user.

GroupStructures(pairs)
Returns available category groups along with their data category structure for objects specified in the request.

getGlobalDescribe()
Returns a map of all sObject names (keys) to sObject tokens (values) for the standard and custom objects defined in your organization.

Signature
public static Map<String, Schema.SObjectType> getGlobalDescribe()

Return Value
Type: Map<String, Schema.SObjectType>

Usage
For more information, see Accessing All sObjects.

Example
Map<String, Schema.SObjectType> gd = Schema.getGlobalDescribe();

describeDataCategoryGroups(sObjectNames)
Returns a list of the category groups associated with the specified objects.

Signature
public static List<Schema.DescribeDataCategoryGroupResult> describeDataCategoryGroups(List<String> sObjectNames)

Parameters
sObjectName
Type: List<String>

Return Value
Type: List<Schema.DescribeDataCategoryGroupResult>
Usage

You can specify one of the following sObject names:

- KnowledgeArticleVersion—to retrieve category groups associated with article types.
- Question—to retrieve category groups associated with questions.

For more information and code examples using describeDataCategoryGroups, see Accessing All Data Categories Associated with an sObject.

For additional information about articles and questions, see "Work with Articles and Translations" and "Answers Overview" in the Salesforce online help.

describeSObjects (sObjectTypes)

Describes metadata (field list and object properties) for the specified sObject or array of sObjects.

Signature

```java
public static List<Schema.DescribeSObjectResult> describeSObjects(List<String> sObjectTypes)
```

Parameters

**sObjectTypes**

Type: `List<String>`

The `sObjectTypes` argument is a list of sObject type names you want to describe.

Return Value

Type: `List<Schema.DescribeSObjectResult>`

Usage

This method is similar to the `getDescribe` method on the `Schema.sObjectType` token. Unlike the `getDescribe` method, this method allows you to specify the sObject type dynamically and describe more than one sObject at a time.

You can first call `getGlobalDescribe` to retrieve a list of all objects for your organization, then iterate through the list and use `describeSObjects` to obtain metadata about individual objects.

Example

```java
Schema.DescribeSObjectResult[] descResult = Schema.describeSObjects(new String[]{'Account','Contact'});
```

describeTabs()

Returns information about the standard and custom apps available to the running user.

Signature

```java
public static List<Schema.DescribeTabSetResult> describeTabs()
```
Return Value
Type: List<Schema.DescribeTabSetResult>

Usage
An app is a group of tabs that works as a unit to provide application functionality. For example, two of the standard Salesforce apps are "Sales" and "Service."

The describeTabs method returns the minimum required metadata that can be used to render apps in another user interface. Typically, this call is used by partner applications to render Salesforce data in another user interface, such as in a mobile or connected app.

In the Salesforce user interface, users have access to standard apps (and might also have access to custom apps) as listed in the Salesforce app menu at the top of the page. Selecting an app name in the menu allows the user to switch between the listed apps at any time.

Note: The "All Tabs" tab isn't included in the list of described tabs.

Example
This example shows how to call the describeTabs method.

```apex
Schema.DescribeTabSetResult[] tabSetDesc = Schema.describeTabs();
```

This is a longer example that shows how to obtain describe metadata information for the Sales app. For each tab, the example gets describe information, such as the icon URL, whether the tab is custom or not, and colors. The describe information is written to the debug output.

```apex
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set describe for each app and display the info
for (DescribeTabSetResult tsr : tabSetDesc) {
    String appLabel = tsr.getLabel();
    System.debug('Label: ' + appLabel);
    System.debug('Logo URL: ' + tsr.getLogoUrl());
    System.debug('isSelected: ' + tsr.isSelected());
    String ns = tsr.getNamespace();
    if (ns == '') {
        System.debug('The ' + appLabel + ' app has no namespace defined.');
    } else {
        System.debug('Namespace: ' + ns);
    }
}

// Display tab info for the Sales app
if (appLabel == 'Sales') {
    List<Schema.DescribeTabResult> tabDesc = tsr.getTabs();
    System.debug('-- Tab information for the Sales app --');
    for (Schema.DescribeTabResult tr : tabDesc) {
        System.debug('getLabel: ' + tr.getLabel());
        System.debug('getColors: ' + tr.getColors());
        System.debug('getIconUrl: ' + tr.getIconUrl());
        System.debug('getIcons: ' + tr.getIcons());
        System.debug('getMiniIconUrl: ' + tr.getMiniIconUrl());
    }
}
```
GroupStructures(pairs)

Returns available category groups along with their data category structure for objects specified in the request.

Signature

```
public static List<Schema.DescribeDataCategoryGroupStructureResult> describeDataCategoryGroupStructures(List<Schema.DataCategoryGroupSobjectTypePair> pairs)
```

Parameters

`pairs`

Type: List<Schema.DataCategoryGroupSobjectTypePair>

The `pairs` argument is one or more category groups and objects to query Schema.DataCategoryGroupSobjectTypePairs. Visible data categories are retrieved for the specified object. For more information on data category group visibility, see “Data Category Visibility” in the Salesforce online help.

Return Value

Type: List<Schema.DescribeDataCategoryGroupStructureResult>
Search Class

Use the methods of the Search class to perform dynamic SOSL queries.

Namespace

System

Search Methods

The following are static methods for Search.

IN THIS SECTION:

find(searchQuery)
Performs a dynamic SOSL query that can include the SOSL WITH SNIPPET clause. Snippets provide more context for users in Salesforce Knowledge article search results.

query(query)
Performs a dynamic SOSL query.

suggest(searchQuery, sObjectType, suggestions)
Returns a list of records or Salesforce Knowledge articles whose names or titles match the user’s search query string. Use this method to provide users with shortcuts to navigate to relevant records or articles before they perform a search.

find(searchQuery)
Performs a dynamic SOSL query that can include the SOSL WITH SNIPPET clause. Snippets provide more context for users in Salesforce Knowledge article search results.

Signature

public static Search.SearchResults find(String searchQuery)

Parameters

searchQuery
Type: String
A SOSL query string.

Return Value

Type: Search.SearchResults

Usage

Use this method wherever a static SOSL query can be used, such as in regular assignment statements and for loops.
See Use Dynamic SOSL to Return Snippets on page 185.

SEE ALSO:

get(sObjectType)
Dynamic SOSL

**query (query)**

Performs a dynamic SOSL query.

**Signature**

```java
public static sObject[sObject[]] query(String query)
```

**Parameters**

- `query`
  - Type: `String`
  - A SOSL query string.
  - To create a SOSL query that includes the `WITH SNIPPET` clause, use the `Search.find(String searchQuery)` method instead.

**Return Value**

Type: `sObject[sObject[]]`

**Usage**

This method can be used wherever a static SOSL query can be used, such as in regular assignment statements and `for` loops.

For more information, see Dynamic SOSL.

**suggest (searchQuery, sObjectType, suggestions)**

Returns a list of records or Salesforce Knowledge articles whose names or titles match the user’s search query string. Use this method to provide users with shortcuts to navigate to relevant records or articles before they perform a search.

**Signature**

```java
public static Search.SuggestionResults suggest(String searchQuery, String sObjectType, Search.SuggestionOption suggestions)
```

**Parameters**

- `searchQuery`
  - Type: `String`
  - A SOSL query string.
- `sObjectType`
  - Type: `String`
  - An sObject type.
options
Type: Search.SuggestionOption
This object contains options that change the suggestion results.
If the searchQuery returns KnowledgeArticleVersion objects, pass an options parameter with a Search.SuggestionOption object that contains a language KnowledgeSuggestionFilter and a publish status KnowledgeSuggestionFilter.
For suggestions for all other record types, the only supported option is a limit, which sets the maximum number of suggestions returned.

Return Value
Type: SuggestionResults

Usage
Use this method to return:

Suggestions for Salesforce Knowledge articles (KnowledgeArticleVersion)
Salesforce Knowledge must be enabled in your organization. The user must have the "View Articles" permission enabled.
The articles suggested include only the articles the user can access, based on the data categories and article types the user has permissions to view.

Suggestions for other record types
The records suggested include only the records the user can access.
This method returns a record if its name field starts with the text in the search string. This method automatically appends an asterisk wildcard (*) at the end of the search string. Records that contain the search string within a word aren’t considered a match.
Records are suggested if the entire search string is found in the record name, in the same order as specified in the search string. For example, the text string national u is treated as national u* and returns “National Utility” and “National Urban Company” but not “National Company Utility” or “Urban National Company”.

Note: If the user’s search query contains quotation marks or wildcards, those symbols are automatically removed from the query string in the URI.

Suggest Salesforce Knowledge Articles

Security Class (Beta)
Contains methods to securely implement Apex applications.

Note: As a beta feature, stripInaccessible method is a preview and isn’t part of the “Services” under your master subscription agreement with Salesforce. Use this feature at your sole discretion, and make your purchase decisions only on the basis of generally available products and features. Salesforce doesn’t guarantee general availability of this feature within any particular time frame or at all, and we can discontinue it at any time. This feature is for evaluation purposes only, not for production use. It’s offered as is and isn’t supported, and Salesforce has no liability for any harm or damage arising out of or in connection with it. All restrictions, Salesforce reservation of rights, obligations concerning the Services, and terms for related Non-Salesforce Applications and Content apply equally to your use of this feature. You can provide feedback and suggestions for this feature in the Security.stripInaccessible group in the IdeaExchange.
Namespace

System

Usage

In the context of the current user’s create, read, update, or upsert access permission, use the Security class methods to:

- Strip fields that aren’t visible from query and subquery results
- Remove inaccessible fields before a DML operation without causing an exception
- Sanitize SObjects that have been deserialized from an untrusted source

IN THIS SECTION:

Security Methods

Security Methods

The following are methods for Security.

IN THIS SECTION:

stripInaccessible(accessCheckType, sourceRecords, enforceRootObjectCRUD)

Creates a list of sObjects from the source records, which are stripped of fields that fail the field-level security checks for the current user. The method also provides an option to enforce an object-level access check.

stripInaccessible(accessCheckType, sourceRecords)

Creates a list of sObjects from the source records, which are stripped of fields that fail the field-level security checks for the current user.

stripInaccessible(accessCheckType, sourceRecords, enforceRootObjectCRUD)

Creates a list of sObjects from the source records, which are stripped of fields that fail the field-level security checks for the current user.

Signature

public static System.SObjectAccessDecision stripInaccessible(System.AccessType accessCheckType, List<SObject> sourceRecords, Boolean enforceRootObjectCRUD)

Parameters

accessCheckType

Type: System.AccessType

Uses values from the AccessType enum. This parameter determines the type of field-level access check to be performed. To check the current user’s field-level access, use the Schema.DescribeFieldResult methods — isCreatable(), isAccessible(), or isUpdatable().

sourceRecords

Type: List<SObject>

A list of sObjects to be checked for fields that aren’t accessible in the context of the current user’s operation.
enforceRootObjectCRUD
Type: Boolean
Indicates whether an object-level access check is performed. If this parameter is set to true and the access check fails, the method throws an exception. The default value of this optional parameter is true.

Return Value
Type: System.SObjectAccessDecision

Example
In this example, the user doesn’t have permission to create the Probability field of an Opportunity.

```apex
List<Opportunity> opportunities = new List<Opportunity>{
    new Opportunity(Name='Opportunity1'),
    new Opportunity(Name='Opportunity2', Probability=95)
};

// Strip fields that are not creatable
SObjectAccessDecision decision = Security.stripInaccessible(
    AccessType.CREATABLE,
    opportunities);

// Print stripped records
for (SObject strippedOpportunity : decision.getRecords()) {
    System.debug(strippedOpportunity);
}

// Print modified indexes
System.debug(decision.getModifiedIndexes());

// Print removed fields
System.debug(decision.getRemovedFields());

// Lines from output log
// |DEBUG|Opportunity:{Name=Opportunity1}
// |DEBUG|Opportunity:{Name=Opportunity2}
// |DEBUG|{1}
// |DEBUG|{Opportunity={Probability}}
```

stripInaccessible(accessCheckType, sourceRecords)
Creates a list of SObjects from the source records, which are stripped of fields that fail the field-level security checks for the current user.

Signature
```
public static System.SObjectAccessDecision stripInaccessible(System.AccessType accessCheckType, List<SObject> sourceRecords)
```
Parameters

accessCheckType
Type: System.AccessType

Uses values from the AccessType enum. This parameter determines the type of field-level access check to be performed. To check the current user's field-level access, use the Schema.DescribeFieldResult methods — isCreatable(), isAccessible(), or isUpdatable().

sourceRecords
Type: List<SObject>

A list of sObjects to be checked for fields that aren't accessible in the context of the current user's operation.

Return Value
Type: System.SObjectAccessDecision

Example

In this example, the user doesn't have permission to read the ActualCost field of a Campaign.

```java
List<Campaign> campaigns = new List<Campaign> {
    new Campaign(Name='Campaign1', BudgetedCost=1000, ActualCost=2000),
    new Campaign(Name='Campaign2', BudgetedCost=4000, ActualCost=1500)
};
insert campaigns;

// Strip fields that are not readable
SObjectAccessDecision decision = Security.stripInaccessible(
    AccessType.READABLE,
    [SELECT Name, BudgetedCost, ActualCost from Campaign]);

// Print stripped records
for (SObject strippedCampaign : decision.getRecords()) {
    System.debug(strippedCampaign); // Does not display ActualCost
}

// Print modified indexes
System.debug(decision.getModifiedIndexes());

// Print removed fields
System.debug(decision.getRemovedFields());

//Lines from output log
//|DEBUG|Campaign:{Name=Campaign1, BudgetedCost=1000, Id=701xx00000011nhAAA}
//|DEBUG|Campaign:{Name=Campaign2, BudgetedCost=4000, Id=701xx00000011niAAA}
//|DEBUG|{0, 1}
//|DEBUG|{Campaign={ActualCost}}
```

SelectOption Class

A SelectOption object specifies one of the possible values for a Visualforce selectCheckboxes, selectList, or selectRadio component.
Namespace

SelectOption consists of a label that is displayed to the end user, and a value that is returned to the controller if the option is selected. A SelectOption can also be displayed in a disabled state, so that a user cannot select it as an option, but can still view it.

Instantiation

In a custom controller or controller extension, you can instantiate a SelectOption in one of the following ways:

- \[
  \text{new SelectOption} \left( \text{value}, \text{label}, \text{isDisabled} \right) \]

  where \text{value} is the String that is returned to the controller if the option is selected by a user, \text{label} is the String that is displayed to the user as the option choice, and \text{isDisabled} is a Boolean that, if true, specifies that the user cannot select the option, but can still view it.

- \[
  \text{new SelectOption} \left( \text{value}, \text{label} \right) \]

  where \text{value} is the String that is returned to the controller if the option is selected by a user, and \text{label} is the String that is displayed to the user as the option choice. Because a value for \text{isDisabled} is not specified, the user can both view and select the option.

Example

The following example shows how a list of SelectOptions objects can be used to provide possible values for a selectCheckboxes component on a Visualforce page. In the following custom controller, the \text{getItems} method defines and returns the list of possible SelectOption objects:

```java
public class sampleCon {

    String[] countries = new String[]{};

    public PageReference test() {
        return null;
    }

    public List<SelectOption> getItems() {
        List<SelectOption> options = new List<SelectOption>();
        options.add(new SelectOption('US','US'));
        options.add(new SelectOption('CANADA','Canada'));
        options.add(new SelectOption('MEXICO','Mexico'));
        return options;
    }

    public String[] getCountries() {
        return countries;
    }

    public void setCountries(String[] countries) {
        this.countries = countries;
    }
}
```
In the following page markup, the `<apex:selectOptions>` tag uses the `getItems` method from the controller above to retrieve the list of possible values. Because `<apex:selectOptions>` is a child of the `<apex:selectCheckboxes>` tag, the options are displayed as checkboxes:

```xml
<apex:page controller="sampleCon">
  <apex:form>
    <apex:selectCheckboxes value="{!countries}">
      <apex:selectOptions value="{!items}"/>
    </apex:selectCheckboxes>
    <br/>
    <apex:commandButton value="Test" action="{!test}" rerender="out" status="status"/>
  </apex:form>
  <apex:outputPanel id="out">
    <apex:actionstatus id="status" startText="testing...">
      <apex:facet name="stop">
        <p>You have selected:</p>
        <apex:outputPanel>
          <apex:dataList value="{!countries}" var="c">{!c}</apex:dataList>
        </apex:outputPanel>
      </apex:facet>
    </apex:actionstatus>
  </apex:outputPanel>
</apex:page>
```

**IN THIS SECTION:**
- **SelectOption Constructors**
- **SelectOption Methods**

**SelectOption Constructors**

The following are constructors for `SelectOption`.

**IN THIS SECTION:**
- **SelectOption(value, label)**
  Creates a new instance of the `SelectOption` class using the specified value and label.
- **SelectOption(value, label, isDisabled)**
  Creates a new instance of the `SelectOption` class using the specified value, label, and disabled setting.

**SelectOption(value, label)**

Creates a new instance of the `SelectOption` class using the specified value and label.

**Signature**

```java
public SelectOption(String value, String label)
```

**Parameters**

- `value`
  Type: `String`
The string that is returned to the Visualforce controller if the option is selected by a user.

**label**

Type: **String**

The string that is displayed to the user as the option choice.

### SelectOption(value, label, isDisabled)

Creates a new instance of the `SelectOption` class using the specified value, label, and disabled setting.

**Signature**

```java
public SelectOption(String value, String label, Boolean isDisabled)
```

**Parameters**

- **value**
  
  Type: **String**
  
  The string that is returned to the Visualforce controller if the option is selected by a user.

- **label**
  
  Type: **String**
  
  The string that is displayed to the user as the option choice.

- **isDisabled**
  
  Type: **Boolean**
  
  If set to true, the option can’t be selected by the user but can still be viewed.

### SelectOption Methods

The following are methods for `SelectOption`. All are instance methods.

**IN THIS SECTION:**

- `getDisabled()`: Returns the current value of the SelectOption object’s `isDisabled` attribute.
- `getEscapeItem()`: Returns the current value of the SelectOption object’s `itemEscaped` attribute.
- `getLabel()`: Returns the option label that is displayed to the user.
- `getValue()`: Returns the option value that is returned to the controller if a user selects the option.
- `setDisabled(isDisabled)`: Sets the value of the SelectOption object’s `isDisabled` attribute.
- `setEscapeItem(itemsEscaped)`: Sets the value of the SelectOption object’s `itemEscaped` attribute.
- `setLabel(label)`: Sets the value of the option label that is displayed to the user.
setValue(value)
Sets the value of the option value that is returned to the controller if a user selects the option.

getDisabled()
Returns the current value of the SelectOption object's isDisabled attribute.

Signature
public Boolean getDisabled()

Return Value
Type: Boolean

Usage
If isDisabled is set to true, the user can view the option, but cannot select it. If isDisabled is set to false, the user can both view and select the option.

getEscapeItem()
Returns the current value of the SelectOption object's itemEscaped attribute.

Signature
public Boolean getEscapeItem()

Return Value
Type: Boolean

Usage
If itemEscaped is set to true, sensitive HTML and XML characters are escaped in the HTML output generated by this component. If itemEscaped is set to false, items are rendered as written.

g.getLabel()
Returns the option label that is displayed to the user.

Signature
public String getLabel()

Return Value
Type: String
**getValue()**
Returns the option value that is returned to the controller if a user selects the option.

Signature
```
public String getValue()
```

Return Value
Type: String

**setDisabled(isDisabled)**
Sets the value of the SelectOption object’s `isDisabled` attribute.

Signature
```
public Void setDisabled(Boolean isDisabled)
```

Parameters
- `isDisabled`
  Type: Boolean

Return Value
Type: Void

Usage
If `isDisabled` is set to `true`, the user can view the option, but cannot select it. If `isDisabled` is set to `false`, the user can both view and select the option.

**setEscapeItem(itemsEscaped)**
Sets the value of the SelectOption object’s `itemEscaped` attribute.

Signature
```
public Void setEscapeItem(Boolean itemsEscaped)
```

Parameters
- `itemsEscaped`
  Type: Boolean

Return Value
Type: Void
Usage

If `itemEscaped` is set to `true`, sensitive HTML and XML characters are escaped in the HTML output generated by this component. If `itemEscaped` is set to `false`, items are rendered as written.

**setLabel(label)**

Sets the value of the option label that is displayed to the user.

**Signature**

```java
public Void setLabel(String label)
```

**Parameters**

`label`

Type: `String`

**Return Value**

Type: `Void`

**setValue(value)**

Sets the value of the option value that is returned to the controller if a user selects the option.

**Signature**

```java
public Void setValue(String value)
```

**Parameters**

`value`

Type: `String`

**Return Value**

Type: `Void`

**Set Class**

Represents a collection of unique elements with no duplicate values.

**Namespace**

`System`
Usage
The Set methods work on a set, that is, an unordered collection of elements that was initialized using the `set` keyword. Set elements can be of any data type—primitive types, collections, sObjects, user-defined types, and built-in Apex types. Set methods are all instance methods, that is, they all operate on a particular instance of a Set. The following are the instance methods for sets.

Note:
- Uniqueness of set elements of user-defined types is determined by the `equals` and `hashCode` methods, which you provide in your classes. Uniqueness of all other non-primitive types is determined by comparing the objects’ fields.
- If the set contains String elements, the elements are case-sensitive. Two set elements that differ only by case are considered distinct.

For more information on sets, see Sets on page 32.

IN THIS SECTION:
- Set Constructors
- Set Methods

Set Constructors
The following are constructors for `Set`.

IN THIS SECTION:
- `Set<T>()`
  Creates a new instance of the `Set` class. A set can hold elements of any data type T.
- `Set<T>(setToCopy)`
  Creates a new instance of the `Set` class by copying the elements of the specified set. T is the data type of the elements in both sets and can be any data type.
- `Set<T>(listToCopy)`
  Creates a new instance of the `Set` class by copying the list elements. T is the data type of the elements in the set and list and can be any data type.

`Set<T>()`
Creates a new instance of the `Set` class. A set can hold elements of any data type T.

Signature
```
public Set<T>()
```

Example
```
// Create a set of strings
Set<String> s1 = new Set<String>();
// Add two strings to it
s1.add('item1');
s1.add('item2');
```
**Set<T>(setToCopy)**

Creates a new instance of the `Set` class by copying the elements of the specified set. `T` is the data type of the elements in both sets and can be any data type.

**Signature**

```java
public Set<T>(Set<T> setToCopy)
```

**Parameters**

`setToCopy`

Type: `Set<T>`

The set to initialize this set with.

**Example**

```java
Set<String> s1 = new Set<String>();
s1.add('item1');
s1.add('item2');
Set<String> s2 = new Set<String>(s1);
// The set elements in s2 are copied from s1
System.debug(s2);
```

**Set<T>(listToCopy)**

Creates a new instance of the `Set` class by coping the list elements. `T` is the data type of the elements in the set and list and can be any data type.

**Signature**

```java
public Set<T>(List<T> listToCopy)
```

**Parameters**

`listToCopy`

Type: `Integer`

The list to copy the elements of into this set.

**Example**

```java
List<Integer> ls = new List<Integer>();
ls.add(1);
ls.add(2);
// Create a set based on a list
Set<Integer> s1 = new Set<Integer>(ls);
// Elements are copied from the list to this set
System.debug(s1); // DEBUG: [1, 2]
```
Set Methods

The following are methods for Set. All are instance methods.

IN THIS SECTION:

- **add(setElement)**
  Adds an element to the set if it is not already present.

- **addAll(fromList)**
  Adds all of the elements in the specified list to the set if they are not already present.

- **addAll(fromSet)**
  Adds all of the elements in the specified set to the set that calls the method if they are not already present.

- **clear()**
  Removes all of the elements from the set.

- **clone()**
  Makes a duplicate copy of the set.

- **contains(setElement)**
  Returns `true` if the set contains the specified element.

- **containsAll(listToCompare)**
  Returns `true` if the set contains all of the elements in the specified list. The list must be of the same type as the set that calls the method.

- **containsAll(setToCompare)**
  Returns `true` if the set contains all of the elements in the specified set. The specified set must be of the same type as the original set that calls the method.

- **equals(set2)**
  Compares this set with the specified set and returns `true` if both sets are equal; otherwise, returns `false`.

- **hashCode()**
  Returns the hashcode corresponding to this set and its contents.

- **isEmpty()**
  Returns `true` if the set has zero elements.

- **remove(setElement)**
  Removes the specified element from the set if it is present.

- **removeAll(listOfElementsToRemove)**
  Removes the elements in the specified list from the set if they are present.

- **removeAll(setOfElementsToRemove)**
  Removes the elements in the specified set from the original set if they are present.

- **retainAll(listOfElementsToRetain)**
  Retains only the elements in this set that are contained in the specified list.

- **retainAll(setOfElementsToRetain)**
  Retains only the elements in the original set that are contained in the specified set.

- **size()**
  Returns the number of elements in the set (its cardinality).
add(setElement)
Adds an element to the set if it is not already present.

Signature
public Boolean add(Object setElement)

Parameters
setElement
Type: Object

Return Value
Type: Boolean

Usage
This method returns true if the original set changed as a result of the call. For example:

```java
Set<String> myString = new Set<String>{'a', 'b', 'c'};
Boolean result = myString.add('d');
System.assertEquals(true, result);
```

addAll(fromList)
Adds all of the elements in the specified list to the set if they are not already present.

Signature
public Boolean addAll(List<Object> fromList)

Parameters
fromList
Type: List

Return Value
Type: Boolean
Returns true if the original set changed as a result of the call.

Usage
This method results in the union of the list and the set. The list must be of the same type as the set that calls the method.

addAll(fromSet)
Adds all of the elements in the specified set to the set that calls the method if they are not already present.
Signature

```java
public Boolean addAll(Set<Object> fromSet)
```

Parameters

- **fromSet**
  Type: `Set<Object>`

Return Value

Type: `Boolean`

This method returns `true` if the original set changed as a result of the call.

Usage

This method results in the union of the two sets. The specified set must be of the same type as the original set that calls the method.

Example

```java
Set<String> myString = new Set<String>{'a', 'b'};
Set<String> sString = new Set<String>{'c'};

Boolean result1 = myString.addAll(sString);
System.assertEquals(true, result1);
```

clear()

Removes all of the elements from the set.

Signature

```java
public Void clear()
```

Return Value

Type: Void

clone()

Makes a duplicate copy of the set.

Signature

```java
public Set<Object> clone()
```

Return Value

Type: `Set` (of same type)
contains(setElement)

Returns `true` if the set contains the specified element.

Signature

```java
public Boolean contains(Object setElement)
```

Parameters

- `setElement`
  
  Type: Object

Return Value

Type: Boolean

Example

```java
Set<String> myString = new Set<String>{'a', 'b'};
Boolean result = myString.contains('z');
System.assertEquals(false, result);
```

containsAll(listToCompare)

Returns `true` if the set contains all of the elements in the specified list. The list must be of the same type as the set that calls the method.

Signature

```java
public Boolean containsAll(List<Object> listToCompare)
```

Parameters

- `listToCompare`
  
  Type: List<Object>

Return Value

Type: Boolean

containsAll(setToCompare)

Returns `true` if the set contains all of the elements in the specified set. The specified set must be of the same type as the original set that calls the method.

Signature

```java
public Boolean containsAll(Set<Object> setToCompare)
```
**equals(set2)**

Compares this set with the specified set and returns `true` if both sets are equal; otherwise, returns `false`.

**Signature**

```java
public Boolean equals(Set<Object> set2)
```

**Parameters**

`set2`

Type: `Set<Object>`

The `set2` argument is the set to compare this set with.

**Return Value**

Type: `Boolean`

**Usage**

Two sets are equal if their elements are equal, regardless of their order. The `==` operator is used to compare the elements of the sets. The `==` operator is equivalent to calling the `equals` method, so you can call `set1.equals(set2);` instead of `set1 == set2;`.

**hashCode()**

Returns the hashcode corresponding to this set and its contents.
Signature
public Integer hashCode()

Return Value
Type: Integer

isEmpty()
Returns true if the set has zero elements.

Signature
public Boolean isEmpty()

Return Value
Type: Boolean

Example
Set<Integer> mySet = new Set<Integer>();
Boolean result = mySet.isEmpty();
System.assertEquals(true, result);

remove(setElement)
Removes the specified element from the set if it is present.

Signature
public Boolean remove(Object setElement)

Parameters
setElement
Type: Object

Return Value
Type: Boolean
Returns true if the original set changed as a result of the call.

removeAll(listOfElementsToRemove)
Removes the elements in the specified list from the set if they are present.

Signature
public Boolean removeAll(List<Object> listOfElementsToRemove)
Parameters

`listOfElementsToRemove`

Type: `List<Object>`

Return Value

Type: `Boolean`

Returns `true` if the original set changed as a result of the call.

Usage

This method results in the relative complement of the two sets. The list must be of the same type as the set that calls the method.

Example

```java
Set<Integer> mySet = new Set<Integer>{1, 2, 3};
List<Integer> myList = new List<Integer>{1, 3};
Boolean result = mySet.removeAll(myList);
System.assertEquals(true, result);
Integer result2 = mySet.size();
System.assertEquals(1, result2);
```

`removeAll(setOfElementsToRemove)`

Removes the elements in the specified set from the original set if they are present.

Signature

```java
public Boolean removeAll(Set<Object> setOfElementsToRemove)
```

Parameters

`setOfElementsToRemove`

Type: `Set<Object>`

Return Value

Type: `Boolean`

This method returns `true` if the original set changed as a result of the call.

Usage

This method results in the relative complement of the two sets. The specified set must be of the same type as the original set that calls the method.

`retainAll(listOfElementsToRetain)`

Retains only the elements in this set that are contained in the specified list.
Signature

```java
public Boolean retainAll(List<Object> listOfElementsToRetain)
```

Parameters

```java
listOfElementsToRetain
```
Type: `List<Object>`

Return Value

Type: `Boolean`

This method returns `true` if the original set changed as a result of the call.

Usage

This method results in the intersection of the list and the set. The list must be of the same type as the set that calls the method.

Example

```java
Set<Integer> mySet = new Set<Integer>{1, 2, 3};
List<Integer> myList = new List<Integer>{1, 3};
Boolean result = mySet.retainAll(myList);
System.assertEquals(true, result);
```

`retainAll(setOfElementsToRetain)`

Retains only the elements in the original set that are contained in the specified set.

Signature

```java
public Boolean retainAll(Set setOfElementsToRetain)
```

Parameters

```java
setOfElementsToRetain
```
Type: `Set`

Return Value

Type: `Boolean`

Returns `true` if the original set changed as a result of the call.

Usage

This method results in the intersection of the two sets. The specified set must be of the same type as the original set that calls the method.

`size()`

Returns the number of elements in the set (its cardinality).
Signature

```java
public Integer size()
```

Return Value

Type: Integer

Example

```java
Set<Integer> mySet = new Set<Integer>{1, 2, 3};
List<Integer> myList = new List<Integer>{1, 3};
Boolean result = mySet.retainAll(myList);

System.assertEquals(true, result);

Integer result2 = mySet.size();
System.assertEquals(2, result2);
```

Site Class

Use the Site Class to manage your Lightning Platform sites.

Namespace

```java
System
```

Usage

If `site.createPortalUser` throws an exception, it returns null and the site system admin receives an email. For more information on sites, see “Salesforce Sites” in Salesforce Help.

Salesforce Sites Examples

The following example creates a class, `SiteRegisterController`, which is used with a Visualforce page (see markup below) to register new Customer Portal users.

Note: In the example below, you must enter the account ID of the account that you want to associate with new portal users. You must also add the account owner to the role hierarchy for this code example to work. For more information, see “Setting Up Your Customer Portal” in Salesforce Help.

```java
/**
 * An Apex class that creates a portal user
 */
public class SiteRegisterController {
    // PORTAL_ACCOUNT_ID is the account on which the contact will be created on
    // and then enabled as a portal user.
    //Enter the account ID in place of <portal_account_id> below.
    private static Id PORTAL_ACCOUNT_ID = '<portal_account_id>';

    public SiteRegisterController () {
    }
}
public String username {get; set;}
public String email {get; set;}
public String password {get; set {password = value == null ? value : value.trim();}}
public String confirmPassword {get; set {confirmPassword = value == null ? value : value.trim();}}
public String communityNickname {get; set {communityNickname = value == null ? value : value.trim();}}

private boolean isValidPassword() {
    return password == confirmPassword;
}

public PageReference registerUser() {
    // If password is null, a random password is sent to the user
    if (!isValidPassword()) {
        ApexPages.Message msg = new ApexPages.Message(ApexPages.Severity.ERROR,
                                                        Label.site.passwords_dont_match);
        ApexPages.addMessage(msg);
        return null;
    }
    User u = new User();
    u.Username = username;
    u.Email = email;
    u.CommunityNickname = communityNickname;

    String accountId = PORTAL_ACCOUNT_ID;

    // lastName is a required field on user, but if it isn't specified,
    // the code uses the username
    String userId = Site.createPortalUser(u, accountId, password);
    if (userId != null) {
        if (password != null && password.length() > 1) {
            return Site.login(username, password, null);
        } else {
            PageReference page = System.Page.SiteRegisterConfirm;
            page.setRedirect(true);
            return page;
        }
    }
    return null;
}

/**
 * Test class.
 */
@isTest
private class SiteRegisterControllerTest {
    // Test method for verifying the positive test case
    static testMethod void testRegistration() {
        SiteRegisterController controller = new SiteRegisterController();
    }
}
controller.username = 'test@force.com';
controller.email = 'test@force.com';
controller.communityNickname = 'test';
// registerUser always returns null when the page isn't accessed as a guest user
System.assert(controller.registerUser() == null);
controller.password = 'abcd1234';
controller.confirmPassword = 'abcd123';
System.assert(controller.registerUser() == null);
}

The following is the Visualforce registration page that uses the SiteRegisterController Apex controller above:

```
<apex:page id="Registration" showHeader="false" controller="SiteRegisterController" standardStylesheets="true">
<apex:outputText value="Registration"/>
<br/>
<apex:form id="theForm">
<apex:messages id="msg" styleClass="errorMsg" layout="table" style="margin-top:1em;"/>
<apex:panelGrid columns="2" style="margin-top:1em;">
<apex:outputLabel value="{$Label.site.username}" for="username"/>
<apex:inputText required="true" id="username" value="{!username}"/>
<apex:outputLabel value="{$Label.site.community_nickname}" for="communityNickname"/>
<apex:inputText required="true" id="communityNickname" required="true" value="{!communityNickname}"/>
<apex:outputLabel value="{$Label.site.email}" for="email"/>
<apex:inputText required="true" id="email" required="true" value="{!email}"/>
<apex:outputLabel value="{$Label.site.password}" for="password"/>
<apex:inputSecret id="password" value="{!password}"/>
<apex:outputLabel value="{$Label.site.confirm_password}" for="confirmPassword"/>
<apex:inputSecret id="confirmPassword" value="{!confirmPassword}"/>
<apex:outputText value=""/>
<apex:commandButton action="{!registerUser}" value="{$Label.site.submit}" id="submit"/>
</apex:panelGrid>
</apex:form>
</apex:page>
```

The sample code for the createPersonAccountPortalUser method is nearly identical to the sample code above, with the following changes:

- Replace all instances of PORTAL_ACCOUNT_ID with OWNER_ID.
- Determine the ownerID instead of the accountID, and use the createPersonAccountPortalUser method instead of the CreatePortalUser method by replacing the following code block:

```java
String accountId = PORTAL_ACCOUNT_ID;
String userId = Site.createPortalUser(u, accountId, password);
```

with

```java
String ownerID = OWNER_ID;
String userId = Site.createPersonAccountPortalUser(u, ownerID, password);
```
Site Methods

The following are methods for Site. All methods are static.

IN THIS SECTION:

- `changePassword(newPassword, verifyNewPassword, oldPassword)`
  Changes the password of the current user.

- `createExternalUser(user, accountId)`
  Creates a community or a portal user for the given account and associates it with the community.

- `createExternalUser(user, accountId, password)`
  Creates a community or a portal user for the given account and associates it with the community. This method sends an email with the specified password to the user.

- `createExternalUser(user, accountId, password, sendEmailConfirmation)`
  Creates a community or portal user and associates it with the given account. This method sends the user an email with the specified password and a new user confirmation email.

- `createPersonAccountPortalUser(user, ownerId, password)`
  Creates a person account using the default record type defined on the guest user's profile, then enables it for the site's portal.

- `createPersonAccountPortalUser(user, ownerId, recordTypeId, password)`
  Creates a person account using the specified `recordTypeId`, then enables it for the site's portal.

- `createPortalUser(user, accountId, password, sendEmailConfirmation)`
  Creates a portal user for the given account and associates it with the site's portal.

- `forgotPassword(username, emailTemplateName)`
  Resets the user's password and sends an email to the user with the user's new password. You can specify a custom email template or use the default email template. Returns a value indicating whether the password reset was successful.

- `forgotPassword(username)`
  Resets the user's password and sends an email to the user with the user’s new password. Returns a value indicating whether the password reset was successful.

- `getAdminEmail()`
  Returns the email address of the site administrator.

- `getAdminId()`
  Returns the user ID of the site administrator.

- `getAnalyticsTrackingCode()`
  The tracking code associated with your site. Services such as Google Analytics can use this code to track page request data for your site.

- `getCurrentSiteUrl()`
  Deprecated. This method was replaced by `getBaseUrl()` in API version 30.0. Returns the base URL of the current site that references and links should use.

- `getBaseCustomUrl()`
  Returns a base URL for the current site that doesn't use a force.com subdomain. The returned URL uses the same protocol (HTTP or HTTPS) as the current request if at least one non-Force.com custom URL that supports HTTPS exists on the site. The returned value never ends with a `/` character. If all the custom URLs in this site end in Force.com or this site has no custom URLs, then this returns an empty string. If the current request is not a site request, then this method returns an empty string. This method replaced `getCustomWebAddress` and includes the custom URL's path prefix.
getBaseInsecureUrl()
Returns a base URL for the current site that uses HTTP instead of HTTPS. The current request’s domain is used. The returned value includes the path prefix and never ends with a / character. If the current request is not a site request, then this method returns an empty string.

getBaseRequestUrl()
Returns the base URL of the current site for the requested URL. This isn’t influenced by the referring page’s URL. The returned URL uses the same protocol (HTTP or HTTPS) as the current request. The returned value includes the path prefix and never ends with a / character. If the current request is not a site request, then this method returns an empty string.

getBaseSecureUrl()
Returns a base URL for the current site that uses HTTPS instead of HTTP. The current request’s domain is preferred if it supports HTTPS. Domains that are not Force.com subdomains are preferred over Force.com subdomains. A Force.com subdomain, if associated with the site, is used if no other HTTPS domains exist in the current site. If no HTTPS custom URLs exist in the site, then this method returns an empty string. The returned value includes the path prefix and never ends with a / character. If the current request is not a site request, then this method returns an empty string.

getBaseUrl()
Returns the base URL of the current site that references and links should use. Note that this field may return the referring page’s URL instead of the current request’s URL. The returned value includes the path prefix and never ends with a / character. If the current request is not a site request, then this field returns an empty string. This field replaces getCurrentSiteUrl.

getCustomWebAddress()
Deprecated. This method was replaced by getBaseCustomUrl() in API version 30.0.

gGetDomain()
Returns the Salesforce Site domain (force.com subdomain URL hostname) for your organization.

ggetErrorDescription()
Returns the error description for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

ggetErrorMessage()
Returns an error message for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

ggetExperienceId()
Returns the value of the experience ID (expid). This expid value comes from a cookie in the user’s web browser.

ggetMasterLabel()
Returns the value of the Master Label field for the current site. If the current request is not a site request, then this field returns null.

ggetName()
Returns the API name of the current site.

ggetOriginalUrl()
Returns the original URL for this page if it’s a designated error page for the site; otherwise, returns null.

ggetPasswordPolicyStatement()
Returns the password requirements for a community created with the Customer Service template.

ggetPathPrefix()
Returns the URL path prefix of the current site or an empty string if none. For example, if the requested site URL is http://myco.force.com/partners, then /partners is the path prefix. If the current request is not a site request, then this method returns an empty string. This method replaced getPrefix in API version 30.0.
getPrefix()
Deprecated. This method was replaced by getPathPrefix() in API version 30.0.

getAddressId()
Returns the ID of the current site. If the current request is not a site request, then this field returns null.

getTemplate()
Returns the template name associated with the current site; returns the default template if no template has been designated.

getSiteType()
Returns the API value of the site type field for the current site. This can be Visualforce for a Salesforce site, Siteforce for a Site.com site, ChatterNetwork for a Communities site, or ChatterNetworkPicasso for a Site.com Communities site. If the current request is not a site request, then this method returns null.

getSiteTypeLabel()
Returns the value of the Site Type field's label for the current site. If the current request is not a site request, then this method returns null.

isLoginEnabled()
Returns true if the current site is associated with an active login-enabled portal; otherwise returns false.

isPasswordExpired()
For authenticated users, returns true if the currently logged-in user's password is expired. For non-authenticated users, returns false.

isRegistrationEnabled()
Returns true if the current site is associated with an active self-registration-enabled Customer Portal; otherwise returns false.

isValidUsername(username)
Returns true if the given username is valid; otherwise, returns false.

login(username, password, startUrl)
Allows users to log in to the current site with the given username and password, then takes them to the startUrl. If startUrl is not a relative path, it defaults to the site's designated index page.

passwordlessLogin(userId, methods, startUrl)
Logs in a user to a community using an identity verification method, such as email or text, instead of a password. Passwordless login is a convenient, mobile-centric way to welcome users into your community. Let your community users log in with something other than their password, like their email address or phone number.

setExperienceId(expIdValue)
Sets the experience ID for the current user. Use this method to populate the value of the experience ID (expid) cookie in the user's web browser.

setPortalUserAsAuthProvider(user, contactId)
Sets the specified user information within the site's portal via an authentication provider.

validatePassword(user, password, confirmPassword)
Indicates whether a given password meets the requirements specified by org-wide or profile-based password policies in the current user's org.

changePassword(newPassword, verifyNewPassword, oldPassword)
Changes the password of the current user.
public static System.PageReference changePassword(String newPassword, String verifyNewPassword, String oldPassword)

Parameters

newPassword
Type: String

verifyNewPassword
Type: String

oldPassword
Type: String
Optional only if the current user’s password has expired; otherwise, required.

Return Value
Type: System.PageReference

Usage
Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

createExternalUser(user, accountId)
Creates a community or a portal user for the given account and associates it with the community.

Signature
public static Id createExternalUser(SObject user, String accountId)

Parameters

user
Type: SObject

accountId
Type: String

Return Value
Type: Id
The ID of the user that this method creates.
**Usage**

This method throws `Site.ExternalUserCreateException` when user creation fails.

The `nickname` field is required for the `User` sObject when using the `createExternalUser` method.

**Note:** This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

**createExternalUser(user, accountId, password)**

Creates a community or a portal user for the given account and associates it with the community. This method sends an email with the specified password to the user.

**Signature**

```java
public static Id createExternalUser(SObject user, String accountId, String password)
```

**Parameters**

**user**

Type: `SObject`

Information required to create a user.

The email address of the user is used to look for matching contacts associated with the specified `accountId`. If a matching contact is found and is already used by an external user, self-registration isn’t successful. If a matching contact is found but isn’t used by an external user, it is used for the new external user. If there is no matching contact, a new contact is created for the new external user.

**accountId**

Type: `String`

The ID of the account you want to associate the user with.

**password**

Type: `String`

The password of the community or portal user. If not specified, or if set to `null` or an empty string, this method sends a new password email to the portal user.

**Return Value**

Type: `Id`

The ID of the user that this method creates.

**Usage**

This method throws `Site.ExternalUserCreateException` when user creation fails.

The `nickname` field is required for the `User` sObject when using the `createExternalUser` method.

**Note:** This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.
createExternalUser(user, accountId, password, sendEmailConfirmation)

Creates a community or portal user and associates it with the given account. This method sends the user an email with the specified password and a new user confirmation email.

Signature

public static Id createExternalUser(SObject user, String accountId, String password, Boolean sendEmailConfirmation)

Parameters

user
Type: SObject
Information required to create a user.

The email address of the user is used to look for matching contacts associated with the specified accountId. If a matching contact is found and is already used by an external user, self-registration isn’t successful. If a matching contact is found but isn’t used by an external user, it is used for the new external user. If there is no matching contact, a new contact is created for the new external user.

accountId
Type: String
The ID of the account you want to associate the user with.

password
Type: String
The password of the community or portal user. If not specified, or if set to null or an empty string, this method sends a new password email to the portal user.

sendEmailConfirmation
Type: Boolean
Determines whether a new user email is sent to the portal user. Set it to true to send a new user email to the portal user. The default is false, that is, the new user email isn’t sent.

Return Value

Type: Id
The ID of the user that this method creates.

Usage

This method throws Site.ExternalUserCreateException when user creation fails.

The nickname field is required for the User sObject when using the createExternalUser method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

createPersonAccountPortalUser(user, ownerId, password)

Creates a person account using the default record type defined on the guest user’s profile, then enables it for the site’s portal.
**Signature**

```java
public static ID createPersonAccountPortalUser(sObject user, String ownerId, String password)
```

**Parameters**

- **user**
  - Type: `sObject`

- **ownerId**
  - Type: `String`

- **password**
  - Type: `String`

**Usage**

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

**Note:** This method is only valid when a site is associated with a Customer Portal, and when the user license for the default new user profile is a high-volume portal user.

**createPersonAccountPortalUser(user, ownerId, recordTypeId, password)**

Creates a person account using the specified `recordTypeId`, then enables it for the site's portal.

**Signature**

```java
public static ID createPersonAccountPortalUser(sObject user, String ownerId, String recordTypeId, String password)
```

**Parameters**

- **user**
  - Type: `sObject`

- **ownerId**
  - Type: `String`

- **recordTypeId**
  - Type: `String`

- **password**
  - Type: `String`

**Return Value**

Type: `ID`
Usage
Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

Note: This method is only valid when a site is associated with a Customer Portal, and when the user license for the default new user profile is a high-volume portal user.

`createPortalUser(user, accountId, password, sendEmailConfirmation)`
Creates a portal user for the given account and associates it with the site's portal.

Signature
```
public static ID createPortalUser(sObject user, String accountId, String password,
                                Boolean sendEmailConfirmation)
```

Parameters

- `user`
  Type: `sObject`

- `accountId`
  Type: `String`

- `password`
  Type: `String`
  (Optional) The password of the portal user. If not specified, or if set to `null` or an empty string, this method sends a new password email to the portal user.

- `sendEmailConfirmation`
  Type: `Boolean`
  (Optional) Determines whether a new user email is sent to the portal user. Set it to `true` to send a new user email to the portal user. The default is `false`, that is, the new user email isn’t sent.

Return Value

Type: `ID`

Usage

If you’re using API version 34.0 or later, we recommend using the `createExternalUser()` methods because they offer better error handling than this method.

The `nickname` field is required for the user `sObject` when using the `createPortalUser` method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.
forgotPassword(username, emailTemplateName)
Resets the user’s password and sends an email to the user with the user’s new password. You can specify a custom email template or use the default email template. Returns a value indicating whether the password reset was successful.

Signature
public static Boolean forgotPassword(String username, String emailTemplateName)

Parameters
username
  Type: String
eemailTemplateName
  Type: String

  If provided, the method applies the template to the email. Otherwise, the method applies the default system template. If an email template that doesn’t exist is provided, the system logs an exception.

Return Value
Type: Boolean

Note: The return value is always true unless it’s called outside of a Visualforce page.

Usage
Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

Note: Site.forgotPassword cannot be used with the @future method, which enables asynchronous execution.

forgotPassword(username)
Resets the user’s password and sends an email to the user with the user’s new password. Returns a value indicating whether the password reset was successful.

Signature
public static Boolean forgotPassword(String username)

Parameters
username
  Type: String

Return Value
Type: Boolean

Note: The return value is always true unless it’s called outside of a Visualforce page.
Usage

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

⚠️ Note: Site.forgotPassword cannot be used with the @future method, which enables asynchronous execution.

**getAdminEmail()**

Returns the email address of the site administrator.

**Signature**

```java
public static String getAdminEmail()
```

**Return Value**

Type: String

**getAdminId()**

Returns the user ID of the site administrator.

**Signature**

```java
public static ID getAdminId()
```

**Return Value**

Type: ID

**getAnalyticsTrackingCode()**

The tracking code associated with your site. Services such as Google Analytics can use this code to track page request data for your site.

**Signature**

```java
public static String getAnalyticsTrackingCode()
```

**Return Value**

Type: String

**getCurrentSiteUrl()**

Deprecated. This method was replaced by `getBaseUrl()` in API version 30.0. Returns the base URL of the current site that references and links should use.

Note that this may return the referring page's URL instead of the current request's URL. The returned value includes the path prefix and always ends with a `/` character. If the current request is not a site request, then this method returns `null`. If the current request is not a site request, then this method returns `null`. This method was replaced by `getBaseUrl` in API version 30.0.
Signature

```java
public static String getCurrentSiteUrl()
```

Return Value

Type: `String`

Usage

Use `getBaseUrl()` instead.

**getBaseCustomUrl()**

Returns a base URL for the current site that doesn’t use a force.com subdomain. The returned URL uses the same protocol (HTTP or HTTPS) as the current request if at least one non-Force.com custom URL that supports HTTPS exists on the site. The returned value never ends with a `/` character. If all the custom URLs in this site end in Force.com or this site has no custom URLs, then this returns an empty string. If the current request is not a site request, then this method returns an empty string. This method replaced `getCustomWebAddress` and includes the custom URL’s path prefix.

Signature

```java
public static String getBaseCustomUrl()
```

Return Value

Type: `String`

Usage

This method replaces `getCustomWebAddress()` and includes the custom URL’s path prefix.

**getBaseInsecureUrl()**

Returns a base URL for the current site that uses HTTP instead of HTTPS. The current request’s domain is used. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

Signature

```java
public static String getBaseInsecureUrl()
```

Return Value

Type: `String`

**getBaseRequestUrl()**

Returns the base URL of the current site for the requested URL. This isn’t influenced by the referring page’s URL. The returned URL uses the same protocol (HTTP or HTTPS) as the current request. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.
Signature

```java
public static String getBaseRequestUrl()
```

Return Value
Type: String

**getBaseSecureUrl()**

Returns a base URL for the current site that uses HTTPS instead of HTTP. The current request's domain is preferred if it supports HTTPS. Domains that are not Force.com subdomains are preferred over Force.com subdomains. A Force.com subdomain, if associated with the site, is used if no other HTTPS domains exist in the current site. If no HTTPS custom URLs exist in the site, then this method returns an empty string. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

Signature

```java
public static String getBaseSecureUrl()
```

Return Value
Type: String

**getBaseUrl()**

Returns the base URL of the current site that references and links should use. Note that this field may return the referring page's URL instead of the current request's URL. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this field returns an empty string. This field replaces `getCurrentSiteUrl()`.

Signature

```java
public static String getBaseUrl()
```

Return Value
Type: String

Usage
This method replaces `getCurrentSiteUrl()`.

**getCustomWebAddress()**

Deprecated. This method was replaced by `getBaseCustomUrl()` in API version 30.0.

Returns the request's custom URL if it doesn't end in Lightning Platform or returns the site's primary custom URL. If neither exist, then this returns null. Note that the URL's path is always the root, even if the request's custom URL has a path prefix. If the current request is not a site request, then this method returns null. The returned value always ends with a `/` character.
public static String getCustomWebAddress()

Return Value
Type: String

Usage
Use getBaseCustomUrl() instead.

getDomain()
Returns the Salesforce Site domain (force.com subdomain URL hostname) for your organization.

Signature
public static String getDomain()

Return Value
Type: String

getErrorDescription()
Returns the error description for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

Signature
public static String getErrorDescription()

Return Value
Type: String

getErrorMessage()
Returns an error message for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

Signature
public static String getErrorMessage()

Return Value
Type: String
getExperienceId()
Returns the value of the experience ID (expid). This expid value comes from a cookie in the user's web browser.

Signature
public static String getExperienceId()

Return Value
Type: String

Usage
Use the `getExperienceId` and `setExperienceId` methods to implement dynamic login experiences. You can set the experience ID with `setExperienceId` or by extending the following endpoints with `expid_value`.

- `community-url/services/oauth2/authorize/expid_value`
- `community-url/idp/endpoint/HttpPost/expid_value`
- `community-url/idp/endpoint/HttpRedirect/expid_value`
- `community-url_login_page/expid={value}`
- `community-url/CommunitiesSelfReg?expid={value}`
- `secur/forgotpassword.jsp?expid={value}`

The cookie is set when the browser loads the URLs with the expid values.

generateExperienceId()
Returns the value of the experience ID (expid). This expid value comes from a cookie in the user's web browser.

Signature
public static String getMasterLabel()

Return Value
Type: String

Usage
getMasterLabel() method returns the value of the Master Label field for the current site. If the current request is not a site request, then this field returns `null`.

Signature
public static String getName()

Return Value
Type: String
getOriginalUrl()
Returns the original URL for this page if it’s a designated error page for the site; otherwise, returns null.

Signature
public static String getOriginalUrl()

Return Value
Type: String

getPasswordPolicyStatement()
Returns the password requirements for a community created with the Customer Service template.

Signature
public static String getPasswordPolicyStatement()

Return Value
Type: String

getPathPrefix()
Returns the URL path prefix of the current site or an empty string if none. For example, if the requested site URL is http://myco.force.com/partners, then /partners is the path prefix. If the current request is not a site request, then this method returns an empty string. This method replaced getPrefix in API version 30.0.

Signature
public static String getPathPrefix()

Return Value
Type: String

getPrefix()
Deprecated. This method was replaced by getPathPrefix() in API version 30.0.
Returns the URL path prefix of the current site. For example, if your site URL is myco.force.com/partners, /partners is the path prefix. Returns null if the prefix isn’t defined. If the current request is not a site request, then this method returns a null.

Signature
public static String getPrefix()

Return Value
Type: String
getSiteId()
Returns the ID of the current site. If the current request is not a site request, then this field returns null.

Signature
public static String getSiteId()

Return Value
Type: Id

getTemplate()
Returns the template name associated with the current site; returns the default template if no template has been designated.

Signature
public static System.PageReference getTemplate()

Return Value
Type: System.PageReference

getSiteType()
Returns the API value of the site type field for the current site. This can be Visualforce for a Salesforce site, Siteforce for a Site.com site, ChatterNetwork for a Communities site, or ChatterNetworkPicasso for a Site.com Communities site. If the current request is not a site request, then this method returns null.

Signature
public static String getSiteType()

Return Value
Type: String

getSiteTypeLabel()
Returns the value of the Site Type field’s label for the current site. If the current request is not a site request, then this method returns null.

Signature
public static String getSiteTypeLabel()

Return Value
Type: String
**isLoginEnabled()**
Returns true if the current site is associated with an active login-enabled portal; otherwise returns false.

Signature
```
public static Boolean isLoginEnabled()
```

Return Value
Type: Boolean

**isPasswordExpired()**
For authenticated users, returns true if the currently logged-in user's password is expired. For non-authenticated users, returns false.

Signature
```
public static Boolean isPasswordExpired()
```

Return Value
Type: Boolean

**isRegistrationEnabled()**
Returns true if the current site is associated with an active self-registration-enabled Customer Portal; otherwise returns false.

Signature
```
public static Boolean isRegistrationEnabled()
```

Return Value
Type: Boolean

**isValidUsername(username)**
Returns true if the given username is valid; otherwise, returns false.

Signature
```
public static Boolean isValidUsername(String username)
```

Parameters
username
  Type: String
  The username to test for validity.
Return Value
Type: Boolean

**login(username, password, startUrl)**

Allows users to log in to the current site with the given username and password, then takes them to the startUrl. If startUrl is not a relative path, it defaults to the site's designated index page.

Signature

```java
public static System.PageReference login(String username, String password, String startUrl)
```

Parameters

- **username**
  Type: String
- **password**
  Type: String
- **startUrl**
  Type: String

Return Value
Type: System.PageReference

Usage

All DML statements before the call to Site.login get committed. It's not possible to roll back to a save point that was created before a call to Site.login.

**Note:** Do not include http:// or https:// in the startURL.

**passwordlessLogin(userId, methods, startUrl)**

Logs in a user to a community using an identity verification method, such as email or text, instead of a password. Passwordless login is a convenient, mobile-centric way to welcome users into your community. Let your community users log in with something other than their password, like their email address or phone number.

Signature

```java
public static System.PageReference passwordlessLogin(Id userId, List<Auth.VerificationMethod> methods, String startUrl)
```

Parameters

- **userId**
  Type: Id
  ID of the user to log in.
methods
Type: List<Auth.VerificationMethod>
List of identity verification methods available to the user for passwordless login.

startUrl
Type: String
Path to the page that users see after they log in.

Return Value
Type: System.PageReference

Usage
Include this method in the Apex controller of a custom login page implementation.

PasswordlessLogin Example
This simple code example of an Apex controller contains the passwordlessLogin method. The PageReference returned by passwordlessLogin redirects the user to the Salesforce Verify page. When the user enters the correct code, the user is redirected to the community page specified by the start URL.

global with sharing class MFILoginController
{

    //Input variables
    global String input {get; set;}
    public String startURL {get; set;}
    public List<Auth.VerificationMethod> methods;
    public String error;

    global MFILoginController()
    {
        // Add verification methods in priority order
        methods = new List<Auth.VerificationMethod>();
        methods.add(Auth.VerificationMethod.SMS);
        methods.add(Auth.VerificationMethod.EMAIL);
        methods.add(Auth.VerificationMethod.U2F);
        methods.add(Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
        methods.add(Auth.VerificationMethod.TOTP);
    }

    global PageReference login() {
        List<User> users = null;

        // Empty input
        if(input == null || input == '')
        {
            error = 'Enter Username';
            return null;
        }

        users = [select name, id, email from User where username=:input];
        if(users == null || users.isEmpty())
        {
            error = 'Username Not Found';
            return null;
        }

        // Add verification methods
        global List<Auth.VerificationMethod> methods = new List<Auth.VerificationMethod>();
        methods.add(Auth.VerificationMethod.SMS);
        methods.add(Auth.VerificationMethod.EMAIL);
        methods.add(Auth.VerificationMethod.U2F);
        methods.add(Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
        methods.add(Auth.VerificationMethod.TOTP);

        // Verify user
        global List<Auth.VerificationResponse> responses = new List<Auth.VerificationResponse>();
        for(Auth.VerificationMethod method : methods)
        {
           responses.add(Auth.VerificationResponse.SEND_CODE(method, input));
        }

        // Receive code
        global System.PageReference pageReference = null;
        for(Auth.VerificationResponse response : responses)
        {
            if(response.getStatus() == Auth.VerificationResponseStatus.SUCCESS)
            {
                pageReference = response.getPageReference();
                break;
            }
        }

        // Redirect to community page
        if(pageReference)
        {
            return pageReference;
        }

        error = 'Verification Failed';
        return null;
    }
}
```java
{
    error = 'Can\'t find a user';
    return null;
}
if (startURL == null) startURL = '/';
return Site.passwordlessLogin(users[0].id, methods, startURL);
}
```

**setExperienceId(expIdValue)**

Sets the experience ID for the current user. Use this method to populate the value of the experience ID (expid) cookie in the user’s web browser.

**Signature**

```java
public static void setExperienceId(String expIdValue)
```

**Parameters**

- **expIdValue**
  - Type: **String**
  - A value that indicates the user’s login experience.
  - The value must contain alphanumeric characters only, up to 30 characters.

**Usage**

Use `setExperienceId` when you’re implementing dynamic login experiences. A login experience refers to a login page plus any secondary pages associated with the login page (such as 2FA authentication or a login flow). You define different login experiences depending on who users are or where they’re logging in from. For example, you can require a different registration process based on the user’s location. In this case, `expIdValue` includes a state or country code. When the user logs in, the URL contains the experience ID parameter, `{expid}`. The `{expid}` parameter is replaced by the value stored in `expIdValue`, such as `.jp`. Then the user is redirected to the Japanese login experience.

**Example**

```java
String expid = ApexPages.currentPage().getParameters().get('expid');
if (expId != null) {
    Site.setExperienceId(expId);
}
```

**setPortalUserAsAuthProvider(user, contactId)**

Sets the specified user information within the site’s portal via an authentication provider.

**Signature**

```java
public static Void setPortalUserAsAuthProvider(sObject user, String contactId)
```
Parameters

user
  Type: sObject

contactId
  Type: String

Return Value

Type: Void

Usage

- This method is only valid when a site is associated with a Customer Portal.
- Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.
- For more information on an authentication provider, see RegistrationHandler on page 771.

validatePassword(user, password, confirmPassword)

Indicates whether a given password meets the requirements specified by org-wide or profile-based password policies in the current user’s org.

Signature

public static void validatePassword(SObject user, String password, String confirmPassword)

Parameters

user
  Type: SObject
  The user attempting to create a password during self-registration for a community.

password
  Type: String
  The password entered by the user.

confirmPassword
  Type: String
  The password reentered by the user to confirm the password.

Return Value

Type: void

Usage

If validation fails when the method is run in a Lightning controller, this method throws an Apex exception describing the failed validation. If validation fails when the method is run in a Visualforce controller, the method provides Visualforce error messages.
**SObject Class**
Contains methods for the sObject data type.

**Namespace**
System

**Usage**
SObject methods are all instance methods: they are called by and operate on an sObject instance such as an account or contact. The following are the instance methods for sObjects.

For more information on sObjects, see Working with sObjects on page 115.

**SObject Methods**
The following are methods for SObject. All are instance methods.

IN THIS SECTION:
- `addError(errorMsg)`
  Marks a trigger record with a custom error message and prevents any DML operation from occurring.
- `addError(errorMsg, escape)`
  Marks a trigger record with a custom error message, specifies if the error message should be escaped, and prevents any DML operation from occurring.
- `addError(exceptionError)`
  Marks a trigger record with a custom exception error message and prevents any DML operation from occurring.
- `addError(exceptionError, escape)`
  Marks a trigger record with a custom exception error message, specifies whether or not the exception error message should be escaped, and prevents any DML operation from occurring.
- `addError(errorMsg)`
  Places the specified error message on a trigger record field in the Salesforce user interface and prevents any DML operation from occurring.
- `addError(errorMsg, escape)`
  Places the specified error message, which can be escaped or unescaped, on a trigger record field in the Salesforce user interface, and prevents any DML operation from occurring.
- `clear()`
  Clears all field values
- `clone(preserveId, isDeepClone, preserveReadOnlyTimestamps, preserveAutonumber)`
  Creates a copy of the SObject record.
- `get(fieldName)`
  Returns the value for the field specified by `fieldName`, such as AccountNumber.
- `get(field)`
  Returns the value for the field specified by the field token `Schema.sObjectField`, such as `Schema.Account.AccountNumber`. 
getCloneSourceId()
Returns the ID of the entity from which an object was cloned. You can use it for objects cloned through the Salesforce user interface. If you don't use a preserveId parameter, or if you use a preserveId value of false, you can also use it for objects created using the System.SObject.clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber) method.

getOptions()
Returns the database.DMLOptions object for the SObject.

getPopulatedFieldsAsMap()
Returns a map of populated field names and their corresponding values. The map contains only the fields that have been populated in memory for the SObject instance.

getSObject(fieldName)
Returns the value for the specified field. This method is primarily used with dynamic DML to access values for external IDs.

getSObject(fieldName)
Returns the value for the field specified by the field token Schema.fieldName, such as, Schema.MyObj.MyExternalId. This method is primarily used with dynamic DML to access values for external IDs.

getSObjects(fieldName)
Returns the values for the specified field. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

getSObjects(fieldName)
Returns the value for the field specified by the field token Schema.fieldName, such as, Schema.Account.Contact. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

getSObjectType()
Returns the token for this SObject. This method is primarily used with describe information.

getQuickActionName()
Retrieves the name of a quick action associated with this SObject. Typically used in triggers.

isClone()
Returns true if an entity is cloned from something, even if the entity hasn’t been saved.

isSet(fieldName)
Returns information about the queried SObject field. Returns true if the SObject field is populated, either by direct assignment or by inclusion in a SOQL query. Returns false if the SObject field is not set. If an invalid field is specified, an SObjectException is thrown.

isSet(field)
Returns information about the queried SObject field. Returns true if the SObject field is populated, either by direct assignment or by inclusion in a SOQL query. Returns false if the SObject field is not set. If an invalid field is specified, an SObjectException is thrown.

put(fieldName, value)
Sets the value for the specified field and returns the previous value for the field.

put(fieldName, value)
Sets the value for the field specified by the field token Schema.sObjectField, such as, Schema.Account.AccountNumber and returns the previous value for the field.

putSObject(fieldName, value)
Sets the value for the specified field. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.
**putSObject(fieldName, value)**
Sets the value for the field specified by the token `Schema.SObjectType`. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

**recalculateFormulas()**
Recalculates all formula fields on an SObject, and sets updated field values. Rather than inserting or updating objects each time you want to test changes to your formula logic, call this method and inspect your new field values. Then make further logic changes as needed.

**setOptions(DMLOptions)**
Sets the DMLOptions object for the SObject.

### addError(errorMsg)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

**Signature**

```
public Void addError(String errorMsg)
```

**Parameters**

- **errorMsg**
  
  Type: String
  
  The error message to mark the record with.

**Return Value**

Type: Void

**Usage**

When used on `Trigger.new` in `before insert` and `before update` triggers, and on `Trigger.old` in `before delete` triggers, the error message is displayed in the application interface.

See [Triggers and Trigger Exceptions](https://developer.salesforce.com/docs/atlas.en-us.apexcode.meta/apexcode/apx_triggers.htm).

**Note:** This method escapes any HTML markup in the specified error message. The escaped characters are: `\n`, `<`, `>`, `&`, `\`, `\u2028`, `\u2029`, and `\u00a9`. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

When used in Visualforce controllers, the generated message is added to the collection of errors for the page. For more information, see [Validation Rules and Standard Controllers](https://developer.salesforce.com/docs/atlas.en-us.weekly_update.meta/weekly_update/whats_new_visualforce.htm) in the *Visualforce Developer's Guide*.

**Example**

```
Trigger.new[0].addError('bad');
```

### addError(errorMsg, escape)
Marks a trigger record with a custom error message, specifies if the error message should be escaped, and prevents any DML operation from occurring.
Signature

```java
public Void addError(String errorMsg, Boolean escape)
```

Parameters

`errorMsg`
Type: `String`
The error message to mark the record with.

`escape`
Type: `Boolean`
Indicates whether any HTML markup in the custom error message should be escaped (`true`) or not (`false`). This parameter is ignored in Lightning Experience and the Salesforce app and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value
Type: `Void`

Usage
The escaped characters are: `\n`, `\t`, `&`, `\`, `u2028`, `u2029`, and `\u00a9`. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

⚠️ **Warning**: Be cautious if you specify `false` for the `escape` argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false escape` argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify `true` for the `escape` argument or call `addError(String errorMsg)` instead.

Example

```java
Trigger.new[0].addError('Fix & resubmit', false);
```

**addError(exceptionError)**

Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature

```java
public Void addError(Exception exceptionError)
```

Parameters

`exceptionError`
Type: `System.Exception`
An Exception object or a custom exception object that contains the error message to mark the record with.
Return Value
Type: Void

Usage
When used on Trigger.new in before insert and before update triggers, and on Trigger.old in before delete triggers, the error message is displayed in the application interface.

See Triggers and Trigger Exceptions.

Note: This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &, \, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

When used in Visualforce controllers, the generated message is added to the collection of errors for the page. For more information, see Validation Rules and Standard Controllers in the Visualforce Developer's Guide.

Example

```java
public class MyException extends Exception {}
Trigger.new[0].addError(new MyException('Invalid Id'));
```

`addError(exceptionError, escape)`
Marks a trigger record with a custom exception error message, specifies whether or not the exception error message should be escaped, and prevents any DML operation from occurring.

Signature

```
public Void addError(Exception exceptionError, Boolean escape)
```

Parameters

`exceptionError`
Type: System.Exception
An Exception object or a custom exception object that contains the error message to mark the record with.

`escape`
Type: Boolean
Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false). This parameter is ignored in Lightning Experience and the Salesforce app and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value
Type: Void

Usage
The escaped characters are: \n, <, >, &, \, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.
**Warning:** Be cautious if you specify `false` for the `escape` argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false` `escape` argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify `true` for the `escape` argument or call `addError(Exception e)` instead.

Example

```java
public class MyException extends Exception {}
Trigger.new[0].addError(new MyException('Invalid Id & other issues', false));
```

**addError(errorMsg)**

Places the specified error message on a trigger record field in the Salesforce user interface and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(String errorMsg)
```

**Parameters**

- `errorMsg`
  - Type: String

**Return Value**

Type: Void

**Usage**

**Note:**

- When used on `Trigger.new` in before insert and before update triggers, and on `Trigger.old` in before delete triggers, the error appears in the application interface.
- When used in Visualforce controllers, if there is an `inputField` component bound to field, the message is attached to the component. For more information, see Validation Rules and Standard Controllers in the Visualforce Developer’s Guide.
- This method is highly specialized because the field identifier is not actually the invoking object—the sObject record is the invoker. The field is simply used to identify the field that should be used to display the error.

See Triggers and Trigger Exceptions.

**Note:** This method escapes any HTML markup in the specified error message. The escaped characters are: `\n`, `<`, `>`, `&`, `\`, `\u2028`, `\u2029`, and `\u00a9`. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

Example

```java
Trigger.new[0].myField__c.addError('bad');
```
addError(errorMsg, escape)
Places the specified error message, which can be escaped or unescaped, on a trigger record field in the Salesforce user interface, and prevents any DML operation from occurring.

Signature
public Void addError(String errorMsg, Boolean escape)

Parameters
errorMsg
Type: String
The error message to mark the record with.

escape
Type: Boolean
Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false). This parameter is ignored in Lightning Experience and the Salesforce app and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value
Type:

Usage
The escaped characters are: \n, <, >, ", \, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

⚠️ Warning: Be cautious if you specify false for the escape argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a false escape argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify true for the escape argument or call field.addError(String errorMsg) instead.

Example
Trigger.new[0].myField__caddError('Fix & resubmit', false);

clear()
Clears all field values

Signature
public Void clear()

Return Value
Type: Void
Example

```java
Account acc = new Account(Name = 'Acme');
acc.clear();
Account expected = new Account();
system.assertEquals(expected, acc);
```

`clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber)`

Creates a copy of the SObject record.

**Signature**

```java
public SObject clone(Boolean preserveId, Boolean isDeepClone, Boolean preserveReadonlyTimestamps, Boolean preserveAutonumber)
```

**Parameters**

- `preserveId`
  - Type: `Boolean`
  - (Optional) Determines whether the ID of the original object is preserved or cleared in the duplicate. If set to `true`, the ID is copied to the duplicate. The default is `false`, that is, the ID is cleared.

- `isDeepClone`
  - Type: `Boolean`
  - (Optional) Determines whether the method creates a full copy of the SObject field or just a reference:
    - If set to `true`, the method creates a full copy of the SObject. All fields on the SObject are duplicated in memory, including relationship fields. Consequently, if you make changes to a field on the cloned SObject, the original SObject is not affected.
    - If set to `false`, the method performs a shallow copy of the SObject fields. All copied relationship fields reference the original SObjects. Consequently, if you make changes to a relationship field on the cloned SObject, the corresponding field on the original SObject is also affected, and vice versa. The default is `false`.

- `preserveReadonlyTimestamps`
  - Type: `Boolean`
  - (Optional) Determines whether the read-only timestamp fields are preserved or cleared in the duplicate. If set to `true`, the read-only fields `CreatedById`, `CreatedDate`, `LastModifiedById`, and `LastModifiedDate` are copied to the duplicate. The default is `false`, that is, the values are cleared.

- `preserveAutonumber`
  - Type: `Boolean`
  - (Optional) Determines whether auto number fields of the original object are preserved or cleared in the duplicate. If set to `true`, auto number fields are copied to the cloned object. The default is `false`, that is, auto number fields are cleared.

**Return Value**

Type: `SObject` (of same type)
Usage

Note: For Apex saved using Salesforce API version 22.0 or earlier, the default value for the `preserveId` argument is `true`, that is, the ID is preserved.

Example

```java
Account acc = new Account(Name = 'Acme', Description = 'Acme Account');
Account clonedAcc = acc.clone(false, false, false, false);
System.assertEquals(acc, clonedAcc);
```

**get(fieldName)**

Returns the value for the field specified by `fieldName`, such as `AccountNumber`.

Signature

```java
public Object get(String fieldName)
```

Parameters

`fieldName`

Type: `String`

Return Value

Type: `Object`

Usage

For more information, see Dynamic SOQL.

Example

```java
Account acc = new Account(Name = 'Acme', Description = 'Acme Account');
String description = (String)acc.get('Description');
System.assertEquals('Acme Account', description);
```

**get(field)**

Returns the value for the field specified by the field token `Schema.sObjectField` such as `Schema.Account.AccountNumber`.

Signature

```java
public Object get(Schema.sObjectField field)
```

Parameters

`field`

Type: `Schema.sObjectField`
Return Value
Type: Object

Usage
For more information, see Dynamic SOQL.

Note: Field tokens aren’t available for person accounts. If you access Schema.Account.fieldname, you get an exception error. Instead, specify the field name as a string.

Example

```
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
String description = (String)acc.get(Schema.Account.Description);
System.assertEquals('Acme Account', description);
```

getCloneSourceId()

Returns the ID of the entity from which an object was cloned. You can use it for objects cloned through the Salesforce user interface. If you don’t use a preserveId parameter, or if you use a preserveId value of false, you can also use it for objects created using the System.SObject.clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber) method.

Signature
```
public Id getCloneSourceId()
```

Return Value
Type: Id

Usage
If A is cloned to B, B is cloned to C, and C is cloned to D, then B, C, and D all point back to A as their clone source.

Example

```
Account acc0 = new Account(Name = 'Acme');
insert acc0;
Account acc1 = acc0.clone();
Account acc2 = acc1.clone();
Account acc3 = acc2.clone();
Account acc4 = acc3.clone();
System.assertEquals(acc0.Id, acc1.getCloneSourceId());
System.assertEquals(acc0.Id, acc2.getCloneSourceId());
System.assertEquals(acc0.Id, acc3.getCloneSourceId());
System.assertEquals(acc0.Id, acc4.getCloneSourceId());
```

**getOptions()**

Returns the database.DMLOptions object for the SObject.

**Signature**

```java
public Database.DMLOptions getOptions()
```

**Return Value**

Type: `Database.DMLOptions`

**Example**

```java
Database.DMLOptions dmo = new Database.dmlOptions();
dmo.assignmentRuleHeader.useDefaultRule = true;

Account acc = new Account(Name = 'Acme');
acc.setOptions(dmo);
Database.DMLOptions accDmo = acc.getOptions();
```

**getPopulatedFieldsAsMap()**

Returns a map of populated field names and their corresponding values. The map contains only the fields that have been populated in memory for the SObject instance.

**Signature**

```java
public Map<String, Object> getPopulatedFieldsAsMap()
```

**Return Value**

Type: `Map<String, Object>`

A map of field names and their corresponding values.

**Usage**

The returned map contains only the fields that have been populated in memory for the SObject instance, which makes it easy to iterate over those fields. A field is populated in memory in the following cases:

- The field has been queried by a SOQL statement.
- The field has been explicitly set before the call to the `getPopulatedFieldsAsMap()` method.

Fields on related objects that are queried or set are also returned in the map.

The following example iterates over the map returned by the `getPopulatedFieldsAsMap()` method after a SOQL query.

```java
Account a = new Account();
a.name = 'TestMapAccount1';
insert a;
a = [select Id,Name from Account where id=:a.Id];
Map<String, Object> fieldsToValue = a.getPopulatedFieldsAsMap();
```
This example iterates over the map returned by the `getPopulatedFieldsAsMap()` method after fields on the SObject are explicitly set.

```java
Account a = new Account();
a.name = 'TestMapAccount2';
a.phone = '123-4567';
insert a;
Map<String, Object> fieldsToValue = a.getPopulatedFieldsAsMap();

for (String fieldName : fieldsToValue.keySet()) {
    System.debug('field name is ' + fieldName + ', value is ' + fieldsToValue.get(fieldName));
}
```

The following example shows how to use the `getPopulatedFieldsAsMap()` method with related objects.

```java
Account a = new Account();
a.name = 'TestMapAccount3';
insert a;
Contact c = new Contact();
c.firstname = 'TestContactFirstName';
c.lastname = 'TestContactLastName';
c.accountid = a.id;
insert c;

c = [SELECT id, Contact.Firstname, Contact.Account.Name FROM Contact
     where id=:c.id limit 1];
Map<String, Object> fieldsToValue = c.getPopulatedFieldsAsMap();

// To get the fields on Account, get the Account object
// and call getMapPopulatedFieldsAsMap() on that object.

a = Account(fieldsToValue.get('Account'));
fieldsToValue = a.getPopulatedFieldsAsMap();

for (String fieldName : fieldsToValue.keySet()) {
    System.debug('field name is ' + fieldName + ', value is ' + fieldsToValue.get(fieldName));
}
```

// Example debug statement output:
Versioned Behavior Changes

In API version 39.0 and later, getPopulatedFieldsAsMap returns all values set on the SObject, even if values were set after the record was queried. This behavior is dependent on the version of the apex class calling this method and not on the version of the class that generated the SObject. If you query an SObject at API version 20.0, and then call this method in a class with API version 40.0, you will get the full set of fields.

**getSObject**

Returns the value for the specified field. This method is primarily used with dynamic DML to access values for external IDs.

**Signature**

```java
public SObject getSObject(String fieldName)
```

**Parameters**

- **fieldName**
  - Type: `String`

**Return Value**

- Type: `SObject`

**Example**

```java
Account acc = new Account(Name = 'Acme', Description = 'Acme Account');
insert acc;
Contact con = new Contact(Lastname = 'AcmeCon', AccountId = acc.id);
insert con;

SObject contactDB =
    [SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1];
Account a = (Account)contactDB.getSObject('Account');
System.assertEquals('Acme', a.name);
```

**getSObject**

Returns the value for the field specified by the field token `Schema.fieldName`, such as, `Schema.MyObj.MyExternalId`. This method is primarily used with dynamic DML to access values for external IDs.

**Signature**

```java
public SObject getSObject(Schema.SObjectField fieldName)
```
Parameters

fieldName
Type: Schema.SObjectField

Return Value
Type: SObject

Example

Account acc = new account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;

Schema.DescribeFieldResult fieldResult = Contact.AccountId.getDescribe();
Schema.SObjectField field = fieldResult.getSObjectField();

SObject contactDB =
(SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1);
Account a = (Account)contactDB.getSObject(field);
System.assertEquals('Acme', a.name);

getSObjects(fieldName)
Returns the values for the specified field. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

Signature

public SObject[] getSObjects(String fieldName)

Parameters

fieldName
Type: String

Return Value
Type: SObject[]

Usage
For more information, see Dynamic DML.

Example

Account acc = new account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;
SObject[] a = [SELECT id, (SELECT Name FROM Contacts LIMIT 1) FROM Account WHERE id = :acc.id];
SObject[] contactsDB = a.get(0).getSObjects('Contacts');
String fieldValue = (String)contactsDB.get(0).get('Name');
System.assertEquals('AcmeCon', fieldValue);

getSObjects(fieldName)
Returns the value for the field specified by the field token Schema.**fieldName**, such as, Schema.Account.Contact. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

Signature
```
public SObject[] getSObjects(Schema.SObjectType fieldName)
```

Parameters
- **fieldName**
  - Type: Schema.SObjectType

Return Value
Type: SObject[]

getSObjectType()
Returns the token for this SObject. This method is primarily used with describe information.

Signature
```
public Schema.SObjectType getSObjectType()
```

Return Value
Type: Schema.SObjectType

Usage
For more information, see Understanding Apex Describe Information.

Example
```
Account acc = new Account(name = 'Acme', description = 'Acme Account');
Schema.SObjectType expected = Schema.Account.getSObjectType();
System.assertEquals(expected, acc.getSObjectType());
```

getQuickActionName()
Retrieves the name of a quick action associated with this SObject. Typically used in triggers.
Signature
public String getQuickActionName()

Return Value
Type: String

Example
trigger accTrig2 on Contact (before insert) {
    for (Contact c : Trigger.new) {
        if (c.getQuickActionName() == QuickAction.CreateContact) {
            c.WhereFrom__c = 'GlobaAction1';
        } else if (c.getQuickActionName() == Schema.Account.QuickAction.CreateContact) {
            c.WhereFrom__c = 'AccountAction';
        } else if (c.getQuickActionName() == null) {
            c.WhereFrom__c = 'NoAction';
        } else {
            System.assert(false);
        }
    }
}

isClone()
Returns true if an entity is cloned from something, even if the entity hasn’t been saved.

Signature
public Boolean isClone()

Return Value
Type: Boolean

Example
Account acc = new Account(Name = 'Acme');
insert acc;
Account acc2 = acc.clone();
// Test before saving
System.assertEquals(true, acc2.isClone());
insert acc2;
// Test after saving
System.assertEquals(true, acc2.isClone());

isSet(fieldName)
Returns information about the queried sObject field. Returns true if the sObject field is populated, either by direct assignment or by inclusion in a SOQL query. Returns false if the sObject field is not set. If an invalid field is specified, an SObjectException is thrown.
Signature

public Void isSet(String fieldName)

Parameters

fieldName
Type: String

Return Value
Type: Boolean

Usage

The `isSet` method doesn’t check if a field is accessible to a specific user via org permissions or other specialized access permissions.

Example

```java
Contact c = new Contact(LastName = 'Joyce');
System.assertEquals(true, c.isSet('LastName'));
System.assertEquals(false, c.isSet('FirstName')); // FirstName field is not written to
System.assertEquals(true, c.isSet('FirstName')); // FirstName field is written to
```

### isSet(field)

Returns information about the queried sObject field. Returns `true` if the sObject field is populated, either by direct assignment or by inclusion in a SOQL query. Returns `false` if the sObject field is not set. If an invalid field is specified, an SObjectException is thrown.

Signature

public Void isSet(Schema.SObjectField field)

Parameters

field
Type: SObjectField Class

Return Value
Type: Boolean

Usage

The `isSet` method doesn’t check if a field is accessible to a specific user via org permissions or other specialized access permissions.

Example

```java
Contact newContact = new Contact(LastName = 'Joyce');
insert(newContact); // Insert a new contact with last name Joyce
```
Contact c = [SELECT FirstName FROM Contact WHERE Id = :newContact.Id];
System.assertEquals(true, c.isSet(Contact.FirstName)); //FirstName field in query
System.assertEquals(false, c.isSet(Contact.LastName)); //LastName field not in query

**put**(fieldName, value)

Sets the value for the specified field and returns the previous value for the field.

**Signature**

```java
public Object put(String fieldName, Object value)
```

**Parameters**

- `fieldName`
  - Type: `String`
- `value`
  - Type: `Object`

**Return Value**

- Type: `Object`

**Example**

```java
Account acc = new Account(name = 'test', description = 'old desc');
String oldDesc = (String) acc.put('description', 'new desc');
System.assertEquals('old desc', oldDesc);
System.assertEquals('new desc', acc.description);
```

**put**(fieldName, value)

Sets the value for the field specified by the field token `Schema.sObjectField` such as, `Schema.Account.AccountNumber` and returns the previous value for the field.

**Signature**

```java
public Object put(Schema.SObjectField fieldName, Object value)
```

**Parameters**

- `fieldName`
  - Type: `Schema.SObjectField`
- `value`
  - Type: `Object`

**Return Value**

- Type: `Object`
Example

```java
Account acc = new Account(name = 'test', description = 'old desc');
String oldDesc = (String)acc.put(Schema.Account.Description, 'new desc');
System.assertEquals('old desc', oldDesc);
System.assertEquals('new desc', acc.description);
```

Note: Field tokens aren’t available for person accounts. If you access `Schema.Account.fieldName`, you get an exception error. Instead, specify the field name as a string.

`putSObject(fieldName, value)`

Sets the value for the specified field. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

Signature

```java
public SObject putSObject(String fieldName, SObject value)
```

Parameters

- `fieldName`
  - Type: String
- `value`
  - Type: SObject

Return Value

- Type: SObject

Example

```java
Account acc = new Account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;
Account acc2 = new account(name = 'Not Acme');
Contact contactDB =
    (Contact)[SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1];
Account a = (Account)contactDB.putSObject('Account', acc2);
System.assertEquals('Acme', a.name);
System.assertEquals('Not Acme', contactDB.Account.name);
```

`putSObject(fieldName, value)`

Sets the value for the field specified by the token `Schema.SObjectType`. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.
public SObject putSObject(Schema.SObjectType fieldName, SObject value)

Parameters

(fieldName)
   Type: Schema.SObjectType

(value)
   Type: SObject

Return Value

Type: SObject

recalculateFormulas()
Recalculates all formula fields on an SObject, and sets updated field values. Rather than inserting or updating objects each time you want to test changes to your formula logic, call this method and inspect your new field values. Then make further logic changes as needed.

Signature

public Void recalculateFormulas()

Return Value

Type: Void

Usage

This method doesn’t recalculate cross-object formulas. If you call this method on objects that have both cross-object and non-cross-object formula fields, only the non-cross-object formula fields are recalculated.

Each recalculateFormulas call counts against the SOQL query limits. See Execution Governors and Limits.

SEE ALSO:
   What Is a Cross-Object Formula?

setOptions(DMLOptions)
Sets the DMLOptions object for the SObject.

Signature

public Void setOptions(database.DMLOptions DMLOptions)

Parameters

(DMLOptions)
   Type: Database.DMLOptions
Return Value
Type: Void

Example

```java
Database.DMLOptions dmo = new Database.dmlOptions();
dmo.assignmentRuleHeader.useDefaultRule = true;

Account acc = new Account(Name = 'Acme');
acc.setOptions(dmo);
```

**SObjectAccessDecision Class**

Contains the results of a call to the Security.stripInaccessible method and methods to retrieve those results.

**Namespace**

*System*

**IN THIS SECTION:**

* SObjectAccessDecision Methods

**SObjectAccessDecision Methods**

The following are methods for SObjectAccessDecision.

**IN THIS SECTION:**

* getModifiedIndexes()
  Returns the indexes of sObjects that are modified by the stripInaccessible method.

* getRecords()
  Returns a list of new sObjects that are identical to the source records, except that they are stripped of fields that fail the field-level security check for the current user.

* getRemovedFields()
  Returns a map of sObject types to their corresponding inaccessible fields. The map key is a string representation of the sObject type. The map value is a set of strings, which denote the fields names that are inaccessible.

**getModifiedIndexes()**

Returns the indexes of sObjects that are modified by the stripInaccessible method.

**Signature**

```java
public Set<Integer> getModifiedIndexes()
```

**Return Value**

Type: `Set<Integer>`
A set of unsigned integers that represent the row indexes of the modified sObjects.

Example

In this example, the user doesn’t have permission to update the AnnualRevenue field of an Account.

```
List<Account> accounts = new List<Account>{
    new Account(Name='Account1', AnnualRevenue=1000),
    new Account(Name='Account2')
};

// Strip fields that are not updatable
SObjectAccessDecision decision = Security.stripInaccessible(
    AccessType.UPDATABLE,
    accounts);

// Print stripped records
for (SObject strippedAccount : decision.getRecords()) {
    System.debug(strippedAccount);
}

// Print modified indexes
System.debug(decision.getModifiedIndexes());
```

getRecords ()

Returns a list of new sObjects that are identical to the source records, except that they are stripped of fields that fail the field-level security check for the current user.

Usage

The stripInaccessible method performs field-level access check for the source records in the context of the current user’s operation. The getRecords() method returns the new records that contain only the fields that the current user has access to.

Signature

```
public List<SObject> getRecords()
```

Return Value

Type: List<SObject>

Even if the result list contains only one sObject, the return type is still a list (of size one).

Example

In this example, the user doesn’t have permission to update the AnnualRevenue field of an Account.

```
List<Account> accounts = new List<Account>{
    new Account(Name='Account1', AnnualRevenue=1000),
    new Account(Name='Account2')
};

// Strip fields that are not updatable
```
SObjectAccessDecision decision = Security.stripInaccessible(
    AccessType.UPDATABLE,
    accounts);

// Print stripped records
for (SObject strippedAccount : decision.getRecords()) {
    System.debug(strippedAccount);
}

getRemovedFields()
Returns a map of sObject types to their corresponding inaccessible fields. The map key is a string representation of the sObject type. The map value is a set of strings, which denote the fields names that are inaccessible.

Signature
public Map<String,Set<String>> getRemovedFields()

Return Value
Type: Map<String,Set<String>>

Example
In this example, the user doesn’t have permission to update the AnnualRevenue field of an Account.

List<Account> accounts = new List<Account>{
    new Account(Name='Account1', AnnualRevenue=1000),
    new Account(Name='Account2')
};

// Strip fields that are not updatable
SObjectAccessDecision decision = Security.stripInaccessible(
    AccessType.UPDATABLE,
    accounts);

// Print stripped records
for (SObject strippedAccount : decision.getRecords()) {
    System.debug(strippedAccount);
}

// Print removed fields
System.debug(decision.getRemovedFields());

StaticResourceCalloutMock Class
Utility class used to specify a fake response for testing HTTP callouts.

Namespace
System
Usage
Use the methods in this class to set the response properties for testing HTTP callouts.

IN THIS SECTION:

StaticResourceCalloutMock Constructors

The following are constructors for StaticResourceCalloutMock.

IN THIS SECTION:

StaticResourceCalloutMock()

Creates a new instance of the StaticResourceCalloutMock class.

Signature

public StaticResourceCalloutMock()

StaticResourceCalloutMock Methods

The following are methods for StaticResourceCalloutMock. All are instance methods.

IN THIS SECTION:

setHeader(headerName, headerValue)
Sets the specified header name and value for the fake response.

setStaticResource(resourceName)
Sets the specified static resource, which contains the response body.

setStatus(httpStatus)
Sets the specified HTTP status for the response.

setStatusCode(httpStatusCode)
Sets the specified HTTP status for the response.

setHeader(headerName, headerValue)
Sets the specified header name and value for the fake response.

Signature

public Void setHeader(String headerName, String headerValue)
setStaticResource(resourceName)
Sets the specified static resource, which contains the response body.

Signature
public Void setStaticResource(String resourceName)

Parameters
resourceName
  Type: String

Return Value
Type: Void

setStatus(httpStatus)
Sets the specified HTTP status for the response.

Signature
public Void setStatus(String httpStatus)

Parameters
httpStatus
  Type: String

Return Value
Type: Void

setStatusCode(httpStatusCode)
Sets the specified HTTP status for the response.
Signature

public Void setStatusCode(Integer httpStatusCode)

Parameters

httpStatusCode
Type: Integer

Return Value
Type: Void

String Class
Contains methods for the String primitive data type.

Namespace
System

Usage
For more information on Strings, see Primitive Data Types on page 26.

String Methods
The following are methods for String.

IN THIS SECTION:

abbreviate(maxWidth)
Returns an abbreviated version of the String, of the specified length and with ellipses appended if the current String is longer than the specified length; otherwise, returns the original String without ellipses.

abbreviate(maxWidth, offset)
Returns an abbreviated version of the String, starting at the specified character offset and of the specified length. The returned String has ellipses appended at the start and the end if characters have been removed at these locations.

capitalize()
Returns the current String with the first letter changed to title case.

center(size)
Returns a version of the current String of the specified size padded with spaces on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without added spaces.

center(size, paddingString)
Returns a version of the current String of the specified size padded with the specified String on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without padding.

charAt(index)
Returns the value of the character at the specified index.
codePointAt(index)
Returns the Unicode code point value at the specified index.

codePointBefore(index)
Returns the Unicode code point value that occurs before the specified index.

codePointCount(beginIndex, endIndex)
Returns the number of Unicode code points within the specified text range.

compareTo(secondString)
Compares two strings lexicographically, based on the Unicode value of each character in the Strings.

contains(substring)
Returns true if and only if the String that called the method contains the specified sequence of characters in substring.

containsAny(inputString)
Returns true if the current String contains any of the characters in the specified String; otherwise, returns false.

containsIgnoreCase(substring)
Returns true if the current String contains the specified sequence of characters without regard to case; otherwise, returns false.

containsNone(inputString)
Returns true if the current String doesn’t contain any of the characters in the specified String; otherwise, returns false.

containsOnly(inputString)
Returns true if the current String contains characters only from the specified sequence of characters and not any other characters; otherwise, returns false.

containsWhitespace()
Returns true if the current String contains any white space characters; otherwise, returns false.

countMatches(substring)
Returns the number of times the specified substring occurs in the current String.

deleteWhitespace()
Returns a version of the current String with all white space characters removed.

difference(secondString)
Returns the difference between the current String and the specified String.

endsWith(suffix)
Returns true if the String that called the method ends with the specified suffix.

endsWithIgnoreCase(suffix)
Returns true if the current String ends with the specified suffix; otherwise, returns false.

equals(secondString)
Deprecated. This method is replaced by equals(stringOrId). Returns true if the passed-in string is not null and represents the same binary sequence of characters as the current string. Use this method to perform case-sensitive comparisons.

equals(stringOrId)
Returns true if the passed-in object is not null and represents the same binary sequence of characters as the current string. Use this method to compare a string to an object that represents a string or an ID.

equalsIgnoreCase(secondString)
Returns true if the secondString is not null and represents the same sequence of characters as the String that called the method, ignoring case.
escapeCsv() 
Returns a String for a CSV column enclosed in double quotes, if required.

escapeEcmaScript() 
Escapes the characters in the String using EcmaScript String rules.

escapeHtml3() 
Escapes the characters in a String using HTML 3.0 entities.

escapeHtml4() 
Escapes the characters in a String using HTML 4.0 entities.

escapeJava() 
Returns a String whose characters are escaped using Java String rules. Characters escaped include quotes and control characters, such as tab, backslash, and carriage return characters.

escapeSingleQuotes(stringToEscape) 
Returns a String with the escape character (\) added before any single quotation marks in the String s.

escapeUnicode() 
Returns a String whose Unicode characters are escaped to a Unicode escape sequence.

escapeXml() 
Escapes the characters in a String using XML entities.

format(stringToFormat, formattingArguments) 
Treat the first argument as a pattern and return a string using the second argument for substitution and formatting. The substitution and formatting are the same as apex:outputText and the Java MessageFormat class. Non-string types in the second argument’s List are implicitly converted to strings, respecting the toString() method overrides that exist on the type.

fromCharArray(charArray) 
Returns a String from the values of the list of integers.

getchars() 
Returns an array of character values that represent the characters in this string.

getCommonPrefix(strings) 
Returns the initial sequence of characters as a String that is common to all the specified Strings.

getLevenshteinDistance(stringToCompare) 
Returns the Levenshtein distance between the current String and the specified String.

getLevenshteinDistance(stringToCompare, threshold) 
Returns the Levenshtein distance between the current String and the specified String if it is less than or equal than the given threshold; otherwise, returns -1.

hashCode() 
Returns a hash code value for this string.

indexOf(substring) 
Returns the index of the first occurrence of the specified substring. If the substring does not occur, this method returns -1.

indexOf(substring, index) 
Returns the zero-based index of the first occurrence of the specified substring from the point of the given index. If the substring does not occur, this method returns -1.
indexOfAny(substring)
Returns the zero-based index of the first occurrence of any character specified in the substring. If none of the characters occur, returns -1.

indexOfAnyBut(substring)
Returns the zero-based index of the first occurrence of a character that is not in the specified substring. Otherwise, returns -1.

indexOfChar(character)
Returns the index of the first occurrence of the character that corresponds to the specified character value.

indexOfChar(character, startIndex)
Returns the index of the first occurrence of the character that corresponds to the specified character value, starting from the specified index.

indexOfDifference(stringToCompare)
Returns the zero-based index of the character where the current String begins to differ from the specified String.

indexOfIgnoreCase(substring)
Returns the zero-based index of the first occurrence of the specified substring without regard to case. If the substring does not occur, this method returns -1.

indexOfIgnoreCase(substring, startPosition)
Returns the zero-based index of the first occurrence of the specified substring from the point of index i, without regard to case. If the substring does not occur, this method returns -1.

isAllLowerCase()
Returns true if all characters in the current String are lowercase; otherwise, returns false.

isAllUpperCase()
Returns true if all characters in the current String are uppercase; otherwise, returns false.

isAlpha()
Returns true if all characters in the current String are Unicode letters only; otherwise, returns false.

isAlphaSpace()
Returns true if all characters in the current String are Unicode letters or spaces only; otherwise, returns false.

isAlphanumeric()
Returns true if all characters in the current String are Unicode letters or numbers only; otherwise, returns false.

isAlphanumericSpace()
Returns true if all characters in the current String are Unicode letters, numbers, or spaces only; otherwise, returns false.

isAsciiPrintable()
Returns true if the current String contains only ASCII printable characters; otherwise, returns false.

isBlank(inputString)
Returns true if the specified String is white space, empty (""), or null; otherwise, returns false.

isEmpty(inputString)
Returns true if the specified String is empty (""), or null; otherwise, returns false.

isNotBlank(inputString)
Returns true if the specified String is not whitespace, not empty (""), and not null; otherwise, returns false.

isEmpty(inputString)
Returns true if the specified String is not empty (""), and not null; otherwise, returns false.
isNumeric()
Returns true if the current String contains only Unicode digits; otherwise, returns false.

isNumericSpace()
Returns true if the current String contains only Unicode digits or spaces; otherwise, returns false.

isWhitespace()
Returns true if the current String contains only white space characters or is empty; otherwise, returns false.

join(iterableObj, separator)
Joins the elements of the specified iterable object, such as a List, into a single String separated by the specified separator.

lastIndexOf(substring)
Returns the index of the last occurrence of the specified substring. If the substring does not occur, this method returns -1.

lastIndexOf(substring, endPosition)
Returns the index of the last occurrence of the specified substring, starting from the character at index 0 and ending at the specified index.

lastIndexOfChar(character)
Returns the index of the last occurrence of the character that corresponds to the specified character value.

lastIndexOfChar(character, endIndex)
Returns the index of the last occurrence of the character that corresponds to the specified character value, starting from the specified index.

lastIndexOfIgnoreCase(substring)
Returns the index of the last occurrence of the specified substring regardless of case.

lastIndexOfIgnoreCase(substring, endPosition)
Returns the index of the last occurrence of the specified substring regardless of case, starting from the character at index 0 and ending at the specified index.

left(length)
Returns the leftmost characters of the current String of the specified length.

leftPad(length)
Returns the current String padded with spaces on the left and of the specified length.

leftPad(length, padStr)
Returns the current String padded with String padStr on the left and of the specified length.

length()
Returns the number of 16-bit Unicode characters contained in the String.

mid(startIndex, length)
Returns a new String that begins with the character at the specified zero-based startIndex with the number of characters specified by length.

normalizeSpace()
Returns the current String with leading, trailing, and repeating white space characters removed.

offsetByCodePoints(index, codePointOffset)
Returns the index of the Unicode code point that is offset by the specified number of code points, starting from the given index.

remove(substring)
Removes all occurrences of the specified substring and returns the String result.
removeEnd(substring)
Removes the specified substring only if it occurs at the end of the String.

removeEndIgnoreCase(substring)
Removes the specified substring only if it occurs at the end of the String using a case-insensitive match.

removeStart(substring)
Removes the specified substring only if it occurs at the beginning of the String.

removeStartIgnoreCase(substring)
Removes the specified substring only if it occurs at the beginning of the String using a case-insensitive match.

repeat(numberOfTimes)
Returns the current String repeated the specified number of times.

repeat(separator, numberOfTimes)
Returns the current String repeated the specified number of times using the specified separator to separate the repeated Strings.

replace(target, replacement)
Replaces each substring of a string that matches the literal target sequence target with the specified literal replacement sequence replacement.

replaceAll(regExp, replacement)
Replaces each substring of a string that matches the regular expression regExp with the replacement sequence replacement.

replaceFirst(regExp, replacement)
Replaces the first substring of a string that matches the regular expression regExp with the replacement sequence replacement.

reverse()
Returns a String with all the characters reversed.

right(length)
Returns the rightmost characters of the current String of the specified length.

rightPad(length)
Returns the current String padded with spaces on the right and of the specified length.

rightPad(length, padStr)
Returns the current String padded with String padStr on the right and of the specified length.

split(regExp)
Returns a list that contains each substring of the String that is terminated by either the regular expression regExp or the end of the String.

split(regExp, limit)
Returns a list that contains each substring of the String that is terminated by either the regular expression regExp or the end of the String.

splitByCharacterType()
Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens.

splitByCharacterTypeCamelCase()
Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens, with the following exception: the uppercase character, if any, immediately preceding a lowercase character token belongs to the following character token rather than to the preceding.

startsWith(prefix)
Returns true if the String that called the method begins with the specified prefix.
startsWithIgnoreCase(prefix)
Returns true if the current String begins with the specified prefix regardless of the prefix case.

stripHtmlTags()
Removes HTML markup and returns plain text.

substring(startIndex)
Returns a new String that begins with the character at the specified zero-based startIndex and extends to the end of the String.

substring(startIndex, endIndex)
Returns a new String that begins with the character at the specified zero-based startIndex and extends to the character at endIndex - 1.

substringAfter(separator)
Returns the substring that occurs after the first occurrence of the specified separator.

substringAfterLast(separator)
Returns the substring that occurs after the last occurrence of the specified separator.

substringBefore(separator)
Returns the substring that occurs before the first occurrence of the specified separator.

substringBeforeLast(separator)
Returns the substring that occurs before the last occurrence of the specified separator.

substringBetween(tag)
Returns the substring that occurs between two instances of the specified tag String.

substringBetween(open, close)
Returns the substring that occurs between the two specified Strings.

swapCase()
Swaps the case of all characters and returns the resulting String by using the default (English US) locale.

toLowerCase()
Converts all of the characters in the String to lowercase using the rules of the default (English US) locale.

toLowerCase(locale)
Converts all of the characters in the String to lowercase using the rules of the specified locale.

toUpperCase()
Converts all of the characters in the String to uppercase using the rules of the default (English US) locale.

toUpperCase(locale)
Converts all of the characters in the String to uppercase using the rules of the specified locale.

trim()
Returns a copy of the string that no longer contains any leading or trailing white space characters.

uncapitalize()
Returns the current String with the first letter in lowercase.

unescapeCsv()
Returns a String representing an unescaped CSV column.

unescapeEcmaScript()
Unescapes any EcmaScript literals found in the String.
unescapeHtml3()
Unescapes the characters in a String using HTML 3.0 entities.

unescapeHtml4()
Unescapes the characters in a String using HTML 4.0 entities.

unescapeJava()
Returns a String whose Java literals are unescaped. Literals unescaped include escape sequences for quotes (\") and control characters, such as tab (\t), and carriage return (\n).

unescapeUnicode()
Returns a String whose escaped Unicode characters are unescaped.

unescapeXml()
Unescapes the characters in a String using XML entities.

valueOf(dateToConvert)
Returns a String that represents the specified Date in the standard "yyyy-MM-dd" format.

valueOf(datetimeToConvert)
Returns a String that represents the specified Datetime in the standard "yyyy-MM-dd HH:mm:ss" format for the local time zone.

valueOf(decimalToConvert)
Returns a String that represents the specified Decimal.

valueOf(doubleToConvert)
Returns a String that represents the specified Double.

valueOf(integerToConvert)
Returns a String that represents the specified Integer.

valueOf(longToConvert)
Returns a String that represents the specified Long.

valueOf(toConvert)
Returns a string representation of the specified object argument.

valueOfGmt(datetimeToConvert)
Returns a String that represents the specified Datetime in the standard "yyyy-MM-dd HH:mm:ss" format for the GMT time zone.

**abbreviate (maxWidth)**

Returns an abbreviated version of the String, of the specified length and with ellipses appended if the current String is longer than the specified length; otherwise, returns the original String without ellipses.

**Signature**

```java
public String abbreviate(Integer maxWidth)
```

**Parameters**

`maxWidth`
Type: Integer

If `maxWidth` is less than four, this method throws a run-time exception.
Return Value
Type: String

Example
```java
String s = 'Hello Maximillian';
String s2 = s.abbreviate(8);
System.assertEquals('Hello...', s2);
System.assertEquals(8, s2.length());
```

**abbreviate(maxWidth, offset)**

Returns an abbreviated version of the String, starting at the specified character offset and of the specified length. The returned String has ellipses appended at the start and the end if characters have been removed at these locations.

**Signature**
```java
public String abbreviate(Integer maxWidth, Integer offset)
```

**Parameters**

- **maxWidth**
  
  Type: Integer
  
  Note that the offset is not necessarily the leftmost character in the returned String or the first character following the ellipses, but it appears somewhere in the result. Regardless, `abbreviate` won't return a String of length greater than `maxWidth`. If `maxWidth` is too small, this method throws a run-time exception.

- **offset**
  
  Type: Integer

**Return Value**
Type: String

Example
```java
String s = 'Hello Maximillian';
// Start at M
String s2 = s.abbreviate(9, 6);
System.assertEquals('...Max...', s2);
System.assertEquals(9, s2.length());
```

**capitalize()**

Returns the current String with the first letter changed to title case.

**Signature**
```java
public String capitalize()
```
Return Value
Type: String

Usage
This method is based on the Character.toTitleCase(char) Java method.

Example
```java
String s = 'hello maximillian';
String s2 = s.capitalize();
System.assertEquals('Hello maximillian', s2);
```

center(size)
Returs a version of the current String of the specified size padded with spaces on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without added spaces.

Signature
```java
public String center(Integer size)
```

Parameters
size
Type: Integer

Return Value
Type: String

Example
```java
String s = 'hello';
String s2 = s.center(9);
System.assertEquals(' hello ', s2);
```

center(size, paddingString)
Returns a version of the current String of the specified size padded with the specified String on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without padding.

Signature
```java
public String center(Integer size, String paddingString)
```
Parameters

\textit{size}

Type: \texttt{Integer}

\textit{paddingString}

Type: \texttt{String}

Return Value

Type: \texttt{String}

Example

\begin{verbatim}
String s = 'hello';
String s2 = s.center\(9, '-');
System.assertEquals('--hello--', s2);
\end{verbatim}

\textbf{charAt(index)}

Returns the value of the character at the specified index.

Signature

\texttt{public \texttt{Integer} \texttt{charAt}(\texttt{Integer} \texttt{index})}

Parameters

\textit{index}

Type: \texttt{Integer}

The index of the character to get the value of.

Return Value

Type: \texttt{Integer}

The integer value of the character.

Usage

The \texttt{charAt} method returns the value of the character pointed to by the specified index. If the index points to the beginning of a surrogate pair (the high-surrogate code point), this method returns only the high-surrogate code point. To return the supplementary code point corresponding to a surrogate pair, call \texttt{codePointAt} instead.

Example

This example gets the value of the first character at index 0.

\begin{verbatim}
String str = 'Ω is Omega.';
System.assertEquals(937, str.charAt(0));
\end{verbatim}
This example shows the difference between `charAt` and `codePointAt`. The example calls these methods on escaped supplementary Unicode characters. `charAt(0)` returns the high surrogate value, which corresponds to \uD835. `codePointAt(0)` returns the value for the entire surrogate pair.

```
String str = '\uD835\uDD0A';
System.assertEquals(55349, str.charAt(0),
  'charAt(0) didn\'t return the high surrogate.');//
System.assertEquals(120074, str.codePointAt(0),
  'codePointAt(0) didn\'t return the entire two-character supplementary value.');
```

codePointAt(index)

Returns the Unicode code point value at the specified index.

Signature

```
public Integer codePointAt(Integer index)
```

Parameters

`index`

Type: `Integer`

The index of the characters (Unicode code units) in the string. The index range is from zero to the string length minus one.

Return Value

Type: `Integer`

The Unicode code point value at the specified index.

Usage

If the `index` points to the beginning of a surrogate pair (the high-surrogate code point), and the character value at the following index points to the low-surrogate code point, this method returns the supplementary code point corresponding to this surrogate pair. Otherwise, this method returns the character value at the given index.

For more information on Unicode and surrogate pairs, see The Unicode Consortium.

Example

This example gets the code point value of the first character at index 0, which is the escaped Omega character. Also, the example gets the code point at index 20, which corresponds to the escaped supplementary Unicode characters (a pair of characters). Finally, it verifies that the escaped and unescaped forms of Omega have the same code point values.

```
String str = '\u03A9 is Ω (Omega), and \uD835\uDD0A is Fraktur Capital G.';
System.assertEquals(937, str.codePointAt(0));
System.assertEquals(120074, str.codePointAt(20));
// Escaped or unescaped forms of the same character have the same code point
System.assertEquals(str.codePointAt(0), str.codePointAt(5));
```
**codePointBefore(index)**

Returns the Unicode code point value that occurs before the specified index.

**Signature**

```java
public Integer codePointBefore(Integer index)
```

**Parameters**

- **index**
  
  Type: `Integer`
  
  The index before the Unicode code point that is to be returned. The index range is from one to the string length.

**Return Value**

Type: `Integer`

The character or Unicode code point value that occurs before the specified index.

**Usage**

If the character value at `index-1` is the low-surrogate code point, and `index-2` is not negative and the character at this index location is the high-surrogate code point, this method returns the supplementary code point corresponding to this surrogate pair. If the character value at `index-1` is an unpaired low-surrogate or high-surrogate code point, the surrogate value is returned.

For more information on Unicode and surrogate pairs, see [The Unicode Consortium](https://www.unicode.org).

**Example**

This example gets the code point value of the first character (before index 1), which is the escaped Omega character. Also, the example gets the code point at index 20, which corresponds to the escaped supplementary characters (the two characters before index 22).

```java
String str = '\u03A9 is Ω (Omega), and \uD835\uDD0A ' +
' is Fraktur Capital G.';
System.assertEquals(937, str.codePointBefore(1));
System.assertEquals(120074, str.codePointBefore(22));
```

**codePointCount(beginIndex, endIndex)**

Returns the number of Unicode code points within the specified text range.

**Signature**

```java
public Integer codePointCount(Integer beginIndex, Integer endIndex)
```

**Parameters**

- **beginIndex**
  
  Type: `Integer`
  
  The index of the first character in the range.
endIndex
  Type: Integer
  The index after the last character in the range.

Return Value
Type: Integer
The number of Unicode code points within the specified range.

Usage
The specified range begins at beginIndex and ends at endIndex−1. Unpaired surrogates within the text range count as one code point each.

Example
This example writes the count of code points in a substring that contains an escaped Unicode character and another substring that contains Unicode supplementary characters, which count as one code point.

```java
String str = '\u03A9 and \uD835\uDD0A characters.,'
System.debug('Count of code points for ' + str.substring(0,1) + ': ' + str.codePointCount(0,1));
System.debug('Count of code points for ' + str.substring(6,8) + ': ' + str.codePointCount(6,8));
// Output:
// Count of code points for Ω: 1
// Count of code points for ☯: 1
```

compareTo(secondString)
Compares two strings lexicographically, based on the Unicode value of each character in the Strings.

Signature
```
public Integer compareTo(String secondString)
```

Parameters
secondString
  Type: String

Return Value
Type: Integer

Usage
The result is:
- A negative Integer if the String that called the method lexicographically precedes secondString
A positive Integer if the String that called the method lexicographically follows `compSecondStringString`

Zero if the Strings are equal

If there is no index position at which the Strings differ, then the shorter String lexicographically precedes the longer String.

Note that this method returns 0 whenever the `equals` method returns true.

Example

```java
String myString1 = 'abcde';
String myString2 = 'abcd';
Integer result =
    myString1.compareTo(myString2);
System.assertEquals(result, 1);
```

`contains(substring)`

Returns `true` if and only if the String that called the method contains the specified sequence of characters in `substring`.

Signature

```java
public Boolean contains(String substring)
```

Parameters

`substring`

Type: `String`

Return Value

Type: `Boolean`

Example

```java
String myString1 = 'abcde';
String myString2 = 'abcd';
Boolean result =
    myString1.contains(myString2);
System.assertEquals(result, true);
```

`containsAny(inputString)`

Returns `true` if the current String contains any of the characters in the specified String; otherwise, returns `false`.

Signature

```java
public Boolean containsAny(String inputString)
```

Parameters

`inputString`

Type: `String`
Return Value
Type: Boolean

Example

String s = 'hello';
Boolean b1 = s.containsAny('hx');
Boolean b2 = s.containsAny('x');
System.assertEquals(true, b1);
System.assertEquals(false, b2);

containsIgnoreCase(substring)
Returns true if the current String contains the specified sequence of characters without regard to case; otherwise, returns false.

Signature
public Boolean containsIgnoreCase(String substring)

Parameters
substring
Type: String

Return Value
Type: Boolean

Example

String s = 'hello';
Boolean b = s.containsIgnoreCase('HE');
System.assertEquals(true, b);

containsNone(inputString)
Returns true if the current String doesn’t contain any of the characters in the specified String; otherwise, returns false.

Signature
public Boolean containsNone(String inputString)

Parameters
inputString
Type: String

If inputString is an empty string or the current String is empty, this method returns true. If inputString is null, this method returns a run-time exception.
Return Value
Type: Boolean

Example
```
String s1 = 'abcde';
System.assert(s1.containsNone('fg'));
```

**containsOnly** *(inputString)*

Returns *true* if the current String contains characters only from the specified sequence of characters and not any other characters; otherwise, returns *false*.

Signature
```
public Boolean containsOnly(String inputString)
```

Parameters

- **inputString**
  Type: String

Return Value
Type: Boolean

Example
```
String s1 = 'abba';
String s2 = 'abba xyz';
Boolean b1 = s1.containsOnly('abcd');
System.assertEquals(true, b1);
Boolean b2 = s2.containsOnly('abcd');
System.assertEquals(false, b2);
```

**containsWhitespace()**

Returns *true* if the current String contains any white space characters; otherwise, returns *false*.

Signature
```
public Boolean containsWhitespace()
```
Return Value

Type: **Boolean**

Example

```java
String s = 'Hello Jane';
System.assert(s.containsWhitespace()); //true
s = 'HelloJane ';
System.assert(s.containsWhitespace()); //true
s = ' HelloJane';
System.assert(s.containsWhitespace()); //true
s = 'HelloJane';
System.assert(!s.containsWhitespace()); //false
```

**countMatches(substring)**

Returns the number of times the specified substring occurs in the current String.

**Signature**

```java
public Integer countMatches(String substring)
```

**Parameters**

- `substring`  
  Type: **String**

**Return Value**

Type: **Integer**

Example

```java
String s = 'Hello Jane';
System.assertEquals(1, s.countMatches('Hello'));
s = 'Hello Hello';
System.assertEquals(2, s.countMatches('Hello'));
s = 'Hello hello';
System.assertEquals(1, s.countMatches('Hello'));
```

**deleteWhitespace()**

Returns a version of the current String with all white space characters removed.

**Signature**

```java
public String deleteWhitespace()
```

**Return Value**

Type: **String**
Example

```java
String s1 = 'Hello Jane';
String s2 = 'HelloJane';
System.assertEquals(s2, s1.deleteWhitespace());
```

difference(secondString)
Returns the difference between the current String and the specified String.

Signature
```java
public String difference(String secondString)
```

Parameters
secondString
Type: String
- If secondString is an empty string, this method returns an empty string.
- If secondString is null, this method throws a run-time exception.

Return Value
Type: String

Example
```java
String s = 'Hello Jane';
String d1 =
    s.difference('Hello Max');
System.assertEquals('Max',
    d1);
String d2 =
    s.difference('Goodbye');
System.assertEquals('Goodbye',
    d2);
```

endsWith(suffix)
Returns true if the String that called the method ends with the specified suffix.

Signature
```java
public Boolean endsWith(String suffix)
```

Parameters
suffix
Type: String
Return Value
Type: Boolean

Example

```java
String s = 'Hello Jason';
System.assert(s.endsWith('Jason'));
```

**endsWithIgnoreCase(suffix)**

Returns `true` if the current String ends with the specified suffix; otherwise, returns `false`.

Signature

```java
public Boolean endsWithIgnoreCase(String suffix)
```

Parameters

- `suffix`
  Type: String

Return Value
Type: Boolean

Example

```java
String s = 'Hello Jason';
System.assert(s.endsWithIgnoreCase('jason'));
```

**equals(secondString)**

Deprecated. This method is replaced by `equals(stringOrId)`. Returns `true` if the passed-in string is not null and represents the same binary sequence of characters as the current string. Use this method to perform case-sensitive comparisons.

Signature

```java
public Boolean equals(String secondString)
```

Parameters

- `secondString`
  Type: String

Return Value
Type: Boolean
Usage

This method returns `true` when the `compareTo` method returns 0.

Use this method to perform case-sensitive comparisons. In contrast, the `==` operator performs case-insensitive string comparisons to match Apex semantics.

Example

```java
String myString1 = 'abcde';
String myString2 = 'abcd';
Boolean result = myString1.equals(myString2);
System.assertEquals(result, false);
```

`equals(stringOrId)`

Returns `true` if the passed-in object is not null and represents the same binary sequence of characters as the current string. Use this method to compare a string to an object that represents a string or an ID.

Signature

```java
public Boolean equals(Object stringOrId)
```

Parameters

`stringOrId`

Type: `Object`

Return Value

Type: `Boolean`

Usage

If you compare ID values, the lengths of IDs don’t need to be equal. For example, if you compare a 15-character ID string to an object that represents the equivalent 18-character ID value, this method returns `true`. For more information about 15-character and 18-character IDs, see the ID data type.

Use this method to perform case-sensitive comparisons. In contrast, the `==` operator performs case-insensitive string comparisons to match Apex semantics.

Example

These examples show comparisons between different types of variables with both equal and unequal values. The examples also show how Apex automatically converts certain values before comparing them.

```java
// Compare a string to an object containing a string
Object obj1 = 'abc';
String str = 'abc';
Boolean result1 = str.equals(obj1);
System.assertEquals(result, true);

// Compare a string to an object containing a number
```
Integer obj2 = 100;
Boolean result2 = str.equals(obj2);
System.assertEquals(false, result2);

// Compare a string to an ID of the same length.
// 15-character ID
Id idValue15 = '001D000000Ju1zH';
// 15-character ID string value
String stringValue15 = '001D000000Ju1zH';
Boolean result3 = stringValue15.equals(IdValue15);
System.assertEquals(true, result3);

// Compare two equal ID values of different lengths:
// 15-character ID and 18-character ID
Id idValue18 = '001D000000Ju1zHlAR';
Boolean result4 = stringValue15.equals(IdValue18);
System.assertEquals(true, result4);

equalsIgnoreCase(secondString)

Returns true if the secondString is not null and represents the same sequence of characters as the String that called the method, ignoring case.

Signature
public Boolean equalsIgnoreCase(String secondString)

Parameters
secondString
  Type: String

Return Value
Type: Boolean

Example
String myString1 = 'abcd';
String myString2 = 'ABCD';
Boolean result =
  myString1.equalsIgnoreCase(myString2);
System.assertEquals(result, true);

escapeCsv()

Returns a String for a CSV column enclosed in double quotes, if required.

Signature
public String escapeCsv()
Return Value

Type: String

Usage

If the String contains a comma, newline or double quote, the returned String is enclosed in double quotes. Also, any double quote characters in the String are escaped with another double quote.

If the String doesn’t contain a comma, newline or double quote, it is returned unchanged.

Example

```java
String s1 = 'Max1, "Max2"';
String s2 = s1.escapeCsv();
System.assertEquals("Max1, "Max2"", s2);
```

**escapeEcmaScript()**

Escapes the characters in the String using EcmaScript String rules.

Signature

```java
public String escapeEcmaScript()
```

Return Value

Type: String

Usage

The only difference between Apex strings and EcmaScript strings is that in EcmaScript, a single quote and forward-slash (/) are escaped.

Example

```java
String s1 = "grade": 3.9/4.0';
String s2 = s1.escapeEcmaScript();
System.debug(s2);
// Output is:
// "grade": 3.9/4.0
System.assertEquals(
    "\"grade\": 3.9\"/4.0",
    s2);
```

**escapeHtml3()**

Escapes the characters in a String using HTML 3.0 entities.

Signature

```java
public String escapeHtml3()
```
Return Value
Type: String

Example

```java
String s1 = '
"<Black&White>"';
String s2 = s1.escapeHtml3();
System.debug(s2);
// Output:
// &quot;&lt;Black&amp; White&gt;&quot;
```

**escapeHtml4()**
Escapes the characters in a String using HTML 4.0 entities.

Signature
```java
public String escapeHtml4()
```

Return Value
Type: String

Example

```java
String s1 = '
"<Black&White>"';
String s2 = s1.escapeHtml4();
System.debug(s2);
// Output:
// &quot;&lt;Black&amp; White&gt;&quot;
```

**escapeJava()**
Returns a String whose characters are escaped using Java String rules. Characters escaped include quotes and control characters, such as tab, backslash, and carriage return characters.

Signature
```java
public String escapeJava()
```

Return Value
Type: String

The escaped string.
escapeSingleQuotes(stringToEscape)

Returns a String with the escape character (\) added before any single quotation marks in the String s.

Signature

public static String escapeSingleQuotes(String stringToEscape)

Parameters

stringToEscape
Type: String

Return Value

Type: String

Usage

This method is useful when creating a dynamic SOQL statement, to help prevent SOQL injection. For more information on dynamic SOQL, see Dynamic SOQL.

Example

String s = '\Hello Jason\'';
system.debug(s); // Outputs 'Hello Jason'
String escapedStr = String.escapeSingleQuotes(s);
// Outputs '\Hello Jason\'
system.debug(escapedStr);
// Escapes the string "\" to string '
system.assertEquals('\\\'Hello Jason\\\'', escapedStr);

escapeUnicode()

Returns a String whose Unicode characters are escaped to a Unicode escape sequence.

Signature

public String escapeUnicode()

Return Value

Type: String
The escaped string.

Example

```java
String s = 'De onde você é?';
String escapedStr = s.escapeUnicode();
System.assertEquals('De onde voc\u00EA \u00E9?', escapedStr);
```

**escapeXml()**

Escapes the characters in a String using XML entities.

**Signature**

```java
public String escapeXml()
```

**Return Value**

Type: String

**Usage**

Supports only the five basic XML entities (gt, lt, quot, amp, apos). Does not support DTDs or external entities. Unicode characters greater than 0x7f are not escaped.

Example

```java
String s1 = """<Black&White>"""";
String s2 =
    s1.escapeXml();
System.debug(s2);
// Output:
// &quot;&lt;Black&amp;White&gt;
```

**format(stringToFormat, formattingArguments)**

Treat the first argument as a pattern and return a string using the second argument for substitution and formatting. The substitution and formatting are the same as apex:outputText and the Java MessageFormat class. Non-string types in the second argument's List are implicitly converted to strings, respecting the toString() method overrides that exist on the type.

**Signature**

```java
public static String format(String stringToFormat, List<Object> formattingArguments)
```

**Parameters**

- `stringToFormat`
  Type: String
**formattingArguments**

Type: `List<Object>`

**Return Value**
Type: `String`

**Example**

```java
String template = '{0} was last updated {1}';
List<Object> parameters = new List<Object> {'Universal Containers',
DateInstance.newInstance(2018, 11, 15) };
String formatted = String.format(template, parameters);
System.debug ('Newly formatted string is:' + formatted);
```

### fromCharArray(charArray)

Returns a String from the values of the list of integers.

**Signature**

```java
public static String fromCharArray(List<Integer> charArray)
```

**Parameters**

`charArray`

Type: `List<Integer>`

**Return Value**
Type: `String`

**Example**

```java
List<Integer> charArr= new Integer[]{74};
String convertedChar = String.fromCharArray(charArr);
System.assertEquals('J', convertedChar);
```

### getChars()

Returns an array of character values that represent the characters in this string.

**Signature**

```java
public List<Integer> getChars()
```

**Return Value**
Type: `List<Integer>`

A list of integers, each corresponding to a character value in the string.
Example
This sample converts a string to a character array and then gets the first array element, which corresponds to the value of 'J'.

```java
String str = 'Jane goes fishing.IFORM; Integer[] chars = str.getChars(); // Get the value of 'J' System.assertEquals(74, chars[0]);
```

**getCommonPrefix(strings)**
Returns the initial sequence of characters as a String that is common to all the specified Strings.

**Signature**

```java
public static String getCommonPrefix(List<String> strings)
```

**Parameters**

- **strings**
  - Type: List<String>

**Return Value**
- Type: String

**Example**

```java
List<String> ls = new List<String>{'SFDCApex', 'SFDCVisualforce'};
String prefix = String.getCommonPrefix(ls);
System.assertEquals('SFDC', prefix);
```

**getLevenshteinDistance(stringToCompare)**
Returns the Levenshtein distance between the current String and the specified String.

**Signature**

```java
public Integer getLevenshteinDistance(String stringToCompare)
```

**Parameters**

- **stringToCompare**
  - Type: String

**Return Value**
- Type: Integer
Usage
The Levenshtein distance is the number of changes needed to change one String into another. Each change is a single character modification (deletion, insertion or substitution).

Example

```java
String s = 'Hello Joe';
Integer i = s.getLevenshteinDistance('Hello Max');
System.assertEquals(3, i);
```

`getLevenshteinDistance(stringToCompare, threshold)`

Returns the Levenshtein distance between the current String and the specified String if it is less than or equal than the given threshold; otherwise, returns -1.

Signature

```java
public Integer getLevenshteinDistance(String stringToCompare, Integer threshold)
```

Parameters

- `stringToCompare`
  - Type: `String`
- `threshold`
  - Type: `Integer`

Return Value

Type: `Integer`

Usage

The Levenshtein distance is the number of changes needed to change one String into another. Each change is a single character modification (deletion, insertion or substitution).

Example:
In this example, the Levenshtein distance is 3, but the threshold argument is 2, which is less than the distance, so this method returns -1.

```java
String s = 'Hello Jane';
Integer i = s.getLevenshteinDistance('Hello Max', 2);
System.assertEquals(-1, i);
```

`hashCode()`

Returns a hash code value for this string.
Signature

```java
public Integer hashCode()
```

Return Value

Type: Integer

Usage

This value is based on the hash code computed by the Java `String.hashCode` counterpart method.

You can use this method to simplify the computation of a hash code for a custom type that contains String member variables. You can compute your type’s hash code value based on the hash code of each String variable. For example:

For more details about the use of hash code methods with custom types, see Using Custom Types in Map Keys and Sets.

Example

```java
public class MyCustomClass {
    String x, y;
    // Provide a custom hash code
    public Integer hashCode() {
        return
            (31*x.hashCode())^(y.hashCode());
    }
}
```

**indexOf(substring)**

Returns the index of the first occurrence of the specified substring. If the substring does not occur, this method returns -1.

Signature

```java
public Integer indexOf(String substring)
```

Parameters

`substring`

Type: String

Return Value

Type: Integer

Example

```java
String myString1 = 'abcde';
String myString2 = 'cd';
Integer result = myString1.indexOf(myString2);
System.assertEquals(2, result);
```
`indexOf(substring, index)`

Returns the zero-based index of the first occurrence of the specified substring from the point of the given index. If the substring does not occur, this method returns -1.

**Signature**

```java
public Integer indexOf(String substring, Integer index)
```

**Parameters**

- `substring`
  - Type: `String`
- `index`
  - Type: `Integer`

**Return Value**

- Type: `Integer`

**Example**

```java
String myString1 = 'abcdabcd';
String myString2 = 'ab';
Integer result = myString1.indexOf(myString2, 1);
System.assertEquals(4, result);
```

`indexOfAny(substring)`

Returns the zero-based index of the first occurrence of any character specified in the substring. If none of the characters occur, returns -1.

**Signature**

```java
public Integer indexOfAny(String substring)
```

**Parameters**

- `substring`
  - Type: `String`

**Return Value**

- Type: `Integer`

**Example**

```java
String s1 = 'abcd';
String s2 = 'xc';
Integer result = s1.indexOfAny(s2);
System.assertEquals(2, result);
```
**indexOfAnyBut(substring)**

Returns the zero-based index of the first occurrence of a character that is not in the specified substring. Otherwise, returns -1.

**Signature**

```
public Integer indexOfAnyBut(String substring)
```

**Parameters**

- `substring`
  - Type: `String`

**Return Value**

- Type: `Integer`

**Example**

```java
String s1 = 'abcd';
String s2 = 'xc';
Integer result = s1.indexOfAnyBut(s2);
System.assertEquals(0, result);
```

**indexOfChar(character)**

Returns the index of the first occurrence of the character that corresponds to the specified character value.

**Signature**

```
public Integer indexOfChar(Integer character)
```

**Parameters**

- `character`
  - Type: `Integer`
  - The integer value of the character in the string.

**Return Value**

- Type: `Integer`
  - The index of the first occurrence of the specified character, -1 if the character is not found.

**Usage**

The index that this method returns is in Unicode code units.
Example

```java
String str = '\u03A9 is Ω (Omega)';
// Returns 0, which is the first character.
System.debug('indexOfChar(937)= ' + str.indexOfChar(937));

// Output:
// indexOfChar(937)=0
```

**indexOfChar(character, startIndex)**

Returns the index of the first occurrence of the character that corresponds to the specified character value, starting from the specified index.

**Signature**

```java
public Integer indexOfChar(Integer character, Integer startIndex)
```

**Parameters**

- `character`
  - Type: `Integer`
  - The integer value of the character to look for.

- `startIndex`
  - Type: `Integer`
  - The index to start the search from.

**Return Value**

- Type: `Integer`
  - The index, starting from the specified start index, of the first occurrence of the specified character, -1 if the character is not found.

**Usage**

The index that this method returns is in Unicode code units.

**Example**

This example shows different ways of searching for the index of the Omega character. The first call to `indexOfChar` doesn’t specify a start index and therefore the returned index is 0, which is the first occurrence of Omega in the entire string. The subsequent calls specify a start index to find the occurrence of Omega in substrings that start at the specified index.

```java
String str = 'Ω and \u03A9 and Ω';
System.debug('indexOfChar(937)= ' + str.indexOfChar(937));
System.debug('indexOfChar(937,1)= ' + str.indexOfChar(937,1));
System.debug('indexOfChar(937,10)= ' + str.indexOfChar(937,10));

// Output:
// indexOfChar(937)=0
// indexOfChar(937,1)=6, (corresponds to the escaped form \u03A9)
// indexOfChar(937,10)=12
```
indexOfDifference(stringToCompare)
Returns the zero-based index of the character where the current String begins to differ from the specified String.

Signature
public Integer indexOfDifference(String stringToCompare)

Parameters
stringToCompare
Type: String

Return Value
Type: Integer

Example
String s1 = 'abcd';
String s2 = 'abxc';
Integer result = s1.indexOfDifference(s2);
System.assertEquals(2, result);

indexOfIgnoreCase(substring)
Returns the zero-based index of the first occurrence of the specified substring without regard to case. If the substring does not occur, this method returns -1.

Signature
public Integer indexOfIgnoreCase(String substring)

Parameters
substring
Type: String

Return Value
Type: Integer

Example
String s1 = 'abcd';
String s2 = 'BC';
Integer result = s1.indexOfIgnoreCase(s2, 0);
System.assertEquals(1, result);
indexOfIgnoreCase(substring, startPosition)

Returns the zero-based index of the first occurrence of the specified substring from the point of index i, without regard to case. If the substring does not occur, this method returns -1.

Signature

public Integer indexOfIgnoreCase(String substring, Integer startPosition)

Parameters

substring
Type: String

startPosition
Type: Integer

Return Value
Type: Integer

isAllLowerCase()

Returns true if all characters in the current String are lowercase; otherwise, returns false.

Signature

public Boolean isAllLowerCase()

Return Value
Type: Boolean

Example

String allLower = 'abcde';
System.assert(allLower.isAllLowerCase());

isAllUpperCase()

Returns true if all characters in the current String are uppercase; otherwise, returns false.

Signature

public Boolean isAllUpperCase()

Return Value
Type: Boolean
Example

```java
String allUpper = 'ABCDE';
System.assert(allUpper.isAllUpperCase());
```

**isAlpha()**

Returns **true** if all characters in the current String are Unicode letters only; otherwise, returns **false**.

Signature

```
public Boolean isAlpha()
```

Return Value

Type: **Boolean**

Example

```java
// Letters only
String s1 = 'abc';
// Returns true
Boolean b1 =
   s1.isAlpha();
System.assertEquals(
   true, b1);

// Letters and numbers
String s2 = 'abc 21';
// Returns false
Boolean b2 =
   s2.isAlpha();
System.assertEquals(
   false, b2);
```

**isAlphaSpace()**

Returns **true** if all characters in the current String are Unicode letters or spaces only; otherwise, returns **false**.

Signature

```
public Boolean isAlphaSpace()
```

Return Value

Type: **Boolean**

Example

```java
String alphaSpace = 'aA Bb';
System.assert(alphaSpace.isAlphaSpace());
String notAlphaSpace = 'ab 12';
```
System.assert(!notAlphaSpace.isAlphaSpace());
notAlphaSpace = 'aA$Bb';
System.assert(!notAlphaSpace.isAlphaSpace());

isAlphanumeric()

Returns true if all characters in the current String are Unicode letters or numbers only; otherwise, returns false.

Signature

public Boolean isAlphanumeric()

Return Value

Type: Boolean

Example

// Letters only
String s1 = 'abc';
// Returns true
Boolean b1 =
   s1.isAlphanumeric();
System.assertEquals(
   true, b1);

// Letters and numbers
String s2 = 'abc021';
// Returns true
Boolean b2 =
   s2.isAlphanumeric();
System.assertEquals(
   true, b2);

isAlphanumericSpace()

Returns true if all characters in the current String are Unicode letters, numbers, or spaces only; otherwise, returns false.

Signature

public Boolean isAlphanumericSpace()

Return Value

Type: Boolean

Example

String alphanumSpace = 'AE 86';
System.assert(alphanumSpace.isAlphanumericSpace());
String notAlphanumSpace = 'aA$12';
System.assert(!notAlphanumSpace.isAlphaSpace());

isAsciiPrintable()  
Returns true if the current String contains only ASCII printable characters; otherwise, returns false.

Signature
public Boolean isAsciiPrintable()

Return Value
Type: Boolean

Example
String ascii = 'abcd1234!@#$%^&*()`~-_=+{}|[]<>?.';
System.assert(ascii.isAsciiPrintable());
String notAscii = '√';
System.assert(!notAscii.isAsciiPrintable());

isBlank(inputString)
Returns true if the specified String is white space, empty (''), or null; otherwise, returns false.

Signature
public static Boolean isBlank(String inputString)

Parameters
inputString
Type: String

Return Value
Type: Boolean

Example
String blank = '';
String nullString = null;
String whitespace = ' ';
System.assert(String.isBlank(blank));
System.assert(String.isBlank(nullString));
System.assert(String.isBlank(whitespace));
String alpha = 'Hello';
System.assert(!String.isBlank(alpha));

**isEmpty(inputString)**

Returns **true** if the specified String is empty ("") or null; otherwise, returns **false**.

**Signature**

```java
public static Boolean isEmpty(String inputString)
```

**Parameters**

- **inputString**
  - Type: **String**

**Return Value**

- Type: **Boolean**

**Example**

```java
String empty = '';
String nullString = null;
System.assert(String.isEmpty(empty));
System.assert(String.isEmpty(nullString));
String whitespace = '  ';
String alpha = 'Hello';
System.assert(!String.isEmpty(whitespace));
System.assert(!String.isEmpty(alpha));
```

**isNotBlank(inputString)**

Returns **true** if the specified String is not whitespace, not empty (""), and not null; otherwise, returns **false**.

**Signature**

```java
public static Boolean isNotBlank(String inputString)
```

**Parameters**

- **inputString**
  - Type: **String**

**Return Value**

- Type: **Boolean**

**Example**

```java
String alpha = 'Hello world!';
System.assert(String.isNotBlank(alpha));
String blank = '';
String nullString = null;
String whitespace = '  ';
```
**isEmpty(inputString)**

Returns **true** if the specified String is not empty (""") and not null; otherwise, returns **false**.

Signature

```java
public static Boolean isEmpty(String inputString)
```

Parameters

- **inputString**
  - Type: **String**

Return Value

- Type: **Boolean**

Example

```java
String whitespace = ' ';
String alpha = 'Hello world!';
System.assert(String.isNotEmpty(whitespace));
System.assert(String.isNotEmpty(alpha));
String empty = '';
String nullString = null;
System.assert(!String.isNotEmpty(empty));
System.assert(!String.isNotEmpty(nullString));
```

**isNumeric()**

Returns **true** if the current String contains only Unicode digits; otherwise, returns **false**.

Signature

```java
public Boolean isNumeric()
```

Return Value

- Type: **Boolean**

Usage

A decimal point (1.2) is not a Unicode digit.
Example

```java
String numeric = '1234567890';
System.assert(numeric.isNumeric());
String alphanumeric = 'R32';
String decimalPoint = '1.2';
System.assert(!alphanumeric.isNumeric());
System.assert(!decimalPoint.isNumeric());
```

**isNumericSpace()**

Returns **true** if the current String contains only Unicode digits or spaces; otherwise, returns **false**.

**Signature**

```java
public Boolean isNumericSpace()
```

**Return Value**

Type: **Boolean**

**Usage**

A decimal point (1.2) is not a Unicode digit.

**Example**

```java
String numericSpace = '1 2 3';
System.assert(numericSpace.isNumericSpace());
String notNumericspace = 'FD3S FC3S';
System.assert(!notNumericspace.isNumericSpace());
```

**isWhitespace()**

Returns **true** if the current String contains only white space characters or is empty; otherwise, returns **false**.

**Signature**

```java
public Boolean isWhitespace()
```

**Return Value**

Type: **Boolean**

**Example**

```java
String whitespace = ' ';
String blank = '';
System.assert(whitespace.isWhitespace());
System.assert(blank.isWhitespace());
```
String alphanum = 'SIL80';
System.assert(!alphanum.isWhitespace());

join(iterableObj, separator)

Joins the elements of the specified iterable object, such as a List, into a single String separated by the specified separator.

Signature

public static String join(Object iterableObj, String separator)

Parameters

iterableObj
Type: Object
separator
Type: String

Return Value
Type: String

Usage

List<Integer> li = new List<Integer>{10, 20, 30};
String s = String.join(li, '/');
System.assertEquals('10/20/30', s);

lastIndexOf(substring)

Returns the index of the last occurrence of the specified substring. If the substring does not occur, this method returns -1.

Signature

public Integer lastIndexOf(String substring)

Parameters

substring
Type: String

Return Value
Type: Integer
Example

```java
String s1 = 'abcdefgc';
Integer i1 = s1.lastIndexOf('c');
System.assertEquals(7, i1);
```

**lastIndexOf(substring, endPosition)**

Returns the index of the last occurrence of the specified substring, starting from the character at index 0 and ending at the specified index.

**Signature**

```java
public Integer lastIndexOf(String substring, Integer endPosition)
```

**Parameters**

- **substring**
  Type: String

- **endPosition**
  Type: Integer

**Return Value**

Type: Integer

**Usage**

If the substring doesn’t occur or `endPosition` is negative, this method returns -1. If `endPosition` is larger than the last index in the current String, the entire String is searched.

Example

```java
String s1 = 'abcdaacd';
Integer i1 = s1.lastIndexOf('c', 7);
System.assertEquals(6, i1);
Integer i2 = s1.lastIndexOf('c', 3);
System.assertEquals(2, i2);
```

**lastIndexOfChar(character)**

Returns the index of the last occurrence of the character that corresponds to the specified character value.

**Signature**

```java
public Integer lastIndexOfChar(Integer character)
```
Parameters

**character**

Type: Integer

The integer value of the character in the string.

Return Value

Type: Integer

The index of the last occurrence of the specified character, -1 if the character is not found.

Usage

The index that this method returns is in Unicode code units.

Example

```java
String str = 'Ω is Ω (Omega)';
// Get the last occurrence of Omega.
System.assertEquals(5, str.lastIndexOfChar(937));
```

**lastIndexOfChar(character, endIndex)**

Returns the index of the last occurrence of the character that corresponds to the specified character value, starting from the specified index.

Signature

```java
public Integer lastIndexOfChar(Integer character, Integer endIndex)
```

Parameters

**character**

Type: Integer

The integer value of the character to look for.

**endIndex**

Type: Integer

The index to end the search at.

Return Value

Type: Integer

The index, starting from the specified start index, of the last occurrence of the specified character. -1 if the character is not found.

Usage

The index that this method returns is in Unicode code units.
Example

This example shows different ways of searching for the index of the last occurrence of the Omega character. The first call to `lastIndexOfChar` doesn't specify an end index and therefore the returned index is 12, which is the last occurrence of Omega in the entire string. The subsequent calls specify an end index to find the last occurrence of Omega in substrings.

```java
String str = 'Ω and \u03A9 and Ω';
System.assertEquals(12, str.lastIndexOfChar(937));
System.assertEquals(6, str.lastIndexOfChar(937,11));
System.assertEquals(0, str.lastIndexOfChar(937,5));
```

`lastIndexOfIgnoreCase(substring)`

Returns the index of the last occurrence of the specified substring regardless of case.

Signature

```java
public Integer lastIndexOfIgnoreCase(String substring)
```

Parameters

`substring`

Type: `String`

Return Value

Type: `Integer`

Usage

If the substring doesn't occur, this method returns -1.

Example

```java
String s1 = 'abcdaacd';
Integer i1 =
    s1.lastIndexOfIgnoreCase('DAAC');
System.assertEquals(3, i1);
```

`lastIndexOfIgnoreCase(substring, endPosition)`

Returns the index of the last occurrence of the specified substring regardless of case, starting from the character at index 0 and ending at the specified index.

Signature

```java
public Integer lastIndexOfIgnoreCase(String substring, Integer endPosition)
```
Parameters

substring
Type: String

endPosition
Type: Integer

Return Value
Type: Integer

Usage
If the substring doesn’t occur or endPosition is negative, this method returns -1. If endPosition is larger than the last index in the current String, the entire String is searched.

Example

```java
String s1 = 'abcdaacd';
Integer i1 =
    s1.lastIndexOfIgnoreCase('C', 7);
System.assertEquals(
    6, i1);
```

**left(length)**

Returns the leftmost characters of the current String of the specified length.

Signature

```java
public String left(Integer length)
```

Parameters

length
Type: Integer

Return Value
Type: String

Usage
If length is greater than the String size, the entire String is returned.

Example

```java
String s1 = 'abcdaacd';
String s2 =
    s1.left(3);
```
leftPad(length)
Returns the current String padded with spaces on the left and of the specified length.

Signature
public String leftPad(Integer length)

Parameters
length
Type: Integer

Usage
If length is less than or equal to the current String size, the entire String is returned without space padding.

Return Value
Type: String

Example
String s1 = 'abc';
String s2 =
   s1.leftPad(5);
System.assertEquals(' abc', s2);

leftPad(length, padStr)
Returns the current String padded with String padStr on the left and of the specified length.

Signature
public String leftPad(Integer length, String padStr)

Parameters
length
Type: Integer

padStr
Type: String
   String to pad with; if null or empty treated as single blank.
Usage

If length is less than or equal to the current String size, the entire String is returned without space padding.

Return Value
Type: String

Example

```java
String s1 = 'abc';
String s2 = 'xy';
String s3 = s1.leftPad(7, s2);
System.assertEquals('xyxyabc', s3);
```

length()

Returns the number of 16-bit Unicode characters contained in the String.

Signature

```java
public Integer length()
```

Return Value
Type: Integer

Example

```java
String myString = 'abcd';
Integer result = myString.length();
System.assertEquals(result, 4);
```

mid(startIndex, length)

Returns a new String that begins with the character at the specified zero-based startIndex with the number of characters specified by length.

Signature

```java
public String mid(Integer startIndex, Integer length)
```

Parameters

startIndex
Type: Integer
If startIndex is negative, it is considered to be zero.

length
Type: Integer
If `length` is negative or zero, an empty string is returned. If `length` is greater than the remaining characters, the remainder of the string is returned.

**Return Value**

Type: `String`

**Usage**

This method is similar to the `substring(startIndex)` and `substring(startIndex, endIndex)` methods, except that the second argument is the number of characters to return.

**Example**

```java
String s = 'abcde';
String s2 = s.mid(2, 3);
System.assertEquals('cde', s2);
```

**normalizeSpace()**

Returns the current string with leading, trailing, and repeating white space characters removed.

**Signature**

```java
public String normalizeSpace()
```

**Return Value**

Type: `String`

**Usage**

This method normalizes the following white space characters: space, tab (`\t`), new line (`\n`), carriage return (`\r`), and form feed (`\f`).

**Example**

```java
String s1 = 'Salesforce \t force.com';
String s2 = s1.normalizeSpace();
System.assertEquals('Salesforce force.com', s2);
```

**offsetByCodePoints(index, codePointOffset)**

Returns the index of the Unicode code point that is offset by the specified number of code points, starting from the given index.

**Signature**

```java
public Integer offsetByCodePoints(Integer index, Integer codePointOffset)
```
Parameters

index
Type: Integer
The start index in the string.

codePointOffset
Type: Integer
The number of code points to be offset.

Return Value
Type: Integer
The index that corresponds to the start index that is added to the offset.

Usage
Unpaired surrogates within the text range that is specified by index and codePointOffset count as one code point each.

Example
This example calls offsetByCodePoints on a string with a start index of 0 (to start from the first character) and an offset of three code points. The string contains one sequence of supplementary characters in escaped form (a pair of characters). After an offset of three code points when counting from the beginning of the string, the returned code point index is four.

```java
String str = 'A \uD835\uDD0A BC';
System.assertEquals(4, str.offsetByCodePoints(0,3));
```

**remove(substring)**
Removes all occurrences of the specified substring and returns the String result.

Signature
```
public String remove(String substring)
```

Parameters

substring
Type: String

Return Value
Type: String

Example
```
String s1 = 'Salesforce and force.com';
String s2 =
    s1.remove('force');
```
removeEnd(String substring)
Removes the specified substring only if it occurs at the end of the String.

Signature

public String removeEnd(String substring)

Parameters

substring
Type: String

Return Value

Type: String

Example

String s1 = 'Salesforce and force.com';
String s2 =
    s1.removeEnd('.com');
System.assertEquals('Salesforce and force', s2);

removeEndIgnoreCase(String substring)
Removes the specified substring only if it occurs at the end of the String using a case-insensitive match.

Signature

public String removeEndIgnoreCase(String substring)

Parameters

substring
Type: String

Return Value

Type: String

Example

String s1 = 'Salesforce and force.com';
String s2 =
    s1.removeEndIgnoreCase('.COM');
System.assertEquals('Salesforce and force', s2);

**removeStart(substring)**
Removes the specified substring only if it occurs at the beginning of the String.

**Signature**

```java
public String removeStart(String substring)
```

**Parameters**

*substring*
Type: `String`

**Return Value**
Type: `String`

**Example**

```java
String s1 = 'Salesforce and force.com';
String s2 =
    s1.removeStart('Sales');
System.assertEquals(
    'force and force.com', s2);
```

**removeStartIgnoreCase(substring)**
Removes the specified substring only if it occurs at the beginning of the String using a case-insensitive match.

**Signature**

```java
public String removeStartIgnoreCase(String substring)
```

**Parameters**

*substring*
Type: `String`

**Return Value**
Type: `String`

**Example**

```java
String s1 = 'Salesforce and force.com';
String s2 =
    s1.removeStartIgnoreCase('SALES');
```
System.assertEquals('force and force.com', s2);

**repeat(numberOfTimes)**

Returns the current String repeated the specified number of times.

**Signature**

```java
public String repeat(Integer numberOfTimes)
```

**Parameters**

- **numberOfTimes**
  
  Type: `Integer`

**Return Value**

Type: `String`

**Example**

```java
String s1 = 'SFDC';
String s2 = s1.repeat(2);
System.assertEquals('SFDCSFDC', s2);
```

**repeat(separator, numberOfTimes)**

Returns the current String repeated the specified number of times using the specified separator to separate the repeated Strings.

**Signature**

```java
public String repeat(String separator, Integer numberOfTimes)
```

**Parameters**

- **separator**
  
  Type: `String`

- **numberOfTimes**
  
  Type: `Integer`

**Return Value**

Type: `String`
Example

```java
String s1 = 'SFDC';
String s2 =
    s1.repeat('-', 2);
System.assertEquals(
    'SFDC-SFDC', s2);
```

**replace(target, replacement)**

Replaces each substring of a string that matches the literal target sequence `target` with the specified literal replacement sequence `replacement`.

**Signature**

```java
public String replace(String target, String replacement)
```

**Parameters**

- `target`
  Type: `String`
- `replacement`
  Type: `String`

**Return Value**

Type: `String`

**Example**

```java
String s1 = 'abcdbca';
String target = 'bc';
String replacement = 'xy';
String s2 = s1.replace(target, replacement);
System.assertEquals('axydxya', s2);
```

**replaceAll(regExp, replacement)**

Replaces each substring of a string that matches the regular expression `regExp` with the replacement sequence `replacement`.

**Signature**

```java
public String replaceAll(String regExp, String replacement)
```

**Parameters**

- `regExp`
  Type: `String`
- `replacement`
  Type: `String`
Return Value
Type: String

Usage
See the Java Pattern class for information on regular expressions.

Example
```java
String s1 = 'a b c 5 xyz';
String regExp = '[a-zA-Z]';
String replacement = '1';
String s2 = s1.replaceAll(regExp, replacement);
System.assertEquals('1 1 1 5 111', s2);
```

replaceFirst(regExp, replacement)
Replaces the first substring of a string that matches the regular expression regExp with the replacement sequence replacement.

Signature
```java
public String replaceFirst(String regExp, String replacement)
```

Parameters
regExp
    Type: String
replacement
    Type: String

Return Value
Type: String

Usage
See the Java Pattern class for information on regular expressions.

Example
```java
String s1 = 'a b c 11 xyz';
String regExp = '[a-zA-Z]{2}';
String replacement = '2';
String s2 = s1.replaceFirst(regExp, replacement);
System.assertEquals('a b c 11 2z', s2);
```

reverse()
Returns a String with all the characters reversed.
Signature

```java
public String reverse()
```

Return Value
Type: String

**right(length)**
Returns the rightmost characters of the current String of the specified length.

Signature

```java
public String right(Integer length)
```

Parameters

`length`
Type: Integer
If `length` is greater than the String size, the entire String is returned.

Return Value
Type: String

Example

```java
String s1 = 'Hello Max';
String s2 =
    s1.right(3);
System.assertEquals(
    'Max', s2);
```

**rightPad(length)**
Returns the current String padded with spaces on the right and of the specified length.

Signature

```java
public String rightPad(Integer length)
```

Parameters

`length`
Type: Integer
If `length` is less than or equal to the current String size, the entire String is returned without space padding.

Return Value
Type: String
Example

```java
String s1 = 'abc';
String s2 =
    s1.rightPad(5);
System.assertEquals(
    'abc ', s2);
```

**rightPad(length, padStr)**

Returns the current String padded with String `padStr` on the right and of the specified length.

**Signature**

```java
public String rightPad(Integer length, String padStr)
```

**Parameters**

- `length`
  - Type: `Integer`
- `padStr`
  - Type: `String`
  - String to pad with; if null or empty treated as single blank.

**Usage**

If `length` is less than or equal to the current String size, the entire String is returned without space padding.

**Return Value**

- Type: `String`

**Example**

```java
String s1 = 'abc';
String s2 = 'xy';
String s3 = s1.rightPad(7, s2);
System.assertEquals('abcxyxy', s3);
```

**split(regExp)**

Returns a list that contains each substring of the String that is terminated by either the regular expression `regExp` or the end of the String.

**Signature**

```java
public String[] split(String regExp)
```
Parameters

`regExp`
Type: `String`

Return Value
Type: `String[]`

Note: In API version 34.0 and earlier, a zero-width `regExp` value produces an empty list item at the beginning of the method’s output.

Usage
See the Java `Pattern` class for information on regular expressions.

The substrings are placed in the list in the order in which they occur in the String. If `regExp` does not match any part of the String, the resulting list has just one element containing the original String.

Example
In the following example, a string is split using a backslash as a delimiter.

```java
public String splitPath(String filename) {
    if (filename == null)
        return null;
    List<String> parts = filename.split('\\');
    filename = parts[parts.size()-1];
    return filename;
}
```

// For example, if the file path is e:\\processed\\PPDSF100111.csv
// This method splits the path and returns the last part.
// Returned filename is PPDSF100111.csv

**split(regExp, limit)**

Returns a list that contains each substring of the String that is terminated by either the regular expression `regExp` or the end of the String.

Signature

```java
public String[] split(String regExp, Integer limit)
```

Parameters

`regExp`
Type: `String`
A regular expression.

`limit`
Type: `Integer`
Return Value
Type: String[]

**Note:** In API version 34.0 and earlier, a zero-width RegExp value produces an empty list item at the beginning of the method’s output.

Usage
The optional `limit` parameter controls the number of times the pattern is applied and therefore affects the length of the list.

- If `limit` is greater than zero:
  - The pattern is applied a maximum of `(limit – 1)` times.
  - The list’s length is no greater than `limit`.
  - The list’s last entry contains all input beyond the last matched delimiter.
- If `limit` is non-positive, the pattern is applied as many times as possible, and the list can have any length.
- If `limit` is zero, the pattern is applied as many times as possible, the list can have any length, and trailing empty strings are discarded.

Example
For example, for `String s = 'boo:and:moo':`

- `s.split(':', 2)` results in `{'boo', 'and:moo'}`
- `s.split(':', 5)` results in `{'boo', 'and', 'moo'}`
- `s.split(':', -2)` results in `{'boo', 'and', 'moo'}`
- `s.split('o', 5)` results in `{'b', '', ':and:m', '', ''}`
- `s.split('o', -2)` results in `{'b', '', ':and:m', '', ''}`
- `s.split('o', 0)` results in `{'b', '', ':and:m'}`

`splitByCharacterType()`
Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens.

Signature
```
public List<String> splitByCharacterType()
```

Return Value
Type: List<String>

Usage
For more information about the character types used, see `java.lang.Character.getType(char)`.
Example

```java
String s1 = 'Lightning.platform';
List<String> ls =
    s1.splitByCharacterType();
System.debug(ls);
// Writes this output:
// (L, ightning, ., platform)
```

**splitByCharacterTypeCamelCase()**

Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens, with the following exception: the uppercase character, if any, immediately preceding a lowercase character token belongs to the following character token rather than to the preceding.

**Signature**

```java
public List<String> splitByCharacterTypeCamelCase()
```

**Return Value**

Type: List<String>

**Usage**

For more information about the character types used, see java.lang.Character.getType(char).

Example

```java
String s1 = 'Lightning.platform';
List<String> ls =
    s1.splitByCharacterTypeCamelCase();
System.debug(ls);
// Writes this output:
// (Lightning, ., platform)
```

**startsWith(prefix)**

Returns `true` if the String that called the method begins with the specified `prefix`.

**Signature**

```java
public Boolean startsWith(String prefix)
```

**Parameters**

`prefix`

Type: String
startsWithIgnoreCase(prefix)

Returns true if the current String begins with the specified prefix regardless of the prefix case.

Signature

```java
public Boolean startsWithIgnoreCase(String prefix)
```

Parameters

prefix

Type: String

Return Value

Type: Boolean

Example

```java
String s1 = 'AE86 vs EK9';
System.assert(s1.startsWith('AE86'));
```

stripHtmlTags()​

Removes HTML markup and returns plain text.

Signature

```java
public String stripHtmlTags(String htmlInput)
```

Return Value

Type: String

Usage

⚠️ Warning: The stripHtmlTags function does not recursively strip tags; therefore, tags may still exist in the returned string. Do not use the stripHtmlTags function to sanitize input for inclusion as a raw HTML page. The unescaped output is not considered safe to include in an HTML document. The function will be deprecated in a future release.
Example

```java
String s1 = '<b>hello world</b>,'
String s2 = s1.stripHtmlTags();
System.assertEquals('hello world', s2);
```

**substring(startIndex)**

Returns a new String that begins with the character at the specified zero-based `startIndex` and extends to the end of the String.

**Signature**

```java
public String substring(Integer startIndex)
```

**Parameters**

- `startIndex`  
  Type: `Integer`

**Return Value**

Type: `String`

**Example**

```java
String s1 = 'hamburger';
System.assertEquals('burger', s1.substring(3));
```

**substring(startIndex, endIndex)**

Returns a new String that begins with the character at the specified zero-based `startIndex` and extends to the character at `endIndex` - 1.

**Signature**

```java
public String substring(Integer startIndex, Integer endIndex)
```

**Parameters**

- `startIndex`  
  Type: `Integer`

- `endIndex`  
  Type: `Integer`

**Return Value**

Type: `String`
Example

```
'hamburger'.substring(4, 8);  // Returns "urge"

'smiles'.substring(1, 5);   // Returns "mile"
```

**substringAfter(separator)**

Returns the substring that occurs after the first occurrence of the specified separator.

**Signature**

```
public String substringAfter(String separator)
```

**Parameters**

*separator*

Type: String

**Return Value**

Type: String

**Example**

```
String s1 = 'Salesforce.Lightning.platform';
String s2 = s1.substringAfter('.');
System.assertEquals('Lightning.platform', s2);
```

**substringAfterLast(separator)**

Returns the substring that occurs after the last occurrence of the specified separator.

**Signature**

```
public String substringAfterLast(String separator)
```

**Parameters**

*separator*

Type: String

**Return Value**

Type: String
Example

```java
String s1 = 'Salesforce.Lightning.platform';
String s2 =
   s1.substringAfterLast('.');
System.assertEquals(
   'platform', s2);
```

**substringBefore(separator)**

Returns the substring that occurs before the first occurrence of the specified separator.

**Signature**

```java
public String substringBefore(String separator)
```

**Parameters**

* separator
  Type: String

**Return Value**

Type: String

**Example**

```java
String s1 = 'Salesforce.Lightning.platform';
String s2 =
   s1.substringBefore('.');
System.assertEquals(
   'Salesforce', s2);
```

**substringBeforeLast(separator)**

Returns the substring that occurs before the last occurrence of the specified separator.

**Signature**

```java
public String substringBeforeLast(String separator)
```

**Parameters**

* separator
  Type: String

**Return Value**

Type: String
Example

```java
String s1 = 'Salesforce.Lightning.platform';
String s2 =
    s1.substringBeforeLast('.');
System.assertEquals('Salesforce.Lightning', s2);
```

**substringBetween(tag)**

Returns the substring that occurs between two instances of the specified `tag` string.

**Signature**

```java
public String substringBetween(String tag)
```

**Parameters**

- `tag`
  - Type: `String`

**Return Value**

- Type: `String`

**Example**

```java
String s1 = 'tagYellowtag';
String s2 = s1.substringBetween('tag');
System.assertEquals('Yellow', s2);
```

**substringBetween(open, close)**

Returns the substring that occurs between the two specified strings.

**Signature**

```java
public String substringBetween(String open, String close)
```

**Parameters**

- `open`
  - Type: `String`
- `close`
  - Type: `String`

**Return Value**

- Type: `String`
**Example**

```java
String s1 = 'xYellowy';
String s2 = s1.substringBetween('x','y');
System.assertEquals('Yellow', s2);
```

**swapCase()**

Swaps the case of all characters and returns the resulting String by using the default (English US) locale.

**Signature**

```
public String swapCase()
```

**Return Value**

Type: String

**Usage**

Upper case and title case converts to lower case, and lower case converts to upper case.

**Example**

```java
String s1 = 'Force.com';
String s2 = s1.swapCase();
System.assertEquals('fORCE.COM', s2);
```

**toLowerCase()**

Converts all of the characters in the String to lowercase using the rules of the default (English US) locale.

**Signature**

```
public String toLowerCase()
```

**Return Value**

Type: String

**Example**

```java
String s1 = 'ThIs iS hArD t0 rEaD';
System.assertEquals('this is hard to read',
                    s1.toLowerCase());
```

**toLowerCase(locale)**

Converts all of the characters in the String to lowercase using the rules of the specified locale.
**toLowerCase()**

Converts all of the characters in the String to lowercase using the rules of the default (English US) locale.

**Signature**

```java
public String toLowerCase(String locale)
```

**Parameters**

- `locale`
  
  Type: `String`

**Return Value**

Type: `String`

**Example**

```java
// Example in Turkish
// An uppercase dotted "i", \u0304, which is İ
// Note this contains both a İ as well as a I
String s1 = 'KIYMETLİ';
String s1Lower = s1.toLowerCase('tr');
// Dotless lowercase "i", \u0131, which is ı
// Note this has both a i and ı
String expected = 'kıymetli';
System.assertEquals(expected, s1Lower);
// Note if this was done in toLowerCase('en'), it would output 'kiymetli'
```

**toUpperCase()**

Converts all of the characters in the String to uppercase using the rules of the default (English US) locale.

**Signature**

```java
public String toUpperCase()
```

**Return Value**

Type: `String`

**Example**

```java
String myString1 = 'abcd';
String myString2 = 'ABCD';
myString1 =
  myString1.toUpperCase();
Boolean result =
  myString1.equals(myString2);
System.assertEquals(result, true);
```

**toUpperCase(locale)**

Converts all of the characters in the String to uppercase using the rules of the specified locale.
Signature

```
public String toUpperCase(String locale)
```

Parameters

`locale`
Type: `String`

Return Value

Type: `String`

Example

```
// Example in Turkish
// Dotless lowercase "ı", \u0131, which is ı
// Note this has both a i and ı
String s1 = 'imkansız';
String s1Upper = s1.toUpperCase('tr');
// An uppercase dotted "ı", \u0304, which is İ
// Note this contains both a İ as well as a I
String expected = 'İMKANȘIZ';
System.assertEquals(expected, s1Upper);
```

`trim()`

Returns a copy of the string that no longer contains any leading or trailing white space characters.

Signature

```
public String trim()
```

Return Value

Type: `String`

Usage

Leading and trailing ASCII control characters such as tabs and newline characters are also removed. White space and control characters that aren’t at the beginning or end of the sentence aren’t removed.

Example

```
String s1 = ' Hello! ';
String trimmed = s1.trim();
System.assertEquals('Hello!', trimmed);
```

`uncapitalize()`

Returns the current String with the first letter in lowercase.
public String uncapitalize()

Return Value
Type: String

Example

```java
String s1 = 'Hello max';
String s2 = s1.uncapitalize();
System.assertEquals('hello max', s2);
```

unescapeCsv()

Returns a String representing an unescaped CSV column.

Signature

```java
public String unescapeCsv()
```

Return Value
Type: String

Usage

If the String is enclosed in double quotes and contains a comma, newline or double quote, quotes are removed. Also, any double quote escaped characters (a pair of double quotes) are unescaped to just one double quote.

If the String is not enclosed in double quotes, or is and does not contain a comma, newline or double quote, it is returned unchanged.

Example

```java
String s1 = "Max1, "Max2"");
String s2 = s1.unescapeCsv();
System.assertEquals("Max1, "Max2", s2);
```

unescapeEcmaScript()

Unescapes any EcmaScript literals found in the String.
Signature

public String unescapeEcmaScript()

Return Value
Type: String

Example

```java
String s1 = "3.8","3.9";
String s2 = s1.unescapeEcmaScript();
System.assertEquals("3.8","3.9", s2);
```

**unescapeHtml3()**

Unescapes the characters in a String using HTML 3.0 entities.

Signature

public String unescapeHtml3()

Return Value
Type: String

Example

```java
String s1 = "<Black&White>";
String s2 = s1.unescapeHtml3();
System.assertEquals("<Black&White>", s2);
```

**unescapeHtml4()**

Unescapes the characters in a String using HTML 4.0 entities.

Signature

public String unescapeHtml4()

Return Value
Type: String
Apex Developer Guide

System Namespace

Usage
If an entity isn’t recognized, it is kept as is in the returned string.

Example
String s1 =
'&quot;&lt;Black&amp;White&gt;&quot;';
String s2 =
s1.unescapeHtml4();
System.assertEquals(
'"<Black&White>"',
s2);

unescapeJava()

Returns a String whose Java literals are unescaped. Literals unescaped include escape sequences for quotes (\\") and control characters,
such as tab (\\t), and carriage return (\\n).

Signature
public String unescapeJava()

Return Value
Type: String
The unescaped string.

Example
String s = 'Company: \\"Salesforce.com\\"';
String unescapedStr = s.unescapeJava();
System.assertEquals('Company: "Salesforce.com"', unescapedStr);

unescapeUnicode()

Returns a String whose escaped Unicode characters are unescaped.

Signature
public String unescapeUnicode()

Return Value
Type: String
The unescaped string.

3083


Example

```java
String s = 'De onde voc\u00E9?';
String unescapedStr = s.unescapeUnicode();
System.assertEquals('De onde você é?', unescapedStr);
```

**unescapeXml()**

Unescapes the characters in a String using XML entities.

**Signature**

```java
public String unescapeXml()
```

**Return Value**

Type: String

**Usage**

Supports only the five basic XML entities (gt, lt, quot, amp, apos). Does not support DTDs or external entities.

Example

```java
String s1 = '"&lt;Black&White&gt;&quot;';
String s2 = s1.unescapeXml();
System.assertEquals('"<Black&White>"', s2);
```

**valueOf(dateToConvert)**

Returns a String that represents the specified Date in the standard "yyyy-MM-dd" format.

**Signature**

```java
public static String valueOf(Date dateToConvert)
```

**Parameters**

`dateToConvert`

Type: Date

**Return Value**

Type: String
valueOf (datetimeToConvert)
Returns a String that represents the specified Datetime in the standard “yyyy-MM-dd HH:mm:ss” format for the local time zone.

Signature
public static String valueOf(Datetime datetimeToConvert)

Parameters
datetimeToConvert
  Type: Datetime

Return Value
Type: String

Example
DateTime dt = datetime.newInstance(1996, 6, 23);
String sDateTime = String.valueOf(dt);
System.assertEquals('1996-06-23 00:00:00', sDateTime);

valueOf (decimalToConvert)
Returns a String that represents the specified Decimal.

Signature
public static String valueOf(Decimal decimalToConvert)

Parameters
decimalToConvert
  Type: Decimal

Return Value
Type: String

Example
Decimal dec = 3.14159265;
String sDecimal = String.valueOf(dec);
System.assertEquals('3.14159265', sDecimal);
**valueOf(doubleToConvert)**

Returns a String that represents the specified Double.

**Signature**

```java
public static String valueOf(Double doubleToConvert)
```

**Parameters**

- **doubleToConvert**
  - Type: `Double`

**Return Value**

- Type: `String`

**Example**

```java
Double myDouble = 12.34;
String myString = String.valueOf(myDouble);
System.assertEquals('12.34', myString);
```

**valueOf(integerToConvert)**

Returns a String that represents the specified Integer.

**Signature**

```java
public static String valueOf(Integer integerToConvert)
```

**Parameters**

- **integerToConvert**
  - Type: `Integer`

**Return Value**

- Type: `String`

**Example**

```java
Integer myInteger = 22;
String sInteger = String.valueOf(myInteger);
System.assertEquals('22', sInteger);
```

**valueOf(longToConvert)**

Returns a String that represents the specified Long.
valueOf(Long longToConvert)

Parameters
longToConvert
Type: Long

Return Value
Type: String

Example
Long myLong = 123456789;
String sLong = String.valueOf(myLong);
System.assertEquals('123456789', sLong);

valueOf(toConvert)

Returns a string representation of the specified object argument.

Signature
public static String valueOf(Object toConvert)

Parameters
toConvert
Type: Object

Return Value
Type: String

Usage
If the argument is not a String, the valueOf method converts it into a String by calling the toString method on the argument, if available, or any overridden toString method if the argument is a user-defined type. Otherwise, if no toString method is available, it returns a String representation of the argument.

Example
List<Integer> ls =
    new List<Integer>(){
        ls.add(10);
        ls.add(20);
    }
String strList =
    String.valueOf(ls);
System.assertEquals('
  (10, 20)', strList);

valueOfGmt(datetimeToConvert)

Returns a String that represents the specified Datetime in the standard "yyyy-MM-dd HH:mm:ss" format for the GMT time zone.

Signature

public static String valueOfGmt(Datetime datetimeToConvert)

Parameters

datetimeToConvert
  Type: Datetime

Return Value

Type: String

Example

// For a PST timezone:
DateTime dt = datetime.newInstance(2001, 9, 14);
String sDateTime = String.valueOfGmt(dt);
System.assertEquals('2001-09-14 07:00:00', sDateTime);

StubProvider Interface

StubProvider is a callback interface that you can use as part of the Apex stub API to implement a mocking framework. Use this interface with the Test.createStub() method to create stubbed Apex objects for testing.

Namespace

System

Usage

The StubProvider interface allows you to define the behavior of a stubbed Apex class. The interface specifies a single method that requires implementing: handleMethodCall(). You specify the behavior of each method of the stubbed class in the handleMethodCall() method.

In your Apex test, you create a stubbed object using the Test.createStub() method. When you invoke methods on the stubbed object, StubProvider.handleMethodCall() is called, which performs the behavior that you've specified for each method.
StubProvider Methods

The following are methods for `StubProvider`.

**handleMethodCall(stubbedObject, stubbedMethodName, returnType, listOfParamTypes, listOfParamNames, listOfArgs)**

Use this method to define the behavior of each method of a stubbed class.

**Signature**

```java
public Object handleMethodCall(Object stubbedObject, String stubbedMethodName, System.Type returnType, List<System.Type> listOfParamTypes, List<String> listOfParamNames, List<Object> listOfArgs)
```

**Parameters**

- **stubbedObject**
  - Type: Object
  - The stubbed object.

- **stubbedMethodName**
  - Type: String
  - The name of the invoked method.

- **returnType**
  - Type: System.Type
  - The return type of the invoked method.

- **listOfParamTypes**
  - Type: List/System.Type
  - A list of the parameter types of the invoked method.

- **listOfParamNames**
  - Type: List/String
  - A list of the parameter names of the invoked method.
listOfArgs
Type: List<Object>
The actual argument values passed into this method at runtime.

Return Value
Type: Object

Usage
You can use the parameters passed into this method to identify which method on the stubbed object was invoked. Then you can define the behavior for each identified method.

SEE ALSO:
Build a Mocking Framework with the Stub API

System Class
Contains methods for system operations, such as writing debug messages and scheduling jobs.

Namespace
System

System Methods
The following are methods for System. All methods are static.

IN THIS SECTION:
abortJob(jobId)
Stops the specified job. The stopped job is still visible in the job queue in the Salesforce user interface.
assert(condition, msg)
Asserts that the specified condition is true. If it is not, a fatal error is returned that causes code execution to halt.
assertEquals(expected, actual, msg)
Asserts that the first two arguments are the same. If they are not, a fatal error is returned that causes code execution to halt.
assertNotEquals(expected, actual, msg)
Asserts that the first two arguments are different. If they are the same, a fatal error is returned that causes code execution to halt.
currentPageReference()
Returns a reference to the current page. This is used with Visualforce pages.
currentTimeMillis()
Returns the current time in milliseconds, which is expressed as the difference between the current time and midnight, January 1, 1970 UTC.
debug(msg)
Writes the specified message, in string format, to the execution debug log. The DEBUG log level is used.
debug(logLevel, msg)
Writes the specified message, in string format, to the execution debug log with the specified log level.

enqueueJob(queueableObj)
Adds a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID.

equals(obj1, obj2)
Returns true if both arguments are equal. Otherwise, returns false.

getAddressReadWriteMode()
Returns the read write mode set for an organization during Salesforce.com upgrades and downtimes.

hashCode(obj)
Returns the hash code of the specified object.

isBatch()
Returns true if a batch Apex job invoked the executing code, or false if not. In API version 35.0 and earlier, also returns true if a queueable Apex job invoked the code.

isFuture()
Returns true if the currently executing code is invoked by code contained in a method annotated with future; false otherwise.

isQueueable()
Returns true if a queueable Apex job invoked the executing code. Returns false if not, including if a batch Apex job or a future method invoked the code.

isScheduled()
Returns true if the currently executing code is invoked by a scheduled Apex job; false otherwise.

movePassword(targetUserId, sourceUserId)
Moves the specified user's password to a different user.

now()
Returns the current date and time in the GMT time zone.

process(workItemIds, action, comments, nextApprover)
Processes the list of work item IDs.

purgeOldAsyncJobs(dt)
Deletes asynchronous Apex job records for jobs that have finished execution before the specified date with a Completed, Aborted, or Failed status, and returns the number of records deleted.

requestVersion()
Returns a two-part version that contains the major and minor version numbers of a package.

resetPassword(userId, sendUserEmail)
Resets the password for the specified user.

resetPasswordWithEmailTemplate(userId, sendUserEmail, emailTemplateName)
Resets the user's password and sends an email to the user with their new password. You specify the email template that is sent to the specified user. Use this method for external users of communities.

runAs(version)
Changes the current package version to the package version specified in the argument.

runAs(userSObject)
Changes the current user to the specified user.
**schedule**(*jobName*, *cronExpression*, *schedulableClass*)

Use `schedule` with an Apex class that implements the `Schedulable` interface to schedule the class to run at the time specified by a Cron expression.

**scheduleBatch**(*batchable*, *jobName*, *minutesFromNow*)

Schedules a batch job to run once in the future after the specified time interval and with the specified job name.

**scheduleBatch**(*batchable*, *jobName*, *minutesFromNow*, *scopeSize*)

Schedules a batch job to run once in the future after the specified the time interval, with the specified job name and scope size. Returns the scheduled job ID (CronTrigger ID).

**setPassword**(*userId*, *password*)

Sets the password for the specified user.

**submit**(*workItemIds*, *comments*, *nextApprover*)

Submits the processed approvals. The current user is the submitter and the entry criteria is evaluated for all processes applicable to the current user.

**today**()

Returns the current date in the current user's time zone.

**abortJob**(*jobId*)

Stops the specified job. The stopped job is still visible in the job queue in the Salesforce user interface.

**assert**(*condition*, *msg*)

Asserts that the specified condition is true. If it is not, a fatal error is returned that causes code execution to halt.
Signature

```java
public static Void assert(Boolean condition, Object msg)
```

Parameters

- `condition`
  - Type: `Boolean`
- `msg`
  - Type: `Object`
  - (Optional) Custom message returned as part of the error message.

Return Value

Type: Void

Usage

You can’t catch an assertion failure using a try/catch block even though it is logged as an exception.

```java
assertEquals(expected, actual, msg)
```

Asserts that the first two arguments are the same. If they are not, a fatal error is returned that causes code execution to halt.

Signature

```java
public static Void assertEquals(Object expected, Object actual, Object msg)
```

Parameters

- `expected`
  - Type: `Object`
  - Specifies the expected value.
- `actual`
  - Type: `Object`
  - Specifies the actual value.
- `msg`
  - Type: `Object`
  - (Optional) Custom message returned as part of the error message.

Return Value

Type: Void

Usage

You can’t catch an assertion failure using a try/catch block even though it is logged as an exception.
assertNotEquals(expected, actual, msg)

Asserts that the first two arguments are different. If they are the same, a fatal error is returned that causes code execution to halt.

Signature

```java
public static Void assertNotEquals(Object expected, Object actual, Object msg)
```

Parameters

- `expected`
  - Type: Object
  - Specifies the expected value.

- `actual`
  - Type: Object
  - Specifies the actual value.

- `msg`
  - Type: Object
  - (Optional) Custom message returned as part of the error message.

Return Value

Type: Void

Usage

You can’t catch an assertion failure using a try/catch block even though it is logged as an exception.

currentPageReference()

Returns a reference to the current page. This is used with Visualforce pages.

Signature

```java
public static System.PageReference currentPageReference()
```

Return Value

Type: `System.PageReference`

Usage

For more information, see `PageReference Class`.

currentTimeMillis()

Returns the current time in milliseconds, which is expressed as the difference between the current time and midnight, January 1, 1970 UTC.
public static Long currentTimeMillis()

Return Value
Type: Long

d debug (msg)
Writes the specified message, in string format, to the execution debug log. The DEBUG log level is used.

Signature
public static Void debug(Object msg)

Parameters
msg
  Type: Object

Return Value
Type: Void

Usage
If the msg argument is not a string, the debug method calls String.valueOf to convert it into a string. The String.valueOf method calls the toString method on the argument, if available, or any overridden toString method if the argument is a user-defined type. Otherwise, if no toString method is available, it returns a string representation of the argument.

If the log level for Apex Code is set to DEBUG or higher, the message of this debug statement will be written to the debug log.

Note that when a map or set is printed, the output is sorted in key order and is surrounded with square brackets ([ ]). When an array or list is printed, the output is enclosed in parentheses (()).

Note: Calls to System.debug are not counted as part of Apex code coverage. Calls to System.debug are not counted as part of Apex code coverage.

For more information on log levels, see “Debug Log Levels” in the Salesforce online help.

d debug (logLevel, msg)
Writes the specified message, in string format, to the execution debug log with the specified log level.

Signature
public static Void debug(LoggingLevel logLevel, Object msg)

Parameters
logLevel
  Type: System.LoggingLevel
The logging level to set for this method.

msg
Type: Object

The message or object to write in string format to the execution debug log.

Return Value
Type: Void

Usage
If the msg argument is not a string, the debug method calls String.valueOf to convert it into a string. The String.valueOf method calls the toString method on the argument, if available, or any overridden toString method if the argument is a user-defined type. Otherwise, if no toString method is available, it returns a string representation of the argument.

Note: Calls to System.debug are not counted as part of Apex code coverage.

System Logging Levels
Use the loggingLevel enum to specify the logging level for the debug method.
Valid log levels are (listed from lowest to highest):
- NONE
- ERROR
- WARN
- INFO
- DEBUG
- FINE
- FINER
- FINEST

Log levels are cumulative. For example, if the lowest level, ERROR, is specified for Apex Code, only debug methods with the log level of ERROR are logged. If the next log level, WARN, is specified, the debug log contains debug methods specified as either ERROR or WARN.

In the following example, the string MsgTxt is not written to the debug log because the log level is ERROR and the debug method has a level of INFO:

```java
System.LoggingLevel level = LoggingLevel.ERROR;
System.debug(logginglevel.INFO, 'MsgTxt');
```

For more information on log levels, see “Debug Log Levels” in the Salesforce online help.

enqueueJob(queueableObj)

Adds a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID.
Signature

```java
public static ID enqueueJob(Object queueableObj)
```

Parameters

`queueableObj`
- Type: Object
  - An instance of the class that implements the Queueable Interface.

Return Value

Type: ID
- The job ID, which corresponds to the ID of an AsyncApexJob record.

Usage

To add a job for asynchronous execution, call `System.enqueueJob` by passing in an instance of your class implementation of the Queueable interface for execution as follows:

```java
ID jobID = System.enqueueJob(new MyQueueableClass());
```

For more information about Queueable Apex, including information about limits, see Queueable Apex.

### equals(obj1, obj2)

Returns `true` if both arguments are equal. Otherwise, returns `false`.

Signature

```java
public static Boolean equals(Object obj1, Object obj2)
```

Parameters

`obj1`
- Type: Object
  - Object being compared.

`obj2`
- Type: Object
  - Object to compare with the first argument.

Return Value

Type: Boolean

Usage

`obj1` and `obj2` can be of any type. They can be values, or object references, such as sObjects and user-defined types.

The comparison rules for `System.equals` are identical to the ones for the `==` operator. For example, string comparison is case insensitive. For information about the comparison rules, see the `==` operator.
**getApplicationReadWriteMode()**

Returns the read write mode set for an organization during Salesforce.com upgrades and downtimes.

**Signature**

```java
public static System.ApplicationReadWriteMode getApplicationReadWriteMode()
```

**Return Value**

Type: `System.ApplicationReadWriteMode`

Valid values are:

- `DEFAULT`
- `READ_ONLY`

**Using the `System.ApplicationReadWriteMode` Enum**

Use the `System.ApplicationReadWriteMode` enum returned by the `getApplicationReadWriteMode` to programmatically determine if the application is in read-only mode during Salesforce upgrades and downtimes.

Valid values for the enum are:

- `DEFAULT`
- `READ_ONLY`

**Example:**

```java
public class myClass {
    public static void execute() {
        ApplicationReadWriteMode mode = System.getApplicationReadWriteMode();

        if (mode == ApplicationReadWriteMode.READ_ONLY) {
            // Do nothing. If DML operation is attempted in readonly mode, 
            // InvalidReadOnlyUserDmlException will be thrown.
        } else if (mode == ApplicationReadWriteMode.DEFAULT) {
            Account account = new Account(name = 'my account');
            insert account;
        }
    }
}
```

**hashCode(obj)**

Returns the hash code of the specified object.

**Signature**

```java
public static Integer hashCode(Object obj)
```

**Parameters**

- `obj`
  
  Type: `Object`
The object to get the hash code for. This parameter can be of any type, including values or object references, such as sObjects or user-defined types.

Return Value
Type: Integer

**isBatch()**
Returns *true* if a batch Apex job invoked the executing code, or *false* if not. In API version 35.0 and earlier, also returns *true* if a queueable Apex job invoked the code.

Signature
```
public static Boolean isBatch()
```

Return Value
Type: Boolean

Usage
A batch Apex job can't invoke a future method. Before invoking a future method, use `isBatch()` to check whether the executing code is a batch Apex job.

**isFuture()**
Returns *true* if the currently executing code is invoked by code contained in a method annotated with `future`; *false* otherwise.

Signature
```
public static Boolean isFuture()
```

Return Value
Type: Boolean

Usage
Since a future method can't be invoked from another future method, use this method to check if the current code is executing within the context of a future method before you invoke a future method.

**isQueueable()**
Returns *true* if a queueable Apex job invoked the executing code. Returns *false* if not, including if a batch Apex job or a future method invoked the code.

Signature
```
public static Boolean isQueueable()
```
Return Value
Type: Boolean

Usage

```java
public class SimpleQueueable implements Queueable {

    String name;

    public SimpleQueueable(String name) {
        this.name = name;
        System.assert(!System.isQueueable()); //Should return false
    }

    public void execute(QueueableContext ctx) {
        Account testAccount = new Account();
        testAccount.name = 'testAcc';
        insert(testAccount);
        System.assert(System.isQueueable()); //Should return true
    }
}
```

```java
global class ComplexBatch implements Database.Batchable<SObject> {

global Database.QueryLocator start(Database.BatchableContext info) {
    System.assert(!System.isQueueable()); //Should return false
    return Database.getQueryLocator([SELECT Id, Name FROM Account LIMIT 1]);
}

global void execute(Database.BatchableContext info, SObject[] scope) {
    System.assert(!System.isQueueable()); //Should return false
    System.enqueueJob(new SimpleQueueable('CallingFromComplexBatch'));
    System.assert(!System.isQueueable()); //Should return false
}

global void finish(Database.BatchableContext info) {
    System.assert(!System.isQueueable()); //Should return false
}
}
```

`isScheduled()`

Returns `true` if the currently executing code is invoked by a scheduled Apex job; `false` otherwise.

Signature

```java
public static Boolean isScheduled()
```

Return Value
Type: Boolean
movePassword(targetUserId, sourceUserId)
Moves the specified user's password to a different user.

Signature
public static Void movePassword(ID targetUserId, ID sourceUserId)

Parameters
- targetUserId
  Type: ID
  The user that the password is moved to.
- sourceUserId
  Type: ID
  The user that the password is moved from.

Return Value
Type: Void

Usage
Moving a password simplifies converting a user to another type of user, such as when converting an external user to a user with less restrictive access. If you require access to the movePassword method, contact Salesforce.

Keep in mind these requirements.
- The targetUserId, sourceUserId, and user performing the move operation must all belong to the same Salesforce org.
- The targetUserId and the sourceUserId cannot be the same as the user performing the move operation.
- A user without a password can't be specified as the sourceUserId. For example, a source user who has already had their password moved is left without a password. That user can't be a source user again.

After the password is moved:
- The target user can log in with the password.
- The source user no longer has a password. To enable logins for this user, a password reset is required.

now() Returns the current date and time in the GMT time zone.

Signature
public static Datetime now()

Return Value
Type: Datetime
process(workItemIds, action, comments, nextApprover)

Processes the list of work item IDs.

Signature

```java
public static List<Id> process(List<Id> workItemIds, String action, String comments, String nextApprover)
```

Parameters

- **workItemIds**
  - Type: List<Id>
- **action**
  - Type: String
- **comments**
  - Type: String
- **nextApprover**
  - Type: String

Return Value

- Type: List<Id>

purgeOldAsyncJobs(dt)

Deletes asynchronous Apex job records for jobs that have finished execution before the specified date with a Completed, Aborted, or Failed status, and returns the number of records deleted.

Signature

```java
public static Integer purgeOldAsyncJobs(Date dt)
```

Parameters

- **dt**
  - Type: Date

  Specifies the date up to which old records are deleted. The date comparison is based on the CompletedDate field of AsyncApexJob, which is in the GMT time zone.

Return Value

- Type: Integer

Usage

Asynchronous Apex job records are records in AsyncApexJob.

The system cleans up asynchronous job records for jobs that have finished execution and are older than seven days. You can use this method to further reduce the size of AsyncApexJob by cleaning up more records.
Each execution of this method counts as a single row against the governor limit for DML statements.

Example
This example shows how to delete all job records for jobs that have finished before today’s date.

```java
Integer count = System.purgeOldAsyncJobs
    (Date.today());
System.debug('Deleted ' + count + ' old jobs.);
```

**requestVersion()**
Returns a two-part version that contains the major and minor version numbers of a package.

Signature

```java
public static System.Version requestVersion()
```

Return Value
Type: System.Version

Usage
Using this method, you can determine the version of an installed instance of your package from which the calling code is referencing your package. Based on the version that the calling code has, you can customize the behavior of your package code.

The `requestVersion` method isn’t supported for unmanaged packages. If you call it from an unmanaged package, an exception will be thrown.

**resetPassword(userId, sendUserEmail)**
Resets the password for the specified user.

Signature

```java
public static System.ResetPasswordResult resetPassword(ID userId, Boolean sendUserEmail)
```

Parameters

- `userId`
  Type: ID
- `sendUserEmail`
  Type: Boolean

Return Value
Type: System.ResetPasswordResult
Usage

When the user logs in with the new password, they are prompted to enter a new password, and to select a security question and answer if they haven’t already. If you specify `true` for `sendUserEmail`, the user is sent an email notifying them that their password was reset. A link to sign onto Salesforce using the new password is included in the email. Use `setPassword(userId, password)` if you don’t want the user to be prompted to enter a new password when they log in.

⚠️ **Warning:** Be careful with this method, and do not expose this functionality to end-users.

`resetPasswordWithEmailTemplate(userId, sendUserEmail, emailTemplateName)`

Resets the user’s password and sends an email to the user with their new password. You specify the email template that is sent to the specified user. Use this method for external users of communities.

**Signature**

```java
public static System.ResetPasswordResult resetPasswordWithEmailTemplate(Id userId, Boolean sendUserEmail, String emailTemplateName)
```

**Parameters**

- `userId`
  - Type: `Id`
  - The ID of the user whose password was reset.

- `sendUserEmail`
  - Type: `Boolean`

- `emailTemplateName`
  - Type: `String`
  - Name of the email template.

**Return Value**

- Type: `System.ResetPasswordResult`

**Usage**

If you specify `true` for `sendUserEmail`, specify the email template that is sent to the user notifying them that their password was reset. When the user logs in with the new password in the email, they are prompted to enter a new password. A link to sign onto Salesforce using the new password is included in the email. Use `setPassword(userId, password)` if you don’t want the user to be prompted to enter a new password when they log in.

⚠️ **Warning:** Be careful with this method, and do not expose this functionality to end-users.

`runAs(version)`

Changes the current package version to the package version specified in the argument.

**Signature**

```java
public static Void runAs(System.Version version)
```
Parameters

version
Type: System.Version

Return Value
Type: Void

Usage
A package developer can use Version methods to continue to support existing behavior in classes and triggers in previous package versions while continuing to evolve the code. Apex classes and triggers are saved with the version settings for each installed managed package that the class or trigger references.

This method is used for testing your component behavior in different package versions that you upload to the AppExchange. This method effectively sets a two-part version consisting of major and minor numbers in a test method so that you can test the behavior for different package versions.

You can only use runAs in a test method. There is no limitation to the number of calls to this method in a transaction. For sample usage of this method, see Testing Behavior in Package Versions.

runAs (userSObject)
Changes the current user to the specified user.

Signature

public static Void runAs(User userSObject)

Parameters

userSObject
Type: User

Return Value
Type: Void

Usage
All of the specified user’s record sharing is enforced during the execution of runAs. You can only use runAs in a test method. For more information, see Using the runAs Method on page 611.

Note: The runAs method ignores user license limits. You can create new users with runAs even if your organization has no additional user licenses.

The runAs method implicitly inserts the user that is passed in as parameter if the user has been instantiated, but not inserted yet.

You can also use runAs to perform mixed DML operations in your test by enclosing the DML operations within the runAs block. In this way, you bypass the mixed DML error that is otherwise returned when inserting or updating setup objects together with other sObjects. See sObjects That Cannot Be Used Together in DML Operations.

Note: Every call to runAs counts against the total number of DML statements issued in the process.
schedule(jobName, cronExpression, schedulableClass)

Use schedule with an Apex class that implements the Schedulable interface to schedule the class to run at the time specified by a Cron expression.

Signature

```
public static String schedule(String jobName, String cronExpression, Object schedulableClass)
```

Parameters

- **jobName**
  Type: String
- **cronExpression**
  Type: String
- **schedulableClass**
  Type: Object

Return Value

Type: String

Returns the scheduled job ID (CronTrigger ID).

Usage

Use extreme care if you're planning to schedule a class from a trigger. You must be able to guarantee that the trigger won't add more scheduled classes than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time. Use the `abortJob` method to stop the job after it has been scheduled.

Note: Salesforce schedules the class for execution at the specified time. Actual execution may be delayed based on service availability.

Using the System.Schedule Method

After you implement a class with the Schedulable interface, use the `System.Schedule` method to execute it. The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.

Note: Use extreme care if you're planning to schedule a class from a trigger. You must be able to guarantee that the trigger won't add more scheduled classes than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time.

The `System.Schedule` method takes three arguments: a name for the job, an expression used to represent the time and date the job is scheduled to run, and the name of the class. This expression has the following syntax:

```
Seconds Minutes Hours Day_of_month Month Day_of_week Optional_year
```

Note: Salesforce schedules the class for execution at the specified time. Actual execution may be delayed based on service availability. The `System.Schedule` method uses the user's timezone for the basis of all schedules.
The following are the values for the expression:

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Special Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seconds</td>
<td>0–59</td>
<td>None</td>
</tr>
<tr>
<td>Minutes</td>
<td>0–59</td>
<td>None</td>
</tr>
<tr>
<td>Hours</td>
<td>0–23</td>
<td>None</td>
</tr>
<tr>
<td>Month</td>
<td>1–12 or the following:</td>
<td>, - * /</td>
</tr>
<tr>
<td></td>
<td>JAN, FEB, MAR, APR, MAY, JUN, JUL, AUG, SEP, OCT, NOV, DEC</td>
<td></td>
</tr>
<tr>
<td>Day_of_week</td>
<td>1–7 or the following:</td>
<td>, - * ? / L #</td>
</tr>
<tr>
<td></td>
<td>SUN, MON, TUE, WED, THU, FRI, SAT</td>
<td></td>
</tr>
<tr>
<td>optional_year</td>
<td>null or 1970–2099</td>
<td>, - * /</td>
</tr>
</tbody>
</table>

The special characters are defined as follows:

<table>
<thead>
<tr>
<th>Special Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>,</td>
<td>Delimits values. For example, use JAN, MAR, APR to specify more than one month.</td>
</tr>
<tr>
<td>-</td>
<td>Specifies a range. For example, use JAN–MAR to specify more than one month.</td>
</tr>
<tr>
<td>*</td>
<td>Specifies all values. For example, if Month is specified as *, the job is scheduled for every month.</td>
</tr>
<tr>
<td>Special Character</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>?</td>
<td>Specifies no specific value. This is only available for <code>Day_of_month</code> and <code>Day_of_week</code>, and is generally used when specifying a value for one and not the other.</td>
</tr>
<tr>
<td>/</td>
<td>Specifies increments. The number before the slash specifies when the intervals will begin, and the number after the slash is the interval amount. For example, if you specify 1/5 for <code>Day_of_month</code>, the Apex class runs every fifth day of the month, starting on the first of the month.</td>
</tr>
<tr>
<td>L</td>
<td>Specifies the end of a range (last). This is only available for <code>Day_of_month</code> and <code>Day_of_week</code>. When used with <code>Day_of_month</code>, L always means the last day of the month, such as January 31, February 29 for leap years, and so on. When used with <code>Day_of_week</code> by itself, it always means 7 or SAT. When used with a <code>Day_of_week</code> value, it means the last of that type of day in the month. For example, if you specify <code>2L</code>, you are specifying the last Monday of the month. Do not use a range of values with L as the results might be unexpected.</td>
</tr>
<tr>
<td>W</td>
<td>Specifies the nearest weekday (Monday-Friday) of the given day. This is only available for <code>Day_of_month</code>. For example, if you specify <code>2W</code>, and the 20th is a Saturday, W the class runs on the 19th. If you specify <code>1W</code>, and the first is a Saturday, the class does not run in the previous month, but on the third, which is the following Monday. <strong>Tip:</strong> Use the L and W together to specify the last weekday of the month.</td>
</tr>
<tr>
<td>#</td>
<td>Specifies the <code>nth</code> day of the month, in the format <code>weekday#day_of_month</code>. This is only available for <code>Day_of_week</code>. The number before the # specifies weekday (SUN-SAT). The number after the # specifies the day of the month. For example, specifying <code>2#2</code> means the class runs on the second Monday of every month.</td>
</tr>
</tbody>
</table>

The following are some examples of how to use the expression.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0 13 * * ?</td>
<td>Class runs every day at 1 PM.</td>
</tr>
<tr>
<td>0 0 22 ? * 6L</td>
<td>Class runs the last Friday of every month at 10 PM.</td>
</tr>
<tr>
<td>0 0 10 ? * MON-FRI</td>
<td>Class runs Monday through Friday at 10 AM.</td>
</tr>
<tr>
<td>0 0 20 * * ? 2010</td>
<td>Class runs every day at 8 PM during the year 2010.</td>
</tr>
</tbody>
</table>

In the following example, the class `proschedule` implements the `Scheduleable` interface. The class is scheduled to run at 8 AM, on the 13th of February.

```java
proschedule p = new proschedule();
String sch = '0 0 8 13 2 ?';
system.schedule('One Time Pro', sch, p);
```
scheduleBatch(batchable, jobName, minutesFromNow)

Schedules a batch job to run once in the future after the specified time interval and with the specified job name.

Signature

```java
public static String scheduleBatch(Database.Batchable batchable, String jobName, Integer minutesFromNow)
```

Parameters

- **batchable**
  - Type: `Database.Batchable`
  - An instance of a class that implements the `Database.Batchable` interface.

- **jobName**
  - Type: `String`
  - The name if the job that this method will start.

- **minutesFromNow**
  - Type: `Integer`
  - The time interval in minutes after which the job should start executing. This argument must be greater than zero.

Return Value

- Type: `String`
- The scheduled job ID (CronTrigger ID).

Usage

**Note:** Some things to note about `System.scheduleBatch`:

- When you call `System.scheduleBatch`, Salesforce schedules the job for execution at the specified time. Actual execution occurs at or after that time, depending on service availability.

- The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.

- When the job’s schedule is triggered, the system queues the batch job for processing. If Apex flex queue is enabled in your org, the batch job is added at the end of the flex queue. For more information, see [Holding Batch Jobs in the Apex Flex Queue](#).

- All scheduled Apex limits apply for batch jobs scheduled using `System.scheduleBatch`. After the batch job is queued (with a status of `Holding` or `Queued`), all batch job limits apply and the job no longer counts toward scheduled Apex limits.

- After calling this method and before the batch job starts, you can use the returned scheduled job ID to abort the scheduled job using the `System.abortJob` method.

For an example, see [Using the System.scheduleBatch Method](#).

scheduleBatch(batchable, jobName, minutesFromNow, scopeSize)

Schedules a batch job to run once in the future after the specified the time interval, with the specified job name and scope size. Returns the scheduled job ID (CronTrigger ID).
Signature

```java
public static String scheduleBatch(Database.Batchable batchable, String jobName, Integer minutesFromNow, Integer scopeSize)
```

Parameters

- `batchable`
  Type: `Database.Batchable`
  The batch class that implements the `Database.Batchable` interface.

- `jobName`
  Type: `String`
  The name of the job that this method will start.

- `minutesFromNow`
  Type: `Integer`
  The time interval in minutes after which the job should start executing.

- `scopeSize`
  Type: `Integer`
  The number of records that should be passed to the batch `execute` method.

Return Value

Type: `String`

Usage

**Note:** Some things to note about `System.scheduleBatch`:

- When you call `System.scheduleBatch`, Salesforce schedules the job for execution at the specified time. Actual execution occurs at or after that time, depending on service availability.
- The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.
- When the job's schedule is triggered, the system queues the batch job for processing. If Apex flex queue is enabled in your org, the batch job is added at the end of the flex queue. For more information, see Holding Batch Jobs in the Apex Flex Queue.
- All scheduled Apex limits apply for batch jobs scheduled using `System.scheduleBatch`. After the batch job is queued (with a status of `Holding` or `Queued`), all batch job limits apply and the job no longer counts toward scheduled Apex limits.
- After calling this method and before the batch job starts, you can use the returned scheduled job ID to abort the scheduled job using the `System.abortJob` method.

For an example, see Using the `System.scheduleBatch` Method.

**setPassword(userId, password)**

Sets the password for the specified user.

Signature

```java
public static Void setPassword(ID userId, String password)
```
Parameters

userId
  Type: ID

password
  Type: String

Return Value
Type: Void

Usage
When the user logs in with this password, they are not prompted to create a new password. Use `resetPassword(userId, sendUserEmail)` if you want the user to go through the reset process and create their own password.

⚠️ Warning: Be careful with this method, and do not expose this functionality to end-users.

`submit(workItemIds, comments, nextApprover)`

Submits the processed approvals. The current user is the submitter and the entry criteria is evaluated for all processes applicable to the current user.

Signature
```
public static List<ID> submit(List<ID> workItemIds, String comments, String nextApprover)
```

Parameters

workItemIds
  Type: List<ID>

comments
  Type: String

nextApprover
  Type: String

Return Value
Type: List<ID>

Usage
For enhanced submit and evaluation features, see the `ProcessSubmitRequest` class.

`today()`

Returns the current date in the current user's time zone.
**Signature**

```java
public static Date today()
```

**Return Value**

Type: Date

**Test Class**

Contains methods related to Apex tests.

**Namespace**

System

**Test Methods**

The following are methods for Test. All methods are static.

**IN THIS SECTION:**

- `clearApexPageMessages()`
  - Clear the messages on a Visualforce page while executing Apex test methods.

- `createStub(parentType, stubProvider)`
  - Creates a stubbed version of an Apex class that you can use for testing. This method is part of the Apex stub API. You can use it with the System.StubProvider interface to create a mocking framework.

- `enableChangeDataCapture()`
  - Use this method in an Apex test so that change event notifications are generated for all supported Change Data Capture entities. Call this method at the beginning of your test before performing DML operations and calling `Test.getEventBus().deliver()`.

- `enqueueBatchJobs(numberOfJobs)`
  - Adds the specified number of jobs with no-operation contents to the test-context queue. It first fills the test batch queue, up to the maximum 5 jobs, and then places jobs in the test flex queue. It throws a limit exception when the number of jobs in the test flex queue exceeds the allowed limit of 100 jobs.

- `getEventBus()`
  - Returns an instance of the test event bus broker, which lets you operate on platform event or change event messages in an Apex test. For example, you can call `Test.getEventBus().deliver()` to deliver event messages.

- `getFlexQueueOrder()`
  - Returns an ordered list of job IDs for jobs in the test-context flex queue. The job at index 0 is the next job slated to run. This method returns only test-context results, even if it's annotated with `@IsTest(SeeAllData=true)`.

- `getStandardPricebookId()`
  - Returns the ID of the standard price book in the organization.

- `invokeContinuationMethod(controller, request)`
  - Invokes the callback method for the specified controller and continuation in a test method.
isRunningTest()
Returns true if the currently executing code was called by code contained in a test method, false otherwise. Use this method if you need to run different code depending on whether it was being called from a test.

loadData(sObjectToken, resourceName)
Inserts test records from the specified static resource .csv file and for the specified sObject type, and returns a list of the inserted sObjects.

newSendEmailQuickActionDefaults(contextId, replyToId)
Creates a new QuickAction.SendEmailQuickActionDefaults instance for testing a class implementing the QuickAction.QuickActionDefaultsHandler interface.

setContinuationResponse(requestLabel, mockResponse)
Sets a mock response for a continuation HTTP request in a test method.

setCreatedDate(recordId, createdDatetime)
Sets CreatedDate for a test-context sObject.

setCurrentPage(page)
A Visualforce test method that sets the current PageReference for the controller.

setCurrentPageReference(page)
A Visualforce test method that sets the current PageReference for the controller.

setFixedSearchResults(fixedSearchResults)
Defines a list of fixed search results to be returned by all subsequent SOSL statements in a test method.

setMock(interfaceType, instance)
Sets the response mock mode and instructs the Apex runtime to send a mock response whenever a callout is made through the HTTP classes or the auto-generated code from WSDLs.

setReadOnlyApplicationMode(applicationMode)
Sets the application mode for an organization to read-only in an Apex test to simulate read-only mode during Salesforce upgrades and downtimes. The application mode is reset to the default mode at the end of each Apex test run.

startTest()
Marks the point in your test code when your test actually begins. Use this method when you are testing governor limits.

stopTest()
Marks the point in your test code when your test ends. Use this method in conjunction with the startTest method.

testInstall(installImplementation, version, isPush)
Tests the implementation of the InstallHandler interface, which is used for specifying a post install script in packages. Tests run as the test initiator in the development environment.

testUninstall(uninstallImplementation)
Tests the implementation of the UninstallHandler interface, which is used for specifying an uninstall script in packages. Tests run as the test initiator in the development environment.

clearApexPageMessages()
Clear the messages on a Visualforce page while executing Apex test methods.

Signature

public static void clearApexPageMessages()
Return Value
Type: void

Usage
This method may only be used in tests.

Example:

```java
@isTest
static void clearMessagesTest() {
    Test.setCurrentPage(new PageReference('/'));
    ApexPages.addMessage(
        new ApexPages.Message(ApexPages.Severity.WARNING, 'Sample Warning')
    );
    System.assertEquals(1, ApexPages.getMessages().size());
    Test.clearApexPageMessages();
    System.assertEquals(0, ApexPages.getMessages().size());
}
```

createStub(parentType, stubProvider)

Creates a stubbed version of an Apex class that you can use for testing. This method is part of the Apex stub API. You can use it with the System.StubProvider interface to create a mocking framework.

Signature
```
public static Object createStub(System.Type parentType, System.StubProvider stubProvider)
```

Parameters

parentType
Type: System.Type

The type of the Apex class to be stubbed.

stubProvider
System.StubProvider

An implementation of the StubProvider interface.

Return Value
Type: Object

Returns the stubbed object to use in testing.

Usage

The createStub() method works together with the System.StubProvider interface. You define the behavior of the stubbed object by implementing the StubProvider interface. Then you create a stubbed object using the createStub() method.
When you invoke methods on the stubbed object, the `handleMethodCall()` method of the `StubProvider` interface is called to perform the behavior of the stubbed method.

**SEE ALSO:**
- `StubProvider Interface`
- `Build a Mocking Framework with the Stub API`

### `enableChangeDataCapture()`

Use this method in an Apex test so that change event notifications are generated for all supported Change Data Capture entities. Call this method at the beginning of your test before performing DML operations and calling `Test.getEventBus().deliver();`.

**Signature**

```java
public static void enableChangeDataCapture()
```

**Return Value**

Type: `void`

**Usage**

The `enableChangeDataCapture()` method ensures that Apex tests can fire change event triggers regardless of the entities selected in Setup in the Change Data Capture page. The `enableChangeDataCapture()` method doesn’t affect the entities selected in Setup.

**SEE ALSO:**
- `Change Data Capture Developer Guide`

### `enqueueBatchJobs(numberOfJobs)`

Adds the specified number of jobs with no-operation contents to the test-context queue. It first fills the test batch queue, up to the maximum 5 jobs, and then places jobs in the test flex queue. It throws a limit exception when the number of jobs in the test flex queue exceeds the allowed limit of 100 jobs.

**Signature**

```java
public static List<Id> enqueueBatchJobs(Integer numberOfJobs)
```

**Parameters**

- `numberOfJobs`
  - Type: `Integer`
  - Number of test jobs to enqueue.

**Return Value**

Type: `List<Id>`
A list of IDs of enqueued test jobs.

Usage
Use this method to reduce testing time. Instead of using your org’s real batch jobs for testing, you can use this method to simulate batch-job enqueueing. Using `enqueueBatchJobs(numberOfJobs)` is faster than enqueuing real batch jobs.

### getEventBus()

Returns an instance of the test event bus broker, which lets you operate on platform event or change event messages in an Apex test. For example, you can call `Test.getEventBus().deliver()` to deliver event messages.

**Signature**

```java
public static EventBus.TestBroker getEventBus()
```

**Return Value**

Type: `EventBus.TestBroker`
A broker for the test event bus.

**Usage**

Enclose `Test.getEventBus().deliver()` within the `Test.startTest()` and `Test.stopTest()` statement block.

```java
Test.startTest();
// Create test events
// ...
// Publish test events with EventBus.publish()
// ...
// Deliver test events
Test.getEventBus().deliver();
// Perform validation
// ...
Test.stopTest();
```

SEE ALSO:

*Platform Events Developer Guide*

### getFlexQueueOrder()

Returns an ordered list of job IDs for jobs in the test-context flex queue. The job at index 0 is the next job slated to run. This method returns only test-context results, even if it’s annotated with `@IsTest(SeeAllData=true)`.

**Signature**

```java
public static List<Id> getFlexQueueOrder()
```

**Return Value**

Type: `List<Id>`
An ordered list of IDs of the jobs in the test’s flex queue.

**getStandardPricebookId()**

Returns the ID of the standard price book in the organization.

**Signature**

```java
public static Id getStandardPricebookId()
```

**Return Value**

Type: Id

The ID of the standard price book.

**Usage**

This method returns the ID of the standard price book in your organization regardless of whether the test can query organization data. By default, tests can’t query organization data unless they’re annotated with `@isTest(SeeAllData=true)`.

Creating price book entries with a standard price requires the ID of the standard price book. Use this method to get the standard price book ID so that you can create price book entries in your tests.

**Example**

This example creates some test data for price book entries. The test method in this example gets the standard price book ID and uses this ID to create a price book entry for a product with a standard price. Next, the test creates a custom price book and uses the ID of this custom price book to add a price book entry with a custom price.

```java
@isTest
public class PriceBookTest {
    // Utility method that can be called by Apex tests to create price book entries.
    static testmethod void addPricebookEntries() {
        // First, set up test price book entries.
        // Insert a test product.
        Product2 prod = new Product2(Name = 'Laptop X200',
            Family = 'Hardware');
        insert prod;

        // Get standard price book ID.
        // This is available irrespective of the state of SeeAllData.
        Id pricebookId = Test.getStandardPricebookId();

        // 1. Insert a price book entry for the standard price book.
        PricebookEntry standardPrice = new PricebookEntry(
            Pricebook2Id = pricebookId, Product2Id = prod.Id,
            UnitPrice = 10000, IsActive = true);
        insert standardPrice;

        // Create a custom price book
        Pricebook2 customPB = new Pricebook2 (Name='Custom Pricebook', isActive=true);
```
insert customPB;

// 2. Insert a price book entry with a custom price.
PricebookEntry customPrice = new PricebookEntry(
    Pricebook2Id = customPB.Id, Product2Id = prod.Id,
    UnitPrice = 12000, IsActive = true);
insert customPrice;

// Next, perform some tests with your test price book entries.

invokeContinuationMethod(controller, request)
Invokes the callback method for the specified controller and continuation in a test method.

Signature

public static Object invokeContinuationMethod(Object controller, Continuation request)

Parameters

controller
Type: Object
An instance of the controller class that invokes the continuation request.

request
Type: Continuation
The continuation that is returned by an action method in the controller class.

Return Value

Type: Object
The response of the continuation callback method.

Usage

Use the Test.setContinuationResponse and Test.invokeContinuationMethod methods to test continuations. In test context, callouts of continuations aren’t sent to the external service. By using these methods, you can set a mock response and cause the runtime to call the continuation callback method to process the mock response.

Call Test.setContinuationResponse before you call Test.invokeContinuationMethod. When you call Test.invokeContinuationMethod, the runtime executes the callback method that is associated with the continuation. The callback method processes the mock response that is set by Test.setContinuationResponse.

isRunningTest()
Returns true if the currently executing code was called by code contained in a test method, false otherwise. Use this method if you need to run different code depending on whether it was being called from a test.
Signature

`public static Boolean isRunningTest()`

Return Value

Type: `Boolean`

`loadData(sObjectToken, resourceName)`

Inserts test records from the specified static resource `.csv` file and for the specified sObject type, and returns a list of the inserted sObjects.

Signature

`public static List<sObject> loadData(Schema.SObjectType sObjectToken, String resourceName)`

Parameters

`sObjectToken`

Type: `Schema.SObjectType`

The sObject type for which to insert test records.

`resourceName`

Type: `String`

The static resource that corresponds to the `.csv` file containing the test records to load. The name is case insensitive.

Return Value

Type: `List<sObject>`

Usage

You must create the static resource prior to calling this method. The static resource is a comma-delimited file ending with a `.csv` extension. The file contains field names and values for the test records. The first line of the file must contain the field names and subsequent lines are the field values. To learn more about static resources, see “Defining Static Resources” in the Salesforce online help.

Once you create a static resource for your `.csv` file, the static resource will be assigned a MIME type. Supported MIME types are:

- `text/csv`
- `application/vnd.ms-excel`
- `application/octet-stream`
- `text/plain`

`newSendEmailQuickActionDefaults(contextId, replyToId)`

Creates a new `QuickAction.SendEmailQuickActionDefaults` instance for testing a class implementing the `QuickAction.QuickActionDefaultsHandler` interface.
Signature

```java
public static QuickAction.SendEmailQuickActionDefaults newSendEmailQuickActionDefaults(ID contextId, ID replyToId)
```

Parameters

contextId
   Type: Id
   Parent record of the email message.

replyToId
   Type: Id
   Previous email message ID if this email message is a reply.

Return Value

Type: SendEmailQuickActionDefaults Class
The default values used for an email message quick action.

`setContinuationResponse(requestLabel, mockResponse)`
Sets a mock response for a continuation HTTP request in a test method.

Signature

```java
public static void setContinuationResponse(String requestLabel, System.HttpResponse mockResponse)
```

Parameters

requestLabel
   Type: String
   The unique label that corresponds to the continuation HTTP request. This label is returned by Continuation.addHttpRequest.

mockResponse
   Type: HttpResponse
   The fake response to be returned by Test.invokeContinuationMethod.

Return Value

Type: void

Usage

Use the Test.setContinuationResponse and Test.invokeContinuationMethod methods to test continuations. In test context, callouts of continuations aren’t sent to the external service. By using these methods, you can set a mock response and cause the runtime to call the continuation callback method to process the mock response.
Call `Test.setContinuationResponse` before you call `Test.invokeContinuationMethod`. When you call `Test.invokeContinuationMethod`, the runtime executes the callback method that is associated with the continuation. The callback method processes the mock response that is set by `Test.setContinuationResponse`.

`setCreatedDate(recordId, createdDatetime)`

Sets CreatedDate for a test-context sObject.

**Signature**

```java
public static void setCreatedDate(Id recordId, Datetime createdDatetime)
```

**Parameters**

- `recordId`
  - Type: `Id`
  - The ID of an sObject.

- `createdDatetime`
  - Type: `Datetime`
  - The value to assign to the sObject's CreatedDate field.

**Return Value**

Type: `void`

**Usage**

All database changes are rolled back at the end of a test. You can’t use this method on records that existed before your test executed. You also can't use `setCreatedDate` in methods annotated with `@isTest(SeeAllData=true)`, because those methods have access to all data in your org. This method takes two parameters—an sObject ID and a Datetime value—neither of which can be null.

Insert your test record before you set its CreatedDate, as shown in this example.

```java
@isTest
private class SetCreatedDateTest {
    static testMethod void testSetCreatedDate() {
        Account a = new Account(name='myAccount');
        insert a;
        Test.setCreatedDate(a.Id, DateTime.newInstance(2012,12,12));
        Test.startTest();
        Account myAccount = [SELECT Id, Name, CreatedDate FROM Account
            WHERE Name = 'myAccount' limit 1];
        System.assertEquals(myAccount.CreatedDate, DateTime.newInstance(2012,12,12));
        Test.stopTest();
    }
}
```

`setCurrentPage(page)`

A Visualforce test method that sets the current PageReference for the controller.
Signature

public static Void setCurrentPage(PageReference page)

Parameters

page
Type: System.PageReference

Return Value
Type: Void

**setCurrentPageReference (page)**

A Visualforce test method that sets the current PageReference for the controller.

Signature

public static Void setCurrentPageReference(PageReference page)

Parameters

page
Type: System.PageReference

Return Value
Type: Void

**setFixedSearchResults (fixedSearchResults)**

Defines a list of fixed search results to be returned by all subsequent SOSL statements in a test method.

Signature

public static Void setFixedSearchResults(ID[] fixedSearchResults)

Parameters

fixedSearchResults
Type: ID[]

The list of record IDs specified by `opt_set_search_results` replaces the results that would normally be returned by the SOSL queries if they were not subject to any `WHERE` or `LIMIT` clauses. If these clauses exist in the SOSL queries, they are applied to the list of fixed search results.

Return Value
Type: Void
Usage
If `opt_set_search_results` is not specified, all subsequent SOSL queries return no results.
For more information, see Adding SOSL Queries to Unit Tests on page 613.

`setMock(interfaceType, instance)`
Sets the response mock mode and instructs the Apex runtime to send a mock response whenever a callout is made through the HTTP classes or the auto-generated code from WSDLs.

Signature
`public static Void setMock(Type interfaceType, Object instance)`

Parameters
- `interfaceType`
  Type: `System.Type`
- `instance`
  Type: `Object`

Return Value
Type: `Void`

Usage

**Note:** To mock a callout if the code that performs the callout is in a managed package, call `Test.setMock` from a test method in the same package with the same namespace.

`setReadOnlyApplicationMode(applicationMode)`
Sets the application mode for an organization to read-only in an Apex test to simulate read-only mode during Salesforce upgrades and downtimes. The application mode is reset to the default mode at the end of each Apex test run.

Signature
`public static Void setReadOnlyApplicationMode(Boolean applicationMode)`

Parameters
- `applicationMode`
  Type: `Boolean`

Return Value
Type: `Void`

Usage
Also see the `getApplicationReadWriteMode()` System method.
Do not use `setReadOnlyApplicationMode` for purposes unrelated to Read-Only Mode testing, such as simulating DML exceptions.

Example

The following example sets the application mode to read-only and attempts to insert a new account record, which results in the exception. It then resets the application mode and performs a successful insert.

```java
@isTest
private class ApplicationReadOnlyModeTestClass {
    public static testmethod void test() {
        // Create a test account that is used for querying later.
        Account testAccount = new Account(Name = 'TestAccount');
        insert testAccount;

        // Set the application read only mode.
        Test.setReadOnlyApplicationMode(true);

        // Verify that the application is in read-only mode.
        System.assertEquals(
            ApplicationReadWriteMode.READ_ONLY,
            System.getApplicationReadWriteMode());

        // Create a new account object.
        Account testAccount2 = new Account(Name = 'TestAccount2');

        try {
            // Get the test account created earlier. Should be successful.
            Account testAccountFromDb =
                [SELECT Id, Name FROM Account WHERE Name = 'TestAccount'];
            System.assertEquals(testAccount.Id, testAccountFromDb.Id);

            // Inserts should result in the InvalidReadOnlyUserDmlException being thrown.
            insert testAccount2;
            System.assertEquals(false, true);
        } catch (System.InvalidReadOnlyUserDmlException e) {
            // Expected
        }

        // Insertion should work after read only application mode gets disabled.
        Test.setReadOnlyApplicationMode(false);

        insert testAccount2;
        Account testAccount2FromDb =
            [SELECT Id, Name FROM Account WHERE Name = 'TestAccount2'];
        System.assertEquals(testAccount2.Id, testAccount2FromDb.Id);
    }
}
```

`startTest()`

Marks the point in your test code when your test actually begins. Use this method when you are testing governor limits.
Signature

```java
public static Void startTest()
```

Return Value
Type: Void

Usage
You can also use this method with `stopTest` to ensure that all asynchronous calls that come after the `startTest` method are run before doing any assertions or testing. Each test method is allowed to call this method only once. All of the code before this method should be used to initialize variables, populate data structures, and so on, allowing you to set up everything you need to run your test. Any code that executes after the call to `startTest` and before `stopTest` is assigned a new set of governor limits.

### stopTest()

Marks the point in your test code when your test ends. Use this method in conjunction with the `startTest` method.

Signature

```java
public static Void stopTest()
```

Return Value
Type: Void

Usage
Each test method is allowed to call this method only once. Any code that executes after the `stopTest` method is assigned the original limits that were in effect before `startTest` was called. All asynchronous calls made after the `startTest` method are collected by the system. When `stopTest` is executed, all asynchronous processes are run synchronously.

**Note:** Asynchronous calls, such as `@future` or `executeBatch`, called in a `startTest`, `stopTest` block, do not count against your limits for the number of queued jobs.

### testInstall(installImplementation, version, isPush)

Tests the implementation of the InstallHandler interface, which is used for specifying a post install script in packages. Tests run as the test initiator in the development environment.

Signature

```java
public static Void testInstall(InstallHandler installImplementation, Version version, Boolean isPush)
```

Parameters

- **installImplementation**
  Type: `System.InstallHandler`
  A class that implements the InstallHandler interface.
version
  Type: System.Version
  The version number of the existing package installed in the subscriber organization.

isPush
  Type: Boolean
  (Optional) Specifies whether the upgrade is a push. The default value is false.

Return Value
Type: Void

Usage
This method throws a run-time exception if the test install fails.

Example
@isTest static void test() {
  PostInstallClass postinstall =
    new PostInstallClass();
  Test.testInstall(postinstall,
    new Version(1,0));
}

testUninstall(uninstallImplementation)
Tests the implementation of the UninstallHandler interface, which is used for specifying an uninstall script in packages. Tests run as the test initiator in the development environment.

Signature
public static Void testUninstall(UninstallHandler uninstallImplementation)

Parameters
uninstallImplementation
  Type: System.UninstallHandler
  A class that implements the UninstallHandler interface.

Return Value
Type: Void

Usage
This method throws a run-time exception if the test uninstall fails.
Example

```java
@isTest static void test() {
    UninstallClass uninstall =
        new UninstallClass();
    Test.testUninstall(uninstall);
}
```

Time Class

Contains methods for the Time primitive data type.

Namespace

System

Usage

For more information on time, see Primitive Data Types on page 26.

Time Methods

The following are methods for `Time`.

IN THIS SECTION:

`addHours(additionalHours)`
Adds the specified number of hours to a Time.

`addMilliseconds(additionalMilliseconds)`
Adds the specified number of milliseconds to a Time.

`addMinutes(additionalMinutes)`
Adds the specified number of minutes to a Time.

`addSeconds(additionalSeconds)`
Adds the specified number of seconds to a Time.

`hour()`
Returns the hour component of a Time.

`millisecond()`
Returns the millisecond component of a Time.

`minute()`
Returns the minute component of a Time.

`newInstance(hour, minutes, seconds, milliseconds)`
Constructs a Time from Integer representations of the specified hour, minutes, seconds, and milliseconds. (UTC is assumed.)

`second()`
Returns the second component of a Time.
addHours(additionalHours)
Adds the specified number of hours to a Time.

Signature
public Time addHours(Integer additionalHours)

Parameters
additionalHours
Type: Integer

Return Value
Type: Time

Example
Time myTime = Time.newInstance(1, 2, 3, 4);
Time expected = Time.newInstance(4, 2, 3, 4);
System.assertEquals(expected, myTime.addHours(3));

addMilliseconds(additionalMilliseconds)
Adds the specified number of milliseconds to a Time.

Signature
public Time addMilliseconds(Integer additionalMilliseconds)

Parameters
additionalMilliseconds
Type: Integer

Return Value
Type: Time

Example
Time myTime = Time.newInstance(1, 2, 3, 0);
Time expected = Time.newInstance(1, 2, 4, 400);
System.assertEquals(expected, myTime.addMilliseconds(1400));

addMinutes(additionalMinutes)
Adds the specified number of minutes to a Time.
**Signature**

```java
public Time addMinutes(Integer additionalMinutes)
```

**Parameters**

- `additionalMinutes`
  
  **Type:** Integer

**Return Value**

**Type:** Time

**Example**

```java
Time myTime = Time.newInstance(18, 30, 2, 20);
Integer myMinutes = myTime.minute();
myMinutes = myMinutes + 5;
System.assertEquals(myMinutes, 35);
```

**addSeconds(additionalSeconds)**

Adds the specified number of seconds to a Time.

**Signature**

```java
public Time addSeconds(Integer additionalSeconds)
```

**Parameters**

- `additionalSeconds`
  
  **Type:** Integer

**Return Value**

**Type:** Time

**Example**

```java
Time myTime = Time.newInstance(1, 2, 55, 0);
Time expected = Time.newInstance(1, 3, 5, 0);
System.assertEquals(expected, myTime.addSeconds(10));
```

**hour()**

Returns the hour component of a Time.

**Signature**

```java
public Integer hour()
```
Return Value
Type: Integer

Example
```java
Time myTime = Time.newInstance(18, 30, 2, 20);
myTime = myTime.addHours(2);
Integer myHour = myTime.hour();
System.assertEquals(myHour, 20);
```

**millisecond()**

Returns the millisecond component of a Time.

Signature
```java
public Integer millisecond()
```

Return Value
Type: Integer

Example
```java
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(926, myTime.millisecond());
```

**minute()**

Returns the minute component of a Time.

Signature
```java
public Integer minute()
```

Return Value
Type: Integer

Example
```java
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(14, myTime.minute());
```

**newInstance(hour, minutes, seconds, milliseconds)**

Constructs a Time from Integer representations of the specified hour, minutes, seconds, and milliseconds. (UTC is assumed.)
public static Time newInstance(Integer hour, Integer minutes, Integer seconds, Integer milliseconds)

Parameters
hour
  Type: Integer
minutes
  Type: Integer
seconds
  Type: Integer
milliseconds
  Type: Integer

Return Value
Type: Time

Example
The following example creates a time of 18:30:2:20 (UTC).

```
Time myTime =
  Time.newInstance(18, 30, 2, 20);
```

second()

Returns the second component of a Time.

Signature

```
public Integer second()
```

Return Value
Type: Integer

Example

```
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(15, myTime.second());
```

TimeZone Class

Represents a time zone. Contains methods for creating a new time zone and obtaining time zone properties, such as the time zone ID, offset, and display name.
namespace

System

Usage

You can use the methods in this class to get properties of a time zone, such as the properties of the time zone returned by
UserInfo.getTimeZone, or the time zone returned by getTimeZone of this class.

Example

This example shows how to get properties of the current user’s time zone and displays them to the debug log.

```java
TimeZone tz = UserInfo.getTimeZone();
System.debug('Display name: ' + tz.getDisplayName());
System.debug('ID: ' + tz.getID());
// During daylight saving time for the America/Los_Angeles time zone
System.debug('Offset: ' + tz.getOffset(DateTime.newInstance(2012,10,23,12,0,0)));
// Not during daylight saving time for the America/Los_Angeles time zone
System.debug('Offset: ' + tz.getOffset(DateTime.newInstance(2012,11,23,12,0,0)));
System.debug('String format: ' + tz.toString());
```

The output of this sample varies based on the user’s time zone. This is an example output if the user’s time zone is America/Los_Angeles.
For this time zone, daylight saving time is -7 hours from GMT (-25200000 milliseconds) and standard time is -8 hours from GMT (-28800000 milliseconds).

Display name: Pacific Standard Time
ID: America/Los_Angeles
Offset: -25200000
Offset: -28800000
String format: America/Los_Angeles

This second example shows how to create a time zone for the New York time zone and get the offset of this time zone to the GMT time zone. The example uses two dates to get the offset from. One date is before DST, and one is after DST. In 2000, DST ended on Sunday, October 29 for the New York time zone. Because the date occurs after DST ends, the offset on the first date is -5 hours to GMT. In 2012, DST ended on Sunday, November 4. Because the date is within DST, the offset on the second date is -4 hours.

```java
// Get the New York time zone
TimeZone tz = Timezone.getTimeZone('America/New_York');
```

```java
// Create a date before the 2007 shift of DST into November
DateTime dtpre = DateTime.newInstanceGMT(2000, 11, 1, 0, 0, 0);
system.debug(tz.getOffset(dtpre));  // -18000000 (= -5 hours = EST)
```

```java
// Create a date after the 2007 shift of DST into November
DateTime dtpost = DateTime.newInstanceGMT(2012, 11, 1, 0, 0, 0);
system.debug(tz.getOffset(dtpost));  // -14400000 (= -4 hours = EDT)
```

This next example is similar to the previous one except that it gets the offset around the boundary of DST. In 2014, DST ended on Sunday, November 2 at 2:00 AM local time for the New York time zone. The first offset is obtained right before DST ends, and the second offset
is obtained right after DST ends. The dates are created by using the `DateTime.newInstanceGMT` method. This method expects the passed-in date values to be based on the GMT time zone.

```java
// Get the New York time zone
Timezone tz = Timezone.getTimeZone('America/New_York');

// Before DST ends
DateTime dtpre = DateTime.newInstanceGMT(2014, 11, 2, 5, 59, 59); // 1:59:59AM local
system.debug(tz.getOffset(dtpre)); // -14400000 (= -4 hours = still on DST)

// After DST ends
DateTime dtpost = DateTime.newInstanceGMT(2014, 11, 2, 6, 0, 0); // 1:00:00AM local
system.debug(tz.getOffset(dtpost)); // -18000000 (= -5 hours = back one hour)
```

### TimeZone Methods

The following are methods for `TimeZone`.

**IN THIS SECTION:**

- **getDisplayName()**
  Returns this time zone's display name.

- **getID()**
  Returns this time zone's ID.

- **getOffset(date)**
  Returns the time zone offset, in milliseconds, of the specified date to the GMT time zone.

- **getTimeZone(timeZoneIdString)**
  Returns the time zone corresponding to the specified time zone ID.

- **toString()**
  Returns the string representation of this time zone.

### getDisplayName() method

**Returns this time zone's display name.**

**Signature**

```java
public String getDisplayName()
```

**Return Value**

*Type: String*

**Versioned Behavior Changes**

In API version 45.0 and later, `getDisplayName` displays Daylight Savings Time appropriately when daylight savings are in effect. For example, British Summer Time is displayed for Europe/London and Pacific Daylight Time for America/Los_Angeles.
**getID()**

Returns this time zone's ID.

**Signature**

```java
public String getID()
```

**Return Value**

**Type:** String

**getOffset(date)**

Returns the time zone offset, in milliseconds, of the specified date to the GMT time zone.

**Signature**

```java
public Integer getOffset(Datetime date)
```

**Parameters**

`date`  
**Type:** Datetime  
The `date` argument is the date and time to evaluate.

**Return Value**

**Type:** Integer

**Usage**

╯**Note:** The returned offset is adjusted for daylight saving time if the `date` argument falls within daylight saving time for this time zone.

**getTimeZone(timeZoneIdString)**

Returns the time zone corresponding to the specified time zone ID.

**Signature**

```java
public static TimeZone getTimeZone(String timeZoneIdString)
```

**Parameters**

`timeZoneIdString`  
**Type:** String  
The time zone values you can use for the `Id` argument are any valid time zone values that the `Java TimeZone class` supports.
Return Value
Type: TimeZone

Example
TimeZone tz = TimeZone.getTimeZone('America/Los_Angeles');
String tzName = tz.getDisplayName();
System.assert(tzName.equals('(GMT-08:00) Pacific Standard Time (America/Los_Angeles)') ||
              tzName.equals('(GMT-07:00) Pacific Daylight Time (America/Los_Angeles)'));

**toString()**

Returns the string representation of this time zone.

Signature

```java
public String toString()
```

Return Value
Type: String

**Trigger Class**

Use the Trigger class to access run-time context information in a trigger, such as the type of trigger or the list of sObject records that the trigger operates on.

**Namespace**

System

**Trigger Context Variables**

The Trigger class provides the following context variables.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>isExecuting</td>
<td>Returns true if the current context for the Apex code is a trigger, not a Visualforce page, a Web service, or an executeanonymous() API call.</td>
</tr>
<tr>
<td>isInsert</td>
<td>Returns true if this trigger was fired due to an insert operation, from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td>isUpdate</td>
<td>Returns true if this trigger was fired due to an update operation, from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td>isDelete</td>
<td>Returns true if this trigger was fired due to a delete operation, from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td>isBefore</td>
<td>Returns true if this trigger was fired before any record was saved.</td>
</tr>
</tbody>
</table>
### Variable Usage

<table>
<thead>
<tr>
<th>Variable</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>isAfter</td>
<td>Returns <code>true</code> if this trigger was fired after all records were saved.</td>
</tr>
<tr>
<td>isUndelete</td>
<td>Returns <code>true</code> if this trigger was fired after a record is recovered from the Recycle Bin. This recovery can occur after an undelete operation from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td>new</td>
<td>Returns a list of the new versions of the sObject records. &lt;br&gt;This sObject list is only available in <code>insert</code>, <code>update</code>, and <code>undelete</code> triggers, and the records can only be modified in <code>before</code> triggers.</td>
</tr>
<tr>
<td>newMap</td>
<td>A map of IDs to the new versions of the sObject records. &lt;br&gt;This map is only available in <code>before update</code>, <code>after insert</code>, <code>after update</code>, and <code>after undelete</code> triggers.</td>
</tr>
<tr>
<td>old</td>
<td>Returns a list of the old versions of the sObject records. &lt;br&gt;This sObject list is only available in <code>update</code> and <code>delete</code> triggers.</td>
</tr>
<tr>
<td>oldMap</td>
<td>A map of IDs to the old versions of the sObject records. &lt;br&gt;This map is only available in <code>update</code> and <code>delete</code> triggers.</td>
</tr>
<tr>
<td>operationType</td>
<td>Returns an enum of type <code>System.TriggerOperation</code> corresponding to the current operation. &lt;br&gt;Possible values of the <code>System.TriggerOperation</code> enum are: <code>BEFORE_INSERT</code>, <code>BEFORE_UPDATE</code>, <code>BEFORE_DELETE</code>, <code>AFTER_INSERT</code>, <code>AFTER_UPDATE</code>, <code>AFTER_DELETE</code>, and <code>AFTER_UNDELETE</code>. If you vary your programming logic based on different trigger types, consider using the <code>switch</code> statement with different permutations of unique trigger execution enum states.</td>
</tr>
<tr>
<td>size</td>
<td>The total number of records in a trigger invocation, both old and new.</td>
</tr>
</tbody>
</table>

⚠️ **Note:** The record firing a trigger can include an invalid field value, such as a formula that divides by zero. In this case, the field value is set to `null` in these variables:

- `new`
- `newMap`
- `old`
- `oldMap`

### Example

For example, in this simple trigger, `Trigger.new` is a list of sObjects and can be iterated over in a `for` loop. It can also be used as a bind variable in the `IN` clause of a SOQL query.

```apex
Trigger simpleTrigger on Account (after insert) {
    for (Account a : Trigger.new) {
        // Iterate over each sObject
    }

    // This single query finds every contact that is associated with any of the
```
// triggering accounts. Note that although Trigger.new is a collection of
// records, when used as a bind variable in a SOQL query, Apex automatically
// transforms the list of records into a list of corresponding Ids.
Contact[] cons = [SELECT LastName FROM Contact
    WHERE AccountId IN :Trigger.new];
}

This trigger uses Boolean context variables like Trigger.isBefore and Trigger.isDelete to define code that only executes for specific trigger conditions:

trigger myAccountTrigger on Account(before delete, before insert, before update,
    after delete, after insert, after update) {
    if (Trigger.isBefore) {
        if (Trigger.isDelete) {
            // In a before delete trigger, the trigger accesses the records that will be
            // deleted with the Trigger.old list.
            for (Account a : Trigger.old) {
                if (a.name != 'okToDelete') {
                    a.addError('You can\'t delete this record!');
                }
            }
        } else {
            // In before insert or before update triggers, the trigger accesses the new records
            // with the Trigger.new list.
            for (Account a : Trigger.new) {
                if (a.name == 'bad') {
                    a.name.addError('Bad name');
                }
            }
        }
    } else {
        if (Trigger.isInsert) {
            for (Account a : Trigger.new) {
                System.assertEquals('xxx', a.accountNumber);
                System.assertEquals('industry', a.industry);
                System.assertEquals(100, a.numberofemployees);
                System.assertEquals(100.0, a.annualrevenue);
                a.accountNumber = 'yyy';
            }
        } else {
            if (Trigger.isInsert) {
                List<Contact> contacts = new List<Contact>();
                for (Account a : Trigger.new) {
                    if (a.Name == 'makeContact') {
                        contacts.add(new Contact (LastName = a.Name,
                            AccountId = a.Id));
                    }
                }
                insert contacts;
            }
        }
    }
}
TriggerOperation Enum

System.TriggerOperation enum values are associated with trigger events.

Enum Values

The following are the values of the System.TriggerOperation enum:

- AFTER_DELETE
- AFTER_INSERT
- AFTER_UNDELETE
- AFTER_UPDATE
- BEFORE_DELETE
- BEFORE_INSERT
- BEFORE_UPDATE

Type Class

Contains methods for getting the Apex type that corresponds to an Apex class and for instantiating new types.

Namespace

System

Usage

Use the fullName methods to retrieve the type of an Apex class, which can be a built-in or a user-defined class. You can use these methods to retrieve the type of public and global classes, and not private classes even if the context user has access. Also, use the newInstance method if you want to instantiate a Type that implements an interface and call its methods while letting someone else, such as a subscriber of your package, provide the methods' implementations.

Example: Instantiating a Type Based on Its Name

The following sample shows how to use the Type methods to instantiate a Type based on its name. A typical application of this scenario is when a package subscriber provides a custom implementation of an interface that is part of an installed package. The package can get the name of the class that implements the interface through a custom setting in the subscriber's org. The package can then instantiate the type that corresponds to this class name and invoke the methods that the subscriber implemented.

In this sample, Vehicle represents the interface that the VehicleImpl class implements. The last class contains the code sample that invokes the methods implemented in VehicleImpl.

This is the Vehicle interface.

global interface Vehicle {
    Long getMaxSpeed();
    String getType();
}

This is the implementation of the Vehicle interface.

global class VehicleImpl implements Vehicle {
    global Long getMaxSpeed() { return 100; }
}
global String getType() { return 'Sedan'; }
}

The method in this class gets the name of the class that implements the Vehicle interface through a custom setting value. It then instantiates this class by getting the corresponding type and calling the newInstance method. Next, it invokes the methods implemented in VehicleImpl. This sample requires that you create a public list custom setting named CustomImplementation with a text field named className. Create one record for this custom setting with a data set name of Vehicle and a class name value of VehicleImpl.

```java
public class CustomerImplInvocationClass {
    public static void invokeCustomImpl() {
        // Get the class name from a custom setting.
        // This class implements the Vehicle interface.
        CustomImplementation__c cs = CustomImplementation__c.getInstance('Vehicle');
        // Get the Type corresponding to the class name
        Type t = Type.forName(cs.className__c);
        // Instantiate the type.
        // The type of the instantiated object
        // is the interface.
        Vehicle v = (Vehicle)t.newInstance();
        // Call the methods that have a custom implementation
        System.debug('Max speed: ' + v.getMaxSpeed());
        System.debug('Vehicle type: ' + v.getType());
    }
}
```

### Class Property

The class property returns the System.Type of the type it is called on. It is exposed on all Apex built-in types including primitive data types and collections, sObject types, and user-defined classes. This property can be used instead of forName methods.

Call this property on the type name. For example:

```java
System.Type t = Integer.class;
```

You can use this property for the second argument of JSON.deserialize, deserializeStrict, JSONParser.readValueAs, and readValueAsStrict methods to get the type of the object to deserialize. For example:

```java
Decimal n = (Decimal)JSON.deserialize('100.1', Decimal.class);
```

### Type Methods

The following are methods for Type.

**IN THIS SECTION:**

- equals(typeToCompare)
  - Returns true if the specified type is equal to the current type; otherwise, returns false.
forName(fullyQualifiedName)
Returns the type that corresponds to the specified fully qualified class name.

forName(namespace, name)
Returns the type that corresponds to the specified namespace and class name.

getName()
Returns the name of the current type.

hashCode()
Returns a hash code value for the current type.

isAssignableFrom(sourceType)
Returns true if an object reference of the specified type can be assigned from the child type; otherwise, returns false.

newInstance()
Creates an instance of the current type and returns this new instance.

toString()
Returns a string representation of the current type, which is the type name.

defines(typeToCompare)
Returns true if the specified type is equal to the current type; otherwise, returns false.

Signature
public Boolean equals(Object typeToCompare)

Parameters
typeToCompare
Type: Object
The type to compare with the current type.

Return Value
Type: Boolean

Example
Type t1 = Account.class;
Type t2 = Type.forName('Account');
System.assert(t1.equals(t2));

forName(fullyQualifiedName)
Returns the type that corresponds to the specified fully qualified class name.

Signature
public static System.Type forName(String fullyQualifiedName)
Parameters

`fullyQualifiedName`

Type: `String`

The fully qualified name of the class to get the type of. The fully qualified class name contains the namespace name, for example, `MyNamespace.ClassName`.

Return Value

Type: `System.Type`

Usage

**Note:**
- This method returns `null` if called outside a managed package to get the type of a non-global class in a managed package. This is because the non-global class is not visible outside the managed package. For Apex saved using Salesforce API version 27.0 and earlier, this method does return the corresponding class type for the non-global managed package class.
- When called from an installed managed package to get the name of a local type in an organization with no defined namespace, the `forName(fullyQualifiedName)` method returns `null`. Instead, use the `forName(namespace, name)` method and specify an empty string or `null` for the namespace argument.

`forName(namespace, name)`

Returns the type that corresponds to the specified namespace and class name.

Signature

```
public static System.Type forName(String namespace, String name)
```

Parameters

`namespace`

Type: `String`

The namespace of the class. If the class doesn’t have a namespace, set the `namespace` argument to `null` or an empty string.

`name`

Type: `String`

The name of the class.

Return Value

Type: `System.Type`

Usage

**Note:**
- This method returns `null` if called outside a managed package to get the type of a non-global class in a managed package. This is because the non-global class is not visible outside the managed package. For Apex saved using Salesforce API version 27.0 and earlier, this method does return the corresponding class type for the non-global managed package class.
- Use this method instead of `forName` if it will be called from a managed package installed in an organization with no defined namespace. To get the name of a local type, set the namespace argument to an empty string or `null`. For example, `Type t = Type.forName('', 'ClassName');`.

Example

This example shows how to get the type that corresponds to the `ClassName` class and the `MyNamespace` namespace.

```plaintext
Type myType =
    Type.forName('MyNamespace', 'ClassName');
```

### getName()

Returns the name of the current type.

Signature

```plaintext
public String getName()
```

Return Value

Type: `String`

Example

This example shows how to get a Type's name. It first obtains a Type by calling `forName`, then calls `getName` on the Type object.

```plaintext
Type t =
    Type.forName('MyClassName');

String typeName =
    t.getName();
System.assertEquals('MyClassName',
    typeName);
```

### hashCode()

Returns a hash code value for the current type.

Signature

```plaintext
public Integer hashCode()
```

Return Value

Type: `Integer`

Usage

The returned hash code value corresponds to the type name hash code that `String.hashCode` returns.
**isAssignableFrom(sourceType)**

Returns **true** if an object reference of the specified type can be assigned from the child type; otherwise, returns **false**.

**Signature**

```java
public Boolean isAssignableFrom(Type sourceType)
```

**Parameters**

`sourceType`

The type of the object with which you are checking compatibility.

**Return Value**

Type: **Boolean**

The method returns **true** when the method is invoked as `parentType.isAssignableFrom(childType)`. When invoked in any of the following ways, the method returns **false**:

- `childType.isAssignableFrom(parentType)`
- `typeA.isAssignableFrom(TypeB)` where TypeB is a sibling of TypeA
- `typeA.isAssignableFrom(TypeB)` where TypeB and TypeA are unrelated

**Note:** A childType is the child of a parentType when it implements an interface, extends a virtual or abstract class, or is the same System.Type as the parentType.

**Usage**

Unlike the `instanceof` operator, this method allows you to check type compatibility without having to create a class instance. This method eliminates static compile-time dependencies that `instanceof` requires.

The following code demonstrates how a typical ISV customer can use `isAssignableFrom()` to check compatibility between a customer-defined type (`customerProvidedPluginType`) and a valid plugin type.

```java
//Scenario: Managed package code loading a "plugin" class that implements a managed interface; the implementation done outside of the package
String pluginNameStr = Config__c.getInstance().PluginApexType__c;
Type customerProvidedPluginType = Type.forName(pluginNameStr);
Type pluginInterface = ManagedPluginInterface.class;

// Constructors may have side-effects, including potentially unsafe DML/callouts. // We want to make sure the class is really designed to be a valid plugin before we instantiate it
Boolean validPlugin = pluginInterface.isAssignableFrom(customerProvidedPluginType); // validate that it implements the right interface

if(!validPlugin){
    throw new SecurityException('Cannot create instance of '+customerProvidedPluginType+'. Does not implement ManagedPluginInterface');
} else {
    return Type.newInstance(validPlugin);
}
```
Example

The following code snippet first defines sibling classes A and B that both implement the Callable interface and an unrelated class C. Then, it explores several type comparisons using `isAssignableFrom()`.

```apex
//Define classes A, B, and C

global class A implements Database.Batchable<String>, Callable {
    global Iterable<String> start(Database.BatchableContext context) { return null; }
    global void execute(Database.BatchableContext context, String[] scope) { }
    global void finish(Database.BatchableContext context) { }
    global Object call(String action, Map<String, Object> args) { return null; }
}

global class B implements Callable {
    global Object call(String action, Map<String, Object> args) { return null; }
}

global class C { }

Type listOfStrings = Type.forName('List<String>');
Type listOfIntegers = Type.forName('List<Integer>');
boolean flagListTypes = listOfIntegers.isAssignableFrom(listOfStrings); // false

//Examples with stringType and idType
Type stringType = Type.forName('String');
Type idType = Type.forName('Id');
boolean isId_assignableFromString = idType.isAssignableFrom(stringType); // true
//isAssignableFrom respects that String can be assigned to Id without an explicit cast

//Examples with typeA, typeB, and typeC
Type typeA = Type.forName('A');
Type typeB = Type.forName('B');
Type typeC = Type.forName('C');
boolean isTypeB_ofTypeA = typeB.isAssignableFrom(typeA); // false - siblings
boolean isTypeA_ofTypeC = typeA.isAssignableFrom(typeC); // false - unrelated types
boolean isTypeA_ofTypeA = typeA.isAssignableFrom(typeA); // true - identity

//Examples with callableType and batchableType
Type callableType = Type.forName('Callable');
Type batchableType = Type.forName('Database.Batchable');
boolean isTypeA_Callable = callableType.isAssignableFrom(typeA); // true - type A is a child of Callable type
boolean isTypeA_Batchable = batchableType.isAssignableFrom(typeA); // true - type A is a child of Batchable type
boolean isCallableOfTypeA = typeA.isAssignableFrom(callableType); // false - Callable type is not a child of type A
boolean isBatchableOfTypeA = typeA.isAssignableFrom(batchableType); // false - Batchable type is not a child of type A

newInstance()

Creates an instance of the current type and returns this new instance.
```
Signature

```java
public Object newInstance()
```

Return Value

Type: Object

Usage

Because `newInstance` returns the generic object type, you should cast the return value to the type of the variable that will hold this value.

This method enables you to instantiate a Type that implements an interface and call its methods while letting someone else provide the methods’ implementation. For example, a package developer can provide an interface that a subscriber who installs the package can implement. The code in the package calls the subscriber’s implementation of the interface methods by instantiating the subscriber’s Type.

 getSupportFragmentManager Calling this method on a type corresponding to a class that has a private no-argument constructor results in a `System.TypeException`, as expected because the type can’t be instantiated. For Apex saved using Salesforce API version 28.0 and earlier, this method returns an instance of the class instead.

Example

This example shows how to create an instance of a Type. It first gets a Type by calling `forName` with the name of a class (ShapeImpl), then calls `newInstance` on this Type object. The newObj instance is declared with the interface type (Shape) that the ShapeImpl class implements. The return value of the `newInstance` method is cast to the Shape type.

```java
Type t = 
    Type.forName('ShapeImpl');

Shape newObj = 
    (Shape)t.newInstance();
```

toString()

Returns a string representation of the current type, which is the type name.

Signature

```java
public String toString()
```

Usage

This method returns the same value as `getName`. `String.valueOf` and `System.debug` use this method to convert their `Type` argument into a String.
Example

This example calls `toString` on the Type corresponding to a list of Integers.

```java
Type t = List<Integer>.class;
String s = t.toString();
System.assertEquals('List<Integer>', s);
```

**UninstallHandler Interface**

Enables custom code to run after a managed package is uninstalled.

**Namespace**

`System`

**Usage**

App developers can implement this interface to specify Apex code that runs automatically after a subscriber uninstalls a managed package. This makes it possible to perform cleanup and notification tasks based on details of the subscriber’s organization.

The uninstall script is subject to default governor limits. It runs as a special system user that represents your package, so all operations performed by the script will appear to be done by your package. You can access this user by using `UserInfo`. You will only see this user at runtime, not while running tests.

If the script fails, the uninstall continues but none of the changes performed by the script are committed. Any errors in the script are emailed to the user specified in the **Notify on Apex Error** field of the package. If no user is specified, the uninstall details will be unavailable.

The uninstall script has the following restrictions. You can’t use it to initiate batch, scheduled, and future jobs, to access Session IDs, or to perform callouts.

The `UninstallHandler` interface has a single method called `onUninstall`, which specifies the actions to be performed on uninstall.

```java
@global interface UninstallHandler {
    void onUninstall(UninstallContext context);
}
```

The `onUninstall` method takes a context object as its argument, which provides the following information.

- The org ID of the organization in which the uninstall takes place.
- The user ID of the user who initiated the uninstall.

The context argument is an object whose type is the `UninstallContext` interface. This interface is automatically implemented by the system. The following definition of the `UninstallContext` interface shows the methods you can call on the context argument.

```java
@global interface UninstallContext {
    ID organizationId();
    ID uninstallerId();
}
```

**IN THIS SECTION:**

- `UninstallHandler Methods`
UninstallHandler Methods

The following are methods for UninstallHandler.

IN THIS SECTION:

onUninstall(context)

Specifies the actions to be performed on uninstall.

onUninstall(context)

Specifies the actions to be performed on uninstall.

Signature

public Void onUninstall(UninstallContext context)

Parameters

context

Type: UninstallContext

Return Value

Type: Void

UninstallHandler Example Implementation

Example of an Uninstall Script

The sample uninstall script below performs the following actions on package uninstall.

- Inserts an entry in the feed describing which user did the uninstall and in which organization
- Creates and sends an email message confirming the uninstall to that user

```java
global class UninstallClass implements UninstallHandler {

global void onUninstall(UninstallContext ctx) {
    FeedItem feedPost = new FeedItem();
    feedPost.parentId = ctx.uninstallerID();
    feedPost.body = 'Thank you for using our application!';
    insert feedPost;

    User u = [Select Id, Email from User where Id =:ctx.uninstallerID()];
    String toAddress = u.Email;
    String[] toAddresses = new String[] {toAddress};
    Messaging.SingleEmailMessage mail = new Messaging.SingleEmailMessage();
    mail.setToAddresses(toAddresses);
    mail.setReplyTo('support@package.dev');
    mail.setSenderDisplayName('My Package Support');
    mail.setSubject('Package uninstall successful');
}```
You can test an uninstall script using the testUninstall method of the Test class. This method takes as its argument a class that implements the UninstallHandler interface.

This sample shows how to test an uninstall script implemented in the UninstallClass Apex class.

```apex
@isTest
static void testUninstallScript() {
    Id UninstallerId = UserInfo.getUserId();
    List<FeedItem> feedPostsBefore = [
        SELECT Id FROM FeedItem WHERE parentId=:UninstallerId AND CreatedDate=TODAY];
    Test.testUninstall(new UninstallClass());
    List<FeedItem> feedPostsAfter = [
        SELECT Id FROM FeedItem WHERE parentId=:UninstallerId AND CreatedDate=TODAY];
    System.assertEquals(feedPostsBefore.size() + 1, feedPostsAfter.size(),
        'Post to uninstaller failed.');
}
```

**URL Class**

Represents a uniform resource locator (URL) and provides access to parts of the URL. Enables access to the Salesforce instance URL.

**Namespace**

System

**Usage**

Use the methods of the System.URL class to create links to objects in your organization. Such objects can be files, images, logos, or records that you want to include in external emails, in activities, or in Chatter posts. For example, you can create a link to a file uploaded as an attachment to a Chatter post by concatenating the Salesforce base URL with the file ID, as shown in the following example:

```apex
// Get a file uploaded through Chatter.
ContentDocument doc = [SELECT Id FROM ContentDocument
    WHERE Title = 'myfile'];
// Create a link to the file.
String fullFileURL = URL.getSalesforceBaseUrl().toExternalForm() +
    '/' + doc.id;
system.debug(fullFileURL);
```

The following example creates a link to a Salesforce record. The full URL is created by concatenating the Salesforce base URL with the record ID.

```apex
Account acct = [SELECT Id FROM Account WHERE Name = 'Acme' LIMIT 1];
String fullRecordURL = URL.getSalesforceBaseUrl().toExternalForm() + '/'+ acct.Id;
```
Example

In this example, the base URL and the full request URL of the current Salesforce server instance are retrieved. Next, a URL pointing to a specific account object is created. Finally, components of the base and full URL are obtained. This example prints out all the results to the debug log output.

```java
// Create a new account called Acme that we will create a link for later.
Account myAccount = new Account(Name='Acme');
insert myAccount;

// Get the base URL.
String sfdcBaseURL = URL.getSalesforceBaseUrl().toExternalForm();
System.debug('Base URL: ' + sfdcBaseURL);

// Get the URL for the current request.
String currentRequestURL = URL.getCurrentRequestUrl().toExternalForm();
System.debug('Current request URL: ' + currentRequestURL);

// Create the account URL from the base URL.
String accountURL = URL.getSalesforceBaseUrl().toExternalForm() + '/'+ myAccount.Id;
System.debug('URL of a particular account: ' + accountURL);

// Get some parts of the base URL.
System.debug('Host: ' + URL.getSalesforceBaseUrl().getHost());
System.debug('Protocol: ' + URL.getSalesforceBaseUrl().getProtocol());

// Get the query string of the current request.
System.debug('Query: ' + URL.getCurrentRequestUrl().getQuery());
```

IN THIS SECTION:

- **URL Constructors**
- **URL Methods**

### URL Constructors

The following are constructors for `URL`.

IN THIS SECTION:

- **Url(spec)**
  - Creates a new instance of the `URL` class using the specified string representation of the URL.
- **Url(context, spec)**
  - Creates a new instance of the `URL` class by parsing the specified spec within the specified context.
- **Url(protocol, host, file)**
  - Creates a new instance of the `URL` class using the specified protocol, host, and file on the host. The default port for the specified protocol is used.
- **Url(protocol, host, port, file)**
  - Creates a new instance of the `URL` class using the specified protocol, host, port, and file on the host.
**Url(spec)**

Creates a new instance of the URL class using the specified string representation of the URL.

Signature

```java
public Url(String spec)
```

Parameters

- **spec**
  - Type: String
  - The string to parse as a URL.

**Url(context, spec)**

Creates a new instance of the URL class by parsing the specified spec within the specified context.

Signature

```java
public Url(Url context, String spec)
```

Parameters

- **context**
  - Type: URL
  - The context in which to parse the specification.
- **spec**
  - Type: String
  - The string to parse as a URL.

Usage

The new URL is created from the given context URL and the spec argument as described in RFC2396 "Uniform Resource Identifiers: Generic Syntax":

```text
<scheme>://<authority><path>?<query>#<fragment>
```

For more information about the arguments of this constructor, see the corresponding `URL(java.net.URL, java.lang.String)` constructor for Java.

**Url(protocol, host, file)**

Creates a new instance of the URL class using the specified protocol, host, and file on the host. The default port for the specified protocol is used.

Signature

```java
public Url(String protocol, String host, String file)
```
Parameters

**protocol**
Type: **String**
The protocol name for this URL.

**host**
Type: **String**
The host name for this URL.

**file**
Type: **String**
The file name for this URL.

**Url(protocol, host, port, file)**

Creates a new instance of the `URL` class using the specified protocol, host, port, and file on the host.

**Signature**

```java
public Url(String protocol, String host, Integer port, String file)
```

Parameters

**protocol**
Type: **String**
The protocol name for this URL.

**host**
Type: **String**
The host name for this URL.

**port**
Type: **Integer**
The port number for this URL.

**file**
Type: **String**
The file name for this URL.

**URL Methods**

The following are methods for `URL`.

**IN THIS SECTION:**

- `getAuthority()`
  Returns the authority portion of the current URL.

- `getCurrentRequestUrl()`
  Returns the URL of an entire request on a Salesforce instance.
getDefaultPort()
Returns the default port number of the protocol associated with the current URL.

getFile()
Returns the file name of the current URL.

getFileFieldURL(entityId, fieldName)
Returns the download URL for a file attachment.

getHost()
Returns the host name of the current URL.

getOrgDomainUrl()
Returns the canonical URL for your org. For example, https://yourDomain.my.salesforce.com or, for orgs without My Domain enabled, https://yourInstance.salesforce.com.

getPath()
Returns the path portion of the current URL.

getPort()
Returns the port of the current URL.

getProtocol()
Returns the protocol name of the current URL, such as, https.

getQuery()
Returns the query portion of the current URL.

getRef()
Returns the anchor of the current URL.

getSalesforceBaseUrl()
Returns the URL of the Salesforce instance.

getUserInfo()
Gets the UserInfo portion of the current URL.

sameFile(URLToCompare)
Compares the current URL with the specified URL object, excluding the fragment component.

toExternalForm()
Returns a string representation of the current URL.

getAuthority()
Returns the authority portion of the current URL.

Signature

public String getAuthority()

Return Value

Type: String
getCurrentRequestUrl()
Returns the URL of an entire request on a Salesforce instance.

Signature
public static System.URL getCurrentRequestUrl()

Return Value
Type: System.URL

Usage
An example of a URL for an entire request is https://yourInstance.salesforce.com/apex/myVfPage.apexp.

getDefaultPort()
Returns the default port number of the protocol associated with the current URL.

Signature
public Integer getDefaultPort()

Return Value
Type: Integer

Usage
Returns -1 if the URL scheme or the stream protocol handler for the URL doesn’t define a default port number.

getFile()
Returns the file name of the current URL.

Signature
public String getFile()

Return Value
Type: String

getFileFieldURL(entityId, fieldName)
Returns the download URL for a file attachment.

Signature
public static String getFileFieldURL(String entityId, String fieldName)
Parameters

entityId
Type: String
Specifies the ID of the entity that holds the file data.

fieldName
Type: String
Specifies the API name of a file field component, such as AttachmentBody.

Return Value
Type: String

Usage
Example:

```
String fileURL =
    URL.getFileFieldURL(
        '087000000000123',
        'AttachmentBody');
```

**getHost()**

Returns the host name of the current URL.

Signature

```
public String getHost()
```

Return Value
Type: String

**getOrgDomainUrl()**

Returns the canonical URL for your org. For example, https://yourDomain.my.salesforce.com or, for orgs without My Domain enabled, https://yourInstance.salesforce.com.

Signature

```
public static System.Url getOrgDomainUrl()
```

Return Value
Type: System.URL

getOrgDomainUrl() always returns the same domain for your org, regardless of context. Use this method to build links to record URLs that work both in Lightning Experience and in Salesforce Classic, or as the domain when making API calls to your org.
Usage

Use `getOrgDomainUrl()` to interact with Salesforce REST and SOAP APIs in Apex code. Get endpoints for User Interface API calls, for creating and customizing picklist value sets and custom fields, and more.

`getOrgDomainUrl()` can access the domain URL only for the org in which the Apex code is running.

You don’t need a RemoteSiteSetting for your org to interact with the Salesforce APIs using domain URLs retrieved with this method. To bypass remote site settings, My Domain must be enabled in your org.

Example

This example uses the Salesforce REST API to get organization limit values. For information on limits, see Limits in the REST API Developer Guide.

```java
Http h = new Http();
HttpRequest req = new HttpRequest();
req.setEndpoint(Url.getOrgDomainUrl().toExternalForm() + '/services/data/v44.0/limits');
req.setMethod('GET');
req.setHeader('Authorization', 'Bearer ' + UserInfo.getSessionId());
HttpResponse res = h.send(req);
```

**getPath()**

Returns the path portion of the current URL.

Signature

```java
public String getPath()
```

Return Value

Type: `String`

**getPort()**

Returns the port of the current URL.

Signature

```java
public Integer getPort()
```
return_value

type: integer

**getProtocol()**

Returns the protocol name of the current URL, such as, https.

**Signature**

```java
public String getProtocol()
```

return_value

type: string

**getQuery()**

Returns the query portion of the current URL.

**Signature**

```java
public String getQuery()
```

return_value

type: string

**Usage**

Returns `null` if no query portion exists.

**getRef()**

Returns the anchor of the current URL.

**Signature**

```java
public String getRef()
```

return_value

type: string

**Usage**

Returns `null` if no query portion exists.

**getSalesforceBaseUrl()**

Returns the URL of the Salesforce instance.
public static System.URL getSalesforceBaseUrl()

Return Value
Type: System.URL

SEE ALSO:
getOrgDomainUrl()

getUserInfo()
Gets the UserInfo portion of the current URL.

public String getUserInfo()

Return Value
Type: String

Usage
Returns null if no UserInfo portion exists.

sameFile(URLToCompare)
Compares the current URL with the specified URL object, excluding the fragment component.

public Boolean sameFile(System.URL URLToCompare)

Parameters
URLToCompare
Type: System.URL

Return Value
Type: Boolean

Returns true if both URL objects reference the same remote resource; otherwise, returns false.
Usage
For more information about the syntax of URIs and fragment components, see RFC3986.

toExternalForm()
Returns a string representation of the current URL.

Signature
public String toExternalForm()

Return Value
Type: String

UserInfo Class
Contains methods for obtaining information about the context user.

Namespace
System

UserInfo Methods
The following are methods for UserInfo. All methods are static.

IN THIS SECTION:

- getDefaultCurrency() Returns the context user’s default currency code for multiple currency organizations or the organization’s currency code for single currency organizations.
- getFirstName() Returns the context user’s first name
- getLanguage() Returns the context user’s language
- getLastName() Returns the context user’s last name
- getLocale() Returns the context user’s locale.
- getName() Returns the context user’s full name. The format of the name depends on the language preferences specified for the organization.
- getOrganizationId() Returns the context organization’s ID.
- getOrganizationName() Returns the context organization’s company name.
getProfileId()
Returns the context user's profile ID.

getSessionId()
Returns the session ID for the current session.

getTimeZone()
Returns the current user's local time zone.

getUiTheme()
Returns the preferred theme for the current user. Use getUiThemeDisplayed to determine the theme actually displayed to the current user.

getUiThemeDisplayed()
Returns the theme being displayed for the current user.

getUserEmail()
Returns the current user's email address.

getUserId()
Returns the context user's ID.

getUserName()
Returns the context user's login name.

getUserRoleId()
Returns the context user's role ID.

getUserType()
Returns the context user's type.

isCurrentUserLicensed(namespace)
Returns true if the context user has a license to any managed package denoted by the namespace. Otherwise, returns false.

isCurrentUserLicensedForPackage(packageID)
Returns true if the context user has a license to the managed package denoted by the package ID. Otherwise, returns false.

isMultiCurrencyOrganization()
Specifies whether the organization uses multiple currencies.

defaultCurrency()
Returns the context user's default currency code for multiple currency organizations or the organization's currency code for single currency organizations.

Signature

public static String getDefaultCurrency()

Return Value
Type: String
Usage

Note: For Apex saved using Salesforce API version 22.0 or earlier, `getDefaultCurrency` returns `null` for single currency organizations.

`getFirstName()`
Returns the context user's first name

Signature
```
public static String getFirstName()
```

Return Value
Type: `String`

`getLanguage()`
Returns the context user's language

Signature
```
public static String getLanguage()
```

Return Value
Type: `String`

`getLastName()`
Returns the context user's last name

Signature
```
public static String getLastName()
```

Return Value
Type: `String`

`getLocale()`
Returns the context user's locale.

Signature
```
public static String getLocale()
```

Return Value
Type: `String`
Example

```java
String result = UserInfo.getLocale();
System.assertEquals('en_US', result);
```

getName()

Returns the context user’s full name. The format of the name depends on the language preferences specified for the organization.

Signature

```java
public static String getName()
```

Return Value

Type: String

Usage

The format is one of the following:
- FirstName LastName
- LastName, FirstName

getOrganizationId()

Returns the context organization’s ID.

Signature

```java
public static String getOrganizationId()
```

Return Value

Type: String

getOrganizationName()

Returns the context organization’s company name.

Signature

```java
public static String getOrganizationName()
```

Return Value

Type: String

goProfileId()

Returns the context user’s profile ID.
Signature

```java
public static String getProfileId()
```

Return Value
Type: String

**getProfileId()**

Returns the session ID for the current session.

Signature

```java
public static String getSessionId()
```

Return Value
Type: String

Usage

You can use `getSessionId()` both synchronously and asynchronously. In asynchronous Apex (Batch, Future, Queueable, or Scheduled Apex), this method returns the session ID only when the code is run by an active, valid user. When the code is run by an internal user, such as the automated process user or a proxy user, the method returns `null`. As a best practice, ensure that your code handles both cases: when a session ID is or is not available.

**getTimeZone()**

Returns the current user's local time zone.

Signature

```java
public static System.TimeZone getTimeZone()
```

Return Value
Type: `System.TimeZone`

Example

```java
TimeZone tz =
    UserInfo.getTimeZone();
System.debug(
    'Display name: ' +
    tz.getDisplayName());
System.debug(
    'ID: ' +
    tz.getID()));
```
**getUiTheme()**

Returns the preferred theme for the current user. Use `getUiThemeDisplayed()` to determine the theme actually displayed to the current user.

**Signature**

```java
public static String getUiTheme()
```

**Return Value**

**Type:** String

The preferred theme for the current user.

Valid values include:

- **Theme1**—Obsolete Salesforce theme
- **Theme2**—Salesforce Classic 2005 user interface theme
- **Theme3**—Salesforce Classic 2010 user interface theme
- **Theme4d**—Modern "Lightning Experience" Salesforce theme
- **Theme4t**—Salesforce mobile app theme
- **Theme4u**—Lightning Console theme
- **PortalDefault**—Salesforce Customer Portal theme
- **Webstore**—Salesforce AppExchange theme

**getUiThemeDisplayed()**

Returns the theme being displayed for the current user.

**Signature**

```java
public static String getUiThemeDisplayed()
```

**Return Value**

**Type:** String

The theme being displayed for the current user.

Valid values include:

- **Theme1**—Obsolete Salesforce theme
- **Theme2**—Salesforce Classic 2005 user interface theme
- **Theme3**—Salesforce Classic 2010 user interface theme
- **Theme4d**—Modern "Lightning Experience" Salesforce theme
- **Theme4t**—Salesforce mobile app theme
- **Theme4u**—Lightning Console theme
- **PortalDefault**—Salesforce Customer Portal theme
- **Webstore**—Salesforce AppExchange theme
getUserEmail()
Returns the current user's email address.

Signature
`public static String getUserEmail()`

Return Value
Type: `String`

Example
```java
String emailAddress = UserInfo.getUserEmail();
System.debug('Email address: ' + emailAddress);
```

getUserId()
Returns the context user's ID

Signature
`public static String getUserId()`

Return Value
Type: `String`

getUserName()
Returns the context user's login name.

Signature
`public static String getUserName()`

Return Value
Type: `String`

getUserRoleId()
Returns the context user's role ID.

Signature
`public static String getUserRoleId()`
getUserType()
Returns the context user’s type.

Signature
public static String getUserType()

Return Value
Type: String

isCurrentUserLicensed(namespace)
Returns true if the context user has a license to any managed package denoted by the namespace. Otherwise, returns false.

Signature
public static Boolean isCurrentUserLicensed(String namespace)

Parameters
namespace
Type: String

Return Value
Type: Boolean

Usage
A TypeException is thrown if namespace is an invalid type.

isCurrentUserLicensedForPackage (packageID)
Returns true if the context user has a license to the managed package denoted by the package ID. Otherwise, returns false.

Signature
public static Boolean isCurrentUserLicensedForPackage(ID packageID)

Parameters
packageID
Type: String
Return Value
Type: Boolean

Usage
Retrieve `packageID` at runtime, with the `getCurrentPackageId()` method. Then, use `packageId` to confirm that the contextual user is licensed to use that managed package.

A `TypeException` is thrown if `packageID` is an invalid type. A `SystemException` is thrown if `packageID` is the ID of an unlocked or unmanaged package, or if the contextual user doesn't have a license to the managed package.

**isMultiCurrencyOrganization()**
Specifies whether the organization uses multiple currencies.

**Signature**
```
public static Boolean isMultiCurrencyOrganization()
```

Return Value
Type: Boolean

**UserManagement Class**
Contains methods to manage end users, for example, to register their verification methods, verify their identity, or remove their personal information.

**Namespace**
System

**Usage**
Let users register and deregister identity verification methods. Create custom Login and Verify pages for passwordless login and self-registration. Convert mobile phone numbers to the proper format before registering users. Scramble user data when users request that Salesforce remove their personal information.

This class is available in API version 43.0 and later.

**IN THIS SECTION:**
- UserManagement Methods

**UserManagement Methods**
The following are methods for `UserManagement`.
IN THIS SECTION:

**clone()**

**deregisterVerificationMethod(userId, method)**
Deregisters an identity verification method. Use this method to let users delete an existing verification method.

**formatPhoneNumber(countryCode, phoneNumber)**
Formats a mobile phone number for a user. Call this method to ensure that the phone number is formatted properly before updating a user’s mobile phone number.

**initPasswordlessLogin(userId, method)**
Invokes a verification challenge for passwordless login when creating custom (Visualforce) Login and Verify pages for external users.

**initRegisterVerificationMethod(method)**
Invokes a verification challenge for registering identity verification methods with a custom (Visualforce) page. Users can register either their email address or phone number.

**initSelfRegistration(method, user)**
Invokes a verification challenge for self-registration when creating a custom (Visualforce) Verify page for community self-registration.

**obfuscateUser(userId, username)**
Scrambles users’ data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it. Use this method to set the username to a specific value after it’s scrambled.

**obfuscateUser(userId)**
Scrambles users’ data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it.

**registerVerificationMethod(method, startUrl)**
Registers an identity verification method. Verification methods can be a time-based one-time password (TOTP), email or text verification code, Salesforce Authenticator, or U2F. End users register their verification methods.

**sendAsyncEmailConfirmation(userId, emailTemplateId, networkId, startUrl)**
Send an email message to a user’s email address for verification. The message contains a verification link (URL) that the user clicks to verify the email address later on. You can send email verifications in bulk.

**verifyPasswordlessLogin(userId, method, identifier, code, startUrl)**
Completes a verification challenge when creating a custom (Visualforce) Verify page for passwordless login. If the user who is trying to login enters the verification code successfully, the user is logged in.

**verifyRegisterVerificationMethod(code, method)**
Completes registering a user’s email address or phone number as a verification method when customizing the identity verification process.

**verifySelfRegistration(method, identifier, code, startUrl)**
Completes a verification challenge when creating a custom (Visualforce) Verify page for community self-registration. If the person who is attempting to register enters the verification code successfully, the user is created and logged in.

**clone()**
Signature

public Object clone()

Return Value
Type: User Management

deregisterVerificationMethod(userId, method)
Deregisters an identity verification method. Use this method to let users delete an existing verification method.

Signature

public static void deregisterVerificationMethod(Id userId, Auth.VerificationMethod method)

Parameters

userId
Type: Id
User ID of the user deregistering the verification method.

method
Type: Auth.VerificationMethod
Verification method used to verify the identity of the user.

Return Value
Type: void

Usage
Use this method to deregister an existing identity verification method. For example, your users can deregister a phone number when their phone number changes. While only end users can register an identity verification method, you and your users can deregister one. Keep this behavior in mind when you implement a custom registration page.
This method is available in API version 43.0 and later.

formatPhoneNumber(countryCode, phoneNumber)
Formats a mobile phone number for a user. Call this method to ensure that the phone number is formatted properly before updating a user’s mobile phone number.

Signature

global static String formatPhoneNumber(String countryCode, String phoneNumber)
A valid country code.

**phoneNumber**

Type: **String**

A mobile number that contains from 3 through 49 numeric characters, without the country code. For example, (415) 555-1234.

**Return Value**

Type: **String**

Returns a user’s mobile phone number in the proper format.

**Usage**

Use this method to ensure a user’s mobile phone number is formatted as required by Salesforce. Then use the method’s return value to update the mobile field of the user’s record. This mobile number is used for SMS-based identity confirmation. For example, mobile phone numbers are stored along with other identity verification methods in Auth.VerificationMethod enum. This method is introduced in API version 43.0. It isn’t available in earlier versions.

Here are some acceptable ways that users can enter their mobile number:

- +1, (415) 555-1234 (with plus signs, parentheses, and dashes)
- 1, 4155551234 (only numbers, no symbols)
- 1, 415-555-1234 (extra spaces)

Now, consider the following examples.

- **Correct examples:**
  - `formatPhoneNumber('1', '4155551234');`
  - `formatPhoneNumber('+1','(415) 555-1234');`
  - `formatPhoneNumber('1', '415-555-1234');`

- **Incorrect example, because the country code and mobile number aren’t separated:**
  - `formatPhoneNumber(null, '+1 415-555-1234');`

- **Example that doesn’t generate an error, but likely won’t work as intended:**
  - `formatPhoneNumber('+1', '+1 (415) 555-1234');`

**Format Phone Number Code Example**

Here’s a code example that uses the `formatPhoneNumber` method. It gets the mobile number from the user and converts it to the format required by Salesforce. Then it updates the user’s record with the formatted mobile number.

```apex
global with sharing class PhoneRegistrationController {
    // Input variables
    global String countryCode {get; set;}
    global String phoneNumber {get; set;}

    global String addPhoneNumber() {
        if(countryCode == null) return 'Country code is required';
        if(phoneNumber == null) return 'Phone number is required';
        return 'Successfully added phone number: ' + formatPhoneNumber(countryCode, phoneNumber);
    }
}
```
String userId = UserInfo.getUserId();
User u = [SELECT Id FROM User WHERE Id=:userId LIMIT 1];
String formatNum = System.UserManagement.formatPhoneNumber(countryCode, phoneNumber);
u.MobilePhone = formatNum;
update u;
return null;
}
}

As long as the country code and phone number are separated, formatPhoneNumber returns a value in the proper format.

**initPasswordlessLogin(userId, method)**

Invokes a verification challenge for passwordless login when creating custom (Visualforce) Login and Verify pages for external users.

**Signature**

```java
public static String initPasswordlessLogin(Id userId, Auth.VerificationMethod method)
```

**Parameters**

- **userId**
  - Type: Id
  - ID of the user who's logging in.

- **method**
  - Type: Auth.VerificationMethod
  - Method used to verify the user's identity, which can be EMAIL or SMS.

**Return Value**

- **Type: String**
  - Identifier of the verification attempt.

**Usage**

Use this method along with its paired `verifyPasswordlessLogin` to customize the login experience with your own Visualforce Login and Verify pages. Invoke `initPasswordlessLogin` from the Login page where the user enters an email address or phone number.

**Note:** An alternative to using this combination of methods is to use `Site.passwordlessLogin`. Both approaches let you customize the Login page in Visualforce. With the paired methods, you can create custom Login and Verify pages. With `Site.passwordlessLogin`, Salesforce supplies the Verify page.

First call the `initPasswordlessLogin` method to initiate an authentication challenge. This method:

- Gets the user ID and verification method, such as EMAIL or SMS, from the Login page.
- Looks up the user and checks that the user is unique and active.
- Sends a verification code to the user.
• Adds an entry for the verification attempt to the Identity Verification History log, assigning an identifier to the verification attempt and setting the status to **User challenged, waiting for response**.
• Adds an entry for the Passwordless Login to the Login History log.
• Returns the identifier to `verifyPasswordlessLogin` to link the transactions.

Then call `verifyPasswordlessLogin`, which, if the user enters the verification code correctly, logs in the user.

**Note:** Users must verify their identity by email address or phone number before they can log in without a password. You can check whether the user is verified from the user’s detail page in Setup. Or you can check programmatically with `TwoFactorsMethodsInfo`.

### `initRegisterVerificationMethod(method)`

Invokes a verification challenge for registering identity verification methods with a custom (Visualforce) page. Users can register either their email address or phone number.

**Signature**

```java
public static String initRegisterVerificationMethod(Auth.VerificationMethod method)
```

**Parameters**

- `method`
  - Type: `Auth.VerificationMethod`
  - Method used to verify the user’s identity, which can be EMAIL or SMS.

**Return Value**

- Type: `String`
  - The method returns an error message if the phone number is already registered, the user is not external, or if the context is not a community.

**Usage**

Use this method along with its paired `verifyRegisterVerificationMethod` on page 3178 to customize the process for registering a user’s verification method using a Visualforce Verify page.

First call the `initRegisterVerificationMethod` method to get the verification code sent to the user as input, and validate it. If the verification code isn’t valid, it returns an error message.

**Example**

Here’s a code example that registers a user’s phone number as a verification method. When the user enters a verification code on the Visualforce page, it invokes `registerUser()`. The method gets the User ID of the user who’s registering the verification method and the user’s phone number. It also gets the user’s registration status to check whether the phone number is verified already. If the user is registered with a different phone number, the number is updated.

```java
public void registerUser() {
    try {
        exceptionText='';
        String userId = UserInfo.getUserId();
```
User u = [Select MobilePhone, Id from User Where Id=:userId];
currPhone = u.MobilePhone;
mobilePhone = getFormattedSms(mobilePhone);
if (mobilePhone != null && mobilePhone != '') {
u.MobilePhone = mobilePhone;
update u;
  // We're updating the email and phone number before verifying. Roll back
  // the change in the verify API if it is unsuccessful.
  exceptionText = System.
  UserManagement.initRegisterVerificationMethod(Auth.VerificationMethod.SMS);
  if(exceptionText!= null && exceptionText!='') {
    isInit = false;
    showInitException = true;
  } else {
    isInit = false;
    isVerify = true;
  }
} else {
  showInitException = true;
}
}
catch (Exception e) {
  exceptionText = e.getMessage();
  isInit = false;
  showInitException = true;
}
}

public void verifyUser() {
  // Take the user’s input for the code sent to their phone number
  exceptionText = System.
  UserManagement.
  verifyRegisterVerificationMethod(code, Auth.VerificationMethod.SMS);
  if(exceptionText != null && exceptionText !=''){
    showInitException = true;
  } else {
    //Success
  }
}

initSelfRegistration(method, user)
Invokes a verification challenge for self-registration when creating a custom (Visualforce) Verify page for community self-registration.

Signature
public static String initSelfRegistration(Auth.VerificationMethod method, User user)

Parameters
method
  Type: Auth.VerificationMethod
  Method used to verify the identity of the user, which can be EMAIL or SMS.
user
Type: User
User object to insert after successful registration.

Return Value
Type: String
Identifier of the registration attempt.

Usage
By default, when users sign up for your community with an email address or phone number, Salesforce sends them a verification code. At the same time, it generates a Verify page for users to confirm their identity. You can replace the default Salesforce Verify page with your own Visualforce page and then invoke the verification process.

Call this method to initiate the authentication challenge, and include a User object to insert if the registration is successful. The method returns the identifier for the self-registration attempt.

Then call verifySelfRegistration, which, if the user enters the verification code correctly, logs in the user.

Example
This code contains the result of a verification challenge that registers a new user.

```java
String id = System.UserManagement.initSelfRegistration
(Auth.VerificationMethod.SMS, user);
Auth.VerificationResult res = System.UserManagement.verifySelfRegistration
(Auth.VerificationMethod.SMS, id, '123456', null);
if(res.status == SUCCESS){
    //redirect
}
```

obfuscateUser(userId, username)
Scrambles users’ data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it. Use this method to set the username to a specific value after it’s scrambled.

Signature
public static void obfuscateUser(Id userId, String username)

Parameters
userId
Type: Id
ID of the user whose data this method scrambles.

username
Type: String
The username after the user’s data is scrambled. Sets the value of the scrambled username to a specific string.
Return Value
Type: void

Usage
This method is introduced in API version 43.0. It isn’t available in earlier versions.

You can use the `obfuscateUser` method to protect the personal information of your org’s users. When invoked, Salesforce permanently scrambles the user’s object data and replaces it with random character strings. The user’s detail page exists, but the fields contain meaningless strings of characters. Salesforce merely obfuscates (scrambles) personal data because you can’t delete a user in Salesforce; you can only disable or deactivate a user. In other words, the user record remains in the database and this method performs a soft delete.

⚠️ Note: Take care when using this method. The users’ data becomes anonymous and can never be recovered.

Considerations
- This method requires that the org’s User Management setting, Scramble Specific Users’ Data, is enabled from Setup.
- This method affects the standard fields of the user object—excluding a few fields such as the user ID, timezone, locale, and profile.
- It is recommended that you note the user’s ID and other attributes for post processing, such as the email address, if you want to send the user a confirmation.
- This method changes only the user object. The association between the user and other objects is removed, but no other objects are changed. For example, contact, ThirdPartyAccountLink (TPAL), and user password authentication (UPA) objects remain unchanged.

⚠️ Note: Assure your admins that invoking this method doesn’t trigger an email change notification.

This method is part of our effort to protect users’ personal data and privacy. For more information on what you can do to actively protect user data, see Data Protection and Privacy in Salesforce Help.

`obfuscateUser(userId)`

Scrambles users’ data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it.

Signature
`public static void obfuscateUser(Id userId)`

Parameters
- `userId`
  
  Type: `Id`
  
  ID of the user whose data this method scrambles.

Return Value
Type: void

Usage
This method is introduced in API version 43.0. It isn’t available in earlier versions.
You can use the `obfuscateUser` method to protect the personal information of your org’s users. When invoked, Salesforce permanently scrambles the user’s object data and replaces it with random character strings. The user’s detail page exists, but the fields contain meaningless strings of characters. Salesforce merely obfuscates (scrambles) personal data because you can’t delete a user in Salesforce; you can only disable or deactivate a user. In other words, the user record remains in the database and this method performs a soft delete.

**Note:** Take care when using this method. The users’ data becomes anonymous and can never be recovered.

**Considerations**

- This method requires that the org’s User Management setting, *Scramble Specific Users’ Data*, is enabled from Setup.
- This method affects the standard fields of the user object—excluding a few fields such as the user ID, timezone, locale, and profile.
- It is recommended that you note the user’s ID and other attributes for post processing, such as the email address, if you want to send the user a confirmation.
- This method changes only the user object. The association between the user and other objects is removed, but no other objects are changed. For example, contact, ThirdPartyAccountLink (TPAL), and user password authentication (UPA) objects remain unchanged.

**Note:** Assure your admins that invoking this method doesn’t trigger an email change notification.

This method is part of our effort to protect users’ personal data and privacy. For more information on what you can do to actively protect user data, see Data Protection and Privacy in Salesforce Help.

**ObfuscateUser Code Example**

```java
public class UserManagementController{
    public List<User> users {get; set;}

    public UserManagementController()
    {
        Profile p = [select id from profile where name = 'Customer Community User'];
        users = [select username, id from User where profileId=:p.id AND isactive=true];
    }

    //Use method with extreme caution. Data can't be recovered.
    @InvocableMethod(label='User Management' description='Obfuscate User data and more')
    static public void obfuscate(List<User> users)
    {
        String uid = ApexPages.currentPage().getParameters().get('uid');
        if(uid == null)
            return;

        User u = [select contactId from user where id=:uid];
        System.UserManagement.obfuscateUser(uid);

        if(u.contactId != null)
        {
            List<Contact> contacts = [select id from Contact where id=:u.contactId LIMIT 1];
            if (contacts == null || contacts.isEmpty() == true)
                return;
        }
    }
```
delete contacts;
}
}

registerVerificationMethod(method, startUrl)

Registers an identity verification method. Verification methods can be a time-based one-time password (TOTP), email or text verification code, Salesforce Authenticator, or U2F. End users register their verification methods.

Signature

```java
```

Parameters

- **method**
  - Type: Auth.VerificationMethod
  - Verification method used to verify the identity of the user.

- **startUrl**
  - Type: String
  - Path to the page that users see after they log in.

Return Value

Type: System.PageReference

Usage

Use this method to enable users to complete identity verification, such as 2FA, or to log in to their community without a password. Users register these methods to verify their identity when logging in. You create a custom registration page when implementing mobile-centric passwordless logins. See VerifyPasswordlessLogin.

The `PageReference` returned by `registerVerificationMethod` redirects the user to the Salesforce Verify page. If the user enters the correct code, the user is redirected to the community page specified by the start URL. For example:

```java
PageReference pr = System.UserManagement.registerVerificationMethod(Auth.VerificationMethod.TOTP, startUrl);
PageReference p = System.UserManagement.deregisterVerificationMethod(userId, Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
```

This method is available in API version 43.0 and later.

**Note:** As a security measure, when users add or update mobile numbers in their detail page, they must log in again to verify their identity. As a result, unsaved changes in the app are lost. To disable this security measure, contact Salesforce Support.
sendAsyncEmailConfirmation(userId, emailTemplateId, networkId, startUrl)

Send an email message to a user’s email address for verification. The message contains a verification link (URL) that the user clicks to verify the email address later on. You can send email verifications in bulk.

Signature

public static Boolean sendAsyncEmailConfirmation(String userId, String emailTemplateId, String networkId, String startUrl)

Parameters

userId
Type: String
ID of the user to receive the email confirmation.

emailTemplateId
Type: String
ID of the email template in which the verification link is defined.

networkId
Type: String
ID of the community.

startUrl
Type: String
The user is redirected to this page after verification, with a success or error message as the parameter. If null, the user is redirected to the login page.

Return Value

Type: Boolean
Indicates whether sending the email message succeeded or failed.

Usage

Sending an async email message is good practice to ensure that users are registered with a valid email address that they truly own. To determine which users receive an email with the verification link, check whether the User Verified Email field in the User detail page is set to true. You can also get this information from the TwoFactorMethodsInfo API.

Send async email verification to external users to verify their email address. External users must verify their email address before they can log in with email OTP (passwordless login).

The error code and description are passed as query parameters so that you can process any errors when building a custom landing page.

Example

System.UserManagement.sendAsyncEmailConfirmation('005RM000001a0Ox', '00XRM000000hxnG', '0DBRM000000015i', '/s/contactsupport');
**verifyPasswordlessLogin(userId, method, identifier, code, startUrl)**

Completes a verification challenge when creating a custom (Visualforce) Verify page for passwordless login. If the user who is trying to login enters the verification code successfully, the user is logged in.

**Signature**

```
public static Auth.VerificationResult verifyPasswordlessLogin(Id userId,
Auth.VerificationMethod method, String identifier, String code, String startUrl)
```

**Parameters**

- **userId**
  Type: `Id`
  ID of the user who's logging in.

- **method**
  Type: `Auth.VerificationMethod`
  Method used to verify the identity of the user, which can be either EMAIL or SMS.

- **identifier**
  Type: `String`
  ID of the verification attempt received from the `initPasswordlessLogin` method.

- **code**
  Type: `String`
  Code used to verify the identity of the user.

- **startUrl**
  Type: `String`
  The page where the user is directed after successful login.

**Return Value**

Type: `Auth.VerificationResult`

Result of the verification challenge, which includes the message displayed, and where the user is directed if they enter the verification code correctly.

**Usage**

Call this method to complete the passwordless login authentication process. It validates the verification method and verification code. It also checks that the identifier is the same as the one returned by `initPasswordlessLogin` on page 3170.

**Example**

For an example, see `Auth.VerificationResult`.

**verifyRegisterVerificationMethod(code, method)**

Completes registering a user's email address or phone number as a verification method when customizing the identity verification process.
Signature

```java
public static String verifyRegisterVerificationMethod(String code, Auth.VerificationMethod method)
```

Parameters

code
- **Type:** String
- Code used to verify the identity of the user.

method
- **Type:** Auth.VerificationMethod
- Method used to verify the identity of the user, which can be either EMAIL or SMS.

Return Value

- **Type:** String
- If the user enters an incorrect verification code, the method returns an error message.

Usage

Call `verifyRegisterVerificationMethod` to complete the process of registering a user's verification method. This method checks whether the user entered the correct verification code. If the verification code is correct, the method

- Confirms that the user entered the correct verification code
- From the user's detail page, updates the user's verification method status (sets the verification bit)
- Sends an email to the user confirming that a verification method has been added to their record

If the verification code is incorrect, an error message is returned.

Note: If users want to change their email address after registering one, don't use the `initRegisterVerificationMethod` and `verifyRegisterVerificationMethod` methods. To enable automatic identity verification for email address changes, from the Identity Verification Setup page, select the field **Require email confirmations for email address changes** (applies to external users in Lightning Communities).

Example

Here's a code example that registers a user's phone number as a verification method. When the user enters a verification code on the Visualforce page, it invokes `registerUser()`. The method gets the User ID of the user who's registering the verification method and the user's phone number. It also gets the user's registration status to check whether the phone number is verified already. If the user is registered with a different phone number, the number is updated.

```java
public void registerUser() {
    try {
        exceptionText = ''; 
        String userId = UserInfo.getUserId();
        User u = [Select MobilePhone, Id from User Where Id=:userId];
        currPhone = u.MobilePhone;
        mobilePhone = getFormattedSms(mobilePhone);
        if (mobilePhone != null && mobilePhone != '') {
            u.MobilePhone = mobilePhone;
    ```
update u;
    // We're updating the email and phone number before verifying. Roll back
    // the change in the verify API if it is unsuccessful.
    exceptionText = System.
    UserManagement.initRegisterVerificationMethod(Auth.VerificationMethod.SMS);
    if(exceptionText!= null && exceptionText!='') {
        isInit = false;
        showInitException = true;
    } else {
        isInit = false;
        isVerify = true;
    }
    } else {
        showInitException = true;
    }
    } catch (Exception e) {
        exceptionText = e.getMessage();
        isInit = false;
        showInitException = true;
    } }

public void verifyUser() {
    // Take the user’s input for the code sent to their phone number
    exceptionText = System.UserManagement.
    verifyRegisterVerificationMethod(code, Auth.VerificationMethod.SMS);
    if(exceptionText != null && exceptionText !='' ){
        showInitException = true;
    } else {
        //Success
    }
}

verifySelfRegistration(method, identifier, code, startUrl)
Completes a verification challenge when creating a custom (Visualforce) Verify page for community self-registration. If the person who
is attempting to register enters the verification code successfully, the user is created and logged in.

Signature
public static Auth.VerificationResult verifySelfRegistration(Auth.VerificationMethod
method, String identifier, String code, String startUrl)

Parameters
method
Type: Auth.VerificationMethod
Method used to verify the identity of the user, which can be either EMAIL or SMS.
identifier
Type: String
The unique identifier received from the initSelfRegistration method.
code
Type: String
Code used to verify the identity of the user.

startUrl
Type: String
The page where the user is directed after successful self-registration.

Return Value
Type: Auth.VerificationResult
Result of the verification challenge, which includes the message displayed, and where the user is directed when they enter the verification code correctly.

Usage
By default, when users sign up for your community with an email address or phone number, Salesforce sends them a verification code and generates a Verify page. This Verify page is where users enter the verification code to confirm their identity. You can replace this Salesforce-generated Verify page with a custom Verify page that you create with Visualforce. Then you invoke the verification process with Apex methods.

First, call the initSelfRegistration method, which returns the identifier of the user to create. Then call this verifySelfRegistration method to complete the verification process. If the user enters the verification code correctly, the user is created and directed to the page specified in the startURL.

This method returns the verification result, which contains the verification status and, if the user is created, the session ID. If the verification method is SMS, the User object must contain a properly formatted mobile number, which is country code, space, and then phone number, for example, +1 1234567890. Use System.UserManagement.formatPhoneNumber to ensure that the phone number is formatted correctly.

Example
This code contains the result of a verification challenge that registers a new user.

```java
String id = System.UserManagement.initSelfRegistration(Auth.VerificationMethod.SMS, user);
Auth.VerificationResult res = System.UserManagement.verifySelfRegistration(Auth.VerificationMethod.SMS, id, '123456', null);
if(res.status == SUCCESS){
    //redirect
}
```

Version Class
Use the Version methods to get the version of a managed package of a subscriber and to compare package versions.

Namespace
System
Usage
A package version is a number that identifies the set of components uploaded in a package. The version number has the format majorNumber.minorNumber.patchNumber (for example, 2.1.3). The major and minor numbers increase to a chosen value during every major release. The patchNumber is generated and updated only for a patch release.

A called component can check the version against which the caller was compiled using the System.requestVersion method and behave differently depending on the caller’s expectations. This allows you to continue to support existing behavior in classes and triggers in previous package versions while continuing to evolve the code.

The value returned by the System.requestVersion method is an instance of this class with a two-part version number containing a major and a minor number. Since the System.requestVersion method doesn’t return a patch number, the patch number in the returned Version object is null.

The System.Version class can also hold also a three-part version number that includes a patch number.

Example
This example shows how to use the methods in this class, along with the requestVersion method, to determine the managed package version of the code that is calling your package.

```java
if (System.requestVersion() == new Version(1,0))
{
    // Do something
}
if ((System.requestVersion().major() == 1)
    && (System.requestVersion().minor() > 0)
    && (System.requestVersion().minor() <=9))
{
    // Do something different for versions 1.1 to 1.9
}
else if (System.requestVersion().compareTo(new Version(2,0)) >= 0)
{
    // Do something completely different for versions 2.0 or greater
}
```

IN THIS SECTION:
Version Constructors
Version Methods

Version Constructors
The following are constructors for Version.

IN THIS SECTION:
Version(major, minor)
Creates a new instance of the Version class as a two-part package version using the specified major and minor version numbers.
Version(major, minor, patch)
Creates a new instance of the Version class as a three-part package version using the specified major, minor, and patch version numbers.
**Version(major, minor)**

Creates a new instance of the `Version` class as a two-part package version using the specified major and minor version numbers.

**Signature**

```java
public Version(Integer major, Integer minor)
```

**Parameters**

- `major`  
  Type: `Integer`  
  The major version number.

- `minor`  
  Type: `Integer`  
  The minor version number.

**Version(major, minor, patch)**

Creates a new instance of the `Version` class as a three-part package version using the specified major, minor, and patch version numbers.

**Signature**

```java
public Version(Integer major, Integer minor, Integer patch)
```

**Parameters**

- `major`  
  Type: `Integer`  
  The major version number.

- `minor`  
  Type: `Integer`  
  The minor version number.

- `patch`  
  Type: `Integer`  
  The patch version number.

**Version Methods**

The following are methods for `Version`. All are instance methods.

**IN THIS SECTION:**

- `compareTo(version)`  
  Compares the current version with the specified version.

- `major()`  
  Returns the major package version of the of the calling code.
minor()
Returns the minor package version of the calling code.

patch()
Returns the patch package version of the calling code or null if there is no patch version.

**compareTo(version)**
Compares the current version with the specified version.

Signature
```
public Integer compareTo(System.Version version)
```

Parameters

`version`
Type: `System.Version`

Return Value
Type: Integer

Returns one of the following values:
- zero if the current package version is equal to the specified package version
- an Integer value greater than zero if the current package version is greater than the specified package version
- an Integer value less than zero if the current package version is less than the specified package version

Usage
If a two-part version is being compared to a three-part version, the patch number is ignored and the comparison is based only on the major and minor numbers.

**major()**
Returns the major package version of the of the calling code.

Signature
```
public Integer major()
```

Return Value
Type: Integer

**minor()**
Returns the minor package version of the calling code.
Signature

```java
public Integer minor()
```

Return Value
Type: Integer

**patch()**
Returns the patch package version of the calling code or `null` if there is no patch version.

Signature

```java
public Integer patch()
```

Return Value
Type: Integer

**WebServiceCallout Class**
Enables making callouts to SOAP operations on an external Web service. This class is used in the Apex stub class that is auto-generated from a WSDL.

**Namespace**
System

**IN THIS SECTION:**
WebServiceCallout Methods

**SEE ALSO:**
SOAP Services: Defining a Class from a WSDL Document

**WebServiceCallout Methods**
The following is the static method for `WebServiceCallout`.

**IN THIS SECTION:**
`invoke(stub, request, response, infoArray)`
Invokes an external SOAP web service operation based on an Apex class that is auto-generated from a WSDL.

```java
invoke(stub, request, response, infoArray)
```

Invokes an external SOAP web service operation based on an Apex class that is auto-generated from a WSDL.
public static void invoke(Object stub, Object request, Map<String, Object> response, List<String> infoArray)

Parameters

stub
Type: Object
An instance of the Apex class that is auto-generated from a WSDL (the stub class).

request
Type: Object
The request to the external service. The request is an instance of a type that is created as part of the auto-generated stub class.

response
Type: Map<String, Object>
A map of key-value pairs that represent the response that the external service sends after receiving the request. In each pair, the key is a response identifier. The value is the response object, which is an instance of a type that is created as part of the auto-generated stub class.

infoArray
Type: String[]
An array of strings that contains information about the callout—web service endpoint, SOAP action, request, and response. The order of the elements in the array matters.

- Element at index 0 ([0]): One of the following options for identifying the URL of the external web service.
  - Endpoint URL. For example: 'http://YourServer/YourService'
  - Named credential URL, which contains the scheme callout, the name of the named credential, and optionally, an appended path. For example: 'callout:MyNamedCredential/some/path'

- Element at index 1 ([1]): The SOAP action. For example: 'urn:dotnet.callouttest.soap.sforce.com/EchoString'

- Element at index 2 ([2]): The request namespace. For example: 'http://doc.sample.com/docSample'

- Element at index 3 ([3]): The request name. For example: 'EchoString'

- Element at index 4 ([4]): The response namespace. For example: 'http://doc.sample.com/docSample'

- Element at index 5 ([5]): The response name. For example: 'EchoStringResponse'

- Element at index 6 ([6]): The response type. For example: 'docSample.EchoStringResponse_element'

Return Value
Type: Void

SEE ALSO:
Named Credentials as Callout Endpoints

WebServiceMock Interface
Enables sending fake responses when testing Web service callouts of a class auto-generated from a WSDL.
Namespace
System

Usage
For an implementation example, see Test Web Service Callouts on page 503.

WebServiceMock Methods
The following are methods for WebServiceMock.

IN THIS SECTION:

doInvoke(stub, soapRequest, responseMap, endpoint, soapAction, requestName, responseNamespace, responseName, responseType)
The implementation of this method is called by the Apex runtime to send a fake response when a Web service callout is made after Test.setMock has been called.

doInvoke(stub, soapRequest, responseMap, endpoint, soapAction, requestName, responseNamespace, responseName, responseType)
The implementation of this method is called by the Apex runtime to send a fake response when a Web service callout is made after Test.setMock has been called.

Signature
public Void doInvoke(Object stub, Object soapRequest, Map<String, Object> responseMap, String endpoint, String soapAction, String requestName, String responseNamespace, String responseName, String responseType)

Parameters
stub
Type: Object
An instance of the auto-generated class.

soapRequest
Type: Object
The SOAP Web service request being invoked.

responseMap
Type: Map<String, Object>
A collection of key/value pairs representing the response to send for the request.
When implementing this interface, set the responseMap argument to a key/value pair representing the response desired.

endpoint
Type: String
The endpoint URL for the request.

soapAction
Type: String
The requested SOAP operation.

**requestName**
Type: String
The requested SOAP operation name.

**responseNamespace**
Type: String
The response namespace.

**responseName**
Type: String
The name of the response element as defined in the WSDL.

**responseType**
Type: String
The class for the response as defined in the auto-generated class.

Return Value
Type: Void

Usage

**XmlStreamReader Class**
The XmlStreamReader class provides methods for forward, read-only access to XML data. You can pull data from XML or skip unwanted events. You can parse nested XML content that's up to 50 nodes deep.

**Namespace**
System

**Usage**
The XmlStreamReader class is similar to the XMLStreamReader utility class from StAX.

**Note:** The XmlStreamReader class in Apex is based on its counterpart in Java. See the Java XMLStreamReader class.

IN THIS SECTION:
- XmlStreamReader Constructors
- XmlStreamReader Methods

SEE ALSO:
- Reading XML Using Streams
XmlStreamReader Constructors

The following are constructors for XmlStreamReader.

IN THIS SECTION:

XmlStreamReader(xmlInput)
Creates a new instance of the XmlStreamReader class for the specified XML input.

XmlStreamReader (xmlInput)
Creates a new instance of the XmlStreamReader class for the specified XML input.

Signature

public XmlStreamReader(String xmlInput)

Parameters

xmlInput
Type: String
The XML string input.

XmlStreamReader Methods

The following are methods for XmlStreamReader. All are instance methods.

IN THIS SECTION:

getAttributeCount()
Returns the number of attributes on the start element, excluding namespace definitions.

getAttributeLocalName(index)
Returns the local name of the attribute at the specified index.

getAttributeNamespace(index)
Returns the namespace URI of the attribute at the specified index.

getAttributePrefix(index)
Returns the prefix of this attribute at the specified index.

getAttributeType(index)
Returns the XML type of the attribute at the specified index.

getAttributeValue(namespaceUri, localName)
Returns the value of the attribute in the specified localName at the specified URI.

getAttributeValueAt(index)
Returns the value of the attribute at the specified index.

getEventType()
Returns the type of XML event the cursor is pointing to.
getLocalName()
Returns the local name of the current event.

getLocation()
Return the current location of the cursor.

getNamespace()
If the current event is a start element or end element, this method returns the URI of the prefix or the default namespace.

getNamespaceCount()
Returns the number of namespaces declared on a start element or end element.

getNamespacePrefix(index)
Returns the prefix for the namespace declared at the index.

getNamespaceURI(prefix)
Return the URI for the given prefix.

getNamespaceURIAt(index)
Returns the URI for the namespace declared at the index.

getPIData()
Returns the data section of a processing instruction.

getPITarget()
Returns the target section of a processing instruction.

getPrefix()
Returns the prefix of the current XML event or null if the event does not have a prefix.

getText()
Returns the current value of the XML event as a string.

getVersion()
Returns the XML version specified on the XML declaration. Returns null if none was declared.

hasName()
Returns true if the current XML event has a name. Returns false otherwise.

hasNext()
Returns true if there are more XML events and false if there are no more XML events.

hasText()
Returns true if the current event has text, false otherwise.

isCharacters()
Returns true if the cursor points to a character data XML event. Otherwise, returns false.

isEndElement()
Returns true if the cursor points to an end tag. Otherwise, it returns false.

isStartElement()
Returns true if the cursor points to a start tag. Otherwise, it returns false.

isWhiteSpace()
Returns true if the cursor points to a character data XML event that consists of all white space. Otherwise it returns false.
next()
Reads the next XML event. A processor may return all contiguous character data in a single chunk, or it may split it into several chunks. Returns an integer which indicates the type of event.

nextTag()
Skips any white space (the isWhiteSpace method returns true), comment, or processing instruction XML events, until a start element or end element is reached. Returns the index for that XML event.

setCoalescing(returnAsSingleBlock)
If you specify true for returnAsSingleBlock, text is returned in a single block, from a start element to the first end element or the next start element, whichever comes first. If you specify it as false, the parser may return text in multiple blocks.

setNamespaceAware(isNamespaceAware)
If you specify true for isNamespaceAware, the parser recognizes namespace. If you specify it as false, the parser does not. The default value is true.

toString()
Returns a string containing the length of the input XML given to XmlStreamReader and the first 50 characters of the input XML.

getAttributeCount()
Returns the number of attributes on the start element, excluding namespace definitions.

Signature
public Integer getAttributeCount()

Return Value
Type: Integer

Usage
This method is only valid on a start element or attribute XML events. The count for the number of attributes for an attribute XML event starts with zero.

getAttributeLocalName(index)
Returns the local name of the attribute at the specified index.

Signature
public String getAttributeLocalName(Integer index)

Parameters
index
Type: Integer

Return Value
Type: String
Usage
If there is no name, an empty string is returned. This method is only valid with start element or attribute XML events.

**getAttributeNamespace(index)**
Returns the namespace URI of the attribute at the specified index.

**Signature**
```
public String getAttributeNamespace(Integer index)
```

**Parameters**

*index*
Type: `Integer`

**Return Value**
Type: `String`

Usage
If no namespace is specified, `null` is returned. This method is only valid with start element or attribute XML events.

**getAttributePrefix(index)**
Returns the prefix of this attribute at the specified index.

**Signature**
```
public String getAttributePrefix(Integer index)
```

**Parameters**

*index*
Type: `Integer`

**Return Value**
Type: `String`

Usage
If no prefix is specified, `null` is returned. This method is only valid with start element or attribute XML events.

**getAttributeType(index)**
Returns the XML type of the attribute at the specified index.

```
Signature

```java
public String getAttributeType(Integer index)
```

Parameters

`index`
Type: `Integer`

Return Value

Type: `String`

Usage

For example, `id` is an attribute type. This method is only valid with start element or attribute XML events.

```java
getAttributeValue(namespaceUri, localName)
```

Returns the value of the attribute in the specified `localName` at the specified URI.

Signature

```java
public String getAttributeValue(String namespaceUri, String localName)
```

Parameters

`namespaceUri`
Type: `String`

`localName`
Type: `String`

Return Value

Type: `String`

Usage

Returns `null` if the value is not found. You must specify a value for `localName`. This method is only valid with start element or attribute XML events.

```java
getAttributeValueAt(index)
```

Returns the value of the attribute at the specified index.

Signature

```java
public String getAttributeValueAt(Integer index)
```
Parameters

\( \text{index} \)
Type: \text{Integer}

Return Value
Type: \text{String}

Usage
This method is only valid with start element or attribute XML events.

\textit{getEventType()}

Returns the type of XML event the cursor is pointing to.

Signature
\[
\text{public System.XmlTag getEventType()}
\]

Return Value
Type: \text{System.XmlTag}

\textit{XmlTag Enum}

The values for \text{XmlTag} are:

- \text{ATTRIBUTE}
- \text{CDATA}
- \text{CHARACTERS}
- \text{COMMENT}
- \text{DTD}
- \text{END\_DOCUMENT}
- \text{END\_ELEMENT}
- \text{ENTITY\_DECLARATION}
- \text{ENTITY\_REFERENCE}
- \text{NAMESPACE}
- \text{NOTATION\_DECLARATION}
- \text{PROCESSING\_INSTRUCTION}
- \text{SPACE}
- \text{START\_DOCUMENT}
- \text{START\_ELEMENT}

\textit{getLocalName()}

Returns the local name of the current event.
Signature

```
public String getLocalName()
```

Return Value
Type: String

Usage
For start element or end element XML events, it returns the local name of the current element. For the entity reference XML event, it returns the entity name. The current XML event must be start element, end element, or entity reference.

`getLocation()`

Return the current location of the cursor.

Signature

```
public String getLocation()
```

Return Value
Type: String

Usage
If the location is unknown, returns -1. The location information is only valid until the next method is called.

`getNamespace()`

If the current event is a start element or end element, this method returns the URI of the prefix or the default namespace.

Signature

```
public String getNamespace()
```

Return Value
Type: String

Usage
Returns null if the XML event does not have a prefix.

`getNamespaceCount()`

Returns the number of namespaces declared on a start element or end element.

Signature

```
public Integer getNamespaceCount()
```

Return Value
Type: Integer

Usage
This method is only valid on a start element, end element, or namespace XML event.

getNamespacePrefix(index)
Returns the prefix for the namespace declared at the index.

Signature
public String getNamespacePrefix(Integer index)

Parameters
index
Type: Integer

Return Value
Type: String

Usage
Returns null if this is the default namespace declaration. This method is only valid on a start element, end element, or namespace XML event.

getNamespaceURI(prefix)
Return the URI for the given prefix.

Signature
public String getNamespaceURI(String prefix)

Parameters
prefix
Type: String

Return Value
Type: String

Usage
The returned URI depends on the current state of the processor.
**getNamespaceURIAt(index)**
Returns the URI for the namespace declared at the index.

Signature
```
public String getNamespaceURIAt(Integer index)
```

Parameters
`index`
- Type: `Integer`

Return Value
Type: `String`

Usage
This method is only valid on a start element, end element, or namespace XML event.

**getPIData()**
Returns the data section of a processing instruction.

Signature
```
public String getPIData()
```

Return Value
Type: `String`

**getPITarget()**
Returns the target section of a processing instruction.

Signature
```
public String getPITarget()
```

Return Value
Type: `String`

**getPrefix()**
Returns the prefix of the current XML event or `null` if the event does not have a prefix.

Signature
```
public String getPrefix()
```
Return Value
Type: String

**getText()**
Returns the current value of the XML event as a string.

**Signature**
```
public String getText()
```

**Return Value**
Type: String

**Usage**
The valid values for the different events are:
- The string value of a character XML event
- The string value of a comment
- The replacement value for an entity reference. For example, assume `getText` reads the following XML snippet:
  ```xml
  <!ENTITY Title "Salesforce For Dummies" >
  <moo a="b">Name &Title;"</moo>'
  ```
  The `getText` method returns `Salesforce for Dummies`, not `&Title`.
- The string value of a CDATA section
- The string value for a space XML event
- The string value of the internal subset of the DTD

**getVersion()**
Returns the XML version specified on the XML declaration. Returns `null` if none was declared.

**Signature**
```
public String getVersion()
```

**Return Value**
Type: String

**hasName()**
Returns `true` if the current XML event has a name. Returns `false` otherwise.
Signature

```java
public Boolean hasName()
```

Return Value

Type: Boolean

Usage

This method is only valid for start element and stop element XML events.

**hasNext()**

Returns true if there are more XML events and false if there are no more XML events.

Signature

```java
public Boolean hasNext()
```

Return Value

Type: Boolean

Usage

This method returns false if the current XML event is end document.

**hasText()**

Returns true if the current event has text, false otherwise.

Signature

```java
public Boolean hasText()
```

Return Value

Type: Boolean

Usage

The following XML events have text: characters, entity reference, comment and space.

**isCharacters()**

Returns true if the cursor points to a character data XML event. Otherwise, returns false.

Signature

```java
public Boolean isCharacters()
```
isEndElement()
Returns true if the cursor points to an end tag. Otherwise, it returns false.

Signature
public Boolean isEndElement()

isStartElement()
Returns true if the cursor points to a start tag. Otherwise, it returns false.

Signature
public Boolean isStartElement()

isWhiteSpace()
Returns true if the cursor points to a character data XML event that consists of all white space. Otherwise it returns false.

Signature
public Boolean isWhiteSpace()

next()
Reads the next XML event. A processor may return all contiguous character data in a single chunk, or it may split it into several chunks. Returns an integer which indicates the type of event.

Signature
public Integer next()
**nextTag()**

Skips any white space (the `isWhiteSpace` method returns `true`), comment, or processing instruction XML events, until a start element or end element is reached. Returns the index for that XML event.

Signature

```java
public Integer nextTag()
```

Return Value

Type: `Integer`

Usage

This method throws an error if elements other than white space, comments, processing instruction, start elements or stop elements are encountered.

**setCoalescing(returnAsSingleBlock)**

If you specify `true` for `returnAsSingleBlock`, text is returned in a single block, from a start element to the first end element or the next start element, whichever comes first. If you specify it as `false`, the parser may return text in multiple blocks.

Signature

```java
public Void setCoalescing(Boolean returnAsSingleBlock)
```

Parameters

`returnAsSingleBlock`

Type: `Boolean`

Return Value

Type: `Void`

**setNamespaceAware(isNamespaceAware)**

If you specify `true` for `isNamespaceAware`, the parser recognizes namespace. If you specify it as `false`, the parser does not. The default value is `true`.

Signature

```java
public Void setNamespaceAware(Boolean isNamespaceAware)
```

Parameters

`isNamespaceAware`

Type: `Boolean`
Return Value
Type: Void

**toString()**
Returns a string containing the length of the input XML given to XmlStreamReader and the first 50 characters of the input XML.

Signature

```java
public String toString()
```

Return Value
Type: String

**XmlStreamWriter Class**
The XmlStreamWriter class provides methods for writing XML data.

**Namespace**
System

**Usage**
You can use the XmlStreamWriter class to programmatically construct an XML document, then use HTTP classes to send the document to an external server.

The XmlStreamWriter class is similar to the XMLStreamWriter utility class from StAX.

**Note:** The XmlStreamWriter class in Apex is based on its counterpart in Java. See the Java XMLStreamWriter class.

**IN THIS SECTION:**
- XmlStreamWriter Constructors
- XmlStreamWriter Methods

**SEE ALSO:**
- Http Class
- HttpRequest Class
- HttpResponse Class

**XmlStreamWriter Constructors**
The following are constructors for XmlStreamWriter.
**XmlStreamWriter()**

Creates a new instance of the `XmlStreamWriter` class.

**Signature**

```
public XmlStreamWriter()
```

**XmlStreamWriter Methods**

The following are methods for `XmlStreamWriter`. All are instance methods.

**IN THIS SECTION:**

- `close()`: Closes this instance of an XmlStreamWriter and free any resources associated with it.
- `getXmlString()`: Returns the XML written by the XmlStreamWriter instance.
- `setDefaultNamespace(uri)`: Binds the specified URI to the default namespace. This URI is bound in the scope of the current START_ELEMENT – END_ELEMENT pair.
- `writeAttribute(prefix, namespaceUri, localName, value)`: Writes an attribute to the output stream.
- `writeCData(data)`: Writes the specified CData to the output stream.
- `writeCharacters(text)`: Writes the specified text to the output stream.
- `writeComment(comment)`: Writes the specified comment to the output stream.
- `writeDefaultNamespace(namespaceUri)`: Writes the specified namespace to the output stream.
- `writeEmptyElement(prefix, localName, namespaceUri)`: Writes an empty element tag to the output stream.
- `writeEndDocument()`: Closes any start tags and writes corresponding end tags to the output stream.
- `writeEndElement()`: Writes an end tag to the output stream, relying on the internal state of the writer to determine the prefix and local name.
- `writeNamespace(prefix, namespaceUri)`: Writes the specified namespace to the output stream.
writeProcessingInstruction(target, data)
Writes the specified processing instruction.

writeStartDocument(encoding, version)
Writes the XML Declaration using the specified XML encoding and version.

writeStartElement(prefix, localName, namespaceUri)
Writes the start tag specified by localName to the output stream.

close()
Closes this instance of an XmlStreamWriter and free any resources associated with it.

Signature
public Void close()

Return Value
Type: Void

getXmlString()
Returns the XML written by the XmlStreamWriter instance.

Signature
public String getXmlString()

Return Value
Type: String

setDefaultNamespace(uri)
Binds the specified URI to the default namespace. This URI is bound in the scope of the current START_ELEMENT – END_ELEMENT pair.

Signature
public Void setDefaultNamespace(String uri)

Parameters
uri
  Type: String

Return Value
Type: Void
writeAttribute(prefix, namespaceUri, localName, value)

Writes an attribute to the output stream.

Signature

```java
public Void writeAttribute(String prefix, String namespaceUri, String localName, String value)
```

Parameters

- **prefix**
  Type: String

- **namespaceUri**
  Type: String

- **localName**
  Type: String
  Specifies the name of the attribute.

- **value**
  Type: String

Return Value

Type: Void

writeCData(data)

 Writes the specified CData to the output stream.

Signature

```java
public Void writeCData(String data)
```

Parameters

- **data**
  Type: String

Return Value

Type: Void

writeCharacters(text)

 Writes the specified text to the output stream.

Signature

```java
public Void writeCharacters(String text)
```
Parameters

text
  Type: String

Return Value
Type: Void

writeComment(comment)
Writes the specified comment to the output stream.

Signature
public Void writeComment(String comment)

Parameters
comment
  Type: String

Return Value
Type: Void

writeDefaultNamespace(namespaceUri)
Writes the specified namespace to the output stream.

Signature
public Void writeDefaultNamespace(String namespaceUri)

Parameters
namespaceUri
  Type: String

Return Value
Type: Void

writeEmptyElement(prefix, localName, namespaceUri)
Writes an empty element tag to the output stream.

Signature
public Void writeEmptyElement(String prefix, String localName, String namespaceUri)
Parameters

prefix
   Type: String

localName
   Type: String
       Specifies the name of the tag to be written.

namespaceUri
   Type: String

Return Value
Type: Void

writeEndDocument()
Closes any start tags and writes corresponding end tags to the output stream.

Signature
public Void writeEndDocument()

Return Value
Type: Void

writeEndElement()
Writes an end tag to the output stream, relying on the internal state of the writer to determine the prefix and local name.

Signature
public Void writeEndElement()

Return Value
Type: Void

writeNamespace(prefix, namespaceUri)
Writes the specified namespace to the output stream.

Signature
public Void writeNamespace(String prefix, String namespaceUri)

Parameters

prefix
   Type: String
namespaceUri
  Type: String

Return Value
Type: Void

writeProcessingInstruction(target, data)
Writes the specified processing instruction.

Signature
public Void writeProcessingInstruction(String target, String data)

Parameters
  target
    Type: String
  data
    Type: String

Return Value
Type: Void

writeStartDocument(encoding, version)
Writes the XML Declaration using the specified XML encoding and version.

Signature
public Void writeStartDocument(String encoding, String version)

Parameters
  encoding
    Type: String
  version
    Type: String

Return Value
Type: Void

writeStartElement(prefix, localName, namespaceUri)
Writes the start tag specified by localName to the output stream.
Signature

```java
public Void writeStartElement(String prefix, String localName, String namespaceUri)
```

Parameters

- `prefix`  
  Type: `String`
- `localName`  
  Type: `String`
- `namespaceUri`  
  Type: `String`

Return Value

Type: `Void`

**TerritoryMgmt Namespace**

The `TerritoryMgmt` namespace provides an interface used for territory management. The following is the interface in the `TerritoryMgmt` namespace.

**IN THIS SECTION:**

- **OpportunityTerritory2AssignmentFilter Global Interface**
  Apex interface that allows an implementing class to assign a single territory to an opportunity.

**OpportunityTerritory2AssignmentFilter Global Interface**

Apex interface that allows an implementing class to assign a single territory to an opportunity.

**Namespace**

`TerritoryMgmt`

**Usage**

Method called by Opportunity Territory Assignment job to assign territory to opportunity. Input is a list of (up to 1000) opportunityIds that have `IsExcludedFromTerritory2Filter=false`. Returns a map of OpportunityId to Territory2Id, which is used to update the Territory2Id field on the Opportunity object.

**IN THIS SECTION:**

- **OpportunityTerritory2AssignmentFilter Methods**
- **OpportunityTerritory2AssignmentFilter Example Implementation**

**OpportunityTerritory2AssignmentFilter Methods**

The following are methods for `OpportunityTerritory2AssignmentFilter`. 
IN THIS SECTION:

getOpportunityTerritory2Assignments(opportunityIds)
Returns the mapping of opportunities to territory IDs. When Salesforce invokes this method, it supplies the list of opportunity IDs, except for opportunities that have been excluded from territory assignment (IsExcludedFromTerritory2Filter=false).

getOpportunityTerritory2Assignments (opportunityIds)
Returns the mapping of opportunities to territory IDs. When Salesforce invokes this method, it supplies the list of opportunity IDs, except for opportunities that have been excluded from territory assignment (IsExcludedFromTerritory2Filter=false).

Signature

public Map<Id,Id> getOpportunityTerritory2Assignments(List<Id> opportunityIds)

Parameters

opportunityIds
Type: List<Id>
Opportunity IDs.

Return Value

Type: Map<Id,Id>
A key value pair associating each Territory ID to an Opportunity ID.

OpportunityTerritory2AssignmentFilter Example Implementation

This is an example implementation of the TerritoryMgmt.OpportunityTerritory2AssignmentFilter interface.

```java
/*** Apex version of the default logic. * If opportunity's assigned account is assigned to * Case 1: 0 territories in active model * then set territory2Id = null * Case 2: 1 territory in active model * then set territory2Id = account's territory2Id * Case 3: 2 or more territories in active model * then set territory2Id = account's territory2Id that is of highest priority. * But if multiple territories have same highest priority, then set territory2Id = null */
global class OppTerrAssignDefaultLogicFilter implements TerritoryMgmt.OpportunityTerritory2AssignmentFilter {
    /**
     * No-arg constructor.
     */
    global OppTerrAssignDefaultLogicFilter() {}

    /**
     * Get mapping of opportunity to territory2Id. The incoming list of opportunityIds contains only those with IsExcludedFromTerritory2Filter=false.
     * If territory2Id = null in result map, clear the opportunity.territory2Id if set.
     */
```
If opportunity is not present in result map, its territory2Id remains intact.

```java
// Get the active territory model Id
Id activeModelId = getActiveModelId();

if (activeModelId != null) {
    List<Opportunity> opportunities =
        [Select Id, AccountId, Territory2Id from Opportunity where Id IN :opportunityIds];
    Set<Id> accountIds = new Set<Id>();
    // Create set of parent accountIds
    for (Opportunity opp:opportunities) {
        if (opp.AccountId != null) {
            accountIds.add(opp.AccountId);
        }
    }

    Map<Id, Territory2Priority> accountMaxPriorityTerritory =
        getAccountMaxPriorityTerritory(activeModelId, accountIds);

    // For each opportunity, assign the highest priority territory if there is no conflict, else assign null.
    for (Opportunity opp: opportunities) {
        Territory2Priority tp = accountMaxPriorityTerritory.get(opp.AccountId);
        // Assign highest priority territory if there is only 1.
        if ((tp != null) && (tp.moreTerritoriesAtPriority == false) && (tp.territory2Id != opp.Territory2Id)) {
            OppIdTerritoryIdResult.put(opp.Id, tp.territory2Id);
        } else {
            OppIdTerritoryIdResult.put(opp.Id, null);
        }
    }
}
```

Query assigned territoryIds in active model for given accountIds. Create a map of accountId to max priority territory.

```java
private Map<Id, Territory2Priority> getAccountMaxPriorityTerritory(Id activeModelId, Set<Id> accountIds) {
    Map<Id, Territory2Priority> accountMaxPriorityTerritory = new Map<Id, Territory2Priority>();

    for (ObjectTerritory2Association ota: [Select ObjectId, Territory2Id, Territory2.Territory2Type.Priority from ObjectTerritory2Association where objectId IN :accountIds and Territory2.Territory2ModelId = :activeModelId]) {
        Territory2Priority tp = accountMaxPriorityTerritory.get(ota.ObjectId);
        if ((tp == null) || (ota.Territory2.Territory2Type.Priority > tp.priority)) {
            // If this is the first territory examined for account or it has greater
```
priority than current highest priority territory, then set this as new highest priority
territory.

```java
tp = new Territory2Priority(ota.Territory2Id, ota.Territory2.Territory2Type.priority, false);
else if (ota.Territory2.Territory2Type.priority == tp.priority) {
    // The priority of current highest territory is same as this, so set
    moreTerritoriesAtPriority to indicate multiple highest priority territories seen so far.
    tp.moreTerritoriesAtPriority = true;
}
accountMaxPriorityTerritory.put(ota.ObjectId, tp);
return accountMaxPriorityTerritory;
```

/**
 * Get the Id of the Active Territory Model.
 * If none exists, return null.
 */
private Id getActiveModelId() {
    List<Territory2Model> models = [Select Id from Territory2Model where State = 'Active'];
    Id activeModelId = null;
    if (models.size() == 1) {
        activeModelId = models.get(0).Id;
    }
    return activeModelId;
}

/**
 * Helper class to help capture territory2Id, its priority, and whether there are more
 * territories with same priority assigned to the account.
 */
private class Territory2Priority {
    public Id territory2Id { get; set; }
    public Integer priority { get; set; }
    public Boolean moreTerritoriesAtPriority { get; set; }

    Territory2Priority(Id territory2Id, Integer priority, Boolean moreTerritoriesAtPriority) {
        this.territory2Id = territory2Id;
        this.priority = priority;
        this.moreTerritoriesAtPriority = moreTerritoriesAtPriority;
    }
}

TxnSecurity Namespace

The `TxnSecurity` namespace provides an interface used for transaction security.

The following is the interface and its supporting class in the `TxnSecurity` namespace.
IN THIS SECTION:

**Event Class**
Contains event information that the `evaluate` method uses to evaluate a transaction security policy.

**EventCondition Interface**
Allows an implementing class to specify whether to take action when certain events occur based on a transaction security policy. This interface is only used for Apex policies created in Real-Time Event Monitoring.

**AsyncCondition Interface**
Allows an implementing class to make asynchronous Apex calls. This interface is used only for transaction security Apex policies created in Real-Time Event Monitoring.

**PolicyCondition Interface**
Apex interface that allows an implementing class to specify actions to take when certain events occur based on a transaction security policy.

### Event Class

Contains event information that the `evaluate` method uses to evaluate a transaction security policy.

### Namespace

**TxnSecurity**

### Usage

The Event class contains the information needed to determine if the event triggers a Transaction Security policy. Not all class attributes are used for every type of event.

**Tip:** For more functionality and support of Enhanced Transaction Security, use the `EventCondition` interface instead of the `PolicyCondition` interface.

### Event Constructors

The following is the constructor for `Event`.

### Event Properties

### Event Constructors

The following is the constructor for `Event`.

### Event

Creates an instance of the `TxnSecurity.Event` class.
**Event Properties**

The following are properties for `Event`.

**IN THIS SECTION:**

- `action`
  Specifies the action being taken on the resource for an Entity event. For example, a Login IP resource for an Entity event could have an action of `create`. The `action` attribute is not used by any other event type.

- `data`
  Contains data used by actions. For example, `data` for a login event includes the login history ID. Returns a map whose keys are the type of event data, like `SourceIp`.

- `entityId`
  The ID of any entity associated with the event. For example, the `entityId` of a DataExport event for an Account object contains the Account ID.

- `entityName`
  The name of the object the event acts on.

- `organizationId`
  The ID of the Salesforce org where the event occurred.

- `resourceType`
  The type of resource for the event. For example, an AccessResource event could have a Connected Application as a resource type. Not all event types have resources.

- `timeStamp`
  The time the event occurred.

- `userId`
  Identifies the user that caused the event.

**action**

Specifies the action being taken on the resource for an Entity event. For example, a Login IP resource for an Entity event could have an action of `create`. The `action` attribute is not used by any other event type.

**Signature**

```java
public String action {get; set;}
```

**Property Value**

- **Type:** `String`
**data**

Contains data used by actions. For example, `data` for a login event includes the login history ID. Returns a map whose keys are the type of event data, like `SourceIp`.

**Signature**

```java
public Map<String, String> data {get; set;}
```

**Property Value**

Type: `Map<String, String>`

The following table lists all the available data types. Not all types appear with all event types. The data type values are always string representations. For example, the `isApi` value is a string in the map, but is actually a Boolean value. Convert the value from a string to its true type this way: `Boolean.valueOf(event.data.get('isApi'))`;

<table>

<tr>
<td>UserName</td>
<td>String</td>
<td>Entity</td>
</tr>
</tbody>
</table>
**entityId**
The ID of any entity associated with the event. For example, the entityId of a DataExport event for an Account object contains the Account ID.

Signature
```java
public String entityId {get; set;}
```

Property Value
Type: String

**entityName**
The name of the object the event acts on.

Signature
```java
public String entityName {get; set;}
```

Property Value
Type: String

**organizationId**
The ID of the Salesforce org where the event occurred.

Signature
```java
public String organizationId {get; set;}
```

Property Value
Type: String

**resourceType**
The type of resource for the event. For example, an AccessResource event could have a Connected Application as a resource type. Not all event types have resources.

Signature
```java
public String resourceType {get; set;}
```

Property Value
Type: String
**timeStamp**

The time the event occurred.

Signature

```csharp
public Datetime timeStamp {get; set;}
```

Property Value

Type: Datetime

**userId**

Identifies the user that caused the event.

Signature

```csharp
public String userId {get; set;}
```

Property Value

Type: String

---

**EventCondition Interface**

Allows an implementing class to specify whether to take action when certain events occur based on a transaction security policy. This interface is only used for Apex policies created in Real-Time Event Monitoring.

**Usage**

The `evaluate` method is called upon the occurrence of a real-time event monitored by a transaction security policy. A typical implementation first selects the fields of interest from the event. Then the fields are tested to see if they meet the conditions being monitored. If the conditions are met, the method returns `true`.

For example, imagine a transaction security policy that triggers when a user queries more than 1,000 lead records. For each API event, the `evaluate` method checks whether the `RowsProcessed` value is greater than 1,000 and the `QueriedEntities` value contains "Lead". If so, `true` is returned.

We recommend having test classes for the policy condition interface to ensure it works correctly. Testing is required regardless of whether the policy is moved from a sandbox to production, with a change set, or some other way. For example, test your policies in your development environment before moving the policies to production.

Don’t include DML statements in your custom policies because they can cause errors. When you send a custom email via Apex during transaction policy evaluation, you get an error, even if the record is not explicitly related to another record. For more information, see Apex DML Operations in the Apex Developer Guide.

---

IN THIS SECTION:

- EventCondition Methods
- EventCondition Example Implementation
EventCondition Methods

The following are methods for EventCondition.

IN THIS SECTION:

evaluate(event)

Evaluates an event against a transaction security policy created in Real-Time Event Monitoring. If the event triggers the policy, the method returns true.

evaluate (event)

Evaluates an event against a transaction security policy created in Real-Time Event Monitoring. If the event triggers the policy, the method returns true.

Signature

public Boolean evaluate(SObject event)

Parameters

var1

Type: SObject

The event to check against the transaction security policy.

Return Value

Type: Boolean

Returns true when the policy is triggered. For example, suppose that the policy is to limit users to a single login session. If a user tries to log in a second time, the policy blocks the attempted login, and updates the Status, PolicyId, and PolicyOutcome fields of that LoginEvent. The policy also sends an email notification to the Salesforce admin. The evaluate method only checks the login event, and returns true if it's the user's second login attempt.

The system performs the action and notification, not the evaluate method.

EventCondition Example Implementation

This example shows an implementation of the TxnSecurity.EventCondition interface. The transaction security policy triggers when the user queries an Account object.

```java
global class BlockAccountQueriesEventCondition implements TxnSecurity.EventCondition {
    public boolean evaluate(SObject event) {
        switch on event {
            when ApiEvent apiEvent {
                return handleApiEvent(apiEvent);
            }
            when null {
                // Trigger action if event is null
                return true;
            }
            when else {
```
// Trigger action for unhandled events
return true;
}

private boolean handleApiEvent(ApiEvent apiEvent){
    if(apiEvent.QueriedEntities.contains('Account')){
        return true;
    } else {
        return false;
    }
}

For more examples, see Enhanced Apex Transaction Security Implementation Examples.

AsyncCondition Interface

Allows an implementing class to make asynchronous Apex calls. This interface is used only for transaction security Apex policies created in Real-Time Event Monitoring.

Namespace

TxnSecurity

Usage

If you make an Asynchronous Apex call in the class that implements your transaction security policy condition, the class must implement the TxnSecurity.AsyncCondition interface in addition to TxnSecurity.EventCondition. Use Asynchronous Apex instead of Apex callouts and DML statements, neither of which is allowed in transaction security Apex policies.

Apex offers multiple ways to run your Apex code asynchronously and all are supported in the TxnSecurity.AsyncCondition interface.

This interface has no methods.

IN THIS SECTION:

AsyncCondition Example Implementation

SEE ALSO:

Apex Developer Guide: Asynchronous Apex

AsyncCondition Example Implementation

Here’s an example implementation of the TxnSecurity.AsyncCondition interface. The transaction security policy triggers when a user logs in. In the example, ExternalValidation__c is a custom object that contains information from an external validation system. The result of the SOQL query on ExternalValidation__c determines whether to block the user from logging in. The policy then queues the CalloutToExternalValidator class for asynchronous execution. When it executes, the CalloutToExternalValidator class makes an external call to the validation system to update it with information about this log in event. Because CalloutToExternalValidator is triggered by Asynchronous Apex, you must implement the

```java
global class ExternallyValidatedLoginCondition implements TxnSecurity.EventCondition,
    TxnSecurity.AsyncCondition {
    public boolean evaluate(SObject event) {
        LoginEvent loginEvent = (LoginEvent) event;
        Boolean userBlocked = [select blocked from ExternalValidation__c where loginId = loginEvent.UserId][0].Blocked;
        System.enqueueJob(new CalloutToExternalValidator(loginEvent.SourceIp, loginEvent.LoginUrl));
        return userBlocked;
    }
}

class CalloutToExternalValidator implements Queueable {
    private String sourceIp;
    private String loginUrl;

    public CalloutToExternalValidator(String sourceIp, String loginUrl) {
        this.sourceIp = sourceIp;
        this.loginUrl = loginUrl;
    }

    public void execute(QueueableContext context) {
        // callout to external validation service
        // pass sourceIp, loginUrl
        // update ExternalValidation__c
    }
}
```

### PolicyCondition Interface

Apex interface that allows an implementing class to specify actions to take when certain events occur based on a transaction security policy.

### Namespace

**TxnSecurity**

### Usage

(desc) **Tip:** For more functionality and support of Enhanced Transaction Security, use the `EventCondition` interface instead of the `PolicyCondition` interface.

The `evaluate` method is called upon the occurrence of an event monitored by a transaction security policy. A typical implementation first selects the item of interest from the event. Then the item is tested to see if it meets the condition being monitored. If the condition is met, the method returns `true`.

For example, imagine a transaction security policy that checks for the same user logging in more than once. For each login event, the method would check if the user logging in already has a login session in progress, and if so, `true` is returned.
We recommend having test classes for the policy condition interface to ensure it works correctly. Testing is required regardless of whether the policy is moved from a sandbox to production, with a change set, or some other way. For example, test your policies in your development environment before moving the policies to production.

Don’t include DML statements in your custom policies because they can cause errors. When you send a custom email via Apex during transaction policy evaluation, you get an error, even if the record is not explicitly related to another record. For more information, see Apex DML Operations in the Apex Developer Guide.

IN THIS SECTION:

- PolicyCondition Methods
- Apex Policies for Transaction Security

PolicyCondition Methods

The following is the method for PolicyCondition.

IN THIS SECTION:

- evaluate(event)
  Evaluates an event against a transaction security policy. If the event triggers the policy, true is returned.

**evaluate**(event)

Evaluates an event against a transaction security policy. If the event triggers the policy, true is returned.

**Signature**

```java
public Boolean evaluate(TxnSecurity.Event event)
```

**Parameters**

- `event`:
  Type: TxnSecurity.Event
  The event to check against the transaction security policy.

**Return Value**

Type: Boolean

When the policy is triggered, True is returned. For example, let’s suppose the policy is to limit users to a single login session. If anyone tries to log in a second time, the policy’s action requires that they end their current session. The policy also sends an email notification to the Salesforce admin. The evaluate() method only checks the login event, and returns True if it’s the user’s second login. The Transaction Security system performs the action and notification, and not the evaluate() method.
Apex Policies for Transaction Security

Every Transaction Security policy must implement the Apex TxnSecurity.PolicyCondition or TxnSecurity.EventCondition interface. If you didn’t specify a condition value before you generated the Apex interface for a policy, you can add the condition later. To change the condition, you can edit the Apex code to include a condition before you activate your policy. If you don’t include a condition, your policy isn’t triggered.

Don’t include DML statements in your custom policies because they can cause errors. When you send a custom email via Apex during transaction policy evaluation, you get an error, even if the record is not explicitly related to another record. For more information, see Apex DML Operations in the Apex Developer Guide.

When you delete a transaction security policy, your TxnSecurity.PolicyCondition or TxnSecurity.EventCondition implementation isn’t deleted. You can reuse your Apex code in other policies.

If you use an API callout in the Apex class that implements TxnSecurity.PolicyCondition, you must select an action when you create the Transaction Security policy in Setup. If you select None as the action, the policy can’t execute. For more information, see Invoking Callouts Using Apex in the Apex Developer Guide.

UserProvisioning Namespace

The UserProvisioning namespace provides methods for monitoring outbound user provisioning requests.

The following is the class in the UserProvisioning namespace.

IN THIS SECTION:

ConnectorTestUtil Class

Enables developers to write Apex test classes for connectors used by the connected app provisioning solution. This class simulates provisioning for the associated app.

UserProvisioningLog Class

Provides methods for writing messages to monitor outbound user provisioning requests.

UserProvisioningPlugin Class

The UserProvisioningPlugin base class implements Process.Plugin for programmatic customization of the user provisioning process for connected apps.

ConnectorTestUtil Class

Enables developers to write Apex test classes for connectors used by the connected app provisioning solution. This class simulates provisioning for the associated app.

Namespace

UserProvisioning

Usage

Use this class for connector-based test accelerators. You can invoke it only from within an Apex test.
Example
This example creates an instance of a connected app, gets a value, and checks whether the value is correct. The test is simply a row inserted in the database table.

```apex
@isTest
private class SCIMCreateUserPluginTest {
    public static void callPlugin(Boolean validInputParams) {
        // Create an instance of a connected app
        ConnectedApplication capp = UserProvisioning.ConnectorTestUtil.createConnectedApp('TestApp');
        Profile p = [SELECT Id FROM Profile WHERE Name='Standard User'];
        // Create a user
        User user = new User(username='testuser1@scimuserprov.test', Firstname='Test', Lastname='User1', email='testuser1@testemail.com', FederationIdentifier='testuser1@testemail.com', profileId= p.Id, communityNickName='tuser1', alias='tuser', TimeZoneSidKey='GMT', LocaleSidKey='en_US', EmailEncodingKey='ISO-8859-1', LanguageLocaleKey='en_US');
        // Insert user into a row in the database table
        insert user;
        // Create a UPR
        UserProvisioningRequest upr = new UserProvisioningRequest(appname = capp.name, connectedAppId=capp.id, operation='Create', state='New', approvalStatus='NotRequired', salesforceUserId=user.id);
        // Insert the UPR to test the flow end to end
        insert upr;
    }
}
```

IN THIS SECTION:
ConnectorTestUtil Method

SEE ALSO:
Salesforce Help: User Provisioning for Connected Apps

ConnectorTestUtil Method
The ConnectorTestUtil class has 1 method.

IN THIS SECTION:
createConnectedApp(connectedAppName)
Creates an instance of a connected app to simulate provisioning.

createConnectedApp(connectedAppName)
Creates an instance of a connected app to simulate provisioning.
Signature

```java
public static ConnectedApplication createConnectedApp(String connectedAppName)
```

Parameters

`connectedAppName`
- Type: `String`
- Name of the connected app to test for provisioning.

Return Value

Type: `ConnectedApplication`

The instance of the connected app to test for provisioning.

**UserProvisioningLog Class**

Provides methods for writing messages to monitor outbound user provisioning requests.

**Namespace**

*UserProvisioning*

**Example**

This example writes the user account information sent to a third-party system for a provisioning request to the UserProvisioningLog object.

```java
String inputParamsStr = 'Input parameters: uprId=' + uprId + ', endpointURL=' + endpointURL + ', adminUsername=' + adminUsername + ', email=' + email + ', username=' + username + ', defaultPassword=' + defaultPassword + ', defaultRoles=' + defaultRoles;
UserProvisioning.UserProvisioningLog.log(uprId, inputParamsStr);
```

**UserProvisioningLog Methods**

The following are methods for `UserProvisioningLog`. All methods are static.

**IN THIS SECTION:**

- **UserProvisioningLog Methods**

**log(userProvisioningRequestId, details)**

Writes a specific message, such as an error message, to monitor the progress of a user provisioning request.

**log(userProvisioningRequestId, status, details)**

Writes a specific status and message, such as a status and detailed error message, to monitor the progress of a user provisioning request.
log(userProvisioningRequestId, externalUserId, externalUserName, userId, details)

Writes a specific message, such as an error message, to monitor the progress of a user provisioning request associated with a specific user.

log(userProvisioningRequestId, details)

Writes a specific message, such as an error message, to monitor the progress of a user provisioning request.

Signature

public void log(String userProvisioningRequestId, String details)

Parameters

userProvisioningRequestId
Type: String
A unique identifier for the user provisioning request.

details
Type: String
The text for the message.

Return Value
Type: void

log(userProvisioningRequestId, status, details)

Writes a specific status and message, such as a status and detailed error message, to monitor the progress of a user provisioning request.

Signature

public void log(String userProvisioningRequestId, String status, String details)

Parameters

userProvisioningRequestId
Type: String
A unique identifier for the user provisioning request.

status
Type: String
A description of the current state. For example, while invoking a third-party API, the status could be invoke.

details
Type: String
The text for the message.

Return Value
Type: void
log(userProvisioningRequestId, externalUserId, externalUserName, userId, details)

Writes a specific message, such as an error message, to monitor the progress of a user provisioning request associated with a specific user.

Signature

```java
public void log(String userProvisioningRequestId, String externalUserId, String externalUserName, String userId, String details)
```

Parameters

- **userProvisioningRequestId**
  - Type: String
  - A unique identifier for the user provisioning request.

- **externalUserId**
  - Type: String
  - The unique identifier for the user in the target system.

- **externalUserName**
  - Type: String
  - The username for the user in the target system.

- **userId**
  - Type: String
  - Salesforce ID of the user making the request.

- **details**
  - Type: String
  - The text for the message.

Return Value

Type: void

UserProvisioningPlugin Class

The `UserProvisioningPlugin` base class implements `Process.Plugin` for programmatic customization of the user provisioning process for connected apps.

Namespace

UserProvisioning

Usage

Extending this class gives you a plug-in that can be used Flow Builder as a legacy Apex action, with the following input and output parameters.
<table>
<thead>
<tr>
<th>Input Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>userProvisioningRequestId</td>
<td>The unique ID of the request for the plug-in to process.</td>
</tr>
<tr>
<td>userId</td>
<td>The ID of the associated user for the request.</td>
</tr>
<tr>
<td>NamedCredDevName</td>
<td>The unique API name for the named credential to use for a request.</td>
</tr>
<tr>
<td></td>
<td>The named credential identifies the third-party system and the third-party authentication settings.</td>
</tr>
<tr>
<td></td>
<td>When the named credential is set in the User Provisioning Wizard, Salesforce stores the value in the</td>
</tr>
<tr>
<td></td>
<td>UserProvisioningConfig.NamedCredentialId field.</td>
</tr>
<tr>
<td>reconFilter</td>
<td>When collecting and analyzing users on a third-party system, the plug-in uses this filter to limit the</td>
</tr>
<tr>
<td></td>
<td>scope of the collection.</td>
</tr>
<tr>
<td></td>
<td>When the filter is set in the User Provisioning Wizard, Salesforce stores the value in the</td>
</tr>
<tr>
<td></td>
<td>UserProvisioningConfig.ReconFilter field.</td>
</tr>
<tr>
<td>reconOffset</td>
<td>When collecting and analyzing users on a third-party system, the plug-in uses this value as the</td>
</tr>
<tr>
<td></td>
<td>starting point for the collection.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Output Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status</td>
<td>The vendor-specific status of the provisioning operation on the third-party system.</td>
</tr>
<tr>
<td>Details</td>
<td>The vendor-specific message related to the status of the provisioning operation on the third-party</td>
</tr>
<tr>
<td></td>
<td>system.</td>
</tr>
<tr>
<td>ExternalUserId</td>
<td>The vendor-specific ID for the associated user on the third-party system.</td>
</tr>
<tr>
<td>ExternalUsername</td>
<td>The vendor-specific username for the associated user on the third-party system.</td>
</tr>
<tr>
<td>ExternalEmail</td>
<td>The email address assigned to the user on the third-party system.</td>
</tr>
<tr>
<td>ExternalFirstName</td>
<td>The first name assigned to the user on the third-party system.</td>
</tr>
<tr>
<td>ExternalLastName</td>
<td>The last name assigned to the user on the third-party system.</td>
</tr>
<tr>
<td>reconState</td>
<td>The state of the collecting and analyzing process on the third-party system. When the value is</td>
</tr>
<tr>
<td></td>
<td>complete, the process is finished and a subsequent call to the plug-in is no longer needed, nor made.</td>
</tr>
<tr>
<td>nextReconOffset</td>
<td>When collecting and analyzing users on a third-party system, the process may encounter a transaction</td>
</tr>
<tr>
<td></td>
<td>limit and have to stop before finishing. The value specified here initiates a call to the plug-in with</td>
</tr>
<tr>
<td></td>
<td>a new quota limit.</td>
</tr>
</tbody>
</table>
If you want to add more custom parameters, use the `buildDescribeCall() method. 

**Example**

The following example uses the `buildDescribeCall()` method to add a new input parameter and a new output parameter. The example also demonstrates how to bypass the limit of the 10,000 records processed in DML statements in an Apex transaction.

```apex
global class SampleConnector extends UserProvisioning.UserProvisioningPlugin {
    // Example of adding more input and output parameters to those defined in the base class
    global override Process.PluginDescribeResult buildDescribeCall() {
        Process.PluginDescribeResult describeResult = new Process.PluginDescribeResult();

        describeResult.inputParameters = new List<Process.PluginDescribeResult.InputParameter>{
                Process.PluginDescribeResult.ParameterType.STRING, false)
        };

        describeResult.outputParameters = new List<Process.PluginDescribeResult.OutputParameter>{
                Process.PluginDescribeResult.ParameterType.STRING)
        };

        return describeResult;
    }

    // Example Plugin that demonstrates how to leverage the reconOffset/nextReconOffset/reconState
    // parameters to create more than 10,000 users. (i.e. go beyond the 10,000 DML limit per transaction)
    global override Process.PluginResult invoke(Process.PluginRequest request) {
        Map<String,String> result = new Map<String,String>();
        String uprId = (String) request.inputParameters.get('userProvisioningRequestId');

        UserProvisioning.UserProvisioningLog.log(uprId, 'Inserting Log from test Apex connector');
        UserProvisioningRequest upr = [SELECT id, operation, connectedAppId, state
            FROM userprovisioningrequest WHERE id = :uprId];
        if (upr.operation.equals('Reconcile')) {
            String reconOffsetStr = (String) request.inputParameters.get('reconOffset');
            Integer reconOffset = 0;
            if (reconOffsetStr != null) {
                reconOffset = Integer.valueOf(reconOffsetStr);
            }
            if (reconOffset > 44999) {
                result.put('reconState', 'Completed');
            }
            Integer i = 0;
            result.put('i', i);
        }
    }
}
```
List<UserProvAccountStaging> upasList = new List<UserProvAccountStaging>();
for (i = 0; i < 5000; i++) {
    UserProvAccountStaging upas = new UserProvAccountStaging();
    upas.Name = i + reconOffset + '';
    upas.ExternalFirstName = upas.Name;
    upas.ExternalEmail = 'externaluser@externalsystem.com';
    upas.LinkState = 'Orphaned';
    upas.Status = 'Active';
    upas.connectedAppId = upr.connectedAppId;
    upasList.add(upas);
}
insert upasList;
result.put('nextReconOffset', reconOffset + 5000 + '');?></
return new Process.PluginResult(result);
}</

IN THIS SECTION:
UserProvisioningPlugin Methods

UserProvisioningPlugin Methods
The following are methods for UserProvisioningPlugin.

IN THIS SECTION:
buildDescribeCall()
User this method to add more input and output parameters to those defined in the base class.
describe()
Returns a Process.PluginDescribeResult object that describes this method call.
getPluginClassName()
Returns the name of the class implementing the plugin.
invoke(request)
Primary method that the system invokes when the class that implements the interface is instantiated.

buildDescribeCall()
Use this method to add more input and output parameters to those defined in the base class.

Signature
public Process.PluginDescribeResult buildDescribeCall()
### describe()

Returns a `Process.PluginDescribeResult` object that describes this method call.

**Signature**

```java
public Process.PluginDescribeResult describe()
```

**Return Value**

Type: `Process.PluginDescribeResult`

### getPluginClassName()

Returns the name of the class implementing the plugin.

**Signature**

```java
public String getPluginClassName()
```

**Return Value**

Type: `String`

### invoke(request)

Primary method that the system invokes when the class that implements the interface is instantiated.

**Signature**

```java
```

**Parameters**

- `request`
  - Type: `Process.PluginRequest`

**Return Value**

Type: `Process.PluginDescribeResult`

---

**VisualEditor Namespace**

The `VisualEditor` namespace provides classes and methods for interacting with the Lightning App Builder. The classes and methods in this namespace operate on Lightning components, which include Lightning web components and Aura components.

As of Spring '19 (API version 45.0), you can build Lightning components using two programming models: the Lightning Web Components model, and the original Aura Components model. Lightning web components are custom HTML elements built using HTML and modern JavaScript. Lightning web components and Aura components can coexist and interoperate on a page.

Configure Lightning web components and Aura components to work in Lightning App Builder and Community Builder. Admins and end users don't know which programming model was used to develop the components. To them, they're simply Lightning components.
The following are the classes in the `VisualEditor` namespace.

**IN THIS SECTION:**

- **DataRow Class**
  Contains information about one item in a picklist used in a Lightning component on a Lightning page.

- **DesignTimePageContext Class**
  An abstract class that provides context information about a Lightning page. It can be used to help define the values of a picklist in a Lightning component on a Lightning page based on the page’s type and the object with which it’s associated.

- **DynamicPickList Class**
  An abstract class, used to display the values of a picklist in a Lightning component on a Lightning page.

- **DynamicPickListRows Class**
  Contains a list of picklist items in a Lightning component on a Lightning page.

---

**DataRow Class**

Contains information about one item in a picklist used in a Lightning component on a Lightning page.

**Namespace**

`VisualEditor`

**IN THIS SECTION:**

- **DataRow Constructors**

- **DataRow Methods**

---

**DataRow Constructors**

The following are constructors for `DataRow`.

**IN THIS SECTION:**

- `DataRow(label, value, selected)`
  Creates an instance of the `VisualEditor.DataRow` class using the specified label, value, and selected option.

- `DataRow(label, value)`
  Creates an instance of the `VisualEditor.DataRow` class using the specified label and value.

**DataRow(label, value, selected)**

Creates an instance of the `VisualEditor.DataRow` class using the specified label, value, and selected option.

**Signature**

```java
public DataRow(String label, Object value, Boolean selected)
```
Parameters

`label`  
Type: `String`  
User-facing label for the picklist item.

`value`  
Type: `Object`  
The value of the picklist item.

`selected`  
Type: `Boolean`  
Specifies whether the picklist item is selected (`true`) or not (`false`).

**DataRow(label, value)**

Creates an instance of the `VisualEditor.DataRow` class using the specified label and value.

Signature

```java
public DataRow(String label, Object value)
```

Parameters

`label`  
Type: `String`  
User-facing label for the picklist item.

`value`  
Type: `Object`  
The value of the picklist item.

**DataRow Methods**

The following are methods for `DataRow`.

IN THIS SECTION:

- `clone()`  
  Makes a duplicate copy of the `VisualEditor.DataRow` object.

- `compareTo(o)`  
  Compares the current `VisualEditor.DataRow` object to the specified one. Returns an integer value that is the result of the comparison.

- `getLabel()`  
  Returns the user-facing label of the picklist item.

- `getValue()`  
  Returns the value of the picklist item.

- `isSelected()`  
  Returns the state of the picklist item, indicating whether it’s selected or not.
clone()
Makes a duplicate copy of the VisualEditor.DataRow object.

Signature
public Object clone()

Return Value
Type: Object

compareTo(o)
Compares the current VisualEditor.DataRow object to the specified one. Returns an integer value that is the result of the comparison.

Signature
public Integer compareTo(VisualEditor.DataRow o)

Parameters

- Type: VisualEditor.DataRow
  A single item in a picklist.

Return Value
Type: Integer
Returns one of the following values:
- Zero if the current package version is equal to the specified package version
- An integer value greater than zero if the current package version is greater than the specified package version
- An integer value less than zero if the current package version is less than the specified package version

getLabel()
Returns the user-facing label of the picklist item.

Signature
public String getLabel()

Return Value
Type: String

g GetValue ()
Returns the value of the picklist item.
Signature
public Object getValue()

Return Value
Type: Object

isSelected()
Returns the state of the picklist item, indicating whether it's selected or not.

Signature
public Boolean isSelected()

Return Value
Type: Boolean

DesignTimePageContext Class
An abstract class that provides context information about a Lightning page. It can be used to help define the values of a picklist in a Lightning component on a Lightning page based on the page's type and the object with which it's associated.

Namespace
VisualEditor

Usage
To use this class, create a parameterized constructor in the custom Apex class that extends VisualEditor.DynamicPickList.

Example
Here's an example of a custom Apex class extending the VisualEditor.DynamicPickList class. It includes VisualEditor.DesignTimePageContext to define a picklist value that is available only if the page type is HomePage.

```apex
global class MyCustomPickList extends VisualEditor.DynamicPickList{
    VisualEditor.DesignTimePageContext context;

    global MyCustomPickList(VisualEditor.DesignTimePageContext context) {
        this.context = context;
    }

    global override VisualEditor.DataRow getDefaultValue(){
        VisualEditor.DataRow defaultValue = new VisualEditor.DataRow('red', 'RED');
        return defaultValue;
    }

    global override VisualEditor.DynamicPickListRows getValues() {
        VisualEditor.DataRow value1 = new VisualEditor.DataRow('red', 'RED');
        VisualEditor.DataRow value2 = new VisualEditor.DataRow('yellow', 'YELLOW');
```
VisualEditor.DynamicPickListRows myValues = new VisualEditor.DynamicPickListRows();

myValues.addRow(value1);
myValues.addRow(value2);

if (context.pageType == 'HomePage') {
  VisualEditor.DataRow value3 = new VisualEditor.DataRow('purple', 'PURPLE');
  myValues.addRow(value3);
}

return myValues;

IN THIS SECTION:

DesignTimePageContext Properties

DesignTimePageContext Methods

DesignTimePageContext Properties

The following are properties for DesignTimePageContext.

IN THIS SECTION:

entityName

The API name of the sObject that a Lightning page is associated with, such as Account, Contact or Custom_object__c. Not all Lightning pages are associated with objects.

pageType

The type of Lightning page, such as HomePage, AppPage, or RecordPage.

textbox

entityName

The API name of the sObject that a Lightning page is associated with, such as Account, Contact or Custom_object__c. Not all Lightning pages are associated with objects.

Signature

public String entityName {get; set;}

Property Value

Type: String

pageType

The type of Lightning page, such as HomePage, AppPage, or RecordPage.
Signature

public String pageType {get; set;}

Property Value
Type: String

DesignTimePageContext Methods
The following are methods for DesignTimePageContext.

IN THIS SECTION:

clone()  

clone()  

Signature

public Object clone()

Return Value
Type: Object

DynamicPickList Class
An abstract class, used to display the values of a picklist in a Lightning component on a Lightning page.

Namespace
VisualEditor

Usage
To use this class as the datasource of a picklist in a Lightning component, it must be extended by a custom Apex class and then that class must be called in the component’s design file.

Example
Here's an example of a custom Apex class extending the VisualEditor.DynamicPickList class.

```
global class MyCustomPickList extends VisualEditor.DynamicPickList{

global override VisualEditor.DataRow getDefaultValue(){
    VisualEditor.DataRow defaultValue = new VisualEditor.DataRow('red', 'RED');
    return defaultValue;
}
```
Here's an example of how the custom Apex class gets called in a design file so that the picklist appears in the Lightning component.

```xml
<design:component>
  <design:attribute name="property1" datasource="apex://MyCustomPickList"/>
</design:component>
```

### IN THIS SECTION:

**DynamicPickList Methods**

The following are methods for `DynamicPickList`.

**IN THIS SECTION:**

- clone()

- getDefaultValue()
  - Returns the picklist item that is set as the default value for the picklist.

- getLabel(attributeValue)
  - Returns the user-facing label for a specified picklist value.

- getValues()
  - Returns the list of picklist item values.

- isValid(attributeValue)
  - Returns the valid state of the picklist item's value. A picklist value is considered valid if it's a part of any `VisualEditor.DataRow` in the `VisualEditor.DynamicPickListRows` returned by `getValues()`.

**clone()**

**Signature**

```java
public Object clone()
```
Return Value
Type: Object

**getDefaultValue()**
Returns the picklist item that is set as the default value for the picklist.

Signature
```
public VisualEditor.DataRow getDefaultValue()
```

Return Value
Type: **VisualEditor.DataRow**

**getLabel(attributeValue)**
Returns the user-facing label for a specified picklist value.

Signature
```
public String getLabel(Object attributeValue)
```

Parameters
*attributeValue*
Type: Object
The value of the picklist item.

Return Value
Type: **String**

**getValues()**
Returns the list of picklist item values.

Signature
```
public VisualEditor.DynamicPickListRows getValues()
```

Return Value
Type: **VisualEditor.DynamicPickListRows**

**isValid(attributeValue)**
Returns the valid state of the picklist item’s value. A picklist value is considered valid if it’s a part of any **VisualEditor.DataRow** in the **VisualEditor.DynamicPickListRows** returned by **getValues()**.
Signature

```java
public Boolean isValid(Object attributeValue)
```

Parameters

`attributeValue`
- Type: Object
- The value of the picklist item.

Return Value

Type: Boolean

**DynamicPickListRows Class**

Contains a list of picklist items in a Lightning component on a Lightning page.

**Namespace**

`VisualEditor`

IN THIS SECTION:

- DynamicPickListRows Constructors
- DynamicPickListRows Methods

**DynamicPickListRows Constructors**

The following are constructors for `DynamicPickListRows`.

IN THIS SECTION:

- DynamicPickListRows(rows, containsAllRows)
  Creates an instance of the `VisualEditor.DynamicPickListRows` class using the specified parameters.
- DynamicPickListRows(rows)
  Creates an instance of the `VisualEditor.DynamicPickListRows` class using the specified parameter.
- DynamicPickListRows()
  Creates an instance of the `VisualEditor.DynamicPickListRows` class. You can then add rows by using the class's `addRow` or `addAllRows` methods.

**DynamicPickListRows(rows, containsAllRows)**

Creates an instance of the `VisualEditor.DynamicPickListRows` class using the specified parameters.

Signature

```java
public DynamicPickListRows(List<VisualEditor.DataRow> rows, Boolean containsAllRows)
```
Parameters

rows
Type: List VisualEditor.DataRow
List of picklist items.

containsAllRows
Type: Boolean
Indicates if all values of the picklist are included in a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

A picklist in a Lightning component can display only the first 200 values of a list. If containsAllRows is set to false, when a user does a type-ahead search to find values in the picklist, the search will only look at those first 200 values that were displayed, not the complete set of picklist values.

DynamicPickListRows(rows)
Creates an instance of the VisualEditor.DynamicPickListRows class using the specified parameter.

Signature
public DynamicPickListRows(List<VisualEditor.DataRow> rows)

Parameters
rows
Type: List VisualEditor.DataRow
List of picklist rows.

DynamicPickListRows()
Creates an instance of the VisualEditor.DynamicPickListRows class. You can then add rows by using the class’s addRow or addAllRows methods.

Signature
public DynamicPickListRows()

DynamicPickListRows Methods
The following are methods for DynamicPickListRows.

IN THIS SECTION:

addAllRows(rows)
Adds a list of picklist items to a dynamic picklist rendered in a Lightning component on a Lightning page.

addRow(row)
Adds a single picklist item to a dynamic picklist rendered in a Lightning component on a Lightning page.

clone()
containsAllRows()
Returns a Boolean value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

get(i)
Returns a picklist element stored at the specified index.
getDataRows()
Returns a list of picklist items.

setContainsAllRows(containsAllRows)
Sets the value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

size()
Returns the size of the list of VisualEditor.DynamicPickListRows.
sort()
Sorts the list of VisualEditor.DynamicPickListRows.

addAllRows(rows)
Adds a list of picklist items to a dynamic picklist rendered in a Lightning component on a Lightning page.

Signature
public void addAllRows(List<VisualEditor.DataRow> rows)

Parameters
rows
Type: List VisualEditor.DataRow
List of picklist items.

Return Value
Type: void

addRow(row)
Adds a single picklist item to a dynamic picklist rendered in a Lightning component on a Lightning page.

Signature
public void addRow(VisualEditor.DataRow row)

Parameters
row
Type: VisualEditor.DataRow
A single picklist item.
Return Value
Type: void

cloned()

Signature
public Object clone()

Return Value
Type: Object

containsAllRows()

Returns a Boolean value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

Signature
public Boolean containsAllRows()

Return Value
Type: Boolean

A picklist in a Lightning component can display only the first 200 values of a list. If containsAllRows is set to false, when a user does a type-ahead search to find values in the picklist, the search will only look at those first 200 values that were displayed, not the complete set of picklist values.

geti()

Returns a picklist element stored at the specified index.

Signature
public VisualEditor.DataRow get(Integer i)

Parameters
i
Type: Integer

The index.

Return Value
Type: VisualEditor.DataRow
getDataRows()  
Returns a list of picklist items.

Signature  
public List<VisualEditor.DataRow> getDataRows()  

Return Value  
Type: List<VisualEditor.DataRow>

setContainsAllRows(containsAllRows)  
Sets the value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

Signature  
public void setContainsAllRows(Boolean containsAllRows)  

Parameters  
containsAllRows  
Type: Boolean  
Indicates if all values of the picklist are included in a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

A picklist in a Lightning component can display only the first 200 values of a list. If containsAllRows is set to false, when a user does a type-ahead search to find values in the picklist, the search will only look at those first 200 values that were displayed, not the complete set of picklist values.

Return Value  
Type: void

size()  
Returns the size of the list of VisualEditor.DynamicPickListRows.

Signature  
public Integer size()  

Return Value  
Type: Integer

sort()  
Sorts the list of VisualEditor.DynamicPickListRows.
Signature

```java
public void sort()
```

Return Value

Type: void

**wave Namespace**

The classes in the `wave` namespace are part of the Wave Analytics SDK, designed to facilitate querying Wave data from Apex code. The following are the classes in the `wave` namespace.

**IN THIS SECTION:**

- **QueryBuilder Class**
  The `QueryBuilder` class provides methods for constructing well-formed SAQL queries to pass to Wave Analytics.

- **QueryNode Class**
  Define each node of the query - such as projection, groups, order, filters. Execute the query.

- **ProjectionNode Class**
  Add aggregate functions to the query, or define an alias.

**QueryBuilder Class**

The `QueryBuilder` class provides methods for constructing well-formed SAQL queries to pass to Wave Analytics.

**Namespace**

`wave`

**Usage**

Use `QueryBuilder` and its associated classes, `Wave.ProjectionNode` and `Wave.QueryNode`, to incrementally build your SAQL statement. For example:

```java
public static void executeApexQuery(String name){
    Wave.ProjectionNode[] projs = new Wave.ProjectionNode[]{
        Wave.QueryBuilder.get('State').alias('State'),
        Wave.QueryBuilder.get('City').alias('City'),
        Wave.QueryBuilder.get('Revenue').avg().alias('avg_Revenue'),
        Wave.QueryBuilder.get('Revenue').sum().alias('sum_Revenue'),
        Wave.QueryBuilder.count().alias('count')};

    ConnectApi.LiteralJson result = Wave.QueryBuilder.load('0FbD00000004DSzKAM',
        '0FcD00000004FEZKA2')
            .group(new String[]{'State', 'City'})
            .foreach(projs)
            .execute('q');
}
Examples

QueryBuilder is the core of this first phase of the Wave Apex SDK, so let’s take a closer look. Here’s a simple count query.

```java
String query = Wave.QueryBuilder.load('datasetId', 'datasetVersionId').group().foreach(projs).build('q');
```

The resulting SAQL query looks like this:

```saql
q = load "datasetId/datasetVersionId";
q = group q by all;
q = foreach q generate count as c;
```

Here’s a more complex example that uses a union statement.

```java
Wave.QueryNode nodeOne = Wave.QueryBuilder.load('datasetOne','datasetVersionOne').foreach(projs);
Wave.QueryNode nodeTwo = Wave.QueryBuilder.load('datasetTwo', 'datasetVersionTwo').foreach(projs);
String query = Wave.QueryBuilder.union(new List<Wave.QueryNode>{nodeOne, nodeTwo}).build('q');
```

The resulting SAQL query has two projection streams, qa and qb.

```saql
qa = load "datasetOne/datasetVersionOne";
qa = foreach q generate Name,AnnualRevenue as Revenue;
qb = load "datasetTwo/datasetVersionTwo";
qb = foreach q generate Name,AnnualRevenue as Revenue;
q = union qa, qb;
```

IN THIS SECTION:

QueryBuilder Methods

QueryBuilder Methods

The following are methods for QueryBuilder.

IN THIS SECTION:

`load(datasetID, datasetVersionID)`
Load a stream from a dataset.

`count()`
Calculate the number of rows that match the query criteria.

`get(projection)`
Query by selecting specific attributes.
union(unionNodes)
Combine multiple result sets into one result set.

cogroup(cogroupNodes, groups)
Cogrouping means that two input streams are grouped independently and arranged side by side. Only data that exists in both groups appears in the results.

load(datasetID, datasetVersionID)
Load a stream from a dataset.

Signature
public static wave.QueryNode load(String datasetID, String datasetVersionID)

Parameters
datasetID
Type: String
The ID of the dataset.
datasetVersionID
Type: String
The ID identifying the version of the dataset.

Return Value
Type: wave.QueryNode

count()
Calculate the number of rows that match the query criteria.

Signature
public static wave.ProjectionNode count()

Return Value
Type: wave.ProjectionNode

get(projection)
Query by selecting specific attributes.

Signature
public static wave.ProjectionNode get(String proj)
Parameters

\( proj \)
Type: String
The name of the column to query.

Return Value
Type: wave.ProjectionNode

**union (unionNodes)**
Combine multiple result sets into one result set.

Signature

```
global static Wave.QueryNode union(List<Wave.QueryNode> unionNodes)
```

Parameters

**unionNodes**
Type: List<wave.QueryNode>
List of nodes to combine.

Return Value
Type: wave.QueryNode

**cogroup (cogroupNodes, groups)**
Cogrouping means that two input streams are grouped independently and arranged side by side. Only data that exists in both groups appears in the results.

Signature

```
global static Wave.QueryNode cogroup(List<Wave.QueryNode> cogroupNodes, List<List<String>> groups)
```

Parameters

**cogroupNodes**
Type: wave.QueryNode
List of nodes to group.

**groups**
Type: String
The type of grouping.

Return Value
Type: wave.QueryNode
QueryNode Class
Define each node of the query - such as projection, groups, order, filters. Execute the query.

Namespace
wave

Usage
Refer to the QueryBuilder example.

IN THIS SECTION:
QueryNode Methods

QueryNode Methods
The following are methods for QueryNode.

build(streamName)
Build the query string represented by this QueryNode and assign it to a stream name.

foreach(projections)
Applies a set of expressions to every row in a dataset. This action is often referred to as projection.

group(groups)
Groups matched records (group by specific dataset attributes).

group()
Groups matched records (group by all).

order(orders)
Sorts in ascending or descending order on one or more fields.

cap(cap)
Limits the number of results that are returned.

filter(filterCondition)
Selects rows from a dataset based on a filter condition (a predicate).

filter(filterConditions)
Selects rows from a dataset based on multiple filter conditions (predicates).

execute(streamName)
Execute the query and return rows as JSON.

build(streamName)
Build the query string represented by this QueryNode and assign it to a stream name.
Signature

```java
public String build(String streamName)
```

Parameters

`streamName`
- Type: `String`
- The identifier for the stream - for example, “q”.

Return Value

Type: `String`
- The SAQL query string represented by the QueryNode.

**foreach** *(projections)*
Applies a set of expressions to every row in a dataset. This action is often referred to as projection.

Signature

```java
public wave.QueryNode foreach(List<wave.ProjectionNode> projections)
```

Parameters

`projections`
- Type: `List<wave.ProjectionNode>`
- A list of ProjectionNodes to be added to this QueryNode.

Return Value

Type: `wave.QueryNode`

**group** *(groups)*
Groups matched records (group by specific dataset attributes).

Signature

```java
public wave.QueryNode group(List<String> groups)
```

Parameters

`groups`
- Type: `List<String>`
- A list of expressions.

Return Value

Type: `wave.QueryNode`
Example

```java
Wave.ProjectionNode[] projs = new Wave.ProjectionNode[]{Wave.QueryBuilder.get('Name'),
Wave.QueryBuilder.get('Revenue').sum().alias('REVENUE_SUM')};
ConnectApi.LiteralJson result = Wave.QueryBuilder.load('datasetId',
'datasetVersionId').group(new String[]{'Name'}).foreach(projs).build('q');
```

`group()`
Groups matched records (group by all).

Signature

```java
public wave.QueryNode group()
```

Return Value
Type: `wave.QueryNode`

Example

```java
String query = Wave.QueryBuilder.load('datasetId',
'datasetVersionId').group().foreach(projs).build('q');
```

`order(orders)`
Sorts in ascending or descending order on one or more fields.

Signature

```java
public wave.QueryNode group(List<String> groups)
```

Parameters
`groups`
Type: `List<String>`
A list of column names and associated ascending or descending keywords, for example

```java
List<List<String>>{new List<String>{'Name', 'asc'}, new List<String>{'Revenue', 'desc'}}
```

Return Value
Type: `wave.QueryNode`

`cap(cap)`
Limits the number of results that are returned.

Signature

```java
global Wave.QueryNode cap(Integer cap)
```
Parameters

cap
   Type: Integer
   The maximum number of rows to return.

Return Value
Type: wave.QueryNode

**filter(filterCondition)**
Selects rows from a dataset based on a filter condition (a predicate).

**Signature**

```java
public wave.QueryNode filter(String filterCondition)
```

**Parameters**

`filterCondition`
   Type: String
   For example: `filter('Name != 'My Name'')`

**Return Value**
Type: wave.QueryNode

**filter(filterConditions)**
Selects rows from a dataset based on multiple filter conditions (predicates).

**Signature**

```java
public wave.QueryNode filter(List<String> filterCondition)
```

**Parameters**

`filterCondition`
   Type: List<String>
   A list of filter conditions.

**Return Value**
Type: wave.QueryNode

**execute(streamName)**
Execute the query and return rows as JSON.
Signature

```
global ConnectApi.LiteralJson execute(String streamName)
```

Parameters

`streamName`

Type: String

The query stream to execute. For example:

```
ConnectApi.LiteralJson result = Wave.QueryBuilder.load('datasetId', 'datasetVersionId').group().foreach(projs).execute('q');
```

Return Value

Type: ConnectApi.LiteralJson

_ProjectionNode Class_

Add aggregate functions to the query, or define an alias.

_Namespace_

_`wave` on page 3244_

_Usage_

Refer to the QueryBuilder example.

_IN THIS SECTION:_

_ProjectionNode Methods_

The following are methods for `ProjectionNode`.

_IN THIS SECTION:_

- `sum()`
  - Returns the sum of a numeric field.
- `avg()`
  - Returns the average value of a numeric field.
- `min()`
  - Returns the minimum value of a field.
- `max()`
  - Returns the maximum value of a field.
- `count()`
  - Returns the number of rows that match the query criteria.
unique()
Returns the count of unique values.

alias(name)
Define output column names.

sum()
Returns the sum of a numeric field.

Signature
public wave.ProjectionNode sum()

Return Value
Type: wave.ProjectionNode

avg()
Returns the average value of a numeric field.

Signature
public wave.ProjectionNode avg()

Return Value
Type: wave.ProjectionNode

min()
Returns the minimum value of a field.

Signature
public wave.ProjectionNode min()

Return Value
Type: wave.ProjectionNode

max()
Returns the maximum value of a field.

Signature
public wave.ProjectionNode max()
Return Value
Type: `wave.ProjectionNode`

count()
Returns the number of rows that match the query criteria.

Signature
```
public wave.ProjectionNode count()
```

Return Value
Type: `wave.ProjectionNode`

unique()
Returns the count of unique values.

Signature
```
public wave.ProjectionNode unique()
```

Return Value
Type: `wave.ProjectionNode`

alias(name)
Define output column names.

Signature
```
public wave.ProjectionNode alias(String name)
```

Parameters
name
Type: `String`
The name to use for this column. For example, this code defines the alias `c`:
```
```

Return Value
Type: `wave.ProjectionNode`
Appendices

Reserved Keywords
Action Links Labels
Use these labels for action link buttons.
API End-of-Life
Salesforce is committed to supporting each API version for a minimum of three years from the date of first release. In order to mature and improve the quality and performance of the API, versions that are more than three years old might cease to be supported.
Documentation Typographical Conventions

SOAP API and SOAP Headers for Apex

This appendix details the SOAP API calls and objects that are available by default for Apex.

Note: Apex class methods can be exposed as custom SOAP Web service calls. This allows an external application to invoke an Apex Web service to perform an action in Salesforce. Use the webservice keyword to define these methods. For more information, see Considerations for Using the webservice Keyword on page 269.

Any Apex code saved using SOAP API calls uses the same version of SOAP API as the endpoint of the request. For example, if you want to use SOAP API version 47.0, use endpoint 47.0:

https://yourInstance.salesforce.com/services/Soap/s/47.0

For information on all other SOAP API calls, including those that can be used to extend or implement any existing Apex IDEs, contact your Salesforce representative.

The following API objects are available:

- ApexTestQueueItem
- ApexTestResult
- ApexTestResultLimits
- ApexTestRunResult

The following are SOAP API calls:

- compileAndTest()
- compileClasses()
- compileTriggers()
- executeAnonymous()
- runTests()

The following SOAP headers are available in SOAP API calls for Apex:

- DebuggingHeader
- PackageVersionHeader

Also see the Metadata API Developer Guide for two additional calls:
• deploy()
• retrieve()

IN THIS SECTION:
1. **ApexTestQueueItem**
   Represents a single Apex class in the Apex job queue. This object is available in API version 23.0 and later.
2. **ApexTestResult**
   Represents the result of an Apex test method execution. This object is available in API version 23.0 and later.
3. **ApexTestResultLimits**
   Captures the Apex test limits used for a particular test method execution. An instance of this object is associated with each ApexTestResult record. This object is available in API version 37.0 and later.
4. **ApexTestRunResult**
   Contains summary information about all the test methods that were run in a particular Apex job. This object is available in API version 37.0 and later.
5. compileAndTest()
6. compileClasses()
7. compileTriggers()
8. executeanonymous()
9. runTests()
10. **DebuggingHeader**
    Return the debug log in the output header, DebuggingInfo, and specify the level of detail in the debug log.
11. **PackageVersionHeader**

**ApexTestQueueItem**

Represents a single Apex class in the Apex job queue. This object is available in API version 23.0 and later.

This object is available in API version 23.0 and later.

**Supported Calls**
create(), describeSObjects(), query(), retrieve(), update(), upsert()

**Fields**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>

<td><strong>Type</strong> picklist&lt;br&gt;&lt;br&gt;<strong>Properties</strong> Filter, Group, Restricted picklist, Sort, Update&lt;br&gt;&lt;br&gt;<strong>Description</strong> The status of the job. Valid values are:&lt;br&gt;• Holding&lt;br&gt;• Queued&lt;br&gt;• Preparing&lt;br&gt;• Processing&lt;br&gt;• Aborted&lt;br&gt;• Completed</td>
</tr>
</tbody>
</table>
### Field Name

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Details</th>
</tr>
</thead>
</table>
| TestRunResultID           | **Type**
                             | reference |
|                           | **Properties**
                             | Filter, Group, Nillable, Sort |
|                           | **Description**
                             | The ID of the associated ApexTestRunResult object. |

### Usage

Insert an ApexTestQueueItem object to place its corresponding Apex class in the Apex job queue for execution. The Apex job executes the test methods in the class.

To abort a class that is in the Apex job queue, perform an update operation on the ApexTestQueueItem object and set its Status field to Aborted.

If you insert multiple Apex test queue items in a single bulk operation, the queue items will share the same parent job. This means that a test run can consist of the execution of the tests of several classes if all the test queue items are inserted in the same bulk operation.

### ApexTestResult

Represents the result of an Apex test method execution. This object is available in API version 23.0 and later.

### Supported Calls

create(), delete(), describeSObjects(), query(), retrieve(), update()
<table>

</table>

### QueueItemId

- **Type**: reference
- **Properties**: Create, Filter, Group, Nillable, Sort, Update
- **Description**: Points to the `ApextestQueueItem` which is the class that this test method is part of.

### RunTime

- **Type**: int
- **Properties**: Create, Filter, Nillable, Sort, Update
- **Description**: The time it took the test method to run, in seconds.

### StackTrace

- **Type**: string
- **Properties**: Create, Filter, Nillable, Sort, Update
- **Description**: The Apex stack trace if the test failed; otherwise, null.

### TestTimestamp

- **Type**: dateTime
- **Properties**: Create, Filter, Sort, Update
- **Description**: The start time of the test method.

### Usage

You can query the fields of the `ApextestResult` record that corresponds to a test method executed as part of an Apex class execution.
Each test method execution is represented by a single ApexTestResult record. For example, if an Apex test class contains six test methods, six ApexTestResult records are created. These records are in addition to the ApexTestQueueItem record that represents the Apex class.

Each ApexTestResult record has an associated ApexTestResultLimits on page 3261 record, which captures the Apex limits used during execution of the test method.

**ApexTestResultLimits**

Captures the Apex test limits used for a particular test method execution. An instance of this object is associated with each ApexTestResult record. This object is available in API version 37.0 and later.

**Supported Calls**

create(), delete(), describeSObjects(), query(), retrieve(), update()

<td>Create, Filter, Group, Nillable, Sort, Update</td>
</tr>
<tr>
<td><strong>Description</strong></td>
<td>Indicates whether the test run was synchronous or asynchronous.</td>
</tr>
<tr>
<td><strong>LimitExceptions</strong></td>
<td><strong>Type</strong> string</td>
</tr>
<tr>
<td><strong>Properties</strong></td>
<td>Create, Filter, Group, Nillable, Sort, Update</td>
</tr>
<tr>
<td><strong>Description</strong></td>
<td>Indicates whether your org has any limits that differ from the default limits.</td>
</tr>
<tr>
<td><strong>MobilePush</strong></td>
<td><strong>Type</strong> int</td>
</tr>
</tbody>
</table>
Usage
The ApexTestResultLimits object is populated for each test method execution, and it captures the limits used between the Test.startTest() and Test.stopTest() methods. If startTest() and stopTest() aren't called, limits usage is not captured. Note the following:

- The associated test method must be run asynchronously.
- Limits for asynchronous Apex operations (batch, scheduled, future, and queueable) that are called within test methods are not captured.
- Limits are captured only for the default namespace.

ApexTestRunResult
Contains summary information about all the test methods that were run in a particular Apex job. This object is available in API version 37.0 and later.
## Supported Calls

create(), delete(), describeSObjects(), query(), retrieve(), update()

Field Name | Details
---|---
**Properties** | Create, Filter, Sort, Update
**Description** | The time at which the test run started.

**Status**

**Type** | picklist

**Properties** | Create, Filter, Group, Sort, Update

**Description** | The status of the test run. Values include:
- Queued
- Processing
- Aborted
- Completed
- Failed

**TestTime**

**Type** | int

**Properties** | Create, Filter, Group, Nillable, Sort, Update

**Description** | The time it took the test to run, in seconds.

**UserId**

**Type** | reference

**Properties** | Create, Filter, Group, Nillable, Sort, Update

**Description** | The user who ran the test run.

`compileAndTest()`

Compile and test your Apex in a single call.

**Syntax**

```java
CompileAndTestResult[] = compileAndTest(CompileAndTestRequest request);
```
Usage

Use this call to both compile and test the Apex you specify with a single call. Production organizations (not a Developer Edition or Sandbox Edition) must use this call instead of compileClasses() or compileTriggers().

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the SOAP API Developer Guide.

All specified tests must pass, otherwise data is not saved to the database. If this call is invoked in a production organization, the RunTestsRequest property of the CompileAndTestRequest is ignored, and all unit tests defined in the organization are run and must pass.

Sample Code—Java

Note that the following example sets checkOnly to true so that this class is compiled and tested, but the classes are not saved to the database.

```java
{
    CompileAndTestRequest request;
    CompileAndTestResult result = null;

    String triggerBody = "trigger t1 on Account (before insert){ " +
    " for(Account a:Trigger.new){ " +
    " a.description = 't1_UPDATE'; }" +
    "}"
    ;

    String testClassBody = "@isTest private class TestT1{ " +
    " // Test for the trigger" +
    " public static testmethod void test1(){ " +
    " Account a = new Account(name='TEST');" +
    " insert(a);" +
    " a = [select id,description from Account where id=:a.id];" +
    " System.assert(a.description.contains('t1_UPDATE'));" +
    " }" +
    " // Test for the class" +
    " public static testmethod void test2(){ " +
    " String s = Cl.method1();" +
    " System.assert(s=='HELLO');" +
    " }" +
    "}"
    ;

    String classBody = "public class Cl{ " +
    " public static String s =""HELLO"";" +
    " public static String method1(){ " +
    " return(s);" +
    " }" +
    "}
    ;

    request = new CompileAndTestRequest();

    request.setClasses(new String[]{classBody, testClassBody});
    request.setTriggers(new String[]{triggerBody});
    request.setCheckOnly(true);

    try {
```
```java
result = apexBinding.compileAndTest(request);
} catch (RemoteException e) {
    System.out.println("An unexpected error occurred: " + e.getMessage());
} assert (result.isSuccess());
```

## Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request</td>
<td>CompileAndTestRequest</td>
<td>A request that includes the Apex and the values for any fields that need to be set for this request.</td>
</tr>
</tbody>
</table>

## Response

CompileAndTestResult

### IN THIS SECTION:
- CompileAndTestRequest
- CompileAndTestResult

### CompileAndTestRequest

The `compileAndTest()` call contains this object, a request with information about the Apex to be compiled.

A CompileAndTestRequest object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checkOnly</td>
<td>boolean</td>
<td>If set to <code>true</code>, the Apex classes and triggers submitted are not saved to your organization, whether or not the code successfully compiles and unit tests pass.</td>
</tr>
<tr>
<td>classes</td>
<td>string</td>
<td>Content of the class or classes to be compiled.</td>
</tr>
<tr>
<td>deleteClasses</td>
<td>string</td>
<td>Name of the class or classes to be deleted.</td>
</tr>
<tr>
<td>deleteTriggers</td>
<td>string</td>
<td>Name of the trigger or triggers to be deleted.</td>
</tr>
<tr>
<td>runTestsRequest</td>
<td>RunTestsRequest</td>
<td>Specifies information about the Apex to be tested. If this request is sent in a production organization, this property is ignored and all unit tests are run for your entire organization.</td>
</tr>
<tr>
<td>triggers</td>
<td>string</td>
<td>Content of the trigger or triggers to be compiled.</td>
</tr>
</tbody>
</table>

Note the following about this object:

- This object contains the `RunTestsRequest` property. If the request is run in a production organization, the property is ignored and all tests are run.
• If any errors occur during compile, delete, testing, or if the goal of 75% code coverage is missed, no classes or triggers are saved to your organization. This is the same requirement as Salesforce AppExchange package testing.

• All triggers must have code coverage. If a trigger has no code coverage, no classes or triggers are saved to your organization.

**CompileAndTestResult**

The `compileAndTest()` call returns information about the compile and unit test run of the specified Apex, including whether it succeeded or failed.

A CompileAndTestResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classes</td>
<td>CompileClassResult</td>
<td>Information about the success or failure of the <code>compileAndTest()</code> call if classes were being compiled.</td>
</tr>
<tr>
<td>deleteClasses</td>
<td>DeleteApexResult</td>
<td>Information about the success or failure of the <code>compileAndTest()</code> call if classes were being deleted.</td>
</tr>
<tr>
<td>deleteTriggers</td>
<td>DeleteApexResult</td>
<td>Information about the success or failure of the <code>compileAndTest()</code> call if triggers were being deleted.</td>
</tr>
<tr>
<td>runTestsResult</td>
<td>RunTestsResult</td>
<td>Information about the success or failure of the Apex unit tests, if any were specified.</td>
</tr>
<tr>
<td>success</td>
<td>boolean*</td>
<td>If true, all of the classes, triggers, and unit tests specified ran successfully. If any class, trigger, or unit test failed, the value is false, and details are reported in the corresponding result object:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CompileClassResult</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CompileTriggerResult</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DeleteApexResult</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• RunTestsResult</td>
</tr>
<tr>
<td>triggers</td>
<td>CompileTriggerResult</td>
<td>Information about the success or failure of the <code>compileAndTest()</code> call if triggers were being compiled.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer Guide.

**CompileClassResult**

This object is returned as part of a `compileAndTest()` or `compileClasses()` call. It contains information about whether or not the compile and run of the specified Apex was successful.

A CompileClassResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bodyCrc</td>
<td>int*</td>
<td>The CRC (cyclic redundancy check) of the class or trigger file.</td>
</tr>
<tr>
<td>column</td>
<td>int*</td>
<td>The column number where an error occurred, if one did.</td>
</tr>
<tr>
<td>id</td>
<td>ID*</td>
<td>An ID is created for each compiled class. The ID is unique within an organization.</td>
</tr>
</tbody>
</table>
A CompileTriggerResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bodyCrc</td>
<td>int*</td>
<td>The CRC (cyclic redundancy check) of the trigger file.</td>
</tr>
<tr>
<td>column</td>
<td>int*</td>
<td>The column where an error occurred, if one did.</td>
</tr>
<tr>
<td>id</td>
<td>ID*</td>
<td>An ID is created for each compiled trigger. The ID is unique within an organization.</td>
</tr>
<tr>
<td>line</td>
<td>int*</td>
<td>The line number where an error occurred, if one did.</td>
</tr>
<tr>
<td>name</td>
<td>string*</td>
<td>The name of the trigger.</td>
</tr>
<tr>
<td>problem</td>
<td>string*</td>
<td>The description of the problem if an error occurred.</td>
</tr>
<tr>
<td>success</td>
<td>boolean*</td>
<td>If true, all the specified triggers compiled and ran successfully. If the compilation or execution of any trigger fails, the value is false.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer Guide.

A DeleteApexResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID*</td>
<td>ID of the deleted trigger or class. The ID is unique within an organization.</td>
</tr>
<tr>
<td>problem</td>
<td>string*</td>
<td>The description of the problem if an error occurred.</td>
</tr>
<tr>
<td>success</td>
<td>boolean*</td>
<td>If true, all the specified classes or triggers were deleted successfully. If any class or trigger is not deleted, the value is false.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer Guide.
**compileClasses()**

Compile your Apex in Developer Edition or sandbox organizations.

**Syntax**

```java
CompileClassResult[] = compileClasses(string[] classList);
```

**Usage**

Use this call to compile Apex classes in Developer Edition or sandbox organizations. Production organizations must use `compileAndTest()`.

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the SOAP API Developer Guide.

**Sample Code—Java**

```java
public void compileClassesSample() {
    String p1 = "public class p1 {
        + "public static Integer var1 = 0;\n"
        + "public static void methodA() {\n"
        + " var1 = 1;\n" + "}\n"
        + "public static void methodB() {\n"
        + " p2.MethodA();\n" + "}\n"
        + "} ;
    String p2 = "public class p2 {
        + "public static Integer var1 = 0;\n"
        + "public static void methodA() {\n"
        + " var1 = 1;\n" + "}\n"
        + "public static void methodB() {\n"
        + " p1.MethodA();\n" + "}\n"
        + "} ;
    CompileClassResult[] r = new CompileClassResult[0];
    try {
        r = apexBinding.compileClasses(new String[]{p1, p2});
    } catch (RemoteException e) {
        System.out.println("An unexpected error occurred: 
        + e.getMessage());
    }
    if (!r[0].isSuccess()) {
        System.out.println("Couldn't compile class p1 because: 
        + r[0].getProblem());
    }
    if (!r[1].isSuccess()) {
        System.out.println("Couldn't compile class p2 because: 
        + r[1].getProblem());
    }
}
```
Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scripts</td>
<td>string*</td>
<td>A request that includes the Apex classes and the values for any fields that need to be set for this request.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer Guide.

Response

CompileClassResult

**compileTriggers()**

Compile your Apex triggers in Developer Edition or sandbox organizations.

Syntax

```
CompileTriggerResult[] = compileTriggers(string[] triggerList);
```

Usage

Use this call to compile the specified Apex triggers in your Developer Edition or sandbox organization. Production organizations must use `compileAndTest()`.

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the SOAP API Developer Guide.

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scripts</td>
<td>string*</td>
<td>A request that includes the Apex trigger or triggers and the values for any fields that need to be set for this request.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer Guide.

Response

CompileTriggerResult

**executeanonymous()**

Executes a block of Apex.
Syntax

```java
ExecuteAnonymousResult[] = binding.executeanonymous(string apexcode);
```

Usage

Use this call to execute an anonymous block of Apex. This call can be executed from AJAX.

This call supports the API DebuggingHeader and SessionHeader.

If a component in a package with restricted API access issues this call, the request is blocked.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>apexcode</td>
<td>string*</td>
<td>A block of Apex.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer Guide.

**SOAP API Developer Guide** contains information about security, access, and SOAP headers.

Response

`ExecuteAnonymousResult[]`

IN THIS SECTION:

`ExecuteAnonymousResult`

**ExecuteAnonymousResult**

The `executeanonymous()` call returns information about whether or not the compile and run of the code was successful. An `ExecuteAnonymousResult` object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>int*</td>
<td>If compiled is False, this field contains the column number of the point where the compile failed.</td>
</tr>
<tr>
<td>compileProblem</td>
<td>string*</td>
<td>If compiled is False, this field contains a description of the problem that caused the compile to fail.</td>
</tr>
<tr>
<td>compiled</td>
<td>boolean*</td>
<td>If True, the code was successfully compiled. If False, the column, line, and compileProblem fields are not null.</td>
</tr>
<tr>
<td>exceptionMessage</td>
<td>string*</td>
<td>If success is False, this field contains the exception message for the failure.</td>
</tr>
<tr>
<td>exceptionStackTrace</td>
<td>string*</td>
<td>If success is False, this field contains the stack trace for the failure.</td>
</tr>
</tbody>
</table>
### runTests()

Run your Apex unit tests.

#### Syntax

```java
RunTestsResult[] = binding.runTests(RunTestsRequest request);
```

#### Usage

To facilitate the development of robust, error-free code, Apex supports the creation and execution of unit tests. Unit tests are class methods that verify whether a particular piece of code is working properly. Unit test methods take no arguments, commit no data to the database, and send no emails. Such methods are flagged with the `@isTest` annotation in the method definition. Unit test methods must be defined in test classes, that is, classes annotated with `@isTest`. Use this call to run your Apex unit tests.

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the [SOAP API Developer Guide](#).

#### Sample Code—Java

```java
public void runTestsSample() {
    String sessionId = "sessionID goes here";
    String url = "url goes here";
    // Set the Apex stub with session ID received from logging in with the partner API
    _SessionHeader sh = new _SessionHeader();
    apexBinding.setHeader(
        new ApexServiceLocator().getServiceName().getNamespaceURI(),
        "SessionHeader", sh);
    // Set the URL received from logging in with the partner API to the Apex stub
    apexBinding._setProperty(ApexBindingStub.ENDPOINT_ADDRESS_PROPERTY, url);

    // Set the debugging header
    _DebuggingHeader dh = new _DebuggingHeader();
    dh.setDebugLevel(LogType.Profiling);
    apexBinding.setHeader(
        new ApexServiceLocator().getServiceName().getNamespaceURI(),
        "DebuggingHeader", dh);

    long start = System.currentTimeMillis();
    RunTestsRequest rtr = new RunTestsRequest();
    rtr.setAllTests(true);
}```
RunTestsResult res = null;
try {
    res = apexBinding.runTests(rtr);
} catch (RemoteException e) {
    System.out.println("An unexpected error occurred: " + e.getMessage());
}

System.out.println("Number of tests: " + res.getNumTestsRun());
System.out.println("Number of failures: " + res.getNumFailures());
if (res.getNumFailures() > 0) {
    for (RunTestFailure rtf : res.getFailures()) {
        System.out.println("Failure: " + (rfp.getNamespace() == null ? "" : rfp.getNamespace() + ".")
            + rfp.getName() + ";" + rfp.getMethodName() + ": "
            + rfp.getMessage() + 
"\n" + rfp.getStackTrace());
    }
}
if (res.getCodeCoverage() != null) {
    for (CodeCoverageResult ccr : res.getCodeCoverage()) {
        System.out.println("Code coverage for " + ccr.getType() +
            (ccr.getNamespace() == null ? "" : ccr.getNamespace() + ".")
            + ccr.getName() + ": "
            + ccr.getNumLocationsNotCovered()
            + " locations not covered out of "
            + ccr.getNumLocations());

        if (ccr.getNumLocationsNotCovered() > 0) {
            for (CodeLocation cl : ccr.getLocationsNotCovered())
                System.out.println("\tLine " + cl.getLine());
        }
    }
}
System.out.println("Finished in " + 
    (System.currentTimeMillis() - start) + "ms");

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request</td>
<td>RunTestsRequest</td>
<td>A request that includes the Apex unit tests and the values for any fields that need to be set for this request.</td>
</tr>
</tbody>
</table>

Response

RunTestsResult

IN THIS SECTION:

- RunTestsRequest
- RunTestsResult
RunTestsRequest

Specifies information about the Apex code to be tested. RunTestsRequest is part of CompileAndTestRequest, which is the request passed to the compileAndTest() call. This object is also passed to the Tooling SOAP API call runTests(). You can specify the same or different classes to be tested and compiled. Since triggers cannot be tested directly, they are not included in this object. Instead, you must specify a class that calls the trigger.

If the request is sent to a production organization, this request is ignored and all unit tests defined for your organization are run.

The RunTestsRequest object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>allTests</td>
<td>boolean*</td>
<td>If allTests is true, all unit tests defined for your organization are run.</td>
</tr>
<tr>
<td>classes</td>
<td>string*[]</td>
<td>An array of one or more objects.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>If specified, the namespace that contains the unit tests to be run. Do not use this property if you specify allTests as true. Also, if you execute compileAndTest() in a production organization, this property is ignored, and all unit tests defined for the organization are run.</td>
</tr>
<tr>
<td>maxFailedTests</td>
<td>int</td>
<td>A mandatory parameter for the Tooling SOAP API call runTests(). To allow all tests in a run to execute, set maxFailedTests to -1. To stop the test run from executing new tests after a given number of tests fail, set maxFailedTests to an integer value from 0 to 1,000,000. This integer value sets the maximum allowable test failures. A value of 0 causes the test run to stop if any failure occurs. A value of 1 causes the test run to stop on the second failure, and so on.</td>
</tr>
<tr>
<td>packages</td>
<td>string*[]</td>
<td>Do not use after version 10.0. For earlier, unsupported releases, the content of the package to be tested.</td>
</tr>
<tr>
<td>skipCodeCoverage</td>
<td>boolean</td>
<td>Indicates whether to opt out of collecting code coverage information during Apex test runs. Available in API version 43.0 and later.</td>
</tr>
<tr>
<td>tests</td>
<td>TestsNode[]</td>
<td>A mandatory parameter for the Tooling SOAP API call runTests(). Specifies individual test methods in an Apex test class. To specify classes or suites instead of a TestsNode[], set tests to null. Although this property accepts an array, the array can contain only one entry.</td>
</tr>
</tbody>
</table>

TestsNode

Specifies individual test methods in an Apex test class.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classId</td>
<td>string</td>
<td>The ID of the Apex class that contains the test methods you want to run.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>classId or className is required.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Supported Methods</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• getClassId()</td>
</tr>
</tbody>
</table>
### RunTestsResult

Contains information about the execution of unit tests, including whether unit tests were completed successfully, code coverage results, and failures.

A RunTestsResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>apexLogId</td>
<td>string</td>
<td>The ID of an ApexLog object that is created at the end of a test run. The ApexLog object is created if there is an active trace flag on the user running an Apex test, or on a class or trigger being executed. This field is available in API version 35.0 and later.</td>
</tr>
<tr>
<td>codeCoverage</td>
<td>CodeCoverageResult[]</td>
<td>An array of one or more CodeCoverageResult objects that contains the details of the code coverage for the specified unit tests.</td>
</tr>
<tr>
<td>codeCoverageWarnings</td>
<td>CodeCoverageWarning[]</td>
<td>An array of one or more code coverage warnings for the test run. The results include both the total number of lines that could have been executed, as well as the number, line, and column positions of code that was not executed.</td>
</tr>
</tbody>
</table>
An array of one or more `RunTestFailure` objects that contain information about the unit test failures, if there are any.

An array of results from test runs that executed flows. This field is available in API version 44.0 and later.

An array of warnings generated by test runs that executed flows. This field is available in API version 44.0 and later.

The number of failures for the unit tests.

The number of unit tests that were run.

An array of one or more `RunTestSuccess` objects that contain information about successes, if there are any.

The total cumulative time spent running tests, in milliseconds. This can be helpful for performance monitoring.

---

**CodeCoverageResult**

The `RunTestsResult` object contains this object. It contains information about whether or not the compile of the specified Apex and run of the unit tests was successful.

A `CodeCoverageResult` object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dmlInfo</td>
<td><code>CodeLocation[]</code></td>
<td>For each class or trigger tested, for each portion of code tested, this property contains the DML statement locations, the number of times the code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.</td>
</tr>
<tr>
<td>id</td>
<td>ID</td>
<td>The ID of the <code>CodeLocation</code>. The ID is unique within an organization.</td>
</tr>
<tr>
<td>locationsNotCovered</td>
<td><code>CodeLocation[]</code></td>
<td>For each class or trigger tested, if any code is not covered, the line and column of the code not tested, and the number of times the code was executed.</td>
</tr>
<tr>
<td>methodInfo</td>
<td><code>CodeLocation[]</code></td>
<td>For each class or trigger tested, the method invocation locations, the number of times the code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name of the class or trigger covered.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The namespace that contained the unit tests, if one is specified. Adamit, this can be helpful for performance monitoring.</td>

</tbody>
</table>
The total number of code locations.

For each class or trigger tested, the location of SOQL statements in the code, the number of times this code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.

For each class tested, the location of SOSL statements in the code, the number of times this code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.

Do not use. In early, unsupported releases, used to specify class or package.

**CodeCoverageWarning**

The `RunTestsResult` object contains this object. It contains information about the Apex class which generated warnings.

This object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID</td>
<td>The ID of the class which generated warnings.</td>
</tr>
<tr>
<td>message</td>
<td>string</td>
<td>The message of the warning generated.</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name of the class that generated a warning.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The namespace that contains the class, if one was specified.</td>
</tr>
</tbody>
</table>

**RunTestFailure**

The `RunTestsResult` object returns information about failures during the unit test run.

This object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID</td>
<td>The ID of the class which generated failures.</td>
</tr>
<tr>
<td>message</td>
<td>string</td>
<td>The failure message.</td>
</tr>
<tr>
<td>methodName</td>
<td>string</td>
<td>The name of the method that failed.</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name of the class that failed.</td>
</tr>
</tbody>
</table>
### Namespace

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>namespace</td>
<td>string</td>
<td>The namespace that contained the class, if one was specified.</td>
</tr>
</tbody>
</table>

### SeeAllData

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seeAllData</td>
<td>boolean</td>
<td>Indicates whether the test method has access to organization data (true) or not (false). This field is available in API version 33.0 and later.</td>
</tr>
</tbody>
</table>

### StackTrace

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stackTrace</td>
<td>string</td>
<td>The stack trace for the failure.</td>
</tr>
</tbody>
</table>

### Time

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>double</td>
<td>The time spent running tests for this failed operation, in milliseconds. This can be helpful for performance monitoring.</td>
</tr>
</tbody>
</table>

### Type

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Do not use. In early, unsupported releases, used to specify class or package.</td>
</tr>
</tbody>
</table>

### FlowCoverageResult

This object contains information about the flow version and the number of elements executed by the test run. This object is available in API version 44.0 and later.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>elementsNotCovered</td>
<td>string</td>
<td>List of elements in the flow version that weren’t executed by the test run.</td>
</tr>
<tr>
<td>flowId</td>
<td>string</td>
<td>The ID of the flow version. The ID is unique within an org.</td>
</tr>
<tr>
<td>flowName</td>
<td>string</td>
<td>The name of the flow that was executed by the test run.</td>
</tr>
<tr>
<td>flowNamespace</td>
<td>string</td>
<td>The namespace that contains the flow, if one is specified.</td>
</tr>
<tr>
<td>numElements</td>
<td>int</td>
<td>The total number of elements in the flow version.</td>
</tr>
<tr>
<td>numElementsNotCovered</td>
<td>int</td>
<td>The number of elements in the flow version that weren’t executed by the test run</td>
</tr>
<tr>
<td>processType</td>
<td>FlowProcessType (enumeration of type string)</td>
<td>The process type of the flow version.</td>
</tr>
</tbody>
</table>

### FlowCoverageWarning

This object contains information about the flow version that generated warnings. This object is available in API version 44.0 and later.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flowId</td>
<td>string</td>
<td>The ID of the flow version that generated the warning.</td>
</tr>
<tr>
<td>flowName</td>
<td>string</td>
<td>The name of the flow that generated the warning. If the warning applies to the overall test coverage of flows within your org, this value is null.</td>
</tr>
<tr>
<td>flowNamespace</td>
<td>string</td>
<td>The namespace that contains the flow, if one was specified.</td>
</tr>
</tbody>
</table>
The message of the warning that was generated.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>string</td>
<td>The message of the warning that was generated.</td>
</tr>
</tbody>
</table>

**RunTestSuccess**

The `RunTestsResult` object returns information about successes during the unit test run.

This object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID</td>
<td>The ID of the class which generated the success.</td>
</tr>
<tr>
<td>methodName</td>
<td>string</td>
<td>The name of the method that succeeded.</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name of the class that succeeded.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The namespace that contained the class, if one was specified.</td>
</tr>
<tr>
<td>seeAllData</td>
<td>boolean</td>
<td>Indicates whether the test method has access to organization data (true) or not (false). This field is available in API version 33.0 and later.</td>
</tr>
<tr>
<td>time</td>
<td>double</td>
<td>The time spent running tests for this operation. This can be helpful for performance monitoring.</td>
</tr>
</tbody>
</table>

**CodeLocation**

The `RunTestsResult` object contains this object in a number of fields.

This object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>int</td>
<td>The column location of the Apex tested.</td>
</tr>
<tr>
<td>line</td>
<td>int</td>
<td>The line location of the Apex tested.</td>
</tr>
<tr>
<td>numExecutions</td>
<td>int</td>
<td>The number of times the Apex was executed in the test run.</td>
</tr>
<tr>
<td>time</td>
<td>double</td>
<td>The total cumulative time spent at this location. This can be helpful for performance monitoring.</td>
</tr>
</tbody>
</table>
DebuggingHeader

Return the debug log in the output header, DebuggingInfo, and specify the level of detail in the debug log.

API Calls

`compileAndTest()`, `executeanonymous()`, `runTests()`

Fields

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>categories</td>
<td>LogInfo[]</td>
<td>Specifies the type and amount of information to be returned in the debug log.</td>
</tr>
</tbody>
</table>
| debugLevel   | DebugLevel (enumeration of type string) | Deprecated. This field is provided only for backward compatibility. If you provide values for both debugLevel and categories, the categories value is used. The debugLevel field specifies the type of information returned in the debug log. The values are listed from the least amount of information returned to the most information returned. Valid values include:  
  - None  
  - Debugonly  
  - Db  
  - Profiling  
  - Callout  
  - Detail |

LogInfo

Specifies the type and amount of information to be returned in the debug log. The categories field takes a list of these objects. LogInfo is a mapping of category to level.

Fields

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| category     | LogCategory | Specify the type of information returned in the debug log. Valid values are:  
  - Db  
  - Workflow  
  - Validation  
  - Callout  
  - Apex_code  
  - Apex_profiling  
  - Visualforce  
  - System |
### PackageVersion

Specifies a version of an installed managed package. A package version is \texttt{majorNumber.minorNumber}, for example 2.1.

**Fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>majorNumber</td>
<td>int</td>
<td>The major version number of a package version.</td>
</tr>
<tr>
<td>minorNumber</td>
<td>int</td>
<td>The minor version number of a package version.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The unique namespace of the managed package.</td>
</tr>
</tbody>
</table>

### PackageVersionHeader

Specifies the package version for each installed managed package.

A managed package can have several versions with different content and behavior. This header allows you to specify the version used for each package referenced by your API client.

If a package version is not specified, the API client uses the version of the package specified in Setup (enter API in the Quick Find box, then select API).

**API Calls**

\texttt{compileAndTest()}, \texttt{compileClasses()}, \texttt{compileTriggers()}, \texttt{executeAnonymous()}

**Fields**

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>packageVersions</td>
<td>PackageVersion[]</td>
<td>A list of package versions for installed managed packages referenced by your API client.</td>
</tr>
</tbody>
</table>
Shipping Invoice Example

This appendix provides an example of an Apex application. This is a more complex example than the Hello World example.

- Shipping Invoice Walk-Through
- Shipping Invoice Example Code

IN THIS SECTION:
1. Shipping Invoice Example Walk-Through
2. Shipping Invoice Example Code

Shipping Invoice Example Walk-Through

The sample application in this section includes traditional Salesforce functionality blended with Apex. Many of the syntactic and semantic features of Apex, along with common idioms, are illustrated in this application.

Note: The Shipping Invoice sample requires custom objects. You can either create these on your own, or download the objects and Apex code as an unmanaged package from the Salesforce AppExchange. To obtain the sample assets in your org, install the Apex Tutorials Package. This package also contains sample code and objects for the Apex Quick Start.

Scenario

In this sample application, the user creates a new shipping invoice, or order, and then adds items to the invoice. The total amount for the order, including shipping cost, is automatically calculated and updated based on the items added or deleted from the invoice.

Data and Code Models

This sample application uses two new objects: Item and Shipping_invoice.

The following assumptions are made:

- Item A cannot be in both orders shipping_invoice1 and shipping_invoice2. Two customers cannot obtain the same (physical) product.
- The tax rate is 9.25%.
- The shipping rate is 75 cents per pound.
- Once an order is over $100, the shipping discount is applied (shipping becomes free).

The fields in the Item custom object include:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>String</td>
<td>The name of the item</td>
</tr>
<tr>
<td>Price</td>
<td>Currency</td>
<td>The price of the item</td>
</tr>
<tr>
<td>Quantity</td>
<td>Number</td>
<td>The number of items in the order</td>
</tr>
<tr>
<td>Weight</td>
<td>Number</td>
<td>The weight of the item, used to calculate shipping costs</td>
</tr>
<tr>
<td>Shipping_invoice</td>
<td>Master-Detail (shipping_invoice)</td>
<td>The order this item is associated with</td>
</tr>
</tbody>
</table>
The fields in the Shipping_invoice custom object include:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>String</td>
<td>The name of the shipping invoice/order</td>
</tr>
<tr>
<td>Subtotal</td>
<td>Currency</td>
<td>The subtotal</td>
</tr>
<tr>
<td>GrandTotal</td>
<td>Currency</td>
<td>The total amount, including tax and shipping</td>
</tr>
<tr>
<td>Shipping</td>
<td>Currency</td>
<td>The amount charged for shipping (assumes $0.75 per pound)</td>
</tr>
<tr>
<td>ShippingDiscount</td>
<td>Currency</td>
<td>Only applied once when subtotal amount reaches $100</td>
</tr>
<tr>
<td>Tax</td>
<td>Currency</td>
<td>The amount of tax (assumes 9.25%)</td>
</tr>
<tr>
<td>TotalWeight</td>
<td>Number</td>
<td>The total weight of all items</td>
</tr>
</tbody>
</table>

All of the Apex for this application is contained in triggers. This application has the following triggers:

<table>
<thead>
<tr>
<th>Object</th>
<th>Trigger Name</th>
<th>When Runs</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Item</td>
<td>Calculate</td>
<td>after insert, after update, after delete</td>
<td>Updates the shipping invoice, calculates the totals and shipping</td>
</tr>
<tr>
<td>Shipping_invoice</td>
<td>ShippingDiscount</td>
<td>after update</td>
<td>Updates the shipping invoice, calculating if there is a shipping discount</td>
</tr>
</tbody>
</table>

The following is the general flow of user actions and when triggers run:
Flow of user action and triggers for the shopping cart application

1. User clicks Orders > New, names the shipping invoice and clicks Save.
2. User clicks New Item, fills out information, and clicks Save.
3. Calculate trigger runs. Part of the Calculate trigger updates the shipping invoice.
4. ShippingDiscount trigger runs.
5. User can then add, delete or change items in the invoice.

In Shipping Invoice Example Code both of the triggers and the test class are listed. The comments in the code explain the functionality.

Testing the Shipping Invoice Application

Before an application can be included as part of a package, 75% of the code must be covered by unit tests. Therefore, one piece of the shipping invoice application is a class used for testing the triggers.

The test class verifies the following actions are completed successfully:

- Inserting items
- Updating items
- Deleting items
- Applying shipping discount
- Negative test for bad input

Shipping Invoice Example Code

The following triggers and test class make up the shipping invoice example application:
Calculate Trigger

```apex
trigger calculate on Item__c (after insert, after update, after delete) {

    // Use a map because it doesn't allow duplicate values
    Map<ID, Shipping_Invoice__C> updateMap = new Map<ID, Shipping_Invoice__C>();

    // Set this integer to -1 if we are deleting
    Integer subtract = 0;

    // Populate the list of items based on trigger type
    List<Item__c> itemList;
    if(trigger.isInsert || trigger.isUpdate) {
        itemList = Trigger.new;
        subtract = 1;
    } else if(trigger.isDelete) {
        // Note -- there is no trigger.new in delete
        itemList = trigger.old;
        subtract = -1;
    }

    // Access all the information we need in a single query
    // rather than querying when we need it.
    // This is a best practice for bulkifying requests

    set<Id> AllItems = new set<id>();
    for(item__c i : itemList) {
        // Assert numbers are not negative.
        // None of the fields would make sense with a negative value
        System.assert(i.quantity__c > 0, 'Quantity must be positive');
        System.assert(i.weight__c >= 0, 'Weight must be non-negative');
        System.assert(i.price__c >= 0, 'Price must be non-negative');

        // If there is a duplicate Id, it won't get added to a set
        AllItems.add(i.Shipping_Invoice__C);
    }

    // Accessing all shipping invoices associated with the items in the trigger
    List<Shipping_Invoice__C> AllShippingInvoices = [SELECT Id, ShippingDiscount__c, SubTotal__c, TotalWeight__c, Tax__c, GrandTotal__c FROM Shipping_Invoice__C WHERE Id IN :AllItems];

    // Take the list we just populated and put it into a Map.
    // This will make it easier to look up a shipping invoice
```
Map<ID, Shipping_Invoice__C> SIMap = new Map<ID, Shipping_Invoice__C>();

for(Shipping_Invoice__C sc : AllShippingInvoices)
{
    SIMap.put(sc.id, sc);
}

// Process the list of items
if(Trigger.isUpdate)
{
    // Treat updates like a removal of the old item and addition of the
    // revised item rather than figuring out the differences of each field
    // and acting accordingly.
    // Note updates have both trigger.new and trigger.old
    for(Integer x = 0; x < Trigger.old.size(); x++)
    {
        Shipping_Invoice__C myOrder;
        myOrder = SIMap.get(Trigger.old[x].Shipping_Invoice__C);

        // Decrement the previous value from the subtotal and weight.
        myOrder.SubTotal__c -= (trigger.old[x].price__c *
                                 trigger.old[x].quantity__c);
        myOrder.TotalWeight__c -= (trigger.old[x].weight__c *
                                   trigger.old[x].quantity__c);

        // Increment the new subtotal and weight.
        myOrder.SubTotal__c += (trigger.new[x].price__c *
                                 trigger.new[x].quantity__c);
        myOrder.TotalWeight__c += (trigger.new[x].weight__c *
                                   trigger.new[x].quantity__c);
    }

    for(Shipping_Invoice__C myOrder : AllShippingInvoices)
    {
        // Set tax rate to 9.25% Please note, this is a simple example.
        // Generally, you would never hard code values.
        // Leveraging Custom Settings for tax rates is a best practice.
        // See Custom Settings in the Apex Developer Guide
        // for more information.
        myOrder.Tax__c = myOrder.Subtotal__c * .0925;

        // Reset the shipping discount
        myOrder.ShippingDiscount__c = 0;

        // Set shipping rate to 75 cents per pound.
        // Generally, you would never hard code values.
        // Leveraging Custom Settings for the shipping rate is a best practice.
        // See Custom Settings in the Apex Developer Guide
        // for more information.
        myOrder.Shipping__c = (myOrder.totalWeight__c * .75);
        myOrder.GrandTotal__c = myOrder.SubTotal__c + myOrder.tax__c +
                              myOrder.Shipping__c;
updateMap.put(myOrder.id, myOrder);
}

else
{
    for(Item__c itemToProcess : itemList)
    {
        Shipping_Invoice__C myOrder;
        // Look up the correct shipping invoice from the ones we got earlier
        myOrder = SIMap.get(itemToProcess.Shipping_Invoice__C);
        myOrder.SubTotal__c += (itemToProcess.price__c *
            itemToProcess.quantity__c * subtract);
        myOrder.TotalWeight__c += (itemToProcess.weight__c *
            itemToProcess.quantity__c * subtract);
    }

    for(Shipping_Invoice__C myOrder : AllShippingInvoices)
    {
        // Set tax rate to 9.25% Please note, this is a simple example.
        // Generally, you would never hard code values.
        // Leveraging Custom Settings for tax rates is a best practice.
        // See Custom Settings in the Apex Developer Guide
        // for more information.
        myOrder.Tax__c = myOrder.Subtotal__c * .0925;

        // Reset shipping discount
        myOrder.ShippingDiscount__c = 0;

        // Set shipping rate to 75 cents per pound.
        // Generally, you would never hard code values.
        // Leveraging Custom Settings for the shipping rate is a best practice.
        // See Custom Settings in the Apex Developer Guide
        // for more information.
        myOrder.Shipping__c = (myOrder.totalWeight__c * .75);
        myOrder.GrandTotal__c = myOrder.SubTotal__c + myOrder.tax__c +
            myOrder.Shipping__c;

        updateMap.put(myOrder.id, myOrder);
    }
}

// Only use one DML update at the end.
// This minimizes the number of DML requests generated from this trigger.
update updateMap.values();

ShippingDiscount Trigger

trigger ShippingDiscount on Shipping_Invoice__C (before update) {
    // Free shipping on all orders greater than $100

for(Shipping_Invoice__C myShippingInvoice : Trigger.new)
{
  if((myShippingInvoice.subtotal__c >= 100.00) &&
      (myShippingInvoice.ShippingDiscount__c == 0))
  {
    myShippingInvoice.ShippingDiscount__c =
        myShippingInvoice.Shipping__c * -1;
    myShippingInvoice.GrandTotal__c += myShippingInvoice.ShippingDiscount__c;
  }
}

Shipping Invoice Test

@IsTest
private class TestShippingInvoice{

  // Test for inserting three items at once
  public static testmethod void testBulkItemInsert(){
    // Create the shipping invoice. It's a best practice to either use defaults
    // or to explicitly set all values to zero so as to avoid having
    // extraneous data in your test.
    Shipping_Invoice__C order1 = new Shipping_Invoice__C(subtotal__c = 0,
                                                          totalweight__c = 0,
                                                          grandtotal__c = 0,
                                                          ShippingDiscount__c = 0,
                                                          Shipping__c = 0,
                                                          tax__c = 0);

**Action Links Labels**

Use these labels for action link buttons.

An action link is a button on a feed element. Clicking an action link can take a user to a Web page, initiate a file download, or invoke an API call to Salesforce or to an external server. An action link includes a URL and an HTTP method, and can include a request body and header information, such as an OAuth token for authentication. Use action links to integrate Salesforce and third-party services into the feed so that users can take action to drive productivity and accelerate innovation.

Specify the key in the `labelKey` property of the Action Link Definition Input request body. When the action link is rendered, the UI uses labels for the “New,” “Pending,” “Success,” and “Failed” states as needed.

**Tip:** If none of the predefined labels work for your action link, use a custom label. To use a custom label, create an action link template and define the label in the template. See Action Link Templates.

API End-of-Life

Salesforce is committed to supporting each API version for a minimum of three years from the date of first release. In order to mature and improve the quality and performance of the API, versions that are more than three years old might cease to be supported. When an API version is to be deprecated, advance notice is given at least one year before support ends. Salesforce will directly notify customers using API versions planned for deprecation.

Documentation Typographical Conventions

Apex and Visualforce documentation uses the following typographical conventions.

<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Courier font</td>
<td>In descriptions of syntax, monospace font indicates items that you should type as shown, except for brackets. For example:</td>
</tr>
<tr>
<td></td>
<td>Public class HelloWorld</td>
</tr>
<tr>
<td>Convention</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><em>Italics</em></td>
<td>In descriptions of syntax, italics represent variables. You supply the actual value. In the following example, three values need to be supplied: data type variable name = value; If the syntax is bold and italic, the text represents a code element that needs a value supplied by you, such as a class name or variable value:</td>
</tr>
<tr>
<td></td>
<td>public static class YourClassHere { ... }</td>
</tr>
<tr>
<td><strong>Bold Courier font</strong></td>
<td>In code samples and syntax descriptions, bold courier font emphasizes a portion of the code or syntax.</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>In descriptions of syntax, less-than and greater-than symbols (&lt; &gt;) are typed exactly as shown.</td>
</tr>
<tr>
<td></td>
<td>&lt;apex:pageBlockTable value=&quot;([{account.Contacts}]&quot; var=&quot;contact&quot;&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;apex:column value=&quot;([{contact.Name}]&quot;/&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;apex:column value=&quot;([{contact.MailingCity}]&quot;/&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;apex:column value=&quot;([{contact.Phone}]&quot;/&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;/apex:pageBlockTable&gt;</td>
</tr>
<tr>
<td>{}</td>
<td>In descriptions of syntax, braces ({{}}) are typed exactly as shown.</td>
</tr>
<tr>
<td></td>
<td><a href="">apex:page</a></td>
</tr>
<tr>
<td></td>
<td>Hello {{User.FirstName}}!</td>
</tr>
<tr>
<td></td>
<td>&lt;/apex:page&gt;</td>
</tr>
<tr>
<td>[]</td>
<td>In descriptions of syntax, anything included in brackets is optional. In the following example, specifying value is optional:</td>
</tr>
<tr>
<td></td>
<td>data type variable name = value;</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Set&lt; data type &gt; set name</td>
</tr>
<tr>
<td></td>
<td>[= new Set&lt;data type&gt;{}];</td>
</tr>
<tr>
<td></td>
<td>[= new Set&lt;data type&gt;[value [, value2. . . ] };</td>
</tr>
<tr>
<td></td>
<td>;</td>
</tr>
</tbody>
</table>

3303
Administrator (System Administrator)
One or more individuals in your organization who can configure and customize the application. Users assigned to the System Administrator profile have administrator privileges.

AJAX Toolkit
A JavaScript wrapper around the API that allows you to execute any API call and access any object you have permission to view from within JavaScript code. For more information, see the AJAX Toolkit Developer’s Guide.

Anti-Join
An anti-join is a subquery on another object in a NOT IN clause in a SOQL query. You can use anti-joins to create advanced queries. See also Semi-Join.

Anonymous Block, Apex
Apex code that does not get stored in Salesforce, but that can be compiled and executed by using the ExecuteAnonymousResult() API call, or the equivalent in the AJAX Toolkit.

Ant Migration Tool
A toolkit that allows you to write an Apache Ant build script for migrating Lightning Platform components between a local file system and a Salesforce organization.

Apex
Apex is a strongly typed, object-oriented programming language that allows developers to execute flow and transaction control statements on the Lightning platform server in conjunction with calls to the Lightning Platform API. Using syntax that looks like Java and acts like database stored procedures, Apex enables developers to add business logic to most system events, including button clicks, related record updates, and Visualforce pages. Apex code can be initiated by Web service requests and from triggers on objects.

Apex Connector Framework
The Apex Connector Framework is a set of classes and methods in the DataSource namespace for creating a custom adapter for Salesforce Connect. Create a custom adapter to connect to data that’s stored outside your Salesforce org when the other available Salesforce Connect adapters aren’t suitable for your needs.

Apex-Managed Sharing
Enables developers to programmatically manipulate sharing to support their application’s behavior. Apex-managed sharing is only available for custom objects.

Apex Page
See Visualforce page.

App
Short for “application.” A collection of components such as tabs, reports, dashboards, and Visualforce pages that address a specific business need. Salesforce provides standard apps such as Sales and Service. You can customize the standard apps to match the way you work. In addition, you can package an app and upload it to the AppExchange along with related components such as custom fields, custom tabs, and custom objects. Then, you can make the app available to other Salesforce users from the AppExchange.

AppExchange
The AppExchange is a sharing interface from Salesforce that allows you to browse and share apps and services for the Lightning Platform.

Application Programming Interface (API)
The interface that a computer system, library, or application provides to allow other computer programs to request services from it and exchange data.

Approval Process
An approval process automates how records are approved in Salesforce. An approval process specifies each step of approval, including who to request approval from and what to do at each point of the process.
**Asynchronous Calls**
A call that doesn't return results immediately because the operation can take a long time. Calls in the Metadata API and Bulk API are asynchronous.

**Batch Apex**
The ability to perform long, complex operations on many records at a scheduled time using Apex.

**Beta, Managed Package**
In the context of managed packages, a beta managed package is an early version of a managed package distributed to a sampling of your intended audience to test it.

**Bulk API**
The REST-based Bulk API is optimized for processing large sets of data. It allows you to query, insert, update, upsert, or delete a large number of records asynchronously by submitting a number of batches which are processed in the background by Salesforce. See also SOAP API.

**Callout, Apex**
An Apex callout enables you to tightly integrate your Apex with an external service by making a call to an external Web service or sending a HTTP request from Apex code and then receiving the response.

**Child Relationship**
A relationship that has been defined on an sObject that references another sObject as the “one” side of a one-to-many relationship. For example, contacts, opportunities, and tasks have child relationships with accounts.

See also sObject.

**Class, Apex**
A template or blueprint from which Apex objects are created. Classes consist of other classes, user-defined methods, variables, exception types, and static initialization code. In most cases, Apex classes are modeled on their counterparts in Java.

**Client App**
An app that runs outside the Salesforce user interface and uses only the Lightning Platform API or Bulk API. It typically runs on a desktop or mobile device. These apps treat the platform as a data source, using the development model of whatever tool and platform for which they are designed.

**Code Coverage**
A way to identify which lines of code are exercised by a set of unit tests, and which are not. This helps you identify sections of code that are completely untested and therefore at greatest risk of containing a bug or introducing a regression in the future.

**Component, Metadata**
A component is an instance of a metadata type in the Metadata API. For example, CustomObject is a metadata type for custom objects, and the `MyCustomObject__c` component is an instance of a custom object. A component is described in an XML file and it can be deployed or retrieved using the Metadata API, or tools built on top of it, such as the Salesforce extensions for Visual Studio Code or the Ant Migration Tool.

**Component, Visualforce**
Something that can be added to a Visualforce page with a set of tags, for example, `<apex:detail>`. Visualforce includes a number of standard components, or you can create your own custom components.
Component Reference, Visualforce
A description of the standard and custom Visualforce components that are available in your organization. You can access the component library from the development footer of any Visualforce page or the Visualforce Developer’s Guide.

Composite App
An app that combines native platform functionality with one or more external Web services, such as Yahoo! Maps. Composite apps allow for more flexibility and integration with other services, but may require running and managing external code. See also Client App and Native App.

Controller, Visualforce
An Apex class that provides a Visualforce page with the data and business logic it needs to run. Visualforce pages can use the standard controllers that come by default with every standard or custom object, or they can use custom controllers.

Controller Extension
A controller extension is an Apex class that extends the functionality of a standard or custom controller.

Cookie
Client-specific data used by some Web applications to store user and session-specific information. Salesforce issues a session “cookie” only to record encrypted authentication information for the duration of a specific session.

Custom App
See App.

Custom Controller
A custom controller is an Apex class that implements all of the logic for a page without leveraging a standard controller. Use custom controllers when you want your Visualforce page to run entirely in system mode, which does not enforce the permissions and field-level security of the current user.

Custom Field
A field that can be added in addition to the standard fields to customize Salesforce for your organization’s needs.

Custom Links
Custom links are URLs defined by administrators to integrate your Salesforce data with external websites and back-office systems. Formerly known as Web links.

Custom Object
Custom records that allow you to store information unique to your organization.

Custom Settings
Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data can then be used by formula fields, validation rules, flows, Apex, and the SOAP API.
See also Hierarchy Custom Settings and List Custom Settings.

D

Database
An organized collection of information. The underlying architecture of the Lightning Platform includes a database where your data is stored.

Database Table
A list of information, presented with rows and columns, about the person, thing, or concept you want to track. See also Object.

Data Loader
A Lightning Platform tool used to import and export data from your Salesforce organization.
**Data Manipulation Language (DML)**
An Apex method or operation that inserts, updates, or deletes records.

**Data State**
The structure of data in an object at a particular point in time.

**Date Literal**
A keyword in a SOQL or SOSL query that represents a relative range of time such as *last month* or *next year*.

**Decimal Places**
Parameter for number, currency, and percent custom fields that indicates the total number of digits you can enter to the right of a decimal point, for example, 4.98 for an entry of 2. Note that the system rounds the decimal numbers you enter, if necessary. For example, if you enter 4.986 in a field with *Decimal Places* of 2, the number rounds to 4.99. Salesforce uses the round half-up rounding algorithm. Half-way values are always rounded up. For example, 1.45 is rounded to 1.5. –1.45 is rounded to –1.5.

**Dependency**
A relationship where one object’s existence depends on that of another. There are a number of different kinds of dependencies including mandatory fields, dependent objects (parent-child), file inclusion (referenced images, for example), and ordering dependencies (when one object must be deployed before another object).

**Dependent Field**
Any custom picklist or multi-select picklist field that displays available values based on the value selected in its corresponding controlling field.

**Deploy**
To move functionality from an inactive state to active. For example, when developing new features in the Salesforce user interface, you must select the “Deployed” option to make the functionality visible to other users.

The process by which an application or other functionality is moved from development to production.

To move metadata components from a local file system to a Salesforce organization.

For installed apps, deployment makes any custom objects in the app available to users in your organization. Before a custom object is deployed, it is only available to administrators and any users with the “Customize Application” permission.

**Deprecated Component**
Developers can refine the functionality in a managed package over time as the requirements evolve, such as redesign some of the components in the managed package. Developers can’t delete some components in a Managed - Released package, but they can deprecate a component in a later package version so that new subscribers don’t receive the component, while the component continues to function for existing subscribers and API integrations.

**Detail**
A page that displays information about a single object record. The detail page of a record allows you to view the information, whereas the edit page allows you to modify it.

A term used in reports to distinguish between summary information and inclusion of all column data for all information in a report. You can toggle the *Show Details/Hide Details* button to view and hide report detail information.

**Developer Edition**
A free, fully-functional Salesforce organization designed for developers to extend, integrate, and develop with the Lightning Platform. Developer Edition accounts are available on developer.salesforce.com.

**Salesforce Developers**
The Salesforce Developers website at developer.salesforce.com provides a full range of resources for platform developers, including sample code, toolkits, an online developer community, and the ability to obtain limited Lightning Platform environments.

**Development Environment**
A Salesforce organization where you can make configuration changes that will not affect users on the production organization. There are two kinds of development environments, sandboxes and Developer Edition organizations.
Email Alert
Email alerts are actions that send emails, using a specified email template, to specified recipients.

Email Template
A form email that communicates a standard message, such as a welcome letter to new employees or an acknowledgment that a customer service request has been received. Email templates can be personalized with merge fields, and can be written in text, HTML, or custom format.

**Note:** Lightning email templates aren't packageable.

Enterprise Edition
A Salesforce edition designed for larger, more complex businesses.

Enterprise WSDL
A strongly-typed WSDL for customers who want to build an integration with their Salesforce organization only, or for partners who are using tools like Tibco or webMethods to build integrations that require strong typecasting. The downside of the Enterprise WSDL is that it only works with the schema of a single Salesforce organization because it is bound to all of the unique objects and fields that exist in that organization's data model.

Entity Relationship Diagram (ERD)
A data modeling tool that helps you organize your data into entities (or objects, as they are called in the Lightning Platform) and define the relationships between them. ERD diagrams for key Salesforce objects are published in the SOAP API Developer's Guide.

Enumeration Field
An enumeration is the WSDL equivalent of a picklist field. The valid values of the field are restricted to a strict set of possible values, all having the same data type.

Facet
A child of another Visualforce component that allows you to override an area of the rendered parent with the contents of the facet.

Field
A part of an object that holds a specific piece of information, such as a text or currency value.

Field Dependency
A filter that allows you to change the contents of a picklist based on the value of another field.

Field-Level Security
Settings that determine whether fields are hidden, visible, read only, or editable for users. Available in Professional, Enterprise, Unlimited, Performance, and Developer Editions.

Foreign Key
A field whose value is the same as the primary key of another table. You can think of a foreign key as a copy of a primary key from another table. A relationship is made between two tables by matching the values of the foreign key in one table with the values of the primary key in another.

Getter Methods
Methods that enable developers to display database and other computed values in page markup.
Methods that return values. See also Setter Methods.
Global Variable
A special merge field that you can use to reference data in your organization. A method access modifier for any method that needs to be referenced outside of the application, either in the SOAP API or by other Apex code.

Governor Limits
Apex execution limits that prevent developers who write inefficient code from monopolizing the resources of other Salesforce users.

Gregorian Year
A calendar based on a 12-month structure used throughout much of the world.

Hierarchy Custom Settings
A type of custom setting that uses a built-in hierarchical logic that lets you “personalize” settings for specific profiles or users. The hierarchy logic checks the organization, profile, and user settings for the current user and returns the most specific, or “lowest,” value. In the hierarchy, settings for an organization are overridden by profile settings, which, in turn, are overridden by user settings.

HTTP Debugger
An application that can be used to identify and inspect SOAP requests that are sent from the AJAX Toolkit. They behave as proxy servers running on your local machine and allow you to inspect and author individual requests.

ID
See Salesforce Record ID.

IdeaExchange
A forum where Salesforce customers can suggest new product concepts, promote favorite enhancements, interact with product managers and other customers, and preview what Salesforce is planning to deliver in future releases. Visit IdeaExchange at ideas.salesforce.com.

Import Wizard
A tool for importing data into your Salesforce organization, accessible from Setup.

Instance
The cluster of software and hardware represented as a single logical server that hosts an organization’s data and runs their applications. The Lightning Platform runs on multiple instances, but data for any single organization is always stored on a single instance.

Integrated Development Environment (IDE)
A software application that provides comprehensive facilities for software developers including a source code editor, testing and debugging tools, and integration with source code control systems.

Integration User
A Salesforce user defined solely for client apps or integrations. Also referred to as the logged-in user in a SOAP API context.

ISO Code
The International Organization for Standardization country code, which represents each country by two letters.
Junction Object
A custom object with two master-detail relationships. Using a custom junction object, you can model a “many-to-many” relationship between two objects. For example, you create a custom object called “Bug” that relates to the standard case object such that a bug could be related to multiple cases and a case could also be related to multiple bugs.

Length
Parameter for custom text fields that specifies the maximum number of characters (up to 255) that a user can enter in the field.
Parameter for number, currency, and percent fields that specifies the number of digits you can enter to the left of the decimal point, for example, 123.98 for an entry of 3.

Lightning Platform
The Salesforce platform for building applications in the cloud. Lightning Platform combines a powerful user interface, operating system, and database to allow you to customize and deploy applications in the cloud for your entire enterprise.

List Custom Settings
A type of custom setting that provides a reusable set of static data that can be accessed across your organization. If you use a particular set of data frequently within your application, putting that data in a list custom setting streamlines access to it. Data in list settings does not vary with profile or user, but is available organization-wide. Examples of list data include two-letter state abbreviations, international dialing prefixes, and catalog numbers for products. Because the data is cached, access is low-cost and efficient: you don’t have to use SOQL queries that count against your governor limits.

List View
A list display of items (for example, accounts or contacts) based on specific criteria. Salesforce provides some predefined views.
In the Agent console, the list view is the top frame that displays a list view of records based on specific criteria. The list views you can select to display in the console are the same list views defined on the tabs of other objects. You cannot create a list view within the console.

Local Name
The value stored for the field in the user’s or account’s language. The local name for a field is associated with the standard name for that field.

Locale
The country or geographic region in which the user is located. The setting affects the format of date and number fields, for example, dates in the English (United States) locale display as 06/30/2000 and as 30/06/2000 in the English (United Kingdom) locale.
In Professional, Enterprise, Unlimited, Performance, and Developer Edition organizations, a user’s individual Locale setting overrides the organization’s Default Locale setting. In Personal and Group Editions, the organization-level locale field is called Locale, not Default Locale.

Long Text Area
Data type of custom field that allows entry of up to 32,000 characters on separate lines.

Lookup Relationship
A relationship between two records so you can associate records with each other. For example, cases have a lookup relationship with assets that lets you associate a particular asset with a case. On one side of the relationship, a lookup field allows users to click a lookup icon and select another record from a popup window. On the associated record, you can then display a related list to show all of the records that have been linked to it. If a lookup field references a record that has been deleted, by default Salesforce clears the lookup field. Alternatively, you can prevent records from being deleted if they’re in a lookup relationship.
M

Managed Package
A collection of application components that is posted as a unit on the AppExchange and associated with a namespace and possibly a License Management Organization. To support upgrades, a package must be managed. An organization can create a single managed package that can be downloaded and installed by many different organizations. Managed packages differ from unmanaged packages by having some locked components, allowing the managed package to be upgraded later. Unmanaged packages do not include locked components and cannot be upgraded. In addition, managed packages obfuscate certain components (like Apex) on subscribing organizations to protect the intellectual property of the developer.

Manual Sharing
Record-level access rules that allow record owners to give read and edit permissions to other users who might not have access to the record any other way.

Many-to-Many Relationship
A relationship where each side of the relationship can have many children on the other side. Many-to-many relationships are implemented through the use of junction objects.

Master-Detail Relationship
A relationship between two different types of records that associates the records with each other. For example, accounts have a master-detail relationship with opportunities. This type of relationship affects record deletion, security, and makes the lookup relationship field required on the page layout.

Metadata
Information about the structure, appearance, and functionality of an organization and any of its parts. Lightning Platform uses XML to describe metadata.

Metadata-Driven Development
An app development model that allows apps to be defined as declarative “blueprints,” with no code required. Apps built on the platform—their data models, objects, forms, workflows, and more—are defined by metadata.

Metadata WSDL
A WSDL for users who want to use the Lightning Platform Metadata API calls.

Multitenancy
An application model where all users and apps share a single, common infrastructure and code base.

MVC (Model-View-Controller)
A design paradigm that deconstructs applications into components that represent data (the model), ways of displaying that data in a user interface (the view), and ways of manipulating that data with business logic (the controller).

N

Namespace
In a packaging context, a one- to 15-character alphanumeric identifier that distinguishes your package and its contents from packages of other developers on AppExchange, similar to a domain name. Salesforce automatically prepends your namespace prefix, followed by two underscores (“__”), to all unique component names in your Salesforce organization.

Native App
An app that is built exclusively with setup (metadata) configuration on Lightning Platform. Native apps do not require any external services or infrastructure.
Object
An object allows you to store information in your Salesforce organization. The object is the overall definition of the type of information you are storing. For example, the case object allow you to store information regarding customer inquiries. For each object, your organization will have multiple records that store the information about specific instances of that type of data. For example, you might have a case record to store the information about Joe Smith's training inquiry and another case record to store the information about Mary Johnson's configuration issue.

Object-Level Help
Custom help text that you can provide for any custom object. It displays on custom object record home (overview), detail, and edit pages, as well as list views and related lists.

Object-Level Security
Settings that allow an administrator to hide whole objects from users so that they don't know that type of data exists. Object-level security is specified with object permissions.

One-to-Many Relationship
A relationship in which a single object is related to many other objects. For example, an account may have one or more related contacts.

Organization
A deployment of Salesforce with a defined set of licensed users. An organization is the virtual space provided to an individual customer of Salesforce. Your organization includes all of your data and applications, and is separate from all other organizations.

Organization-Wide Defaults
Settings that allow you to specify the baseline level of data access that a user has in your organization. For example, you can set organization-wide defaults so that any user can see any record of a particular object that is enabled via their object permissions, but they need extra permissions to edit one.

Outbound Call
Any call that originates from a user to a number outside of a call center in Salesforce CRM Call Center.

Outbound Message
An outbound message sends information to a designated endpoint, like an external service. Outbound messages are configured from Setup. You must configure the external endpoint and create a listener for the messages using the SOAP API.

Owner
Individual user to which a record (for example, a contact or case) is assigned.

P

PaaS
See Platform as a Service.

Package
A group of Lightning Platform components and applications that are made available to other organizations through the AppExchange. You use packages to bundle an app along with any related components so that you can upload them to AppExchange together.

Package Dependency
This is created when one component references another component, permission, or preference that is required for the component to be valid. Components can include but are not limited to:

- Standard or custom fields
- Standard or custom objects
- Visualforce pages
• Apex code

Permissions and preferences can include but are not limited to:
• Divisions
• Multicurrency
• Record types

Package Installation
Installation incorporates the contents of a package into your Salesforce organization. A package on the AppExchange can include an app, a component, or a combination of the two. After you install a package, you may need to deploy components in the package to make it generally available to the users in your organization.

Package Version
A package version is a number that identifies the set of components uploaded in a package. The version number has the format **majorNumber.minorNumber.patchNumber** (for example, 2.1.3). The major and minor numbers increase to a chosen value during every major release. The **patchNumber** is generated and updated only for a patch release.

Unmanaged packages are not upgradeable, so each package version is simply a set of components for distribution. A package version has more significance for managed packages. Packages can exhibit different behavior for different versions. Publishers can use package versions to evolve the components in their managed packages gracefully by releasing subsequent package versions without breaking existing customer integrations using the package. See also Patch and Patch Development Organization.

Partner WSDL
A loosely-typed WSDL for customers, partners, and ISVs who want to build an integration or an AppExchange app that can work across multiple Salesforce organizations. With this WSDL, the developer is responsible for marshaling data in the correct object representation, which typically involves editing the XML. However, the developer is also freed from being dependent on any particular data model or Salesforce organization. Contrast this with the Enterprise WSDL, which is strongly typed.

Patch
A patch enables a developer to change the functionality of existing components in a managed package, while ensuring subscribing organizations that there are no visible behavior changes to the package. For example, you can add new variables or change the body of an Apex class, but you may not add, deprecate, or remove any of its methods. Patches are tracked by a **patchNumber** appended to every package version. See also Patch Development Organization and Package Version.

Patch Development Organization
The organization where patch versions are developed, maintained, and uploaded. Patch development organizations are created automatically for a developer organization when they request to create a patch. See also Patch and Package Version.

Personal Edition
Product designed for individual sales representatives and single users.

Platform as a Service (PaaS)
An environment where developers use programming tools offered by a service provider to create applications and deploy them in a cloud. The application is hosted as a service and provided to customers via the Internet. The PaaS vendor provides an API for creating and extending specialized applications. The PaaS vendor also takes responsibility for the daily maintenance, operation, and support of the deployed application and each customer's data. The service alleviates the need for programmers to install, configure, and maintain the applications on their own hardware, software, and related IT resources. Services can be delivered using the PaaS environment to any market segment.

Platform Edition
A Salesforce edition based on Enterprise, Unlimited, or Performance Edition that does not include any of the standard Salesforce apps, such as Sales or Service & Support.
Primary Key
A relational database concept. Each table in a relational database has a field in which the data value uniquely identifies the record. This field is called the primary key. The relationship is made between two tables by matching the values of the foreign key in one table with the values of the primary key in another.

Production Organization
A Salesforce organization that has live users accessing data.

Professional Edition
A Salesforce edition designed for businesses who need full-featured CRM functionality.

Prototype
The classes, methods and variables that are available to other Apex code.

Query Locator
A parameter returned from the `query()` or `queryMore()` API call that specifies the index of the last result record that was returned.

Query String Parameter
A name-value pair that's included in a URL, typically after a '?' character. For example:

```
https://yourInstance.salesforce.com/001/e?name=value
```

Record
A single instance of a Salesforce object. For example, "John Jones" might be the name of a contact record.

Record ID
The unique identifier for each record.

Record-Level Security
A method of controlling data in which you can allow a particular user to view and edit an object, but then restrict the records that the user is allowed to see.

Record Locking
Record locking prevents users from editing a record, regardless of field-level security or sharing settings. By default, Salesforce locks records that are pending approval. Only admins can edit locked records.

Record Name
A standard field on all Salesforce objects. Whenever a record name is displayed in a Lightning Platform application, the value is represented as a link to a detail view of the record. A record name can be either free-form text or an autonumber field. Record Name does not have to be a unique value.

Recycle Bin
A page that lets you view and restore deleted information. Access the Recycle Bin by using the link in the sidebar.

Relationship
A connection between two objects, used to create related lists in page layouts and detail levels in reports. Matching values in a specified field in both objects are used to link related data; for example, if one object stores data about companies and another object stores data about people, a relationship allows you to find out which people work at the company.
Relationship Query
In a SOQL context, a query that traverses the relationships between objects to identify and return results. Parent-to-child and child-to-parent syntax differs in SOQL queries.

Role Hierarchy
A record-level security setting that defines different levels of users such that users at higher levels can view and edit information owned by or shared with users beneath them in the role hierarchy, regardless of the organization-wide sharing model settings.

Roll-Up Summary Field
A field type that automatically provides aggregate values from child records in a master-detail relationship.

Running User
Each dashboard has a running user, whose security settings determine which data to display in a dashboard. If the running user is a specific user, all dashboard viewers see data based on the security settings of that user—regardless of their own personal security settings. For dynamic dashboards, you can set the running user to be the logged-in user, so that each user sees the dashboard according to his or her own access level.

S

SaaS
See Software as a Service (SaaS).

S-Control

Note: S-controls have been superseded by Visualforce pages. After March 2010 organizations that have never created s-controls, as well as new organizations, won’t be allowed to create them. Existing s-controls will remain unaffected, and can still be edited.

Custom Web content for use in custom links. Custom s-controls can contain any type of content that you can display in a browser, for example a Java applet, an Active-X control, an Excel file, or a custom HTML Web form.

Salesforce Certificate and Key Pair
Salesforce certificates and key pairs are used for signatures that verify a request is coming from your organization. They are used for authenticated SSL communications with an external web site, or when using your organization as an Identity Provider. You only need to generate a Salesforce certificate and key pair if you’re working with an external website that wants verification that a request is coming from a Salesforce organization.

Salesforce Connect
Salesforce Connect provides access to data that’s stored outside the Salesforce org, such as data in an enterprise resource planning (ERP) system and records in another org. Salesforce Connect represents the data in external objects and accesses the external data in real time via Web service callouts to external data sources.

Salesforce Extensions for Visual Studio Code
The Salesforce extension pack for Visual Studio Code includes tools for developing on the Salesforce platform in the lightweight, extensible VS Code editor. These tools provide features for working with development orgs (scratch orgs, sandboxes, and DE orgs), Apex, Aura components, and Visualforce.

Salesforce Record ID
A unique 15- or 18-character alphanumeric string that identifies a single record in Salesforce.

Salesforce SOA (Service-Oriented Architecture)
A powerful capability of Lightning Platform that allows you to make calls to external Web services from within Apex.

Sandbox
A nearly identical copy of a Salesforce production organization for development, testing, and training. The content and size of a sandbox varies depending on the type of sandbox and the edition of the production organization associated with the sandbox.
Semi-Join
A semi-join is a subquery on another object in an `IN` clause in a SOQL query. You can use semi-joins to create advanced queries, such as getting all contacts for accounts that have an opportunity with a particular record type. See also Anti-Join.

Session ID
An authentication token that is returned when a user successfully logs in to Salesforce. The Session ID prevents a user from having to log in again every time they want to perform another action in Salesforce. Different from a record ID or Salesforce ID, which are terms for the unique ID of a Salesforce record.

Session Timeout
The time after login before a user is automatically logged out. Sessions expire automatically after a predetermined length of inactivity, which can be configured in Salesforce from Setup by clicking Security Controls. The default is 120 minutes (two hours). The inactivity timer is reset to zero if a user takes an action in the web interface or makes an API call.

Setter Methods
Methods that assign values. See also Getter Methods.

Setup
A menu where administrators can customize and define organization settings and Lightning Platform apps. Depending on your organization’s user interface settings, Setup may be a link in the user interface header or in the dropdown list under your name.

Sharing
Allowing other users to view or edit information you own. There are different ways to share data:

- **Sharing Model**—defines the default organization-wide access levels that users have to each other’s information and whether to use the hierarchies when determining access to data.
- **Role Hierarchy**—defines different levels of users such that users at higher levels can view and edit information owned by or shared with users beneath them in the role hierarchy, regardless of the organization-wide sharing model settings.
- **Sharing Rules**—allow an administrator to specify that all information created by users within a given group or role is automatically shared to the members of another group or role.
- **Manual Sharing**—allows individual users to share records with other users or groups.
- **Apex-Managed Sharing**—enables developers to programmatically manipulate sharing to support their application’s behavior. See Apex-Managed Sharing.

Sharing Model
Behavior defined by your administrator that determines default access by users to different types of records.

Sharing Rule
Type of default sharing created by administrators. Allows users in a specified group or role to have access to all information created by users within a given group or role.

Sites
Salesforce Sites enables you to create public websites and applications that are directly integrated with your Salesforce organization—without requiring users to log in with a username and password.

SOAP (Simple Object Access Protocol)
A protocol that defines a uniform way of passing XML-encoded data.

SOAP API
A SOAP-based Web services application programming interface that provides access to your Salesforce organization’s information.

sObject
The abstract or parent object for all objects that can be stored in the Lightning Platform.

Software as a Service (SaaS)
A delivery model where a software application is hosted as a service and provided to customers via the Internet. The SaaS vendor takes responsibility for the daily maintenance, operation, and support of the application and each customer’s data. The service...
alleviates the need for customers to install, configure, and maintain applications with their own hardware, software, and related IT resources. Services can be delivered using the SaaS model to any market segment.

**SOQL (Salesforce Object Query Language)**
A query language that allows you to construct simple but powerful query strings and to specify the criteria that selects data from the Lightning Platform database.

**SOSL (Salesforce Object Search Language)**
A query language that allows you to perform text-based searches using the Lightning Platform API.

**Standard Object**
A built-in object included with the Lightning Platform. You can also build custom objects to store information that is unique to your app.

**System Log**
Part of the Developer Console, a separate window console that can be used for debugging code snippets. Enter the code you want to test at the bottom of the window and click Execute. The body of the System Log displays system resource information, such as how long a line took to execute or how many database calls were made. If the code did not run to completion, the console also displays debugging information.

**Tag**
In Salesforce, a word or short phrases that users can associate with most records to describe and organize their data in a personalized way. Administrators can enable tags for accounts, activities, assets, campaigns, cases, contacts, contracts, dashboards, documents, events, leads, notes, opportunities, reports, solutions, tasks, and any custom objects (except relationship group members). Tags can also be accessed through the SOAP API.

**Test Case Coverage**
Test cases are the expected real-world scenarios in which your code will be used. Test cases are not actual unit tests, but are documents that specify what your unit tests should do. High test case coverage means that most or all the real-world scenarios you have identified are implemented as unit tests. See also Code Coverage and Unit Test.

**Test Method**
An Apex class method that verifies whether a particular piece of code is working properly. Test methods take no arguments, commit no data to the database, and can be executed by the `runTests()` system method either through the command line or in an Apex IDE, such as the Salesforce extensions for Visual Studio Code.

**Test Organization**
See Sandbox.

**Transaction, Apex**
An Apex transaction represents a set of operations that are executed as a single unit. All DML operations in a transaction either complete successfully, or if an error occurs in one operation, the entire transaction is rolled back and no data is committed to the database. The boundary of a transaction can be a trigger, a class method, an anonymous block of code, a Visualforce page, or a custom Web service method.

**Trigger**
A piece of Apex that executes before or after records of a particular type are inserted, updated, or deleted from the database. Every trigger runs with a set of context variables that provide access to the records that caused the trigger to fire, and all triggers run in bulk mode—that is, they process several records at once, rather than just one record at a time.

**Trigger Context Variable**
Default variables that provide access to information about the trigger and the records that caused it to fire.
**U**

**Unit Test**
A unit is the smallest testable part of an application, usually a method. A unit test operates on that piece of code to make sure it works correctly. See also Test Method.

**Unlimited Edition**
Unlimited Edition is Salesforce’s solution for maximizing your success and extending that success across the entire enterprise through the Lightning Platform.

**Unmanaged Package**
A package that cannot be upgraded or controlled by its developer.

**URL (Uniform Resource Locator)**
The global address of a website, document, or other resource on the Internet. For example, http://www.salesforce.com.

**User Acceptance Testing (UAT)**
A process used to confirm that the functionality meets the planned requirements. UAT is one of the final stages before deployment to production.

**V**

**Validation Rule**
A rule that prevents a record from being saved if it does not meet the standards that are specified.

**Version**
A number value that indicates the release of an item. Items that can have a version include API objects, fields, and calls; Apex classes and triggers; and Visualforce pages and components.

**View**
The user interface in the Model-View-Controller model, defined by Visualforce.

**View State**
Where the information necessary to maintain the state of the database between requests is saved.

**Visualforce**
A simple, tag-based markup language that allows developers to easily define custom pages and components for apps built on the platform. Each tag corresponds to a coarse or fine-grained component, such as a section of a page, a related list, or a field. The components can either be controlled by the same logic that is used in standard Salesforce pages, or developers can associate their own logic with a controller written in Apex.

**Visualforce Controller**
See Controller, Visualforce.

**Visualforce Lifecycle**
The stages of execution of a Visualforce page, including how the page is created and destroyed during a user session.

**Visualforce Page**
A web page created using Visualforce. Typically, Visualforce pages present information relevant to your organization, but they can also modify or capture data. They can be rendered in several ways, such as a PDF document or an email attachment, and can be associated with a CSS style.
W

Web Service
A mechanism by which two applications can easily exchange data over the Internet, even if they run on different platforms, are written in different languages, or are geographically remote from each other.

WebService Method
An Apex class method or variable that external systems can use, like a mash-up with a third-party application. Web service methods must be defined in a global class.

Web Services API
A Web services application programming interface that provides access to your Salesforce organization’s information. See also SOAP PI and Bulk API.

Automated Actions
Automated actions, such as email alerts, tasks, field updates, and outbound messages, can be triggered by a process, workflow rule, approval process, or milestone.

Wrapper Class
A class that abstracts common functions such as logging in, managing sessions, and querying and batching records. A wrapper class makes an integration more straightforward to develop and maintain, keeps program logic in one place, and affords easy reuse across components. Examples of wrapper classes in Salesforce include the AJAX Toolkit, which is a JavaScript wrapper around the Salesforce SOAP API, wrapper classes such as Critical Section in the CTI Adapter for Salesforce CRM Call Center, or wrapper classes created as part of a client integration application that accesses Salesforce using the SOAP API.

WSDL (Web Services Description Language) File
An XML file that describes the format of messages you send and receive from a Web service. Your development environment’s SOAP client uses the Salesforce Enterprise WSDL or Partner WSDL to communicate with Salesforce using the SOAP API.

X

XML (Extensible Markup Language)
A markup language that enables the sharing and transportation of structured data. All Lightning Platform components that are retrieved or deployed through the Metadata API are represented by XML definitions.
