IN THIS SECTION:  
ThresholdInformation Constructors  
ThresholdInformation Methods

ThresholdInformation Constructors  
The following are constructors for ThresholdInformation.

IN THIS SECTION:  
ThresholdInformation(evaluatedConditions)  
Creates a new instance of the Reports.EvaluatedCondition class.

ThresholdInformation (evaluatedConditions)  
Creates a new instance of the Reports.EvaluatedCondition class.

Signature  
public ThresholdInformation(List<Reports.EvaluatedCondition> evaluatedConditions)

Parameters  
evaluatedConditions  
Type: List<Reports.EvaluatedCondition>  
A list of Reports.EvaluatedCondition objects.
ThresholdInformation Methods

The following are methods for ThresholdInformation.

IN THIS SECTION:

getEvaluatedConditions()
Returns a list of evaluated conditions for a report notification.

getEvaluatedConditions()
Returns a list of evaluated conditions for a report notification.

Signature

public List<Reports.EvaluatedCondition> getEvaluatedConditions()

Return Value

Type: List<Reports.EvaluatedCondition>

TopRows Class

Contains methods and constructors for working with information about a row limit filter.

Namespace

Reports

IN THIS SECTION:

TopRows Constructors
TopRows Methods

TopRows Constructors

The following are constructors for TopRows.

IN THIS SECTION:

TopRows(rowLimit, direction)
Creates an instance of the Reports.TopRows class using the specified parameters.

TopRows()
Creates an instance of the Reports.TopRows class. You can then set values by using the class’s set methods.

TopRows (rowLimit, direction)
Creates an instance of the Reports.TopRows class using the specified parameters.
Signature

```java
public TopRows(Integer rowLimit, Reports.ColumnSortOrder direction)
```

Parameters

- **rowLimit**
  - Type: `Integer`
  - The number of rows returned in the report.

- **direction**
  - Type: `Reports.ColumnSortOrder`
  - The sort order of the report rows.

**TopRows()**

Creates an instance of the `Reports.TopRows` class. You can then set values by using the class's `set` methods.

Signature

```java
public TopRows()
```

**TopRows Methods**

The following are methods for `TopRows`.

In this section:

- `getDirection()`: Returns the sort order of the report rows.
- `getRowLimit()`: Returns the maximum number of rows shown in the report.
- `setDirection(value)`: Sets the sort order of the report's rows.
- `setDirection(direction)`: Sets the sort order of the report's rows.
- `setRowLimit(rowLimit)`: Sets the maximum number of rows included in the report.
- `toString()`: Returns a string.

**getDirection()**

Returns the sort order of the report rows.

Signature

```java
public Reports.ColumnSortOrder getDirection()
```
Return Value
Type: Reports.ColumnSortOrder

getRowLimit()
Returns the maximum number of rows shown in the report.

Signature
public Integer getRowLimit()

Return Value
Type: Integer

setDirection(value)
Sets the sort order of the report’s rows.

Signature
public void setDirection(String value)

Parameters
value
Type: String
For possible values, see Reports.ColumnSortOrder.

Return Value
Type: void

setDirection(direction)
Sets the sort order of the report’s rows.

Signature
public void setDirection(Reports.ColumnSortOrder direction)

Parameters
direction
Type: Reports.ColumnSortOrder

Return Value
Type: void
setRowLimit(rowLimit)
Sets the maximum number of rows included in the report.

Signature
public void setRowLimit(Integer rowLimit)

Parameters
rowLimit
Type: Integer

Return Value
Type: void

toString()
Returns a string.

Signature
public String toString()

Return Value
Type: String

Reports Exceptions
The Reports namespace contains exception classes.
All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions on page 3076.
The Reports namespace contains these exceptions:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reports.FeatureNotSupportedException</td>
<td>Invalid report format</td>
<td></td>
</tr>
<tr>
<td>Reports.InstanceAccessException</td>
<td>Unable to access report instance</td>
<td></td>
</tr>
<tr>
<td>Reports.InvalidFilterException</td>
<td>Filter validation error</td>
<td>List&lt;String&gt; getFilterErrors() returns a list of filter errors</td>
</tr>
<tr>
<td>Reports.InvalidReportMetadataException</td>
<td>Missing metadata for filters</td>
<td>List&lt;String&gt; getReportMetadataErrors() returns a list of metadata errors</td>
</tr>
<tr>
<td>Reports.InvalidSnapshotDateException</td>
<td>Invalid historical report format</td>
<td>List&lt;String&gt; getSnapshotDateErrors() returns a list of snapshot date errors</td>
</tr>
</tbody>
</table>
RichMessaging Namespace

Provides objects and methods for handling content in enhanced Messaging channels.

The following are the classes in the RichMessaging namespace.

IN THIS SECTION:

AbstractTiming Class
Parent class for other RichMessaging timing classes.

AddressableContact Class
Represents an addressable contact.

AuthRequestHandler Interface
Use this interface to handle authorization request responses.

AuthRequestResponse Class
This class contains authorization request response data.

AuthRequestResult Class
This class contains the result from handling the authorization request response.

AuthRequestResultStatus Enum
This enum describes the authentication result status.

DeferredTiming Class
Represents timing for a transaction that occurs in the future.

MessageDefinitionInputParameter Class
Represents a messaging component parameter value. This class is used to provide parameter payloads that can be translated to structured content payloads in rich content messages.

PaymentItemStatus Enum
Represents the status of a payment item in payment requests sent in enhanced Messaging channels.

PaymentLineItem Class
Represents a payment line item in payment requests sent in enhanced Messaging channels.

PaymentMethod Class
Represents a payment method.

PostalAddress Class
Represents the postal address.
ProcessPaymentHandler Interface
Interface used to process payment requests.

ProcessPaymentRequest Class
Represents a request to process a payment.

ProcessPaymentResult Class
Represents the result of a payment processing operation.

ProcessPaymentResultStatus Enum
Represents the status of a payment processing result.

RecurringTiming Class
Represents a payment that occurs on a regular basis.

ShippingMethod Class
Represents a shipping method listed in payment requests sent in enhanced Messaging channels.

TimeSlotOption Class
Represents a complex time slot option type. This class is used to provide time option payloads that can be translated to structured content payloads in rich content messages.

TimeIntervalUnit Enum
Represents an enumerated type that describes the timing interval.

TimingType Enum
Represents an enumerated type that describes the type of timing.

AbstractTiming Class
Parent class for other RichMessaging timing classes.

Namespace
RichMessaging

SEE ALSO:
DeferredTiming Class
RecurringTiming Class

AddressableContact Class
Represents an addressable contact.

Namespace
RichMessaging

IN THIS SECTION:
AddressableContact Constructors
AddressableContact Properties
AddressableContact Constructors

The following are constructors for AddressableContact.

IN THIS SECTION:

AddressableContact(givenName, phoneticGivenName, familyName, phoneticFamilyName, emailAddress, phoneNumber, postalAddress)

Creates a new instance of the RichMessaging.AddressableContact class.

AddressableContact(givenName, phoneticGivenName, familyName, phoneticFamilyName, emailAddress, phoneNumber, postalAddress)

Creates a new instance of the RichMessaging.AddressableContact class.

Signature

public AddressableContact(String givenName, String phoneticGivenName, String familyName, String phoneticFamilyName, String emailAddress, String phoneNumber, RichMessaging.PostalAddress postalAddress)

Parameters

givenName
Type: String
The contact’s first name.

phoneticGivenName
Type: String
The phonetic spelling of the contact’s first name.

familyName
Type: String
The contact’s surname.

phoneticFamilyName
Type: String
The phonetic spelling of the contact’s surname.

emailAddress
Type: String
The contact’s email address.

phoneNumber
Type: String
The contact’s phone number.

postalAddress
Type: RichMessaging.PostalAddress
The contact’s postal address.
AddressableContact Properties

The following are properties for AddressableContact.

IN THIS SECTION:

- **emailAddress**
  The contact’s email address.

- **familyName**
  The contact’s surname.

- **givenName**
  The contact’s first name.

- **phoneNumber**
  The contact’s phone number.

- **phoneticFamilyName**
  The phonetic spelling of the contact’s surname.

- **phoneticGivenName**
  The phonetic spelling of the contact’s first name.

- **postalAddress**
  The contact’s postal address.

**emailAddress**

The contact’s email address.

**Signature**

```csharp
public String emailAddress {get; set;}
```

**Property Value**

Type: String

**familyName**

The contact’s surname.

**Signature**

```csharp
public String familyName {get; set;}
```

**Property Value**

Type: String

**givenName**

The contact’s first name.

**Signature**

```csharp
public String givenName {get; set;}
```

**Property Value**

Type: String
Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.

Signature
public String givenName {get; set;}

Property Value
Type: String

givenName
The contact’s given name.
Property Value
Type: RichMessaging.PostalAddress

AuthRequestHandler Interface
Use this interface to handle authorization request responses.

Namespace
RichMessaging on page 2653

Usage
When using this interface, the following limits are overridden. See Execution Governors and Limits in the Apex Developer Guide.

Table 1: Overridden Limits

<table>
<thead>
<tr>
<th>Limit Name</th>
<th>Overridden Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total number of SOQL queries issued</td>
<td>2</td>
</tr>
<tr>
<td>Total number of records retrieved by a single SOSL query</td>
<td>2</td>
</tr>
<tr>
<td>Total number of DML statements issued</td>
<td>1</td>
</tr>
<tr>
<td>Total number of records processed as a result of DML statements</td>
<td>1</td>
</tr>
<tr>
<td>Total number of callouts (HTTP requests or web services calls) in a transaction</td>
<td>2</td>
</tr>
</tbody>
</table>

IN THIS SECTION:
AuthRequestHandler Methods
AuthRequestHandler Example Implementation

AuthRequestHandler Methods
The following are methods for AuthRequestHandler.

IN THIS SECTION:
handleAuthRequest(var1)
Handles authorization request response.

handleAuthRequest(var1)
Handles authorization request response.
Signature

public RichMessaging.AuthRequestResult
handleAuthRequest(RichMessaging.AuthRequestResponse var1)

Parameters

var1
  Type: RichMessaging.AuthRequestResponse on page 2660
  The authorization response.

Return Value

Type: RichMessaging.AuthRequestResult on page 2662

AuthRequestHandler Example Implementation

This is an example implementation of the RichMessaging.AuthRequestHandler interface.

global class SampleAuthRequestHandler implements RichMessaging.AuthRequestHandler {
    global RichMessaging.AuthRequestResult
    handleAuthRequest(RichMessaging.AuthRequestResponse authReqResponse) {

        // Get contact email from messaging session
        String sessionId = authReqResponse.getContextRecordId();
        String contactEmail = [select MessagingSession.EndUserContact.Email from MessagingSession where id = :sessionId].EndUserContact.Email;

        DateTime dt = DateTime.now();

        // Get user info if there's a valid contact email
        if (!String.isBlank(contactEmail)) {
            String userInfoUrl = 'https://api.MY_AUTH_DOMAIN.com/v1/';

            HttpRequest req = new HttpRequest();
            req.setEndpoint(userInfoUrl);
            req.setHeader('Content-Type', 'application/json');
            req.setMethod('GET');
            req.setHeader('Authorization', 'Bearer ' + authReqResponse.getAccessToken());
            Http http = new Http();
            HTTPResponse res = http.send(req);

            String responseBody = res.getBody();
            UserWrapper userInfo = (UserWrapper)System.JSON.deserialize(responseBody, UserWrapper.class);

            if (userInfo.email == contactEmail) {
                authRequestStatus = RichMessaging.AuthRequestResultStatus.AUTHENTICATED;
            }
        }
    }
}
AuthRequestResponse Class

This class contains authorization request response data.

Namespace

RichMessaging

IN THIS SECTION:

AuthRequestResponse Constructors
AuthRequestResponse Methods

AuthRequestResponse Constructors

The following are constructors for AuthRequestResponse.

IN THIS SECTION:

AuthRequestResponse(accessToken, contextRecordId, authProviderName)

AuthRequestResponse(accessToken, contextRecordId, authProviderName)

Signature

public AuthRequestResponse(String accessToken, String contextRecordId, String authProviderName)
Parameters

accessToken
Type: String
The authorization access token.

contextRecordId
Type: String
The context record ID.

authProviderName
Type: String
The provider name.

AuthRequestResponse Methods

The following are methods for AuthRequestResponse.

IN THIS SECTION:

getAccessToken()
Gets the authorization access token.

getAuthProviderName()
Get the authorization provider name.

getContextRecordId()
Gets the context record ID.

getAccessToken ()

Gets the authorization access token.

Signature

public String getAccessToken()  

Return Value

Type: String
The access token.

getAuthProviderName ()

Get the authorization provider name.

Signature

public String getAuthProviderName()
Return Value
Type: String
The authorization provider name.

getContextRecordId()
Gets the context record ID.

Signature
public String getContextRecordId()

Return Value
Type: String
The context record ID.

AuthRequestResult Class
This class contains the result from handling the authorization request response.

Namespace
RichMessaging

IN THIS SECTION:

AuthRequestResult Constructors
AuthRequestResult Properties

AuthRequestResult Constructors
The following are constructors for AuthRequestResult.

IN THIS SECTION:

AuthRequestResult(redirectPageReference, resultStatus, expirationDateTime)

AuthRequestResult(redirectPageReference, resultStatus, expirationDateTime)

Signature
public AuthRequestResult(System.PageReference redirectPageReference, RichMessaging.AuthRequestResultStatus resultStatus, Datetime expirationDateTime)
Parameters

`redirectPageReference`
Type: `System.PageReference` on page 3268
The reference to the redirect page.

`resultStatus`
Type: `RichMessaging.AuthRequestResultStatus` on page 2664
The result status value.

`expirationDateTime`
Type: `Datetime`
The expiration time.

AuthRequestResult Properties

The following are properties for AuthRequestResult.

IN THIS SECTION:

`expirationDateTime`
The expiration date and time.

`redirectPageReference`
The reference to the redirect page.

`resultStatus`
The result status value.

`expirationDateTime`
The expiration date and time.

Signature

```
public Datetime expirationDateTime {get; set;}
```

Property Value
Type: `Datetime`

`redirectPageReference`
The reference to the redirect page.

Signature

```
public System.PageReference redirectPageReference {get; set;}
```

Property Value
Type: `System.PageReference` on page 3268
**resultStatus**
The result status value.

**Signature**
public RichMessaging.AuthRequestResultStatus resultStatus {get; set;}

**Property Value**
Type: RichMessaging.AuthRequestResultStatus on page 2664

**AuthRequestResultStatus Enum**
This enum describes the authentication result status.

**Enum Values**
The following are the values of the RichMessaging.AuthRequestResultStatus enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTHENTICATED</td>
<td>Authenticated result.</td>
</tr>
<tr>
<td>DECLINED</td>
<td>Declined result.</td>
</tr>
</tbody>
</table>

**DeferredTiming Class**
Represents timing for a transaction that occurs in the future.

**Namespace**
RichMessaging

**IN THIS SECTION:**
- DeferredTiming Constructors
- DeferredTiming Properties

**DeferredTiming Constructors**
The following are constructors for DeferredTiming.

**IN THIS SECTION:**
- DeferredTiming(deferredDate)
- DeferredTiming()
**DeferredTiming (deferredDate)**

**Signature**
public DeferredTiming(Datetime deferredDate)

**Parameters**
*deferredDate*
- Type: Datetime
  - The deferred date.

**DeferredTiming ()**

**Signature**
public DeferredTiming()

**DeferredTiming Properties**
The following are properties for DeferredTiming.

**IN THIS SECTION:**
- deferredDate
  - The deferred date. Invocable variable.
- deferredDateValue
  - The deferred date. Enabled for Lightning components.
- timingType
  - Always returns “DeferredTiming”.

**deferredDate**
The deferred date. Invocable variable.

**Signature**
public Datetime deferredDate {get; set;}

**Property Value**
Type: Datetime
**deferredDateValue**

The deferred date. Enabled for Lightning components.

**Signature**

public Datetime deferredDateValue {get; set;}

**Property Value**

Type: Datetime

**timingType**

Always returns “DeferredTiming”.

**Signature**

public String timingType {get; set;}

**Property Value**

Type: String

**MessageDefinitionInputParameter Class**

Represents a messaging component parameter value. This class is used to provide parameter payloads that can be translated to structured content payloads in rich content messages.

**Namespace**

RichMessaging

IN THIS SECTION:

MessageDefinitionInputParameter Properties

**MessageDefinitionInputParameter Properties**

The following are properties for MessageDefinitionInputParameter.

IN THIS SECTION:

booleanValue
A boolean input parameter.

booleanValues
A list of boolean parameters.

dateTimeValue
A datetime input parameter.
dateTimeValues
A list of datetime input parameters.

dateValue
A date input parameter.

dateValues
A list of date input parameters.

name
A name input parameter.

numberValue
A number input parameter.

numberValues
A list of number input parameters.

recordIdValue
A record ID input parameter.

recordIdValues
A list of record ID input parameters.

textValue
A text input parameter.

textValues
A list of text input parameters.

**booleanValue**
A boolean input parameter.

**Signature**

```csharp
public Boolean booleanValue {get; set;}
```

**Property Value**
Type: Boolean

**booleanValues**
A list of boolean parameters.

**Signature**

```csharp
public List<Boolean> booleanValues {get; set;}
```

**Property Value**
Type: List on page 3177<Boolean>
**dateTimeValue**
A datetime input parameter.

**Signature**
```java
public Datetime dateTimeValue {get; set;}
```

**Property Value**
Type: Datetime

**dateTimeValues**
A list of datetime input parameters.

**Signature**
```java
public List<Datetime> dateTimeValues {get; set;}
```

**Property Value**
Type: List on page 3177<Datetime>

**dateValue**
A date input parameter.

**Signature**
```java
public Date dateValue {get; set;}
```

**Property Value**
Type: Date

**dateValues**
A list of date input parameters.

**Signature**
```java
public List<Date> dateValues {get; set;}
```

**Property Value**
Type: List on page 3177<Date>

**name**
A name input parameter.
Signature
public String name {get; set;}

Property Value
Type: String

**numberValue**
A number input parameter.

Signature
public Double numberValue {get; set;}

Property Value
Type: Double

**numberValues**
A list of number input parameters.

Signature
public List<Double> numberValues {get; set;}

Property Value
Type: List on page 3177<Double>

**recordIdValue**
A record ID input parameter.

Signature
public String recordIdValue {get; set;}

Property Value
Type: String

**recordIdValues**
A list of record ID input parameters.

Signature
public List<String> recordIdValues {get; set;}
Property Value
Type: List on page 3177<String>

textValue
A text input parameter.

Signature
public String textValue {get; set;}

Property Value
Type: String
textValues
A list of text input parameters.

Signature
public List<String> textValues {get; set;}

Property Value
Type: List on page 3177<String>

PaymentItemStatus Enum
Represents the status of a payment item in payment requests sent in enhanced Messaging channels.

Enum Values
The following are the values of the RichMessaging.PaymentItemStatus enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FinalCost</td>
<td>Indicates that the payment item's cost is final and has been determined.</td>
</tr>
<tr>
<td>PendingCost</td>
<td>Indicates that the payment item's cost is pending and has not been determined yet.</td>
</tr>
</tbody>
</table>

PaymentLineItem Class
Represents a payment line item in payment requests sent in enhanced Messaging channels.

Namespace
RichMessaging
Example

```java
public with sharing class MessagingPaymentLineItems {

    @InvocableMethod
    public static List<List<RichMessaging.PaymentLineItem>> getLineItems() {
        Double amount = 0.25;
            RichMessaging.PaymentLineItem pizza = new RichMessaging.PaymentLineItem('pizza', amount);
            RichMessaging.PaymentLineItem pasta = new RichMessaging.PaymentLineItem('pasta', amount);
            pizza.statusValue = RichMessaging.PaymentItemStatus.FinalCost;
            pasta.statusValue = RichMessaging.PaymentItemStatus.FinalCost;

                pizza, pasta
            };
            result.add(options);
        return result;
    }
}
```

IN THIS SECTION:
- PaymentLineItem Constructors
- PaymentLineItem Properties
- PaymentLineItem Methods

PaymentLineItem Constructors

The following are constructors for PaymentLineItem.

IN THIS SECTION:
- PaymentLineItem(label, amount, timing)
  Creates a new instance of the RichMessaging.PaymentLineItem class.
- PaymentLineItem(label, amount)
  Creates a new instance of the RichMessaging.PaymentLineItem class.
- PaymentLineItem()
  Creates a new instance of the RichMessaging.PaymentLineItem class.

PaymentLineItem(label, amount, timing)

Creates a new instance of the RichMessaging.PaymentLineItem class.
Signature

public PaymentLineItem(String label, Double amount, RichMessaging.AbstractTiming timing)

Parameters

label
Type: String
The label of the payment line item.

amount
Type: Double
The amount of the payment line item.

timing
Type: RichMessaging.AbstractTiming
The timing of the payment line item.

PaymentLineItem(label, amount)
Creates a new instance of the RichMessaging.PaymentLineItem class.

Signature

public PaymentLineItem(String label, Double amount)

Parameters

label
Type: String
The label of the payment line item.

amount
Type: Double
The amount of the payment line item.

PaymentLineItem()
Creates a new instance of the RichMessaging.PaymentLineItem class.

Signature

public PaymentLineItem()

PaymentLineItem Properties
The following are properties for PaymentLineItem.
IN THIS SECTION:

- **amount**
  The amount of the payment line item.

- **amountValue**
  The amount value of the payment line item.

- **automaticReloadPaymentThresholdAmount**
  The automatic reload payment threshold amount of the payment line item.

- **automaticReloadPaymentThresholdAmountValue**
  The automatic reload payment threshold amount value of the payment line item.

- **label**
  The label of the payment line item.

- **labelValue**
  The label value of the payment line item.

- **lineItemType**
  The line item type of the payment line item. Read-only variable.

- **status**
  The status of the payment line item.

- **statusValue**
  The status value of the payment line item.

- **timing**
  The timing of the payment line item.

- **timingValue**
  The timing value of the payment line item.

**amount**

The amount of the payment line item.

**Signature**

```csharp
public Double amount {get; set;}
```

**Property Value**

Type: **Double**

**amountValue**

The amount value of the payment line item.

**Signature**

```csharp
public Double amountValue {get; set;}
```
Property Value
Type: Double

automaticReloadPaymentThresholdAmount
The automatic reload payment threshold amount of the payment line item.

Signature
public Double automaticReloadPaymentThresholdAmount {get; set;}

Property Value
Type: Double

automaticReloadPaymentThresholdAmountValue
The automatic reload payment threshold amount value of the payment line item.

Signature
public Double automaticReloadPaymentThresholdAmountValue {get; set;}

Property Value
Type: Double

label
The label of the payment line item.

Signature
public String label {get; set;}

Property Value
Type: String

labelValue
The label value of the payment line item.

Signature
public String labelValue {get; set;}

Property Value
Type: String
**lineItemType**
The line item type of the payment line item. Read-only variable.

**Signature**
public String lineItemType {get; set;}

**Property Value**
Type: String

**status**
The status of the payment line item.

**Signature**
public String status {get; set;}

**Property Value**
Type: String

**statusValue**
The status value of the payment line item.

**Signature**
public RichMessaging.PaymentItemStatus statusValue {get; set;}

**Property Value**
Type: RichMessaging.PaymentItemStatus

**timing**
The timing of the payment line item.

**Signature**
public RichMessaging.AbstractTiming timing {get; set;}

**Property Value**
Type: RichMessaging.AbstractTiming

**timingValue**
The timing value of the payment line item.
Signature

public RichMessaging.AbstractTiming timingValue {get; set;}

Property Value

Type: RichMessaging.AbstractTiming

PaymentLineItem Methods

The following are methods for PaymentLineItem.

PaymentMethod Class

Represents a payment method.

Namespace

RichMessaging

IN THIS SECTION:

PaymentMethod Constructors
PaymentMethod Properties

PaymentMethod Constructors

The following are constructors for PaymentMethod.

IN THIS SECTION:

PaymentMethod(network, paymentType, displayName)

PaymentMethod(network, paymentType, displayName)

Signature

public PaymentMethod(String network, String paymentType, String displayName)

Parameters

network
Type: String
The network associated with the payment method.

paymentType
Type: String
The payment type of the payment method.

**displayName**
Type: String
The display name of the payment method.

**PaymentMethod Properties**
The following are properties for **PaymentMethod**.

**IN THIS SECTION:**
- **displayName**
  The display name of the payment method.
- **network**
  The network associated with the payment method.
- **paymentType**
  The payment type of the payment method.

**displayName**
The display name of the payment method.

**Signature**
```java
public String displayName {get; set;}
```

**Property Value**
Type: String

**network**
The network associated with the payment method.

**Signature**
```java
public String network {get; set;}
```

**Property Value**
Type: String

**paymentType**
The payment type of the payment method.

**Signature**
```java
public String paymentType {get; set;}
```
PostalAddress Class

Represents the postal address.

Namespace

RichMessaging

PostalAddress Constructors

The following are constructors for PostalAddress.

PostalAddress(addressLines, subLocality, locality, postalCode, subAdministrativeArea, administrativeArea, country, countryCode)

Creates a new instance of the RichMessaging.PostalAddress class.

Signature

public PostalAddress(List<String> addressLines, String subLocality, String locality, String postalCode, String subAdministrativeArea, String administrativeArea, String country, String countryCode)

Parameters

addressLines
Type: List<String>
The street address.

subLocality
Type: String
The sub-locality of the address.

locality
Type: String
The locality of the address.
PostalAddress Properties

The following are properties for PostalAddress.

IN THIS SECTION:
  addressLines
  The street address.
  administrativeArea
  The administrative area.
  country
  The country.
  countryCode
  The country code.
  locality
  The locality of the address.
  postalCode
  The postal code.
  subAdministrativeArea
  The sub-administrative area.
  subLocality
  The sub-locality of the address.

addressLines
The street address.
Signature
public List<String> addressLines {get; set;}

Property Value
Type: List<String>

administrativeArea
The administrative area.

Signature
public String administrativeArea {get; set;}

Property Value
Type: String

country
The country.

Signature
public String country {get; set;}

Property Value
Type: String

countryCode
The country code.

Signature
public String countryCode {get; set;}

Property Value
Type: String

locality
The locality of the address.

Signature
public String locality {get; set;}

2680
Property Value
Type: String

**postalCode**
The postal code.

Signature
public String postalCode {get; set;}

Property Value
Type: String

**subAdministrativeArea**
The sub-administrative area.

Signature
public String subAdministrativeArea {get; set;}

Property Value
Type: String

**subLocality**
The sub-locality of the address.

Signature
public String subLocality {get; set;}

ProcessPaymentHandler Interface
Interface used to process payment requests.

Namespace
RichMessaging

IN THIS SECTION:
  ProcessPaymentHandler Methods
ProcessPaymentHandler Example Implementation

ProcessPaymentHandler Methods
The following are methods for ProcessPaymentHandler.

IN THIS SECTION:

processPaymentRequest(var1)
Processes a payment request.

processPaymentRequest(var1)
Processes a payment request.

Signature
public RichMessaging.ProcessPaymentResult
processPaymentRequest(RichMessaging.ProcessPaymentRequest var1)

Parameters
var1
Type: RichMessaging.ProcessPaymentRequest
The payment request.

Return Value
Type: RichMessaging.ProcessPaymentResult

ProcessPaymentRequest Class
Represents a request to process a payment.
Namespace

RichMessaging

IN THIS SECTION:

ProcessPaymentRequest Constructors
ProcessPaymentRequest Properties

ProcessPaymentRequest Constructors

The following are constructors for ProcessPaymentRequest.

IN THIS SECTION:

ProcessPaymentRequest(transactionIdentifier, paymentData, billingContact, shippingContact, paymentMethod, shippingMethod, contextRecordId)

ProcessPaymentRequest(transactionIdentifier, paymentData, billingContact, shippingContact, paymentMethod, shippingMethod, contextRecordId)

Signature

Parameters

transactionIdentifier
Type: String
The transaction identifier associated with the payment request.

paymentData
Type: String
The encrypted payment data for the payment request.

billingContact
Type: RichMessaging.AddressableContact
The billing contact information for the payment request.

shippingContact
Type: RichMessaging.AddressableContact
The shipping contact information for the payment request.

paymentMethod
Type: RichMessaging.PaymentMethod
The payment method for the payment request.

shippingMethod
Type: RichMessaging.ShippingMethod
The shipping method for the payment request.

contextRecordId
Type: String
The context record ID associated with the payment request.

ProcessPaymentRequest Properties
The following are properties for ProcessPaymentRequest.

IN THIS SECTION:

  billingContact
  The billing contact information for the payment request.

  contextRecordId
  The context record ID associated with the payment request.

  paymentData
  The encrypted payment data for the payment request.

  paymentMethod
  The payment method for the payment request.

  shippingContact
  The shipping contact information for the payment request.

  shippingMethod
  The shipping method for the payment request.

  transactionIdentifier
  The transaction identifier associated with the payment request.

billingContact
The billing contact information for the payment request.

Signature

public RichMessaging.AddressableContact billingContact {get; set;}

Property Value
Type: RichMessaging.AddressableContact

contextRecordId
The context record ID associated with the payment request.
Signature
public String contextRecordId {get; set;}

Property Value
Type: String

paymentData
The encrypted payment data for the payment request.

Signature
public String paymentData {get; set;}

Property Value
Type: String

paymentMethod
The payment method for the payment request.

Signature
public RichMessaging.PaymentMethod paymentMethod {get; set;}

Property Value
Type: RichMessaging.PaymentMethod

shippingContact
The shipping contact information for the payment request.

Signature
public RichMessaging.AddressableContact shippingContact {get; set;}

Property Value
Type: RichMessaging.AddressableContact

shippingMethod
The shipping method for the payment request.

Signature
public RichMessaging.ShippingMethod shippingMethod {get; set;}

2685
Property Value
Type: RichMessaging.ShippingMethod

**transactionIdentifier**
The transaction identifier associated with the payment request.

**Signature**
public String transactionIdentifier {get; set;}

Property Value
Type: String

## ProcessPaymentResult Class
Represents the result of a payment processing operation.

### Namespace
RichMessaging

### IN THIS SECTION:
- ProcessPaymentResult Constructors
- ProcessPaymentResult Properties

### ProcessPaymentResult Constructors
The following are constructors for ProcessPaymentResult.

**IN THIS SECTION:**
- ProcessPaymentResult(resultStatus, errorMessage)
- ProcessPaymentResult(resultStatus)

### ProcessPaymentResult (resultStatus, errorMessage)

**Signature**
public ProcessPaymentResult (RichMessaging.ProcessPaymentResultStatus resultStatus, String errorMessage)
Parameters

resultStatus
  Type: RichMessaging.ProcessPaymentResultStatus
  The status of the payment processing result.

errorMessage
  Type: String
  The error message associated with the payment processing result, if any.

ProcessPaymentResult (resultStatus)

Signature

public ProcessPaymentResult (RichMessaging.ProcessPaymentResultStatus resultStatus)

Parameters

resultStatus
  Type: RichMessaging.ProcessPaymentResultStatus
  The status of the payment processing result.

ProcessPaymentResult Properties

The following are properties for ProcessPaymentResult.

IN THIS SECTION:
  errorMessage
  The error message associated with the payment processing result, if any.
  resultStatus
  The status of the payment processing result.

errorMessage

The error message associated with the payment processing result, if any.

Signature

public String errorMessage {get; set;}

Property Value

Type: String

resultStatus

The status of the payment processing result.
Signature

```
public RichMessaging.ProcessPaymentResultStatus resultStatus {get; set;}
```

Property Value

Type: `RichMessaging.ProcessPaymentResultStatus`

**ProcessPaymentResultStatus Enum**

Represents the status of a payment processing result.

**Enum Values**

The following are the values of the `RichMessaging.ProcessPaymentResultStatus` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROCESSOR_ERROR</td>
<td>Indicates an error occurred during payment processing at the processor level.</td>
</tr>
<tr>
<td>SUCCESS</td>
<td>Indicates a successful payment processing result.</td>
</tr>
</tbody>
</table>

**RecurringTiming Class**

Represents a payment that occurs on a regular basis.

**Namespace**

`RichMessaging`

**IN THIS SECTION:**

- RecurringTiming Constructors
- RecurringTiming Properties

**RecurringTiming Constructors**

The following are constructors for `RecurringTiming`.

**IN THIS SECTION:**

- `RecurringTiming(startDate, endDate, intervalCount, intervalUnit)`
- `RecurringTiming()`

`RecurringTiming(startDate, endDate, intervalCount, intervalUnit)`

Signature

public RecurringTiming(Date startDate, Date endDate, Integer intervalCount, RichMessaging.TimingIntervalUnit intervalUnit)

Parameters

startDate
Type: Date
The start date. Invocable variable.

endDate
Type: Date
The end date. Invocable variable.

intervalCount
Type: Integer
The number of interval units that make up the total payment interval. Invocable variable.

intervalUnit
Type: RichMessaging.TimingIntervalUnit
The amount of time—in calendar units, such as day, month, or year—that represents a fraction of the total payment interval. Invocable variable.

RecurringTiming()

Signature

public RecurringTiming()

RecurringTiming Properties

The following are properties for RecurringTiming.

IN THIS SECTION:

endDate
The end date. Invocable variable.

endDateValue
The end date. Enabled for Lightning components.

intervalCount
The number of interval units that make up the total payment interval. Invocable variable.

intervalCountValue
The number of interval units that make up the total payment interval. Enabled for Lightning components.

intervalUnit
The amount of time—in calendar units, such as day, month, or year—that represents a fraction of the total payment interval. Invocable variable.
intervalUnitValue
The amount of time—in calendar units, such as day, month, or year—that represents a fraction of the total payment interval. Enabled for Lightning components.

startDate
The start date. Invocable variable.

startDateValue
The start date. Enabled for Lightning components.

timingType
Always returns “RecurringTiming”.

endDate
The end date. Invocable variable.

Signature
generic Date endDate {get; set;}

Property Value
Type: Date

endDateValue
The end date. Enabled for Lightning components.

Signature
generic Date endDateValue {get; set;}

Property Value
Type: Date

intervalCount
The number of interval units that make up the total payment interval. Invocable variable.

Signature
generic Integer intervalCount {get; set;}

Property Value
Type: Integer

intervalCountValue
The number of interval units that make up the total payment interval. Enabled for Lightning components.
**Signature**

```java
public Integer intervalCountValue {get; set;}
```

**Property Value**

Type: `Integer`

---

**intervalUnit**

The amount of time—in calendar units, such as day, month, or year—that represents a fraction of the total payment interval. Invocable variable.

**Signature**

```java
public String intervalUnit {get; set;}
```

**Property Value**

Type: `String`

---

**intervalUnitValue**

The amount of time—in calendar units, such as day, month, or year—that represents a fraction of the total payment interval. Enabled for Lightning components.

**Signature**

```java
public RichMessaging.TimingIntervalUnit intervalUnitValue {get; set;}
```

**Property Value**

Type: `RichMessaging.TimingIntervalUnit`

---

**startDate**

The start date. Invocable variable.

**Signature**

```java
public Date startDate {get; set;}
```

**Property Value**

Type: `Date`

---

**startDateValue**

The start date. Enabled for Lightning components.
Signature

```java
public Date startDateValue {get; set;}
```

Property Value

Type: Date

**timingType**

Always returns “RecurringTiming”.

Signature

```java
public String timingType {get; set;}
```

Property Value

Type: String

**ShippingMethod Class**

Represents a shipping method listed in payment requests sent in enhanced Messaging channels.

**Namespace**

RichMessaging

**Example**

```java
public with sharing class MessagingShippingMethods {
    @InvocableMethod
    public static List<List<RichMessaging.ShippingMethod>> getShippingMethods(){
        Double amount = 0.25;
            new RichMessaging.ShippingMethod('doordash', amount, '1 hour delivery to your door', 'ddash'),
            new RichMessaging.ShippingMethod('UPS', amount, '2 days delivery', 'UPS')
        };
        result.add(options);
        return result;
    }
}
```
ShippingMethod Constructors

The following are constructors for ShippingMethod.

ShippingMethod(label, amount, detail, identifier)

Signature

public ShippingMethod(String label, Double amount, String detail, String identifier)

Parameters

label
Type: String
The label of the shipping method.

amount
Type: Double
The amount of the shipping method.

detail
Type: String
Details about the shipping method.

identifier
Type: String
The identifier of the shipping method.

ShippingMethod()

Signature

public ShippingMethod()
ShippingMethod Properties
The following are properties for ShippingMethod.

IN THIS SECTION:
  amount
  The amount of the shipping method.
  amountValue
  The amount value of the shipping method.
  detail
  Details about the shipping method.
  detailValue
  The detail value of the shipping method.
  identifier
  The identifier of the shipping method.
  identifierValue
  The identifier value of the shipping method.
  label
  The label of the shipping method.
  labelValue
  The label value of the shipping method.
  shippingMethodType
  The shipping method type. Read only.

amount
The amount of the shipping method.

Signature
public Double amount {get; set;}

Property Value
Type: Double

amountValue
The amount value of the shipping method.

Signature
public Double amountValue {get; set;}
Property Value
Type: Double

detail
Details about the shipping method.

Signature
public String detail {get; set;}

Property Value
Type: String

detailValue
The detail value of the shipping method.

Signature
public String detailValue {get; set;}

Property Value
Type: String

identifier
The identifier of the shipping method.

Signature
public String identifier {get; set;}

Property Value
Type: String

identifierValue
The identifier value of the shipping method.

Signature
public String identifierValue {get; set;}

Property Value
Type: String
**label**
The label of the shipping method.

**Signature**
public String label {get; set;}

**Property Value**
Type: String

**labelValue**
The label value of the shipping method.

**Signature**
public String labelValue {get; set;}

**Property Value**
Type: String

**shippingMethodType**
The shipping method type. Read only.

**Signature**
public String shippingMethodType {get; set;}

**Property Value**
Type: String

**TimeSlotOption Class**
Represents a complex time slot option type. This class is used to provide time option payloads that can be translated to structured content payloads in rich content messages.

**Namespace**
RichMessaging

IN THIS SECTION:
  - TimeSlotOption Constructors
  - TimeSlotOption Properties
TimeSlotOption Constructors

The following are constructors for TimeSlotOption.

IN THIS SECTION:

TimeSlotOption(startTime, endTime)
Creates a TimeSlotOption object with a start and end time.

TimeSlotOption(startTime, duration)
Creates a TimeSlotOption object with a start time and a duration.

TimeSlotOption()
Creates a TimeSlotOption object.

TimeSlotOption(startTime, endTime)

Creates a TimeSlotOption object with a start and end time.

Signature

public TimeSlotOption(Datetime startTime, Datetime endTime)

Parameters

startTime
Type: Datetime
Start time.

endTime
Type: Datetime
End time.

TimeSlotOption(startTime, duration)

Creates a TimeSlotOption object with a start time and a duration.

Signature

public TimeSlotOption(Datetime startTime, Integer duration)

Parameters

startTime
Type: Datetime
Start time.

duration
Type: Integer
Duration in seconds.
**TimeSlotOption()**

Creates a `TimeSlotOption` object.

**Signature**

```java
public TimeSlotOption()
```

**TimeSlotOption Properties**

The following are properties for `TimeSlotOption`.

**IN THIS SECTION:**

- `duration`
  - The duration in seconds.

- `durationValue`
  - The duration in seconds. Enabled for Lightning components.

- `endTimeValue`
  - The end time. Enabled for Lightning components.

- `startTime`
  - The start time.

- `startTimeValue`
  - The start time. Enabled for Lightning components.

**duration**

The duration in seconds.

**Signature**

```java
public Integer duration {get; set;}
```

**Property Value**

Type: `Integer`

**durationValue**

The duration in seconds. Enabled for Lightning components.

**Signature**

```java
public Integer durationValue {get; set;}
```

**Property Value**

Type: `Integer`
**endTimeValue**
The end time. Enabled for Lightning components.

**Signature**
public Datetime endTimeValue {get; set;}

**Property Value**
Type: Datetime

**startTime**
The start time.

**Signature**
public Datetime startTime {get; set;}

**Property Value**
Type: Datetime

**startTimeValue**
The start time. Enabled for Lightning components.

**Signature**
public Datetime startTimeValue {get; set;}

**Property Value**
Type: Datetime

## TimingIntervalUnit Enum
Represents an enumerated type that describes the timing interval.

### Enum Values
The following are the values of the RichMessaging.TimingIntervalUnit enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Day</td>
<td>Day interval.</td>
</tr>
<tr>
<td>Hour</td>
<td>Hour interval.</td>
</tr>
<tr>
<td>Minute</td>
<td>Minute interval.</td>
</tr>
</tbody>
</table>
TimingType Enum

Represents an enumerated type that describes the type of timing.

Enum Values

The following are the values of the RichMessaging.TimingType enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DeferredTiming</td>
<td>Indicates that the timing is deferred. See DeferredTiming Class.</td>
</tr>
<tr>
<td>RecurringTiming</td>
<td>Indicates that the timing recurs. See RecurringTiming Class.</td>
</tr>
</tbody>
</table>

Schema Namespace

The Schema namespace provides classes and methods for schema metadata information.

The following are the classes in the Schema namespace.

IN THIS SECTION:

- ChildRelationship Class
  Contains methods for accessing the child relationship as well as the child sObject for a parent sObject.

- DataCategory Class
  Represents the categories within a category group.

- DataCategoryGroupSObjectTypePair Class
  Specifies a category group and an associated object.

- DescribeColorResult Class
  Contains color metadata information for a tab.

- DescribeDataCategoryGroupResult Class
  Contains the list of the category groups associated with KnowledgeArticleVersion and Question.

- DescribeDataCategoryGroupStructureResult Class
  Contains the category groups and categories associated with KnowledgeArticleVersion and Question.

- DescribeFieldResult Class
  Contains methods for describing sObject fields.

- DescribeIconResult Class
  Contains icon metadata information for a tab.
DescribeSObjectResult Class
Contains methods for describing SObjects. None of the methods take an argument.

DescribeTabResult Class
Contains tab metadata information for a tab in a standard or custom app available in the Salesforce user interface.

DescribeTabSetResult Class
Contains metadata information about a Salesforce Classic standard or custom app available in the Salesforce user interface.

DisplayType Enum
A Schema.DisplayType enum value is returned by the field describe result's getType method.

FieldDescribeOptions Enum
A Schema.FieldDescribeOptions enum value is a parameter in the SObjectType.getDescribe method.

FieldSet Class
Contains methods for discovering and retrieving the details of field sets created on sObjects.

FieldSetMember Class
Contains methods for accessing the metadata for field set member fields.

PicklistEntry Class
Represents a picklist entry.

RecordTypeInfo Class
Contains methods for accessing record type information for an sObject with associated record types.

SOAPType Enum
A Schema.SOAPType enum value is returned by the field describe result getSoapType method.

SObjectDescribeOptions Enum
A Schema.SObjectDescribeOptions enum value is a parameter in the SObjectType.getDescribe method.

SObjectField Class
A Schema.sObjectField object is returned from the field describe result using the getController and getSObjectField methods.

SObjectType Class
A Schema.sObjectType object is returned from the field describe result using the getReferenceTo method, or from the sObject describe result using the getSObjectType method.

ChildRelationship Class
Contains methods for accessing the child relationship as well as the child sObject for a parent sObject.

Namespace
Schema

Example
A ChildRelationship object is returned from the sObject describe result using the getChildRelationship method. For example:

```java
Schema.DescribeSObjectResult R = Account.SObjectType.getDescribe();
```
**ChildRelationship Methods**

The following are methods for `ChildRelationship`. All are instance methods.

**IN THIS SECTION:**

- `getChildSObject()`: Returns the token of the child sObject on which there is a foreign key back to the parent sObject.
- `getField()`: Returns the token of the field that has a foreign key back to the parent sObject.
- `getRelationshipName()`: Returns the name of the relationship.
- `isCascadeDelete()`: Returns `true` if the child object is deleted when the parent object is deleted, `false` otherwise.
- `is DeprecatedAndHidden()`: Reserved for future use.
- `isRestrictedDelete()`: Returns `true` if the parent object can't be deleted because it is referenced by a child object, `false` otherwise.

### `getChildSObject()`

Returns the token of the child sObject on which there is a foreign key back to the parent sObject.

**Signature**

```
public Schema.SObjectType getChildSObject()
```

**Return Value**

Type: `Schema.SObjectType`

### `getField()`

Returns the token of the field that has a foreign key back to the parent sObject.

**Signature**

```
public Schema.SObjectField getField()
```

**Return Value**

Type: `Schema.SObjectField`

### `getRelationshipName()`

Returns the name of the relationship.
**Signature**

```java
public String getRelationshipName()
```

**Return Value**

Type: String

**isCascadeDelete()**

Returns `true` if the child object is deleted when the parent object is deleted, `false` otherwise.

**Signature**

```java
public Boolean isCascadeDelete()
```

**Return Value**

Type: Boolean

**isDeprecatedAndHidden()**

Reserved for future use.

**Signature**

```java
public Boolean isDeprecatedAndHidden()
```

**Return Value**

Type: Boolean

**isRestrictedDelete()**

Returns `true` if the parent object can’t be deleted because it is referenced by a child object, `false` otherwise.

**Signature**

```java
public Boolean isRestrictedDelete()
```

**Return Value**

Type: Boolean

---

**DataCategory Class**

Represents the categories within a category group.

**Namespace**

Schema
Usage

The Schema.DataCategory object is returned by the getTopCategories method.

DataCategory Methods

The following are methods for DataCategory. All are instance methods.

IN THIS SECTION:

getChildCategories()
Returns a recursive object that contains the visible sub categories in the data category.

getLabel()
Returns the label for the data category used in the Salesforce user interface.

getName()
Returns the unique name used by the API to access to the data category.

getChildCategories()

Returns a recursive object that contains the visible sub categories in the data category.

Signature

public Schema.DataCategory getChildCategories()

Return Value

Type: List<Schema.DataCategory>

getLabel()

Returns the label for the data category used in the Salesforce user interface.

Signature

public String getLabel()

Return Value

Type: String

getName()

Returns the unique name used by the API to access to the data category.

Signature

public String getName()
Return Value
Type: String

DataCategoryGroupSobjectTypePair Class
Specifies a category group and an associated object.

Namespace
Schema

Usage
Schema.DataCategoryGroupSobjectTypePair is used by the describeDataCategory GroupStructures method to return the categories available to this object.

IN THIS SECTION:
DataCategoryGroupSobjectTypePair Constructors
DataCategoryGroupSobjectTypePair Methods

DataCategoryGroupSobjectTypePair Constructors
The following are constructors for DataCategoryGroupSobjectTypePair.

IN THIS SECTION:
DataCategoryGroupSobjectTypePair()
Creates a new instance of the Schema.DataCategoryGroupSobjectTypePair class.

DataCategoryGroupSobjectTypePair()
Creates a new instance of the Schema.DataCategoryGroupSobjectTypePair class.

Signature
public DataCategoryGroupSobjectTypePair()

DataCategoryGroupSobjectTypePair Methods
The following are methods for DataCategoryGroupSobjectTypePair. All are instance methods.

IN THIS SECTION:
getDataCategoryGroupName() Returns the unique name used by the API to access the data category group.
getSobject() Returns the object name associated with the data category group.
setDataCategoryGroupName(name)
Specifies the unique name used by the API to access the data category group.

setSobject(sObjectName)
Sets the sObject associated with the data category group.

getDataCategoryGroupName()
Returns the unique name used by the API to access the data category group.

Signature
public String getDataCategoryGroupName()

Return Value
Type: String

getSobject()
Returns the object name associated with the data category group.

Signature
public String getSobject()

Return Value
Type: String

setDataCategoryGroupName(name)
Specifies the unique name used by the API to access the data category group.

Signature
public String setDataCategoryGroupName(String name)

Parameters
name
Type: String

Return Value
Type: Void

setSobject(sObjectName)
Sets the sObject associated with the data category group.
Signature

public Void setSobject(String sObjectName)

Parameters

sObjectName
Type: String

The sObjectName is the object name associated with the data category group. Valid values are:

- KnowledgeArticleVersion—for article types.
- Question—for questions from Answers.

Return Value
Type: Void

DescribeColorResult Class

Contains color metadata information for a tab.

Namespace

Schema

Usage

The getColors method of the Schema.DescribeTabResult class returns a list of Schema.DescribeColorResult objects that describe colors used in a tab.

The methods in the Schema.DescribeColorResult class can be called using their property counterparts. For each method starting with get, you can omit the get prefix and the ending parentheses () to call the property counterpart. For example, colorResultObj.color is equivalent to colorResultObj.getColor().

Example

This sample shows how to get the color information in the Sales app for the first tab's first color.

```apex
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.DescribeTabs();

// Iterate through each tab set describe for each app and display the info
for (Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Display tab info for the Sales app
    if (tsr.getLabel() == 'Sales') {
        // Get color information for the first tab
        List<Schema.DescribeColorResult> colorDesc = tsr.getTabs()[0].getColors();
        // Display the icon color, theme, and context of the first color returned
        System.debug('Color: ' + colorDesc[0].getColor());
        System.debug('Theme: ' + colorDesc[0].getTheme());
        System.debug('Context: ' + colorDesc[0].getContext());
    }
}
DescribeColorResult Methods

The following are methods for DescribeColorResult. All are instance methods.

IN THIS SECTION:

getColor()
Returns the Web RGB color code, such as 00FF00.

getContext()
Returns the color context. The context determines whether the color is the main color for the tab or not.

getTheme()
Returns the color theme.

gColor()
Returns the Web RGB color code, such as 00FF00.

Signature

public String getColor()

Return Value
Type: String

gContext()
Returns the color context. The context determines whether the color is the main color for the tab or not.

Signature

public String getContext()

Return Value
Type: String

gTheme()
Returns the color theme.
public String getTheme()

Return Value
Type: String
Possible theme values include theme3, theme4, and custom.

- theme3 is the Salesforce theme introduced during Spring ’10.
- theme4 is the Salesforce theme introduced in Winter ’14 for the mobile touchscreen version of Salesforce.
- custom is the theme name associated with a custom icon.

DescribeDataCategoryGroupResult Class
Contains the list of the category groups associated with KnowledgeArticleVersion and Question.

Namespace
Schema

Usage
The describeDataCategoryGroups method returns a Schema.DescribeDataCategoryGroupResult object containing the list of the category groups associated with the specified object.

For additional information and code examples using describeDataCategoryGroups, see Accessing All Data Categories Associated with an sObject.

Example
The following is an example of how to instantiate a data category group describe result object:

```java
List<String> objType = new List<String>();
objType.add('KnowledgeArticleVersion');
objType.add('Question');

List<Schema.DescribeDataCategoryGroupResult> describeCategoryResult =
    Schema.describeDataCategoryGroups(objType);
```

DescribeDataCategoryGroupResult Methods
The following are methods for DescribeDataCategoryGroupResult. All are instance methods.

IN THIS SECTION:
- getCategoryCount()
  Returns the number of visible data categories in the data category group.
- getDescription()
  Returns the description of the data category group.
getLabel()
Returns the label for the data category group used in the Salesforce user interface.

getName()
Returns the unique name used by the API to access to the data category group.

getSobject()
Returns the object name associated with the data category group.

getCategoryCount()
Returns the number of visible data categories in the data category group.

**Signature**

```java
public Integer getCategoryCount()
```

**Return Value**

Type: Integer

ggetDescription()
Returns the description of the data category group.

**Signature**

```java
public String getDescription()
```

**Return Value**

Type: String

getLabel()
Returns the label for the data category group used in the Salesforce user interface.

**Signature**

```java
public String getLabel()
```

**Return Value**

Type: String

getName()
Returns the unique name used by the API to access to the data category group.

**Signature**

```java
public String getName()
```
Return Value
Type: String

getSobject()
Returns the object name associated with the data category group.

Signature
public String getSobject()

Return Value
Type: String

DescribeDataCategoryGroupStructureResult Class
Contains the category groups and categories associated with KnowledgeArticleVersion and Question.

Namespace
Schema

Usage
The describeDataCategoryGroupStructures method returns a list of Schema.DescribeDataCategoryGroupStructureResult objects containing the category groups and categories associated with the specified object. For additional information and code examples, see Accessing All Data Categories Associated with an sObject.

Example
The following is an example of how to instantiate a data category group structure describe result object:

```java
List<DataCategoryGroupSobjectTypePair> pairs =
    new List<DataCategoryGroupSobjectTypePair>();

DataCategoryGroupSobjectTypePair pair1 =
    new DataCategoryGroupSobjectTypePair();
pair1.setSobject('KnowledgeArticleVersion');
pair1.setDataCategoryGroupName('Regions');

DataCategoryGroupSobjectTypePair pair2 =
    new DataCategoryGroupSobjectTypePair();
pair2.setSobject('Questions');
pair2.setDataCategoryGroupName('Regions');

pairs.add(pair1);
pairs.add(pair2);
```
DescribeDataCategoryGroupStructureResult Methods

The following are methods for DescribeDataCategoryGroupStructureResult. All are instance methods.

IN THIS SECTION:
- getDescription()
- getLabel()
- getName()
- getSobject()
- getTopCategories()

getDescription()

Returns the description of the data category group.

Signature

public String getDescription()

Return Value

Type: String

getLabel()

Returns the label for the data category group used in the Salesforce user interface.

Signature

public String getLabel()

Return Value

Type: String

getName()

Returns the unique name used by the API to access to the data category group.

Signature

public String getName()

Return Value

Type: String

getTopCategories()

Returns a Schema.DataCategory object, that contains the top categories visible depending on the user's data category group visibility settings.

Signature

public List<Schema.DataCategory> getTopCategories()

Return Value

Type: List<Schema.DataCategory>
**Signature**

```java
public String getName()
```

**Return Value**

Type: String

**getSobject()**

Returns the name of object associated with the data category group.

**Signature**

```java
public String getSobject()
```

**Return Value**

Type: String

**getTopCategories()**

Returns a `Schema.DataCategory` object, that contains the top categories visible depending on the user's data category group visibility settings.

**Signature**

```java
public List<Schema.DataCategory> getTopCategories()
```

**Return Value**

Type: `List<Schema.DataCategory>`

**Usage**

For more information on data category group visibility, see “Data Category Visibility” in the Salesforce online help.

**DescribeFieldResult Class**

Contains methods for describing sObject fields.

**Namespace**

`Schema`

**Usage**

Instances of field describe results on the same `DescribeFieldResult` aren't guaranteed to be equal because the state and behavior of a describe object is determined by various factors including the API version used. To compare describe results, call the
getSObjectField() method on the field describe results and use the equality operator (==) to compare the SObjectField values.

Example

The following is an example of how to instantiate a field describe result object:

```java
Schema.DescribeFieldResult dfr = Account.Description.getDescribe();
```

DescribeFieldResult Methods

The following are methods for DescribeFieldResult. All are instance methods.

IN THIS SECTION:

- `getByteLength()`: For variable-length fields (including binary fields), returns the maximum size of the field, in bytes.
- `getCalculatedFormula()`: Returns the formula specified for this field.
- `getController()`: Returns the token of the controlling field.
- `getDefaultValue()`: Returns the default value for this field.
- `getDefaultValueFormula()`: Returns the default value specified for this field if a formula is not used.
- `getDigits()`: Returns the maximum number of digits specified for the field. This method is only valid with Integer fields.
- `getInlineHelpText()`: Returns the content of the field-level help.
- `getLabel()`: Returns the text label that is displayed next to the field in the Salesforce user interface. This label can be localized.
- `getLength()`: Returns the maximum size of the field for the DescribeFieldResult object in Unicode characters (not bytes).
- `getLocalName()`: Returns the name of the field, similar to the `getName` method. However, if the field is part of the current namespace, the namespace portion of the name is omitted.
- `getName()`: Returns the field name used in Apex.
- `getPicklistValues()`: Returns a list of PicklistEntry objects. A runtime error is returned if the field is not a picklist.
- `getPrecision()`: For fields of type Double, returns the maximum number of digits that can be stored, including all numbers to the left and to the right of the decimal point (but excluding the decimal point character).
getReferenceTargetField()
Returns the name of the custom field on the parent standard or custom object whose values are matched against the values of the child external object’s indirect lookup relationship field. The match is done to determine which records are related to each other.

gerReferenceTo()
Returns a list of Schema.sObjectType objects for the parent objects of this field. If the isNamePointing method returns true, there is more than one entry in the list, otherwise there is only one.

gerRelationshipName()
Returns the name of the relationship.

gerRelationshipOrder()
Returns 1 if the field is a child, 0 otherwise.

gerScale()
For fields of type Double, returns the number of digits to the right of the decimal point. Any extra digits to the right of the decimal point are truncated.

gerSOAPType()
Returns one of the SoapType enum values, depending on the type of field.

gerSObjectField()
Returns the token for this field.

gerSObjectType()
Returns the Salesforce object type from which this field originates.

gerType()
Returns one of the DisplayType enum values, depending on the type of field.

isAccessible()
Returns true if the current user can see this field, false otherwise.

isAiPredictionField() (Beta)
Returns true if the current field is enabled to display Einstein prediction data, false otherwise.

isAutoNumber()
Returns true if the field is an Auto Number field, false otherwise.

isCalculated()
Returns true if the field is a custom formula field, false otherwise. Note that custom formula fields are always read-only.

isCascadeDelete()
Returns true if the child object is deleted when the parent object is deleted, false otherwise.

isCaseSensitive()
Returns true if the field is case sensitive, false otherwise.

isCreateable()
Returns true if the field can be created by the current user, false otherwise.

isCustom()
Returns true if the field is a custom field, false if it is a standard field, such as Name.

isDefaultedOnCreate()
Returns true if the field receives a default value when created, false otherwise.

isDependentPicklist()
Returns true if the picklist is a dependent picklist, false otherwise.
isDeprecatedAndHidden()
Reserved for future use.

isEncrypted()
Returns true if the field is encrypted with Shield Platform Encryption, false otherwise.

isExternalId()
Returns true if the field is used as an external ID, false otherwise.

isFilterable()
Returns true if the field can be used as part of the filter criteria of a WHERE statement, false otherwise.

isFormulaTreatNullNumberAsZero()
Returns true if null is treated as zero in a formula field, false otherwise.

isGroupable()
Returns true if the field can be included in the GROUP BY clause of a SOQL query, false otherwise. This method is only available for Apex classes and triggers saved using API version 18.0 and higher.

isHtmlFormatted()
Returns true if the field has been formatted for HTML and should be encoded for display in HTML, false otherwise. One example of a field that returns true for this method is a hyperlink custom formula field. Another example is a custom formula field that has an IMAGE text function.

isIdLookup()
Returns true if the field can be used to specify a record in an upsert method, false otherwise.

isNameField()
Returns true if the field is a name field, false otherwise.

isNamePointing()
Returns true if the field can have multiple types of objects as parents. For example, a task can have both the Contact/Lead ID (WhoId) field and the Opportunity/Account ID (WhatId) field return true for this method, because either of those objects can be the parent of a particular task record. This method returns false otherwise.

isNillable()
Returns true if the field is nillable, false otherwise. A nillable field can have empty content. A non-nillable field must have a value for the object to be created or saved.

isPermissionable()
Returns true if field permissions can be specified for the field, false otherwise.

isRestrictedDelete()
Returns true if the parent object can't be deleted because it is referenced by a child object, false otherwise.

isRestrictedPicklist()
Returns true if the field is a restricted picklist, false otherwise.

isSearchPrefilterable()
Returns true if a foreign key can be included in prefiltering when used in a SOSL WHERE clause, false otherwise.

isSortable()
Returns true if a query can sort on the field, false otherwise.

isUnique()
Returns true if the value for the field must be unique, false otherwise.
isUpdateable()  
Returns true if the field can be edited by the current user, or child records in a master-detail relationship field on a custom object can be reparented to different parent records; false otherwise.

isWriteRequiresMasterRead()  
Returns true if writing to the detail object requires read sharing instead of read/write sharing of the parent.

getByteLength()  
For variable-length fields (including binary fields), returns the maximum size of the field, in bytes.

Signature  
public Integer getByteLength()

Return Value  
Type: Integer

getCalculatedFormula()  
Returns the formula specified for this field.

Signature  
public String getCalculatedFormula()

Return Value  
Type: String

getController()  
Returns the token of the controlling field.

Signature  
public Schema.sObjectField getController()

Return Value  
Type: Schema.SObjectField

getDefaultValue()  
Returns the default value for this field.

Signature  
public Object getDefaultValue()
Return Value
Type: Object

getDefaultValueFormula()  
Returns the default value specified for this field if a formula is not used.

Signature
public String getDefaultValueFormula()

Return Value
Type: String

getDigits()  
Returns the maximum number of digits specified for the field. This method is only valid with Integer fields.

Signature
public Integer getDigits()

Return Value
Type: Integer

getInlineHelpText()  
Returns the content of the field-level help.

Signature
public String getInlineHelpText()

Return Value
Type: String

Usage
For more information, see “Define Field-Level Help” in the Salesforce online help.

getLabel()  
Returns the text label that is displayed next to the field in the Salesforce user interface. This label can be localized.

Signature
public String getLabel()
Return Value
Type: String

Usage

Note: For the Type field on standard objects, getLabel returns a label different from the default label. It returns a label of the form Object Type, where Object is the standard object label. For example, for the Type field on Account, getLabel returns Account Type instead of the default label Type. If the Type label is renamed, getLabel returns the new label. You can check or change the labels of all standard object fields from Setup by entering Rename Tabs and Labels in the Quick Find box, then selecting Rename Tabs and Labels.

**getLength()**
Returns the maximum size of the field for the DescribeFieldResult object in Unicode characters (not bytes).

Signature

```java
public Integer getLength()
```

**Return Value**
Type: Integer

**getLocalName()**
Returns the name of the field, similar to the getName method. However, if the field is part of the current namespace, the namespace portion of the name is omitted.

Signature

```java
public String getLocalName()
```

**Return Value**
Type: String

**getName()**
Returns the field name used in Apex.

Signature

```java
public String getName()
```

**Return Value**
Type: String
getPicklistValues()
Returns a list of PicklistEntry objects. A runtime error is returned if the field is not a picklist.

Signature
public List<Schema.PicklistEntry> getPicklistValues()

Return Value
Type: List<Schema.PicklistEntry>

getPrecision()
For fields of type Double, returns the maximum number of digits that can be stored, including all numbers to the left and to the right of the decimal point (but excluding the decimal point character).

Signature
public Integer getPrecision()

Return Value
Type: Integer

getReferenceTargetField()
Returns the name of the custom field on the parent standard or custom object whose values are matched against the values of the child external object’s indirect lookup relationship field. The match is done to determine which records are related to each other.

Signature
public String getReferenceTargetField()

Return Value
Type: String

Usage
For information about indirect lookup relationships, see “Indirect Lookup Relationship Fields on External Objects” in the Salesforce Help.

getReferenceTo()
Returns a list of Schema.sObjectType objects for the parent objects of this field. If the isNamePointing method returns true, there is more than one entry in the list, otherwise there is only one.

Signature
public List<Schema.sObjectType> getReferenceTo()
Return Value
Type: List<Schema.sObjectType>

Versioned Behavior Changes
In API version 51.0 and later, the getReferenceTo() method returns referenced objects that aren’t accessible to the context user. If the context user has access to an object’s field that references another object, irrespective of the context user’s access to the cross-referenced object, the method returns references. In API version 50.0 and earlier, if the context user doesn’t have access to the cross-referenced object, the method returns an empty list.

getRelationshipName()
Returns the name of the relationship.

Signature
public String getRelationshipName()

Return Value
Type: String

Usage
For more information about relationships and relationship names, see Understanding Relationship Names in the SOQL and SOSL Reference.

getRelationshipOrder()
Returns 1 if the field is a child, 0 otherwise.

Signature
public Integer getRelationshipOrder()

Return Value
Type: Integer

Usage
For more information about relationships and relationship names, see Understanding Relationship Names in the SOQL and SOSL Reference.

getScale()
For fields of type Double, returns the number of digits to the right of the decimal point. Any extra digits to the right of the decimal point are truncated.

Signature
public Integer getScale()
Return Value
Type: Integer

Usage
This method returns a fault response if the number has too many digits to the left of the decimal point.

getSOAPType()
Returns one of the SoapType enum values, depending on the type of field.

Signature
public Schema.SOAPType getSOAPType()

Return Value
Type: Schema.SOAPType

g getSObjectField()
Returns the token for this field.

Signature
public Schema.sObjectField getSObjectField()

Return Value
Type: Schema.sObjectField

g getSObjectType()
Returns the Salesforce object type from which this field originates.

Signature
public Schema.SObjectType getSObjectType()

Return Value
Type: Schema.SObjectType

Example
```
Schema.DescribeFieldResult f = Account.Industry.getDescribe();
Schema.sObjectType sourceType = f.getSObjectType();
Assert.areEqual(Account.sObjectType, sourceType);
```
**getType()**

Returns one of the DisplayType enum values, depending on the type of field.

**Signature**

`public Schema.DisplayType getType()`

**Return Value**

Type: `Schema.DisplayType`

**isAccessible()**

Returns `true` if the current user can see this field, `false` otherwise.

**Signature**

`public Boolean isAccessible()`

**Return Value**

Type: `Boolean`

**isAiPredictionField() (Beta)**

Returns `true` if the current field is enabled to display Einstein prediction data, `false` otherwise.

**Signature**

`public Boolean isAiPredictionField()`

**Return Value**

Type: `Boolean`

**Usage**

Custom number fields can be set to display Einstein prediction values. If you are participating in the Einstein Prediction Builder Beta program, use Einstein Prediction Builder to set up the value to display. Use this method to find out if a field is enabled to display an Einstein prediction value.

**isAutoNumber()**

Returns `true` if the field is an Auto Number field, `false` otherwise.

**Signature**

`public Boolean isAutoNumber()`
Return Value
Type: Boolean

Usage
Analogous to a SQL IDENTITY type, Auto Number fields are read-only, non-createable text fields with a maximum length of 30 characters. Auto Number fields are used to provide a unique ID that is independent of the internal object ID (such as a purchase order number or invoice number). Auto Number fields are configured entirely in the Salesforce user interface.

isCalculated()
Returns true if the field is a custom formula field, false otherwise. Note that custom formula fields are always read-only.

Signature
public Boolean isCalculated()

Return Value
Type: Boolean

isCascadeDelete()
Returns true if the child object is deleted when the parent object is deleted, false otherwise.

Signature
public Boolean isCascadeDelete()

Return Value
Type: Boolean

isCaseSensitive()
Returns true if the field is case sensitive, false otherwise.

Signature
public Boolean isCaseSensitive()

Return Value
Type: Boolean

isCreateable()
Returns true if the field can be created by the current user, false otherwise.
Signature

public Boolean isCreateable()

Return Value

Type: Boolean

isCustom()

Returns true if the field is a custom field, false if it is a standard field, such as Name.

Signature

public Boolean isCustom()

Return Value

Type: Boolean

isDefaultedOnCreate()

Returns true if the field receives a default value when created, false otherwise.

Signature

public Boolean isDefaultedOnCreate()

Return Value

Type: Boolean

Usage

If this method returns true, Salesforce implicitly assigns a value for this field when the object is created, even if a value for this field is not passed in on the create call. For example, in the Opportunity object, the Probability field has this attribute because its value is derived from the Stage field. Similarly, the Owner has this attribute on most objects because its value is derived from the current user (if the Owner field is not specified).

isDependentPicklist()

Returns true if the picklist is a dependent picklist, false otherwise.

Signature

public Boolean isDependentPicklist()

Return Value

Type: Boolean
isDeprecatedAndHidden()
Reserved for future use.

Signature
public Boolean isDeprecatedAndHidden()

Return Value
Type: Boolean

isEncrypted()
Returns true if the field is encrypted with Shield Platform Encryption, false otherwise.

Signature
public Boolean isEncrypted()

Return Value
Type: Boolean

isExternalID()
Returns true if the field is used as an external ID, false otherwise.

Signature
public Boolean isExternalID()

Return Value
Type: Boolean

isFilterable()
Returns true if the field can be used as part of the filter criteria of a WHERE statement, false otherwise.

Signature
public Boolean isFilterable()

Return Value
Type: Boolean

isFormulaTreatNullNumberAsZero()
Returns true if null is treated as zero in a formula field, false otherwise.
Signature
public Boolean isFormulaTreatNullNumberAsZero()

Return Value
Type: Boolean

isGroupable()
Returns true if the field can be included in the GROUP BY clause of a SOQL query, false otherwise. This method is only available for Apex classes and triggers saved using API version 18.0 and higher.

Signature
public Boolean isGroupable()

Return Value
Type: Boolean

isHtmlFormatted()
Returns true if the field has been formatted for HTML and should be encoded for display in HTML, false otherwise. One example of a field that returns true for this method is a hyperlink custom formula field. Another example is a custom formula field that has an IMAGE text function.

Signature
public Boolean isHtmlFormatted()

Return Value
Type: Boolean

isIdLookup()
Returns true if the field can be used to specify a record in an upsert method, false otherwise.

Signature
public Boolean isIdLookup()

Return Value
Type: Boolean

isNameField()
Returns true if the field is a name field, false otherwise.
Signature

public Boolean isNameField()

Return Value
Type: Boolean

Usage
This method is used to identify the name field for standard objects (such as AccountName for an Account object) and custom objects. Objects can only have one name field, except where the FirstName and LastName fields are used instead (such as on the Contact object). If a compound name is present, for example, the Name field on a person account, isNameField is set to true for that record.

isNamePointing()

Returns true if the field can have multiple types of objects as parents. For example, a task can have both the Contact/Lead ID (WhoId) field and the Opportunity/Account ID (WhatId) field return true for this method, because either of those objects can be the parent of a particular task record. This method returns false otherwise.

Signature

public Boolean isNamePointing()

Return Value
Type: Boolean

isNillable()

Returns true if the field is nillable, false otherwise. A nillable field can have empty content. A non-nillable field must have a value for the object to be created or saved.

Signature

public Boolean isNillable()

Return Value
Type: Boolean

isPermissionable()

Returns true if field permissions can be specified for the field, false otherwise.

Signature

public Boolean isPermissionable()
Return Value
Type: Boolean

**isRestrictedDelete()**
Returns `true` if the parent object can’t be deleted because it is referenced by a child object, `false` otherwise.

**Signature**
```java
public Boolean isRestrictedDelete()
```

Return Value
Type: Boolean

**isRestrictedPicklist()**
Returns `true` if the field is a restricted picklist, `false` otherwise.

**Signature**
```java
public Boolean isRestrictedPicklist()
```

Return Value
Type: Boolean

**isSearchPrefilterable()**
Returns `true` if a foreign key can be included in prefiltering when used in a SOSL WHERE clause, `false` otherwise.

**Signature**
```java
public Boolean isSearchPrefilterable()
```

Return Value
Type: Boolean

**Usage**
Prefiltering means to filter by a specific field value before executing the full search query. Prefiltering is supported only in WHERE clauses with the equals (==) operator.

**issSortable()**
Returns `true` if a query can sort on the field, `false` otherwise.
Signature
public Boolean isSortable()

Return Value
Type: Boolean

isUnique()
Returns true if the value for the field must be unique, false otherwise

Signature
public Boolean isUnique()

Return Value
Type: Boolean

isUpdateable()
Returns true if the field can be edited by the current user, or child records in a master-detail relationship field on a custom object can be reparented to different parent records; false otherwise.

⚠️ Important: Where possible, we changed noninclusive terms to align with our company value of Equality. We maintained certain terms to avoid any effect on customer implementations.

Signature
public Boolean isUpdateable()

Return Value
Type: Boolean

isWriteRequiresMasterRead()
Returns true if writing to the detail object requires read sharing instead of read/write sharing of the parent.

Signature
public Boolean isWriteRequiresMasterRead()

Return Value
Type: Boolean

DescribelconResult Class
Contains icon metadata information for a tab.
Namespace

Schema

Usage

The `getIcons` method of the `Schema.DescribeTabResult` class returns a list of `Schema.DescribeIconResult` objects that describe colors used in a tab.

The methods in the `Schema.DescribeIconResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses () to call the property counterpart. For example, `iconResultObj.url` is equivalent to `iconResultObj.getUrl()`.

Example

This sample shows how to get the icon information in the Sales app for the first tab's first icon.

```java
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set
for(Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Get tab info for the Sales app
    if (tsr.getLabel() == 'Sales') {
        // Get icon information for the first tab
        List<Schema.DescribeIconResult> iconDesc = tsr.getTabs()[0].getIcons();
        // Display the icon height and width of the first icon
        System.debug('Height: ' + iconDesc[0].getHeight());
        System.debug('Width: ' + iconDesc[0].getWidth());
    }
}
```

// Example debug statement output
// DEBUG|Height: 32
// DEBUG|Width: 32

DescribeIconResult Methods

The following are methods for `DescribeIconResult`. All are instance methods.

IN THIS SECTION:

- `getContentType()`
  Returns the tab icon’s content type, such as `image/png`.

- `getHeight()`
  Returns the tab icon’s height in pixels.

- `getTheme()`
  Returns the tab’s icon theme.

- `getUrl()`
  Returns the tab’s icon fully qualified URL.
getWidth()
Returns the tab’s icon width in pixels.

getContentType()
Returns the tab icon’s content type, such as image/png.

Signature
public String getContentType()

Return Value
Type: String

getHeight()
Returns the tab icon’s height in pixels.

Signature
public Integer getHeight()

Return Value
Type: Integer

Usage
Note: If the icon content type is SVG, the icon won’t have a size and its height is zero.

getTheme()
Returns the tab’s icon theme.

Signature
public String getTheme()

Return Value
Type: String
Possible theme values include theme3, theme4, and custom.
• theme3 is the Salesforce theme introduced during Spring ’10.
• theme4 is the Salesforce theme introduced in Winter ’14 for the mobile touchscreen version of Salesforce.
• custom is the theme name associated with a custom icon.
DescribeSObjectResult Class

Contains methods for describing SObjects. None of the methods take an argument.

Namespace

Schema

Usage

Note: If the icon content type is SVG, the icon won’t have a size and its width is zero.

DescribeSObjectResult Properties

The following are properties for DescribeSObjectResult.
**associateentitytype**

The type of associated object. For example, History or Share.

**Signature**

```java
public String associateentitytype {get; set;}
```

**Property Value**

Type: String

---

**associateparententity**

The parent object of an associated object.

**Signature**

```java
public String associateparententity {get; set;}
```

**Property Value**

Type: String

---

**DescribeSObjectResult Methods**

The following are methods for DescribeSObjectResult. All are instance methods.

**IN THIS SECTION:**

- **fields**
  - Follow fields with a field member variable name or with the `getMap` method.

- **fieldSets**
  - Follow fieldSets with a field set name or with the `getMap` method.

- **getAssociateEntityType()**
  - Returns additional metadata for an associated object of a specified parent but only if it’s a specific associated object type. Used in combination with the `getAssociateParentEntity()` method to get the parent object. For example, invoking the method on `AccountHistory` returns the parent object as `Account` and the type of associated object as `History`.

- **getAssociateParentEntity()**
  - Returns additional metadata for an associated object but only if it’s associated to a specific parent object. Used in combination with the `getAssociateEntityType()` method to get the type of associated object. For example, invoking the method on `AccountHistory` returns the parent object as `Account` and the type of associated object as `History`.

- **getChildRelationships()**
  - Returns a list of child relationships, which are the names of the sObjects that have a foreign key to the sObject being described.

- **getDefaultImplementation()**
  - Reserved for future use.

- **getHasSubtypes()**
  - Reserved for future use.
getImplementedBy()
Reserved for future use.

getImplementsInterfaces()
Reserved for future use.

getInterface()
Reserved for future use.

getKeyPrefix()
Returns the three-character prefix code for the object. Record IDs are prefixed with three-character codes that specify the type of the object (for example, accounts have a prefix of 001 and opportunities have a prefix of 006).

getLabel()
Returns the object's label, which may or may not match the object name.

getLabelPlural()
Returns the object's plural label, which may or may not match the object name.

getLocalName()
Returns the name of the object, similar to the getName method. However, if the object is part of the current namespace, the namespace portion of the name is omitted.

getName()
Returns the name of the object.

getRecordTypeInfos()
Returns a list of the record types supported by this object. The current user is not required to have access to a record type to see it in this list.

getRecordTypeInfosByDeveloperName()
Returns a map that matches developer names to their associated record type. The current user is not required to have access to a record type to see it in this map.

getRecordTypeInfosById()
Returns a map that matches record IDs to their associated record types. The current user is not required to have access to a record type to see it in this map.

getRecordTypeInfosByName()
Returns a map that matches record labels to their associated record type. The current user is not required to have access to a record type to see it in this map.

getSObjectDescribeOption()
Returns the effective describe option used by the system for the SObject.

getType()
Returns the Schema.SObjectType object for the sObject. You can use this to create a similar sObject.

isAccessible()
Returns true if the current user can see this object, false otherwise.

isCreateable()
Returns true if the object can be created by the current user, false otherwise.

isCustom()
Returns true if the object is a custom object, false if it is a standard object.
isCustomSetting()
Returns true if the object is a custom setting, false otherwise.

isDeletable()
Returns true if the object can be deleted by the current user, false otherwise.

isDeprecatedAndHidden()
Reserved for future use.

isFeedEnabled()
Returns true if Chatter feeds are enabled for the object, false otherwise. This method is only available for Apex classes and triggers saved using SalesforceAPI version 19.0 and later.

isMergeable()
Returns true if the object can be merged with other objects of its type by the current user, false otherwise. true is returned for leads, contacts, and accounts.

isMruEnabled()
Returns true if Most Recently Used (MRU) list functionality is enabled for the object, false otherwise.

isQueryable()
Returns true if the object can be queried by the current user, false otherwise.

isSearchable()
Returns true if the object can be searched by the current user, false otherwise.

isUndeletable()
Returns true if the object can be undeleted by the current user, false otherwise.

isUpdateable()
Returns true if the object can be updated by the current user, false otherwise.

fields
Follow fields with a field member variable name or with the getMap method.

Signature
public Schema.SObjectTypeFields fields()

Return Value
Type: The return value is a special data type. See the example to learn how to use fields.

Usage
Note: When you describe sObjects and their fields from within an Apex class, custom fields of new field types are returned regardless of the API version that the class is saved in. If a field type, such as the geolocation field type, is available only in a recent API version, components of a geolocation field are returned even if the class is saved in an earlier API version.

Example
To get a custom field name, specify the custom field name.

SEE ALSO:
   - Apex Developer Guide: Using Field Tokens
   - Apex Developer Guide: Describing sObjects Using Schema Method
   - Apex Developer Guide: Understanding Apex Describe Information

**fieldSets**

Follow `fieldSets` with a field set name or with the `getMap` method.

**Signature**

```java
public Schema.SObjectTypeFields fieldSets()
```

**Return Value**

Type: The return value is a special data type. See the example to learn how to use `fieldSets`.

**Example**

```java
Schema.DescribeSObjectResult d = Account.sObjectType.getDescribe();
Map<String, Schema.FieldSet> FsMap = d.fieldSets.getMap();
```

SEE ALSO:
   - Apex Developer Guide: Using Field Tokens
   - Apex Developer Guide: Describing sObjects Using Schema Method
   - Apex Developer Guide: Understanding Apex Describe Information

**getAssociateEntityType()**

Returns additional metadata for an associated object of a specified parent but only if it's a specific associated object type. Used in combination with the `getAssociateParentEntity()` method to get the parent object. For example, invoking the method on `AccountHistory` returns the parent object as `Account` and the type of associated object as `History`.

**Signature**

```java
public String associateentitytype {get; set;}
```

**Return Value**

Type: `String`

SEE ALSO:
   - DescribeSObjectResult Properties
getAssociateParentEntity()
Returns additional metadata for an associated object but only if it’s associated to a specific parent object. Used in combination with the getAssociateEntityType() method to get the type of associated object. For example, invoking the method on AccountHistory returns the parent object as Account and the type of associated object as History.

Signature
public String getAssociateParentEntity()

Return Value
Type: String

SEE ALSO:
DescribeSObjectResult Properties

getChildRelationships()
Returns a list of child relationships, which are the names of the sObjects that have a foreign key to the sObject being described.

Signature
public Schema.ChildRelationship getChildRelationships()

Return Value
Type: List<Schema.ChildRelationship>

Example
For example, the Account object includes Contacts and Opportunities as child relationships.

getDefaultImplementation()
Reserved for future use.

Signature
public String getDefaultImplementation()

Return Value
Type: String

getHasSubtypes()
Reserved for future use.
To check if Person Accounts are enabled for the current org, use this code snippet:
Schema.SObjectType.Account.fields.getMap().containsKey( 'isPersonAccount' );
Signature
public Boolean getHasSubtypes()

Return Value
Type: Boolean

getImplementedBy()
Reserved for future use.

Signature
public String getImplementedBy()

Return Value
Type: String

getImplementsInterfaces()
Reserved for future use.

Signature
public String getImplementsInterfaces()

Return Value
Type: String

getIsInterface()
Reserved for future use.

Signature
public Boolean getIsInterface()

Return Value
Type: Boolean

getKeyPrefix()
Returns the three-character prefix code for the object. Record IDs are prefixed with three-character codes that specify the type of the object (for example, accounts have a prefix of 001 and opportunities have a prefix of 006).
**Signature**

```
public String getKeyPrefix()
```

**Return Value**

Type: String

**Usage**

The DescribeSObjectResult object returns a value for objects that have a stable prefix. For object types that do not have a stable or predictable prefix, this field is blank. Client applications that rely on these codes can use this way of determining object type to ensure forward compatibility.

**getLabel()**

Returns the object's label, which may or may not match the object name.

**Signature**

```
public String getLabel()
```

**Return Value**

Type: String

**Usage**

The object's label might not always match the object name. For example, an organization in the medical industry might change the label for Account to Patient. This label is then used in the Salesforce user interface. See the Salesforce online help for more information.

**getLabelPlural()**

Returns the object's plural label, which may or may not match the object name.

**Signature**

```
public String getLabelPlural()
```

**Return Value**

Type: String

**Usage**

The object's plural label might not always match the object name. For example, an organization in the medical industry might change the plural label for Account to Patients. This label is then used in the Salesforce user interface. See the Salesforce online help for more information.
**getLocalName()**
Returns the name of the object, similar to the `getName` method. However, if the object is part of the current namespace, the namespace portion of the name is omitted.

**Signature**
```
public String getLocalName()
```

**Return Value**
Type: `String`

**getName()**
Returns the name of the object.

**Signature**
```
public String getName()
```

**Return Value**
Type: `String`

**getRecordTypeInfos()**
Returns a list of the record types supported by this object. The current user is not required to have access to a record type to see it in this list.

**Signature**
```
public List<Schema.RecordTypeInfo> getRecordTypeInfos()
```

**Return Value**
Type: `List<Schema.RecordTypeInfo>`

**getRecordTypeInfosByDeveloperName()**
Returns a map that matches developer names to their associated record type. The current user is not required to have access to a record type to see it in this map.

**Signature**
```
public Map<String, Schema.RecordTypeInfo> getRecordTypeInfosByDeveloperName()
```

**Return Value**
Type: `Map<String, Schema.RecordTypeInfo>`
**getRecordTypeInfosById()**
Returns a map that matches record IDs to their associated record types. The current user is not required to have access to a record type to see it in this map.

**Signature**

```java
public Schema.RecordTypeInfo getRecordTypeInfosById()
```

**Return Value**

Type: `Map<ID, Schema.RecordTypeInfo>`

**getRecordTypeInfosByName()**
Returns a map that matches record labels to their associated record type. The current user is not required to have access to a record type to see it in this map.

**Signature**

```java
public Schema.RecordTypeInfo getRecordTypeInfosByName()
```

**Return Value**

Type: `Map<String, Schema.RecordTypeInfo>`

**getSObjectDescribeOption()**
Returns the effective describe option used by the system for the SObject.

**Signature**

```java
public Schema.SObjectDescribeOptions getSObjectDescribeOption()
```

**Return Value**

Type: `Schema.SObjectDescribeOptions`

Valid values are:

- `SObjectDescribeOptions.FULL`: Indicates eager-load all elements of the describe, including child relationships, up-front at the time of method invocation.
- `SObjectDescribeOptions.DEFERRED`: Indicates lazy-load child relationships. This means that all child relationships will not be loaded at the time of first invocation of the method.

**getSObjectType()**
Returns the `Schema.SObjectType` object for the sObject. You can use this to create a similar sObject.

**Signature**

```java
public Schema.SObjectType getSObjectType()
```
Return Value
Type: Schema.SObjectType

**isAccessible()**
Returns `true` if the current user can see this object, `false` otherwise.

**Signature**
```java
public Boolean isAccessible()
```

**Return Value**
Type: Boolean

**Versioned Behavior Changes**
In API version 54.0 and later, for custom settings and custom metadata type objects,
DescribeSObjectResult.isAccessible() returns `false` if the user doesn't have permissions to access the queried objects. In API version 53.0 and earlier, the method returns `true` even if the user doesn't have the required permissions.

**isCreateable()**
Returns `true` if the object can be created by the current user, `false` otherwise.

**Signature**
```java
public Boolean isCreateable()
```

**Return Value**
Type: Boolean

**isCustom()**
Returns `true` if the object is a custom object, `false` if it is a standard object.

**Signature**
```java
public Boolean isCustom()
```

**Return Value**
Type: Boolean
Signature

public Boolean isCustomSetting()

Return Value

Type: Boolean

isDeletable()

Returns true if the object can be deleted by the current user, false otherwise.

Signature

public Boolean isDeletable()

Return Value

Type: Boolean

isDeprecatedAndHidden()

Reserved for future use.

Signature

public Boolean isDeprecatedAndHidden()

Return Value

Type: Boolean

isFeedEnabled()

Returns true if Chatter feeds are enabled for the object, false otherwise. This method is only available for Apex classes and triggers saved using SalesforceAPI version 19.0 and later.

Signature

public Boolean isFeedEnabled()

Return Value

Type: Boolean

isMergeable()

Returns true if the object can be merged with other objects of its type by the current user, false otherwise. true is returned for leads, contacts, and accounts.
Signature
public Boolean isMergeable()

Return Value
Type: Boolean

isMruEnabled()
Returns true if Most Recently Used (MRU) list functionality is enabled for the object, false otherwise.

Signature
public Boolean isMruEnabled()

Return Value
Type: Boolean

isQueryable()
Returns true if the object can be queried by the current user, false otherwise.

Signature
public Boolean isQueryable()

Return Value
Type: Boolean

isSearchable()
Returns true if the object can be searched by the current user, false otherwise.

Signature
public Boolean isSearchable()

Return Value
Type: Boolean

isUndeletable()
Returns true if the object can be undeleted by the current user, false otherwise.

Signature
public Boolean isUndeletable()
Return Value
Type: Boolean

isUpdateable()
Returns true if the object can be updated by the current user, false otherwise.

Signature
public Boolean isUpdateable()

Return Value
Type: Boolean

DescribeTabResult Class
Contains tab metadata information for a tab in a standard or custom app available in the Salesforce user interface.

Namespace
Schema

Usage
The getTabs method of the Schema.DescribeTabSetResult returns a list of Schema.DescribeTabResult objects that describe the tabs of one app.

The methods in the Schema.DescribeTabResult class can be called using their property counterparts. For each method starting with get, you can omit the get prefix and the ending parentheses () to call the property counterpart. For example, tabResultObj.label is equivalent to tabResultObj.getLabel(). Similarly, for each method starting with is, omit the is prefix and the ending parentheses (). For example, tabResultObj.isCustom is equivalent to tabResultObj.custom.

DescribeTabResult Methods
The following are methods for DescribeTabResult. All are instance methods.

IN THIS SECTION:
getColors()
Returns a list of color metadata information for all colors associated with this tab. Each color is associated with a theme and context.

getIconUrl()
Returns the URL for the main 32 x 32-pixel icon for a tab. This icon corresponds to the current theme (theme3) and appears next to the heading at the top of most pages.

getIcons()
Returns a list of icon metadata information for all icons associated with this tab. Each icon is associated with a theme and context.
getLabel()
Returns the display label of this tab.

getMiniIconUrl()
Returns the URL for the 16 x 16-pixel icon that represents a tab. This icon corresponds to the current theme (theme3) and appears in related lists and other locations.

getObjectName()
Returns the name of the sObject that is primarily displayed on this tab (for tabs that display a particular SOBject).

getUrl()
Returns a fully qualified URL for viewing this tab.

isCustom()
Returns true if this is a custom tab, or false if this is a standard tab.

gGetColors() (getColors)
Returns a list of color metadata information for all colors associated with this tab. Each color is associated with a theme and context.

Signature
public List<Schema.DescribeColorResult> getColors()

Return Value
Type: List<Schema.DescribeColorResult>

gGetIconUrl() (getIconUrl)
Returns the URL for the main 32 x 32-pixel icon for a tab. This icon corresponds to the current theme (theme3) and appears next to the heading at the top of most pages.

Signature
public String getIconUrl()

Return Value
Type: String

gGetIcons() (getIcons)
Returns a list of icon metadata information for all icons associated with this tab. Each icon is associated with a theme and context.

Signature
public List<Schema.DescribeIconResult> getIcons()

Return Value
Type: List<Schema.DescribeIconResult>
**getLabel()**

Returns the display label of this tab.

**Signature**

```java
public String getLabel()
```

**Return Value**

Type: `String`

**getMiniIconUrl()**

Returns the URL for the 16 x 16-pixel icon that represents a tab. This icon corresponds to the current theme (theme3) and appears in related lists and other locations.

**Signature**

```java
public String getMiniIconUrl()
```

**Return Value**

Type: `String`

**getSobjectName()**

Returns the name of the sObject that is primarily displayed on this tab (for tabs that display a particular SObject).

**Signature**

```java
public String getSobjectName()
```

**Return Value**

Type: `String`

**getUrl()**

Returns a fully qualified URL for viewing this tab.

**Signature**

```java
public String getUrl()
```

**Return Value**

Type: `String`
isCustom()
Returns true if this is a custom tab, or false if this is a standard tab.

Signature
public Boolean isCustom()

Return Value
Type: Boolean

DescribeTabSetResult Class
Contains metadata information about a Salesforce Classic standard or custom app available in the Salesforce user interface.

Namespace
Schema

Usage
The Schema.describeTabs method returns a list of Schema.DescribeTabSetResult objects that describe Salesforce Classic standard and custom apps.

The methods in the Schema.DescribeTabSetResult class can be called using their property counterparts. For each method starting with get, you can omit the get prefix and the ending parentheses () to call the property counterpart. For example, tabSetResultObj.label is equivalent to tabSetResultObj.getLabel(). Similarly, for each method starting with is, omit the is prefix and the ending parentheses (). For example, tabSetResultObj.isSelected is equivalent to tabSetResultObj.selected.

Example
This example shows how to call the Schema.describeTabs method to get describe information for all available Salesforce Classic apps. This example iterates through each describe result and gets more metadata information for the Sales app.

```java
// App we're interested to get more info about
String appName = 'Sales';

// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set describe for each app and display the info
for (Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Get more information for the Sales app
    if (tsr.getLabel() == appName) {
        // Find out if the app is selected
        if (tsr.isSelected()) {
            System.debug('The ' + appName + ' app is selected.');
        }
        // Get the app's Logo URL and namespace
        String logo = tsr.getLogoUrl();
    }
}
```
System.debug('Logo URL: ' + logo);
String ns = tsr.getNamespace();
if (ns == '') {
    System.debug('The ' + appName + ' app has no namespace defined.');
} else {
    System.debug('Namespace: ' + ns);
}
// Get the number of tabs
System.debug('The ' + appName + ' app has ' + tsr.getTabs().size() + ' tabs.');

// Example debug statement output
// DEBUG|The Sales app is selected.
// DEBUG|Logo URL: https://MyDomainName.my.salesforce.com/img/seasonLogos/2014_winter_aloha.png
// DEBUG|The Sales app has no namespace defined.
// DEBUG|The Sales app has 14 tabs.

DescribeTabSetResult Methods

The following are methods for DescribeTabSetResult. All are instance methods.

IN THIS SECTION:

getDescription()
Returns the display description for the standard or custom app.

getLabel()
Returns the display label for the standard or custom app.

getLogoUrl()
Returns a fully qualified URL to the logo image associated with the standard or custom app.

getNamespace()
Returns the developer namespace prefix of a Salesforce AppExchange managed package.

getTabs()
Returns metadata information about the standard or custom app's displayed tabs.

isSelected()
Returns true if this standard or custom app is the user's currently selected app. Otherwise, returns false.

getDescription()
Returns the display description for the standard or custom app.

Signature

public String getDescription()
Return Value
Type: String

getLabel()
Returns the display label for the standard or custom app.

Signature
public String getLabel()

Return Value
Type: String

Usage
The display label changes when tabs are renamed in the Salesforce user interface. See the Salesforce online help for more information.

getLogoUrl()
Returns a fully qualified URL to the logo image associated with the standard or custom app.

Signature
public String getLogoUrl()

Return Value
Type: String

getAddress()
Returns the developer namespace prefix of a Salesforce AppExchange managed package.

Signature
public String getNamespace()

Return Value
Type: String

Usage
This namespace prefix corresponds to the namespace prefix of the Developer Edition organization that was enabled to allow publishing a managed package. This method applies to a custom app containing a set of tabs and installed as part of a managed package.
**getTabs()**
Returns metadata information about the standard or custom app's displayed tabs.

**Signature**
```
public List<Schema.DescribeTabResult> getTabs()
```

**Return Value**
Type: `List<Schema.DescribeTabResult>`

**isSelected()**
Returns `true` if this standard or custom app is the user's currently selected app. Otherwise, returns `false`.

**Signature**
```
public Boolean isSelected()
```

**Return Value**
Type: `Boolean`

### DisplayType Enum
A `Schema.DisplayType` enum value is returned by the field describe result's `getType` method.

**Namespace**
`Schema`

<table>
<thead>
<tr>
<th>Type Field Value</th>
<th>What the Field Object Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>Address values</td>
</tr>
<tr>
<td>anytype</td>
<td>Any value of the following types: <code>String</code>, <code>Picklist</code>, <code>Boolean</code>, <code>Integer</code>, <code>Double</code>, <code>Percent</code>, <code>ID</code>, <code>Date</code>, <code>DateTime</code>, <code>URL</code>, or <code>Email</code>.</td>
</tr>
<tr>
<td>base64</td>
<td>Base64-encoded arbitrary binary data (of type <code>base64Binary</code>)</td>
</tr>
<tr>
<td>Boolean</td>
<td>Boolean (<code>true</code> or <code>false</code>) values</td>
</tr>
<tr>
<td>Combobox</td>
<td>Comboboxes, which provide a set of enumerated values and allow the user to specify a value not in the list</td>
</tr>
<tr>
<td>Currency</td>
<td>Currency values</td>
</tr>
<tr>
<td>DataCategoryGroupReference</td>
<td>Reference to a data category group or a category unique name</td>
</tr>
<tr>
<td>Date</td>
<td>Date values</td>
</tr>
<tr>
<td>DateTime</td>
<td>DateTime values</td>
</tr>
<tr>
<td>Type Field Value</td>
<td>What the Field Object Contains</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>Double</td>
<td>Double values</td>
</tr>
<tr>
<td>Email</td>
<td>Email addresses</td>
</tr>
<tr>
<td>EncryptedString</td>
<td>Encrypted string</td>
</tr>
<tr>
<td>ID</td>
<td>Primary key field for an object</td>
</tr>
<tr>
<td>Integer</td>
<td>Integer values</td>
</tr>
<tr>
<td>Location</td>
<td>Location values, including latitude and longitude.</td>
</tr>
<tr>
<td>Long</td>
<td>Long values</td>
</tr>
<tr>
<td>MultiPicklist</td>
<td>Multi-select picklists, which provide a set of enumerated values from which multiple values can be selected</td>
</tr>
<tr>
<td>Percent</td>
<td>Percent values</td>
</tr>
<tr>
<td>Phone</td>
<td>Phone numbers. Values can include alphabetic characters. Client applications are responsible for phone number formatting.</td>
</tr>
<tr>
<td>Picklist</td>
<td>Single-select picklists, which provide a set of enumerated values from which only one value can be selected</td>
</tr>
<tr>
<td>Reference</td>
<td>Cross-references to a different object, analogous to a foreign key field</td>
</tr>
<tr>
<td>String</td>
<td>String values</td>
</tr>
<tr>
<td>TextArea</td>
<td>String values that are displayed as multiline text fields</td>
</tr>
<tr>
<td>Time</td>
<td>Time values</td>
</tr>
<tr>
<td>URL</td>
<td>URL values that are displayed as hyperlinks</td>
</tr>
</tbody>
</table>

**Usage**

For more information, see Field Types in the Object Reference for Salesforce. For more information about the methods shared by all enums, see Enum Methods.

**FieldDescribeOptions Enum**

A Schema.FieldDescribeOptions enum value is a parameter in the SObjectType.getDescribe method.

**Usage**

For more information about the method using this enum, see getDescribe(options).

**Enum Values**

The following are the values of the Schema.FieldDescribeOptions enum.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>Compute context-specific, describe field results.</td>
</tr>
<tr>
<td>FULL_DESCRIBE</td>
<td>Compute all aspects of describe field results.</td>
</tr>
</tbody>
</table>

### FieldSet Class

Contains methods for discovering and retrieving the details of field sets created on sObjects.

#### Namespace

*Schema*

#### Usage

Use the methods in the `Schema.FieldSet` class to discover the fields contained within a field set, and get details about the field set itself, such as the name, namespace, label, and so on. The following example shows how to get a collection of field set describe result objects for an sObject. The key of the returned Map is the field set name, and the value is the corresponding field set describe result.

```java
Map<String, Schema.FieldSet> FsMap =
    Schema.SObjectType.Account.fieldSets.getMap();
```

Field sets are also available from sObject describe results. The following lines of code are equivalent to the prior sample:

```java
Schema.DescribeSObjectResult d =
    Account.sObjectType.getDescribe();
Map<String, Schema.FieldSet> FsMap =
    d.fieldSets.getMap();
```

To work with an individual field set, you can access it via the map of field sets on an sObject or, when you know the name of the field set in advance, using an explicit reference to the field set. The following two lines of code retrieve the same field set:

```java
Schema.FieldSet fs1 = Schema.SObjectType.Account.fieldSets.getMap().get('field_set_name');
Schema.FieldSet fs2 = Schema.SObjectType.Account.fieldSets.field_set_name;
```

### Example: Displaying a Field Set on a Visualforce Page

This sample uses `Schema.FieldSet` and `Schema.FieldSetMember` methods to dynamically get all the fields in the Dimensions field set for the Merchandise custom object. The list of fields is then used to construct a SOQL query that ensures those fields are available for display. The Visualforce page uses the `MerchandiseDetails` class as its controller.

```java
public class MerchandiseDetails {
    public Merchandise__c merch { get; set; }

    public MerchandiseDetails() {
        this.merch = getMerchandise();
    }

    public List<Schema.FieldSetMember> getFields() {
```
private Merchandise__c getMerchandise() {
    String query = 'SELECT Id, Name FROM Merchandise__c LIMIT 1';
    return Database.query(query);
}

The Visualforce page using the above controller is simple:

One thing to note about the above markup is the expression used to determine if a field on the form should be indicated as being a required field. A field in a field set can be required by either the field set definition, or the field's own definition. The expression handles both cases.

FieldSet Methods

The following are methods for FieldSet. All are instance methods.

IN THIS SECTION:

    getDescription()
    Returns the field set's description.

    getFields()
    Returns a list of Schema.FieldSetMember objects for the fields making up the field set.

    getLabel()
    Returns the translation of the text label that is displayed next to the field in the Salesforce user interface.
**getSObjectType()**
Returns the `Schema.sObjectType` of the sObject containing the field set definition.

**getDescription()**
Returns the field set’s description.

**Signature**
```
public String getDescription()
```

**Return Value**
Type: `String`

**Usage**
Description is a required field for a field set, intended to describe the context and content of the field set. It’s often intended for administrators who might be configuring a field set defined in a managed package, rather than for end users.

**getFields()**
Returns a list of `Schema.FieldSetMember` objects for the fields making up the field set.

**Signature**
```
public List<FieldSetMember> getFields()
```

**Return Value**
Type: `List<Schema.FieldSetMember>`

**getLabel()**
Returns the translation of the text label that is displayed next to the field in the Salesforce user interface.

**Signature**
```
public String getLabel()
```

**Return Value**
Type: `String`
**getName()**

Returns the field set’s name.

**Signature**

```java
public String getName()
```

**Return Value**

Type: `String`

**getNamespace()**

Returns the field set’s namespace.

**Signature**

```java
public String getNamespace()
```

**Return Value**

Type: `String`

**Usage**

The returned namespace is an empty string if your organization hasn’t set a namespace, and the field set is defined in your organization. Otherwise, it’s the namespace of your organization, or the namespace of the managed package containing the field set.

**getSObjectType()**

Returns the `Schema.sObjectType` of the sObject containing the field set definition.

**Signature**

```java
public Schema.SObjectType getSObjectType()
```

**Return Value**

Type: `Schema.SObjectType`

---

**FieldSetMember Class**

Contains methods for accessing the metadata for field set member fields.

**Namespace**

`Schema`
Usage

Use the methods in the `Schema.FieldSetMember` class to get details about fields contained within a field set, such as the field label, type, a dynamic SOQL-ready field path, and so on. The following example shows how to get a collection of field set member describe result objects for a specific field set on an sObject:

```java
List<Schema.FieldSetMember> fields =
    Schema.SObjectType.Account.fieldSets.getMap().get('field_set_name').getFields();
```

If you know the name of the field set in advance, you can access its fields more directly using an explicit reference to the field set:

```java
List<Schema.FieldSetMember> fields =
    Schema.SObjectType.Account.fieldSets.field_set_name.getFields();
```

SEE ALSO:
- FieldSet Class

FieldSetMember Methods

The following are methods for `FieldSetMember`. All are instance methods.

IN THIS SECTION:
- `getDBRequired`
  Returns `true` if the field is required by the field's definition in its sObject, otherwise, `false`.
- `getFieldPath`
  Returns a field path string in a format ready to be used in a dynamic SOQL query.
- `getLabel`
  Returns the text label that's displayed next to the field in the Salesforce user interface.
- `getRequired`
  Returns `true` if the field is required by the field set, otherwise, `false`.
- `getType`
  Returns the field's Apex data type.
- `getSObjectField`
  Returns the token for this field.

`getDBRequired()`

Returns `true` if the field is required by the field's definition in its sObject, otherwise, `false`.

**Signature**

```java
public Boolean getDBRequired()
```

**Return Value**

Type: `Boolean`
getFieldPath()
Returns a field path string in a format ready to be used in a dynamic SOQL query.

Signature
public String getFieldPath()

Return Value
Type: String

Example
See Displaying a Field Set on a Visualforce Page for an example of how to use this method.

getLabel()
Returns the text label that’s displayed next to the field in the Salesforce user interface.

Signature
public String getLabel()

Return Value
Type: String

getRequired()
Returns true if the field is required by the field set, otherwise, false.

Signature
public Boolean getRequired()

Return Value
Type: Boolean

getType()
Returns the field’s Apex data type.

Signature
public Schema.DisplayType getType()

Return Value
Type: Schema.DisplayType
getSObjectField()  
Returns the token for this field.

Signature
public Schema.sObjectField getSObjectField()

Return Value
Type: Schema.SObjectField

PicklistEntry Class
Represents a picklist entry.

Namespace
Schema

Usage
Picklist fields contain a list of one or more items from which a user chooses a single item. They display as drop-down lists in the Salesforce user interface. One of the items can be configured as the default item.

A Schema.PicklistEntry object is returned from the field describe result using the getPicklistValues method. For example:

```java
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
List<Schema.PicklistEntry> P = F.getPicklistValues();
```

PicklistEntry Methods
The following are methods for PicklistEntry. All are instance methods.

IN THIS SECTION:
- getLabel()  
  Returns the display name of this item in the picklist.
- getValue()  
  Returns the value of this item in the picklist.
- isActive()  
  Returns true if this item must be displayed in the drop-down list for the picklist field in the user interface, false otherwise.
- isDefaultValue()  
  Returns true if this item is the default value for the picklist, false otherwise. Only one item in a picklist can be designated as the default.
getLabel()
Returns the display name of this item in the picklist.

Signature
public String getLabel()

Return Value
Type: String

getValue()
Returns the value of this item in the picklist.

Signature
public String getValue()

Return Value
Type: String

isActive()
Returns true if this item must be displayed in the drop-down list for the picklist field in the user interface, false otherwise.

Signature
public Boolean isActive()

Return Value
Type: Boolean

isDefaultValue()
Returns true if this item is the default value for the picklist, false otherwise. Only one item in a picklist can be designated as the default.

Signature
public Boolean isDefaultValue()

Return Value
Type: Boolean
RecordTypeInfo Class

Contains methods for accessing record type information for an sObject with associated record types.

Namespace

Schema

Usage

A RecordTypeInfo object is returned from the sObject describe result using the `getRecordTypeInfos` method. For example:

```java
Schema.DescribeSObjectResult R = Account.SObjectType.getDescribe();
List<Schema.RecordTypeInfo> RT = R.getRecordTypeInfos();
```

In addition to the `getRecordTypeInfos` method, you can use the `getRecordTypeInfosById` and the `getRecordTypeInfosByName` methods. These methods return maps that associate RecordTypeInfo with record IDs and record labels, respectively.

Example

The following example assumes at least one record type has been created for the Account object:

```java
RecordType rt = [SELECT Id,Name FROM RecordType WHERE SobjectType='Account' LIMIT 1];
Map<Id,Schema.RecordTypeInfo> rtMapById = d.getRecordTypeInfosById();
Schema.RecordTypeInfo rtById = rtMapById.get(rt.id);
Map<String,Schema.RecordTypeInfo> rtMapByName = d.getRecordTypeInfosByName();
Schema.RecordTypeInfo rtByName = rtMapByName.get(rt.name);
System.assertEquals(rtById,rtByName);
```

RecordTypeInfo Methods

The following are methods for RecordTypeInfo. All are instance methods.

IN THIS SECTION:

- `getDeveloperName()`: Returns the developer name for this record type.
- `getName()`: Returns the UI label of this record type. The label can be translated into any language that Salesforce supports.
- `getRecordTypeId()`: Returns the ID of this record type.
- `isActive()`: Returns `true` if this record type is active, `false` otherwise.
- `isAvailable()`: Returns `true` if this record type is available to the current user, `false` otherwise. Use this method to display a list of available record types to the user when he or she is creating a new record.
isDefaultRecordTypeMapping()
Returns true if this is the default record type for the user, false otherwise.

isMaster()
Returns true if this is the master record type and false otherwise. The master record type is the default record type that’s used when a record has no custom record type associated with it.

getDeveloperName()
Returns the developer name for this record type.

Signature
public String getDeveloperName()

Return Value
Type: String

getName()
Returns the UI label of this record type. The label can be translated into any language that Salesforce supports.

Signature
public String getName()

Return Value
Type: String

getRecordTypeId()
Returns the ID of this record type.

Signature
public ID getRecordTypeId()

Return Value
Type: ID

isActive()
Returns true if this record type is active, false otherwise.

Signature
public Boolean isActive()
Return Value
Type: Boolean

isAvailable()
Returns true if this record type is available to the current user, false otherwise. Use this method to display a list of available record types to the user when he or she is creating a new record.

Signature
public Boolean isAvailable()

Return Value
Type: Boolean

isDefaultRecordTypeMapping()
Returns true if this is the default record type for the user, false otherwise.

Signature
public Boolean isDefaultRecordTypeMapping()

Return Value
Type: Boolean

isMaster()
Returns true if this is the master record type and false otherwise. The master record type is the default record type that’s used when a record has no custom record type associated with it.

Signature
public Boolean isMaster()

Return Value
Type: Boolean

SOAPType Enum
A Schema.SOAPType enum value is returned by the field describe result getSoapType method.

Namespace
Schema
### Type Field Value

<table>
<thead>
<tr>
<th>Type Field Value</th>
<th>What the Field Object Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>anytype</td>
<td>Any value of the following types: <em>String</em>, <em>Boolean</em>, <em>Integer</em>, <em>Double</em>, <em>ID</em>, <em>Date</em> or <em>DateTime</em>.</td>
</tr>
<tr>
<td>base64binary</td>
<td>Base64-encoded arbitrary binary data (of type base64Binary)</td>
</tr>
<tr>
<td>Boolean</td>
<td>Boolean (<em>true</em> or <em>false</em>) values</td>
</tr>
<tr>
<td>Date</td>
<td>Date values</td>
</tr>
<tr>
<td>DateTime</td>
<td>DateTime values</td>
</tr>
<tr>
<td>Double</td>
<td>Double values</td>
</tr>
<tr>
<td>ID</td>
<td>Primary key field for an object</td>
</tr>
<tr>
<td>Integer</td>
<td>Integer values</td>
</tr>
<tr>
<td>String</td>
<td>String values</td>
</tr>
<tr>
<td>Time</td>
<td>Time values</td>
</tr>
</tbody>
</table>

### Usage

For more information, see [SOAPTypes](https://documentation.salesforce.com/soapapi/soapapi.htm#SOAPTypes) in the *SOAP API Developer Guide*. For more information about the methods shared by all enums, see [Enum Methods](https://developer.salesforce.com/docs/atlas.en-us.ipick.doapick.meta/ipick.doapick.htm).

### SObjectDescribeOptions Enum

A `Schema.SObjectDescribeOptions` enum value is a parameter in the `SObjectType.getDescribe()` method.

#### Usage

For more information about the method using this enum, see `getDescribe(options)`.

#### Enum Values

The following are the values of the `Schema.SObjectDescribeOptions` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>Either eager-load or lazy-load depending on the API version.</td>
</tr>
<tr>
<td>DEFERRED</td>
<td>Lazy-load child relationships; do not load all child relationships at the time of first invocation of the method.</td>
</tr>
<tr>
<td>FULL</td>
<td>Eager-load all elements of the describe, including child relationships, up-front at the time of method invocation.</td>
</tr>
</tbody>
</table>

See `getDescribe(options)`. 
SOBJECTFIELD Class

A Schema.sObjectField object is returned from the field describe result using the getController and getSObjectField methods.

Namespace

Schema

Example

```java
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
Schema.sObjectField T = F.getSObjectField();
```

sObjectField Methods

The following are instance methods for sObjectField.

IN THIS SECTION:

- `getDescribe()`
  - Returns the describe field result for this field.
- `getDescribe(options)`
  - Returns the describe field result for this field. This method also provides an option to get all the describe field results for an object.

`getDescribe()`

Returns the describe field result for this field.

**Signature**

```java
public Schema.DescribeFieldResult getDescribe()
```

**Return Value**

Type: Schema.DescribeFieldResult

`getDescribe(options)`

Returns the describe field result for this field. This method also provides an option to get all the describe field results for an object.

**Signature**

```java
public Schema.DescribeFieldResult getDescribe(Object options)
```

**Parameters**

- `options`  
  Type: Object
Use this parameter to pass FieldDescribeOptions.FULL_DESCRIBE when a subset of system objects could have different results for picklist values based on the context they're invoked in. This parameter computes all aspects of describe field results.

For example, AICConversationContext.PersonType field is a picklist that contains a list of accessible object types.

**Return Value**

Type: Schema.DescribeFieldResult

### SObjectType Class

A Schema.sObjectType object is returned from the field describe result using the getReferenceTo method, or from the sObject describe result using the getSObjectType method.

### Namespace

Schema

### Usage

```java
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
List<Schema.sObjectType> P = F.getReferenceTo();
```

### SObjectType Methods

The following are methods for SObjectType. All are instance methods.

**IN THIS SECTION:**

- `getDescribe()`
  
  Returns the describe sObject result for this field.

- `getDescribe(options)`
  
  Returns the describe sObject result for this field; the parameter value determines whether all child relationships are loaded up-front, or not.

- `newSObject()`
  
  Constructs a new sObject of this type.

- `newSObject(id)`
  
  Constructs a new sObject of this type, with the specified ID.

- `newSObject(recordTypeId, loadDefaults)`
  
  Constructs a new sObject of this type, and optionally, of the specified record type ID and with default custom field values.

**getDescribe()**

Returns the describe sObject result for this field.
Signature

```java
public Schema.DescribeSObjectResult getDescribe()
```

Return Value
Type: `Schema.DescribeSObjectResult`

**getDescribe(options)**
Returns the describe sObject result for this field; the parameter value determines whether all child relationships are loaded up-front, or not.

Signature

```java
public Schema.DescribeSObjectResult getDescribe(Object options)
```

Parameters

- `options`
  Type: `Object`
  The parameter values determine how the elements of the describe operation are loaded.
  - Use `SObjectDescribeOptions.FULL` to eager-load all elements of the describe, including child relationships, up-front at the time of method invocation. This describe guarantees fully coherent results, even if the describe object is passed to another namespace, API version, or other Apex context that may have different results when generating describe attributes.
  - Use `SObjectDescribeOptions.DEFERRED` to enable lazy initialization of describe attributes on first use. This means that all child relationships will not be loaded at the time of first invocation of the method.
  - Use `SObjectDescribeOptions.DEFAULT` to default to either eager-load or lazy-load depending on the API version.

The type of describe operation, as determined by the parameter value is depicted in this table.

<table>
<thead>
<tr>
<th>Parameter Value</th>
<th>API Version 43.0 and Earlier</th>
<th>API Version 44.0 and Later</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full</td>
<td>Eager</td>
<td>Eager</td>
</tr>
<tr>
<td>Deferred</td>
<td>Lazy</td>
<td>Lazy</td>
</tr>
<tr>
<td>Default</td>
<td>Lazy</td>
<td>Lazy</td>
</tr>
</tbody>
</table>

Return Value
Type: `Schema.DescribeSObjectResult`

**newSObject()**
Constructs a new sObject of this type.

Signature

```java
public sObject newSObject()
```
Return Value
Type: sObject

Example
For an example, see Dynamic DML.

newSObject(id)
Constructs a new sObject of this type, with the specified ID.

Signature
public sObject newSObject(ID id)

Parameters
id
Type: ID

Return Value
Type: sObject

Usage
For the argument, pass the ID of an existing record in the database.
After you create a new sObject, the sObject returned has all fields set to null. You can set any updateable field to desired values and then update the record in the database. Only the fields you set new values for are updated and all other fields which are not system fields are preserved.

newSObject(recordTypeId, loadDefaults)
Constructs a new sObject of this type, and optionally, of the specified record type ID and with default custom field values.

Important: Where possible, we changed noninclusive terms to align with our company value of Equality. We maintained certain terms to avoid any effect on customer implementations.

Signature
public sObject newSObject(ID recordTypeId, Boolean loadDefaults)

Parameters
recordTypeId
Type: ID
Specifies the record type ID of the sObject to create. If no record type exists for this sObject, use null. If the sObject has record types and you specify null, the default record type is used.
loadDefaults
Type: Boolean
Specifies whether to populate custom fields with their predefined default values (true) or not (false).

Return Value
Type: sObject

Usage
• For required fields that have no default values, make sure to provide a value before inserting the new sObject. Otherwise, the insertion results in an error. An example is the Account Name field or a master-detail relationship field.
• Since picklists and multi-select picklists can have default values specified per record type, this method populates the default value corresponding to the record type specified.
• If fields have no predefined default values and the loadDefaults argument is true, this method creates the sObject with field values of null.
• If the loadDefaults argument is false, this method creates the sObject with field values of null.
• This method populates read-only custom fields of the new sObject with default values. You can then insert the new sObject with the read-only fields, even though these fields cannot be edited after they’re inserted.
• If a custom field is marked as unique and also provides a default value, inserting more than one new sObject will cause a run-time exception because of duplicate field values.

To learn more about default field values, see “Default Field Values” in the Salesforce online help.

Example: Creating New sObject with Default Values
This sample creates an account with any default values populated for its custom fields, if any, using the newSObject method. It also creates a second account for a specific record type. For both accounts, the sample sets the Name field, which is a required field that doesn’t have a default value, before inserting the new accounts.

```apex
// Create an account with predefined default values
Account acct = (Account)Account.sObjectType.newSObject(null, true);
// Provide a value for Name
acct.Name = 'Acme';
// Insert new account
insert acct;

// This is for record type RT1 of Account
ID rtId = [SELECT Id FROM RecordType WHERE sObjectType='Account' AND Name='RT1'].Id;
Account acct2 = (Account)Account.sObjectType.newSObject(rtId, true);
// Provide a value for Name
acct2.Name = 'Acme2';
// Insert new account
insert acct2;
```

Search Namespace

The Search namespace provides classes for getting search results and suggestion results.
The following are the classes in the Search namespace.
IN THIS SECTION:

KnowledgeSuggestionFilter Class
Filter settings that narrow the results from a call to System.Search.suggest(searchQuery, sObjectType, options) when the SOSL search query contains a KnowledgeArticleVersion object.

QuestionSuggestionFilter Class
The Search.QuestionSuggestionFilter class filters results from a call to System.Search.suggest(searchQuery, sObjectType, options) when the SOSL searchQuery contains a FeedItem object.

SearchResult Class
A wrapper object that contains an sObject and search metadata.

SearchResults Class
Wraps the results returned by the Search.find(String) method.

SuggestionOption Class
Options that narrow record and article suggestion results returned from a call to System.Search.suggest(String, String, Search.SuggestionOption).

SuggestionResult Class
A wrapper object that contains an sObject.

SuggestionResults Class
Wraps the results returned by the Search.suggest(String, String, Search.SuggestionOption) method.

SEE ALSO:

find(searchQuery)
suggest(searchQuery, sObjectType, suggestions)

KnowledgeSuggestionFilter Class
Filter settings that narrow the results from a call to System.Search.suggest(searchQuery, sObjectType, options) when the SOSL search query contains a KnowledgeArticleVersion object.

Namespace
Search

KnowledgeSuggestionFilter Methods
The following are methods for KnowledgeSuggestionFilter.

IN THIS SECTION:

addArticleType(articleType)
Adds a filter that narrows suggestion results to display the specified article type. This filter is optional.

addDataCategory(dataCategoryGroupName, dataCategoryName)
Adds a filter that narrows suggestion results to display articles in the specified data category. This filter is optional.
addTopic(topic)
Specifies the article topic to return. This filter is optional.

setChannel(channelName)
Sets a channel to narrow the suggestion results to articles in the specified channel. This filter is optional.

setDataCategories(dataCategoryFilters)
Adds filters that narrow suggestion results to display articles in the specified data categories. Use this method to set multiple data category group and name pairs in one call. This filter is optional.

setLanguage(localeCode)
Sets a language to narrow the suggestion results to display articles in that language. This filter value is required in calls to System.Search.suggest(String, String, Search.SuggestionOption).

setPublishStatus(publishStatus)
Sets a publish status to narrow the suggestion results to display articles with that status. This filter value is required in calls to System.Search.suggest(String, String, Search.SuggestionOption).

setValidationStatus(validationStatus)
Sets a validation status to narrow the suggestion results to display articles with that status. This filter is optional.

addArticleType(articleType)
Adds a filter that narrows suggestion results to display the specified article type. This filter is optional.

**Signature**

public void addArticleType(String articleType)

**Parameters**

*articleType*
  
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A three-character ID prefix indicating the desired article type.</td>
</tr>
</tbody>
</table>

**Return Value**

Type: void

**Usage**

To add more than 1 article type, call the method multiple times.

addDataCategory(dataCategoryGroupName, dataCategoryName)
Adds a filter that narrows suggestion results to display articles in the specified data category. This filter is optional.

**Signature**

public void addDataCategory(String dataCategoryGroupName, String dataCategoryName)
Parameters

dataCategoryGroupName
  Type: String
  The name of the data category group

dataCategoryName
  Type: String
  The name of the data category.

Return Value
Type: void

Usage
To set multiple data categories, call the method multiple times. The name of the data category group and name of the data category for desired articles, expressed as a mapping, for example,
Search.KnowledgeSuggestionFilter.addDataCategory('Regions', 'Asia').

addTopic(topic)
Specifies the article topic to return. This filter is optional.

Signature
public void addTopic(String topic)

Parameters
addTopic
  Type: String
  The name of the article topic.

Return Value
Type: void

Usage
To add more than 1 article topic, call the method multiple times.

setChannel(channelName)
Sets a channel to narrow the suggestion results to articles in the specified channel. This filter is optional.

Signature
public void setChannel(String channelName)
Parameters

channelName
  Type: String
  The name of a channel. Valid values are:
  • AllChannels—Visible in all channels the user has access to
  • App—Visible in the internal Salesforce Knowledge application
  • Pkb—Visible in the public knowledge base
  • Csp—Visible in the Customer Portal
  • Prm—Visible in the Partner Portal
  If channel isn’t specified, the default value is determined by the type of user.
  • Pkb for a guest user
  • Csp for a Customer Portal user
  • Prm for a Partner Portal user
  • App for any other type of user
  If channel is specified, the specified value may not be the actual value requested, because of certain requirements.
  • For guest, Customer Portal, and Partner Portal users, the specified value must match the default value for each user type. If the values don’t match or AllChannels is specified, then App replaces the specified value.
  • For all users other than guest, Customer Portal, and Partner Portal users:
    – If Pkb, Csp, Prm, or App are specified, then the specified value is used.
    – If AllChannels is specified, then App replaces the specified value.

Return Value

Type: void

setDataCategories(dataCategoryFilters)

Adds filters that narrow suggestion results to display articles in the specified data categories. Use this method to set multiple data category group and name pairs in one call. This filter is optional.

Signature

public void setDataCategories(Map dataCategoryFilters)

Parameters

dataCategoryFilters
  Type: Map
  A map of data category group and data category name pairs.

Return Value

Type: void
**setLanguage(localeCode)**

Sets a language to narrow the suggestion results to display articles in that language. This filter value is required in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`.

**Signature**

```java
public void setLanguage(String localeCode)
```

**Parameters**

- `localeCode`
  - Type: `String`
  - A locale code. For example, 'en_US' (English–United States), or 'es' (Spanish).

**Return Value**

Type: void

**SEE ALSO:**

- Supported Locales

**setPublishStatus(publishStatus)**

Sets a publish status to narrow the suggestion results to display articles with that status. This filter value is required in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`.

**Signature**

```java
public void setPublishStatus(String publishStatus)
```

**Parameters**

- `publishStatus`
  - Type: `String`
  - A publish status. Valid values are:
    - Draft—Articles aren’t published in Salesforce Knowledge.
    - Online—Articles are published in Salesforce Knowledge.
    - Archived—Articles aren’t published and are available in Archived Articles view.

**setValidationStatus(validationStatus)**

Sets a validation status to narrow the suggestion results to display articles with that status. This filter is optional.

**Signature**

```java
public void setValidationStatus(String validationStatus)
```
Parameters

validationStatus
Type: String
An article validation status. These values are available in the ValidationStatus field on the KnowledgeArticleVersion object.

Return Value
Type: void

QuestionSuggestionFilter Class
The Search.QuestionSuggestionFilter class filters results from a call to System.Search.suggest(searchQuery, sObjectType, options) when the SOSL searchQuery contains a FeedItem object.

Namespace
Search

IN THIS SECTION:
QuestionSuggestionFilter Methods

QuestionSuggestionFilter Methods
The following are methods for QuestionSuggestionFilter.

IN THIS SECTION:
addGroupId(groupId)
Adds a filter to display questions associated with the single specified group whose ID is passed in as an argument. This filter is optional.
addNetworkId(networkId)
Adds a filter to display questions associated with the single specified network whose ID is passed in as an argument. This filter is optional.
addUserId(userId)
Adds a filter to display questions belonging to the single specified user whose ID is passed in as an argument. This filter is optional.
setGroupIds(groupIds)
Sets a new list of groups to replace the current list of groups where the group IDs are passed in as an argument. This filter is optional.
setNetworkIds(networkIds)
Sets a new list of networks to replace the current list of networks where the network IDs are passed in as an argument. This filter is optional.
setTopicId(topicId)
Sets a filter to display questions associated with the single specified topic whose ID is passed in as an argument. This filter is optional.
setUserIds(userIds)
Sets a new list of users to replace the current list of users where the users IDs are passed in as an argument. This filter is optional.
addGroupId(groupId)

Adds a filter to display questions associated with the single specified group whose ID is passed in as an argument. This filter is optional.

Signature

public void addGroupId(String groupId)

Parameters

groupId

Type: String

The ID for a group.

Return Value

Type: void

Usage

To add more than one group, call the method multiple times.

addNetworkId(networkId)

Adds a filter to display questions associated with the single specified network whose ID is passed in as an argument. This filter is optional.

Signature

public void addNetworkId(String networkId)

Parameters

networkId

Type: String

The ID of the Experience Cloud site about which you’re retrieving this information.

Return Value

Type: void

Usage

To add more than one network, call the method multiple times.

addUserId(userId)

Adds a filter to display questions belonging to the single specified user whose ID is passed in as an argument. This filter is optional.

Signature

public void addUserId(String userId)
Parameters

`userId`
  Type: `String`
  The ID for the user.

Return Value

Type: `void`

Usage

To add more than one user, call the method multiple times.

`setGroupIds(groupIds)`

Sets a new list of groups to replace the current list of groups where the group IDs are passed in as an argument. This filter is optional.

Signature

`public void setGroupIds(List<String> groupIds)`

Parameters

`groupIds`
  Type: `List<String>`
  A list of group IDs.

Return Value

Type: `void`

`setNetworkIds(networkIds)`

Sets a new list of networks to replace the current list of networks where the network IDs are passed in as an argument. This filter is optional.

Signature

`public void setNetworkIds(List<String> networkIds)`

Parameters

`networkIds`
  Type: `List<String>`
  A list of network IDs.

Return Value

Type: `void`
**setTopicId(topicId)**
Sets a filter to display questions associated with the single specified topic whose ID is passed in as an argument. This filter is optional.

**Signature**
```
public void setTopicId(String topicId)
```

**Parameters**
- **topicId**
  Type: `String`  
The ID for a topic.

**Return Value**
Type: `void`

**setUserIds(userIds)**
Sets a new list of users to replace the current list of users where the users IDs are passed in as an argument. This filter is optional.

**Signature**
```
public void setUserIds(List<String> userIds)
```

**Parameters**
- **userIds**
  Type: `List<String>`  
  A list of user IDs.

**Return Value**
Type: `void`

**SearchResult Class**
A wrapper object that contains an sObject and search metadata.

**Namespace**
`Search`

**SearchResult Methods**
The following are methods for `SearchResult`. 
IN THIS SECTION:

- **getSObject()**
  Returns an sObject from a SearchResult object.

- **getSnippet(fieldName)**
  Returns a snippet from a Case, Feed, or Knowledge Article SearchResult object based on the specified field name.

- **getSnippet()**
  Returns a snippet from a SearchResult object based on the default field.

### getSObject()

Returns an sObject from a SearchResult object.

**Signature**

```java
public SObject getSObject()
```

**Return Value**

Type: SObject

**SEE ALSO:**

- **find(searchQuery)**
  Apex Developer Guide: Dynamic SOSL

### getSnippet(fieldName)

Returns a snippet from a Case, Feed, or Knowledge Article SearchResult object based on the specified field name.

**Signature**

```java
public String getSnippet(String fieldName)
```

**Parameters**

- **fieldName**
  Type: String

  The field name to use for creating the snippet.

  Valid values: Case.Casenumber, FeedPost.Title, KnowledgeArticleVersion.Title

**Return Value**

Type: String

**SEE ALSO:**

- **find(searchQuery)**
  Apex Developer Guide: Dynamic SOSL
getSnippet()  
Returns a snippet from a SearchResult object based on the default field.

Signature

public String getSnippet()

Return Value

Type: String

SEE ALSO:

- find(searchQuery)
- Apex Developer Guide: Dynamic SOSL

SearchResults Class

Wraps the results returned by the Search.find(String) method.

Namespace

Search

SearchResults Methods

The following are methods for SearchResults.

IN THIS SECTION:

- get(sObjectType)
  - Returns a list of Search.SearchResult objects that contain an sObject of the specified type.

get(sObjectType)

Returns a list of Search.SearchResult objects that contain an sObject of the specified type.

Signature

public List<Search.SearchResult> get(String sObjectType)

Parameters

sObjectType
  - Type: String

  The name of an sObject in the dynamic SOSL query passed to the Search.find(String) method.
Return Value
Type: List<Search.SearchResult>

Usage
SOSL queries passed to the Search.find(String) method can return results for multiple objects. For example, the query
Search.find('FIND map IN ALL FIELDS RETURNING Account, Contact, Opportunity') includes results for 3 objects. You can call get(string) to retrieve search results for 1 object at a time. For example, to get results for the Account object, call Search.SearchResults.get('Account').

SEE ALSO:
- find(searchQuery)
- SearchResult Methods
- Apex Developer Guide: Dynamic SOSL

SuggestionOption Class
Options that narrow record and article suggestion results returned from a call to System.Search.suggest(String, String, Search.SuggestionOption).

Namespace
Search

SuggestionOption Methods
The following are methods for SuggestionOption.

IN THIS SECTION:
- setFilter(knowledgeSuggestionFilter)
  Set filters that narrow Salesforce Knowledge article results in a call to System.Search.suggest(String, String, Search.SuggestionOption).
- setLimit(limit)
  The maximum number of record or article suggestions to retrieve.

setFilter (knowledgeSuggestionFilter)
Set filters that narrow Salesforce Knowledge article results in a call to System.Search.suggest(String, String, Search.SuggestionOption).

Signature
public void setFilter(Search.KnowledgeSuggestionFilter knowledgeSuggestionFilter)
Parameters

knowledgeSuggestionFilter
Type: KnowledgeSuggestionFilter
An object containing filters that narrow the search results.

Return Value
Type: void

Usage

Search.KnowledgeSuggestionFilter filters = new Search.KnowledgeSuggestionFilter();
filters.setLanguage('en_US');
filters.setPublishStatus('Online');
filters.setChannel('app');

Search.SuggestionOption options = new Search.SuggestionOption();
options.setFilter(filters);

Search.SuggestionResults suggestionResults = Search.suggest('all', 'KnowledgeArticleVersion',
options);

for (Search.SuggestionResult searchResult : suggestionResults.getSuggestionResults()) {
    KnowledgeArticleVersion article = (KnowledgeArticleVersion) searchResult.getSObject();
    System.debug(article.title);
}

setLimit(limit)
The maximum number of record or article suggestions to retrieve.

Signature

public void setLimit(Integer limit)

Parameters

limit
Type: Integer
The maximum number of record or article suggestions to retrieve.

Return Value
Type: void

Usage

By default, the System.Search.suggest(String, String, Search.SuggestionOption) method returns the
5 most relevant results. However, if your query is broad, it could match more than 5 results. If
Search.SuggestionResults.hasMoreResults() returns true, there are more than 5 results. To retrieve them, call setLimit(Integer) to increase the number of suggestions results.

```java
Search.SuggestionOption option = new Search.SuggestionOption();
option.setLimit(10);
Search.suggest('my query', 'mySObjectType', option);
```

**SuggestionResult Class**

A wrapper object that contains an sObject.

**Namespace**

Search

**SuggestionResult Methods**

The following are methods for SuggestionResult.

IN THIS SECTION:

getSObject()

Returns the sObject from a SuggestionResult object.

**getSObject()**

Returns the sObject from a SuggestionResult object.

**Signature**

```java
public SObject getSObject()
```

**Return Value**

Type: SObject

**SuggestionResults Class**

Wraps the results returned by the Search.suggest(String, String, Search.SuggestionOption) method.

**Namespace**

Search

**SuggestionResults Methods**

The following are methods for SuggestionResults.
getSuggestionResults()
Returns a list of SuggestionResult objects from the response to a call to Search.suggest(String, String, Search.SuggestionOption).

hasMoreResults()
Indicates whether a call to System.Search.suggest(String, String, Search.SuggestionOption) has more results available than were returned.

g getSuggestionResults()
Returns a list of SuggestionResult objects from the response to a call to Search.suggest(String, String, Search.SuggestionOption).

Signature
public List<Search.SuggestionResult> getSuggestionResults()

Return Value
Type: List<SuggestionResult>

hasMoreResults()
Indicates whether a call to System.Search.suggest(String, String, Search.SuggestionOption) has more results available than were returned.

Signature
public Boolean hasMoreResults()

Return Value
Type: Boolean

Usage
If a limit isn’t specified, 5 records are returned in calls to System.Search.suggest(String, String, Search.SuggestionOption). If there are more suggested records than the limit specified, a call to hasMoreResults() returns true.

Sfc Namespace

The Sfc namespace contains classes used in Salesforce Files.
The following are the classes in the Sfc namespace.
ContentDownloadContext Enum

This enum specifies the download context.

Usage

If the operationContext is CONTENT, CHATTER, DELIVERY, S1, or MOBILE, it can be used in a shepherd servlet as a query parameter. It's possible for a user to change the query parameters. If a user enters a value other than CONTENT, CHATTER, DELIVERY, S1, or MOBILE, the value is treated as the default value CONTENT.

Users can't set query parameters to REST_API, SOQL, or RETRIEVE, so these values can be assumed to be accurate.

Enum Values

The Sfc.ContentDownloadContext enum value identifies the content download context. The enum value is provided as a query parameter in the file download servlet. The following are the values of the Sfc.ContentDownloadContext enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHATTER</td>
<td>Download from Chatter.</td>
</tr>
<tr>
<td>CONTENT</td>
<td>Default value. Downloads from the Salesforce CRM Content product.</td>
</tr>
<tr>
<td>DELIVERY</td>
<td>Download of a content delivery.</td>
</tr>
<tr>
<td>REST_API</td>
<td>Download from the Connect API(/connect/files/${fileId}/content endpoint). Used in both Android and iOS apps.</td>
</tr>
<tr>
<td>RETRIEVE</td>
<td>Retrieve VersionData from SObject API.</td>
</tr>
<tr>
<td>S1</td>
<td>Download from Lightning Experience.</td>
</tr>
<tr>
<td>SOQL</td>
<td>Select VersionData from SOQL.</td>
</tr>
</tbody>
</table>

ContentDownloadHandler Class

Use ContentDownloadHandler to define a custom download handler that controls how content is downloaded.

Namespace

Sfc on page 2785
ContentDownloadHandler Properties

The following are properties for ContentDownloadHandler.

**downloadErrorMessage**
A customized error message explaining why the download isn’t allowed.

**isDownloadAllowed**
Indicates whether or not download is allowed.

**redirectUrl**
The URL the user should be redirected to, for applying Information Rights Management (IRM) control, virus scanning, or other behavior.

**downloadErrorMessage**
A customized error message explaining why the download isn’t allowed.

**Signature**
```java
public String downloadErrorMessage {get; set;}
```

**Property Value**
- **Type:** String
- This message is used if a redirectUrl is not provided. If the download is not allowed, Salesforce will throw a ContentCustomizedDownloadException exception that contains the downloadErrorMessage.

**isDownloadAllowed**
Indicates whether or not download is allowed.

**Signature**
```java
public Boolean isDownloadAllowed {get; set;}
```

**Property Value**
- **Type:** Boolean

**redirectUrl**
The URL the user should be redirected to, for applying Information Rights Management (IRM) control, virus scanning, or other behavior.
Signature

public String redirectUrl {get; set;}

Property Value

Type: String

The URL must be a valid relative URL. For example, the redirect can be a custom Visualforce page such as "/apex/IRMControl". URLs with no path, such as "www.domain.com", will result in an InvalidParameterValueException.

ContentDownloadHandlerFactory Interface

Use this interface to provide a class factory that Salesforce can call to create instances of your custom ContentDownloadHandler.

Namespace

Sfc on page 2785

Usage

ContentDownloadHandler getContentDownloadHandler(List<ID> ids, ContentDownloadContext context);

ContentDownloadHandlerFactory Methods

The following are methods for ContentDownloadHandlerFactory.

getContentDownloadHandler(var1, var2)

Returns a ContentDownloadHandler for a given list of content IDs and a download context.

getContentDownloadHandler(var1, var2)

Returns a ContentDownloadHandler for a given list of content IDs and a download context.

Signature

public Sfc.ContentDownloadHandler getContentDownloadHandler(List<Id> var1, Sfc.ContentDownloadContext var2)

Parameters

var1

Type: List<Id>
ContentDownloadHandlerFactory Example Implementation

This example creates a class that implements the `Sfc.ContentDownloadHandlerFactory` interface and returns a download handler that blocks downloading content to mobile devices.

```java
// Allow customization of the content download experience
public class ContentDownloadHandlerFactoryImpl implements Sfc.ContentDownloadHandlerFactory {

    public Sfc.ContentDownloadHandler getContentDownloadHandler(List<ID> ids, Sfc.ContentDownloadContext context) {
        Sfc.ContentDownloadHandler contentDownloadHandler = new Sfc.ContentDownloadHandler();

        if (context == Sfc.ContentDownloadContext.MOBILE) {
            contentDownloadHandler.isDownloadAllowed = false;
            contentDownloadHandler.downloadErrorMessage = 'Downloading a file from a mobile device is not allowed.';
            return contentDownloadHandler;
        }

        contentDownloadHandler.isDownloadAllowed = true;
        return contentDownloadHandler;
    }
}
```

### Sfdc_Checkout Namespace

The `Sfdc_Checkout` namespace provides an interface and classes for B2B Commerce apps in Salesforce.

The following are the classes in the `Sfdc_Checkout` namespace.

**IN THIS SECTION:**

- **AsyncCartProcessor Interface**
  Use this interface to implement asynchronous integrations in B2B Commerce.

- **B2BCheckoutController Class**
  Communicate with simple checkout Apex methods to work with data related to B2B Commerce checkout.

- **IntegrationInfo Class**
  Provides the values that B2B Commerce Checkout uses to map requests to responses, necessary metadata, and context.

- **IntegrationStatus Class**
  Supports synchronous execution of Apex integrations for B2B Commerce. The implementation must return the status of the execution.
IntegrationStatus.Status Enum
The IntegrationStatus.Status enum describes the status of the current integration.

AsyncCartProcessor Interface
Use this interface to implement asynchronous integrations in B2B Commerce.

Namespace
Sfdc_Checkout

IN THIS SECTION:
AsyncCartProcessor Methods
AsyncCartProcessor Example Implementation

AsyncCartProcessor Methods
The following are methods for AsyncCartProcessor.

IN THIS SECTION:
startCartProcessAsync(integrationInfo, cartId)
The startCartProcessAsync method is called asynchronously by the integration framework. Calling this method begins cart processing for Commerce checkout.

startCartProcessAsync(integrationInfo, cartId)
The startCartProcessAsync method is called asynchronously by the integration framework. Calling this method begins cart processing for Commerce checkout.

Signature
public sfdc_checkout.IntegrationStatus startCartProcessAsync(sfdc_checkout.IntegrationInfo integrationInfo, Id cartId)

Parameters
integrationInfo
Type: IntegrationInfo
Provides values that B2B Commerce checkout APIs use to map requests to responses, necessary metadata, and context.
cartId
Type: Id
ID of the WebCart object.

Return Value
Type: IntegrationStatus
Status of the current integration. Possible values are SUCCESS and FAILED.

AsyncCartProcessor Example Implementation

This is an example implementation of the sfdc_checkout.AsyncCartProcessor interface.

```java
global interface checkout_AsyncCartProcessor {
    //Integration for async processing
    IntegrationStatus startCartProcessAsync(
        IntegrationInfo integrationInfo,
        Id cartId);
}
```

AsyncCartProcessor is a base interface. There are four interfaces that extend it, including CartInventoryValidation, CartPriceCalculations, CartShippingCharges, and CartTaxCalculations. For more information about these interfaces, including code examples and test classes, see Checkout Integrations.

B2BCheckoutController Class

Communicate with simple checkout Apex methods to work with data related to B2B Commerce checkout.

Namespace

sfdc_checkout

Usage

You must specify the sfdc_checkout namespace when creating an instance of this class.

IN THIS SECTION:

B2BCheckoutController Methods

B2BCheckoutController Methods

The following are methods for B2BCheckoutController.

IN THIS SECTION:

licenseCompliance(cartId, orderId)

If you implement your own cart-to-order process without invoking the Cart to Order flow core action, you must invoke this method to correctly track your orders for GMV (Gross Merchandise Value) recognition.

```java
licenseCompliance(cartId, orderId)
```

If you implement your own cart-to-order process without invoking the Cart to Order flow core action, you must invoke this method to correctly track your orders for GMV (Gross Merchandise Value) recognition.

licenseCompliance(cartId, orderId)
Signature

```java
public static void licenseCompliance(String cartId, String orderId)
```

Parameters

cartId
  Type: `String`
  The `cartId` of a web cart from which an order is created.

orderId
  Type: `String`
  The `orderId` of the order you created from the cart.

Return Value

Type: `Void`

IntegrationInfo Class

Provides the values that B2B Commerce Checkout uses to map requests to responses, necessary metadata, and context.

Namespace

`sfdc_checkout` on page 2789

Usage

This class provides information about a B2B Commerce integration. An instance of this class is passed as a parameter into the integration interface.

IN THIS SECTION:

IntegrationInfo Properties

IntegrationInfo Properties

The following are properties for `IntegrationInfo`.

IN THIS SECTION:

- `integrationId`
  The unique ID of a B2B Commerce integration.

- `jobId`
  The ID of the job, specific to the Salesforce Background Operation framework.

- `siteLanguage`
  Site language to be used by third party services.
**integrationId**
The unique ID of a B2B Commerce integration.

**Signature**
```java
public String integrationId {get; set;}
```

**Property Value**
Type: String

**jobId**
The ID of the job, specific to the Salesforce Background Operation framework.

**Signature**
```java
public String jobId {get; set;}
```

**Property Value**
Type: String

**siteLanguage**
Site language to be used by third party services.

**Signature**
```java
public String siteLanguage {get; set;}
```

**Property Value**
Type: String

**IntegrationStatus Class**
Supports synchronous execution of Apex integrations for B2B Commerce. The implementation must return the status of the execution.

**Namespace**
sfdc_checkout

**Usage**
You must specify the sfdc_checkout namespace when creating an instance of this class.

IN THIS SECTION:
  IntegrationStatus Properties
IntegrationStatus Properties
The following are properties for IntegrationStatus.

IN THIS SECTION:

status
Indicates the status of the integration process and whether or not it completed successfully.

status
Indicates the status of the integration process and whether or not it completed successfully.

Signature

public sfdc_checkout.IntegrationStatus.Status status {get; set;}

Property Value
Type: sfdc_checkout.IntegrationStatus.Status on page 2794

IntegrationStatus.Status Enum
The IntegrationStatus.Status enum describes the status of the current integration.

Enum Values
The following are the values of the sfdc_checkout.IntegrationStatus.Status enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FAILED</td>
<td>Indicates transient, unknown error, managed by the implementor. The buyer can retry this action.</td>
</tr>
<tr>
<td>SUCCESS</td>
<td>Indicates the integration executed successfully.</td>
</tr>
</tbody>
</table>

sfdc_surveys Namespace
The sfdc_surveys namespace provides an interface for shortening survey invitations.

The following are the classes in the sfdc_surveys namespace.

IN THIS SECTION:

SurveyInvitationLinkShortener Interface
Use this interface to provide a class factory that Salesforce can call to create instances of your custom SurveyInvitationLinkShortener.

Example Implementation to Associate SurveySubjects with SurveyInvitation and SurveyResponses
If no survey responses are populated, create a custom code to associate SurveySubjects with SurveyInvitation and SurveyResponses.
SurveyInvitationLinkShortener Interface

Use this interface to provide a class factory that Salesforce can call to create instances of your custom SurveyInvitationLinkShortener.

Namespace

sfdc_surveys

Usage

Implement an instance of the SurveyInvitationLinkShortener interface to shorten the survey invitation that can be distributed as short URLs over customer engaged channels, such as SMS, WhatsApp, or Facebook Messenger.

Special access rules

To implement this interface, you must have the Salesforce Feedback Management license enabled in your Salesforce organization.

IN THIS SECTION:

SurveyInvitationLinkShortener Methods

SurveyInvitationLinkShortener Example Implementation

SurveyInvitationLinkShortener Methods

The following are methods for SurveyInvitationLinkShortener.

IN THIS SECTION:

getShortenedURL(var1)

Returns a shortened URL for a given survey invitation.

getShortenedURL(var1)

Returns a shortened URL for a given survey invitation.

IN THIS SECTION:

getShortenedURL(var1)

Returns a shortened URL for a given survey invitation.

getShortenedURL(var1)

Returns a shortened URL for a given survey invitation.

Signature

public String getShortenedURL(String var1)

Parameters

var1

Type: String

Return Value

Type: String
SurveyInvitationLinkShortener Example Implementation

This is an example implementation of the sfdc_surveys.SurveyInvitationLinkShortener interface.
This sample code uses Named Credentials for authentication. For more information on Named Credentials, see Named Credentials as Callout Endpoints.

```java
public class SurveyInvitationLinkShortenerImpl implements sfdc_surveys.SurveyInvitationLinkShortener {
    public String getShortenedURL(String invitationURL) {
        return shortenUrlUsingBitlyService(invitationURL);
    }

    public String shortenUrlUsingBitlyService(String invitationURL) {
        HttpRequest request = new HttpRequest();
        request.setEndpoint('callout:bitly/v4/shorten');
        request.setMethod('POST');
        request.setHeader('Authorization', 'Bearer {!$Credential.Password}');
        request.setHeader('Accept', 'application/json');
        request.setHeader('Content-Type', 'application/json');
        request.setBody(JSON.serialize(new Map<String, Object>{{'group_guid' => '{!$Credential.UserName}', 'long_url' => invitationURL}}));

        Http http = new Http();
        HttpResponse res = http.send(request);

        Object result = JSON.deserializeUntyped(res.getBody());
        if (result instanceof Map<String, Object>) {
            Map<String, Object> resultMap = (Map<String, Object>) result;
            Object shortenedLinkVal = resultMap.get('link');
            if (shortenedLinkVal != null && shortenedLinkVal instanceof String) {
                return (String) shortenedLinkVal;
            }
        }
        return invitationURL;
    }
}
```

Example Implementation to Associate SurveySubjects with SurveyInvitation and SurveyResponses

If no survey responses are populated, create a custom code to associate SurveySubjects with SurveyInvitation and SurveyResponses.

This example shows how to associate SurveySubjects with SurveyInvitation and SurveyResponses.

```java
public class CreateEntriesInSurveyInvitationRespRL {
    // Utility to create SurveyInvitation and SurveySubject record
    public static void addEntry(String associatedRecordId, String surveyId, String participantId) {
        String invitationId = createSurveyInvitation(surveyId, participantId);
        createSurveySubject(invitationId, associatedRecordId);
    }
}
```
private static String createSurveyInvitation(String surveyId, String participantId) {
    SurveyInvitation surveyInv = new SurveyInvitation();
    surveyInv.Name = 'SurveyInvitationForCase'; // add your survey invitation name here
    surveyInv.ParticipantId = participantId;
    surveyInv.CommunityId = '0DBRM0000004n4y'; // add your community id here
    surveyInv.OptionsAllowGuestUserResponse = true;
    surveyInv.SurveyId = surveyId;

    // Insert the SurveyInvitation Record
    insert surveyInv;

    return surveyInv.Id;
}

private static void createSurveySubject(String invitationId, String associatedRecordId) {
    SurveySubject subj = new SurveySubject();
    subj.Name = 'Sur_Subject_for_invitation';
    subj.ParentId = invitationId; // similarly you can use survey response id to associate survey subject to a response record.
    subj.SubjectId = associatedRecordId;

    // Insert the SurveySubject Record
    insert subj;
}

trigger SurveyResponseForCaseTrigger on SurveyResponse (after insert) {
    System.debug('Inside Survey response trigger ');
    for(SurveyResponse sr: Trigger.New) {
        SurveySubject subj = new SurveySubject();
        subj.Name = 'Sur_Subject_for_response';
        subj.ParentId = sr.id; // Associating survey response id
        subj.SubjectId = associatedRecordId;

        // Get the associatedRecordId recordId (like Case, Opportunity etc) using the SurveyInvitation Id and
        // assigning it to SubjectId, assuming we inserted SurveySubject record for the associated invitation
        // using the previous code
        List<SurveySubject> SurSubj=[select subjectid from SurveySubject where parentid =

        List<SurveySubject> SurSubj=[select subjectid from SurveySubject where parentid =

        List<SurveySubject> SurSubj=[select subjectid from SurveySubject where parentid =
for (SurveySubject sub: SurSubj) {
    String ids = String.valueOf(sub.subjectid).substring(0, 3);
    if ('500'.equals(ids)) {
        subj.SubjectId = sub.subjectid;
        // Insert the SurveySubject Record
        insert subj;
        break;
    }
}

Site Namespace

The Site namespace provides an interface for rewriting Sites URLs.
The following is the interface in the Site namespace.

IN THIS SECTION:

- UrlRewriter Interface
  Enables rewriting Sites URLs.
- Site Exceptions
  The Site namespace contains an exception class.

UrlRewriter Interface

Enables rewriting Sites URLs.

Namespace

Site

Usage

Sites provides built-in logic that helps you display user-friendly URLs and links to site visitors. Create rules to rewrite URL requests typed into the address bar, launched from bookmarks, or linked from external websites. You can also create rules to rewrite the URLs for links within site pages. URL rewriting not only makes URLs more descriptive and intuitive for users, it allows search engines to better index your site pages.

For example, let’s say that you have a blog site. Without URL rewriting, a blog entry's URL might look like this: https://myblog.my.salesforce-sites.com/posts?id=003D000000QOPcN

To rewrite URLs for a site, create an Apex class that maps the original URLs to user-friendly URLs, and then add the Apex class to your site.
UrlRewriter Methods

The following are methods for UrlRewriter. All are instance methods.

IN THIS SECTION:
  generateUrlFor(salesforceUrls)
  Maps a list of Salesforce URLs to a list of user-friendly URLs.
  mapRequestUrl(userFriendlyUrl)
  Maps a user-friendly URL to a Salesforce URL.

generateUrlFor(salesforceUrls)
Maps a list of Salesforce URLs to a list of user-friendly URLs.

Signature
public System.PageReference[] generateUrlFor(System.PageReference[] salesforceUrls)

Parameters
salesforceUrls
  Type: System.PageReference[]

Return Value
Type: System.PageReference[]

Usage
You can use List<PageReference> instead of PageReference [], if you prefer.

⚠️ Important: The size and order of the input list of Salesforce URLs must exactly correspond to the size and order of the generated list of user-friendly URLs. The generateUrlFor method maps input URLs to output URLs based on the order in the lists.

mapRequestUrl(userFriendlyUrl)
Maps a user-friendly URL to a Salesforce URL.

Signature
public System.PageReference mapRequestUrl(System.PageReference userFriendlyUrl)

Parameters
userFriendlyUrl
  Type: System.PageReference

Return Value
Type: System.PageReference
Site Exceptions

The Site namespace contains an exception class. All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions.

The Site namespace contains this exception:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>Site.ExternalUserCreateException</td>
<td>Unable to create external user</td>
<td>Use the String getMessage() to get the error message and write it to debug log.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Use List&lt;String&gt; getDisplayMessages() to get a list of errors displayed to the end user.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This exception can’t be subclassed or thrown in code.</td>
</tr>
</tbody>
</table>

Support Namespace

The Support namespace provides an interface used for Case Feed. The following is the interface in the Support namespace.

IN THIS SECTION:

EmailTemplateSelector Interface
The Support.EmailTemplateSelector interface enables providing default email templates in Case Feed. With default email templates, specified email templates are preloaded for cases based on criteria such as case origin or subject.

MilestoneTriggerTimeCalculator Interface
The Support.MilestoneTriggerTimeCalculator interface calculates the time trigger for a milestone.

EmailTemplateSelector Interface

The Support.EmailTemplateSelector interface enables providing default email templates in Case Feed. With default email templates, specified email templates are preloaded for cases based on criteria such as case origin or subject.

Namespace

Support
To specify default templates, you must create a class that implements Support.EmailTemplateSelector.

When you implement this interface, provide an empty parameterless constructor.

IN THIS SECTION:

EmailTemplateSelector Methods
EmailTemplateSelector Example Implementation
EmailTemplateSelector Methods

The following are methods for EmailTemplateSelector.

IN THIS SECTION:

getDefaultTemplateId(caseId)
Returns the ID of the email template to preload for the case currently being viewed in the case feed using the specified case ID.

**getDefaultTemplateId(caseId)**

Returns the ID of the email template to preload for the case currently being viewed in the case feed using the specified case ID.

**Signature**

```java
public ID getDefaultTemplateId(ID caseId)
```

**Parameters**

caseId
Type: ID

**Return Value**
Type: ID

EmailTemplateSelector Example Implementation

This is an example implementation of the Support.EmailTemplateSelector interface.

The `getDefaultEmailTemplateId` method implementation retrieves the subject and description of the case corresponding to the specified case ID. Next, it selects an email template based on the case subject and returns the email template ID.

```java
global class MyCaseTemplateChooser implements Support.EmailTemplateSelector {
    // Empty constructor
    global MyCaseTemplateChooser() { }

    // The main interface method
    global ID getDefaultEmailTemplateId(ID caseId) {
        // Select the case we're interested in, choosing any fields that are relevant to our decision
        Case c = [SELECT Subject, Description FROM Case WHERE Id=:caseId];

        EmailTemplate et;
        if (c.subject.contains('LX-1150')) {
            et = [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1150_template'];
        } else if(c.subject.contains('LX-1220')) {
            et = [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1220_template'];
        }

        // Return the ID of the template selected
        return et.id;
    }
}```
The following example tests the above code:

```java
@isTest
private class MyCaseTemplateChooserTest {

    static testMethod void testChooseTemplate() {

        MyCaseTemplateChooser chooser = new MyCaseTemplateChooser();

        // Create a simulated case to test with
        Case c = new Case();
        c.Subject = 'I\'m having trouble with my LX-1150';
        Database.insert(c);

        // Make sure the proper template is chosen for this subject
        Id actualTemplateId = chooser.getDefaultEmailTemplateId(c.Id);
        EmailTemplate expectedTemplate =
            [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1150_template'];
        Id expectedTemplateId = expectedTemplate.Id;
        System.assertEquals(actualTemplateId, expectedTemplateId);

        // Change the case properties to match a different template
        c.Subject = 'My LX1220 is overheating';
        Database.update(c);

        // Make sure the correct template is chosen in this case
        actualTemplateId = chooser.getDefaultEmailTemplateId(c.Id);
        expectedTemplate =
            [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1220_template'];
        expectedTemplateId = expectedTemplate.Id;
        System.assertEquals(actualTemplateId, expectedTemplateId);
    }
}
```

**MilestoneTriggerTimeCalculator Interface**

The `Support.MilestoneTriggerTimeCalculator` interface calculates the time trigger for a milestone.

**Namespace**

`Support`

Implement the `Support.MilestoneTriggerTimeCalculator` interface to calculate a dynamic time trigger for a milestone based on the milestone type, the properties of the case, and case-related objects. To implement the `Support.MilestoneTriggerTimeCalculator` interface, you must first declare a class with the `implements` keyword as follows:

```java
global class Employee implements Support.MilestoneTriggerTimeCalculator {
```
Next, your class must provide an implementation for the following method:

```plaintext
global Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId)
```

The implemented method must be declared as `global` or `public`.

IN THIS SECTION:
- MilestoneTriggerTimeCalculator Methods
- MilestoneTriggerTimeCalculator Example Implementation

**MilestoneTriggerTimeCalculator Methods**

The following are instance methods for `MilestoneTriggerTimeCalculator`.

IN THIS SECTION:
- `calculateMilestoneTriggerTime(caseId, milestoneTypeId)`
  - Calculates the milestone trigger time based on the specified case and milestone type and returns the time in minutes.

**calculateMilestoneTriggerTime(caseId, milestoneTypeId)**

Calculates the milestone trigger time based on the specified case and milestone type and returns the time in minutes.

**Syntax**

```plaintext
public Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId)
```

**Parameters**

- `caseId`
  - Type: String
  - ID of the case the milestone is applied to.

- `milestoneTypeId`
  - Type: String
  - ID of the milestone type.

**Return Value**

Type: Integer

The calculated trigger time in minutes.

**MilestoneTriggerTimeCalculator Example Implementation**

This sample class demonstrates the implementation of the `Support.MilestoneTriggerTimeCalculator` interface. In this sample, the case's priority and the milestone `m1` determine that the time trigger is 18 minutes.

```plaintext
global class myMilestoneTimeCalculator implements Support.MilestoneTriggerTimeCalculator {

2803
```
global Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId) {
    Case c = [SELECT Priority FROM Case WHERE Id=:caseId];
    MilestoneType mt = [SELECT Name FROM MilestoneType WHERE Id=:milestoneTypeId];
    if (c.Priority != null && c.Priority.equals('High')){
        if (mt.Name != null && mt.Name.equals('m1')) { return 7; }
        else { return 5; }
    }
    else {
        return 18;
    }
}

This test class can be used to test the implementation of Support.MilestoneTriggerTimeCalculator.

@isTest
private class MilestoneTimeCalculatorTest {
    static testMethod void testMilestoneTimeCalculator() {
        // Select an existing milestone type to test with
        MilestoneType[] mtLst = [SELECT Id, Name FROM MilestoneType LIMIT 1];
        if(mtLst.size() == 0) { return; }
        MilestoneType mt = mtLst[0];

        // Create case data.
        // Typically, the milestone type is related to the case,
        // but for simplicity, the case is created separately for this test.
        Case c = new Case(priority = 'High');
        insert c;

        myMilestoneTimeCalculator calculator = new myMilestoneTimeCalculator();
        Integer actualTriggerTime = calculator.calculateMilestoneTriggerTime(c.Id, mt.Id);

        if(mt.name != null && mt.Name.equals('m1')) {
            System.assertEquals(actualTriggerTime, 7);
        }
        else {
            System.assertEquals(actualTriggerTime, 5);
        }

        c.priority = 'Low';
        update c;
        actualTriggerTime = calculator.calculateMilestoneTriggerTime(c.Id, mt.Id);
        System.assertEquals(actualTriggerTime, 18);
    }
}

System Namespace

The System namespace provides classes and methods for core Apex functionality.

The following are the classes in the System namespace.
IN THIS SECTION:

**AccessLevel Class**
Defines the different modes, such as system or user mode, that Apex database operations execute in.

**AccessType Enum**
Specifies the access check type for the fields of an sObject.

**Address Class**
Contains methods for accessing the component fields of address compound fields.

**Answers Class**
Represents zone answers.

**ApexPages Class**
Use `ApexPages` to add and check for messages associated with the current page, as well as to reference the current page.

**Approval Class**
Contains methods for processing approval requests and setting approval-process locks and unlocks on records.

**Assert Class**
Contains methods to assert various conditions with test methods, such as whether two values are the same, a condition is true, or a variable is null.

**AsyncInfo Class**
Provides methods to get the current stack depth, maximum stack depth, and the minimum queueable delay for Queueable transactions, and to determine if maximum stack depth is set.

**AsyncOptions Class**
Contains maximum stack depths for queueable transactions and the minimum queueable delay in minutes. Passed as parameter to the `System.enqueueJob()` method to define a unique queueable job signature, the maximum stack depth for queueable transactions and the minimum queueable delay in minutes.

**Blob Class**
Contains methods for the Blob primitive data type.

**Boolean Class**
Contains methods for the Boolean primitive data type.

**BusinessHours Class**
Use the `BusinessHours` methods to set the business hours at which your customer support team operates.

**Callable Interface**
Enables developers to use a common interface to build loosely coupled integrations between Apex classes or triggers, even for code in separate packages. Agreeing upon a common interface enables developers from different companies or different departments to build upon one another’s solutions. Implement this interface to enable the broader community, which might have different solutions than the ones you had in mind, to extend your code’s functionality.

**Cases Class**
Use the `Cases` class to interact with case records.

**Collator Class**
Contains methods to get locale-specific instances that can be used for comparisons and sorting. Use the `getInstance()` method to obtain the Collator instance for a given locale and pass the Collator as the Comparator parameter to the `list.sort()` method.
Comparable Interface
Adds sorting support for Lists that contain non-primitive types, that is, Lists of user-defined types. Your implementation must explicitly handle null inputs in the `compareTo()` method to avoid a null pointer exception.

Comparator Interface
Implement different sort orders with the Comparator interface’s `compare()` method, and pass the Comparator as a parameter to `List.sort()`. Your implementation must explicitly handle null inputs in the `compare()` method to avoid a null pointer exception.

Continuation Class
Use the `Continuation` class to make callouts asynchronously to a SOAP or REST Web service.

Cookie Class
The `Cookie` class lets you access cookies for your Salesforce site using Apex.

Crypto Class
Provides methods for creating digests, message authentication codes, and signatures, as well as encrypting and decrypting information.

Custom Metadata Type Methods
Custom metadata types are customizable, deployable, packageable, and upgradeable application metadata. All custom metadata is exposed in the application cache, which allows access without repeated queries to the database. The metadata is then available for formula fields, validation rules, flows, Apex, and SOAP API. All methods are static.

Custom Settings Methods
Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data is then available for formula fields, validation rules, flows, Apex, and the SOAP API.

Database Class
Contains methods for creating and manipulating data.

Date Class
Contains methods for the Date primitive data type.

Datetime Class
Contains methods for the Datetime primitive data type.

Decimal Class
Contains methods for the Decimal primitive data type.

Domain Class
Represents an existing domain hosted by Salesforce that serves the org or its content. Contains methods to obtain information about these domains, such as the domain type, My Domain name, and sandbox name.

DomainCreator Class
Use the `DomainCreator` class to return a hostname specific to the org. For example, get the org’s Visualforce hostname. Values are returned as a hostname, such as `MyDomainName.lightning.force.com`.

DomainParser Class
Use the `DomainParser` class to parse a domain that Salesforce hosts for the org and extract information about the domain.

DomainType Enum
Specifies the domain type for a `System.Domain`.

Double Class
Contains methods for the Double primitive data type.
EmailMessages Class
Use the methods in the EmailMessages class to interact with emails and email threading.

EncodingUtil Class
Use the methods in the EncodingUtil class to encode and decode URL strings, and convert strings to hexadecimal format.

Enum Methods
An enum is an abstract data type with values that each take on exactly one of a finite set of identifiers that you specify. Apex provides built-in enums, such as LoggingLevel, and you can define your own enum.

EventBus Class
Contains methods for publishing platform events.

Exception Class and Built-In Exceptions
An exception denotes an error that disrupts the normal flow of code execution. You can use Apex built-in exceptions or create custom exceptions. All exceptions have common methods.

FlexQueue Class
Contains methods that reorder batch jobs in the Apex flex queue.

FeatureManagement Class
Use the methods in the System.FeatureManagement class to check and modify the values of feature parameters, and to show or hide custom objects and custom permissions in your subscribers' orgs.

Formula Class
Contains the recalculateFormulas method that updates (recalculates) all formula fields on the input SObjects.

FormulaRecalcFieldError Class
The return type of the FormulaRecalcResult.getErrors method.

FormulaRecalcResult Class
The return type of the Formula.recalculateFormulas method.

Http Class
Use the Http class to initiate an HTTP request and response.

HttpCalloutMock Interface
Enables sending fake responses when testing HTTP callouts.

HttpRequest Class
Use the HttpRequest class to programmatically create HTTP requests like GET, POST, PATCH, PUT, and DELETE.

HttpResponse Class
Use the HttpResponse class to handle the HTTP response returned by the Http class.

Id Class
Contains methods for the ID primitive data type.

Ideas Class
Represents zone ideas.

InstallHandler Interface
Enables custom code to run after a managed package installation or upgrade.

Integer Class
Contains methods for the Integer primitive data type.
JSON Class
Contains methods for serializing Apex objects into JSON format and deserializing JSON content that was serialized using the `serialize` method in this class.

JSONGenerator Class
Contains methods used to serialize objects into JSON content using the standard JSON encoding.

JSONParser Class
Represents a parser for JSON-encoded content.

JSONToken Enum
Contains all token values used for parsing JSON content.

Label Class
Provides methods to retrieve a custom label or to check if translation exists for a label in a specific language and namespace. Label names are dynamically resolved at run time, overriding the user’s current language if a translation exists for the requested language. You can’t access labels that are protected in a different namespace.

Limits Class
Contains methods that return limit information for specific resources.

List Class
Contains methods for the List collection type.

Location Class
Contains methods for accessing the component fields of geolocation compound fields.

LoggingLevel Enum
Specifies the logging level for the `System.debug` method.

Long Class
Contains methods for the Long primitive data type.

Map Class
Contains methods for the Map collection type.

Matcher Class
Matchers use Patterns to perform match operations on a character string.

Math Class
Contains methods for mathematical operations.

Messaging Class
Contains messaging methods used when sending a single or mass email.

MultiStaticResourceCalloutMock Class
Utility class used to specify a fake response using multiple resources for testing HTTP callouts.

Network Class
Manage Experience Cloud sites.

OrgLimit Class
Contains methods that provide the name, maximum value, and current value of an org limit.

OrgLimits Class
Contains methods that provide a list or map of all OrgLimit instances for Salesforce your org, such as SOAP API requests, Bulk API requests, and Streaming API limits.
**PageReference Class**
A PageReference is a reference to an instantiation of a page. Among other attributes, PageReferences consist of a URL and a set of query parameter names and values.

**Packaging Class**
Contains a method for obtaining information about managed and unlocked packages.

**Pattern Class**
Represents a compiled representation of a regular expression.

**Queueable Interface**
Enables the asynchronous execution of Apex jobs that can be monitored.

**QueueableContext Interface**
Represents the parameter type of the `execute()` method in a class that implements the `Queueable` interface and contains the job ID. This interface is implemented internally by Apex.

**QueueableDuplicateSignature Class**
Used in the `AsyncOptions` class to store the queueable job signature in the `DuplicateSignature` property.

**QueueableDuplicateSignature.Builder Class**
Build a unique signature for your queueable job using this inner builder class. The `build()` class method builds a `QueueableDuplicateSignature` object, with input from the `addId()`, `addInteger()`, and `addString()` methods. Use the `DuplicateSignature` property in the `AsyncOptions` class to store the queueable job signature. Enqueue your job by using the `System.enqueueJob()` with the `AsyncOptions` parameter.

**QuickAction Class**
Use Apex to request and process actions on objects that allow custom fields, on objects that appear in a Chatter feed, or on objects that are available globally.

**Quiddity Enum**
Specifies a Quiddity value used by the methods in the `System.Request` class.

**RemoteObjectController**
Use `RemoteObjectController` to access the standard Visualforce Remote Objects operations in your Remote Objects override methods.

**Request Class**
Contains methods to obtain the request ID and Quiddity value of the current Salesforce request.

**ResetPasswordResult Class**
Represents the result of a password reset.

**RestContext Class**
Contains the `RestRequest` and `RestResponse` objects.

**RestRequest Class**
Use the `System.RestRequest` class to access and pass request data in a RESTful Apex method.

**RestResponse Class**
Represents an object used to pass data from an Apex RESTful Web service method to an HTTP response.

**SandboxPostCopy Interface**
To make your sandbox environment business ready, automate data manipulation or business logic tasks. Extend this interface and add methods to perform post-copy tasks, then specify the class during sandbox creation.

**Schedulable Interface**
The class that implements this interface can be scheduled to run at different intervals.
**SchedulableContext Interface**

Represents the parameter type of a method in a class that implements the Schedulable interface and contains the scheduled job ID. This interface is implemented internally by Apex.

**Schema Class**

Contains methods for obtaining schema describe information.

**Search Class**

Use the methods of the Search class to perform dynamic SOSL queries.

**Security Class**

Contains methods to securely implement Apex applications.

**SelectOption Class**

A SelectOption object specifies one of the possible values for a Visualforce selectCheckboxes, selectList, or selectRadio component.

**Set Class**

Represents a collection of unique elements with no duplicate values.

**Site Class**

Use the Site Class to manage your sites. Change, reset, validate, and check the expiration of passwords. Create site users, person accounts, and portal users. Get the admin email and ID. Get various URLs, the path prefix, the ID, the template, and the type of the site. Log in to the site.

**SObject Class**

Contains methods for the sObject data type.

**SObjectAccessDecision Class**

Contains the results of a call to the Security.stripInaccessible method and methods to retrieve those results.

**StaticResourceCalloutMock Class**

Utility class used to specify a fake response for testing HTTP callouts.

**String Class**

Contains methods for the String primitive data type.

**StubProvider Interface**

StubProvider is a callback interface that you can use as part of the Apex stub API to implement a mocking framework. Use this interface with the Test.createStub() method to create stubbed Apex objects for testing.

**System Class**

Contains methods for system operations, such as writing debug messages and scheduling jobs.

**Test Class**

Contains methods related to Apex tests.

**Time Class**

Contains methods for the Time primitive data type.

**TimeZone Class**

Represents a time zone. Contains methods for creating a new time zone and obtaining time zone properties, such as the time zone ID, offset, and display name.

**Trigger Class**

Use the Trigger class to access run-time context information in a trigger, such as the type of trigger or the list of sObject records that the trigger operates on.
TriggerOperation Enum
System.TriggerOperation enum values are associated with trigger events.

Type Class
Contains methods for getting the Apex type that corresponds to an Apex class and for instantiating new types.

UninstallHandler Interface
Enables custom code to run after a managed package is uninstalled.

URL Class
Represents a uniform resource locator (URL) and provides access to parts of the URL. Enables access to the base URL used to access your Salesforce org.

UserInfo Class
Contains methods for obtaining information about the context user.

UserManagement Class
Contains methods to manage end users, for example, to register their verification methods, verify their identity, or remove their personal information.

Version Class
Use the Version methods to get the version of a first-generation managed package, and to compare package versions.

WebServiceCallout Class
Enables making callouts to SOAP operations on an external Web service. This class is used in the Apex stub class that is auto-generated from a WSDL.

WebServiceMock Interface
Enables sending fake responses when testing Web service callouts of a class auto-generated from a WSDL.

XmlStreamReader Class
The XmlStreamReader class provides methods for forward, read-only access to XML data. You can pull data from XML or skip unwanted events. You can parse nested XML content that’s up to 50 nodes deep.

XmlStreamWriter Class
The XmlStreamWriter class provides methods for writing XML data.

AccessLevel Class
Defines the different modes, such as system or user mode, that Apex database operations execute in.

Namespace
System

Usage
By default, Apex code runs in system mode, which means that it runs with substantially elevated permissions over the user running the code. In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the current user’s object permissions, field-level security, and sharing rules are enforced. Many of the DML methods of the System.Database and System.Search classes include an accessLevel parameter to specify the execution mode.
Example

If the user running this Apex code doesn’t have write access to the Account object, the `Database.insert()` method returns an error.

```java
List<Account> toInsert = new List<Account>{new Account(Name = 'Exciting New Account')};
List<Database.SaveResult> sr = Database.insert(toInsert, AccessLevel.USER_MODE);
```

In contrast, this example shows the method running in system mode. The success of the insert doesn’t depend on whether the user running the Apex code has create access to the Account object.

```java
List<Account> toInsert = new List<Account>{new Account(Name = 'Exciting New Account')};
List<Database.SaveResult> sr = Database.insert(toInsert, AccessLevel.SYSTEM_MODE);
```

IN THIS SECTION:

- AccessLevel Methods
- AccessLevel Properties

AccessLevel Methods

The following are methods for `AccessLevel`.

IN THIS SECTION:

- `withPermissionSetId(permissionSetId)` (Developer Preview)

  Supports database and search operations to be run with permissions specified in a permission set. Apex enforces field-level security (FLS) and object permissions as per the specified permission set, in addition to the running user’s permissions.

`withPermissionSetId(permissionSetId)` (Developer Preview)

Supports database and search operations to be run with permissions specified in a permission set. Apex enforces field-level security (FLS) and object permissions as per the specified permission set, in addition to the running user’s permissions.

**Note:** Feature is available as a developer preview. Feature isn’t generally available unless or until Salesforce announces its general availability in documentation or in press releases or public statements. All commands, parameters, and other features are subject to change or deprecation at any time, with or without notice. Don’t implement functionality developed with these commands or tools in a production environment. You can provide feedback and suggestions for the “Permission Sets with User Mode” feature in the Trailblazer Community.

This feature is available in scratch orgs where the `ApexUserModeWithPermset` feature is enabled. If the feature isn’t enabled, Apex code with this feature can be compiled but not executed.

**Signature**

```java
public System.AccessLevel withPermissionSetId(String permissionSetId)
```
Parameters

permissionSetId
Type: String

Permissions in the specified permission set are enforced while running user-mode DML operations, in addition to the running user’s permissions.

Return Value

Type: Access Level Class

Example: This example runs the AccessLevel.withPermissionSetId() method with the specified permission set and inserts a custom object.

```java
@isTest
public with sharing class ElevateUserModeOperations_Test {
    @isTest
    static void objectCreatePermViaPermissionSet() {
        Profile p = [SELECT Id FROM Profile WHERE Name='Minimum Access - Salesforce'];

        User u = new User(Alias = 'standt', Email='standarduser@testorg.com',
                          EmailEncodingKey='UTF-8', LastName='Testing', LanguageLocaleKey='en_US',
                          LocaleSidKey='en_US', ProfileId = p.Id,
                          TimeZoneSidKey='America/Los_Angeles',
                          UserName='standarduser' + DateTime.now().getTime() + '@testorg.com');

        System.runAs(u) {
            try {
                Database.insert(new Account(name='foo'), AccessLevel.User_mode);
                Assert.fail();
            } catch (SecurityException ex) {
                Assert.isTrue(ex.getMessage().contains('Account'));
            }

            Id permissionSetId = [Select Id from PermissionSet
                                  where Name = 'AllowCreateToAccount' limit 1].Id;

            Database.insert(new Account(name='foo'),
                            AccessLevel.User_mode.withPermissionSetId(permissionSetId));

            // The elevated access level in not persisted to subsequent operations
            try {
                Database.insert(new Account(name='foo2'), AccessLevel.User_mode);
                Assert.fail();
            } catch (SecurityException ex) {
```
Assert.isTrue(ex.getMessage().contains('Account'));

AccessLevel Properties

The following are properties for AccessLevel.

IN THIS SECTION:

SYSTEM_MODE
Execution mode in which the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords.

USER_MODE
Execution mode in which the object permissions, field-level security, and sharing rules of the current user are enforced.

SYSTEM_MODE

Execution mode in which the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords.

Signature

public System.AccessLevel SYSTEM_MODE {get;}

Property Value
Type: System.AccessLevel

USER_MODE

Execution mode in which the object permissions, field-level security, and sharing rules of the current user are enforced.

Signature

public System.AccessLevel USER_MODE {get;}

Property Value
Type: System.AccessLevel

AccessType Enum

Specifies the access check type for the fields of an sObject.
Usage

Use these enum values for the `accessCheckType` parameter of the `stripInaccessible` method.

Enum Values

The following are the values of the `System.AccessType` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATABLE</td>
<td>Check the fields of an sObject for create access.</td>
</tr>
<tr>
<td>READABLE</td>
<td>Check the fields of an sObject for read access.</td>
</tr>
<tr>
<td>UPDATABLE</td>
<td>Check the fields of an sObject for update access.</td>
</tr>
<tr>
<td>UPSERTABLE</td>
<td>Check the fields of an sObject for both insert and update access.</td>
</tr>
</tbody>
</table>

Address Class

Contains methods for accessing the component fields of address compound fields.

Namespace

System

Usage

Each of these methods is also equivalent to a read-only property. For each getter method, you can access the property using dot notation. For example, `myAddress.getCity()` is equivalent to `myAddress.city`.

You can’t use dot notation to access compound fields’ subfields directly on the parent field. Instead, assign the parent field to a variable of type `Address`, and then access its components. For example, to access the `City` field in `myAccount.BillingAddress`, do the following:

```java
Address addr = myAccount.BillingAddress;
String acctCity = addr.City;
```

⚠️ **Important:** “Address” in Salesforce can also refer to the Address standard object. When referencing the Address object in your Apex code, always use `Schema.Address` instead of `Address` to prevent confusion with the standard Address compound field. If referencing both the Address object and the Address standard field in the same snippet, you can differentiate between the two by using `System.Address` for the field and `Schema.Address` for the object.

Example

```java
// Select and access Address fields.
// Call the getDistance() method in different ways.
Account[] records = [SELECT id, BillingAddress FROM Account LIMIT 10];
for(Account acct : records) {
    Address addr = acct.BillingAddress;
```
Double lat = addr.latitude;
Double lon = addr.longitude;
Location loc1 = Location.newInstance(30.1944,-97.6682);
Double apexDist1 = addr.getDistance(loc1, 'mi');
Double apexDist2 = loc1.getDistance(addr, 'mi');
System.assertEquals(apexDist1, apexDist2);
Double apexDist3 = Location.getDistance(addr, loc1, 'mi');
System.assertEquals(apexDist2, apexDist3);
}

IN THIS SECTION:
Address Methods

Address Methods

The following are methods for Address.

IN THIS SECTION:
getCity()  
Returns the city field of this address.

getCountry() 
Returns the text-only country/territory name component of this address.

getCountryCode() 
Returns the country/territory code of this address if state and country/territory picklists are enabled in your organization. Otherwise, returns null.

getAddress(toLocation, unit)  
Returns the distance from this location to the specified location using the specified unit.

getGeocodeAccuracy()  
When using geolocation data for a given address, this method gives you relative location information based on latitude and longitude values. For example, you can find out if the latitude and longitude values point to the middle of the street, instead of the exact address.

getLatitude()  
Returns the latitude field of this address.

getLongitude()  
Returns the longitude field of this address.

getPostalCode()  
Returns the postal code of this address.

getState()  
Returns the text-only state name component of this address.

getStateCode()  
Returns the state code of this address if state and country/territory picklists are enabled in your organization. Otherwise, returns null.
**getStreet()**
Returns the street field of this address.

**getCity()**
Returns the city field of this address.

**Signature**
```
public String getCity()
```

**Return Value**
Type: String

**getCountry()**
Returns the text-only country/territory name component of this address.

**Signature**
```
public String getCountry()
```

**Return Value**
Type: String

**getCountryCode()**
Returns the country/territory code of this address if state and country/territory picklists are enabled in your organization. Otherwise, returns null.

**Signature**
```
public String getCountryCode()
```

**Return Value**
Type: String

**getDistance(toLocation, unit)**
Returns the distance from this location to the specified location using the specified unit.

**Signature**
```
public Double getDistance(Location toLocation, String unit)
```
Parameters

toLocation
  Type: Location
  The Location to which you want to calculate the distance from the current Location.

unit
  Type: String
  The distance unit you want to use: mi or km.

Return Value
  Type: Double

getGeocodeAccuracy()
When using geolocation data for a given address, this method gives you relative location information based on latitude and longitude values. For example, you can find out if the latitude and longitude values point to the middle of the street, instead of the exact address.

Signature
  public String getGeocodeAccuracy()

Return Value
  Type: String
  The getGeocodeAccuracy() return value tells you more about the location at a latitude and longitude for a given address. For example, Zip means the latitude and longitude point to the center of the zip code area, in case a match for an exact street address can’t be found.

<table>
<thead>
<tr>
<th>Accuracy Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address</td>
<td>In the same building</td>
</tr>
<tr>
<td>NearAddress</td>
<td>Near the address</td>
</tr>
<tr>
<td>Block</td>
<td>Midway point of the block</td>
</tr>
<tr>
<td>Street</td>
<td>Midway point of the street</td>
</tr>
<tr>
<td>ExtendedZip</td>
<td>Center of the extended zip code area</td>
</tr>
<tr>
<td>Zip</td>
<td>Center of the zip code area</td>
</tr>
<tr>
<td>Neighborhood</td>
<td>Center of the neighborhood</td>
</tr>
<tr>
<td>City</td>
<td>Center of the city</td>
</tr>
<tr>
<td>County</td>
<td>Center of the county</td>
</tr>
<tr>
<td>State</td>
<td>Center of the state</td>
</tr>
<tr>
<td>Unknown</td>
<td>No match for the address was found</td>
</tr>
</tbody>
</table>
Geocodes are added only for some standard addresses.

- Billing Address on accounts
- Shipping Address on accounts
- Mailing Address on contacts
- Address on leads

Person accounts are not supported.

**Note:** For `getGeocodeAccuracy()` to work, set up and activate the geocode data integration rules for the related address fields.

### getLatitude()

Returns the latitude field of this address.

**Signature**

```java
public Double getLatitude()
```

**Return Value**

Type: **Double**

### getLongitude()

Returns the longitude field of this address.

**Signature**

```java
public Double getLongitude()
```

**Return Value**

Type: **Double**

### getPostalCode()

Returns the postal code of this address.

**Signature**

```java
public String getPostalCode()
```

**Return Value**

Type: **String**

### getState()

Returns the text-only state name component of this address.
Signature
public String getState()

Return Value
Type: String

getStateCode()
Returns the state code of this address if state and country/territory picklists are enabled in your organization. Otherwise, returns null.

Signature
public String getStateCode()

Return Value
Type: String

getStreet()
Returns the street field of this address.

Signature
public String getStreet()

Return Value
Type: String

Answers Class
Represents zone answers.

Namespace
System

Usage
Answers is a feature that enables users to ask questions and have zone members post replies. Members can then vote on the helpfulness of each reply, and the person who asked the question can mark one reply as the best answer.

For more information on answers, see “Answers Overview” in the Salesforce online help.
Example

The following example finds questions in an internal zone that have similar titles as a new question:

```java
public class FindSimilarQuestionController {

    public static void test() {
        // Instantiate a new question
        Question question = new Question();

        // Specify a title for the new question
        question.title = 'How much vacation time do full-time employees get?';

        // Specify the communityID (INTERNAL_COMMUNITY) in which to find similar questions.
        Community community = [ SELECT Id FROM Community WHERE Name = 'INTERNAL_COMMUNITY' ];

        question.communityId = community.id;

        ID[] results = Answers.findSimilar(question);
    }
}
```

The following example marks a reply as the best reply:

```java
ID questionId = [SELECT Id FROM Question WHERE Title = 'Testing setBestReplyId' LIMIT 1].Id;
ID replyId = [SELECT Id FROM Reply WHERE QuestionId = :questionId LIMIT 1].Id;
Answers.setBestReply(questionId,replyId);
```

Answers Methods

The following are methods for Answers. All methods are static.

**findSimilar(yourQuestion)**

Returns a list of similar questions based on the title of the specified question.

**setBestReply(questionId, replyId)**

Sets the specified reply for the specified question as the best reply. Because a question can have multiple replies, setting the best reply helps users quickly identify the reply that contains the most helpful information.

**findSimilar (yourQuestion)**

Returns a list of similar questions based on the title of the specified question.

**Signature**

```java
public static ID[] findSimilar(Question yourQuestion)
```
Parameters

yourQuestion
  Type: Question

Return Value

Type: ID[]

Usage

Each findSimilar call counts against the SOSL statements governor limit allowed for the process.

setBestReply(questionId, replyId)

Sets the specified reply for the specified question as the best reply. Because a question can have multiple replies, setting the best reply helps users quickly identify the reply that contains the most helpful information.

Signature

public static Void setBestReply(String questionId, String replyId)

Parameters

questionId
  Type: String
replyId
  Type: String

Return Value

Type: Void

ApexPages Class

Use ApexPages to add and check for messages associated with the current page, as well as to reference the current page.

Namespace

System

Usage

In addition, ApexPages is used as a namespace for the PageReference Class and the Message Class.

ApexPages Methods

The following are methods for ApexPages. All are instance methods.
IN THIS SECTION:

- **addMessage(message)**
  Add a message to the current page context.

- **addMessages(exceptionThrown)**
  Adds a list of messages to the current page context based on a thrown exception.

- **currentPage()**
  Returns the current page's PageReference.

- **getMessages()**
  Returns a list of the messages associated with the current context.

- **hasMessages()**
  Returns `true` if there are messages associated with the current context, `false` otherwise.

- **hasMessages(severity)**
  Returns `true` if messages of the specified severity exist, `false` otherwise.

### addMessage (message)

Add a message to the current page context.

**Signature**

```java
public Void addMessage(ApexPages.Message message)
```

**Parameters**

- **message**
  Type: `ApexPages.Message`

**Return Value**

Type: `Void`

### addMessages (exceptionThrown)

Adds a list of messages to the current page context based on a thrown exception.

**Signature**

```java
public Void addMessages(Exception exceptionThrown)
```

**Parameters**

- **exceptionThrown**
  Type: `Exception`

**Return Value**

Type: `Void`
currentPage()
Returns the current page's PageReference.

Signature
public System.PageReference currentPage()

Return Value
Type: System.PageReference

Example
This code segment returns the id parameter of the current page.

```java
public MyController() {
    account = [
        SELECT Id, Name, Site
        FROM Account
        WHERE Id = :ApexPages.currentPage().
            getParameters().
            get('id')
    ];
}
```

getMessages()
Returns a list of the messages associated with the current context.

Signature
public ApexPages.Message[] getMessages()

Return Value
Type: ApexPages.Message[]

hasMessages()
Returns true if there are messages associated with the current context, false otherwise.

Signature
public Boolean hasMessages()

Return Value
Type: Boolean
hasMessages(severity)

Returns true if messages of the specified severity exist, false otherwise.

Signature

public Boolean hasMessages(ApexPages.Severity severity)

Parameters

severity

Type: ApexPages.Severity

Return Value

Type: Boolean

Approval Class

Contains methods for processing approval requests and setting approval-process locks and unlocks on records.

Namespace

System

Usage

Salesforce admins can edit locked records. Depending on your approval process configuration settings, an assigned approver can also edit locked records. Locks and unlocks that are set programmatically use the same record editability settings as other approval-process locks and unlocks.

Record locks and unlocks are treated as DML. They’re blocked before a callout, they count toward your DML limits, and if a failure occurs, they’re rolled back along with the rest of your transaction. To change this rollback behavior, use an allOrNone parameter.

Approval is also used as a namespace for the ProcessRequest and ProcessResult classes.

SEE ALSO:

Approval Process Considerations

Approval Methods

The following are methods for Approval. All methods are static.

IN THIS SECTION:

isLocked(id)

Returns true if the record with the ID id is locked, or false if it’s not.

isLocked(ids)

Returns a map of record IDs and their lock statuses. If the record is locked the status is true. If the record is not locked the status is false.
isLocked(sobject)
Returns true if the sobject record is locked, or false if it's not.
isLocked(sobjects)
Returns a map of record IDs to lock statuses. If the record is locked the status is true. If the record is not locked the status is false.
lock(recordId)
Locks an object, and returns the lock results.
lock(recordIds)
Locks a set of objects, and returns the lock results, including failures.
lock(recordToLock)
Locks an object, and returns the lock results.
lock(recordsToLock)
Locks a set of objects, and returns the lock results, including failures.
lock(recordId, allOrNothing)
Locks an object, with the option for partial success, and returns the lock result.
lock(recordIds, allOrNothing)
Locks a set of objects, with the option for partial success. It returns the lock results, including failures.
lock(recordToLock, allOrNothing)
Locks an object, with the option for partial success, and returns the lock result.
lock(recordsToLock, allOrNothing)
Locks a set of objects, with the option for partial success. It returns the lock results, including failures.
process(approvalRequest)
Submits a new approval request and approves or rejects existing approval requests.
process(approvalRequest, allOrNone)
Submits a new approval request and approves or rejects existing approval requests.
process(approvalRequests)
Submits a list of new approval requests, and approves or rejects existing approval requests.
process(approvalRequests, allOrNone)
Submits a list of new approval requests, and approves or rejects existing approval requests.
unlock(recordId)
Unlocks an object, and returns the unlock results.
unlock(recordIds)
Unlocks a set of objects, and returns the unlock results, including failures.
unlock(recordToUnlock)
Unlocks an object, and returns the unlock results.
unlock(recordsToUnlock)
Unlocks a set of objects, and returns the unlock results, including failures.
unlock(recordId, allOrNothing)
Unlocks an object, with the option for partial success, and returns the unlock result.
unlock(recordIds, allOrNothing)
Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.
unlock(recordToUnlock, allOrNothing)
Unlocks an object, with the option for partial success, and returns the unlock result.

unlock(recordsToUnlock, allOrNothing)
Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

isLocked(id)
Returns true if the record with the ID id is locked, or false if it's not.

Signature
public static Boolean isLocked(Id id)

Parameters
id
Type: Id
The ID of the record whose lock or unlock status is in question.

Return Value
Type: Boolean

isLocked(ids)
Returns a map of record IDs and their lock statuses. If the record is locked the status is true. If the record is not locked the status is false.

Signature
public static Map<Id,Boolean> isLocked(List<Id> ids)

Parameters
ids
Type: List<Id>
The IDs of the records whose lock or unlock statuses are in question.

Return Value
Type: Map<Id,Boolean>

isLocked(sobject)
Returns true if the sobject record is locked, or false if it's not.

Signature
public static Boolean isLocked(SObject sobject)
Parameters

\texttt{sobject}

Type: SObject

The record whose lock or unlock status is in question.

Return Value

Type: Boolean

\texttt{isLocked(sobjects)}

Returns a map of record IDs to lock statuses. If the record is locked the status is \texttt{true}. If the record is not locked the status is \texttt{false}.

Signature

\texttt{public static Map<Id, Boolean> isLocked(List<SObject> sobjects)}

Parameters

\texttt{sobjects}

Type: List<SObject>

The records whose lock or unlock statuses are in question.

Return Value

Type: Map<Id, Boolean>

\texttt{lock(recordId)}

Locks an object, and returns the lock results.

Signature

\texttt{public static Approval.LockResult lock(Id recordId)}

Parameters

\texttt{recordId}

Type: Id

ID of the object to lock.

Return Value

Type: Approval.LockResult

\texttt{lock(recordIds)}

Locks a set of objects, and returns the lock results, including failures.
Signature

```java
public static List<Approval.LockResult> lock(List<Id> ids)
```

**Parameters**

`ids`
Type: `List<Id>`
IDs of the objects to lock.

**Return Value**
Type: `List<Approval.LockResult>`

`lock(recordToLock)`
Locks an object, and returns the lock results.

**Signature**

```java
public static Approval.LockResult lock(SObject recordToLock)
```

**Parameters**

`recordToLock`
Type: `SObject`

**Return Value**
Type: `Approval.LockResult`

`lock(recordsToLock)`
Locks a set of objects, and returns the lock results, including failures.

**Signature**

```java
public static List<Approval.LockResult> lock(List<SObject> recordsToLock)
```

**Parameters**

`recordsToLock`
Type: `List<SObject>`

**Return Value**
Type: `List<Approval.LockResult>`

`lock(recordId, allOrNothing)`
Locks an object, with the option for partial success, and returns the lock result.
Signature

public static Approval.LockResult lock(Id recordId, Boolean allOrNothing)

Parameters

recordId
Type: Id
ID of the object to lock.

allOrNothing
Type: Boolean
Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: Approval.LockResult

lock(recordIds, allOrNothing)
Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

Signature

public static List<Approval.LockResult> lock(List<Id> recordIds, Boolean allOrNothing)

Parameters

recordIds
Type: List<Id>
IDs of the objects to lock.

allOrNothing
Type: Boolean
Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: List<Approval.LockResult>

lock(recordToLock, allOrNothing)
_locks an object, with the option for partial success, and returns the lock result.

Signature

public static Approval.LockResult lock(SObject recordToLock, Boolean allOrNothing)
Parameters

recordToLock
Type: SObject

allOrNothing
Type: Boolean

Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: Approval.LockResult

lock(recordsToLock, allOrNothing)
Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

Signature
public static List<Approval.LockResult> lock(List<SObject> recordsToLock, Boolean allOrNothing)

Parameters

recordsToLock
Type: List<SObject>

allOrNothing
Type: Boolean

Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: List<Approval.LockResult>

process(approvalRequest)
Submits a new approval request and approves or rejects existing approval requests.

Signature
public static Approval.ProcessResult process(Approval.ProcessRequest approvalRequest)

Parameters

approvalRequest
Type: Approval.ProcessRequest
Return Value
Type: Approval.ProcessResult

Example

```java
// Insert an account
Account a = new Account(Name='Test',
    annualRevenue=100.0);
insert a;

// Create an approval request for the account
Approval.ProcessSubmitRequest req1 =
    new Approval.ProcessSubmitRequest();
req1.setObjectId(a.id);

// Submit the approval request for the account
Approval.ProcessResult result =
    Approval.process(req1);
```

`process(approvalRequest, allOrNone)`
Submits a new approval request and approves or rejects existing approval requests.

Signature

```java
public static Approval.ProcessResult process(Approval.ProcessRequest approvalRequest,
    Boolean allOrNone)
```

Parameters

- `approvalRequest` Approval.ProcessRequest
- `allOrNone` Type: Boolean
  The optional `allOrNone` parameter specifies whether the operation allows for partial success. If you specify `false` for this parameter and an approval fails, the remainder of the approval processes can still succeed.

Return Value
Approval.ProcessResult

`process(approvalRequests)`
Submits a list of new approval requests, and approves or rejects existing approval requests.
### process(approvalRequests, allOrNone)

Submits a list of new approval requests, and approves or rejects existing approval requests.

#### Signature

```java
public static Approval.ProcessResult[] process(Approval.ProcessRequest[] approvalRequests, Boolean allOrNone)
```

#### Parameters

- `approvalRequests`
  - Type: `Approval.ProcessRequest[]`

- `allOrNone`
  - Type: `Boolean`
  - The optional `allOrNone` parameter specifies whether the operation allows for partial success. If you specify `false` for this parameter and an approval fails, the remainder of the approval processes can still succeed.

#### Return Value

- `Approval.ProcessResult[]`

### unlock(recordId)

Unlocks an object, and returns the unlock results.

#### Signature

```java
public static Approval.UnlockResult unlock(Id recordId)
```

#### Parameters

- `recordId`
  - Type: `Id`
  - ID of the object to unlock.
Return Value
Type: Approval.UnlockResult

unlock(recordIds)
Unlocks a set of objects, and returns the unlock results, including failures.

Signature
public static List<Approval.UnlockResult> unlock(List<Id> recordIds)

Parameters
recordIds
Type: List<Id>
IDs of the objects to unlock.

Return Value
Type: List<Approval.UnlockResult>

unlock(recordToUnlock)
Unlocks an object, and returns the unlock results.

Signature
public static Approval.UnlockResult unlock(SObject recordToUnlock)

Parameters
recordToUnlock
Type: SObject

Return Value
Type: Approval.UnlockResult

unlock(recordsToUnlock)
Unlocks a set of objects, and returns the unlock results, including failures.

Signature
public static List<Approval.UnlockResult> unlock(List<SObject> recordsToUnlock)

Parameters
recordsToUnlock
Type: List<SObject>
Return Value
Type: List<Approval.UnlockResult>

unlock(recordId, allOrNothing)
Unlocks an object, with the option for partial success, and returns the unlock result.

Signature
public static Approval.UnlockResult unlock(Id recordId, Boolean allOrNothing)

Parameters
recordId
Type: Id
ID of the object to lock.

allOrNothing
Type: Boolean
Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: Approval.UnlockResult

unlock(recordIds, allOrNothing)
Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

Signature
public static List<Approval.UnlockResult> unlock(List<Id> recordIds, Boolean allOrNothing)

Parameters
recordIds
Type: List<Id>
IDs of the objects to unlock.

allOrNothing
Type: Boolean
Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: List<Approval.UnlockResult>
unlock(recordToUnlock, allOrNothing)
Unlocks an object, with the option for partial success, and returns the unlock result.

Signature
public static Approval.UnlockResult unlock(SObject recordToUnlock, Boolean allOrNothing)

Parameters
recordToUnlock
  Type: SObject
allOrNothing
  Type: Boolean
  Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: Approval.UnlockResult

unlock(recordsToUnlock, allOrNothing)
Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

Signature
public static List<Approval.UnlockResult> unlock(List<SObject> recordsToUnlock, Boolean allOrNothing)

Parameters
recordsToUnlock
  Type: List<SObject>
allOrNothing
  Type: Boolean
  Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: List<Approval.UnlockResult>

Assert Class
Contains methods to assert various conditions with test methods, such as whether two values are the same, a condition is true, or a variable is null.
Namespace

System

Assert Methods

The following are methods for Assert.

IN THIS SECTION:

- `areEqual(expected, actual, msg)`
  Asserts that the first two arguments are the same.
- `areEqual(expected, actual)`
  Asserts that the two arguments are the same.
- `areNotEqual(notExpected, actual, msg)`
  Asserts that the first two arguments aren’t the same.
- `areNotEqual(notExpected, actual)`
  Asserts that the two arguments aren’t the same.
- `fail(msg)`
  Immediately return a fatal error that causes code execution to halt.
- `fail()`
  Immediately return a fatal error that causes code execution to halt.
- `isFalse(condition, msg)`
  Asserts that the specified condition is false.
- `isFalse(condition)`
  Asserts that the specified condition is false.
- `isInstanceOfType(instance, expectedType, msg)`
  Asserts that the instance is of the specified type.
- `isInstanceOfType(instance, expectedType)`
  Asserts that the instance is of the specified type.
- `isNotInstanceOfType(instance, notExpectedType, msg)`
  Asserts that the instance isn’t of the specified type.
- `isNotInstanceOfType(instance, notExpectedType)`
  Asserts that the instance isn’t of the specified type.
- `isNotNull(value, msg)`
  Asserts that the value isn’t null.
- `isNotNull(value)`
  Asserts that the value isn’t null.
- `isNull(value, msg)`
  Asserts that the value is null.
- `isNull(value)`
  Asserts that the value is null.
**isTrue(condition, msg)**
Asserts that the specified condition is true.

**isTrue(condition)**
Asserts that the specified condition is true.

**areEqual(expected, actual, msg)**
Asserts that the first two arguments are the same.

**Signature**
```
public static void areEqual(Object expected, Object actual, String msg)
```

**Parameters**
- **expected**
  - Type: Object
  - Expected value.
- **actual**
  - Type: Object
  - Actual value.
- **msg**
  - Type: String
  - (Optional) Custom message returned as part of the error message.

**Return Value**
Type: void

**Usage**
If the first two arguments aren't the same, a fatal error is returned that causes code execution to halt.
You can't catch an assertion failure using a try/catch block even though it's logged as an exception.

**Example**
```
String sub = 'abcde'.substring(2);
Assert.areEqual('cde', sub, 'Expected characters after first two'); // Succeeds
```

**areEqual(expected, actual)**
Asserts that the two arguments are the same.

**Signature**
```
public static void areEqual(Object expected, Object actual)
```
Parameters

expected
  Type: Object
  Expected value.

actual
  Type: Object
  Actual value.

Return Value
Type: void

Usage
If the two arguments aren’t the same, a fatal error is returned that causes code execution to halt.

You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

Example

```java
String sub = 'abcde'.substring(2);
Assert.areEqual('cde', sub); // Succeeds
```

areNotEqual(notExpected, actual, msg)

Asserts that the first two arguments aren’t the same.

Signature

```java
public static void areNotEqual(Object notExpected, Object actual, String msg)
```

Parameters

notExpected
  Type: Object
  Value that’s not expected.

actual
  Type: Object
  Actual value.

msg
  Type: String
  (Optional) Custom message returned as part of the error message.

Return Value
Type: void
Usage
If the first two arguments are the same, a fatal error is returned that causes code execution to halt.
You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

Example

```java
String sub = 'abcde'.substring(2);
Assert.areNotEqual('xyz', sub, 'Characters not expected after first two'); // Succeeds
```

**areNotEqual(notExpected, actual)**

Asserts that the two arguments aren’t the same.

**Signature**

```java
public static void areNotEqual(Object notExpected, Object actual)
```

**Parameters**

- **notExpected**
  - Type: Object
  - Value that’s not expected.

- **actual**
  - Type: Object
  - Actual value.

**Return Value**

Type: void

Usage

If the two arguments are the same, a fatal error is returned that causes code execution to halt.
You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

Example

```java
String sub = 'abcde'.substring(2);
Assert.areNotEqual('xyz', sub); // Succeeds
```

**fail(msg)**

Immediately return a fatal error that causes code execution to halt.

**Signature**

```java
public static void fail(String msg)
```
Parameters

msg
Type: String
(Optional) Custom message returned as part of the error message.

Return Value
Type: void

Usage
Commonly used in a try/catch block test case where an exception is expected to be thrown. You can't, however, catch the assertion failure in the try/catch block even though it's logged as an exception.

Example

```java
// test case where exception is expected
try {
    SomeClass.methodUnderTest();
    Assert.fail('DmlException Expected');
} catch (DmlException ex) {
    // Add assertions here about the expected exception
}
```

fail()
Immediately return a fatal error that causes code execution to halt.

Signature

public static void fail()

Return Value
Type: void

Usage
Commonly used in a try/catch block test case where an exception is expected to be thrown. You can't, however, catch the assertion failure in the try/catch block even though it's logged as an exception.

Example

```java
// test case where exception is expected
try {
    SomeClass.methodUnderTest();
    Assert.fail();
} catch (DmlException ex) {
    // Add assertions here about the expected exception
}
```
isFalse(condition, msg)

Asserts that the specified condition is false.

Signature

public static void isFalse(Boolean condition, String msg)

Parameters

condition
Type: Boolean
Condition you're checking to determine if it's false.

msg
Type: String
(Optional) Custom message returned as part of the error message.

Return Value

Type: void

Usage

If the condition is true, a fatal error is returned that causes code execution to halt.
You can't catch an assertion failure using a try/catch block even though it's logged as an exception.

Example

Boolean containsCode = 'Salesforce'.contains('code');
Assert.isFalse(containsCode, 'No code'); // Assertion succeeds

isFalse(condition)

Asserts that the specified condition is false.

Signature

public static void isFalse(Boolean condition)

Parameters

condition
Type: Boolean
Condition you're checking to determine if it's false.

Return Value

Type: void
Usage
If the condition is `true`, a fatal error is returned that causes code execution to halt.
You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

Example
```java
Boolean containsCode = 'Salesforce'.contains('code');
Assert.isFalse(containsCode); // Assertion succeeds
```

`isInstanceOfType(instance, expectedType, msg)`
Asserts that the instance is of the specified type.

Signature
```java
public static void isInstanceOfType(Object instance, System.Type expectedType, String msg)
```

Parameters
- `instance`
  - Type: Object
  - Instance whose type you’re checking.
- `expectedType`
  - Type: `System.Type` on page 3532
  - Expected type.
- `msg`
  - Type: String
  - (Optional) Custom message returned as part of the error message.

Return Value
Type: void

Usage
If the instance isn’t of the specified type, a fatal error is returned that causes code execution to halt.
You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

Example
```java
Account o = new Account();
Assert.isInstanceOfType(o, Account.class); // Succeeds
```

`isInstanceOfType(instance, expectedType)`
Asserts that the instance is of the specified type.
### isInstanceOfType

#### Signature

```
public static void isInstanceOfType(Object instance, System.Type expectedType)
```

#### Parameters

- `instance`  
  Type: Object  
  Instance whose type you’re checking.

- `expectedType`  
  Type: System.Type on page 3532  
  Expected type.

#### Return Value

Type: void

#### Usage

If the instance isn’t of the specified type, a fatal error is returned that causes code execution to halt.

You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

#### Example

```
Account o = new Account();
Assert.isInstanceOfType(o, Account.class); // Succeeds
```

```
Account o = new Account();
Assert.isInstanceOfType(o, Account.class, 'Expected type.'); // Succeeds
```

### isNotInstanceOfType

#### Signature

```
public static void isNotInstanceOfType(Object instance, System.Type notExpectedType, String msg)
```

#### Parameters

- `instance`  
  Type: Object  
  Instance whose type you’re checking.

- `notExpectedType`  
  Type: System.Type on page 3532  
  Type that’s not expected.

#### Description

`isNotInstanceOfType` asserts that the instance isn’t of the specified type.
msg
  Type: String
  (Optional) Custom message returned as part of the error message.

Return Value
Type: void

Usage
If the instance is of the specified type, a fatal error is returned that causes code execution to halt.
You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

Example
Contact con = new Contact();
Assert.isNotInstanceOfType(con, Account.class, 'Not expected type'); // Succeeds

isNotInstanceOfType(instance, notExpectedType)
Asserts that the instance isn’t of the specified type.

Signature
public static void isNotInstanceOfType(Object instance, System.Type notExpectedType)

Parameters
instance
  Type: Object
  Instance whose type you’re checking.
notExpectedType
  Type: System.Type
  Type that’s not expected.

Return Value
Type: void

Usage
If the instance is of the specified type, a fatal error is returned that causes code execution to halt.
You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

Example
Contact con = new Contact();
Assert.isNotInstanceOfType(con, Account.class); // Succeeds
**isNotNull(value, msg)**

Asserts that the value isn’t null.

**Signature**

```java
public static void isNotNull(Object value, String msg)
```

**Parameters**

- **value**
  - Type: `Object`
  - Value you’re checking to determine if it’s not null.

- **msg**
  - Type: `String`
  - (Optional) Custom message returned as part of the error message.

**Return Value**

Type: `void`

**Usage**

If the value is null, a fatal error is returned that causes code execution to halt.

You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

**Example**

```java
String myString = 'value';
Assert.isNotNull(myString, 'myString should not be null'); // Succeeds
```

**isNotNull(value)**

Asserts that the value isn’t null.

**Signature**

```java
public static void isNotNull(Object value)
```

**Parameters**

- **value**
  - Type: `Object`
  - Value you’re checking to determine if it’s not null.

**Return Value**

Type: `void`
Usage
If the value is null, a fatal error is returned that causes code execution to halt.
You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

Example
String myString = 'value';
Assert.isNotNull(myString); // Succeeds

isNull(value, msg)
Asserts that the value is null.

Signature
public static void isNull(Object value, String msg)

Parameters
value
Type: Object
Value you’re checking to determine if it’s null.

msg
Type: String
(Optional) Custom message returned as part of the error message.

Return Value
Type: void

Usage
If the value isn’t null, a fatal error is returned that causes code execution to halt.
You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

Example
String myString = null;
Assert.isNull(myString, 'String should be null'); // Succeeds

isNull(value)
Asserts that the value is null.

Signature
public static void isNull(Object value)
Parameters
value
Type: Object
Value you’re checking to determine if it’s null.

Return Value
Type: void

Usage
If the value isn’t null, a fatal error is returned that causes code execution to halt.
You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

Example
String myString = null;
Assert.isNull(myString); // Succeeds

isTrue(condition, msg)
Asserts that the specified condition is true.

Signature
public static void isTrue(Boolean condition, String msg)

Parameters
condition
Type: Boolean
Condition you’re checking to determine if it’s true.

msg
Type: String
(Optional) Custom message returned as part of the error message.

Return Value
Type: void

Usage
If the specified condition is false, a fatal error is returned that causes code execution to halt.
You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.
Example

```java
Boolean containsForce = 'Salesforce'.contains('force');
Assert.isTrue(containsForce, 'Contains force'); // Assertion succeeds
```

**isTrue(condition)**

Asserts that the specified condition is true.

**Signature**

```java
public static void isTrue(Boolean condition)
```

**Parameters**

- `condition`  
  Type: `Boolean`  
  Condition you're checking to determine if it's true.

**Return Value**

Type: `void`

**Usage**

If the specified condition is `false`, a fatal error is returned that causes code execution to halt.

You can't catch an assertion failure using a try/catch block even though it's logged as an exception.

Example

```java
Boolean containsForce = 'Salesforce'.contains('force');
Assert.isTrue(containsForce); // Assertion succeeds
```

**AsyncInfo Class**

Provides methods to get the current stack depth, maximum stack depth, and the minimum queueable delay for Queueable transactions, and to determine if maximum stack depth is set.

**Namespace**

`System`

**AsyncInfo Methods**

The following are methods for `AsyncInfo`. 
IN THIS SECTION:

- `getCurrentQueueableStackDepth()`
  Get the current queueable stack depth for queueable transactions.

- `getMaximumQueueableStackDepth()`
  Get the maximum queueable stack depth for queueable transactions.

- `getMinimumQueueableDelayInMinutes()`
  Get the minimum queueable delay for queueable transactions (in minutes).

- `hasMaxStackDepth()`
  Determine if maximum stack depth is set for your queueable requests.

---

**getCurrentQueueableStackDepth()**

Get the current queueable stack depth for queueable transactions.

**Signature**

```java
public static Integer getCurrentQueueableStackDepth()
```

**Return Value**

Type: `Integer`

---

**getMaximumQueueableStackDepth()**

Get the maximum queueable stack depth for queueable transactions.

**Signature**

```java
public static Integer getMaximumQueueableStackDepth()
```

**Return Value**

Type: `Integer`

---

**getMinimumQueueableDelayInMinutes()**

Get the minimum queueable delay for queueable transactions (in minutes).

**Signature**

```java
public static Integer getMinimumQueueableDelayInMinutes()
```

**Return Value**

Type: `Integer`

Returns null if no delay is defined.
**hasMaxStackDepth()**
Determine if maximum stack depth is set for your queueable requests.

**Signature**
public static Boolean hasMaxStackDepth()

**Return Value**
Type: Boolean

**AsyncOptions Class**
Contains maximum stack depths for queueable transactions and the minimum queueable delay in minutes. Passed as parameter to the `System.enqueueJob()` method to define a unique queueable job signature, the maximum stack depth for queueable transactions and the minimum queueable delay in minutes.

**Namespace**
System

**AsyncOptions Properties**
The following are properties for AsyncOptions.

**DuplicateSignature**
A unique signature for a Queueable job.

**MaximumQueueableStackDepth**
Maximum stack depth for queueable transactions.

**MinimumQueueableDelayInMinutes**
Minimum queueable delay for queueable transactions.

**DuplicateSignature**
A unique signature for a Queueable job.

**Signature**
public System.QueueableDuplicateSignature DuplicateSignature {get; set;}
Property Value
Type: QueueableDuplicateSignature Class

**MaximumQueueableStackDepth**
Maximum stack depth for queueable transactions.

Signature
public Integer MaximumQueueableStackDepth {get; set;}

Property Value
Type: Integer

**MinimumQueueableDelayInMinutes**
Minimum queueable delay for queueable transactions.

Signature
public Integer MinimumQueueableDelayInMinutes {get; set;}

Property Value
Type: Integer

**Blob Class**
Contains methods for the Blob primitive data type.

**Namespace**
System

**Usage**
For more information on Blobs, see Primitive Data Types.

**Blob Methods**
The following are methods for Blob.

IN THIS SECTION:
- size()
  - Returns the number of characters in the Blob.
- toPdf(stringToConvert)
  - Creates a binary object out of the given string, encoding it as a PDF file.
toString()
Casts the Blob into a String.

valueOf(stringToBlob)
Casts the specified String to a Blob.

size()
Returns the number of characters in the Blob.

Signature
public Integer size()

Return Value
Type: Integer

Example
```java
String myString = 'StringToBlob';
Blob myBlob = Blob.valueOf(myString);
Integer size = myBlob.size();
```

toPdf(stringToConvert)
Creates a binary object out of the given string, encoding it as a PDF file.

Signature
public static Blob toPdf(String stringToConvert)

Parameters
stringToConvert
Type: String

Note: Referencing a static resource throws an InvalidParameterValue exception.

Return Value
Type: Blob

Example
```java
String pdfContent = 'This is a test string';
Account a = new account(name = 'test');
insert a;
Attachment attachmentPDF = new Attachment();
attachmentPdf.parentId = a.id;
attachmentPdf.name = a.name + '.pdf';
```
**attachmentPdf.body** = blob.toPDF(pdfContent);
insert attachmentPDF;

**toString()**
Casts the Blob into a String.

**Signature**
public String toString()

**Return Value**
Type: String

**Example**
```java
String myString = 'StringToBlob';
Blob myBlob = Blob.valueOf(myString);
System.assertEquals('StringToBlob', myBlob.toString());
```

**valueOf (stringToBlob)**
Casts the specified String to a Blob.

**Signature**
public static Blob valueOf(String stringToBlob)

**Parameters**
stringToBlob
Type: String

**Return Value**
Type: Blob

**Example**
```java
String myString = 'StringToBlob';
Blob myBlob = Blob.valueOf(myString);
```

**Boolean Class**
Contains methods for the Boolean primitive data type.
Namespace
System

Boolean Methods
The following are methods for Boolean. All methods are static.

IN THIS SECTION:
 valueOf(stringToBoolean)
Converts the specified string to a Boolean value and returns true if the specified string value is true. Otherwise, returns false.
 valueOf(fieldValue)
Converts the specified object to a Boolean value. Use this method to convert a history tracking field value or an object that represents a Boolean value.

valueOf(stringToBoolean)
Converts the specified string to a Boolean value and returns true if the specified string value is true. Otherwise, returns false.

Signature
public static Boolean valueOf(String stringToBoolean)

Parameters
stringToBoolean
Type: String

Return Value
Type: Boolean

Usage
If the specified argument is null, this method throws an exception.

Example
```java
Boolean b = Boolean.valueOf('true');
System.assertEquals(true, b);
```

valueOf(fieldValue)
Converts the specified object to a Boolean value. Use this method to convert a history tracking field value or an object that represents a Boolean value.

Signature
public static Boolean valueOf(Object fieldValue)
Parameters

`fieldValue`  
Type: Object

Return Value

Type: Boolean

Usage

Use this method with the `OldValue` or `NewValue` fields of history sObjects, such as `AccountHistory`, when the field type corresponds to a Boolean type, like a checkbox field.

Example

```java
List<AccountHistory> ahlist =
    [SELECT Field, OldValue, NewValue
     FROM AccountHistory];
for(AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'IsPlatinum__c') {
        Boolean oldValue =
            Boolean.valueOf(ah.OldValue);
        Boolean newValue =
            Boolean.valueOf(ah.NewValue);
    }
}
```

BusinessHours Class

Use the `BusinessHours` methods to set the business hours at which your customer support team operates.

Namespace

`System`

BusinessHours Methods

The following are methods for `BusinessHours`. All methods are static.

IN THIS SECTION:

- `add-businessHoursId, startDate, intervalMilliseconds)`
  Adds an interval of time from a start Datetime traversing business hours only. Returns the result Datetime in the local time zone.
- `addGmt-businessHoursId, startDate, intervalMilliseconds)`
  Adds an interval of milliseconds from a start Datetime traversing business hours only. Returns the result Datetime in GMT.
- `diff-businessHoursId, startDate, endDate)`
  Returns the difference in milliseconds between a start and end Datetime based on a specific set of business hours.
isWithin(businessHoursId, targetDate)
Returns true if the specified target date occurs within business hours. Holidays are included in the calculation.

nextStartDate(businessHoursId, targetDate)
Starting from the specified target date, returns the next date when business hours are open. If the specified target date falls within business hours, this target date is returned.

add(businessHoursId, startDate, intervalMilliseconds)
Adds an interval of time from a start Datetime traversing business hours only. Returns the result Datetime in the local time zone.

Signature
public static Datetime add(String businessHoursId, Datetime startDate, Long intervalMilliseconds)

Parameters
businessHoursId
Type: String
startDate
Type: Datetime
intervalMilliseconds
Type: Long
Interval value should be provided in milliseconds, however time precision smaller than one minute is ignored.

Return Value
Type: Datetime

addGmt(businessHoursId, startDate, intervalMilliseconds)
Adds an interval of milliseconds from a start Datetime traversing business hours only. Returns the result Datetime in GMT.

Signature
public static Datetime addGmt(String businessHoursId, Datetime startDate, Long intervalMilliseconds)

Parameters
businessHoursId
Type: String
startDate
Type: Datetime
intervalMilliseconds
Type: Long
**diff(businessHoursId, startDate, endDate)**

Returns the difference in milliseconds between a start and end Datetime based on a specific set of business hours.

**Signature**

```java
public static Long diff(String businessHoursId, Datetime startDate, Datetime endDate)
```

**Parameters**

- `businessHoursId`
  - Type: String
- `startDate`
  - Type: Datetime
- `endDate`
  - Type: Datetime

**Return Value**

Type: Long

**isWithin(businessHoursId, targetDate)**

Returns `true` if the specified target date occurs within business hours. Holidays are included in the calculation.

**Signature**

```java
public static Boolean isWithin(String businessHoursId, Datetime targetDate)
```

**Parameters**

- `businessHoursId`
  - Type: String
  - The business hours ID.
- `targetDate`
  - Type: Datetime
  - The date to verify.

**Return Value**

Type: Boolean
Example
The following example finds whether a given time is within the default business hours.

```java
// Get the default business hours
BusinessHours bh = [SELECT Id FROM BusinessHours WHERE IsDefault=true];

// Create Datetime on May 28, 2013 at 1:06:08 AM in the local timezone.
Datetime targetTime = Datetime.newInstance(2013, 5, 28, 1, 6, 8);

// Find whether the time is within the default business hours
Boolean isWithin = BusinessHours.isWithin(bh.id, targetTime);
```

**nextStartDate(businessHoursId, targetDate)**

Starting from the specified target date, returns the next date when business hours are open. If the specified target date falls within business hours, this target date is returned.

**Signature**

```java
public static Datetime nextStartDate(String businessHoursId, Datetime targetDate)
```

**Parameters**

- **businessHoursId**
  - Type: `String`
  - The business hours ID.

- **targetDate**
  - Type: `Datetime`
  - The date used as a start date to obtain the next date.

**Return Value**

Type: `Datetime`

**Example**

The following example finds the next date starting from the target date when business hours reopens. If the target date is within the given business hours, the target date is returned. The returned time is in the local time zone.

```java
// Get the default business hours
BusinessHours bh = [SELECT Id FROM BusinessHours WHERE IsDefault=true];

// Create Datetime on May 28, 2013 at 1:06:08 AM in the local timezone.
Datetime targetTime = Datetime.newInstance(2013, 5, 28, 1, 6, 8);
// Starting from the targetTime, find the next date when business hours reopens. Return the target time.

// if it is within the business hours. The returned time will be in the local time zone
Datetime nextStart = BusinessHours.nextStartDate(bh.id, targetTime);
```
Callable Interface

Enables developers to use a common interface to build loosely coupled integrations between Apex classes or triggers, even for code in separate packages. Agreeing upon a common interface enables developers from different companies or different departments to build upon one another’s solutions. Implement this interface to enable the broader community, which might have different solutions than the ones you had in mind, to extend your code’s functionality.

Note: This interface is not an analog of the Java Callable interface, which is used for asynchronous invocation. Don’t confuse the two.

Namespace
System

Usage
To implement the Callable interface, you need to write only one method: `call(String action, Map<String, Object> args)`.

In code that utilizes or tests an implementation of Callable, cast an instance of your type to Callable.

This interface is not intended to replace defining more specific interfaces. Rather, the Callable interface allows integrations in which code from different classes or packages can use common base types.

IN THIS SECTION:
Callable Methods
Callable Example Implementation

Callable Methods

The following are methods for Callable.

IN THIS SECTION:
call(action, args)
Provides functionality that other classes or packages can utilize and build upon.

call(action, args)
Provides functionality that other classes or packages can utilize and build upon.

Signature

public Object call(String action, Map<String, Object> args)

Parameters

action
Type: String
The behavior for the method to exhibit.
**args**

Type: Map on page 3198<String,Object>

Arguments to be used by the specified action.

**Return Value**

Type: Object

The result of the method invocation.

**Callable Example Implementation**

This class is an example implementation of the `System.Callable` interface.

```java
public class Extension implements Callable {

    // Actual method
    String concatStrings(String stringValue) {
        return stringValue + stringValue;
    }

    // Actual method
    Decimal multiplyNumbers(Decimal decimalValue) {
        return decimalValue * decimalValue;
    }

    // Dispatch actual methods
    public Object call(String action, Map<String, Object> args) {
        switch (action) {
            case 'concatStrings':
                return this.concatStrings((String)args.get('stringValue'));
            case 'multiplyNumbers':
                return this.multiplyNumbers((Decimal)args.get('decimalValue'));
            default:
                throw new ExtensionMalformedCallException('Method not implemented');
        }
    }

    public class ExtensionMalformedCallException extends Exception {}
}
```

The following test code illustrates how calling code utilizes the interface to call a method.

```java
@IsTest
private with sharing class ExtensionCaller {

    @IsTest
    private static void givenConfiguredExtensionWhenCalledThenValidResult() {

        // Given
        String extensionClass = 'Extension'; // Typically set via configuration
```

2861
Decimal decimalTestValue = 10;

// When
Callable extension =
    (Callable) Type.forName(extensionClass).newInstance();
Decimal result = (Decimal)
    extension.call('multiplyNumbers', new Map<String, Object> {
        'decimalValue' => decimalTestValue
    });

// Then
System.assertEquals(100, result);
}

Apex Developer Guide: Classes and Casting

Cases Class

Use the Cases class to interact with case records.

Namespace

System

Cases Methods

The following are static methods for Cases.

IN THIS SECTION:

generateThreadingMessageId(caseId)
Returns an RFC 2822-compliant message identifier that contains information used to match the email and its replies to a case.

getCaseIdFromEmailHeaders(headers)
Returns the case ID corresponding to the specified email header information, or returns null if none is found.

getCaseIdFromEmailThreadId(emailThreadId)
Returns the case ID corresponding to the specified email thread ID. (Deprecated. Use getCaseIdFromEmailHeaders and EmailMessages.getRecordIdFromEmail instead.)

generateThreadingMessageId(caseId)
Returns an RFC 2822-compliant message identifier that contains information used to match the email and its replies to a case.

Signature

public static String generateThreadingMessageId(Id caseId)
Parameters

caseId
   Type: Id

   The case SObject ID to which replies to this email should be attached.

Return Value

Type: String

Usage

Use the returned message identifier when sending case-related emails in Apex. The returned message identifier can be used in Message-ID or References headers. However, because Salesforce doesn’t let users specify the Message-ID, we set this identifier in the References header. When users reply to the sent email, replies should be attached to the specified case.

Example

In this sample, we create an email with a message identifier so that the email and any responses can be associated with the related case.

```java
//Get your Case ID. Here we use a dummy ID
ID caseId = Id.valueOf('500xx000000bpkTAAQ');
//Create a SingleEmailMessage object
Messaging.SingleEmailMessage email = new Messaging.SingleEmailMessage();
//Set recipients and other fields
email.setToAddresses(new String[] {'test@salesforce.com'});
email.setPlainTextBody('Test Email Notification');
//........... more fields ...........
//Get the threading message identifier
String messageId = Cases.generateThreadingMessageId(caseId);
//Insert the message identifier into the References header
email.setReferences(messageId);
//Send out the email
Messaging.sendEmail(new Messaging.SingleEmailMessage[]{email});
```

getCaseIdFromEmailHeaders(headers)

Returns the case ID corresponding to the specified email header information, or returns null if none is found.

Signature

```java
public static Id getCaseIdFromEmailHeaders(List<Messaging.InboundEmail.Header> headers)
```

Parameters

headers
   Type: List<Messaging.InboundEmail.Header>

Return Value

Type: Id
Usage

To optimize finding a match between email threads and cases in your custom code, we recommend that you use this method and EmailMessages.getRecordIdFromEmail to implement a combination of token- and header-based threading.

If you are transitioning from Ref ID threading, we recommend that you replace Cases.getCaseIdFromEmailThreadId with a combination of Cases.getCaseIdFromEmailHeaders and EmailMessages.getRecordIdFromEmail. If you choose to implement header-based threading only, replace Cases.getCaseIdFromEmailThreadId with Cases.getCaseIdFromEmailHeaders.

The headers argument is used to find the matching Case Id using values for the In-Reply-To and References headers based on RFC 2822. If Email-to-Case can’t find any emails with a matching In-Reply-To or References header, it also checks the incoming email for an Outlook-specific header called Thread-Index. The first 22 bytes of this header uniquely identify the thread. If Email-to-Case detects a Thread-Index header on the incoming mail, it looks for matching information in the ClientThreadIdentifier field in EmailMessage records. If a match is found, the customer’s reply email is linked to the related case.

Typically this method is used in Email Services so that you can provide your own handling of inbound emails using Apex code.

Example

If you implement header-based threading in your Email Services currently, we recommend that you use Lightning threading, which combines token-based threading and header-based threading. For header-based threading to continue to work, store emails as EmailMessage records with the MessagedIdentifier field set properly. With Lightning threading, you can use threading tokens as the primary threading method and rely on header-based threading as a fallback, or vice versa.

In this example, we rely on threading tokens and use header-based threading as a fallback.

```apex
global class AttachEmailMessageToCaseExample implements Messaging.InboundEmailHandler {
    global Messaging.InboundEmailResult handleInboundEmail(Messaging.inboundEmail email,
        Messaging.InboundEnvelope env) {
        // Create an InboundEmailResult object for returning the result of the
        // Apex Email Service.
        Messaging.InboundEmailResult result = new Messaging.InboundEmailResult();

        // Try to find the Case ID using threading tokens in email attributes.
        Id caseId = EmailMessages.getRecordIdFromEmail(email.subject, email.plainTextBody,
            email.htmlBody);

        // If we haven’t found the Case ID, try finding it using headers.
        if (caseId == null) {
            caseId = Cases.getCaseIdFromEmailHeaders(email.headers);
        }

        // If a Case isn’t found, create a new Case record.
        if (caseId == null) {
            Case c = new Case(Subject = email.subject);
            insert c;
            System.debug('New Case Object: ' + c);
            caseId = c.Id;
        }

        // Process recipients
        String toAddresses;
        if (email.toAddresses != null) {
```
toAddresses = String.join(email.toAddresses, '; ');

EmailMessage em = new EmailMessage(
    Status = '0',
    MessageIdentifier = email.messageId,
    ParentId = caseId,
    // Other important fields.
    FromAddress = email.fromAddress,
    FromName = email.fromName,
    ToAddress = toAddresses,
    TextBody = email.plainTextBody,
    HtmlBody = email.htmlBody,
    Subject = email.subject,
    // Parse thread-index header to remain consistent with Email-to-Case.
    ClientThreadIdentifier = getClientThreadIdentifier(email.headers)
    // Other fields you wish to add.
);

// Insert the new EmailMessage.
insert em;
System.debug('New EmailMessage Object: ' + em);

// Set the result to true. No need to send an email back to the user
// with an error message.
result.success = true;

// Return the result for the Apex Email Service.
return result;

private String getClientThreadIdentifier(List<Messaging.InboundEmail.Header> headers) {
    if (headers == null || headers.size() == 0) return null;
    try {
        for (Messaging.InboundEmail.Header header : headers) {
            if (header.name.equalsIgnoreCase('thread-index')) {
                Blob threadIndex = EncodingUtil.base64Decode(header.value.trim());
                return EncodingUtil.convertToHex(threadIndex).substring(0, 44).toUpperCase();
            }
        }
    } catch (Exception e) {
        return null;
    }
    return null;
}
**getCaseIdFromEmailThreadId(emailThreadId)**

Returns the case ID corresponding to the specified email thread ID. *(Deprecated. Use getCaseIdFromEmailHeaders and EmailMessages.getRecordIdFromEmail instead.)*

**Signature**

``` java
public static ID getCaseIdFromEmailThreadId(String emailThreadId)
```

**Parameters**

- `emailThreadId`
  
  Type: *String*

**Return Value**

Type: *ID*

**Usage**

The argument for `emailThreadId`, also known as Ref ID, has the format `!00Dxx01gEW.!500xx0Yktl`. This format was introduced in the Winter ’24 release. The previous format, `_00Dxx1gEW._500xxYktl`, is supported for backward compatibility, but emails sent from the Winter ’24 release onward use the new format. Other formats that include ref: or [ref: aren’t supported by this method.

**Collator Class**

Contains methods to get locale-specific instances that can be used for comparisons and sorting. Use the `getInstance()` method to obtain the Collator instance for a given locale and pass the Collator as the Comparator parameter to the `list.sort()` method.

**Namespace**

*System*

**Usage**

Because locale-sensitive sorting can produce different results depending on the user running the code, avoid using it in triggers or in code that expects a particular sort order.

**Example**

This example performs a default list sort and then uses Collator to sort based on the user locale.

``` java
@IsTest
static void userLocaleSort() {
    string userLocale = 'fr_FR';

    User u = new User(Alias = 'standt', Email='standarduser@testorg.com',
                      EmailEncodingKey='UTF-8', LastName='Testing', LanguageLocaleKey='en_US',
                      LocaleSidKey=userLocale, TimeZoneSidKey='America/Los_Angeles',
```
ProfileId = [SELECT Id FROM Profile WHERE Name='Standard User'].Id,
UserName='standarduser' + DateTime.now().getTime() + '@testorg.com');

System.runAs(u) {
    List<String> shoppingList = new List<String> {
        'épaule désosé Agneau',
        'Juice',
        'à la mélasse Galette 5 kg',
        'Bread',
        'Grocery'
    };

    // Default sort
    shoppingList.sort();
    Assert.areEqual('Bread', shoppingList[0]);

    // Sort based on user Locale
    Collator myCollator = Collator.getInstance();
    shoppingList.sort(myCollator);
    Assert.areEqual('à la mélasse Galette 5 kg', shoppingList[0]);
    Assert.areEqual('Bread', shoppingList[1]);
    Assert.areEqual('épaule désosé Agneau', shoppingList[2]);
    Assert.areEqual('Grocery', shoppingList[3]);
    Assert.areEqual('Juice', shoppingList[4]);
}

IN THIS SECTION:
Collator Methods

Collator Methods
The following are methods for Collator.

IN THIS SECTION:
compare(source, target)
Perform string comparisons for a given locale.
getInstance()
Gets the Collator instance for the current user’s locale.

compare(source, target)
Perform string comparisons for a given locale.

Signature
public Integer compare(String source, String target)
Parameters

source
Type: String

target
Type: String

Return Value
Type: Integer

getInstance()
Gets the Collator instance for the current user’s locale.

Signature
public static System.Collator getInstance()

Return Value
Type: Collator Class

Comparable Interface
Adds sorting support for Lists that contain non-primitive types, that is, Lists of user-defined types. Your implementation must explicitly handle null inputs in the compareTo() method to avoid a null pointer exception.

Namespace
System

Usage
To add List sorting support for your Apex class, you must implement the Comparable interface with its compareTo method in your class.

To implement the Comparable interface, you must first declare a class with the implements keyword as follows:

```java
public class Employee implements Comparable {
    // Your code here
}
```

Next, your class must provide an implementation for the following method:

```java
public Integer compareTo(Object compareTo) {
    // Your code here
}
```

The implemented method must be declared as global or public.

IN THIS SECTION:
    Comparable Methods
Comparable Example Implementation

SEE ALSO:
  - List Class

Comparable Methods
The following are methods for Comparable.

IN THIS SECTION:
  - compareTo(objectToCompareTo)
    - Returns an Integer value that is the result of the comparison.

**compareTo(objectToCompareTo)**
Returns an Integer value that is the result of the comparison.

**Signature**
```
public Integer compareTo(Object objectToCompareTo)
```

**Parameters**
- **objectToCompareTo**
  - Type: Object

**Return Value**
- Type: Integer

**Usage**
The implementation of this method returns the following values:
- 0 if this instance and objectToCompareTo are equal
- > 0 if this instance is greater than objectToCompareTo
- < 0 if this instance is less than objectToCompareTo

If this object instance and objectToCompareTo are incompatible, a System.TypeException is thrown.

Comparable Example Implementation
This example implements the Comparable interface. The compareTo method in this example compares the employee of this class instance with the employee passed in the argument. The method returns an Integer value based on the comparison of the employee IDs.

```
public class Employee implements Comparable {

    public Long id;

```
public String name;
public String phone;

// Constructor
public Employee(Long i, String n, String p) {
    id = i;
    name = n;
    phone = p;
}

// Implement the compareTo() method
public Integer compareTo(Object compareTo) {
    Employee compareToEmp = (Employee)compareTo;
    if (id == compareToEmp.id) return 0;
    if (id > compareToEmp.id) return 1;
    return -1;
}

This example tests the sort order of a list of Employee objects.

@isTest
private class EmployeeSortingTest {
  @isTest
  static void test1() {
    List<Employee> empList = new List<Employee>();
    empList.add(new Employee(101,'Joe Smith', '4155551212'));
    empList.add(new Employee(101,'J. Smith', '4155551212'));
    empList.add(new Employee(25,'Caragh Smith', '4155551000'));
    empList.add(new Employee(105,'Mario Ruiz', '4155551099'));
    // Sort using the custom compareTo() method
    empList.sort();
    // Write list contents to the debug log
    System.debug(empList);
    // Verify list sort order.
    Assert.areEqual('Caragh Smith', empList[0].Name);
    Assert.areEqual('Joe Smith', empList[1].Name);
    Assert.areEqual('J. Smith', empList[2].Name);
    Assert.areEqual('Mario Ruiz', empList[3].Name);
  }
}

Comparator Interface

Implement different sort orders with the Comparator interface’s compareTo() method, and pass the Comparator as a parameter to List.sort(). Your implementation must explicitly handle null inputs in the compareTo() method to avoid a null pointer exception.

Namespace

System
Comparator Methods

The following are methods for Comparator.

Comparator Example Implementation

Use the Comparator interface to impose different kinds of sorting.

public class Employee {
    private Long id;
    private String name;
}
private Integer yearJoined;

// Constructor
public Employee(Long i, String n, Integer y) {
    id = i;
    name = n;
    yearJoined = y;
}

public String getName() { return name; }
public Integer getYear() { return yearJoined; }

// Class to compare Employees by name
public class NameCompare implements Comparator<Employee> {
    public Integer compare(Employee e1, Employee e2) {
        if(e1?.getName() == null && e2?.getName() == null) {
            return 0;
        } else if(e1?.getName() == null) {
            return -1;
        } else if(e2?.getName() == null) {
            return 1;
        }
        return e1.getName().compareTo(e2.getName());
    }
}

// Class to compare Employees by year joined
public class YearCompare implements Comparator<Employee> {
    public Integer compare(Employee e1, Employee e2) {
        // Guard against null operands for '<' or '>' operators because
        // they will always return false and produce inconsistent sorting
        Integer result;
        if(e1?.getYear() == null && e2?.getYear() == null) {
            result = 0;
        } else if(e1?.getYear() == null) {
            result = -1;
        } else if(e2?.getYear() == null) {
            result = 1;
        } else if (e1.getYear() < e2.getYear()) {
            result = -1;
        } else if (e1.getYear() > e2.getYear()) {
            result = 1;
        } else {
            result = 0;
        }
        return result;
    }
}

The following example tests the implementation:

@isTest
private class EmployeeSortingTest {
    @isTest
static void sortWithComparators() {
    List<Employee> empList = new List<Employee>();
    empList.add(new Employee(101,'Joe Smith', 2020));
    empList.add(new Employee(102,'J. Smith', 2020));
    empList.add(new Employee(25,'Caragh Smith', 2021));
    empList.add(new Employee(105,'Mario Ruiz', 2019));
    // Sort by name
    NameCompare nameCompare = new NameCompare();
    empList.sort(nameCompare);
    // Expected order: Caragh Smith, J. Smith, Joe Smith, Mario Ruiz
    Assert.areEqual('Caragh Smith', empList.get(0).getName());

    // Sort by year joined
    YearCompare yearCompare = new YearCompare();
    empList.sort(yearCompare);
    // Expected order: Mario Ruiz, J. Smith, Joe Smith, Caragh Smith
    Assert.areEqual('Mario Ruiz', empList.get(0).getName());
}

Continuation Class

Use the Continuation class to make callouts asynchronously to a SOAP or REST Web service.

Namespace

System

Example

For a code example, see Make Long-Running Callouts from a Visualforce Page.

IN THIS SECTION:

Continuation Constructors

Continuation Properties

Continuation Methods

Continuation Constructors

The following are constructors for Continuation.

IN THIS SECTION:

Continuation(timeout)

Continuation(timeout)

Continuation Class

Continuation Class

Continuation Class

Continuation Class

Continuation Class

Continuation Class

Continuation Class

Continuation Class
**Signature**

`public Continuation(Integer timeout)`

**Parameters**

`timeout`

Type: `Integer`

The timeout for this continuation in seconds.

**Continuation Properties**

The following are properties for `Continuation`.

**IN THIS SECTION:**

- `continuationMethod`
  The name of the callback method that is called after the callout response returns.
- `timeout`
  The timeout of the continuation in seconds. Maximum: 120 seconds.
- `state`
  Data that is stored in this continuation and that can be retrieved after the callout is finished and the callback method is invoked.

**continuationMethod**

The name of the callback method that is called after the callout response returns.

**Signature**

`public String continuationMethod {get; set;}`

**Property Value**

Type: `String`

**Usage**

**Note:** If the `continuationMethod` property is not set for a Continuation, the same action method that made the asynchronous callout is called again when the callout response returns.

**timeout**

The timeout of the continuation in seconds. Maximum: 120 seconds.

**Signature**

`public Integer timeout {get; set;}`
Property Value
Type: Integer

**state**
Data that is stored in this continuation and that can be retrieved after the callout is finished and the callback method is invoked.

**Signature**
```
public Object state {get; set;}
```

Property Value
Type: Object

**Example**
This example shows how to save state information for a continuation in a controller.

```
// Declare inner class to hold state info
private class StateInfo {
    String msg { get; set; }
    List<String> urls { get; set; }
    StateInfo(String msg, List<String> urls) {
        this.msg = msg;
        this.urls = urls;
    }
}

// Then in the action method, set state for the continuation
continuationInstance.state = new StateInfo('Some state data', urls);
```

**Continuation Methods**
The following are methods for Continuation.

**addHttpRequest(request)**
Adds the HTTP request for the callout that is associated with this continuation.

**getRequests()**
Returns all labels and requests that are associated with this continuation as key-value pairs.

**getResponse(requestLabel)**
Returns the response for the request that corresponds to the specified label.

**addHttpRequest(request)**
Adds the HTTP request for the callout that is associated with this continuation.
Signature

public String addHttpRequest(System.HttpRequest request)

Parameters

request
Type: HttpRequest
The HTTP request to be sent to the external service by this continuation.

Return Value

Type: String
A unique label that identifies the HTTP request that is associated with this continuation. This label is used in the map that getRequests() returns to identify individual requests in a continuation.

Usage

You can add up to three requests to a continuation.

Note: The timeout that is set in each passed-in request is ignored. Only the global timeout maximum of 120 seconds applies for a continuation.

getRequests()

Returns all labels and requests that are associated with this continuation as key-value pairs.

Signature

public Map<String, System.HttpRequest> getRequests()

Return Value

Type: Map<String, HttpRequest>
A map of all requests that are associated with this continuation. The map key is the request label, and the map value is the corresponding HTTP request.

getResponse(requestLabel)

Returns the response for the request that corresponds to the specified label.

Signature

public static HttpResponse getResponse(String requestLabel)

Parameters

requestLabel
Type: String
The request label to get the response for.
Return Value
Type: HttpResponse

Usage
The status code is returned in the HttpResponse object and can be obtained by calling getStatusCode() on the response. A status code of 200 indicates that the request was successful. Other status code values indicate the type of problem that was encountered.

Sample of Error Status Codes
When a problem occurs with the response, some possible status code values are:

- 2000: The timeout was reached, and the server didn’t get a chance to respond.
- 2001: There was a connection failure.
- 2002: Exceptions occurred.
- 2003: The response hasn’t arrived (which also means that the Apex asynchronous callout framework hasn’t resumed).
- 2004: The response size is too large (greater than 1 MB).

Cookie Class
The Cookie class lets you access cookies for your Salesforce site using Apex.

Namespace
System

Usage
Use the setCookies method of the PageReference Class to attach cookies to a page.

Important:
- Cookie names and values set in Apex are URL encoded, that is, characters such as @ are replaced with a percent sign and their hexadecimal representation.
- The setCookies method adds the prefix “apex__” to the cookie names.
- Setting a cookie’s value to null sends a cookie with an empty string value instead of setting an expired attribute.
- After you create a cookie, the properties of the cookie can’t be changed.
- Be careful when storing sensitive information in cookies. Pages are cached regardless of a cookie value. If you use a cookie value to generate dynamic content, you should disable page caching. For more information, see Configure Site Caching in Salesforce Help.

Consider the following limitations when using the Cookie class:
- The Cookie class can only be accessed using Apex that is saved using the Salesforce API version 19 and above.
- The maximum number of cookies that can be set per Salesforce Sites domain depends on your browser. Newer browsers have higher limits than older ones.
- Cookies must be less than 4K, including name and attributes.
- The maximum header size of a Visualforce page, including cookies, is 8,192 bytes.

For more information on sites, see “Salesforce Sites” in the Salesforce online help.
Example

The following example creates a class, CookieController, which is used with a Visualforce page (see markup below) to update a counter each time a user displays a page. The number of times a user goes to the page is stored in a cookie.

```java
// A Visualforce controller class that creates a cookie
// used to keep track of how often a user displays a page
public class CookieController {
    public CookieController() {
        Cookie counter = ApexPages.currentPage().getCookies().get('counter');

        // If this is the first time the user is accessing the page,
        // create a new cookie with name 'counter', an initial value of '1',
        // path 'null', maxAge '-1', and isSecure 'true'.
        if (counter == null) {
            counter = new Cookie('counter', '1', null, -1, true);
        } else {
            // If this isn't the first time the user is accessing the page
            // create a new cookie, incrementing the value of the original count by 1
            Integer count = Integer.valueOf(counter.getValue());
            counter = new Cookie('counter', String.valueOf(count + 1), null, -1, true);
        }

        // Set the new cookie for the page
        ApexPages.currentPage().setCookies(new Cookie[]{counter});
    }

    // This method is used by the Visualforce action {!count} to display the current
    // value of the number of times a user had displayed a page.
    // This value is stored in the cookie.
    public String getCount() {
        Cookie counter = ApexPages.currentPage().getCookies().get('counter');
        if (counter == null) {
            return '0';
        }
        return counter.getValue();
    }
}

// Test class for the Visualforce controller
@isTest
private class CookieControllerTest {
    // Test method for verifying the positive test case
    static testMethod void testCounter() {
        // first page view
        CookieController controller = new CookieController();
        System.assert(controller.getCount() == '1');

        // second page view
        controller = new CookieController();
        System.assert(controller.getCount() == '2');
    }
}
```
The following is the Visualforce page that uses the CookieController Apex controller above. The action {!count} calls the getCount method in the controller above.

```apex
<apex:page controller="CookieController">
    You have seen this page {!count} times
</apex:page>
```

IN THIS SECTION:
- Cookie Constructors
- Cookie Methods

### Cookie Constructors

The following are constructors for Cookie.

IN THIS SECTION:
- `Cookie(name, value, path, maxAge, isSecure)`
  Creates a new instance of the Cookie class using the specified name, value, path, age, and the secure setting.
- `Cookie(name, value, path, maxAge, isSecure, SameSite)`
  Creates a new instance of the Cookie class using the specified name, value, path, and age, and settings for security and cross-domain behavior.

### `Cookie(name, value, path, maxAge, isSecure)`

Creates a new instance of the Cookie class using the specified name, value, path, age, and the secure setting.

**Signature**

```
public Cookie(String name, String value, String path, Integer maxAge, Boolean isSecure)
```

**Parameters**

- `name`
  - Type: String
  - The cookie name. It can't be null.

- `value`
  - Type: String
  - The cookie data, such as session ID.

- `path`
  - Type: String
  - The path from where you can retrieve the cookie.

- `maxAge`
  - Type: Integer
  - A number representing how long a cookie is valid for in seconds. If set to less than zero, a session cookie is issued. If set to zero, the cookie is deleted.
isSecure
  Type: Boolean
  A value indicating whether the cookie can only be accessed through HTTPS (true) or not (false).

Cookie(name, value, path, maxAge, isSecure, SameSite)
Creates a new instance of the Cookie class using the specified name, value, path, and age, and settings for security and cross-domain behavior.

Note: Google Chrome 80 introduces a new default cookie attribute setting of SameSite, which is set to Lax. Previously, the SameSite cookie attribute defaulted to the value of None. When SameSite is set to None, cookies must be tagged with the isSecure attribute indicating that they require an encrypted HTTPS connection.

Signature
public Cookie(String name, String value, String path, Integer maxAge, Boolean isSecure, String SameSite)

Parameters
name
  Type: String
  The cookie name. It can’t be null.

value
  Type: String
  The cookie data, such as session ID.

path
  Type: String
  The path from where you can retrieve the cookie.

maxAge
  Type: Integer
  A number representing how long a cookie is valid for in seconds. If set to less than zero, a session cookie is issued. If set to zero, the cookie is deleted.

isSecure
  Type: Boolean
  A value indicating whether the cookie can only be accessed through HTTPS (true) or not (false).

SameSite
  Type: String
The SameSite attribute on a cookie controls its cross-domain behavior. The valid values are None, Lax, and Strict. After the Chrome 80 release, a cookie with a SameSite value of None must also be marked secure by setting a value of None; Secure.

SEE ALSO:

Salesforce Spring '20 Release Notes: Prepare for Google Chrome's Changes in SameSite Cookie Behavior That Can Break Salesforce Integrations
Chrome Platform Status: Reject insecure SameSite=None cookies

Cookie Methods

The following are methods for Cookie. All are instance methods.

IN THIS SECTION:

getDomain()
Returns the name of the server making the request.

getMaxAge()
Returns a number representing how long the cookie is valid for, in seconds. If set to < 0, a session cookie is issued. If set to 0, the cookie is deleted.

getName()
Returns the name of the cookie. Can't be null.

getPath()
Returns the path from which you can retrieve the cookie. If null or blank, the location is set to root, or "/".

getSameSite()
Returns the value for the SameSite attribute of the cookie.

getValue()
Returns the data captured in the cookie, such as Session ID.

isSecure()
Returns true if the cookie can only be accessed through HTTPS, otherwise returns false.

getDomain()
Returns the name of the server making the request.

Signature

public String getDomain()
**getMaxAge()**
Returns a number representing how long the cookie is valid for, in seconds. If set to $< 0$, a session cookie is issued. If set to 0, the cookie is deleted.

**Signature**
```
public Integer getMaxAge()
```

**Return Value**
Type: Integer

**getName()**
Returns the name of the cookie. Can't be null.

**Signature**
```
public String getName()
```

**Return Value**
Type: String

**getPath()**
Returns the path from which you can retrieve the cookie. If null or blank, the location is set to root, or "/".

**Signature**
```
public String getPath()
```

**Return Value**
Type: String

**getSameSite()**
Returns the value for the SameSite attribute of the cookie.

**Signature**
```
public String getSameSite()
```

**Return Value**
Type: String

SEE ALSO:
web.dev: SameSite Cookies Explained
getValue()  
Returns the data captured in the cookie, such as Session ID.

Signature  
public String getValue()  

Return Value  
Type: String

isSecure()  
Returns true if the cookie can only be accessed through HTTPS, otherwise returns false.

Signature  
public Boolean isSecure()  

Return Value  
Type: Boolean

Crypto Class  
Provides methods for creating digests, message authentication codes, and signatures, as well as encrypting and decrypting information.

Namespace  
System

Usage  
The methods in the Crypto class can be used for securing content in Lightning Platform, or for integrating with external services such as Google or Amazon WebServices (AWS).

Encrypt and Decrypt Exceptions  
The following exceptions can be thrown for these methods:

- decrypt  
- encrypt  
- decryptWithManagedIV  
- encryptWithManagedIV
<table>
<thead>
<tr>
<th>Exception</th>
<th>Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>InvalidParameterValue</td>
<td>Unable to parse initialization vector from encrypted data.</td>
<td>Thrown if you’re using managed initialization vectors, and the cipher text is less than 16 bytes.</td>
</tr>
<tr>
<td>InvalidParameterValue</td>
<td>Invalid algorithm <code>algoName</code>. Must be AES128, AES192, AES256, AES384, or AES512.</td>
<td>Thrown if the algorithm name isn’t one of the valid values.</td>
</tr>
<tr>
<td>InvalidParameterValue</td>
<td>Invalid private key. Must be <code>size</code> bytes.</td>
<td>Thrown if size of the private key doesn’t match the specified algorithm.</td>
</tr>
<tr>
<td>InvalidParameterValue</td>
<td>Invalid initialization vector. Must be 16 bytes.</td>
<td>Thrown if the initialization vector isn’t 16 bytes.</td>
</tr>
<tr>
<td>InvalidParameterValue</td>
<td>Invalid data. Input data is <code>size</code> bytes, which exceeds the limit of 1048576 bytes.</td>
<td>Thrown if the data is greater than 1 MB. For decryption, 1048608 bytes are allowed for the initialization vector header, plus any additional padding the encryption added to align to block size.</td>
</tr>
<tr>
<td>NullPointer.Exception</td>
<td>Argument cannot be null.</td>
<td>Thrown if one of the required method arguments is null.</td>
</tr>
<tr>
<td>SecurityException</td>
<td>Given final block not properly padded.</td>
<td>Thrown if the data isn’t properly block-aligned or similar issues occur during encryption or decryption.</td>
</tr>
<tr>
<td>SecurityException</td>
<td>Message Varies</td>
<td>Thrown if something goes wrong during either encryption or decryption.</td>
</tr>
</tbody>
</table>

**Crypto Methods**

The following are methods for `Crypto`. All methods are static.

**IN THIS SECTION:**

- `decrypt(algorithmName, privateKey, initializationVector, cipherText)`
  - Decrypts the Blob `cipherText` using the specified algorithm, private key, and initialization vector. Use this method to decrypt blobs encrypted using a third party application or the `encrypt` method.

- `decryptWithManagedIV(algorithmName, privateKey, IVAndCipherText)`
  - Decrypts the Blob `IVAndCipherText` using the specified algorithm and private key. Use this method to decrypt blobs encrypted using a third party application or the `encryptWithManagedIV` method.

- `encrypt(algorithmName, privateKey, initializationVector, clearText)`
  - Encrypts the Blob `clearText` using the specified algorithm, private key and initialization vector. Use this method when you want to specify your own initialization vector.

- `encryptWithManagedIV(algorithmName, privateKey, clearText)`
  - Encrypts the Blob `clearText` using the specified algorithm and private key. Use this method when you want Salesforce to generate the initialization vector for you.
generateAesKey(size)
Generates an Advanced Encryption Standard (AES) key.
generateDigest(algorithmName, input)
Computes a secure, one-way hash digest based on the supplied input string and algorithm name.
generateMac(algorithmName, input, privateKey)
Computes a message authentication code (MAC) for the input string, using the private key and the specified algorithm.
getRandomInteger()
Returns a random Integer.
getRandomLong()
Returns a random Long.
sign(algorithmName, input, privateKey)
Computes a unique digital signature for the input string, using the specified algorithm and the supplied private key.
signWithCertificate(algorithmName, input, certDevName)
Computes a unique digital signature for the input string, using the specified algorithm and the supplied certificate and key pair.
signXML(algorithmName, node, idAttributeName, certDevName)
Envelops the signature into an XML document.
signXML(algorithmName, node, idAttributeName, certDevName, refChild)
Inserts the signature envelope before the specified child node.
verify(String algorithmName, Blob data, Blob signature, Blob publicKey)
Verifies the digital signature for the Blob data using the specified algorithm and the supplied public key. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.
verify(String algorithmName, Blob data, Blob signature, String certDevName)
Verifies the digital signature for the Blob data using the specified algorithm and the public key associated with the certDevName. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.
verifyHmac(String algorithmName, Blob input, Blob privateKey, Blob macToVerify)
Verifies the HMAC signature for Blob data using the specified algorithm, input data, privateKey, and the mac. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

decrypt(algorithmName, privateKey, initializationVector, cipherText)
Decrypts the Blob cipherText using the specified algorithm, private key, and initialization vector. Use this method to decrypt blobs encrypted using a third party application or the encrypt method.

Signature

public static Blob decrypt(String algorithmName, Blob privateKey, Blob initializationVector, Blob cipherText)

Parameters

algorithmName
  Type: String
privateKey
  Type: Blob
**initializationVector**
Type: Blob

**cipherText**
Type: Blob

**Return Value**
Type: Blob

**Usage**
Valid values for *algorithmName* are:
- AES128
- AES192
- AES256

These algorithms are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS7 padding.

The length of *privateKey* must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16 bytes, 24 bytes, or 32 bytes, respectively. You can use a third-party application or the *generateAesKey* method to generate this key for you.

The initialization vector must be 128 bits (16 bytes.)

**Example**

```java
Blob exampleIv = Blob.valueOf('Example of IV123');
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encrypt('AES128', key, exampleIv, data);

Blob decrypted = Crypto.decrypt('AES128', key, exampleIv, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

**decryptWithManagedIV(algorithmName, privateKey, IVAndCipherText)**

Decrypts the Blob *IVAndCipherText* using the specified algorithm and private key. Use this method to decrypt blobs encrypted using a third party application or the *encryptWithManagedIV* method.

**Signature**

```java
public static Blob decryptWithManagedIV(String algorithmName, Blob privateKey, Blob IVAndCipherText)
```

**Parameters**

*algorithmName*
Type: String
**privateKey**
Type: Blob

**IVAndCipherText**
Type: Blob
The first 128 bits (16 bytes) of IVAndCipherText must contain the initialization vector.

**Return Value**
Type: Blob

**Usage**
Valid values for `algorithmName` are:
- AES128
- AES192
- AES256

These algorithms are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS7 padding.

The length of privateKey must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16 bytes, 24 bytes, or 32 bytes, respectively. You can use a third-party application or the `generateAesKey` method to generate this key for you.

**Example**

```java
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encryptWithManagedIV('AES128', key, data);

Blob decrypted = Crypto.decryptWithManagedIV('AES128', key, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

**encrypt(algorithmName, privateKey, initializationVector, clearText)**
Encrypts the Blob `clearText` using the specified algorithm, private key and initialization vector. Use this method when you want to specify your own initialization vector.

**Signature**

```java
public static Blob encrypt(String algorithmName, Blob privateKey, Blob initializationVector, Blob clearText)
```

**Parameters**

- `algorithmName`
  Type: String
- `privateKey`
  Type: Blob
**Usage**

The initialization vector must be 128 bits (16 bytes.) Use either a third-party application or the `decrypt` method to decrypt blobs encrypted using this method. Use the `encryptWithManagedIV` method if you want Salesforce to generate the initialization vector for you. It is stored as the first 128 bits (16 bytes) of the encrypted Blob.

Valid values for `algorithmName` are:

- AES128
- AES192
- AES256

These algorithms are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS7 padding.

The length of `privateKey` must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16 bytes, 24 bytes, or 32 bytes, respectively. You can use a third-party application or the `generateAesKey` method to generate this key for you.

**Example**

```java
Blob exampleIv = Blob.valueOf('Example of IV123');
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encrypt('AES128', key, exampleIv, data);

Blob decrypted = Crypto.decrypt('AES128', key, exampleIv, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

**encryptWithManagedIV(algorithmName, privateKey, clearText)**

Encrypts the Blob `clearText` using the specified algorithm and private key. Use this method when you want Salesforce to generate the initialization vector for you.

**Signature**

```java
public static Blob encryptWithManagedIV(String algorithmName, Blob privateKey, Blob clearText)
```

**Parameters**

- `algorithmName`
  Type: `String`
privateKey
  Type: Blob
clearText
  Type: Blob

Return Value
Type: Blob

Usage
The initialization vector is stored as the first 128 bits (16 bytes) of the encrypted Blob. Use either third-party applications or the decryptWithManagedIV method to decrypt blobs encrypted with this method. Use the encrypt method if you want to generate your own initialization vector.

Valid values for algorithmName are:

- AES128
- AES192
- AES256

These algorithms are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS7 padding.

The length of privateKey must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16 bytes, 24 bytes, or 32 bytes, respectively. You can use a third-party application or the generateAesKey method to generate this key for you.

Example

```java
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encryptWithManagedIV('AES128', key, data);

Blob decrypted = Crypto.decryptWithManagedIV('AES128', key, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

generateAesKey(size)
Generates an Advanced Encryption Standard (AES) key.

Signature
public static Blob generateAesKey(Integer size)

Parameters
size
  Type: Integer
  The key's size in bits. Valid values are:
  - 128
Return Value
Type: Blob

Example

```java
Blob key = Crypto.generateAesKey(128);
```

generateDigest(algorithmName, input)
Computes a secure, one-way hash digest based on the supplied input string and algorithm name.

Signature

```java
public static Blob generateDigest(String algorithmName, Blob input)
```

Parameters

- `algorithmName`
  Type: String
  Valid values for `algorithmName` are:
  - MD5
  - SHA1
  - SHA3-256
  - SHA3-384
  - SHA3-512
  - SHA-256
  - SHA-512

- `input`
  Type: Blob

Return Value
Type: Blob

Example

```java
Blob targetBlob = Blob.valueOf('ExampleMD5String');
Blob hash = Crypto.generateDigest('MD5', targetBlob);
```

generateMac(algorithmName, input, privateKey)
Computes a message authentication code (MAC) for the input string, using the private key and the specified algorithm.
Signature

```java
public static Blob generateMac(String algorithmName, Blob input, Blob privateKey)
```

Parameters

- `algorithmName`
  - Type: `String`
  - The valid values for `algorithmName` are:
    - hmacMD5
    - hmacSHA1
    - hmacSHA256
    - hmacSHA512

- `input`
  - Type: `Blob`

- `privateKey`
  - Type: `Blob`
  - The value of `privateKey` does not need to be in decoded form. The value cannot exceed 4 KB.

Return Value

- Type: `Blob`

Example

```java
String salt = String.valueOf(Crypto.getRandomInteger());
String key = 'key';
Blob data = crypto.generateMac('HmacSHA256',
   Blob.valueOf(salt), Blob.valueOf(key));
```

`getRandomInteger()`

Returns a random Integer.

Signature

```java
public static Integer getRandomInteger()
```

Return Value

- Type: `Integer`

Example

```java
Integer randomInt = Crypto.getRandomInteger();
```
**getRandomLong()**

Returns a random Long.

**Signature**

```java
public static Long getRandomLong()
```

**Return Value**

Type: Long

**Example**

```java
Long randomLong = Crypto.getRandomLong();
```

**sign(algorithmName, input, privateKey)**

Computes a unique digital signature for the input string, using the specified algorithm and the supplied private key.

**Signature**

```java
public static Blob sign(String algorithmName, Blob input, Blob privateKey)
```

**Parameters**

- **algorithmName**
  - Type: String
  - The algorithm name. The valid values for `algorithmName` are RSA, RSA-SHA1, RSA-SHA256, RSA-SHA384, RSA-SHA512, ECDSA-SHA256, ECDSA-SHA384, and ECDSA-SHA512.
  - RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.
  - RSA-SHA256 is an RSA signature of an SHA256 hash.
  - RSA-SHA384 is an RSA signature of an SHA384 hash.
  - RSA-SHA512 is an RSA signature of an SHA512 hash.
  - RSA is the same as RSA-SHA1.
  - ECDSA-SHA256 is an ECDSA signature of an SHA256 hash.
  - ECDSA-SHA384 is an ECDSA signature of an SHA384 hash.
  - ECDSA-SHA512 is an ECDSA signature of an SHA512 hash.

- **input**
  - Type: Blob
  - The data to sign.

- **privateKey**
  - Type: Blob
  - The value of `privateKey` must be decoded using the `EncodingUtilBase64Decode` method, and should be in RSA's PKCS #8 (1.2) Private-Key Information Syntax Standard form. The value cannot exceed 4 KB.
Return Value

Type: Blob

Example

The following snippet shows how to call the `sign` method.

```java
String algorithmName = 'RSA';
String key = '';
Blob privateKey = EncodingUtil.base64Decode(key);
Blob input = Blob.valueOf('12345qwerty');
Crypto.sign(algorithmName, input, privateKey);
```

`signWithCertificate(algorithmName, input, certDevName)`

Computes a unique digital signature for the input string, using the specified algorithm and the supplied certificate and key pair.

**Signature**

```java
public static Blob signWithCertificate(String algorithmName, Blob input, String certDevName)
```

**Parameters**

- `algorithmName`
  - Type: String
  - The algorithm name. The valid values for `algorithmName` are `RSA`, `RSA-SHA1`, `RSA-SHA256`, `RSA-SHA384`, `RSA-SHA512`, `ECDSA-SHA256`, `ECDSA-SHA384`, and `ECDSA-SHA512`.
  - `RSA-SHA1` is an RSA signature (with an asymmetric key pair) of an SHA1 hash.
  - `RSA-SHA256` is an RSA signature of an SHA256 hash.
  - `RSA-SHA384` is an RSA signature of an SHA384 hash.
  - `RSA-SHA512` is an RSA signature of an SHA512 hash.
  - `RSA` is the same as `RSA-SHA1`.
  - `ECDSA-SHA256` is an ECDSA signature of an SHA256 hash.
  - `ECDSA-SHA384` is an ECDSA signature of an SHA384 hash.
  - `ECDSA-SHA512` is an ECDSA signature of an SHA512 hash.

- `input`
  - Type: Blob
  - The data to sign.

- `certDevName`
  - Type: String
  - The `Unique Name` for a certificate stored in the Salesforce org’s Certificate and Key Management page to use for signing.

To access the Certificate and Key Management page from Setup, enter `Certificate and Key Management` in the Quick Find box, then select `Certificate and Key Management`.
Return Value

Type: Blob

Example

The following snippet is an example of the method for signing the content referenced by `data`.

```java
Blob data = Blob.valueOf('12345qwerty');
System.Crypto.signWithCertificate('RSA-SHA512', data, 'signingCert');
```

`signXML(algorithmName, node, idAttributeName, certDevName)`

Envelops the signature into an XML document.

Signature

```java
public Void signXML(String algorithmName, Dom.XmlNode node, String idAttributeName, String certDevName)
```

Parameters

`algorithmName`

Type: String

The RSA encryption algorithm name. Valid names are RSA, RSA-SHA1, RSA-SHA256, RSA-SHA384, RSA-SHA512, ECDSA-SHA256, ECDSA-SHA384, and ECDSA-SHA512.

- RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.
- RSA-SHA256 is an RSA signature of an SHA256 hash.
- RSA-SHA384 is an RSA signature of an SHA384 hash.
- RSA-SHA512 is an RSA signature of an SHA512 hash.
- RSA is the same as RSA-SHA1.
- ECDSA-SHA256 is an ECDSA signature of an SHA256 hash.
- ECDSA-SHA384 is an ECDSA signature of an SHA384 hash.
- ECDSA-SHA512 is an ECDSA signature of an SHA512 hash.

`node`

Type: Dom.XmlNode

The XML node to sign and insert the signature into.

`idAttributeName`

Type: String

The full name (including the namespace) of the attribute on the node (XmlNode) to use as the reference ID. If `null`, this method uses the ID attribute on the node. If there is no ID attribute, Salesforce generates a new ID and adds it to the node.

`certDevName`

Type: String

The unique name for a certificate stored in the Salesforce org’s Certificate and Key Management page to use for signing.
To access the Certificate and Key Management page from Setup, enter Certificate and Key Management in the Quick Find box, then select Certificate and Key Management.

Return Value
Type: void

Example
The following is an example declaration and initialization.

```java
doc.load(...);
System.Crypto.signXml('RSA-SHA512', doc.getRootElement(), null, 'signingCert');
return doc.toXmlString();
```

signXML(algorithmName, node, idAttributeName, certDevName, refChild)
Inserts the signature envelope before the specified child node.

Signature

```java
public static void signXml(String algorithmName, Dom.XmlNode node, String idAttributeName, String certDevName, Dom.XmlNode refChild)
```

Parameters

**algorithmName**
Type: String
The RSA encryption algorithm name. Valid names are RSA, RSA-SHA1, RSA-SHA256, RSA-SHA384, RSA-SHA512, ECDSA-SHA256, ECDSA-SHA384, and ECDSA-SHA512.

RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.

RSA-SHA256 is an RSA signature of an SHA256 hash.

RSA-SHA384 is an RSA signature of an SHA384 hash.

RSA-SHA512 is an RSA signature of an SHA512 hash.

RSA is the same as RSA-SHA1.

ECDSA-SHA256 is an ECDSA signature of an SHA256 hash.

ECDSA-SHA384 is an ECDSA signature of an SHA384 hash.

ECDSA-SHA512 is an ECDSA signature of an SHA512 hash.

**node**
Type: Dom.XmlNode
The XML node to sign and insert the signature into.

**idAttributeName**
Type: String
The full name (including the namespace) of the attribute on the node (XmlNode) to use as the reference ID. If null, this method uses the ID attribute on the node. If there is no ID attribute, Salesforce generates a new ID and adds it to the node.
certDevName
  Type: String
  The unique name for a certificate stored in the Salesforce org’s Certificate and Key Management page to use for signing.
  To access the Certificate and Key Management page from Setup, enter Certificate and Key Management in the Quick Find box, then select Certificate and Key Management.

refChild
  Dom.XmlNode
  The XML node before which to insert the signature. If refChild is null, the signature is added at the end.

Return Value
  Type: Void

verify(String algorithmName, Blob data, Blob signature, Blob publicKey)
  Verifies the digital signature for the Blob data using the specified algorithm and the supplied public key. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

Signature
  public static Blob verify(String algorithmName, Blob data, Blob signature, Blob publicKey)

Parameters
  algorithmName
    Type: String
    The algorithm name. The valid values for algorithmName are RSA, RSA-SHA1, RSA-SHA256, RSA-SHA384, RSA-SHA512, ECDSA-SHA256, ECDSA-SHA384, and ECDSA-SHA512.
    RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.
    RSA-SHA256 is an RSA signature of an SHA256 hash.
    RSA-SHA384 is an RSA signature of an SHA384 hash.
    RSA-SHA512 is an RSA signature of an SHA512 hash.
    RSA is the same as RSA-SHA1.
    ECDSA-SHA256 is an ECDSA signature of an SHA256 hash.
    ECDSA-SHA384 is an ECDSA signature of an SHA384 hash.
    ECDSA-SHA512 is an ECDSA signature of an SHA512 hash.

data
    Type: Blob
    The data to sign.

signature
    Type:
    Blob
The RSA signature.

**publicKey**

Type: Blob

The value of *publicKey* must be decoded using the `EncodingUtil.base64Decode` method, and be in X.509 standard.

### Return Value

Type: Blob

### Example

```java
String algorithmName = 'RSA';
String privateKey = '';
String publicKey = '';  // Ensure to decode the publicKey
Blob privateKey = EncodingUtil.base64Decode(privateKey);
Blob publicKey = EncodingUtil.base64Decode(publicKey);
Blob input = Blob.valueOf('12345qwerty');
Blob signature = Crypto.sign(algorithmName, input, privateKey);
Boolean verified = Crypto.verify(algorithmName, input, signature, publicKey);
```

### verify(String algorithmName, Blob data, Blob signature, String certDevName)

Verifies the digital signature for the Blob *data* using the specified algorithm and the public key associated with the `certDevName`. Use this method to verify a Blob signed by a digital signature created using a third-party application or the `sign` method.

### Signature

```java
public static Blob verify(String algorithmName, Blob data, Blob signature, String certDevName)
```

### Parameters

- **algorithmName**
  Type: String
  The algorithm name. The valid values for *algorithmName* are RSA, RSA-SHA1, RSA-SHA256, RSA-SHA384, RSA-SHA512, ECDSA-SHA256, ECDSA-SHA384, and ECDSA-SHA512.
  - RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.
  - RSA-SHA256 is an RSA signature of an SHA256 hash.
  - RSA-SHA384 is an RSA signature of an SHA384 hash.
  - RSA-SHA512 is an RSA signature of an SHA512 hash.
  - RSA is the same as RSA-SHA1.
  - ECDSA-SHA256 is an ECDSA signature of an SHA256 hash.
  - ECDSA-SHA384 is an ECDSA signature of an SHA384 hash.
  - ECDSA-SHA512 is an ECDSA signature of an SHA512 hash.

- **data**
  Type: Blob
The data to sign.

**signature**

Type: Blob

The RSA signature.

**certDevName**

Type: String

The Unique Name for a certificate stored in the Salesforce organization’s Certificate and Key Management page to use for signing.

To access the Certificate and Key Management page from Setup, enter Certificate and Key Management in the Quick Find box, then select Certificate and Key Management.

**Return Value**

Type: Blob

**Example**

```java
Blob data = Blob.valueOf('12345qwerty');
Blob signature = Crypto.signWithCertificate('RSA-SHA256', data, 'signingCert');
Boolean verified = Crypto.verify('RSA-SHA512', data, signature, 'signingCert');
```

**verifyHMac(String algorithmName, Blob input, Blob privateKey, Blob macToVerify)**

Verifies the HMAC signature for Blob `data` using the specified algorithm, input data, privateKey, and the mac. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

**Signature**

```java
public static Blob verifyHMac(String algorithmName, Blob input, Blob privateKey, Blob macToVerify)
```

**Parameters**

- **algorithmName**
  Type: String
  The valid values for `algorithmName` are:
  - hmacMD5
  - hmacSHA1
  - hmacSHA256
  - hmacSHA512

- **data**
  Type: Blob
  The data to sign.

- **privateKey**
  Type: Blob
The value of `privateKey` does not need to be in decoded form. The value cannot exceed 4 KB.

`hmacToVerify`
- Type: `Blob`

The value of the mac must be verified against the provided `privateKey`, data, and algorithm.

**Return Value**
- Type: `Boolean`

**Example**
```
String salt = String.valueOf(Crypto.getRandomInteger());
String key = 'key';
Blob mac = Crypto.generateMac('HmacSHA256', Blob.valueOf(salt), Blob.valueOf(key));
Boolean verified = Crypto.verifyHMac('HmacSHA256', Blob.valueOf(salt), Blob.valueOf(key),
                                    mac);
```

**Custom Metadata Type Methods**
Custom metadata types are customizable, deployable, packageable, and upgradeable application metadata. All custom metadata is exposed in the application cache, which allows access without repeated queries to the database. The metadata is then available for formula fields, validation rules, flows, Apex, and SOAP API. All methods are static.

**Usage**
Custom metadata types methods are instance type methods and are called by and operate on a specific instance of a custom metadata type.

**Custom Metadata Types Example**
The following example uses the `getAll()` method. The custom metadata type named Games has a field called `GameType__c`. This example determines if the field value of the first record is equal to the string `PC`.

```
List<Games__mdt> mcs = Games__mdt.getAll().values();
boolean textField = null;
if (mcs[0].GameType__c == 'PC') {
    textField = true;
}
```

**IN THIS SECTION:**
- `getAll()`: Returns a map containing custom metadata records for the specific custom metadata type. The map keys are the record DeveloperNames and the map values are the record sObjects.
- `getInstance(recordId)`: Returns a single custom metadata type record sObject for a specified record ID.
getInstance(developerName)
Returns a single custom metadata type record sObject for a specified developerName field of the custom metadata type object.

getInstance(qualifiedApiName)
Returns a single custom metadata type record sObject for a qualified API name.

getAll()
Returns a map containing custom metadata records for the specific custom metadata type. The map keys are the record DeveloperNames and the map values are the record sObjects.

Signature
public Map<String, CustomMetadataType__mdt> getAll()

Return Value
Type: Map<String, CustomMetadataType__mdt>

Usage
If no records are defined for the type, this method returns an empty map. To iterate over the list of custom metadata type record sObjects, use getAll().values(). Only the first 255 characters are returned for any field in a custom metadata type record, so longer text fields get truncated. If you want all the field data from a custom metadata type record, use a SOQL query.

Example
This sample returns a map of all the records for a custom metadata type named Games__mdt.

Map<String, Games__mdt> mcs = Games__mdt.getAll();

gGetInstance(recordId)
Returns a single custom metadata type record sObject for a specified record ID.

Signature
public CustomMetadataType__mdt getInstance(recordId)

Parameters
recordId
Type: String

Return Value
Type: CustomMetadataType__mdt
Usage
Use this method to explicitly retrieve custom metadata type information at the user level. Only the first 255 characters of any field in a custom metadata type record are returned. Therefore, fields such as long text fields can be truncated. If you want all the field data from a custom metadata type record, use a SOQL query.

Example
This sample returns a single record sObject for the custom metadata type named Games_mdt with recordID specified as m000000000000000001.

Games__mdt mc = Games__mdt.getInstance('m000000000000000001');

getInstance(developerName)
Returns a single custom metadata type record sObject for a specified developerName field of the custom metadata type object.

Signature
public CustomMetadataType__mdt getInstance(String developerName)

Parameters
developerName
Type: String

Return Value
Type: CustomMetadataType__mdt

Usage
Use this method to return a single custom metadata type record for the specified developerName. The developerName is the unique name of the custom metadata type object in the API. Only the first 255 characters of any field in a custom metadata type record are returned. Therefore, fields such as long text fields can be truncated. If you want all the field data from a custom metadata type record, use a SOQL query.

Example
Returns a single record sObject for the custom metadata type named Games_mdt with developerName specified as FirstRecord.

Games__mdt mc = Games__mdt.getInstance('FirstRecord');

getInstance(qualifiedApiName)
Returns a single custom metadata type record sObject for a qualified API name.
Signature

public CustomMetadataType__mdt getInstance(String qualifiedApiName)

Parameters

qualifiedApiName

Type: String

Return Value

Type: CustomMetadataType__mdt

Usage

Use this method to return a single custom metadata type record for the specified qualifiedApiName. The qualifiedApiName is a concatenation of the namespace prefix and developerName, and has this format: namespacePrefix__developerName. The developerName is the unique name of the custom metadata type object in the API. Only the first 255 characters of any field in a custom metadata type record are returned. Therefore, fields such as long text fields can be truncated. If you want all the field data from a custom metadata type record, use a SOQL query.

Example

This sample returns a single record sObject for the custom metadata type named Games__mdt with qualified API name specified as MyNamespace__FirstRecord.

    Games__mdt mc = Games__mdt.getInstance('MyNamespace__FirstRecord');

Custom Settings Methods

Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data is then available for formula fields, validation rules, flows, Apex, and the SOAP API.

Usage

Custom settings methods are all instance methods, that is, they are called by and operate on a specific instance of a custom setting. There are two types of custom settings: hierarchy and list. There are two types of methods: methods that work with list custom settings, and methods that work with hierarchy custom settings.

Note: All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. However, querying custom settings data using Standard Object Query Language (SOQL) doesn't use the application cache and is similar to querying a custom object. To benefit from caching, use other methods for accessing custom settings data such as the Apex Custom Settings methods.

For more information on creating custom settings in the Salesforce user interface, see “Create Custom Settings” in the Salesforce online help.
Custom Setting Examples

The following example uses a list custom setting called Games. The Games setting has a field called GameType. This example determines if the value of the first data set is equal to the string 'PC'.

```java
List<Games__C> mcs = Games__c.getall().values();
boolean textField = null;
if (mcs[0].GameType__c == 'PC') {
    textField = true;
}
System.assertEquals(textField, true);
```

The following example uses a custom setting called Foundation_Countries. This example demonstrates that the getValues and getInstance methods return identical values.

```java
Foundation_Countries__c myCS1 = Foundation_Countries__c.getValues('United States');
String myCCVal = myCS1.Country_code__c;
Foundation_Countries__c myCS2 = Foundation_Countries__c.getInstance('United States');
String myCCInst = myCS2.Country_code__c;
System.assertEquals(myCCInst, myCCVal);
```

Hierarchy Custom Setting Examples

In the following example, the hierarchy custom setting GamesSupport has a field called Corporate_number. The code returns the value for the profile specified with pid.

```java
GamesSupport__c mhc = GamesSupport__c.getInstance(pid);
string mPhone = mhc.Corporate_number__c;
```

The example is identical if you choose to use the getValues method.

The following example shows how to use hierarchy custom settings methods. For getInstance, the example shows how field values that aren't set for a specific user or profile are returned from fields defined at the next lowest level in the hierarchy. The example also shows how to use getOrgDefaults.

Finally, the example demonstrates how getValues returns fields in the custom setting record only for the specific user or profile, and doesn't merge values from other levels of the hierarchy. Instead, getValues returns null for any fields that aren't set. This example uses a hierarchy custom setting called Hierarchy. Hierarchy has two fields: OverrideMe and DontOverrideMe. In addition, a user named Robert has a System Administrator profile. The organization, profile, and user settings for this example are as follows:

**Organization settings**
- OverrideMe: Hello
- DontOverrideMe: World

**Profile settings**
- OverrideMe: Goodbye
- DontOverrideMe is not set.

**User settings**
- OverrideMe: Fluffy
- DontOverrideMe is not set.
The following example demonstrates the result of the getInstance method when Robert calls it in his organization:

```java
Hierarchy__c CS = Hierarchy__c.getInstance();
System.Assert(CS.OverrideMe__c == 'Fluffy');
System.assert(CS.DontOverrideMe__c == 'World');
```

If Robert passes his user ID specified by RobertId to getInstance, the results are the same. The identical results are because the lowest level of data in the custom setting is specified at the user level.

```java
Hierarchy__c CS = Hierarchy__c.getInstance(RobertId);
System.Assert(CS.OverrideMe__c == 'Fluffy');
System.assert(CS.DontOverrideMe__c == 'World');
```

If Robert passes the System Administrator profile ID specified by SysAdminID to getInstance, the result is different. The data specified for the profile is returned:

```java
Hierarchy__c CS = Hierarchy__c.getInstance(SysAdminID);
System.Assert(CS.OverrideMe__c == 'Goodbye');
System.assert(CS.DontOverrideMe__c == 'World');
```

When Robert tries to return the data set for the organization using getOrgDefaults, the result is:

```java
Hierarchy__c CS = Hierarchy__c.getOrgDefaults();
System.Assert(CS.OverrideMe__c == 'Hello');
System.assert(CS.DontOverrideMe__c == 'World');
```

By using the getValues method, Robert can get the hierarchy custom setting values specific to his user and profile settings. For example, if Robert passes his user ID RobertId to getValues, the result is:

```java
Hierarchy__c CS = Hierarchy__c.getValues(RobertId);
System.Assert(CS.OverrideMe__c == 'Fluffy');
// Note how this value is null, because you are returning
// data specific for the user
System.assert(CS.DontOverrideMe__c == null);
```

If Robert passes his System Administrator profile ID SysAdminID to getValues, the result is:

```java
Hierarchy__c CS = Hierarchy__c.getValues(SysAdminID);
System.Assert(CS.OverrideMe__c == 'Goodbye');
// Note how this value is null, because you are returning
// data specific for the profile
System.assert(CS.DontOverrideMe__c == null);
```

**Country and State Code Custom Settings Example**

This example illustrates using two custom setting objects for storing related information, and a Visualforce page to display the data in a set of related picklists.

In the following example, country and state codes are stored in two different custom settings: Foundation_Countries and Foundation_States.

The Foundation_Countries custom setting is a list type custom setting and has a single field, Country_Code.
The Foundation_States custom setting is also a List type of custom setting and has the following fields:

- Country Code
- State Code
- State Name

The Visualforce page shows two picklists: one for country and one for state.
The Apex controller `CountryStatePicker` finds the values entered into the custom settings, then returns them to the Visualforce page.

```apex
public with sharing class CountryStatePicker {
    // Variables to store country and state selected by user
```
public String state { get; set; }
public String country {get; set;}

// Generates country dropdown from country settings
public List<SelectOption> getCountriesSelectList() {
    List<SelectOption> options = new List<SelectOption>();
    options.add(new SelectOption('', '-- Select One --'));

    // Find all the countries in the custom setting
    Map<String, Foundation_Countries__c> countries = Foundation_Countries__c.getAll();

    // Sort them by name
    List<String> countryNames = new List<String>();
    countryNames.addAll(countries.keySet());
    countryNames.sort();

    // Create the Select Options.
    for (String countryName : countryNames) {
        Foundation_Countries__c country = countries.get(countryName);
        options.add(new SelectOption(country.country_code__c, country.Name));
    }

    return options;
}

// To generate the states picklist based on the country selected by user.
public List<SelectOption> getStatesSelectList() {
    List<SelectOption> options = new List<SelectOption>();

    // Find all the states we have in custom settings.
    Map<String, Foundation_States__c> allstates = Foundation_States__c.getAll();

    // Filter states that belong to the selected country
    Map<String, Foundation_States__c> states = new Map<String, Foundation_States__c>();
    for (Foundation_States__c state : allstates.values()) {
        if (state.country_code__c == this.country) {
            states.put(state.name, state);
        }
    }

    // Sort the states based on their names
    List<String> stateNames = new List<String>();
    stateNames.addAll(states.keySet());
    stateNames.sort();

    // Generate the Select Options based on the final sorted list
    for (String stateName : stateNames) {
        Foundation_States__c state = states.get(stateName);
        options.add(new SelectOption(state.state_code__c, state.state_name__c));
    }

    // If no states are found, just say not required in the dropdown.
    if (options.size() > 0) {
        options.add(0, new SelectOption('', '-- Select One --'));
    }

List Custom Setting Methods
Hierarchy Custom Setting Methods

SEE ALSO:

Apex Developer Guide: Custom Settings

List Custom Setting Methods
The following are instance methods for list custom settings.

IN THIS SECTION:

getAll()
Returns a map of the data sets defined for the custom setting.
getInstance(dataSetName)
Returns the custom setting data set record for the specified data set name. This method returns the exact same object as
getValues(dataSetName).
getValues(dataSetName)
Returns the custom setting data set record for the specified data set name. This method returns the exact same object as
getInstance(dataSetName).

getAll()
Returns a map of the data sets defined for the custom setting.

Signature
public Map<String, CustomSetting__c> getAll()

Return Value
Type: Map<String, CustomSetting__c>

Usage
If no data set is defined, this method returns an empty map.

Note: For Apex saved using Salesforce API version 20.0 or earlier, the data set names, which are the keys in the returned map, are
converted to lower case. For Apex saved using Salesforce API version 21.0 and later, the case of the data set names in the returned
map keys is not changed and the original case is preserved.
getInstance (dataSetName)
Returns the custom setting data set record for the specified data set name. This method returns the exact same object as getValues (dataSetName).

Signature
public CustomSetting__c getInstance(String dataSetName)

Parameters

dataSetName
Type: String

Return Value
Type: CustomSetting__c

Usage
If no data is defined for the specified data set, this method returns null.

getValues (dataSetName)
Returns the custom setting data set record for the specified data set name. This method returns the exact same object as getInstance (dataSetName).

Signature
public CustomSetting__c getValues(String dataSetName)

Parameters

dataSetName
Type: String

Return Value
Type: CustomSetting__c

Usage
If no data is defined for the specified data set, this method returns null.

Hierarchy Custom Setting Methods
The following are instance methods for hierarchy custom settings.
Note:
- In API version 41.0 and below, each method in an Apex test class, including testSetup methods, are able to insert hierarchy custom setting values. This behavior is true even when the methods have the same SetupOwnerId value as a hierarchy custom setting record inserted in a different test method.
- In API version 42.0 and later, if a hierarchy custom setting is inserted in a testSetup method, inserting a hierarchy custom setting record with the same SetupOwnerId in a test method throws a DUPLICATE_VALUE exception.

IN THIS SECTION:

getInstance()
Returns a custom setting data set record for the current user. The fields returned in the custom setting record are merged based on the lowest level fields that are defined in the hierarchy.

getInstance(userId)
Returns the custom setting data set record for the specified user ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the user level.

getInstance(profileId)
Returns the custom setting data set record for the specified profile ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the profile level.

getOrgDefaults()
Returns the custom setting data set record for the organization.

getValues(userId)
Returns the custom setting data set record for the specified user ID.

getValues(profileId)
Returns the custom setting data set for the specified profile ID.

**getInstance()**

Returns a custom setting data set record for the current user. The fields returned in the custom setting record are merged based on the lowest level fields that are defined in the hierarchy.

**Signature**

```
public CustomSetting__c getInstance()
```

**Return Value**

Type: CustomSetting__c

**Usage**

If no custom setting data is defined for the user, this method returns a new custom setting object. The new custom setting object contains an ID set to `null` and merged fields from higher in the hierarchy. You can add this new custom setting record for the user by using `insert` or `upsert`. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the SetupOwnerId field which contains the user ID.
Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the user. Also, if no custom setting data is defined in the hierarchy, this method returns `null`.

This method is equivalent to a method call to `getInstance(User_Id)` for the current user.

Example

- Custom setting data set defined for the user: If you have a custom setting data set defined for the user “Uriel Jones,” for the profile “System Administrator,” and for the organization as a whole, and the user running the code is Uriel Jones, this method returns the custom setting record defined for Uriel Jones.

- Merged fields: If you have a custom setting data set with fields A and B for the user “Uriel Jones” and for the profile “System Administrator,” and field A is defined for Uriel Jones, field B is `null` but is defined for the System Administrator profile, this method returns the custom setting record for Uriel Jones with field A for Uriel Jones and field B from the System Administrator profile.

- No custom setting data set record defined for the user: If the current user is “Barbara Mahonie,” who also shares the “System Administrator” profile, but no data is defined for Barbara as a user, this method returns a new custom setting record with the ID set to `null` and with fields merged based on the fields defined in the lowest level in the hierarchy.

`getInstance(userId)`

Returns the custom setting data set record for the specified user ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the user level.

**Signature**

```java
public CustomSetting__c getInstance(ID userId)
```

**Parameters**

- `userId`
  
  Type: ID

**Return Value**

Type: CustomSetting__c

**Usage**

If no custom setting data is defined for the user, this method returns a new custom setting object. The new custom setting object contains an ID set to `null` and merged fields from higher in the hierarchy. You can add this new custom setting record for the user by using `insert` or `upsert`. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the `SetupOwnerId` field which contains the user ID.

**Note:** For Apex saved using Salesforce API version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the user. Also, if no custom setting data is defined in the hierarchy, this method returns `null`.

`getInstance(profileId)`

Returns the custom setting data set record for the specified profile ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the profile level.
Signature
public CustomSetting__c getInstance(ID profileId)

Parameters
profileId
Type: ID

Return Value
Type: CustomSetting__c

Usage
If no custom setting data is defined for the profile, this method returns a new custom setting record. The new custom setting object contains an ID set to null and with merged fields from your organization's default values. You can add this new custom setting for the profile by using insert or upsert. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the SetupOwnerId field which contains the profile ID.

Note: For Apex saved using SalesforceAPI version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the profile. Also, if no custom setting data is defined in the hierarchy, this method returns null.

getOrgDefaults ()
Returns the custom setting data set record for the organization.

Signature
public CustomSetting__c getOrgDefaults()

Return Value
Type: CustomSetting__c

Usage
If no custom setting data is defined for the organization, this method returns an empty custom setting object.

Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns null if no custom setting data is defined for the organization.

getValues (userId)
Returns the custom setting data set record for the specified user ID.

Signature
public CustomSetting__c getValues(ID userId)
Parameters

userId
Type: ID

Return Value
Type: CustomSetting__c

Usage
Use this if you only want the subset of custom setting data that has been defined at the user level. For example, suppose you have a custom setting field that has been assigned a value of "alpha" at the organizational level, but has no value assigned at the user or profile level. Using getValues (userId) returns null for this custom setting field.

getValues (profileId)
Returns the custom setting data set for the specified profile ID.

Signature
public CustomSetting__c getValues (ID profileId)

Parameters
profileId
Type: ID

Return Value
Type: CustomSetting__c

Usage
Use this if you only want the subset of custom setting data that has been defined at the profile level. For example, suppose you have a custom setting field that has been assigned a value of "alpha" at the organizational level, but has no value assigned at the user or profile level. Using getValues (ProfileId) returns null for this custom setting field.

Database Class
Contains methods for creating and manipulating data.

Namespace
System
Usage

Some Database methods also exist as DML statements.

Apex DML Operations

Database Methods

The following are methods for Database. All methods are static.

IN THIS SECTION:

convertLead(leadToConvert, allOrNone)
Converts a lead into an account and contact, as well as (optionally) an opportunity.

convertLead(leadsToConvert, allOrNone)
Converts a list of LeadConvert objects into accounts and contacts, as well as (optionally) opportunities.

convertLead(leadToConvert, dmlOptions)
Converts a lead into an account and contact, as well as (optionally) an opportunity.

convertLead(leadsToConvert, dmlOptions)
Converts a list of LeadConvert objects into accounts and contacts, as well as (optionally) opportunities.

convertLead(leadToConvert, allOrNone, accessLevel)
Converts a lead into an account and contact, as well as (optionally) an opportunity.

convertLead(leadsToConvert, allOrNone, accessLevel)
Converts a list of LeadConvert objects into accounts and contacts, as well as (optionally) opportunities.

convertLead(leadToConvert, dmlOptions, accessLevel)
Converts a lead into an account and contact, as well as (optionally) an opportunity.

convertLead(leadsToConvert, dmlOptions, accessLevel)
Converts a list of LeadConvert objects into accounts and contacts, as well as (optionally) opportunities.

countQuery(query)
Returns the number of records that a dynamic SOQL query would return when executed.

countQuery(query, accessLevel)
Returns the number of records that a dynamic SOQL query would return when executed.

countQueryWithBinds(query, bindMap, accessLevel)
Returns the number of records that a dynamic SOQL query would return when executed. Bind variables in the query are resolved from the bindMap Map parameter directly with the key, rather than from Apex code variables.

delete(recordToDelete, allOrNone)
Deletes an existing sObject record, such as an individual account or contact, from your organization's data.

delete(recordsToDelete, allOrNone)
Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization's data.

delete(recordID, allOrNone)
Deletes existing sObject records, such as individual accounts or contacts, from your organization's data.
delete(recordIDs, allOrNone)
Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.

delete(recordToDelete, allOrNone, accessLevel)
Deletes an existing sObject record, such as an individual account or contact, from your organization’s data.

delete(recordsToDelete, allOrNone, accessLevel)
Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.

delete(recordID, allOrNone, accessLevel)
Deletes existing sObject records, such as individual accounts or contacts, from your organization’s data.

delete(recordIDs, allOrNone, accessLevel)
Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.

deleteAsync(sobjects, callback)
Initiates requests to delete the external data that corresponds to the specified external object records. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processDelete method is called for each record after deletion.

deleteAsync(sobject, callback)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processDelete method is called after deletion.

deleteAsync(sobjects)
Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

deleteAsync(sobject)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

deleteAsync(sobjects, callback, accessLevel)
Initiates requests to delete the external data that corresponds to the specified external object records. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processDelete method is called for each record after deletion.

deleteAsync(sobject, callback, accessLevel)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processDelete method is called after deletion.

deleteAsync(sobjects, accessLevel)
Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

deleteAsync(sobject, accessLevel)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.
deleteImmediate(sobjects)
Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

deleteImmediate(sobject)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed synchronously and is sent to the external system that's defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

deleteImmediate(sobjects, accessLevel)
Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

deleteImmediate(sobject, accessLevel)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

emptyRecycleBin(recordIds)
Permanently deletes the specified records from the Recycle Bin.

emptyRecycleBin(sObject)
Permanently deletes the specified sObject from the Recycle Bin.

emptyRecycleBin(listOfSObjects)
Permanently deletes the specified sObjects from the Recycle Bin.

executeBatch(batchClassObject)
Submits a batch Apex job for execution corresponding to the specified class.

executeBatch(batchClassObject, scope)
Submits a batch Apex job for execution using the specified class and scope.

getAsyncDeleteResult(deleteResult)
Retrieves the status of an asynchronous delete operation that’s identified by a Database.DeleteResult object.

getAsyncDeleteResult(asyncLocator)
Retrieves the result of an asynchronous delete operation based on the result’s unique identifier.

getAsyncLocator(result)
Returns the asyncLocator associated with the result of a specified asynchronous insert, update, or delete operation.

getAsyncSaveResult(saveResult)
Returns the status of an asynchronous insert or update operation that’s identified by a Database.SaveResult object.

getAsyncSaveResult(asyncLocator)
Returns the status of an asynchronous insert or update operation based on the unique identifier associated with each modification.

getDeleted(sObjectType, startDate, endDate)
Returns the list of individual records that have been deleted for an sObject type within the specified start and end dates and times and that are still in the Recycle Bin.

getQueryLocator(listOfQueries)
Creates a QueryLocator object used in batch Apex or Visualforce.
**getQueryLocator(query)**
Creates a QueryLocator object used in batch Apex or Visualforce.

**getQueryLocator(listOfQueries, accessLevel)**
Creates a QueryLocator object used in batch Apex or Visualforce.

**getQueryLocator(query, accessLevel)**
Creates a QueryLocator object used in batch Apex or Visualforce.

**getQueryLocatorWithBinds(query, bindMap, accessLevel)**
Creates a QueryLocator object used in batch Apex or Visualforce. Bind variables in the query are resolved from the bindMap Map parameter directly with the key, rather than from Apex code variables.

**getUpdated(sobjectType, startDate, endDate)**
Returns the list of individual records that have been updated for an sObject type within the specified start and end dates and times.

**insert(recordToInsert, allOrNone)**
Adds an sObject, such as an individual account or contact, to your organization's data.

**insert(recordsToInsert, allOrNone)**
Adds one or more sObjects, such as individual accounts or contacts, to your organization's data.

**insert(recordToInsert, dmlOptions)**
Adds an sObject, such as an individual account or contact, to your organization's data.

**insert(recordsToInsert, dmlOptions)**
Adds one or more sObjects, such as individual accounts or contacts, to your organization's data.

**insert(recordToInsert, allOrNone, accessLevel)**
Adds an sObject, such as an individual account or contact, to your organization's data.

**insert(recordsToInsert, allOrNone, accessLevel)**
Adds one or more sObjects, such as individual accounts or contacts, to your organization's data.

**insert(recordToInsert, dmlOptions, accessLevel)**
Adds an sObject, such as an individual account or contact, to your organization's data.

**insert(recordsToInsert, dmlOptions, accessLevel)**
Adds one or more sObjects, such as individual accounts or contacts, to your organization's data.

**insertAsync(sobjects, callback)**
Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources. Allows referencing a callback class whose processSave method is called for each record after the remote operations are completed.

**insertAsync(sobject, callback)**
Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose processSave method is called after the remote operation is completed.

**insertAsync(sobjects)**
Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.

**insertAsync(sobject)**
Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.
insertAsync(sobjects, callback, accessLevel)
Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources. Allows referencing a callback class whose processSave method is called for each record after the remote operations are completed.

insertAsync(object, callback, accessLevel)
Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose processSave method is called after the remote operation is completed.

insertAsync(sobjects, accessLevel)
Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.

insertAsync(object, accessLevel)
Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.

insertImmediate(sobjects)
Initiates requests to add external object data to the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can't be completed and throw exceptions.

insertImmediate(object)
Initiates a request to add external object data to the relevant external system. The request is executed synchronously and is sent to the external system that's defined by the external object's associated external data source. If the Apex transaction contains pending changes, the synchronous operation can't be completed and throws an exception.

insertImmediate(sobjects, accessLevel)
Initiates requests to add external object data to the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can't be completed and throw exceptions.

insertImmediate(object, accessLevel)
Initiates a request to add external object data to the relevant external system. The request is executed synchronously and is sent to the external system that's defined by the external object's associated external data source. If the Apex transaction contains pending changes, the synchronous operation can't be completed and throws an exception.

merge(masterRecord, duplicateId)
Merges the specified duplicate record into the master sObject record of the same type, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

merge(masterRecord, duplicateRecord)
Merges the specified duplicate sObject record into the master sObject of the same type, deleting the duplicate, and reparenting any related records.

merge(masterRecord, duplicateIds)
Merges up to two records of the same sObject type into the master sObject record, deleting the others, and reparenting any related records.

merge(masterRecord, duplicateRecords)
Merges up to two records of the same object type into the master sObject record, deleting the others, and reparenting any related records.
merge(masterRecord, duplicateId, allOrNone)
Merges the specified duplicate record into the master sObject record of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

merge(masterRecord, duplicateRecord, allOrNone)
Merges the specified duplicate sObject record into the master sObject of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records.

merge(masterRecord, duplicateIds, allOrNone)
Merges up to two records of the same sObject type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

merge(masterRecord, duplicateRecords, allOrNone)
Merges up to two records of the same object type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

merge(masterRecord, duplicateId, accessLevel)
Merges the specified duplicate record into the master sObject record of the same type, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

merge(masterRecord, duplicateRecord, accessLevel)
Merges the specified duplicate sObject record into the master sObject of the same type, deleting the duplicate, and reparenting any related records.

merge(masterRecord, duplicateIds, accessLevel)
Merges up to two records of the same sObject type into the master sObject record, deleting the others, and reparenting any related records.

merge(masterRecord, duplicateRecords, accessLevel)
Merges up to two records of the same object type into the master sObject record, deleting the others, and reparenting any related records.

merge(masterRecord, duplicateId, allOrNone, accessLevel)
Merges the specified duplicate record into the master sObject record of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

merge(masterRecord, duplicateRecord, allOrNone, accessLevel)
Merges the specified duplicate sObject record into the master sObject of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records.

merge(masterRecord, duplicateIds, allOrNone, accessLevel)
Merges up to two records of the same sObject type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

merge(masterRecord, duplicateRecords, allOrNone, accessLevel)
Merges up to two records of the same object type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

query(queryString)
Creates a dynamic SOQL query at runtime.

query(queryString, accessLevel)
Creates a dynamic SOQL query at runtime.

queryWithBinds(queryString, bindMap, accessLevel)
Creates a dynamic SOQL query at runtime. Bind variables in the query are resolved from the $bindMap Map parameter directly with the key, rather than from Apex code variables.
**rollback(databaseSavepoint)**
Restores the database to the state specified by the savepoint variable. Any emails submitted since the last savepoint are also rolled back and not sent.

**setSavepoint()**
Returns a savepoint variable that can be stored as a local variable, then used with the `rollback` method to restore the database to that point.

**undelete(recordToUndelete, allOrNone)**
Restores an existing sObject record, such as an individual account or contact, from your organization's Recycle Bin.

**undelete(recordsToUndelete, allOrNone)**
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization's Recycle Bin.

**undelete(recordID, allOrNone)**
Restores an existing sObject record, such as an individual account or contact, from your organization's Recycle Bin.

**undelete(recordIDs, allOrNone)**
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization's Recycle Bin.

**undelete(recordToUndelete, allOrNone, accessLevel)**
Restores an existing sObject record, such as an individual account or contact, from your organization's Recycle Bin.

**undelete(recordsToUndelete, allOrNone, accessLevel)**
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization's Recycle Bin.

**undelete(recordID, allOrNone, accessLevel)**
Restores an existing sObject record, such as an individual account or contact, from your organization's Recycle Bin.

**undelete(recordIDs, allOrNone, accessLevel)**
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization's Recycle Bin.

**update(recordToUpdate, allOrNone)**
Modifies an existing sObject record, such as an individual account or contact, in your organization's data.

**update(recordsToUpdate, allOrNone)**
Modifies one or more existing sObject records, such as individual accounts or contacts, in your organization's data.

**update(recordToUpdate, dmlOptions)**
Modifies an existing sObject record, such as an individual account or contact, in your organization's data.

**update(recordsToUpdate, dmlOptions)**
Modifies one or more existing sObject records, such as individual accounts or contacts, in your organization's data.

**update(recordToUpdate, allOrNone, accessLevel)**
Modifies an existing sObject record, such as an individual account or contact, in your organization's data.

**update(recordsToUpdate, allOrNone, accessLevel)**
Modifies one or more existing sObject records, such as individual accounts or contacts, in your organization's data.

**update(recordToUpdate, dmlOptions, accessLevel)**
Modifies an existing sObject record, such as an individual account or contact, in your organization's data.

**update(recordsToUpdate, dmlOptions, accessLevel)**
Modifies one or more existing sObject records, such as individual accounts or contacts, in your organization's data.

**upsert(recordToUpsert, externalIdField, allOrNone)**
Creates a new sObject record or updates an existing sObject record within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.
upsert(recordsToUpsert, externalIdField, allOrNone)
Creates new sObject records or updates existing sObject records within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

upsert(recordToUpsert, externalIdField, allOrNone, accessLevel)
Creates a new sObject record or updates an existing sObject record within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

upsert(recordsToUpsert, externalIdField, allOrNone, accessLevel)
Creates new sObject records or updates existing sObject records within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

updateAsync(sobjects, callback)
Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose processSave method is called for each record after the remote operations are completed.

updateAsync(sobject, callback)
Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processSave method is called after the remote operation is completed.

updateAsync(sobjects)
Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

updateAsync(sobject)
Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

updateAsync(sobjects, callback, accessLevel)
Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose processSave method is called for each record after the remote operations are completed.

updateAsync(sobject, callback, accessLevel)
Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processSave method is called after the remote operation is completed.

updateAsync(sobjects, accessLevel)
Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

updateAsync(sobject, accessLevel)
Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

updateImmediate(sobjects)
Initiates requests to update external object data on the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.
updateImmediate(sobject)
Initiates a request to update external object data on the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

updateImmediate(sobjects, accessLevel)
Initiates requests to update external object data on the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

updateImmediate(sobject, accessLevel)
Initiates a request to update external object data on the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

convertLead(leadToConvert, allOrNone)
Converts a lead into an account and contact, as well as (optionally) an opportunity.

Signature
public static Database.LeadConvertResult convertLead(Database.LeadConvert leadToConvert, Boolean allOrNone)

Parameters
leadToConvert
Type: Database.LeadConvert

callOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value
Type: Database.LeadConvertResult

Usage
The convertLead method accepts up to 100 LeadConvert objects.
Each executed convertLead method counts against the governor limit for DML statements.

convertLead(leadsToConvert, allOrNone)
Converts a list of LeadConvert objects into accounts and contacts, as well as (optionally) opportunities.
Signature

public static Database.LeadConvertResult[] convertLead(Database.LeadConvert[] leadsToConvert, Boolean allOrNone)

Parameters

leadsToConvert
Type: Database.LeadConvert[]

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value

Type: Database.LeadConvertResult[]

Usage

The convertLead method accepts up to 100 LeadConvert objects. Each executed convertLead method counts against the governor limit for DML statements.

convertLead(leadToConvert, dmlOptions)

Converts a lead into an account and contact, as well as (optionally) an opportunity.

Signature

public static Database.LeadConvertResult convertLead(Database.LeadConvert leadToConvert, Database.DMLOptions dmlOptions)

Parameters

leadToConvert
Type: Database.LeadConvert

dmlOptions
Type: Database.DMLOptions

The optional dmlOptions parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value

Type: Database.LeadConvertResult
Usage

The `convertLead` method accepts up to 100 `LeadConvert` objects. Each executed `convertLead` method counts against the governor limit for DML statements.

`convertLead(leadToConvert, allOrNone, accessLevel)`

Converts a lead into an account and contact, as well as (optionally) an opportunity.

Signature

```
public static Database.LeadConvertResult convertLead(Database.LeadConvert leadToConvert,
                                                      Boolean allOrNone, System.AccessLevel accessLevel)
```

Parameters

`leadToConvert`
- Type: `Database.LeadConvert`

`allOrNone`
- Type: `Boolean`

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to
verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

accessLevel
Type: System.AccessLevel
(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: Database.LeadConvertResult

Usage
The convertLead method accepts up to 100 LeadConvert objects. Each executed convertLead method counts against the governor limit for DML statements.

convertLead(leadstoConvert, allOrNone, accessLevel)
Converts a list of LeadConvert objects into accounts and contacts, as well as (optionally) opportunities.

Signature
public static List<Database.LeadConvertResult> convertLead(List<Database.LeadConvert> leadstoConvert, Boolean allOrNone, System.AccessLevel accessLevel)

Parameters
leadstoConvert
Type: List<Database.LeadConvert>
allOrNone
Type: Boolean
The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

accessLevel
Type: System.AccessLevel
(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: List<Database.LeadConvertResult>
**Usage**

The `convertLead` method accepts up to 100 `LeadConvert` objects. Each executed `convertLead` method counts against the governor limit for DML statements.

\[
\text{convertLead(leadToConvert, dmlOptions, accessLevel)}
\]

Converts a lead into an account and contact, as well as (optionally) an opportunity.

**Signature**

```
public static Database.LeadConvertResult convertLead(Database.LeadConvert leadToConvert, 
                                                  Database.DMLOptions dmlOptions, System.AccessLevel accessLevel)
```

**Parameters**

- **leadToConvert**
  - Type: `Database.LeadConvert`

- **dmlOptions**
  - Type: `Database.DMLOptions`
    - The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

- **accessLevel**
  - Type: `System.AccessLevel`
    - (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**

Type: `Database.LeadConvertResult`

**Usage**

The `convertLead` method accepts up to 100 `LeadConvert` objects. Each executed `convertLead` method counts against the governor limit for DML statements.

\[
\text{convertLead(leadsToConvert, dmlOptions, accessLevel)}
\]

Converts a list of `LeadConvert` objects into accounts and contacts, as well as (optionally) opportunities.

**Signature**

```
public static List<Database.LeadConvertResult> convertLead(List<Database.LeadConvert> 
                            leadsToConvert, Database.DMLOptions dmlOptions, System.AccessLevel accessLevel)
```
Parameters

`leadsToConvert`
Type: List<Database.LeadConvert>

`dmlOptions`
Type: Database.DMLOptions

The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

`accessLevel`
Type: System.AccessLevel

(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: List<Database.LeadConvertResult>

Usage

The `convertLead` method accepts up to 100 `LeadConvert` objects.

Each executed `convertLead` method counts against the governor limit for DML statements.

`countQuery(query)`

Returns the number of records that a dynamic SOQL query would return when executed.

Signature

`public static Integer countQuery(String query)`

Parameters

`query`
Type: String

Return Value
Type: Integer

Usage

For more information, see Dynamic SOQL.

Each executed `countQuery` method counts against the governor limit for SOQL queries.
Example

```java
String queryString = 'SELECT count() FROM Account';
Integer i = Database.countQuery(queryString);
```

countQuery(query, accessLevel)

Returns the number of records that a dynamic SOQL query would return when executed.

Signature

```java
public static Integer countQuery(String query, System.AccessLevel accessLevel)
```

Parameters

- `query`
  - Type: `String`
- `accessLevel`
  - Type: `System.AccessLevel`

  (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value

- Type: `Integer`

Usage

For more information, see Dynamic SOQL.

Each executed `countQuery` method counts against the governor limit for SOQL queries.

countQueryWithBinds(query, bindMap, accessLevel)

Returns the number of records that a dynamic SOQL query would return when executed. Bind variables in the query are resolved from the `bindMap` Map parameter directly with the key, rather than from Apex code variables.

Signature

```java
public static Integer countQueryWithBinds(String query, Map<String, Object> bindMap, System.AccessLevel accessLevel)
```

Parameters

- `query`
  - Type: `String`
SOQL query that includes Apex bind variables preceded by a colon. All bind variables must have a key in the `bindMap` Map.

`bindMap`
Type: `Map<String, Object>`
A map that contains keys for each bind variable specified in the SOQL `queryString` and its value. The keys can’t be null or duplicates, and the values can’t be null or empty strings.

`accessLevel`
Type: `System.AccessLevel`
The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced.

**Return Value**
Type: `Integer`

**Usage**
For more information, see Dynamic SOQL.
Each executed `countQueryWithBinds` method counts against the governor limit for SOQL queries.

**Example**
In this example, the SOQL query uses a bind variable for an Account name. Its value (`Acme Inc.`) is passed in to the method using the `nameBind` Map. The `accountName` variable isn’t (and doesn’t have to be) in scope when the query is executed within the method.

```java
public static Integer simpleBindingSoqlQuery(Map<String, Object> bindParams) {
    String queryString =
        'SELECT count() ' +
        'FROM Account ' +
        'WHERE name = :name';
    return Database.countQueryWithBinds(
        queryString,
        bindParams,
        AccessLevel.USER_MODE
    );
}

String accountName = 'Acme Inc.';
Map<String, Object> nameBind = new Map<String, Object>('name' => accountName);
Integer acctCount = simpleBindingSoqlQuery(nameBind);
System.debug(acctCount);
```

`delete(recordToDelete, allOrNone)`
Deletes an existing sObject record, such as an individual account or contact, from your organization’s data.
public static Database.DeleteResult delete(SObject recordToDelete, Boolean allOrNone)

Parameters

recordToDelete
Type: sObject

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value

Type: Database.DeleteResult

Usage

delete is analogous to the delete() statement in the SOAP API.

Each executed delete method counts against the governor limit for DML statements.

delete(recordsToDelete, allOrNone)

Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.

Signature

public static Database.DeleteResult[] delete(SObject[] recordsToDelete, Boolean allOrNone)

Parameters

recordsToDelete
Type: sObject[]

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value

Type: Database.DeleteResult[]
Usage

delete is analogous to the delete() statement in the SOAP API.
Each executed delete method counts against the governor limit for DML statements.

Example

The following example deletes an account named 'DotCom':

```java
Account[] doomedAccts = [SELECT Id, Name FROM Account WHERE Name = 'DotCom'];
Database.DeleteResult[] DR_Dels = Database.delete(doomedAccts);
```

delete(recordID, allOrNone)

Deletes existing sObject records, such as individual accounts or contacts, from your organization's data.

Signature

```java
public static Database.DeleteResult delete(ID recordID, Boolean allOrNone)
```

Parameters

- **recordID**
  - Type: ID
- **allOrNone**
  - Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value

Type: Database.DeleteResult

Usage

delete is analogous to the delete() statement in the SOAP API.
Each executed delete method counts against the governor limit for DML statements.

delete(recordIDs, allOrNone)

Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization's data.

Signature

```java
public static Database.DeleteResult[] delete(ID[] recordIDs, Boolean allOrNone)
```
Parameters

recordIDs
  Type: ID[]

allOrNone
  Type: Boolean

  The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value

Type: Database.DeleteResult[]

Usage

delete is analogous to the delete() statement in the SOAP API.

Each executed delete method counts against the governor limit for DML statements.

delete(recordToDelete, allOrNone, accessLevel)

Deletes an existing sObject record, such as an individual account or contact, from your organization’s data.

Signature

public static Database.DeleteResult delete(SObject recordToDelete, Boolean allOrNone, System.AccessLevel accessLevel)

Parameters

recordToDelete
  Type: SObject

allOrNone
  Type: Boolean

  The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

accessLevel
  Type: System.AccessLevel

  (Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.
Return Value
Type: Database.DeleteResult

Usage
delete is analogous to the delete() statement in the SOAP API.
Each executed delete method counts against the governor limit for DML statements.

delete(recordsToDelete, allOrNone, accessLevel)
Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.

Signature
public static List<Database.DeleteResult> delete(List<SObject> recordsToDelete, Boolean allOrNone, System.AccessLevel accessLevel)

Parameters
recordsToDelete
Type: List<sObject>

allOrNone
Type: Boolean
The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

accessLevel
Type: System.AccessLevel
(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: List<Database.DeleteResult>

Usage
delete is analogous to the delete() statement in the SOAP API.
Each executed delete method counts against the governor limit for DML statements.

delete(recordID, allOrNone, accessLevel)
Deletes existing sObject records, such as individual accounts or contacts, from your organization’s data.
public static Database.DeleteResult delete(Id recordID, Boolean allOrNone, System.AccessLevel accessLevel)

Parameters

recordID
Type: ID

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

accessLevel
Type: System.AccessLevel

(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value

Type: Database.DeleteResult

Usage

delete is analogous to the delete() statement in the SOAP API.

Each executed delete method counts against the governor limit for DML statements.

delete(recordIDs, allOrNone, accessLevel)

Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.

public static List<Database.DeleteResult> delete(List<Id> recordIDs, Boolean allOrNone, System.AccessLevel accessLevel)

Parameters

recordIDs
Type: List<Id>

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to
verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

accessLevel
Type: System.AccessLevel

(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: List<Database.DeleteResult>

Usage
delete is analogous to the delete() statement in the SOAP API.
Each executed delete method counts against the governor limit for DML statements.

deleteAsync(sobjects, callback)
_Initiates requests to delete the external data that corresponds to the specified external object records. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processDelete method is called for each record after deletion._

Signature

public static List<Database.DeleteResult> deleteAsync(List<SObject> sobjects, DataSource.AsyncDeleteCallback callback)

Parameters

sobjects
Type: List<SObject>
List of external object records to delete.

callback
Type: DataSource.AsyncDeleteCallback
The callback that contains the state in the originating context and an action (the processDelete method) that is executed after the insert operation is completed. Use the action callback to update org data according to the operation’s results. The callback object must extend DataSource.AsyncDeleteCallback.

Return Value
Type: List<Database.DeleteResult>
Status results for the delete operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncDeleteResult().
**deleteAsync(sobject, callback)**

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose `processDelete` method is called after deletion.

**Signature**

```java
public static Database.DeleteResult deleteAsync(SObject sobject, DataSource.AsyncDeleteCallback callback)
```

**Parameters**

- **sobject**
  - Type: `SObject`
  - The external object record to delete.

- **callback**
  - Type: `DataSource.AsyncDeleteCallback`
  - The callback that contains the state in the originating context and an action (the `processDelete` method) that is executed after the insert operation is completed. Use the action callback to update org data according to the operation’s results. The callback object must extend `DataSource.AsyncDeleteCallback`.

**Return Value**

Type: `Database.DeleteResult`

Status result for the delete operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncDeleteResult()`.

**deleteAsync(sobjects)**

Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

**Signature**

```java
public static List<Database.DeleteResult> deleteAsync(List<SObject> sobjects)
```

**Parameters**

- **sobjects**
  - Type: `List<SObject>`
  - List of external object records to delete.

**Return Value**

Type: `List<Database.DeleteResult>`
Status results for the delete operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncDeleteResult()`.

**deleteAsync(sobject)**

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.

**Signature**

```java
public static Database.DeleteResult deleteAsync(SObject sobject)
```

**Parameters**

`sobject`

Type: `SObject`

The external object record to delete.

**Return Value**

Type: `Database.DeleteResult`

Status result for the delete operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncDeleteResult()`.

**deleteAsync(sobjects, callback, accessLevel)**

Initiates requests to delete the external data that corresponds to the specified external object records. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processDelete` method is called for each record after deletion.

**Signature**

```java
public static List<Database.DeleteResult> deleteAsync(List<SObject> sobjects,
Data Source.AsyncDeleteCallback callback, System.AccessLevel accessLevel)
```

**Parameters**

`sobjects`

Type: `List<SObject>`

List of external object records to delete.

`callback`

Type: `DataSource.AsyncDeleteCallback`

The callback that contains the state in the originating context and an action (the `processDelete` method) that is executed after the insert operation is completed. The execution is in system mode regardless of the `accessLevel` parameter. Use the
action callback to update org data according to the operation's results. The callback object must extend
`DataSource.AsyncDeleteCallback`.

**accessLevel**
Type: `System.AccessLevel`

(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**
Type: `List<Database.DeleteResult>`

Status results for the delete operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncDeleteResult()`.

**deleteAsync(sobject, callback, accessLevel)**

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processDelete` method is called after deletion.

**Signature**

```java
public static Database.DeleteResult deleteAsync(SObject sobject, DataSource.AsyncDeleteCallback callback, System.AccessLevel accessLevel)
```

**Parameters**

- **sobject**
  Type: `SObject`
  The external object record to delete.

- **callback**
  Type: `DataSource.AsyncDeleteCallback`
  The callback that contains the state in the originating context and an action (the `processDelete` method) that is executed after the insert operation is completed. The execution is in system mode regardless of the `accessLevel` parameter. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncDeleteCallback`.

- **accessLevel**
  Type: `System.AccessLevel`

  (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.
Return Value
Type: Database.DeleteResult
Status result for the delete operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncDeleteResult().

deleteAsync(sobjects, accessLevel)
Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

Signature
public static List<Database.DeleteResult> deleteAsync(List<SObject> sobjects, System.AccessLevel accessLevel)

Parameters
sobjects
Type: List<SObject>
List of external object records to delete.
accessLevel
Type: System.AccessLevel
(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: List<Database.DeleteResult>
Status results for the delete operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncDeleteResult().

deleteAsync(object, accessLevel)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

Signature
public static Database.DeleteResult deleteAsync(SObject object, System.AccessLevel accessLevel)
Parameters

`sobject`
Type: `SObject`
The external object record to delete.

`accessLevel`
Type: `System.AccessLevel`
(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value

Type: `Database.DeleteResult`
Status result for the delete operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncDeleteResult()`.

deleteImmediate(sobjects)

Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

Signature

`public static List<Database.DeleteResult> deleteImmediate(List<SObject> sobjects)`

Parameters

`sobjects`
Type: `List<SObject>`
List of external object records to delete.

Return Value

Type: `List<Database.DeleteResult>`
Status results for the delete operation.

Usage

The batch limit for big objects using `deleteImmediate()` is 50,000 records at once.

deleteImmediate(object)

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.
Signature

public static Database.DeleteResult deleteImmediate(SObject sobject)

Parameters

sobject
Type: SObject
The external object record to delete.

Return Value

Type: Database.DeleteResult
Status result for the delete operation.

databaseImmediate(sobjects, accessLevel)

Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can't be completed and throw exceptions.

Signature

public static List<Database.DeleteResult> deleteImmediate(List<SObject> sobjects, System.AccessLevel accessLevel)

Parameters

sobjects
Type: List<SObject>
List of external object records to delete.

accessLevel
Type: System.AccessLevel
(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value

Type: List<Database.DeleteResult>
Status results for the delete operation.

Usage

The batch limit for big objects using deleteImmediate() is 50,000 records at once.
**deleteImmediate(sobject, accessLevel)**

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

**Signature**

```
public static Database.DeleteResult deleteImmediate(SObject sobject, System.AccessLevel accessLevel)
```

**Parameters**

- **sobject**
  - Type: SObject
  - The external object record to delete.

- **accessLevel**
  - Type: System.AccessLevel
  - (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**

- Type: Database.DeleteResult
  - Status result for the delete operation.

**emptyRecycleBin(recordIds)**

Permanently deletes the specified records from the Recycle Bin.

**Signature**

```
public static Database.EmptyRecycleBinResult[] emptyRecycleBin(ID [] recordIds)
```

**Parameters**

- **recordIds**
  - Type: ID[]

**Return Value**

- Type: Database.EmptyRecycleBinResult[]

**Usage**

Note the following:

- After records are deleted using this method, they cannot be undeleted.
Empty Recycle Bin (obj)

Permanently deletes the specified sObject from the Recycle Bin.

Signature

public static Database.EmptyRecycleBinResult emptyRecycleBin(sObject obj)

Parameters

obj
Type: sObject

Return Value

Type: Database.EmptyRecycleBinResult

Usage

Note the following:

- After an sObject is deleted using this method, it cannot be undeleted.
- Only 10,000 sObjects can be specified for deletion.
- The logged-in user can delete any sObject (that can be queried) in their Recycle Bin, or the recycle bins of any subordinates. If the logged-in user has “Modify All Data” permission, they can query and delete sObjects from any Recycle Bin in the organization.
- Do not include an sObject that was deleted due to a cascade delete; otherwise an error occurs. For example, if an account is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include sObjects of the top-level account. All related sObjects are automatically removed.

Empty Recycle Bin (listOfSObjects)

Permanently deletes the specified sObjects from the Recycle Bin.

Signature

public static Database.EmptyRecycleBinResult[] emptyRecycleBin(sObject[] listOfSObjects)

Parameters

listOfSObjects
Type: sObject[]
Return Value
Type: Database.EmptyRecycleBinResult[]

Usage
Note the following:
• After an sObject is deleted using this method, it cannot be undeleted.
• Only 10,000 sObjects can be specified for deletion.
• The logged-in user can delete any sObject (that can be queried) in their Recycle Bin, or the recycle bins of any subordinates. If the logged-in user has “Modify All Data” permission, they can query and delete sObjects from any Recycle Bin in the organization.
• Do not include an sObject that was deleted due to a cascade delete; otherwise an error occurs. For example, if an account is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include sObjects of the top-level account. All related sObjects are automatically removed.

executeBatch (batchClassObject)
Submits a batch Apex job for execution corresponding to the specified class.

Signature
public static ID executeBatch(Object batchClassObject)

Parameters
batchClassObject
Type: Object
An instance of a class that implements the Database.Batchable interface.

Return Value
Type: ID
The ID of the new batch job (AsyncApexJob).

Usage
When calling this method, Salesforce chunks the records returned by the start method of the batch class into batches of 200, and then passes each batch to the execute method. Apex governor limits are reset for each execution of execute.
For more information, see Using Batch Apex.

Versioned Behavior Changes
If the executeBatch call fails to acquire an Apex flex queue lock:
• In API version 52.0 and later, the call throws a System.AsyncException.
• In API version 51.0 and earlier, the call returns an empty ID, “000000000000000”, instead of throwing an exception.
**executeBatch(batchClassObject, scope)**
Submits a batch Apex job for execution using the specified class and scope.

**Signature**
```
public static ID executeBatch(Object batchClassObject, Integer scope)
```

**Parameters**
- **batchClassObject**
  - Type: Object
  - An instance of a class that implements the Database.Batchable interface.
- **scope**
  - Type: Integer
  - Number of records to be passed into the execute method for batch processing.

**Return Value**
- Type: ID
- The ID of the new batch job (AsyncApexJob).

**Usage**
The value for `scope` must be greater than 0.

If the `start` method of the batch class returns a `Database.QueryLocator`, the scope parameter of `Database.executeBatch` can have a maximum value of 2,000. If set to a higher value, Salesforce chunks the records returned by the `QueryLocator` into smaller batches of up to 200 records. If the `start` method of the batch class returns an iterable, the scope parameter value has no upper limit; however, if you use a very high number, you could run into other limits.

Apex governor limits are reset for each execution of `execute`.

For more information, see Using Batch Apex.

**Versioned Behavior Changes**
If the `executeBatch` call fails to acquire an Apex flex queue lock:
- In API version 52.0 and later, the call throws a `System.AsyncException`.
- In API version 51.0 and earlier, the call returns an empty ID, "000000000000000", instead of throwing an exception.

**getAsyncDeleteResult(deleteResult)**
Retrieves the status of an asynchronous delete operation that’s identified by a `Database.DeleteResult` object.

**Signature**
```
public static Database.DeleteResult getAsyncDeleteResult(Database.DeleteResult deleteResult)
```
Parameters

deleteResult
   Type: Database.DeleteResult
   The result record for the delete operation being retrieved.

Return Value

Type: Database.DeleteResult
The result of a completed asynchronous delete of a record or records.

getAsyncDeleteResult(asyncLocator)

Retrieves the result of an asynchronous delete operation based on the result’s unique identifier.

Signature

public static Database.DeleteResult getAsyncDeleteResult(String asyncLocator)

Parameters

asyncLocator
   Type: String
   The unique identifier associated with the result of an asynchronous operation.

Return Value

Type: Database.DeleteResult
The result of a completed asynchronous delete of a record or records.

getAsyncLocator(result)

Returns the asyncLocator associated with the result of a specified asynchronous insert, update, or delete operation.

Signature

public static String getAsyncLocator(Object result)

Parameters

result
   Type: Object
   The saved result of an asynchronous insert, update, or delete operation. The result object can be of type Database.SaveResult or Database.DeleteResult.

Return Value

Type: String
The unique identifier associated with the result of the specified operation.
getAsyncSaveResult (saveResult)
Returns the status of an asynchronous insert or update operation that’s identified by a Database.SaveResult object.

Signature
public static Database.SaveResult getAsyncSaveResult(Database.SaveResult saveResult)

Parameters
saveResult
Type: Database.SaveResult
The result record for the insert or update operation being retrieved.

Return Value
Database.SaveResult
The result of a completed asynchronous operation on a record or records.

getAsyncSaveResult (asyncLocator)
Returns the status of an asynchronous insert or update operation based on the unique identifier associated with each modification.

Signature
public static Database.SaveResult getAsyncSaveResult(String asyncLocator)

Parameters
asyncLocator
Type: String
The unique identifier associated with the result of an asynchronous operation.

Return Value
Database.SaveResult
The result of a completed asynchronous operation on a record or records.

getDeleted(sObjectType, startDate, endDate)
Returns the list of individual records that have been deleted for an sObject type within the specified start and end dates and times and that are still in the Recycle Bin.

Signature
public static Database.GetDeletedResult getDeleted(String sObjectType, Datetime startDate, Datetime endDate)
Parameters

sObjectType
Type: String
The sObjectType argument is the sObject type name for which to get the deleted records, such as account or merchandise__c.

startDate
Type: Datetime
Start date and time of the deleted records time window.

endDate
Type: Datetime
End date and time of the deleted records time window.

Return Value
Type: Database.GetDeletedResult

Usage
Because the Recycle Bin holds records up to 15 days, results are returned for no more than 15 days previous to the day the call is executed (or earlier if an administrator has purged the Recycle Bin).

Example
```
Database.GetDeletedResult r =
    Database.getDeleted(
        'Merchandise__c',
        Datetime.now().addHours(-1),
        Datetime.now());
```

getQueryLocator(listOfQueries)
Creates a QueryLocator object used in batch Apex or Visualforce.

Signature
```
public static Database.QueryLocator getQueryLocator(sObject [] listOfQueries)
```

Parameters

listOfQueries
Type: sObject []

Return Value
Type: Database.QueryLocator

Usage
You can't use getQueryLocator with any query that contains an aggregate function.
Each executed `getQueryLocator` method counts against the governor limit of 10,000 total records retrieved and the total number of SOQL queries issued.

For more information, see Understanding Apex Managed Sharing, and `IdeaStandardSetController` Class.

**getQueryLocator**(query)

Creates a QueryLocator object used in batch Apex or Visualforce.

**Signature**

```java
public static Database.QueryLocator getQueryLocator(String query)
```

**Parameters**

- **query**
  - Type: String

**Return Value**

Type: Database.QueryLocator

**Usage**

You can’t use `getQueryLocator` with any query that contains an aggregate function.

Each executed `getQueryLocator` method counts against the governor limit of 10,000 total records retrieved and the total number of SOQL queries issued.

For more information, see Understanding Apex Managed Sharing, and `StandardSetController` Class.

**getQueryLocator**(listOfQueries, accessLevel)

Creates a QueryLocator object used in batch Apex or Visualforce.

**Signature**

```java
public static Database.QueryLocator getQueryLocator(sObject [] listofQueries, System.AccessLevel accessLevel)
```

**Parameters**

- **listOfQueries**
  - Type: sObject []

- **accessLevel**
  - Type: System.AccessLevel

(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.
Return Value
Type: Database.QueryLocator

Usage
The access level is evaluated only when the QueryLocator is created. A QueryLocator can be long lived, such as when used in a batch. We don’t reevaluate the object and field-level security with each iteration of the QueryLocator. As a result, if you specify user mode, and then change the security settings after the QueryLocator is created, the new settings aren’t enforced.

You can’t use getQueryLocator with any query that contains an aggregate function.

Each executed getQueryLocator method counts against the governor limit of 10,000 total records retrieved and the total number of SOQL queries issued.

For more information, see Understanding Apex Managed Sharing, and IdeaStandardSetController Class.

ggetQueryLocator(query, accessLevel)
Creates a QueryLocator object used in batch Apex or Visualforce.

Signature
public static Database.QueryLocator getQueryLocator(String query, System.AccessLevel accessLevel)

Parameters
query
  Type: String
accessLevel
  Type: System.AccessLevel
    (Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: Database.QueryLocator

Usage
The access level is evaluated only when the QueryLocator is created. A QueryLocator can be long lived, such as when used in a batch. We don’t reevaluate the object and field-level security with each iteration of the QueryLocator. As a result, if you specify user mode, and then change the security settings after the QueryLocator is created, the new settings aren’t enforced.

You can’t use getQueryLocator with any query that contains an aggregate function.

Each executed getQueryLocator method counts against the governor limit of 10,000 total records retrieved and the total number of SOQL queries issued.

For more information, see Understanding Apex Managed Sharing, and StandardSetController Class.
**getQueryLocatorWithBinds** *(query, bindMap, accessLevel)*

Creates a QueryLocator object used in batch Apex or Visualforce. Bind variables in the query are resolved from the bindMap Map parameter directly with the key, rather than from Apex code variables.

**Signature**

```java
public static Database.QueryLocator getQueryLocatorWithBinds(String query, Map<String, Object> bindMap, System.AccessLevel accessLevel)
```

**Parameters**

- **query**
  - Type: **String**
  - SOQL query that includes Apex bind variables preceded by a colon. All bind variables must have a key in the bindMap Map.

- **bindMap**
  - Type: **Map<String, Object>**
  - A map that contains keys for each bind variable specified in the SOQL queryString and its value. The keys can’t be null or duplicates, and the values can’t be null or empty strings.

- **accessLevel**
  - Type: **System.AccessLevel**
  - The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced.

**Return Value**

- Type: **Database.QueryLocator**

**Usage**

The access level is evaluated only when the QueryLocator is created. A QueryLocator can be long lived, such as when used in a batch. We don’t reevaluate the object and field-level security with each iteration of the QueryLocator. As a result, if you specify user mode, and then change the security settings after the QueryLocator is created, the new settings aren’t enforced.

You can’t use `getQueryLocatorWithBinds` with any query that contains an aggregate function.

Each executed `getQueryLocatorWithBinds` method counts against the governor limit for the total number of records retrieved by Database.getQueryLocator(10,000) and the total number of SOQL queries issued. See Per Transaction Apex Limits.

For more information, see Understanding Apex Managed Sharing, and StandardSetController Class.

**Example**

In this example, the SOQL query uses a bind variable for an Account name. Its value (Acme Corporation) is passed in using the acctBinds Map.

```java
public class TestBatch implements Database.Batchable<sObject>{

    private Map<String, Object> acctBinds = new Map<String, Object>{'acctName' => 'Acme
```
Corporation'};

    private String query = 'Select Id From Account where name = :acctName';

    public Database.QueryLocator start(Database.BatchableContext BC)
    {
        return Database.getQueryLocatorWithBinds(query, acctBinds, AccessLevel.USER_MODE);
    }

    public void execute(Database.BatchableContext BC, List<sObject> scope)
    {
    }

    public void finish(Database.BatchableContext BC)
    {
    }

getUpdated( objectType, startDate, endDate)

Returns the list of individual records that have been updated for an sObject type within the specified start and end dates and times.

Signature

public static Database.GetUpdatedResult getUpdated(String objectType, Datetime startDate, Datetime endDate)

Parameters

objectType
    Type: String
    The objectType argument is the sObject type name for which to get the updated records, such as account or merchandise__c.

startDate
    Type: Datetime
    The startDate argument is the start date and time of the updated records time window.

endDate
    Type: Datetime
    The endDate argument is the end date and time of the updated records time window.

Return Value

Type: Database.GetUpdatedResult

Usage

The date range for the returned results is no more than 30 days previous to the day the call is executed.

Example

Database.GetUpdatedResult r =
    Database.getUpdated(
        'Merchandise__c',
    )
**insert(recordToInsert, allOrNone)**

Adds an sObject, such as an individual account or contact, to your organization’s data.

**Signature**

```java
public static Database.SaveResult insert(sObject recordToInsert, Boolean allOrNone)
```

**Parameters**

- `recordToInsert`
  - Type: `sObject`
- `allOrNone`
  - Type: `Boolean`

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

**Return Value**

Type: `Database.SaveResult`

**Usage**

`insert` is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `insert` method counts against the governor limit for DML statements.

**insert(recordsToInsert, allOrNone)**

Adds one or more sObjects, such as individual accounts or contacts, to your organization’s data.

**Signature**

```java
public static Database.SaveResult[] insert(sObject[] recordsToInsert, Boolean allOrNone)
```

**Parameters**

- `recordsToInsert`
  - Type: `sObject[]`
- `allOrNone`
  - Type: `Boolean`
The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter isn’t set or is set `true`, an exception is thrown if the method isn’t successful. If the parameter is specified as `false` and a before-trigger assigns an invalid value to a field, the partial set of valid records isn’t inserted.

**Return Value**

Type: `Database.SaveResult[]`

**Usage**

`insert` is analogous to the `INSERT` statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `insert` method counts against the governor limit for DML statements.

**Example**

Example:

The following example inserts two accounts:

```java
Account a = new Account(name = 'Acme1');
Database.SaveResult[] lsr = Database.insert(
    new Account[]{a, new Account(Name = 'Acme2')},
    false);
```

**insert(recordToInsert, dmlOptions)**

Adds an sObject, such as an individual account or contact, to your organization’s data.

**Signature**

```java
public static Database.SaveResult insert(sObject recordToInsert, Database.DMLOptions dmlOptions)
```

**Parameters**

`recordToInsert`

Type: `sObject`

`dmlOptions`

Type: `Database.DMLOptions`

The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

**Return Value**

Type: `Database.SaveResult`
Usage

*insert* is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed *insert* method counts against the governor limit for DML statements.

**insert(recordsToInsert, dmlOptions)**

Adds one or more sObjects, such as individual accounts or contacts, to your organization’s data.

**Signature**

```java
public static Database.SaveResult insert(sObject[] recordsToInsert, Database.DMLOptions dmlOptions)
```

**Parameters**

- `recordsToInsert`
  
  Type: `sObject[]`

- `dmlOptions`
  
  Type: `Database.DMLOptions`

  The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

**Return Value**

Type: `Database.SaveResult[]`

Usage

*insert* is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed *insert* method counts against the governor limit for DML statements.

**insert(recordToInsert, allOrNone, accessLevel)**

Adds an sObject, such as an individual account or contact, to your organization’s data.

**Signature**

```java
public static Database.SaveResult insert(SObject recordToInsert, Boolean allOrNone, System.AccessLevel accessLevel)
```

**Parameters**

- `recordToInsert`
  
  Type: `sObject`
**allOrNone**

Type: Boolean

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

**accessLevel**

Type: System.AccessLevel

(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**

Type: Database.SaveResult

**Usage**

If you use the `accessLevel` parameter to specify that the method runs in user mode, we report all encountered inaccessible fields. The way to retrieve the names of these inaccessible fields depends on the value of this method’s `allOrNone` parameter, or the equivalent `DmlOptions.optAllOrNone` property. If you specify that:

- `allOrNone=true` or `DmlOptions.optAllOrNone=true`: Catch the `DMLException` and use the `DMLException.getDMLFieldNames()` method to retrieve the list of inaccessible fields. See Exception Class and Built-In Exceptions for more information.

- `allOrNone=false` or `DmlOptions.optAllOrNone=false`: For each failing record, we update the `Database.Error` object that results from the DML operation. Use the `Error.getFields()` method to retrieve the list of inaccessible fields. See the Error Class methods for more information.

**insert** is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `insert` method counts against the governor limit for DML statements.

**insert(recordsToInsert, allOrNone, accessLevel)**

Adds one or more sObjects, such as individual accounts or contacts, to your organization's data.

**Signature**

```java
public static List<Database.SaveResult> insert(List<SObject> recordsToInsert, Boolean allOrNone, System.AccessLevel accessLevel)
```

**Parameters**

**recordsToInsert**

Type: List<sObject>
allOrNone
Type: Boolean
The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter isn’t set or is set true, an exception is thrown if the method isn’t successful. If the parameter is specified as false and a before-trigger assigns an invalid value to a field, the partial set of valid records isn’t inserted.

accessLevel
Type: System.AccessLevel
(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: List<Database.SaveResult>

Usage
If you use the accessLevel parameter to specify that the method runs in user mode, we report all encountered inaccessible fields. The way to retrieve the names of these inaccessible fields depends on the value of this method’s allOrNone parameter, or the equivalent DmlOptions.optAllOrNone property. If you specify that:

• allOrNone=true or DmlOptions.optAllOrNone=true: Catch the DMLException and use the DMLException.getDMLFieldNames() method to retrieve the list of inaccessible fields. See Exception Class and Built-In Exceptions for more information.
• allOrNone=false or DmlOptions.optAllOrNone=false: For each failing record, we update the Database.Error object that results from the DML operation. Use the Error.getFields() method to retrieve the list of inaccessible fields. See the Error Class methods for more information.

insert is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed insert method counts against the governor limit for DML statements.

insert(recordToInsert, dmlOptions, accessLevel)
Adds an sObject, such as an individual account or contact, to your organization’s data.

Signature
public static Database.SaveResult insert(SObject recordToInsert, Database.DMLOptions dmlOptions, System.AccessLevel accessLevel)

Parameters
recordToInsert
Type: sObject
**dmlOptions**
Type: `Database.DMLOptions`

The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

**accessLevel**
Type: `System.AccessLevel`

(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**
Type: `Database.SaveResult`

**Usage**
`insert` is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `insert` method counts against the governor limit for DML statements.

\[\text{insert(recordsToInsert, dmlOptions, accessLevel)}\]

Adds one or more sObjects, such as individual accounts or contacts, to your organization's data.

**Signature**

```java
public static List<Database.SaveResult> insert(List<SObject> recordsToInsert, Database.DMLOptions dmlOptions, System.AccessLevel accessLevel)
```

**Parameters**

- **recordsToInsert**
  Type: `List<SObject>`

- **dmlOptions**
  Type: `Database.DMLOptions`

  The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

- **accessLevel**
  Type: `System.AccessLevel`

  (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.
Return Value
Type: List<Database.SaveResult>

Usage
insert is analogous to the INSERT statement in SQL.
Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.
Each executed insert method counts against the governor limit for DML statements.

insertAsync(sobjects, callback)
Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose processSave method is called for each record after the remote operations are completed.

Signature
public static List<Database.SaveResult> insertAsync(List<SObject> sobjects, DataSource.AsyncSaveCallback callback)

Parameters
sobjects
Type: List<SObject>
List of external object records to insert.
callback
Type: DataSource.AsyncSaveCallback
The callback object that contains the state in the originating context and an action (the processSave method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation’s results. The callback object must extend DataSource.AsyncSaveCallback.

Return Value
Type: List<Database.SaveResult>
Status results for the insert operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

Usage
Database.insertAsync() methods can't be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use Database.insertImmediate() methods.
**insertAsync(object, callback)**

Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processSave` method is called after the remote operation is completed.

**Signature**

```java
public static Database.SaveResult insertAsync(SObject object,
DataSource.AsyncSaveCallback callback)
```

**Parameters**

- `object`
  - Type: `SObject`
  - The external object record to insert.

- `callback`
  - Type: `DataSource.AsyncSaveCallback`
  - The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncSaveCallback`.

**Return Value**

Type: `Database.SaveResult`

Status result for the insert operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

**Usage**

`Database.insertAsync()` methods can't be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use `Database.insertImmediate()` methods.

**insertAsync(objects)**

Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.

**Signature**

```java
public static List<Database.SaveResult> insertAsync(List<SObject> objects)
```

**Parameters**

- `objects`
  - Type: `List<SObject>`
  - List of external object records to insert.
Return Value

Type: List<Database.SaveResult>

Status results for the insert operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

Usage

Database.insertAsync() methods can’t be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use Database.insertImmediate() methods.

insertAsync(sobject)

Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

Signature

public static Database.SaveResult insertAsync(SObject object)

Parameters

object

Type: SObject

The external object record to insert.

Return Value

Type: Database.SaveResult

Status result for the insert operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

Usage

Database.insertAsync() methods can’t be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use Database.insertImmediate() methods.

insertAsync(sobjects, callback, accessLevel)

Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose processSave method is called for each record after the remote operations are completed.

Signature

public static List<Database.SaveResult> insertAsync(List<SObject> objects, DataSource.AsyncSaveCallback callback, System.AccessLevel accessLevel)
Parameters>

`sobjects`  
Type: List<SObject>  
List of external object records to insert.

`callback`  
Type: DataSource.AsyncSaveCallback  
The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. The execution is in system mode regardless of the `accessLevel` parameter. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncSaveCallback`.

`accessLevel`  
Type: System.AccessLevel  
(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value>

Type: List<Database.SaveResult>  
Status results for the insert operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

Usage>

`Database.insertAsync()` methods can't be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use `Database.insertImmediate()` methods.

`insertAsync(sobject, callback, accessLevel)`  
Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processSave` method is called after the remote operation is completed.

Signature  

```java
public static Database.SaveResult insertAsync(SObject sobject,  
DataSource.AsyncSaveCallback callback, System.AccessLevel accessLevel)
```

Parameters  

`sobject`  
Type: SObject  
The external object record to insert.

`callback`  
Type: DataSource.AsyncSaveCallback
The callback object that contains the state in the originating context and an action (the processSave method) that executes after the insert operation is completed. The execution is in system mode regardless of the accessLevel parameter. Use the action callback to update org data according to the operation's results. The callback object must extend DataSource.AsyncSaveCallback.

accessLevel
Type: System.AccessLevel
(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: Database.SaveResult
Status result for the insert operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

Usage
Database.insertAsync() methods can’t be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use Database.insertImmediate() methods.

insertAsync(sobjects, accessLevel)
Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

Signature
public static List<Database.SaveResult> insertAsync(List<SObject> sobjects, System.AccessLevel accessLevel)

Parameters
sobjects
Type: List<SObject>
List of external object records to insert.

accessLevel
Type: System.AccessLevel
(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: List<Database.SaveResult>
Status results for the insert operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

Usage

Database.insertAsync() methods can't be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use Database.insertImmediate() methods.

insertAsync(object, accessLevel)

Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.

Signature

public static Database.SaveResult insertAsync(SObject object, System.AccessLevel accessLevel)

Parameters

object

Type: SObject

The external object record to insert.

accessLevel

Type: System.AccessLevel

(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value

Type: Database.SaveResult

Status result for the insert operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

Usage

Database.insertAsync() methods can't be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use Database.insertImmediate() methods.

insertImmediate(objects)

Initiates requests to add external object data to the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can't be completed and throw exceptions.
public static List<Database.SaveResult> insertImmediate(List<SObject> objects)

Parameters
objects
  Type: List<SObject>
  List of external object records to insert.

Return Value
Type: List<Database.SaveResult>
Status results for the insert operation.

Usage
The operation allows partial success. If one or more record inserts fail, the method doesn’t throw an exception and the remainder of the DML operation can still succeed. The returned SaveResult objects indicate whether the operation was successful. If it wasn’t successful, the objects also return the error code and description.

insertImmediate(object)
Initiates a request to add external object data to the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

public static Database.SaveResult insertImmediate(SObject object)

Parameters
object
  Type: SObject
  The external object record to insert.

Return Value
Type: Database.SaveResult
Status result for the insert operation.

Usage
If a record insert fails, the method doesn’t throw an exception. The returned SaveResult object indicates whether the operation was successful. If it wasn’t successful, the object returns the error code and description.
**insertImmediate**(*objects*, *accessLevel*)

Initiates requests to add external object data to the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

**Signature**

```java
public static List<Database.SaveResult> insertImmediate(List<SObject> objects, System.AccessLevel accessLevel)
```

**Parameters**

- **objects**
  - Type: List<SObject>
  - List of external object records to insert.

- **accessLevel**
  - Type: System.AccessLevel
  - (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**

- Type: List<Database.SaveResult>
- Status results for the insert operation.

**Usage**

The operation allows partial success. If one or more record inserts fail, the method doesn’t throw an exception and the remainder of the DML operation can still succeed. The returned `SaveResult` objects indicate whether the operation was successful. If it wasn’t successful, the objects also return the error code and description.

**insertImmediate**(*object*, *accessLevel*)

Initiates a request to add external object data to the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

**Signature**

```java
public static Database.SaveResult insertImmediate(SObject object, System.AccessLevel accessLevel)
```

**Parameters**

- **object**
  - Type: SObject
The external object record to insert.

`accessLevel`
Type: `System.AccessLevel`  
(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**
Type: `Database.SaveResult`  
Status result for the insert operation.

**Usage**
If a record update fails, the method doesn’t throw an exception. The returned `SaveResult` object indicates whether the operation was successful. If it failed, the object returns the error code and description.

**merge (masterRecord, duplicateId)**
Merges the specified duplicate record into the master sObject record of the same type, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

**Signature**
`public static Database.MergeResult merge(sObject masterRecord, Id duplicateId)`

**Parameters**
- `masterRecord`
  Type: `sObject`  
  The master sObject record the duplicate record is merged into.
- `duplicateId`
  Type: `ID`  
  The ID of the record to merge with the master. This record must be of the same sObject type as the master.

**Return Value**
Type: `Database.MergeResult`  

**Usage**
Each executed `merge` method counts against the governor limit for DML statements.

**merge (masterRecord, duplicateRecord)**
Merges the specified duplicate sObject record into the master sObject of the same type, deleting the duplicate, and reparenting any related records.
Signature
`public static Database.MergeResult merge(sObject masterRecord, sObject duplicateRecord)`

Parameters
- `masterRecord`
  - Type: `sObject`
  - The master `sObject` record the duplicate record is merged into.
- `duplicateRecord`
  - Type: `sObject`
  - The `sObject` record to merge with the master. This `sObject` must be of the same type as the master.

Return Value
Type: `Database.MergeResult`

Usage
Each executed `merge` method counts against the governor limit for DML statements.

`merge(masterRecord, duplicateIds)`
Merges up to two records of the same `sObject` type into the master `sObject` record, deleting the others, and reparenting any related records.

Signature
`public static List<Database.MergeResult> merge(sObject masterRecord, List<Id> duplicateIds)`

Parameters
- `masterRecord`
  - Type: `sObject`
  - The master `sObject` record the other records are merged into.
- `duplicateIds`
  - Type: `List<Id>`
  - A list of `Ids` of up to two records to merge with the master. These records must be of the same `sObject` type as the master.

Return Value
Type: `List<Database.MergeResult>`

Usage
Each executed `merge` method counts against the governor limit for DML statements.
**merge (masterRecord, duplicateRecords)**

Merges up to two records of the same object type into the master sObject record, deleting the others, and reparenting any related records.

**Signature**

```java
public static List<Database.MergeResult> merge(sObject masterRecord, List<sObject> duplicateRecords)
```

**Parameters**

- **masterRecord**
  - Type: `sObject`
  - The master sObject record the other sObjects are merged into.

- **duplicateRecords**
  - Type: `List<sObject>`
  - A list of up to two sObject records to merge with the master. These sObjects must be of the same type as the master.

**Return Value**

Type: `List<Database.MergeResult>`

**Usage**

Each executed `merge` method counts against the governor limit for DML statements.

**merge (masterRecord, duplicateId, allOrNone)**

Merges the specified duplicate record into the master sObject record of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

**Signature**

```java
public static Database.MergeResult merge(sObject masterRecord, Id duplicateId, Boolean allOrNone)
```

**Parameters**

- **masterRecord**
  - Type: `sObject`
  - The master sObject record the duplicate record is merged into.

- **duplicateId**
  - Type: `ID`
  - The ID of the record to merge with the master. This record must be of the same sObject type as the master.

- **allOrNone**
  - Type: `Boolean`
Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

**Return Value**
Type: `Database.MergeResult`

**Usage**
Each executed `merge` method counts against the governor limit for DML statements.

**merge (masterRecord, duplicateRecord, allOrNone)**
Merges the specified duplicate sObject record into the master sObject of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records.

**Signature**
```
public static Database.MergeResult merge(sObject masterRecord, sObject duplicateRecord, Boolean allOrNone)
```

**Parameters**
- `masterRecord`
  Type: `sObject`
  The master sObject record the duplicate record is merged into.
- `duplicateRecord`
  Type: `sObject`
  The sObject record to merge with the master. This sObject must be of the same type as the master.
- `allOrNone`
  Type: `Boolean`
  Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

**Return Value**
Type: `Database.MergeResult`

**Usage**
Each executed `merge` method counts against the governor limit for DML statements.

**merge (masterRecord, duplicateIds, allOrNone)**
Merges up to two records of the same sObject type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.
**Signature**

```
public static List<Database.MergeResult> merge(sObject masterRecord, List<Id> duplicateIds, Boolean allOrNone)
```

**Parameters**

- **masterRecord**
  - Type: `sObject`
  - The master `sObject` record the other records are merged into.

- **duplicateIds**
  - Type: `List<Id>`
  - A list of IDs of up to two records to merge with the master. These records must be of the same `sObject` type as the master.

- **allOrNone**
  - Type: `Boolean`
  - Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

**Return Value**

Type: `List<Database.MergeResult>`

**Usage**

Each executed `merge` method counts against the governor limit for DML statements.

**merge (masterRecord, duplicateRecords, allOrNone)**

Merges up to two records of the same object type into the master `sObject` record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

**Signature**

```
public static List<Database.MergeResult> merge(sObject masterRecord, List<sObject> duplicateRecords, Boolean allOrNone)
```

**Parameters**

- **masterRecord**
  - Type: `sObject`
  - The master `sObject` record the other `sObjects` are merged into.

- **duplicateRecords**
  - Type: `List<sObject>`
  - A list of up to two `sObject` records to merge with the master. These `sObjects` must be of the same type as the master.

- **allOrNone**
  - Type: `Boolean`
Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

**Return Value**
Type: `List<Database.MergeResult>`

**Usage**
Each executed `merge` method counts against the governor limit for DML statements.

**merge(masterRecord, duplicateId, accessLevel)**
Merges the specified duplicate record into the master sObject record of the same type, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

**Signature**

```java
public static Database.MergeResult merge(SObject masterRecord, Id duplicateId, System.AccessLevel accessLevel)
```

**Parameters**

- `masterRecord`
  Type: `sObject`
  The master sObject record the duplicate record is merged into.

- `duplicateId`
  Type: `ID`
  The ID of the record to merge with the master. This record must be of the same sObject type as the master.

- `accessLevel`
  Type: `System.AccessLevel`
  (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**
Type: `Database.MergeResult`

**Usage**
Each executed `merge` method counts against the governor limit for DML statements.

**merge(masterRecord, duplicateRecord, accessLevel)**
Merges the specified duplicate sObject record into the master sObject of the same type, deleting the duplicate, and reparenting any related records.
Signature

public static Database.MergeResult merge(SObject masterRecord, SObject duplicateRecord, System.AccessLevel accessLevel)

Parameters

masterRecord
Type: SObject
The master sObject record the duplicate record is merged into.

duplicateRecord
Type: SObject
The sObject record to merge with the master. This sObject must be of the same type as the master.

accessLevel
Type: System.AccessLevel
(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value

Type: Database.MergeResult

Usage

Each executed merge method counts against the governor limit for DML statements.

merge(masterRecord, duplicateIds, accessLevel)
Merges up to two records of the same sObject type into the master sObject record, deleting the others, and reparenting any related records.

Signature

public static List<Database.MergeResult> merge(SObject masterRecord, List<Id> duplicateIds, System.AccessLevel accessLevel)

Parameters

masterRecord
Type: SObject
The master sObject record the other records are merged into.

duplicateIds
Type: List<Id>
A list of IDs of up to two records to merge with the master. These records must be of the same sObject type as the master.

accessLevel
Type: System.AccessLevel
(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**

Type: `List<Database.MergeResult>`

**Usage**

Each executed `merge` method counts against the governor limit for DML statements.

**merge (masterRecord, duplicateRecords, accessLevel)**

Merges up to two records of the same object type into the master sObject record, deleting the others, and reparenting any related records.

**Signature**

```java
public static List<Database.MergeResult> merge(SObject masterRecord, List<SObject> duplicateRecords, System.AccessLevel accessLevel)
```

**Parameters**

**masterRecord**

Type: `SObject`

The master sObject record the other sObjects are merged into.

**duplicateRecords**

Type: `List<SObject>`

A list of up to two sObject records to merge with the master. These sObjects must be of the same type as the master.

**accessLevel**

Type: `System.AccessLevel`

(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**

Type: `List<Database.MergeResult>`

**Usage**

Each executed `merge` method counts against the governor limit for DML statements.
merge(masterRecord, duplicateId, allOrNone, accessLevel)

Merges the specified duplicate record into the master sObject record of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

Signature

public static Database.MergeResult merge(SObject masterRecord, Id duplicateId, Boolean allOrNone, System.AccessLevel accessLevel)

Parameters

masterRecord
Type: sObject
The master sObject record the duplicate record is merged into.

duplicateId
Type: ID
The ID of the record to merge with the master. This record must be of the same sObject type as the master.

allOrNone
Type: Boolean
Set to false to return any errors encountered in this operation as part of the returned result. If set to true, this method throws an exception if the operation fails. The default is true.

accessLevel
Type: System.AccessLevel
(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: Database.MergeResult

Usage

If you use the accessLevel parameter to specify that the method runs in user mode, we report all encountered inaccessible fields. The way to retrieve the names of these inaccessible fields depends on the value of this method's allOrNone parameter, or the equivalent DmlOptions.optAllOrNone property. If you specify that:

- allOrNone=true or DmlOptions.optAllOrNone=true: Catch the DMLException and use the DMLException.getDMLFieldNames() method to retrieve the list of inaccessible fields. See Exception Class and Built-In Exceptions for more information.
- allOrNone=false or DmlOptions.optAllOrNone=false: For each failing record, we update the Database.Error object that results from the DML operation. Use the Error.getFields() method to retrieve the list of inaccessible fields. See the Error Class methods for more information.

Each executed merge method counts against the governor limit for DML statements.
**merge(masterRecord, duplicateRecord, allOrNone, accessLevel)**

Merges the specified duplicate sObject record into the master sObject of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records.

**Signature**

```java
public static Database.MergeResult merge(SObject masterRecord, SObject duplicateRecord, Boolean allOrNone, System.AccessLevel accessLevel)
```

**Parameters**

- **masterRecord**
  - Type: `sObject`
  - The master sObject record the duplicate record is merged into.

- **duplicateRecord**
  - Type: `sObject`
  - The sObject record to merge with the master. This sObject must be of the same type as the master.

- **allOrNone**
  - Type: `Boolean`
  - Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

- **accessLevel**
  - Type: `System.AccessLevel`
  - (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**

- Type: `Database.MergeResult`

**Usage**

If you use the `accessLevel` parameter to specify that the method runs in user mode, we report all encountered inaccessible fields. The way to retrieve the names of these inaccessible fields depends on the value of this method's `allOrNone` parameter, or the equivalent `DmlOptions.optAllOrNone` property. If you specify that:

- `allOrNone=true` or `DmlOptions.optAllOrNone=true`: Catch the `DMLException` and use the `DMLException.getDMLFieldNames()` method to retrieve the list of inaccessible fields. See Exception Class and Built-In Exceptions for more information.

- `allOrNone=false` or `DmlOptions.optAllOrNone=false`: For each failing record, we update the `Database.Error` object that results from the DML operation. Use the `Error.getFields()` method to retrieve the list of inaccessible fields. See the Error Class methods for more information.

Each executed `merge` method counts against the governor limit for DML statements.
merge(masterRecord, duplicateIds, allOrNone, accessLevel)

Merges up to two records of the same sObject type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

**Signature**

```
public static List<Database.MergeResult> merge(SObject masterRecord, List<Id> duplicateIds, Boolean allOrNone, System.AccessLevel accessLevel)
```

**Parameters**

- `masterRecord`
  
  Type: `SObject`

  The master sObject record the other records are merged into.

- `duplicateIds`
  
  Type: `List<Id>`

  A list of IDs of up to two records to merge with the master. These records must be of the same sObject type as the master.

- `allOrNone`
  
  Type: `Boolean`

  Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

- `accessLevel`
  
  Type: `System.AccessLevel`

  (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**

Type: `List<Database.MergeResult>`

**Usage**

If you use the `accessLevel` parameter to specify that the method runs in user mode, we report all encountered inaccessible fields. The way to retrieve the names of these inaccessible fields depends on the value of this method's `allOrNone` parameter, or the equivalent `DmlOptions.optAllOrNone` property. If you specify that:

- `allOrNone=true` or `DmlOptions.optAllOrNone=true`: Catch the `DMLException` and use the `DMLException.getDMLFieldNames()` method to retrieve the list of inaccessible fields. See Exception Class and Built-In Exceptions for more information.
- `allOrNone=false` or `DmlOptions.optAllOrNone=false`: For each failing record, we update the `Database.Error` object that results from the DML operation. Use the `Error.getFields()` method to retrieve the list of inaccessible fields. See the Error Class methods for more information.

Each executed `merge` method counts against the governor limit for DML statements.
merge (masterRecord, duplicateRecords, allOrNone, accessLevel)

Merges up to two records of the same object type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

Signature

public static List<Database.MergeResult> merge(SObject masterRecord, List<SObject> duplicateRecords, Boolean allOrNone, System.AccessLevel accessLevel)

Parameters

masterRecord
Type: sObject
The master sObject record the other sObjects are merged into.

duplicateRecords
Type: List<SObject>
A list of up to two sObject records to merge with the master. These sObjects must be of the same type as the master.

allOrNone
Type: Boolean
Set to false to return any errors encountered in this operation as part of the returned result. If set to true, this method throws an exception if the operation fails. The default is true.

accessLevel
Type: System.AccessLevel
(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value

Type: List<Database.MergeResult>

Usage

If you use the accessLevel parameter to specify that the method runs in user mode, we report all encountered inaccessible fields. The way to retrieve the names of these inaccessible fields depends on the value of this method's allOrNone parameter, or the equivalent DmlOptions.optAllOrNone property. If you specify that:

- allOrNone=true or DmlOptions.optAllOrNone=true: Catch the DMLException and use the DMLException.getDMLFieldNames() method to retrieve the list of inaccessible fields. See Exception Class and Built-In Exceptions for more information.
- allOrNone=false or DmlOptions.optAllOrNone=false: For each failing record, we update the Database.Error object that results from the DML operation. Use the Error.getFields() method to retrieve the list of inaccessible fields. See the Error Class methods for more information.

Each executed merge method counts against the governor limit for DML statements.
**query (queryString)**

Creates a dynamic SOQL query at runtime.

**Signature**

```java
public static List<SObject> query(String queryString)
```

**Parameters**

- `queryString`
  - Type: `String`

**Return Value**

Type: `List on page 3177 <sObject>`

**Usage**

This method can be used wherever a static SOQL query can be used, such as in regular assignment statements and `for` loops. Unlike inline SOQL, fields in bind variables are not supported.

For more information, see Dynamic SOQL.

Each executed `query` method counts against the governor limit for SOQL queries.

**query (queryString, accessLevel)**

Creates a dynamic SOQL query at runtime.

**Signature**

```java
public static List<SObject> query(String queryString, System.AccessLevel accessLevel)
```

**Parameters**

- `queryString`
  - Type: `String`
- `accessLevel`
  - Type: `System.AccessLevel`

(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**

Type: `List on page 3177 <sObject>`
Usage

This method can be used wherever a static SOQL query can be used, such as in regular assignment statements and for loops. Unlike inline SOQL, fields in bind variables are not supported.

For more information, see Dynamic SOQL.

Each executed query method counts against the governor limit for SOQL queries.

**queryWithBinds**(queryString, bindMap, accessLevel)

Creates a dynamic SOQL query at runtime. Bind variables in the query are resolved from the bindMap Map parameter directly with the key, rather than from Apex code variables.

**Signature**

public static List<SObject> queryWithBinds(String queryString, Map<String, Object> bindMap, System.AccessLevel accessLevel)

**Parameters**

**queryString**

Type: String

SOQL query that includes Apex bind variables or expressions preceded by a colon. All bind variables must have a key in the bindMap Map.

**bindMap**

Type: Map<String, Object>

A map that contains keys for each bind variable specified in the SOQL queryString and its value. The keys can’t be null or duplicates, and the values can’t be null or empty strings.

**accessLevel**

Type: System.AccessLevel

The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced.

**Return Value**

Type: List on page 3177<SObject>

Usage

This method can be used wherever a static SOQL query can be used, such as in regular assignment statements and for loops.

For more information, see Dynamic SOQL.

Each executed queryWithBinds method counts against the governor limit for SOQL queries.
Example

In this example, the SOQL query uses a bind variable for an Account name. Its value (Acme Inc.) is passed in to the method using the `nameBind` Map. The `accountName` variable isn’t (and doesn’t have to be) in scope when the query is executed within the method.

```java
public static List<Account> simpleBindingSoqlQuery(Map<String, Object> bindParams) {
    String queryString =
        'SELECT Id, Name ' +
        'FROM Account ' +
        'WHERE name = :name';
    return Database.queryWithBinds(
        queryString,
        bindParams,
        AccessLevel.USER_MODE
    );
}

String accountName = 'Acme Inc.';
Map<String, Object> nameBind = new Map<String, Object>{'name' => accountName};
List<Account> accounts = simpleBindingSoqlQuery(nameBind);
System.debug(accounts);
```

**rollback (databaseSavepoint)**

Restores the database to the state specified by the savepoint variable. Any emails submitted since the last savepoint are also rolled back and not sent.

**Signature**

```java
public static Void rollback(System.Savepoint databaseSavepoint)
```

**Parameters**

- `databaseSavepoint`
  - Type: System.Savepoint

**Return Value**

Type: Void

**Usage**

Note the following:

- Static variables are not reverted during a rollback. If you try to run the trigger again, the static variables retain the values from the first run.
- Each rollback counts against the governor limit for DML statements. You will receive a runtime error if you try to rollback the database additional times.
- The ID on an sObject inserted after setting a savepoint is not cleared after a rollback. Create an sObject to insert after a rollback. Attempting to insert the sObject using the variable created before the rollback fails because the sObject variable has an ID. Updating or upserting the sObject using the same variable also fails because the sObject is not in the database and, thus, cannot be updated.
For an example, see Transaction Control.

**setSavepoint()**

Returns a savepoint variable that can be stored as a local variable, then used with the rollback method to restore the database to that point.

**Signature**

```java
public static System.Savepoint setSavepoint()
```

**Return Value**

Type: System.Savepoint

**Usage**

Note the following:

- If you set more than one savepoint, then roll back to a savepoint that is not the last savepoint you generated, the later savepoint variables become invalid. For example, if you generated savepoint SP1 first, savepoint SP2 after that, and then you rolled back to SP1, the variable SP2 would no longer be valid. You will receive a runtime error if you try to use it.
- References to savepoints cannot cross trigger invocations because each trigger invocation is a new trigger context. If you declare a savepoint as a static variable then try to use it across trigger contexts, you will receive a run-time error.
- Each savepoint you set counts against the governor limit for DML statements.

For an example, see Transaction Control.

**undelete(recordToUndelete, allOrNone)**

Restores an existing sObject record, such as an individual account or contact, from your organization’s Recycle Bin.

**Signature**

```java
public static Database.UndeleteResult undelete(sObject recordToUndelete, Boolean allOrNone)
```

**Parameters**

- `recordToUndelete`
  Type: sObject
- `allOrNone`
  Type: Boolean

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

**Return Value**

Type: Database.UndeleteResult
Usage

`undelete` is analogous to the UNDELETE statement in SQL.
Each executed `undelete` method counts against the governor limit for DML statements.

`undelete(recordsToUndelete, allOrNone)`
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

Signature

```java
public static Database.UndeleteResult[] undelete(sObject[] recordsToUndelete, Boolean allOrNone)
```

Parameters

- `recordsToUndelete`  
  Type: `sObject[]`
- `allOrNone`  
  Type: `Boolean`
  The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: `Database.UndeleteResult[]`

Usage

`undelete` is analogous to the UNDELETE statement in SQL.
Each executed `undelete` method counts against the governor limit for DML statements.

Example

The following example restores all accounts named ‘Universal Containers’. The `ALL ROWS` keyword queries all rows for both top-level and aggregate relationships, including deleted records and archived activities.

```java
Account[] savedAccts = [SELECT Id, Name FROM Account WHERE Name = 'Universal Containers' ALL ROWS];
Database.UndeleteResult[] UDR_Dels = Database.undelete(savedAccts);
```

`undelete(recordID, allOrNone)`
Restores an existing sObject record, such as an individual account or contact, from your organization’s Recycle Bin.
Signature

public static Database.UndeleteResult undelete(ID recordID, Boolean allOrNone)

Parameters

recordID
Type: ID

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value

Type: Database.UndeleteResult

Usage

undelete is analogous to the UNDELETE statement in SQL.

Each executed undelete method counts against the governor limit for DML statements.

undelete(recordIDs, allOrNone)

Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

Signature

public static Database.UndeleteResult[] undelete(ID[] recordIDs, Boolean allOrNone)

Parameters

RecordIDs
Type: ID[]

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value

Type: Database.UndeleteResult[]
Usage

undelete is analogous to the UNDELETE statement in SQL.

Each executed undelete method counts against the governor limit for DML statements.

undelete(recordToUndelete, allOrNone, accessLevel)

Restores an existing sObject record, such as an individual account or contact, from your organization’s Recycle Bin.

Signature

public static Database.UndeleteResult undelete(SObject recordToUndelete, Boolean allOrNone, System.AccessLevel accessLevel)

Parameters

recordToUndelete
  Type: SObject

allOrNone
  Type: Boolean
  The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

accessLevel
  Type: System.AccessLevel
  (Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value

Type: Database.UndeleteResult

Usage

undelete is analogous to the UNDELETE statement in SQL.

Each executed undelete method counts against the governor limit for DML statements.

undelete(recordsToUndelete, allOrNone, accessLevel)

Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

Signature

public static List<Database.UndeleteResult> undelete(List<SObject> recordsToUndelete, Boolean allOrNone, System.AccessLevel accessLevel)
Parameters

recordsToUndelete
  Type: List<sObject>

allOrNone
  Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

accessLevel
  Type: System.AccessLevel

(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value

Type: List<Database.UndeleteResult>

Usage

undelete is analogous to the UNDELETE statement in SQL.

Each executed undelete method counts against the governor limit for DML statements.

undelete(recordID, allOrNone, accessLevel)

Restores an existing sObject record, such as an individual account or contact, from your organization's Recycle Bin.

Signature

public static Database.UndeleteResult undelete(Id recordID, Boolean allOrNone, System.AccessLevel accessLevel)

Parameters

recordID
  Type: Id

allOrNone
  Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

accessLevel
  Type: System.AccessLevel
(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**
Type: `Database.UndeleteResult`

**Usage**

`undelete` is analogous to the UNDELETE statement in SQL.

Each executed `undelete` method counts against the governor limit for DML statements.

`undelete(recordIDs, allOrNone, accessLevel)`
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

**Signature**

```java
public static List<Database.UndeleteResult> undelete(List<Id> recordIDs, Boolean allOrNone, System.AccessLevel accessLevel)
```

**Parameters**

- `recordIDs`
  Type: `List<Id>`

- `allOrNone`
  Type: `Boolean`
  The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

- `accessLevel`
  Type: `System.AccessLevel`
  (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**
Type: `List<Database.UndeleteResult>`

**Usage**

`undelete` is analogous to the UNDELETE statement in SQL.

Each executed `undelete` method counts against the governor limit for DML statements.
**update**(recordToUpdate, allOrNone)

Modifies an existing sObject record, such as an individual account or contact, in your organization’s data.

**Signature**

```
public static Database.SaveResult update(sObject recordToUpdate, Boolean allOrNone)
```

**Parameters**

- **recordToUpdate**
  - Type: sObject
- **allOrNone**
  - Type: Boolean

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

**Return Value**

Type: `Database.SaveResult`

**Usage**

`update` is analogous to the UPDATE statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `update` method counts against the governor limit for DML statements.

**Example**

The following example updates the `BillingCity` field on a single account.

```java
Account a = new Account(Name='SFDC');
insert(a);

Account myAcct =
    [SELECT Id, Name, BillingCity
     FROM Account WHERE Id = :a.Id];
myAcct.BillingCity = 'San Francisco';

Database.SaveResult SR =
    Database.update(myAcct);
```

**update**(recordsToUpdate, allOrNone)

Modifies one or more existing sObject records, such as individual accounts or contacts, in your organization’s data.
Signature

public static Database.SaveResult[] update(sObject[] recordsToUpdate, Boolean allOrNone)

Parameters

recordsToUpdate
Type: sObject []

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value

Type: Database.SaveResult[]

Usage

update is analogous to the UPDATE statement in SQL.

Each executed update method counts against the governor limit for DML statements.

update(recordToUpdate, dmlOptions)

Modifies an existing sObject record, such as an individual account or contact, in your organization's data.

Signature

public static Database.SaveResult update(sObject recordToUpdate, Database.DmlOptions dmlOptions)

Parameters

recordToUpdate
Type: sObject

dmlOptions
Type: Database.DmlOptions

The optional dmlOptions parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value

Type: Database.SaveResult

Usage

update is analogous to the UPDATE statement in SQL.
Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `update` method counts against the governor limit for DML statements.

### `update(recordsToUpdate, dmlOptions)`

Modifies one or more existing sObject records, such as individual accounts or contacts, in your organization's data.

**Signature**

```java
public static Database.SaveResult[] update(sObject[] recordsToUpdate, Database.DMLOptions dmlOptions)
```

**Parameters**

- `recordsToUpdate`  
  Type: `sObject []`

- `dmlOptions`  
  Type: `Database.DMLOptions`

  The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

**Return Value**

Type: `Database.SaveResult[]`

**Usage**

`update` is analogous to the UPDATE statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `update` method counts against the governor limit for DML statements.

### `update(recordToUpdate, allOrNone, accessLevel)`

Modifies an existing sObject record, such as an individual account or contact, in your organization's data.

**Signature**

```java
public static Database.SaveResult update(SObject recordToUpdate, Boolean allOrNone, System.AccessLevel accessLevel)
```

**Parameters**

- `recordToUpdate`  
  Type: `SObject`

- `allOrNone`  
  Type: `Boolean`
The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

accessLevel
Type: System.AccessLevel
(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: Database.SaveResult

Usage
If you use the accessLevel parameter to specify that the method runs in user mode, we report all encountered inaccessible fields. The way to retrieve the names of these inaccessible fields depends on the value of this method’s allOrNone parameter, or the equivalent DmlOptions.optAllOrNone property. If you specify that:

- allOrNone=true or DmlOptions.optAllOrNone=true: Catch the DMLException and use the DMLException.getDMLFieldNames() method to retrieve the list of inaccessible fields. See Exception Class and Built-In Exceptions for more information.
- allOrNone=false or DmlOptions.optAllOrNone=false: For each failing record, we update the Database.Error object that results from the DML operation. Use the Error.getFields() method to retrieve the list of inaccessible fields. See the Error Class methods for more information.

update(recordsToUpdate, allOrNone, accessLevel)
Modifies one or more existing sObject records, such as individual accounts or contacts, in your organization’s data.

Signature
public static List<Database.SaveResult> update(List<SObject> recordsToUpdate, Boolean allOrNone, System.AccessLevel accessLevel)

Parameters
recordsToUpdate
Type: List<SObject>

allOrNone
Type: Boolean
The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

accessLevel
Type: System.AccessLevel
(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**
Type: `List<Database.SaveResult>`

**Usage**
If you use the `accessLevel` parameter to specify that the method runs in user mode, we report all encountered inaccessible fields. The way to retrieve the names of these inaccessible fields depends on the value of this method's `allOrNone` parameter, or the equivalent `DmlOptions.optAllOrNone` property. If you specify that:

- `allOrNone=true` or `DmlOptions.optAllOrNone=true`: Catch the `DMLException` and use the `DMLException.getDMLFieldNames()` method to retrieve the list of inaccessible fields. See Exception Class and Built-In Exceptions for more information.
- `allOrNone=false` or `DmlOptions.optAllOrNone=false`: For each failing record, we update the `Database.Error` object that results from the DML operation. Use the `Error.getFields()` method to retrieve the list of inaccessible fields. See the Error Class methods for more information.

**`update(recordToUpdate, dmlOptions, accessLevel)`**
Modifies an existing sObject record, such as an individual account or contact, in your organization's data.

**Signature**
```java
public static Database.SaveResult update(SObject recordToUpdate, Database.DMLOptions dmlOptions, System.AccessLevel accessLevel)
```

**Parameters**
- `recordToUpdate`
  Type: `SObject`
- `dmlOptions`
  Type: `Database.DMLOptions`
  The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.
- `accessLevel`
  Type: `System.AccessLevel`
  (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**
Type: `Database.SaveResult`
update(recordsToUpdate, dmlOptions, accessLevel)

Modifies one or more existing sObject records, such as individual accounts or contacts, in your organization’s data.

Signature

public static List<Database.SaveResult> update(List<SObject> recordsToUpdate, Database.DMLOptions dmlOptions, System.AccessLevel accessLevel)

Parameters

recordsToUpdate
- Type: List<sObject>

dmlOptions
- Type: Database.DMLOptions

The optional dmlOptions parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

accessLevel
- Type: System.AccessLevel

(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value

Type: List<Database.SaveResult>

upsert(recordToUpsert, externalIdField, allOrNone)

Creates a new sObject record or updates an existing sObject record within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

Signature

public static Database.UpsertResult upsert(sObject recordToUpsert, Schema.SObjectField externalIdField, Boolean allOrNone)

Parameters

recordToUpsert
- Type: sObject

externalIdField
- Type: Schema.SObjectField

(Optional) The externalIdField parameter is of type Schema.SObjectField, that is, a field token. Find the token for the field by using the fields special method. For example, Schema.SObjectField f = Account.Fields.MyExternalId. The externalIdField parameter is the field that upsert() uses to match sObjects with existing records. This field can be a custom field marked as external ID, or a standard field with the idLookup attribute.
Note: If `externalIdField` isn’t specified, then the ID field is used to determine a match with existing records.

**allOrNone**
Type: `Boolean`

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

**Return Value**
Type: `Database.UpsertResult`

**Usage**
Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `upsert` method counts against the governor limit for DML statements.

For more information on how the `upsert` operation works, see the `upsert()` statement.

**upsert**(recordsToUpsert, externalIdField, allOrNone)**

Creates new sObject records or updates existing sObject records within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

**Signature**
```
public static Database.UpsertResult[] upsert(sObject[] recordsToUpsert, Schema.SObjectField externalIdField, Boolean allOrNone)
```

**Parameters**
- **recordsToUpsert**
  Type: `sObject` []

- **externalIdField**
  Type: `Schema.SObjectField`

  (Optional) The `externalIdField` is of type `Schema.SObjectField`, that is, a field token. Find the token for the field by using the `fields` special method. For example, `Schema.SObjectField f = Account.Fields.MyExternalId`. The `externalIdField` parameter is the field that `upsert()` uses to match sObjects with existing records. This field can be a custom field marked as external ID, or a standard field with the `idLookup` attribute.

  **Note:** If `externalIdField` isn’t specified, then the ID field is used to determine a match with existing records.

- **allOrNone**
  Type: `Boolean`

  The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter isn’t set or is set `true`, an exception is thrown if the method
isn’t successful. If the parameter is specified as false and a before-trigger assigns an invalid value to a field, the partial set of valid records isn’t inserted.

Return Value
Type: Database.UpsertResult[]

Usage
Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.
Each executed upsert method counts against the governor limit for DML statements.
For more information on how the upsert operation works, see the upsert() statement.

upsert(recordToUpsert, externalIdField, allOrNone, accessLevel)

Creates a new sObject record or updates an existing sObject record within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

Signature
public static Database.UpsertResult upsert(SObject recordToUpsert, Schema.SObjectField externalIdField, Boolean allOrNone, System.AccessLevel accessLevel)

Parameters
recordToUpsert
Type: SObject

externalIdField
Type: Schema.SObjectField
(Optional) The externalIdField is of type Schema.SObjectField, that is, a field token. Find the token for the field by using the fields special method. For example, Schema.SObjectField f = Account.Fields.MyExternalId. The externalIdField parameter is the field that upsert() uses to match sObjects with existing records. This field can be a custom field marked as external ID, or a standard field with the idLookup attribute.

Note: If externalIdField isn’t specified, then the ID field is used to determine a match with existing records.

allOrNone
Type: Boolean
The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

accessLevel
Type: System.AccessLevel
(Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are
ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: Database.UpsertResult

Usage
If you use the accessLevel parameter to specify that the method runs in user mode, we report all encountered inaccessible fields. The way to retrieve the names of these inaccessible fields depends on the value of this method’s allOrNone parameter, or the equivalent DmlOptions.optAllOrNone property. If you specify that:

- allOrNone=true or DmlOptions.optAllOrNone=true: Catch the DMLException and use the DMLException.getDMLFieldNames() method to retrieve the list of inaccessible fields. See Exception Class and Built-In Exceptions for more information.
- allOrNone=false or DmlOptions.optAllOrNone=false: For each failing record, we update the Database.Error object that results from the DML operation. Use the Error.getFields() method to retrieve the list of inaccessible fields. See the Error Class methods for more information.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed upsert method counts against the governor limit for DML statements.

For more information on how the upsert operation works, see the upsert() statement.

upsert(recordsToUpsert, externalIdField, allOrNone, accessLevel)
Creates new sObject records or updates existing sObject records within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

Signature
public static List<Database.UpsertResult> upsert(List<SObject> recordsToUpsert, Schema.SObjectField externalIdField, Boolean allOrNone, System.AccessLevel accessLevel)

Parameters
recordsToUpsert
Type: List<SObject>

externalIdField
Type: Schema.SObjectField
(Optional) The externalIdField is of type Schema.SObjectField, that is, a field token. Find the token for the field by using the fields special method. For example, Schema.SObjectField f = Account.Fields.MyExternalId. The externalIdField parameter is the field that upsert () uses to match sObjects with existing records. This field can be a custom field marked as external ID, or a standard field with the idLookup attribute.

Note: If externalIdField isn’t specified, then the ID field is used to determine a match with existing records.

allOrNone
Type: Boolean
The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter isn’t set or is set `true`, an exception is thrown if the method isn’t successful. If the parameter is specified as `false` and a before-trigger assigns an invalid value to a field, the partial set of valid records isn’t inserted.

**accessLevel**

Type: `System.AccessLevel`

(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**

Type: `List<Database.UpsertResult>`

**Usage**

If you use the `accessLevel` parameter to specify that the method runs in user mode, we report all encountered inaccessible fields. The way to retrieve the names of these inaccessible fields depends on the value of this method’s `allOrNone` parameter, or the equivalent `DmlOptions.optAllOrNone` property. If you specify that:

- `allOrNone=true` or `DmlOptions.optAllOrNone=true`: Catch the `DMLException` and use the `DMLException.getDMLFieldNames()` method to retrieve the list of inaccessible fields. See Exception Class and Built-In Exceptions for more information.
- `allOrNone=false` or `DmlOptions.optAllOrNone=false`: For each failing record, we update the `Database.Error` object that results from the DML operation. Use the `Error.getFields()` method to retrieve the list of inaccessible fields. See the Error Class methods for more information.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `upsert` method counts against the governor limit for DML statements.

For more information on how the upsert operation works, see the `upsert()` statement.

**updateAsync(sobjects, callback)**

Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose `processSave` method is called for each record after the remote operations are completed.

**Signature**

```
public static List<Database.SaveResult> updateAsync(List<SObject> sobjects,
DataSource.AsyncSaveCallback callback)
```

**Parameters**

- `sobjects`
  Type: `List<SObject>`

---

2997
List of external object records to modify.

callback
   Type: DataSource.AsyncSaveCallback

   The callback object that contains the state in the originating context and an action (the processSave method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation’s results. The callback object must extend DataSource.AsyncSaveCallback.

Return Value
Type: List<Database.SaveResult>

Status results for the update operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

updateAsync(sobject, callback)

Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processSave method is called after the remote operation is completed.

Signature

public static Database.SaveResult updateAsync(SObject sobject, DataSource.AsyncSaveCallback callback)

Parameters

sobject
   Type: SObject

   External object record to modify.

callback
   Type: DataSource.AsyncSaveCallback

   The callback object that contains the state in the originating context and an action (the processSave method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation’s results. The callback object must extend DataSource.AsyncSaveCallback.

Return Value
Type: Database.SaveResult

Status result for the insert operation. The result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

updateAsync(sobjects)

Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.
Signature

```java
public static List<Database.SaveResult> updateAsync(List<SObject> sobjects)
```

Parameters

- **sobjects**  
  Type: List<SObject>  
  List of external object records to modify.

Return Value

Type: List<Database.SaveResult>

Status results for the update operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

**updateAsync(sobject)**

Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

Signature

```java
public static Database.SaveResult updateAsync(SObject sobject)
```

Parameters

- **sobject**  
  Type: SObject  
  External object record to modify.

Return Value

Type: Database.SaveResult

Status result for the insert operation. The result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

**updateAsync(sobjects, callback, accessLevel)**

Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose `processSave` method is called for each record after the remote operations are completed.

Signature

```java
public static List<Database.SaveResult> updateAsync(List<SObject> sobjects, DataSource.AsyncSaveCallback callback, System.AccessLevel accessLevel)
```
Parameters

`sobjects`
  Type: List<SObject>
  List of external object records to modify.

`callback`
  Type: DataSource.AsyncSaveCallback
  The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. The execution is in system mode regardless of the `accessLevel` parameter. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncSaveCallback`.

`accessLevel`
  Type: System.AccessLevel
  (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value

Type: List<Database.SaveResult>
Status results for the update operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsycnLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

`updateAsync(sobject, callback, accessLevel)`
Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processSave` method is called after the remote operation is completed.

Signature

`public static Database.SaveResult updateAsync(SObject sobject, DataSource.AsyncSaveCallback callback, System.AccessLevel accessLevel)`

Parameters

`sobject`
  Type: SObject
  External object record to modify.

`callback`
  Type: DataSource.AsyncSaveCallback
  The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. The execution is in system mode regardless of the `accessLevel` parameter. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncSaveCallback`. 
accessLevel
Type: System.AccessLevel
(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: Database.SaveResult
Status result for the insert operation. The result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

updateAsync(sobjects, accessLevel)
Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.

Signature
```
public static List<Database.SaveResult> updateAsync(List<SObject> sobjects,
System.AccessLevel accessLevel)
```

Parameters
sobjects
Type: List<SObject>
List of external object records to modify.

accessLevel
Type: System.AccessLevel
(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: List<Database.SaveResult>
Status results for the update operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

updateAsync(sobject, accessLevel)
Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.
Signature

`public static Database.SaveResult updateAsync(SObject sobject, System.AccessLevel accessLevel)`

Parameters

- `sobject`
  Type: `SObject`
  External object record to modify.
- `accessLevel`
  Type: `System.AccessLevel`
  (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value

Type: `Database.SaveResult`

Status result for the insert operation. The result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

`updateImmediate(sobjects)`

Initiates requests to update external object data on the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

Signature

`public static List<Database.SaveResult> updateImmediate(List<SObject> sobjects)`

Parameters

- `sobjects`
  Type: `List<SObject>`
  List of external object records to modify.

Return Value

Type: `List<Database.SaveResult>`

Status results for the update operation.
Usage

The operation allows partial success. If one or more record updates fail, the method doesn’t throw an exception and the remainder of the DML operation can still succeed. The returned `SaveResult` objects indicate whether the operation was successful. If it wasn’t successful, the objects also return the error code and description.

**updateImmediate(sobject)**

Initiates a request to update external object data on the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

**Signature**

```java
public static Database.SaveResult updateImmediate(SObject sobject)
```

**Parameters**

- `sobject`  
  Type: `SObject`  
  External object record to modify.

**Return Value**

Type: `Database.SaveResult`  
Status result for the update operation.

**Usage**

If a record update fails, the method doesn’t throw an exception. The returned `SaveResult` object indicates whether the operation was successful. If it wasn’t successful, the object returns the error code and description.

**updateImmediate(sobjects, accessLevel)**

Initiates requests to update external object data on the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

**Signature**

```java
public static List<Database.SaveResult> updateImmediate(List<SObject> sobjects, System.AccessLevel accessLevel)
```

**Parameters**

- `sobjects`  
  Type: `List<SObject>`  
  List of external object records to modify.

- `accessLevel`  
  Type: `System.AccessLevel`
(Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: `List<Database.SaveResult>`
Status results for the update operation.

Usage
The operation allows partial success. If one or more record updates fail, the method doesn’t throw an exception and the remainder of the DML operation can still succeed. The returned `SaveResult` objects indicate whether the operation was successful. If it wasn’t successful, the objects also return the error code and description.

`updateImmediate(sobject, accessLevel)`
Initiates a request to update external object data on the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

Signature
```java
public static Database.SaveResult updateImmediate(SObject sobject, System.AccessLevel accessLevel)
```

Parameters
- `sobject`  
  Type: `SObject`
  External object record to modify.
- `accessLevel`  
  Type: `System.AccessLevel`
  (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: `Database.SaveResult`
Status result for the update operation.

Usage
If a record update fails, the method doesn’t throw an exception. The returned `SaveResult` object indicates whether the operation was successful. If it failed, the object returns the error code and description.
Date Class

Contains methods for the Date primitive data type.

Namespace

System

Usage

For more information on Dates, see Date Data Type.

Date Methods

The following are methods for `Date`.

IN THIS SECTION:

- `addDays(additionalDays)`
  Adds the specified number of additional days to a Date.
- `addMonths(additionalMonths)`
  Adds the specified number of additional months to a Date.
- `addYears(additionalYears)`
  Adds the specified number of additional years to a Date.
- `day()`
  Returns the day-of-month component of a Date.
- `dayOfYear()`
  Returns the day-of-year component of a Date.
- `daysBetween(secondDate)`
  Returns the number of days between the Date that called the method and the specified date.
- `daysInMonth(year, month)`
  Returns the number of days in the month for the specified `year` and `month` (1=Jan).
- `format()`
  Returns the Date as a string using the locale of the context user.
- `isLeapYear(year)`
  Returns `true` if the specified year is a leap year.
- `isSameDay(dateToCompare)`
  Returns `true` if the Date that called the method is the same as the specified date.
- `month()`
  Returns the month component of a Date (1=Jan).
- `monthsBetween(secondDate)`
  Returns the number of months between the Date that called the method and the specified date, ignoring the difference in days.
- `newInstance(year, month, day)`
  Constructs a Date from Integer representations of the `year`, `month` (1=Jan), and `day`.
parse(stringDate)
Constructs a Date from a String. The format of the String depends on the local date format.

today()
Returns the current date in the current user’s time zone.
toStartOfMonth()
Returns the first of the month for the Date that called the method.
toStartOfWeek()
Returns the start of the week for the Date that called the method, depending on the context user’s locale.
valueOf(stringDate)
Returns a Date that contains the value of the specified String.
valueOf(fieldValue)
Converts the specified object to a Date. Use this method to convert a history tracking field value or an object that represents a Date value.
year()
Returns the year component of a Date

addDays (additionalDays)
Adds the specified number of additional days to a Date.

Signature

```java
class public Date addDays(Integer additionalDays)
```

Parameters

- **additionalDays**
  - Type: Integer

Return Value

Type: Date

Example

```java
Date myDate = Date.newInstance(1960, 2, 17);
Date newDate = myDate.addDays(2);
```

addMonths (additionalMonths)
Adds the specified number of additional months to a Date

Signature

```java
class public Date addMonths(Integer additionalMonths)
```
Parameters

*additionalMonths*
  Type: Integer

Return Value

Type: Date

Example

date myDate = date.newInstance(1990, 11, 21);
date newDate = myDate.addMonths(3);
date expectedDate = date.newInstance(1991, 2, 21);
system.assertEquals(expectedDate, newDate);

**addYears (additionalYears)**

Adds the specified number of additional years to a Date

Signature

public Date addYears(Integer additionalYears)

Parameters

*additionalYears*
  Type: Integer

Return Value

Type: Date

Example

date myDate = date.newInstance(1983, 7, 15);
date newDate = myDate.addYears(2);
date expectedDate = date.newInstance(1985, 7, 15);
system.assertEquals(expectedDate, newDate);

day ()

Returns the day-of-month component of a Date.

Signature

public Integer day()
Example

date myDate = date.newInstance(1989, 4, 21);
Integer day = myDate.day();
System.assertEquals(21, day);

dayOfYear()
Returns the day-of-year component of a Date.

Signature

public Integer dayOfYear()

Return Value
Type: Integer

Example

date myDate = date.newInstance(1998, 10, 21);
Integer day = myDate.dayOfYear();
System.assertEquals(294, day);

daysBetween(secondDate)
Returns the number of days between the Date that called the method and the specified date.

Signature

public Integer daysBetween(Date secondDate)

Parameters

secondDate
Type: Date

Return Value
Type: Integer

Usage
If the Date that calls the method occurs after the secondDate, the return value is negative.

Example

Date startDate = Date.newInstance(2008, 1, 1);
Date dueDate = Date.newInstance(2008, 1, 30);
Integer numberDaysDue = startDate.daysBetween(dueDate);
**daysInMonth(year, month)**

Returns the number of days in the month for the specified `year` and `month` (1=Jan).

**Signature**

```java
public static Integer daysInMonth(Integer year, Integer month)
```

**Parameters**

- **year**
  - Type: `Integer`
- **month**
  - Type: `Integer`

**Return Value**

Type: `Integer`

**Example**

The following example finds the number of days in the month of February in the year 1960.

```java
Integer numberDays = date.daysInMonth(1960, 2);
```

**format()**

Returns the Date as a string using the locale of the context user

**Signature**

```java
public String format()
```

**Return Value**

Type: `String`

**Example**

```java
// In American-English locale
date myDate = date.newInstance(2001, 3, 21);
String dayString = myDate.format();
system.assertEquals('3/21/2001', dayString);
```

**isLeapYear(year)**

Returns `true` if the specified year is a leap year.

**Signature**

```java
public static Boolean isLeapYear(Integer year)
```
Parameters

*year*
Type: *Integer*

Return Value
Type: *Boolean*

Example

```java
system.assert(Date.isLeapYear(2004));
```

**isSameDay(dateToCompare)**

Returns *true* if the Date that called the method is the same as the specified date.

Signature

```java
public Boolean isSameDay(Date dateToCompare)
```

Parameters

*dateToCompare*
Type: *Date*

Return Value
Type: *Boolean*

Example

```java
date myDate = date.today();
date dueDate = date.newInstance(2008, 1, 30);
boolean dueNow = myDate.isSameDay(dueDate);
```

**month()**

Returns the month component of a Date (1=Jan).

Signature

```java
public Integer month()
```

Return Value
Type: *Integer*
Example

date myDate = date.newInstance(2004, 11, 21);
Integer month = myDate.month();
system.assertEquals(11, month);

monthsBetween(secondDate)
Returns the number of months between the Date that called the method and the specified date, ignoring the difference in days.

Signature

public Integer monthsBetween(Date secondDate)

Parameters

secondDate
Type: Date

Return Value

Type: Integer

Example

Date firstDate = Date.newInstance(2006, 12, 2);
Date secondDate = Date.newInstance(2012, 12, 8);
Integer monthsBetween = firstDate.monthsBetween(secondDate);
System.assertEquals(72, monthsBetween);

newInstance(year, month, day)
Constructs a Date from Integer representations of the year, month (1=Jan), and day.

Signature

public static Date newInstance(Integer year, Integer month, Integer day)

Parameters

year
Type: Integer

month
Type: Integer

day
Type: Integer

Return Value

Type: Date
Example
The following example creates the date February 17th, 1960:

```java
Date myDate = date.newInstance(1960, 2, 17);
```

**parse(stringDate)**
Constructs a Date from a String. The format of the String depends on the local date format.

**Signature**

```
public static Date parse(String stringDate)
```

**Parameters**

stringDate
Type: String

**Return Value**

Type: Date

**Example**
The following example works in some locales.

```java
date mydate = date.parse('12/27/2009');
```

**today()**
Returns the current date in the current user's time zone.

**Signature**

```
public static Date today()
```

**Return Value**

Type: Date

**toStartOfMonth()**
Returns the first of the month for the Date that called the method.

**Signature**

```
pUBLIC Date toStartOfMonth()
```

**Return Value**

Type: Date
**Example**

date myDate = date.newInstance(1987, 12, 17);
date firstDate = myDate.toStartOfMonth();
date expectedDate = date.newInstance(1987, 12, 1);
system.assertEquals(expectedDate, firstDate);

toStartOfWeek()

Returns the start of the week for the Date that called the method, depending on the context user's locale.

**Signature**

```
public Date toStartOfWeek()
```

**Return Value**

Type: Date

**Example**

For example, the start of a week is Sunday in the United States locale, and Monday in European locales. For example:

```
Date myDate = Date.today();
Date weekStart = myDate.toStartOfWeek();
```

valueOf(stringDate)

Returns a Date that contains the value of the specified String.

**Signature**

```
public static Date valueOf(String stringDate)
```

**Parameters**

```
stringDate
    Type: String
```

**Return Value**

Type: Date

**Usage**

The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the local time zone.

**Example**

```
string year = '2008';
string month = '10';
```
string day = '5';
string hour = '12';
string minute = '20';
string second = '20';
string stringDate = year + '-' + month + '-' + day + ' ' + hour + ':' + minute + ':' + second;
Date myDate = date.valueOf(stringDate);

valueOf(fieldValue)
Converts the specified object to a Date. Use this method to convert a history tracking field value or an object that represents a Date value.

Signature
public static Date valueOf(Object fieldValue)

Parameters
 fieldValue
  Type: Object

Return Value
 Type: Date

Usage
Use this method with the OldValue or NewValue fields of history sObjects, such as AccountHistory, when the field is a Date field.

Example
This example converts history tracking fields to Date values.

List<AccountHistory> ahlist = [SELECT Field,OldValue,NewValue FROM AccountHistory];
for(AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'MyDate__c') {
        Date oldValue = Date.valueOf(ah.OldValue);
        Date newValue = Date.valueOf(ah.NewValue);
    }
}

Versioned Behavior Changes
Date.valueOf has been versioned in these releases.
API version 33.0 or earlier
If you call `Date.valueOf` with a `Datetime` object, the method returns a `Date` value that contains the hours, minutes, seconds, and milliseconds set.

API version 34.0 to API version 53.0
If you call `Date.valueOf` with a `Datetime` object, the method converts `Datetime` to a valid `Date` without the time information, but the result depends on the manner in which the `Datetime` object was initialized. For example, if the `Datetime` object was initialized using `Datetime.valueOf(stringDate)`, the returned `Date` value contains time (hours) information. If the `Datetime` object is initialized using `Datetime.newInstance(year, month, day, hour, minute, second)` the returned `Date` value doesn't contain time information.

API version 54.0 and later
If you call `Date.valueOf` with a `Datetime` object, the method converts the object to a valid `Date` without the time information.

`year()`
Returns the year component of a `Date`

Signature
```
public Integer year()
```

Return Value
Type: `Integer`

Example
```
date myDate = date.newInstance(1988, 12, 17);
system.assertEquals(1988, myDate.year());
```

Datetime Class
Contains methods for the `Datetime` primitive data type.

Namespace
`System`

Usage
For more information about the `Datetime`, see `Datetime Data Type`.

Datetime Methods
The following are methods for `Datetime`. 
IN THIS SECTION:

addDays(additionalDays)
Adds the specified number of days to a Datetime.

addHours(additionalHours)
Adds the specified number of hours to a Datetime.

addMinutes(additionalMinutes)
Adds the specified number of minutes to a Datetime.

addMonths(additionalMonths)
Adds the specified number of months to a Datetime.

addSeconds(additionalSeconds)
Adds the specified number of seconds to a Datetime.

addYears(additionalYears)
Adds the specified number of years to a Datetime.

date()
Returns the Date component of a Datetime in the local time zone of the context user.

dateGMT()
Return the Date component of a Datetime in the GMT time zone.

day()
Returns the day-of-month component of a Datetime in the local time zone of the context user.

dayGmt()  
Returns the day-of-month component of a Datetime in the GMT time zone.

dayOfYear()
Returns the day-of-year component of a Datetime in the local time zone of the context user.

dayOfYearGmt()  
Returns the day-of-year component of a Datetime in the GMT time zone.

format()
Converts the date to the local time zone and returns the converted date as a formatted string using the locale of the context user. If the time zone cannot be determined, GMT is used.

format(dateFormatString)
Converts the date to the local time zone and returns the converted date as a string using the supplied Java simple date format. If the time zone cannot be determined, GMT is used.

format(dateFormatString, timezone)
Converts the date to the specified time zone and returns the converted date as a string using the supplied Java simple date format. If the supplied time zone is not in the correct format, GMT is used.

formatGmt(dateFormatString)
Returns a Datetime as a string using the supplied Java simple date format and the GMT time zone.

formatLong()
Converts the date to the local time zone and returns the converted date in long date format.

gTime()
Returns the number of milliseconds since January 1, 1970, 00:00:00 GMT represented by this DateTime object.
hour()
Returns the hour component of a Datetime in the local time zone of the context user.

hourGmt()
Returns the hour component of a Datetime in the GMT time zone.

isSameDay(dateToCompare)
Returns true if the Datetime that called the method is the same as the specified Datetime in the local time zone of the context user.

millisecond()
Returns the millisecond component of a Datetime in the local time zone of the context user.

millisecondGmt()
Returns the millisecond component of a Datetime in the GMT time zone.

minute()
Returns the minute component of a Datetime in the local time zone of the context user.

minuteGmt()
Returns the minute component of a Datetime in the GMT time zone.

month()
Returns the month component of a Datetime in the local time zone of the context user (1=Jan).

monthGmt()
Returns the month component of a Datetime in the GMT time zone (1=Jan).

newInstance(milliseconds)
Constructs a Datetime and initializes it to represent the specified number of milliseconds since January 1, 1970, 00:00:00 GMT.

newInstance(date, time)
Constructs a DateTime from the specified date and time in the local time zone.

newInstance(year, month, day)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the local time zone.

newInstance(year, month, day, hour, minute, second)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), hour, minute, and second in the local time zone.

newInstanceGmt(date, time)
Constructs a DateTime from the specified date and time in the GMT time zone.

newInstanceGmt(year, month, day)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the GMT time zone.

newInstanceGmt(year, month, day, hour, minute, second)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the GMT time zone.

now()
Returns the current Datetime based on a GMT calendar.

parse(datetimeString)
Constructs a Datetime from the given String in the local time zone and in the format of the user locale.

second()
Returns the second component of a Datetime in the local time zone of the context user.
secondGmt()
Returns the second component of a Datetime in the GMT time zone.

time()
Returns the time component of a Datetime in the local time zone of the context user.

timeGmt()
Returns the time component of a Datetime in the GMT time zone.

valueOf(dateTimeString)
Returns a Datetime that contains the value of the specified string.

valueOf(fieldValue)
Converts the specified object to a Datetime. Use this method to convert a history tracking field value or an object that represents a Datetime value.

valueOfGmt(dateTimeString)
Returns a Datetime that contains the value of the specified String.

year()
Returns the year component of a Datetime in the local time zone of the context user.

yearGmt()
Returns the year component of a Datetime in the GMT time zone.

addDays(additionalDays)
Adds the specified number of days to a Datetime.

Signature

public Datetime addDays(Integer additionalDays)

Parameters

additionalDays
Type: Integer

Return Value

Type: Datetime

Example

DateTime myDateTime = Datetime.newInstance(1960, 2, 17);
DateTime newDateTime = myDateTime.addDays(2);
DateTime expected = Datetime.newInstance(1960, 2, 19);
System.assertEquals(expected, newDateTime);

addHours(additionalHours)
Adds the specified number of hours to a Datetime.
Signature

public Datetime addHours(Integer additionalHours)

Parameters

additionalHours
Type: Integer

Return Value

Type: Datetime

Example

DateTime myDateTime = DateTime.newInstance(1997, 1, 31, 7, 8, 16);
DateTime newDateTime = myDateTime.addHours(3);
DateTime expected = DateTime.newInstance(1997, 1, 31, 10, 8, 16);
System.assertEquals(expected, newDateTime);

addMinutes(additionalMinutes)

Adds the specified number of minutes to a Datetime.

Signature

public Datetime addMinutes(Integer additionalMinutes)

Parameters

additionalMinutes
Type: Integer

Return Value

Type: Datetime

Example

DateTime myDateTime = DateTime.newInstance(1999, 2, 11, 8, 6, 16);
DateTime newDateTime = myDateTime.addMinutes(7);
DateTime expected = DateTime.newInstance(1999, 2, 11, 8, 13, 16);
System.assertEquals(expected, newDateTime);

addMonths(additionalMonths)

Adds the specified number of months to a Datetime.

Signature

public Datetime addMonths(Integer additionalMonths)
Parameters

`additionalMonths`

Type: `Integer`

Return Value

Type: `DateTime`

Example

```java
DateTime myDateTime = DateTime.newInstance(2000, 7, 7, 7, 8, 12);
DateTime newDateTime = myDateTime.addMonths(1);
DateTime expected = DateTime.newInstance(2000, 8, 7, 7, 8, 12);
System.assertEquals(expected, newDateTime);
```

`addSeconds(additionalSeconds)`

Adds the specified number of seconds to a Datetime.

Signature

```java
public Datetime addSeconds(Integer additionalSeconds)
```

Parameters

`additionalSeconds`

Type: `Integer`

Return Value

Type: `DateTime`

Example

```java
DateTime myDateTime = DateTime.newInstance(2001, 7, 19, 10, 7, 12);
DateTime newDateTime = myDateTime.addSeconds(4);
DateTime expected = DateTime.newInstance(2001, 7, 19, 10, 7, 16);
System.assertEquals(expected, newDateTime);
```

`addYears(additionalYears)`

Adds the specified number of years to a Datetime.

Signature

```java
public Datetime addYears(Integer additionalYears)
```
Parameters

\texttt{additionalYears}

Type: \texttt{Integer}

Return Value

Type: \texttt{Datetime}

Example

```java
DateTime myDateTime = DateTime.newInstance(2009, 12, 17, 13, 6, 6);
DateTime newDateTime = myDateTime.addYears(1);
DateTime expected = DateTime.newInstance(2010, 12, 17, 13, 6, 6);
System.assertEquals(expected, newDateTime);
```

\texttt{date()}

Returns the Date component of a Datetime in the local time zone of the context user.

Signature

\texttt{public Date date()}

Return Value

Type: \texttt{Date}

Example

```java
DateTime myDateTime = DateTime.newInstance(2006, 3, 16, 12, 6, 13);
Date myDate = myDateTime.date();
Date expected = Date.newInstance(2006, 3, 16);
System.assertEquals(expected, myDate);
```

\texttt{dateGMT()}

Return the Date component of a Datetime in the GMT time zone.

Signature

\texttt{public Date dateGMT()}

Return Value

Type: \texttt{Date}

Example

```java
// California local time, PST
DateTime myDateTime = DateTime.newInstance(2006, 3, 16, 23, 0, 0);
```
Date myDate = myDateTime.dateGMT();
Date expected = Date.newInstance(2006, 3, 17);
System.assertEquals(expected, myDate);

day()
Returns the day-of-month component of a Datetime in the local time zone of the context user.

Signature
public Integer day()

Return Value
Type: Integer

Example
DateTime myDateTime = DateTime.newInstance(1986, 2, 21, 23, 0, 0);
System.assertEquals(21, myDateTime.day());

dayGmt()
Returns the day-of-month component of a Datetime in the GMT time zone.

Signature
public Integer dayGmt()

Return Value
Type: Integer

Example
// California local time, PST
DateTime myDateTime = DateTime.newInstance(1987, 1, 14, 23, 0, 3);
System.assertEquals(15, myDateTime.dayGMT());

dayOfYear()
Returns the day-of-year component of a Datetime in the local time zone of the context user.

Signature
public Integer dayOfYear()

Return Value
Type: Integer
Example

For example, February 5, 2008 08:30:12 would be day 36.

```java
Datetime myDate = Datetime.newInstance(2008, 2, 5, 8, 30, 12);
system.assertEquals(myDate.dayOfYear(), 36);
```

dayOfYearGmt()

Returns the day-of-year component of a Datetime in the GMT time zone.

**Signature**

```java
public Integer dayOfYearGmt()
```

**Return Value**

Type: Integer

**Example**

```java
// This sample assumes we are in the PST timezone
DateTime myDateTime = DateTime.newInstance(1999, 2, 5, 23, 0, 3);
// January has 31 days + 5 days in February = 36 days
// dayOfYearGmt() adjusts the time zone from the current time zone to GMT
// by adding 8 hours to the PST time zone, so it's 37 days and not 36 days
System.assertEquals(37, myDateTime.dayOfYearGmt());
```

format()

Converts the date to the local time zone and returns the converted date as a formatted string using the locale of the context user. If the time zone cannot be determined, GMT is used.

**Signature**

```java
public String format()
```

**Return Value**

Type: String

**Example**

```java
Note: The sample is executed in an org where the “Enable ICU Locale Formats” crucial update is enabled. See https://releasenotes.docs.salesforce.com/en-us/spring20/release-notes/rn_forcecom_globalization_enable_icu_cruc.htm.

DateTime.myDateTime = DateTime.newInstance(1993, 6, 6, 3, 3, 3);
system.assertEquals('6/6/1993, 3:03 AM', mydatetime.format());
```
format(dateFormatString)
Converts the date to the local time zone and returns the converted date as a string using the supplied Java simple date format. If the time zone cannot be determined, GMT is used.

Signature
public String format(String dateFormatString)

Parameters
dateFormatString
Type: String

Return Value
Type: String

Usage
For more information on the Java simple date format, see Java SimpleDateFormat.

Example
```
Datetime myDT = DateTime.newInstance(2022, 5, 4, 19, 37, 55);
String myDate = myDT.format('yyyy-MM-dd h:mm a');
String expected = '2022-05-04 7:37 PM';
System.assertEquals(expected, myDate);
```

format(dateFormatString, timezone)
Converts the date to the specified time zone and returns the converted date as a string using the supplied Java simple date format. If the supplied time zone is not in the correct format, GMT is used.

Signature
public String format(String dateFormatString, String timezone)

Parameters
dateFormatString
Type: String
timezone
Type: String

Valid time zone values for the timezone argument are the time zones of the Java TimeZone class that correspond to the time zones returned by the TimeZone.getAvailableIDs method in Java. We recommend you use full time zone names, not the three-letter abbreviations.
**Return Value**
Type: `String`

**Usage**
For more information on the Java simple date format, see Java `SimpleDateFormat`.

**Example**
This example uses `format` to convert a GMT date to the America/New_York time zone and formats the date using the specified date format.

```java
Datetime GMTDate = Datetime.newInstanceGmt(2011, 6, 1, 12, 1, 5);
String strConvertedDate = GMTDate.format('MM/dd/yyyy HH:mm:ss', 'America/New_York');
// Date is converted to
// the new time zone and is adjusted
// for daylight saving time.
System.assertEquals('06/01/2011 08:01:05', strConvertedDate);
```

**formatGmt(dateFormatString)**
Returns a Datetime as a string using the supplied Java simple date format and the GMT time zone.

**Signature**
```java
public String formatGmt(String dateFormatString)
```

**Parameters**
`dateFormatString`
Type: `String`

**Return Value**
Type: `String`

**Usage**
For more information on the Java simple date format, see Java `SimpleDateFormat`.

**Example**
```java
DateTime myDateTime = DateTime.newInstance(1993, 6, 6, 3, 3, 3);
String formatted = myDateTime.formatGMT('EEE, MMM d yyyy HH:mm:ss');
String expected = 'Sun, Jun 6 1993 10:03:03';
System.assertEquals(expected, formatted);
```
**formatLong()**
Converting the date to the local time zone and returns the converted date in long date format.

**Signature**
```
public String formatLong()
```

**Return Value**
Type: String

**Example**
```java
// Passing local date based on the PST time zone
Datetime dt = DateTime.newInstance(2012,12,28,10,0,0);
// Writes 12/28/2012 10:00:00 AM PST
System.debug('dt.formatLong()=' + dt.formatLong());
```

**getTime()**
Returns the number of milliseconds since January 1, 1970, 00:00:00 GMT represented by this DateTime object.

**Signature**
```
public Long getTime()
```

**Return Value**
Type: Long

**Example**
```java
DateTime dt = DateTime.newInstance(2007, 6, 23, 3, 3, 3);
Long gettime = dt.getTime();
Long expected = 1182592983000L;
System.assertEquals(expected, gettime);
```

**hour()**
Returns the hour component of a Datetime in the local time zone of the context user.

**Signature**
```
public Integer hour()
```

**Return Value**
Type: Integer
Example

```java
DateTime myDateTime = DateTime.newInstance(1998, 11, 21, 3, 3, 3);
System.assertEquals(3 , myDateTime.hour());
```

`hourGmt()`

Returns the hour component of a Datetime in the GMT time zone.

**Signature**

```java
public Integer hourGmt()
```

**Return Value**

Type: `Integer`

Example

```java
// California local time
DateTime myDateTime = DateTime.newInstance(2000, 4, 27, 3, 3, 3);
System.assertEquals(10 , myDateTime.hourGmt());
```

`isSameDay(dateToCompare)`

Returns true if the Datetime that called the method is the same as the specified Datetime in the local time zone of the context user.

**Signature**

```java
public Boolean isSameDay(Datetime dateToCompare)
```

**Parameters**

`dateToCompare`  
Type: `Datetime`

**Return Value**

Type: `Boolean`

Example

```java
datetime myDate = datetime.now();
datetime dueDate =
  datetime.newInstance(2008, 1, 30);
boolean dueNow = myDate.isSameDay(dueDate);
```

`millisecond()`

Return the millisecond component of a Datetime in the local time zone of the context user.
Signature

public Integer millisecond()

Return Value
Type: Integer

Example

DateTime myDateTime = DateTime.now();
system.debug(myDateTime.millisecond());

millisecondGmt()
Return the millisecond component of a DateTime in the GMT time zone.

Signature

public Integer millisecondGmt()

Return Value
Type: Integer

Example

DateTime myDateTime = DateTime.now();
system.debug(myDateTime.millisecondGMT());

minute()
Returns the minute component of a DateTime in the local time zone of the context user.

Signature

public Integer minute()

Return Value
Type: Integer

Example

DateTime myDateTime = DateTime.newInstance(2001, 2, 27, 3, 3, 3);
system.assertEquals(3, myDateTime.minute());

minuteGmt()
Returns the minute component of a DateTime in the GMT time zone.

Signature

public Integer minuteGmt()
Signature

public Integer minuteGmt()

Return Value
Type: Integer

Example

```java
DateTime myDateTime = DateTime.newInstance(2002, 12, 3, 3, 3, 3);
System.assertEquals(3, myDateTime.minuteGMT());
```

**month()**

Returns the month component of a Datetime in the local time zone of the context user (1=Jan).

Signature

public Integer month()

Return Value
Type: Integer

Example

```java
DateTime myDateTime = DateTime.newInstance(2004, 11, 4, 3, 3, 3);
System.assertEquals(11, myDateTime.month());
```

**monthGmt()**

Returns the month component of a Datetime in the GMT time zone (1=Jan).

Signature

public Integer monthGmt()

Return Value
Type: Integer

Example

```java
DateTime myDateTime = DateTime.newInstance(2006, 11, 19, 3, 3, 3);
System.assertEquals(11, myDateTime.monthGmt());
```

**newInstance(milliseconds)**

Constructs a Datetime and initializes it to represent the specified number of milliseconds since January 1, 1970, 00:00:00 GMT.
Signature

public static Datetime newInstance(Long milliseconds)

Parameters

milliseconds
Type: Long

Return Value

Type: Datetime
The returned date is in the GMT time zone.

Example

```
Long longtime = 1341828183000L;
DateTime dt = DateTime.newInstance(longtime);
DateTime expected = DateTime.newInstance(2012, 7, 09, 3, 3, 3);
System.assertEquals(expected, dt);
```

newInstance(date, time)
Constructs a DateTime from the specified date and time in the local time zone.

Signature

public static Datetime newInstance(Date date, Time time)

Parameters

date
Type: Date
time
Type: Time

Return Value

Type: Datetime
The returned date is in the GMT time zone.

Example

```
Date myDate = Date.newInstance(2011, 11, 18);
Time myTime = Time.newInstance(3, 3, 3, 0);
DateTime dt = DateTime.newInstance(myDate, myTime);
DateTime expected = DateTime.newInstance(2011, 11, 18, 3, 3, 3);
System.assertEquals(expected, dt);
```
**newInstance(year, month, day)**

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the local time zone.

**Signature**

```java
public static Datetime newInstance(Integer year, Integer month, Integer day)
```

**Parameters**

- **year**
  - Type: Integer
- **month**
  - Type: Integer
- **day**
  - Type: Integer

**Return Value**

Type: Datetime

The returned date is in the GMT time zone.

**Example**

```java
datetime myDate = datetime.newInstance(2008, 12, 1);
```

**newInstance(year, month, day, hour, minute, second)**

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the local time zone.

**Signature**

```java
public static Datetime newInstance(Integer year, Integer month, Integer day, Integer hour, Integer minute, Integer second)
```

**Parameters**

- **year**
  - Type: Integer
- **month**
  - Type: Integer
- **day**
  - Type: Integer
- **hour**
  - Type: Integer
- **minute**
  - Type: Integer
- **second**
  - Type: Integer
second
Type: Integer

Return Value
Type: Datetime
The returned date is in the GMT time zone.

Example
```
Datetime myDate = Datetime.newInstance(2008, 12, 1, 12, 30, 2);
```

newInstanceGmt(date, time)
Constructs a DateTime from the specified date and time in the GMT time zone.

Signature
```
public static Datetime newInstanceGmt(Date date, Time time)
```

Parameters
- date  
  Type: Date
- time  
  Type: Time

Return Value
Type: Datetime

Example
```
Date myDate = Date.newInstance(2013, 11, 12);
Time myTime = Time.newInstance(3, 3, 3, 0);
DateTime dt = DateTime.newInstanceGMT(myDate, myTime);
DateTime expected = DateTime.newInstanceGMT(2013, 11, 12, 3, 3, 3);
System.assertEquals(expected, dt);
```

newInstanceGmt(year, month, date)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the GMT time zone.

Signature
```
public static Datetime newInstanceGmt(Integer year, Integer month, Integer date)
```
Parameters

*year*
  Type: Integer

*month*
  Type: Integer

$date*$
  Type: Integer

Return Value

Type: Datetime

Example

```java
DateTime dt = DateTime.newInstanceGMT(1996, 3, 22);
```

**newInstanceGmt**(*year*, *month*, *date*, *hour*, *minute*, *second*)

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the GMT time zone

Signature

```java
public static Datetime newInstanceGmt(Integer year, Integer month, Integer date, Integer hour, Integer minute, Integer second)
```

Parameters

*year*
  Type: Integer

*month*
  Type: Integer

$date*$
  Type: Integer

*hour*
  Type: Integer

*minute*
  Type: Integer

*second*
  Type: Integer

Return Value

Type: Datetime
Example

```
//California local time
DateTime dt = DateTime.newInstanceGMT(1998, 1, 29, 2, 2, 3);
DateTime expected = DateTime.newInstance(1998, 1, 28, 18, 2, 3);
System.assertEquals(expected, dt);
```

`now()`

Returns the current Datetime based on a GMT calendar.

Signature

```
public static Datetime now()
```

Return Value

Type: Datetime

The format of the returned datetime is: 'MM/DD/YYYY HH:MM PERIOD'

Example

```
datetime myDateTime = datatime.now();
```

`parse(datatimeString)`

Constructs a Datetime from the given String in the local time zone and in the format of the user locale.

Signature

```
public static Datetime parse(String datatimeString)
```

Parameters

```
datatimeString
    Type: String
```

Return Value

Type: Datetime

The returned date is in the GMT time zone.

Example

This example uses parse to create a Datetime from a date passed in as a string and that is formatted for the English (United States) locale. You may need to change the format of the date string if you have a different locale.
Note: This sample is executed in an org where the “Enable ICU Locale Formats” crucial update is enabled. See https://releasenotes.docs.salesforce.com/en-us/spring20/release-notes/rn_forcecom_globalization_enable_icu_cruc.htm.

```java
Datetime dt = DateTime.parse('10/14/2011, 11:46 AM');
String myDtString = dt.format();
system.assertEquals(myDtString, '10/14/2011, 11:46 AM');
```

**second()**

Returns the second component of a Datetime in the local time zone of the context user.

**Signature**

```java
public Integer second()
```

**Return Value**

Type: Integer

**Example**

```java
DateTime dt = DateTime.newInstanceGMT(1999, 9, 22, 3, 1, 2);
System.assertEquals(2, dt.second());
```

**secondGmt()**

Returns the second component of a Datetime in the GMT time zone.

**Signature**

```java
public Integer secondGmt()
```

**Return Value**

Type: Integer

**Example**

```java
DateTime dt = DateTime.newInstance(2000, 2, 3, 3, 1, 5);
System.assertEquals(5, dt.secondGMT());
```

**time()**

Returns the time component of a Datetime in the local time zone of the context user.

**Signature**

```java
public Time time()
```
Return Value
Type: Time

Example
```java
DateTime dt = DateTime.newInstance(2002, 11, 21, 0, 2, 2);
Time expected = Time.newInstance(0, 2, 2, 0);
System.assertEquals(expected, dt.time());
```

`timeGmt()`
Returns the time component of a Datetime in the GMT time zone.

Signature
```java
public Time timeGmt()
```

Return Value
Type: Time

Example
```java
// This sample is based on the PST time zone
DateTime dt = DateTime.newInstance(2004, 1, 27, 4, 1, 2);
Time expected = Time.newInstance(12, 1, 2, 0);
// 8 hours are added to the time to convert it from
// PST to GMT
System.assertEquals(expected, dt.timeGMT());
```

`valueOf(dateTimeString)`
Returns a Datetime that contains the value of the specified string.

Signature
```java
public static Datetime valueOf(String dateTimeString)
```

Parameters
- `dateTimeString`  
  Type: `String`

Return Value
Type: `Datetime`  
The returned date is in the GMT time zone.
Usage

The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the local time zone.

Example

```java
string year = '2008';
string month = '10';
string day = '5';
string hour = '12';
string minute = '20';
string second = '20';
string stringDate = year + '-' + month + '-' + day + ' ' + hour + ':'
    + minute + ':' + second;
Datetime myDate = Datetime.valueOf(stringDate);
```

valueOf(fieldValue)

Converts the specified object to a Datetime. Use this method to convert a history tracking field value or an object that represents a Datetime value.

Signature

```java
public static Datetime valueOf(Object fieldValue)
```

Parameters

- **fieldValue**
  
  Type: Object

Return Value

Type: Datetime

Usage

Use this method with the **OldValue** or **NewValue** fields of history sObjects, such as **AccountHistory**, when the field is a Date/Time field.

Example

```java
List<AccountHistory> ahlist = [SELECT Field,OldValue,NewValue FROM AccountHistory];
for(AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'MyDatetime__c') {
        Datetime oldValue = Datetime.valueOf(ah.OldValue);
        Datetime newValue = Datetime.valueOf(ah.NewValue);
    }
}
```
valueOfGmt(dateTimeString)
Returns a Datetime that contains the value of the specified String.

Signature

public static Datetime valueOfGmt(String dateTimeString)

Parameters

datTimeString
Type: String

Return Value

Type: Datetime

Usage

The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the GMT time zone.

Example

// California locale time
string year = '2009';
string month = '3';
string day = '5';
string hour = '5';
string minute = '2';
string second = '2';
string stringDate = year + '-' + month + '-' + day + ' ' + hour + ':'
   + minute + ':' + second;

DateTime myDate = Datetime.valueOfGMT(stringDate);

DateTime expected = DateTime.newInstance(2009, 3, 4, 21, 2, 2);
System.assertEquals(expected, myDate);

year()

Returns the year component of a Datetime in the local time zone of the context user.

Signature

public Integer year()
Example

```java
DateTime dt = DateTime.newInstance(2012, 1, 26, 5, 2, 4);
System.assertEquals(2012, dt.year());
```

```
yearGmt()
```

Returns the year component of a Datetime in the GMT time zone.

Signature

```
public Integer yearGmt()
```

Return Value

Type: Integer

Example

```java
DateTime dt = DateTime.newInstance(2012, 10, 4, 6, 4, 6);
System.assertEquals(2012, dt.yearGMT());
```

Decimal Class

Contains methods for the Decimal primitive data type.

Namespace

```
System
```

Usage

Note: Two Decimal objects that are numerically equivalent but differ in scale (such as 1.1 and 1.10) generally do not have the same hashcode. Use caution when such Decimal objects are used in Sets or as Map keys.

For more information on Decimal, see Decimal Data Type.

IN THIS SECTION:

Rounding Mode

Rounding mode specifies the rounding behavior for numerical operations capable of discarding precision.

Decimal Methods

Rounding Mode

Rounding mode specifies the rounding behavior for numerical operations capable of discarding precision.

Each rounding mode indicates how the least significant returned digit of a rounded result is to be calculated. The following are the valid values for `roundingMode`. 
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| CEILING| Rounds towards positive infinity. That is, if the result is positive, this mode behaves the same as the **UP** rounding mode; if the result is negative, it behaves the same as the **DOWN** rounding mode. Note that this rounding mode never decreases the calculated value. For example:  
  - Input number 5.5: **CEILING** round mode result: 6  
  - Input number 1.1: **CEILING** round mode result: 2  
  - Input number -1.1: **CEILING** round mode result: -1  
  - Input number -2.7: **CEILING** round mode result: -2  
  ```java
  Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
  Long[] expected = new Long[]{6, 2, -1, -2};
  for(integer x = 0; x < example.size(); x++){
      System.assertEquals(expected[x],
                           example[x].round(System.RoundingMode.CEILING));
  }
  ```                                                                                                                                                                                                                                                                                                                                                                      |
| DOWN   | Rounds towards zero. This rounding mode always discards any fractions (decimal points) prior to executing. Note that this rounding mode never increases the magnitude of the calculated value. For example:  
  - Input number 5.5: **DOWN** round mode result: 5  
  - Input number 1.1: **DOWN** round mode result: 1  
  - Input number -1.1: **DOWN** round mode result: -1  
  - Input number -2.7: **DOWN** round mode result: -2  
  ```java
  Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
  Long[] expected = new Long[]{5, 1, -1, -2};
  for(integer x = 0; x < example.size(); x++){
      System.assertEquals(expected[x],
                           example[x].round(System.RoundingMode.DOWN));
  }
  ```                                                                                                                                                                                                                                                                                                                                                                      |
| FLOOR  | Rounds towards negative infinity. That is, if the result is positive, this mode behaves the same as the **DOWN** rounding mode; if negative, this mode behaves the same as the **UP** rounding mode. Note that this rounding mode never increases the calculated value. For example:  
  - Input number 5.5: **FLOOR** round mode result: 5  
  - Input number 1.1: **FLOOR** round mode result: 1  
  - Input number -1.1: **FLOOR** round mode result: -2  
  - Input number -2.7: **FLOOR** round mode result: -3  
  ```java
  Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
  Long[] expected = new Long[]{5, 1, -2, -3};
  for(integer x = 0; x < example.size(); x++){
      System.assertEquals(expected[x],
                           example[x].round(System.RoundingMode.FLOOR));
  }
  ```                                                                                                                                                                                                                                                                                                                                                                      |
### HALF_DOWN

Rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case this mode rounds down. This rounding mode behaves the same as the UP rounding mode if the discarded fraction (decimal point) is > 0.5; otherwise, it behaves the same as DOWN rounding mode. For example:

- Input number 5.5: HALF_DOWN round mode result: 5
- Input number 1.1: HALF_DOWN round mode result: 1
- Input number -1.1: HALF_DOWN round mode result: -1
- Input number -2.7: HALF_DOWN round mode result: -3

```java
decimal example = new decimal[]{5.5, 1.1, -1.1, -2.7};
long[] expected = new long[]{5, 1, -1, -3};
for (integer x = 0; x < example.size(); x++) {
    system.assertEquals(expected[x],
        example[x].round(system.roundingmode.half_down));
}
```

### HALF_EVEN

Rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor. This rounding mode behaves the same as the HALF_UP rounding mode if the digit to the left of the discarded fraction (decimal point) is odd. It behaves the same as the HALF_DOWN rounding method if it is even. For example:

- Input number 5.5: HALF_EVEN round mode result: 6
- Input number 1.1: HALF_EVEN round mode result: 1
- Input number -1.1: HALF_EVEN round mode result: -1
- Input number -2.7: HALF_EVEN round mode result: -3

```java

decimal[] example = new decimal[](5.5, 1.1, -1.1, -2.7);
long[] expected = new long[]{6, 1, -1, -3};
for (integer x = 0; x < example.size(); x++) {
    system.assertEquals(expected[x],
        example[x].round(system.roundingmode.half_even));
}
```

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

### HALF_UP

Rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds up. This rounding method behaves the same as the UP rounding method if the discarded fraction (decimal point) is >= 0.5; otherwise, this rounding method behaves the same as the DOWN rounding method. For example:

- Input number 5.5: HALF_UP round mode result: 6
- Input number 1.1: HALF_UP round mode result: 1
- Input number -1.1: HALF_UP round mode result: -1
- Input number -2.7: HALF_UP round mode result: -3

```java

decimal[] example = new decimal[](5.5, 1.1, -1.1, -2.7);
long[] expected = new long[]{6, 1, -1, -3};
for (integer x = 0; x < example.size(); x++) {
    system.assertEquals(expected[x],
        example[x].round(system.roundingmode.half_up));
}
```
**UNNECESSARY**

Asserts that the requested operation has an exact result, which means that no rounding is necessary. If this rounding mode is specified on an operation that yields an inexact result, a `MathException` is thrown. For example:

- Input number 5.5: **UNNECESSARY** round mode result: `MathException`
- Input number 1.1: **UNNECESSARY** round mode result: `MathException`
- Input number 1.0: **UNNECESSARY** round mode result: 1
- Input number -1.0: **UNNECESSARY** round mode result: -1
- Input number -2.2: **UNNECESSARY** round mode result: `MathException`

```java
Decimal example1 = 5.5;
Decimal example2 = 1.0;
system.assertEquals(1,
    example2.round(System.RoundingMode.UNNECESSARY));
try{
    example1.round(System.RoundingMode.UNNECESSARY);
} catch(Exception E) {
    system.assertEquals('System.MathException', E.getTypeName());
}
```

**UP**

Rounds away from zero. This rounding mode always truncates any fractions (decimal points) prior to executing. Note that this rounding mode never decreases the magnitude of the calculated value. For example:

- Input number 5.5: **UP** round mode result: 6
- Input number 1.1: **UP** round mode result: 2
- Input number -1.1: **UP** round mode result: -2
- Input number -2.7: **UP** round mode result: -3

```java
Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
Long[] expected = new Long[]{6, 2, -2, -3};
for(integer x = 0; x < example.size(); x++){
    System.assertEquals(expected[x],
        example[x].round(System.RoundingMode.UP));
}
```

---

**Decimal Methods**

The following are methods for `Decimal`.

**IN THIS SECTION:**

`abs()`

Returns the absolute value of the `Decimal`.

---

3042
divide(divisor, scale)
Divides this Decimal by the specified divisor, and sets the scale, that is, the number of decimal places, of the result using the specified scale.

divide(divisor, scale, roundingMode)
Divides this Decimal by the specified divisor, sets the scale, that is, the number of decimal places, of the result using the specified scale, and if necessary, rounds the value using the rounding mode.

doubleValue()
Returns the Double value of this Decimal.

format()
Returns the String value of this Decimal using the locale of the context user.

intValue()
Returns the Integer value of this Decimal.

longValue()
Returns the Long value of this Decimal.

pow(exponent)
Returns the value of this decimal raised to the power of the specified exponent.

precision()
Returns the total number of digits for the Decimal.

round()
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

round(roundingMode)
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using the rounding mode specified by the rounding mode.

scale()
Returns the scale of the Decimal, that is, the number of decimal places.

setScale(scale)
Returns the Decimal scaled to the specified number of decimal places, using half-even rounding, if necessary. Half-even rounding mode rounds toward the “nearest neighbor.” If both neighbors are equidistant, the number is rounded toward the even neighbor.

setScale(scale, roundingMode)
Returns the Decimal scaled to the specified number of decimal places, using the specified rounding mode, if necessary.

stripTrailingZeros()
Returns the Decimal with any trailing zeros removed.

toPlainString()
Returns the String value of this Decimal, without using scientific notation.

valueOf(doubleToDecimal)
Returns a Decimal that contains the value of the specified Double.

valueOf(longToDecimal)
Returns a Decimal that contains the value of the specified Long.
valueOf(stringToDecimal)
Returns a Decimal that contains the value of the specified String. As in Java, the string is interpreted as representing a signed Decimal.

abs()
Returns the absolute value of the Decimal.

Signature
public Decimal abs()

Return Value
Type: Decimal

Example
Decimal myDecimal = -6.02214129;
System.assertEquals(6.02214129, myDecimal.abs());

divide(divisor, scale)
Divides this Decimal by the specified divisor, and sets the scale, that is, the number of decimal places, of the result using the specified scale.

Signature
public Decimal divide(Decimal divisor, Integer scale)

Parameters
divisor
Type: Decimal
scale
Type: Integer

Return Value
Type: Decimal

Example
Decimal decimalNumber = 19;
Decimal result = decimalNumber.divide(100, 3);
System.assertEquals(0.190, result);

divide(divisor, scale, roundingMode)
Divides this Decimal by the specified divisor, sets the scale, that is, the number of decimal places, of the result using the specified scale, and if necessary, rounds the value using the rounding mode.
Decide Class

**Signature**

public Decimal divide(Decimal divisor, Integer scale, System.RoundingMode roundingMode)

**Parameters**

divisor
  Type: Decimal

scale
  Type: Integer

roundingMode
  Type: System.RoundingMode

**Return Value**

Type: Decimal

**Example**

```java
Decimal myDecimal = 12.4567;
Decimal divDec = myDecimal.divide(7, 2, System.RoundingMode.UP);
System.assertEquals(divDec, 1.78);
```

**doubleValue()**

Returns the Double value of this Decimal.

**Signature**

public Double doubleValue()

**Return Value**

Type: Double

**Example**

```java
Decimal myDecimal = 6.62606957;
Double value = myDecimal.doubleValue();
System.assertEquals(6.62606957, value);
```

**format()**

Returns the String value of this Decimal using the locale of the context user.

**Signature**

public String format()
Return Value
Type: String

Usage
Scientific notation will be used if an exponent is needed.

Example
```java
// U.S. locale
Decimal myDecimal = 12345.6789;
system.assertEquals('12,345.679', myDecimal.format());
```

`intValue()`
Returns the Integer value of this Decimal.

Signature
```java
public Integer intValue()
```

Return Value
Type: Integer

Example
```java
Decimal myDecimal = 1.602176565;
system.assertEquals(1, myDecimal.intValue());
```

`longValue()`
Returns the Long value of this Decimal.

Signature
```java
public Long longValue()
```

Return Value
Type: Long

Example
```java
Decimal myDecimal = 376.730313461;
system.assertEquals(376, myDecimal.longValue());
```

`pow(exponent)`
Returns the value of this decimal raised to the power of the specified exponent.
Signature

public Decimal pow(Integer exponent)

Parameters

exponent
Type: Integer
The value of exponent must be between 0 and 32,767.

Return Value
Type: Decimal

Usage
If you use MyDecimal.pow(0), 1 is returned.
The Math.pow method does accept negative values.

Example

Decimal myDecimal = 4.12;
Decimal powDec = myDecimal.pow(2);
System.assertEquals(powDec, 16.9744);

precision()

Returns the total number of digits for the Decimal.

Signature

public Integer precision()

Return Value
Type: Integer

Example

For example, if the Decimal value was 123.45, precision returns 5. If the Decimal value is 123.123, precision returns 6.

Decimal D1 = 123.45;
Integer precision1 = D1.precision();
System.assertEquals(precision1, 5);
Decimal D2 = 123.123;
Integer precision2 = D2.precision();
System.assertEquals(precision2, 6);
round()

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

**Signature**

```java
public Long round()
```

**Return Value**

Type: `Long`

**Usage**

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

**Example**

```java
Decimal D = 4.5;
Long L = D.round();
System.assertEquals(4, L);

Decimal D1 = 5.5;
Long L1 = D1.round();
System.assertEquals(6, L1);

Decimal D2 = 5.2;
Long L2 = D2.round();
System.assertEquals(5, L2);

Decimal D3 = -5.7;
Long L3 = D3.round();
System.assertEquals(-6, L3);
```

round(roundingMode)

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using the rounding mode specified by the rounding mode.

**Signature**

```java
public Long round(System.RoundingMode roundingMode)
```

**Parameters**

- **roundingMode**
  Type: `System.RoundingMode`
Return Value
Type: Long

scale()
Returns the scale of the Decimal, that is, the number of decimal places.

Signature
public Integer scale()

Return Value
Type: Integer

Example
Decimal myDecimal = 9.27400968;
system.assertEquals(8, myDecimal.scale());

setScale(scale)
Returns the Decimal scaled to the specified number of decimal places, using half-even rounding, if necessary. Half-even rounding mode rounds toward the “nearest neighbor.” If both neighbors are equidistant, the number is rounded toward the even neighbor.

Signature
public Decimal setScale(Integer scale)

Parameters
scale
Type: Integer
The value of scale must be between –33 and 33. If the value of scale is negative, your unscaled value is multiplied by 10 to the power of the negation of scale. For example, after this operation, the value of d is $4 \times 10^{-3}$.

Decimal d = 4000;
d = d.setScale(-3);

Return Value
Type: Decimal

Usage
If you do not explicitly set the scale for a Decimal, the item from which the Decimal is created determines the scale.

- If the Decimal is created as part of a query, the scale is based on the scale of the field returned from the query.
- If the Decimal is created from a String, the scale is the number of characters after the decimal point of the String.
If the Decimal is created from a non-decimal number, the number is first converted to a String. Scale is then set using the number of characters after the decimal point.

Example

```java
Decimal myDecimal = 8.987551787;
Decimal setScaled = myDecimal.setScale(3);
System.assertEquals(8.988, setScaled);
```

**setScale(scale, roundingMode)**

Returns the Decimal scaled to the specified number of decimal places, using the specified rounding mode, if necessary.

**Signature**

```java
public Decimal setScale(Integer scale, System.RoundingMode roundingMode)
```

**Parameters**

- `scale`
  - Type: `Integer`
  - The value of `scale` must be between -33 and 33. If the value of `scale` is negative, your unscaled value is multiplied by 10 to the power of the negation of `scale`. For example, after this operation, the value of `d` is $4 \times 10^{-3}$.

  ```java
  Decimal d = 4000;
  d = d.setScale(-3);
  ```

- `roundingMode`
  - Type: `System.RoundingMode`

**Return Value**

Type: `Decimal`

**Usage**

If you do not explicitly set the scale for a Decimal, the item from which the Decimal is created determines the scale.

- If the Decimal is created as part of a query, the scale is based on the scale of the field returned from the query.
- If the Decimal is created from a String, the scale is the number of characters after the decimal point of the String.
- If the Decimal is created from a non-decimal number, the number is first converted to a String. Scale is then set using the number of characters after the decimal point.

**stripTrailingZeros()**

Returns the Decimal with any trailing zeros removed.

**Signature**

```java
public Decimal stripTrailingZeros()
```
Return Value
Type: Decimal

Example
```java
Decimal myDecimal = 1.10000;
Decimal stripped = myDecimal.stripTrailingZeros();
System.assertEquals(stripped, 1.1);
```

toPlainString()
Returns the String value of this Decimal, without using scientific notation.

Signature
```java
public String toPlainString()
```

Return Value
Type: String

Example
```java
Decimal myDecimal = 12345.6789;
System.assertEquals('12345.6789', myDecimal.toPlainString());
```

valueOf(doubleToDecimal)
Returns a Decimal that contains the value of the specified Double.

Signature
```java
public static Decimal valueOf(Double doubleToDecimal)
```

Parameters
doubleToDecimal
  Type: Double

Return Value
Type: Decimal

Example
```java
Double myDouble = 2.718281828459045;
Decimal myDecimal = Decimal.valueOf(myDouble);
System.assertEquals(2.718281828459045, myDecimal);
```
**valueOf (longToDecimal)**

Returns a Decimal that contains the value of the specified Long.

**Signature**

```java
public static Decimal valueOf(Long longToDecimal)
```

**Parameters**

- `longToDecimal`
  
  Type: Long

**Return Value**

Type: Decimal

**Example**

```java
Long myLong = 299792458;
Decimal myDecimal = Decimal.valueOf(myLong);
System.assertEquals(299792458, myDecimal);
```

**valueOf (stringToDecimal)**

Returns a Decimal that contains the value of the specified String. As in Java, the string is interpreted as representing a signed Decimal.

**Signature**

```java
public static Decimal valueOf(String stringToDecimal)
```

**Parameters**

- `stringToDecimal`
  
  Type: String

**Return Value**

Type: Decimal

**Example**

```java
String temp = '12.4567';
Decimal myDecimal = Decimal.valueOf(temp);
```

**Domain Class**

Represents an existing domain hosted by Salesforce that serves the org or its content. Contains methods to obtain information about these domains, such as the domain type, My Domain name, and sandbox name.
Namespace

System

Usage

Use the Domain class to obtain information about the domains that Salesforce hosts for your org. This class only applies to domains hosted by Salesforce, and can’t be used to generate a new domain.

Example

This code uses the System.DomainParser class to parse a hostname. It then gets the associated domain type.

```java
System.Domain d = DomainParser.parse('mycompany.lightning.force.com');
String myDomainName = d.getMyDomainName();
System.DomainType domainType = d.getDomainType();
```

IN THIS SECTION:

Domain Methods

Domain Methods

The following are methods for Domain.

IN THIS SECTION:

getDomainType()

Returns the domain’s type, such as CONTENT_DOMAIN, EXPERIENCE_CLOUD_SITES_DOMAIN, or LIGHTNING_DOMAIN.

getMyDomainName()

Returns the domain’s My Domain name.

getPackageName()

For a domain that includes the package name, such as a Lightning Component domain or Visualforce page domain, returns the package name. For a domain that doesn’t contain a package name, this method returns null.

g getSandboxName()

For a sandbox org domain, returns the sandbox name. For a production org domain, returns null.

g getSitesSubdomainName()

For a system-managed Experience Cloud site domain or Salesforce Site domain, returns the sites subdomain name. If enhanced domains are enabled, this method always returns null. When enhanced domains are enabled, the org’s My Domain name is the subdomain for the system-managed domains for Experience Cloud sites and Salesforce Sites domains.

getDomainType()

Returns the domain’s type, such as CONTENT_DOMAIN, EXPERIENCE_CLOUD_SITES_DOMAIN, or LIGHTNING_DOMAIN.

Signature

```java
public System.DomainType getDomainType()
```
Return Value
Type: System.DomainType

getMyDomainName()
Returns the domain's My Domain name.

Signature
public String getMyDomainName()

Return Value
Type: String

getPackageName()
For a domain that includes the package name, such as a Lightning Component domain or Visualforce page domain, returns the package name. For a domain that doesn't contain a package name, this method returns null.

Signature
public String getPackageName()

Return Value
Type: String

getSandboxName()
For a sandbox org domain, returns the sandbox name. For a production org domain, returns null.

Signature
public String getSandboxName()

Return Value
Type: String

getSitesSubdomainName()
For a system-managed Experience Cloud site domain or Salesforce Site domain, returns the sites subdomain name. If enhanced domains are enabled, this method always returns null. When enhanced domains are enabled, the org's My Domain name is the subdomain for the system-managed domains for Experience Cloud sites and Salesforce Sites domains.

Signature
public String getSitesSubdomainName()
Return Value
Type: String

DomainCreator Class
Use the DomainCreator class to return a hostname specific to the org. For example, get the org’s Visualforce hostname. Values are returned as a hostname, such as `MyDomainName.lightning.force.com`.

Namespace
System

Examples

This example code fetches the org’s My Domain login hostname and the Visualforce hostname for the `uat` package.

```java
//Get the My Domain login hostname
String myDomainHostname = DomainCreator.getOrgMyDomainHostname();

//Get the Visualforce hostname
String vfHostname = DomainCreator.getVisualforceHostname('uat');
```

In this case, in a production org with a My Domain name of **mycompany**, `myDomainHostname` returns **mycompany.my.salesforce.com**. And in the same production org with enhanced domains, `vfHostname` returns **mycompany--uat.vf.force.com**.

This example code creates a link to a Salesforce Account record. It gets the Lightning hostname associated with this org. It then gets the Account record ID and uses concatenation to build the link URL.

```java
//Get the org’s Lightning hostname
String myLightningHostname = DomainCreator.getLightningHostname();

//Get the ID of a record Account with the name 'Acme'
Account acct = [SELECT Id FROM Account WHERE Name = 'Acme' LIMIT 1];

//Build the URL to view the account record
String fullRecordURL = 'https://' + myLightningHostname + '/lightning/r/Account/' + acct.Id + '/view';
```

IN THIS SECTION:
DomainCreator Methods

DomainCreator Methods
The following are methods for DomainCreator.

IN THIS SECTION:
getContentHostname()
Returns the hostname for content stored in the org, such as files.
getExperienceCloudSitesBuilderHostname()
Returns the hostname to access Experience Builder for the org’s Experience Cloud sites.

getExperienceCloudSitesHostname()
Returns the system-managed hostname for the org’s Experience Cloud sites, such as
ExperienceCloudSitesSubdomainName.force.com. If Digital Experiences aren’t enabled, this method throws an
InvalidParameterValueException.

getExperienceCloudSitesLivePreviewHostname()
Returns the hostname to access Experience Builder Live Preview for the org’s Experience Cloud sites.

getExperienceCloudSitesPreviewHostname()
Returns the hostname to access Experience Builder Preview for the org’s Experience Cloud sites.

getLightningContainerComponentHostname(packageName)
Returns the hostname for the org’s Lightning Container Components.

getLightningHostname()
Returns the hostname for the org’s Lightning pages.

getOrgMyDomainHostname()
Returns the hostname for the org’s My Domain login domain.

getSalesforceSitesHostname()
Returns the hostname for the org’s Salesforce Sites. If Salesforce Sites aren’t enabled, this method throws an
InvalidParameterValueException.

getSetupHostname()
This method is reserved for future use.

getVisualforceHostname(packageName)
Returns the hostname for the org’s Visualforce pages.

getContentHostname()
Returns the hostname for content stored in the org, such as files.

Signature
public static String getContentHostname()  

Return Value
Type: String

gExperienceCloudSitesBuilderHostname()
Returns the hostname to access Experience Builder for the org’s Experience Cloud sites.

Signature
public static String getExperienceCloudSitesBuilderHostname()
Return Value
Type: String

getExperienceCloudSitesHostname()
Returns the system-managed hostname for the org’s Experience Cloud sites, such as
ExperienceCloudSitesSubdomainName.force.com. If Digital Experiences aren’t enabled, this method throws an
InvalidParameterValueException.

Signature
public static String getExperienceCloudSitesHostname()

Return Value
Type: String

getExperienceCloudSitesLivePreviewHostname()
Returns the hostname to access Experience Builder Live Preview for the org’s Experience Cloud sites.

Signature
public static String getExperienceCloudSitesLivePreviewHostname()

Return Value
Type: String

getExperienceCloudSitesPreviewHostname()
Returns the hostname to access Experience Builder Preview for the org’s Experience Cloud sites.

Signature
public static String getExperienceCloudSitesPreviewHostname()

Return Value
Type: String

getLightningContainerComponentHostname(String packageName)
Returns the hostname for the org’s Lightning Container Components.

Signature
public static String getLightningContainerComponentHostname(String packageName)
Parameters

packageName
Type: String
The package name for this component.
If packageName is null, this method uses the org’s namespace prefix as the package name. Otherwise, it uses the default namespace.

Return Value
Type: String

ggetLightningHostname()
Returns the hostname for the org’s Lightning pages.

Signature
public static String getLightningHostname()

Return Value
Type: String

ggetOrgMyDomainHostname()
Returns the hostname for the org’s My Domain login domain.

Signature
public static String getOrgMyDomainHostname()

Return Value
Type: String

ggetSalesforceSitesHostname()
Returns the hostname for the org’s Salesforce Sites. If Salesforce Sites aren’t enabled, this method throws an InvalidParameterValueException.

Signature
public static String getSalesforceSitesHostname()

Return Value
Type: String

ggetSetupHostname()
This method is reserved for future use.
**getVisualforceHostname (packageName)**

Returns the hostname for the org’s Visualforce pages.

**Signature**

```java
public static String getVisualforceHostname(String packageName)
```

**Parameters**

- `packageName`  
  Type: `String`  
  The package name for this component.  
  If `packageName` is `null`, this method uses the org’s namespace prefix as the package name. Otherwise, it uses the default namespace.

**Return Value**

Type: `String`

**DomainParser Class**

Use the DomainParser class to parse a domain that Salesforce hosts for the org and extract information about the domain.

**Namespace**

- `System`

**Examples**

This example code parses the org’s Lightning domain and gets the My Domain name and domain type from the `System.Domain` object.

```java
System.Domain d = DomainParser.parser('mycompany.lightning.force.com');
String myDomainName = d.getMyDomainName();
System.DomainType domainType = d.getDomainType();
```

This example code parses a known Visualforce URL to get the domain type, the org’s My Domain name, and the package name.

```java
//Parse a known URL

//Get the domain type
System.DomainType domainType = domain.getDomainType(); // Returns VISUALFORCE_DOMAIN

//Get the org’s My Domain name
String myDomainName = domain.getMyDomainName(); // Returns mycompany

//Get the package name
String packageName = domain.getPackageName(); // Returns abcpackage
```
IN THIS SECTION:
DomainParser Methods

DomainParser Methods
The following are methods for DomainParser.

parse(hostname)
Parses a passed hostname of a domain that Salesforce hosts for the org, and returns the System.Domain.

Signature
public static System.Domain parse(String hostname)

Parameters
hostname
Type: String
The label that identifies a Salesforce host, including all subdomains but without the protocol, path, or any parameters. For example, mycompany.my.site.com or mycompany--sandbox1.sandbox.my.salesforceforce.com.
If the hostname format is invalid, it isn’t a Salesforce hosted domain, or it isn’t owned by this org, this method throws an InvalidParameterValueException.

Return Value
Type: System.Domain

parse(url)
Parses a passed uniform resource locator (URL) of a domain that Salesforce hosts for the org, and returns the System.Domain.

Signature
public static System.Domain parse(System.Url url)

Parameters
url
Type: System.Url
A uniform resource locator (URL) for a Salesforce org, including all subdomains and the protocol. For example, https://mycompany--sandbox1.sandbox.my.salesforceforce.com.

If the URL format is invalid, it isn’t a Salesforce hosted domain, or it isn’t owned by this org, this method throws an InvalidParameterValueException.

Return Value
Type: System.Domain

DomainType Enum
Specifies the domain type for a System.Domain.

Usage
Use the DomainType enum to obtain the type of a domain parsed through the System.DomainParser class.

Enum Values
The following are the values of the System.DomainType enum. These values only apply to Salesforce-hosted domains.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMS_DOMAIN</td>
<td>Content Management System (CMS) public channel domains.</td>
</tr>
<tr>
<td>CONTENT_DOMAIN</td>
<td>Domains that serve content (files) stored in Salesforce.</td>
</tr>
<tr>
<td>CUSTOMER_360_ADMIN_DOMAIN</td>
<td>Customer 360 Data Manager domains.</td>
</tr>
<tr>
<td>CUSTOMER_360_DOMAIN</td>
<td>Customer 360 Data Manager Admin domains.</td>
</tr>
<tr>
<td>EXPERIENCE_CLOUD_SITES_BUILDER_DOMAIN</td>
<td>Experience Builder for Experience Cloud sites domains.</td>
</tr>
<tr>
<td>EXPERIENCE_CLOUD_SITES_DOMAIN</td>
<td>Salesforce-hosted domains that serve Experience Cloud sites.</td>

</tr>
<tr>
<td>SETUP_DOMAIN</td>
<td>Reserved for future use.</td>
</tr>
<tr>
<td>VISUALFORCE_DOMAIN</td>
<td>Domains that serve Visualforce pages.</td>
</tr>
</tbody>
</table>
Double Class

Contains methods for the Double primitive data type.

Namespace

System

Usage

For more information on Double, see Double Data Type.

Double Methods

The following are methods for Double.

IN THIS SECTION:

- format()
  Returns the String value for this Double using the locale of the context user
- intValue()
  Returns the Integer value of this Double by casting it to an Integer.
- longValue()
  Returns the Long value of this Double.
- round()
  Returns the closest Long to this Double value.
- valueOf(stringToDouble)
  Returns a Double that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal.
- valueOf(fieldValue)
  Converts the specified object to a Double value. Use this method to convert a history tracking field value or an object that represents a Double value.

format()

Returns the String value for this Double using the locale of the context user

Signature

public String format()

Return Value

Type: String
Example

```java
Double myDouble = 1261992;
System.assertEquals('1,261,992', myDouble.format());
```

**intValue()**

Returns the Integer value of this Double by casting it to an Integer.

**Signature**

```java
public Integer intValue()
```

**Return Value**

Type: Integer

**Example**

```java
Double DD1 = Double.valueOf('3.14159');
Integer value = DD1.intValue();
System.assertEquals(value, 3);
```

**longValue()**

Returns the Long value of this Double.

**Signature**

```java
public Long longValue()
```

**Return Value**

Type: Long

**Example**

```java
Double myDouble = 421994;
Long value = myDouble.longValue();
System.assertEquals(421994, value);
```

**round()**

Returns the closest Long to this Double value.

**Signature**

```java
public Long round()
```
Return Value
Type: Long

Example
```
Double D1 = 4.5;
Long L1 = D1.round();
System.assertEquals(5, L1);

Double D2 = 4.2;
Long L2 = D2.round();
System.assertEquals(4, L2);

Double D3 = -4.7;
Long L3 = D3.round();
System.assertEquals(-5, L3);
```

**valueOf**(stringToDouble)
Returns a Double that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal.

Signature
```
public static Double valueOf(String stringToDouble)
```

Parameters
```
stringToDouble
  Type: String
```

Return Value
Type: Double

Example
```
Double DD1 = double.valueOf('3.14159');
```

**valueOf**(fieldValue)
Converts the specified object to a Double value. Use this method to convert a history tracking field value or an object that represents a Double value.

Signature
```
public static Double valueOf(Object fieldValue)
```
Parameters

fieldValue
  Type: Object

Return Value

Type: Double

Usage

Use this method with the OldValue or NewValue fields of history sObjects, such as AccountHistory, when the field type corresponds to a Double type, like a number field.

Example

```java
List<AccountHistory> ahlist =
  [SELECT Field, OldValue, NewValue
   FROM AccountHistory];
for (AccountHistory ah : ahlist) {
  System.debug('Field: ' + ah.Field);
  if (ah.field == 'NumberOfEmployees') {
    Double oldValue =
      Double.valueOf(ah.OldValue);
    Double newValue =
      Double.valueOf(ah.NewValue);
  }
}
```

EmailMessages Class

Use the methods in the EmailMessages class to interact with emails and email threading.

Namespace

System

EmailMessages Methods

The following are static methods for EmailMessages.

IN THIS SECTION:

- `getFormattedThreadingToken(recordId)`
  - Returns an email threading token that’s formatted with the correct prefix and suffix. This token can be embedded in an outbound email body, email subject, or both the body and subject. When users reply to the email, threading tokens can be used to attach responses to a record, such as a Case record in Email-to-Case.

- `getRecordIdFromEmail(subject, textBody, htmlBody)`
  - Returns the record ID corresponding to the specified email threading token, or returns null if none is found.
getFormattedThreadingToken (recordId)

Returns an email threading token that’s formatted with the correct prefix and suffix. This token can be embedded in an outbound email body, email subject, or both the body and subject. When users reply to the email, threading tokens can be used to attach responses to a record, such as a Case record in Email-to-Case.

**Signature**

```java
public static Id getFormattedThreadingToken(Id recordId)
```

**Parameters**

- **recordId**
  - Type: `Id`
  - The record ID associated with the threading token. Only Case record IDs are supported.

**Return Value**

- Type: `String`
  - The returned value is a formatted string that includes a prefix and suffix, for example:

  ```
  thread::pp5XPgfMzNf2hZdRCrNrohc::
  ```

**Usage**

Requires Lightning threading to be enabled in Email-to-Case.

When sending emails in Apex, use the returned string to match emails to a record, such as a Case record, that’s associated with the email thread. Embed the formatted token in the body or subject of outgoing emails. To find the corresponding record ID in incoming emails, use `EmailMessages.getRecordIdFromEmail(subject, textBody, htmlBody)` on page 3067.

**Example**

In this sample, we send an email with a threading token so that the email and any responses are associated with the related case.

```java
// Get your Record ID. Here, we're using a dummy Case ID.
ID caseId = Id.valueOf('500xx000000bpkTAAQ');

// Get the formatted threading token.
String formattedToken = EmailMessages.getFormattedThreadingToken(caseId);

// Create a SingleEmailMessage object.
Messaging.SingleEmailMessage email = new Messaging.SingleEmailMessage();

// Set recipients and other fields.
email.setToAddresses(new String[] {'test@example.com'});

// Append the threading token to the email body (text or html), subject,
// or both body and subject.
email.setPlainTextBody('Test Email Notification text body' + '

' + formattedToken);
email.setHtmlBody('Test Email Notification html body' + '<br><br>' + formattedToken);
email.setSubject('Test Notification ' + '

' + formattedToken + ' ]');

// ............ more fields ............
```
// Send out the email.
Messaging.sendEmail(new Messaging.SingleEmailMessage[]{email});

getRecordIdFromEmail(subject, textBody, htmlBody)

Returns the record ID corresponding to the specified email threading token, or returns null if none is found.

Signature

```java
public static Id getRecordIdFromEmail(String subject, String textBody, String htmlBody)
```

Parameters

- `subject`
  - Type: `String`
  - The subject of the email.

- `textBody`
  - Type: `String`
  - The body of the email in text format.

- `htmlBody`
  - Type: `String`
  - The body of the email in HTML format.

Return Value

- Type: `Id`
- The record ID that corresponds to the embedded threading token.

Usage

Requires Lightning threading to be enabled in Email-to-Case.

When you send emails with threading tokens embedded in the email subject, the email body, or in both the subject and body, most email clients quote the email body and maintain the email subject in a response. This method finds a corresponding record that matches the embedded threading token in a response.

Typically this method is used in Email Services so that you can provide your own handling of inbound emails using Apex code.

Example

If you implement header-based threading in your Email Services currently, we recommend that you use Lightning threading, which combines token-based threading and header-based threading. For header-based threading to continue to work, store emails as EmailMessage records with the MessagedIdentifier field set properly. With Lightning threading, you can use threading tokens as the primary threading method and rely on header-based threading as a fallback, or vice versa.

In this example, we rely on threading tokens and use header-based threading as a fallback.

```java
global class AttachEmailMessageToCaseExample implements Messaging.InboundEmailHandler {
    global Messaging.InboundEmailResult handleInboundEmail(Messaging.inboundEmail email,
```
Messaging.InboundEnvelope env) {

    // Create an InboundEmailResult object for returning the result of the
    // Apex Email Service.
    Messaging.InboundEmailResult result = new Messaging.InboundEmailResult();

    // Try to find the Case ID using threading tokens in email attributes.
    Id caseId = EmailMessages.getRecordIdFromEmail(email.subject, email.plainTextBody, email.htmlBody);

    // If we haven't found the Case ID, try finding it using headers.
    if (caseId == null) {
        caseId = Cases.getCaseIdFromEmailHeaders(email.headers);
    }

    // If a Case isn't found, create a new Case record.
    if (caseId == null) {
        Case c = new Case(Subject = email.subject);
        insert c;
        System.debug('New Case Object: ' + c);
        caseId = c.Id;
    }

    // Process recipients
    String toAddresses;
    if (email.toAddresses != null) {
        toAddresses = String.join(email.toAddresses, '; ');
    }

    // To store an EmailMessage for threading, you need at minimum
    // the Status, the MessageIdentifier, and the ParentId fields.
    EmailMessage em = new EmailMessage(
        Status = '0',
        MessageIdentifier = email.messageId,
        ParentId = caseId,
        // Other important fields.
        FromAddress = email.fromAddress,
        FromName = email.fromName,
        ToAddress = toAddresses,
        TextBody = email.plainTextBody,
        HtmlBody = email.htmlBody,
        Subject = email.subject,
        // Parse thread-index header to remain consistent with Email-to-Case.
        ClientThreadIdentifier = getClientThreadIdentifier(email.headers)
    // Other fields you wish to add.
    );

    // Insert the new EmailMessage.
    insert em;
    System.debug('New EmailMessage Object: ' + em);

    // Set the result to true. No need to send an email back to the user
    // with an error message.
public class ApexEmailService
{
    public static result EmailServiceResult = new result();

    public static void sendEmail(String from, String to, String subject, String body)
    {
        result = new result();
        result.success = true;
        // Return the result for the Apex Email Service.
        return result;
    }

    private String getClientThreadIdentifier(List<Messaging.InboundEmail.Header> headers)
    {
        if (headers == null || headers.size() == 0) return null;
        try {
            for (Messaging.InboundEmail.Header header : headers) {
                if (header.name.equalsIgnoreCase('thread-index')) {
                    Blob threadIndex = EncodingUtil.base64Decode(header.value.trim());
                    return EncodingUtil.convertToHex(threadIndex).substring(0, 44).toUpperCase();
                }
            }
        }
        catch (Exception e){
            return null;
        }
        return null;
    }
}

EncodingUtil Class

Use the methods in the EncodingUtil class to encode and decode URL strings, and convert strings to hexadecimal format.

Namespace

System

Usage

Note: You cannot use the EncodingUtil methods to move documents with non-ASCII characters to Salesforce. You can, however, download a document from Salesforce. To do so, query the ID of the document using the API query call, then request it by ID.

EncodingUtil Methods

The following are methods for EncodingUtil. All methods are static.

IN THIS SECTION:

    base64Decode(inputString)
    Converts a Base64-encoded String to a Blob representing its normal form.

    base64Encode(inputBlob)
    Converts a Blob to an unencoded String representing its normal form.

    convertFromHex(inputString)
    Converts the specified hexadecimal (base 16) string to a Blob value and returns this Blob value.
convertToHex(inputBlob)
Returns a hexadecimal (base 16) representation of the inputBlob. This method can be used to compute the client response (for example, HA1 or HA2) for HTTP Digest Authentication (RFC2617).

urlDecode(inputString, encodingScheme)
Decodes a string in application/x-www-form-urlencoded format using a specific encoding scheme, for example “UTF-8.”

urlEncode(inputString, encodingScheme)
Encodes a string into the application/x-www-form-urlencoded format using a specific encoding scheme, for example “UTF-8.”

### base64Decode(inputString)
Converts a Base64-encoded String to a Blob representing its normal form.

**Signature**

```java
public static Blob base64Decode(String inputString)
```

**Parameters**

- `inputString`
  - Type: `String`

**Return Value**

- Type: `Blob`

### base64Encode(inputBlob)
Converts a Blob to an unencoded String representing its normal form.

**Signature**

```java
public static String base64Encode(Blob inputBlob)
```

**Parameters**

- `inputBlob`
  - Type: `Blob`

**Return Value**

- Type: `String`

### convertFromHex(inputString)
Converts the specified hexadecimal (base 16) string to a Blob value and returns this Blob value.
public static Blob convertFromHex(String inputString)

Parameters
inputString
Type: String
The hexadecimal string to convert. The string can contain only valid hexadecimal characters (0-9, a-f, A-F) and must have an even number of characters.

Return Value
Type: Blob

Usage
Each byte in the Blob is constructed from two hexadecimal characters in the input string.

The convertFromHex method throws the following exceptions.
• NullPointerException — the inputString is null.
• InvalidParameterValueException — the inputString contains invalid hexadecimal characters or doesn’t contain an even number of characters.

Example
Blob blobValue = EncodingUtil.convertFromHex('4A4B4C');
System.assertEquals('JKL', blobValue.toString());

Signature
covnertToHex(Blob inputBlob)

Returns a hexadecimal (base 16) representation of the inputBlob. This method can be used to compute the client response (for example, HA1 or HA2) for HTTP Digest Authentication (RFC2617).

Signature
covnertToHex(String inputBlob)

Parameters
inputBlob
Type: Blob

Return Value
Type: String

urlDecode(inputString, encodingScheme)
Decodes a string in application/x-www-form-urlencoded format using a specific encoding scheme, for example “UTF-8.”
Signature

```java
public static String urlDecode(String inputString, String encodingScheme)
```

Parameters

- `inputString`
  Type: `String`

- `encodingScheme`
  Type: `String`

Return Value

Type: `String`

Usage

This method uses the supplied encoding scheme to determine which characters are represented by any consecutive sequence of the form `"\%xy"`. For more information about the format, see The form-urlencoded Media Type in Hypertext Markup Language - 2.0.

`urlEncode(inputString, encodingScheme)`

Encodes a string into the `application/x-www-form-urlencoded` format using a specific encoding scheme, for example “UTF-8.”

Signature

```java
public static String urlEncode(String inputString, String encodingScheme)
```

Parameters

- `inputString`
  Type: `String`

- `encodingScheme`
  Type: `String`

Return Value

Type: `String`

Usage

This method uses the supplied encoding scheme to obtain the bytes for unsafe characters. For more information about the format, see The form-urlencoded Media Type in Hypertext Markup Language - 2.0.

Example

```java
String encoded = EncodingUtil.urlEncode(url, 'UTF-8');
```
Enum Methods

An enum is an abstract data type with values that each take on exactly one of a finite set of identifiers that you specify. Apex provides built-in enums, such as `LoggingLevel`, and you can define your own enum.

All Apex enums, whether user-defined enums or built-in enums, have these common methods:

- **values**
  
  This method returns the values of the Enum as a list of the same Enum type.

- **valueOf(string enumStr)**
  
  This method converts a specified string to an enum constant value. An exception is thrown if the input string doesn’t match an enum value.

Each Enum value has the following methods that take no arguments.

- **name**
  
  Returns the name of the Enum item as a String.

- **ordinal**
  
  Returns the position of the item, as an Integer, in the list of Enum values starting with zero.

Enum values cannot have user-defined methods added to them.

For more information about Enum, see Enums.

Example

```java
Integer i = StatusCode.DELETE_FAILED.ordinal();
String s = StatusCode.DELETE_FAILED.name();
List<StatusCode> values = StatusCode.values();
StatusCode statusCodeValue = StatusCode.valueOf('delete_failed');
```

EventBus Class

Contains methods for publishing platform events.

Namespace

System

IN THIS SECTION:

  EventBus Methods

SEE ALSO:

  Platform Events Developer Guide: Publishing Platform Events

EventBus Methods

The following are methods for EventBus. All methods are static.
IN THIS SECTION:

**getOperationId(result)**
Returns the event UUID, which identifies a published event message.

**publish(event)**
Publishes the given platform event.

**publish(events)**
Publishes the given list of platform events.

---

**getOperationId(result)**
Returns the event UUID, which identifies a published event message.

**Signature**

```java
public static String getOperationId(Object result)
```

**Parameters**

- **result**
  Type: `Object`
  The `SaveResult` that is returned by the `EventBus.publish` call.

**Return Value**

Type: `String`

---

**publish(event)**
Publishes the given platform event.

**Signature**

```java
public static Database.SaveResult publish(SObject event)
```

**Parameters**

- **event**
  Type: `SObject`
  An instance of a platform event. For example, an instance of `MyEvent__e`. You must first define your platform event object in your org.

**Return Value**

Type: `Database.SaveResult`

The result of publishing the given event. `Database.SaveResult` contains information about whether the operation was successful and the errors encountered. If the `isSuccess()` method returns `true`, the publish request is queued in Salesforce and the event message is published asynchronously. For more information, see **High-Volume Platform Event Persistence**. If `isSuccess()` returns
false, the event publish operation resulted in errors, which are returned in the `Database.Error` object. This method doesn’t throw an exception due to an unsuccessful publish operation.

`Database.SaveResult` also contains the `Id` system field. The `Id` field value isn’t included in the event message delivered to subscribers. It isn’t used to identify an event message, and isn’t always unique.

**Usage**

- The platform event message is published either immediately or after a transaction is committed, depending on the publish behavior you set in the platform event definition. For more information, see Platform Event Fields in the Platform Events Developer Guide.
- Apex governor limits apply. For events configured with the Publish After Commit behavior, each method execution is counted as one DML statement against the Apex DML statement limit. You can check limit usage using the Apex `Limits.getDMLStatements()` on page 3169 method. For events configured with the Publish Immediately behavior, each method execution is counted against a separate event publishing limit of 150 `EventBus.publish()` calls. You can check limit usage using the Apex `Limits.getPublishImmediateDML()` on page 3172 method.

**publish(events)**

Publishes the given list of platform events.

**Signature**

```java
public static List<Database.SaveResult> publish(List<SObject> events)
```

**Parameters**

- `events`
  - Type: `List<SObject>`
  - A list of platform event instances. For example, a list of `MyEvent__e` objects. You must first define your platform event object in your Salesforce org.

**Return Value**

- Type: `List<Database.SaveResult>`
  - A list of results, each corresponding to the result of publishing one event. For each event, `Database.SaveResult` contains information about whether the operation was successful and the errors encountered. If the `isSuccess()` method returns `true`, the publish request is queued in Salesforce and the event message is published asynchronously. For more information, see High-Volume Platform Event Persistence. If `isSuccess()` returns `false`, the publish operation resulted in errors, which are returned in the `Database.Error` object. `EventBus.publish()` can publish some passed-in events, even when other events can’t be published due to errors. The `EventBus.publish()` method doesn’t throw exceptions caused by an unsuccessful publish operation. It’s similar in behavior to the Apex `Database.insert` method when called with the partial success option.

`Database.SaveResult` also contains the `Id` system field. The `Id` field value isn’t included in the event message delivered to subscribers. It isn’t used to identify an event message, and isn’t always unique.

**Usage**

- The platform event message is published either immediately or after a transaction is committed, depending on the publish behavior you set in the platform event definition. For more information, see Platform Event Fields in the Platform Events Developer Guide.
Apex governor limits apply. For events configured with the Publish After Commit behavior, each method execution is counted as one DML statement against the Apex DML statement limit. You can check limit usage using the Apex

`Limits.getDMLStatements()` on page 3169 method. For events configured with the Publish Immediately behavior, each method execution is counted against a separate event publishing limit of 150 `EventBus.publish()` calls. You can check limit usage using the Apex `Limits.getPublishImmediateDML()` on page 3172 method.

### Exception Class and Built-In Exceptions

An exception denotes an error that disrupts the normal flow of code execution. You can use Apex built-in exceptions or create custom exceptions. All exceptions have common methods.

All exceptions support built-in methods for returning the error message and exception type. In addition to the standard `exception` class, there are several different types of exceptions:

The following are exceptions in the `System` namespace.

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>AssertionException</code></td>
<td>A <code>System.assert</code> failure that halts code execution. Optionally contains the custom message specified in the last (<code>msg</code>) argument to the <code>assert()</code> method.</td>
</tr>
<tr>
<td><code>AuraException</code></td>
<td>Legacy Aura-related exception. Use <code>System.AuraHandledException</code> instead.</td>
</tr>
<tr>
<td><code>AuraHandledException</code></td>
<td>Returns a custom error message to a JavaScript controller. See Returning Errors from an Apex Server-Side Controller.</td>
</tr>
<tr>
<td><code>AsyncException</code></td>
<td>Any problem with an asynchronous operation, such as failing to enqueue an asynchronous call.</td>
</tr>
<tr>
<td><code>BigObjectException</code></td>
<td>Any problem with big object records, such as connection timeouts during attempts to access or insert big object records.</td>
</tr>
<tr>
<td><code>CalloutException</code></td>
<td>Any problem with a Web service operation, such as failing to make a callout to an external system.</td>
</tr>
<tr>
<td><code>DataWeaveScriptException</code></td>
<td>Any run-time script errors that occur within DataWeave in Apex.</td>
</tr>
<tr>
<td><code>DmlException</code></td>
<td>Any problem with a DML statement, such as an <code>insert</code> statement missing a required field on a record.</td>
</tr>
<tr>
<td><code>DuplicateMessageException</code></td>
<td>Attempt to enqueue job with duplicate queueable signature</td>
</tr>
<tr>
<td><code>EmailException</code></td>
<td>Any problem with email, such as failure to deliver. For more information, see Outbound Email.</td>
</tr>
<tr>
<td><code>ExternalObjectException</code></td>
<td>Any problem with external object records, such as connection timeouts during attempts to access the data that's stored on external systems.</td>
</tr>
<tr>
<td><code>FinalException</code></td>
<td>Any attempt to mutate a read-only collection or record such as an <code>sObject</code> in an after-update trigger, or a final variable. This exception causes execution to halt.</td>
</tr>
<tr>
<td><code>FlowException</code></td>
<td>Any problem with starting flow interviews from Apex. For example, if an active version of the flow can't be found or it can't be started from Apex.</td>
</tr>
<tr>
<td><code>HandledException</code></td>
<td>A generic handled exception.</td>
</tr>
<tr>
<td>Exception</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IllegalArgumentException</td>
<td>An illegal argument was provided to a method call. For example, a method that requires a non-null argument throws this exception if a null value is passed into the method.</td>
</tr>
<tr>
<td>InvalidHeaderException</td>
<td>An illegal header argument was provided to an Apex REST call. For example, a call to the <code>RestResponse.addHeader(name, value)</code> method throws this exception if the header name is <code>cookie</code>.</td>
</tr>
<tr>
<td>InvalidParameterValueException</td>
<td>This exception is used with both Visualforce pages and Salesforce Functions.</td>
</tr>
<tr>
<td></td>
<td><strong>Visualforce</strong></td>
</tr>
<tr>
<td></td>
<td>The exception is thrown when an invalid parameter is supplied for a method, or any problem is encountered with a URL used with Visualforce pages. For more information on Visualforce, see the Visualforce Developer’s Guide.</td>
</tr>
<tr>
<td></td>
<td><strong>Salesforce Functions</strong></td>
</tr>
<tr>
<td></td>
<td>The exception is thrown when the <code>functionName</code> parameter to <code>Function.get()</code> doesn’t have the correct project name.function name format. For more information on Salesforce functions, see <code>Function.get()</code></td>
</tr>
<tr>
<td>LimitException</td>
<td>A governor limit has been exceeded. This exception can’t be caught.</td>
</tr>
<tr>
<td>JSONException</td>
<td>Any problem with JSON serialization and deserialization operations. For more information, see the methods of <code>System.JSON</code>, <code>System.JSONParser</code>, and <code>System.JSONGenerator</code>.</td>
</tr>
<tr>
<td>ListException</td>
<td>Any problem with a list, such as attempting to access an index that is out of bounds.</td>
</tr>
<tr>
<td>MathException</td>
<td>Any problem with a mathematical operation, such as dividing by zero.</td>
</tr>
<tr>
<td>NoAccessException</td>
<td>Any problem with unauthorized access, such as trying to access an sObject that the current user doesn’t have access to. This exception is used with Visualforce pages. For more information on Visualforce, see the Visualforce Developer’s Guide.</td>
</tr>
<tr>
<td>NoDataFoundException</td>
<td>This exception is used with both Visualforce pages and Salesforce Functions.</td>
</tr>
<tr>
<td></td>
<td><strong>Visualforce</strong></td>
</tr>
<tr>
<td></td>
<td>The exception is thrown with data that doesn’t exist, such as trying to access an sObject that has been deleted. For more information on Visualforce, see the Visualforce Developer’s Guide.</td>
</tr>
<tr>
<td></td>
<td><strong>Salesforce Functions</strong></td>
</tr>
<tr>
<td></td>
<td>The exception is thrown when the project or function name provided in the <code>functionName</code> parameter to the <code>Function.get()</code> method can’t be found. For more information on Salesforce functions, see <code>Function.get()</code></td>
</tr>
<tr>
<td>NoSuchElementException</td>
<td>This exception is thrown if you try to access items that are outside the bounds of a list. This exception is used by the <code>Iterator next</code> method. For example, if <code>iterator.hasNext() == false</code> and you call <code>iterator.next()</code>, this exception is thrown. This exception is also used by the Apex Flex Queue methods and is thrown if you attempt to access a job at an invalid position in the flex queue.</td>
</tr>
<tr>
<td>Exception</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NullPointerException</td>
<td>Any problem with dereferencing null, such as in the following code:</td>
</tr>
<tr>
<td></td>
<td>```java</td>
</tr>
<tr>
<td></td>
<td>String s;</td>
</tr>
<tr>
<td></td>
<td>s.toLowerCase(); // Since s is null, this call causes</td>
</tr>
<tr>
<td></td>
<td>// a NullPointerException</td>
</tr>
<tr>
<td>QueryException</td>
<td>Any problem with SOQL queries, such as assigning a query that returns no</td>
</tr>
<tr>
<td></td>
<td>records or more than one record to a singleton sObject variable.</td>
</tr>
<tr>
<td>RequiredFeatureMissing</td>
<td>A Chatter feature is required for code that has been deployed to an</td>
</tr>
<tr>
<td></td>
<td>organization that doesn't have Chatter enabled.</td>
</tr>
<tr>
<td>SearchException</td>
<td>Any problem with SOSL queries executed with SOAP API search() call, for</td>
</tr>
<tr>
<td></td>
<td>example, when the searchString parameter contains fewer than two characters.</td>
</tr>
<tr>
<td></td>
<td>For more information, see the <a href="#">SOAP API Developer Guide</a>.</td>
</tr>
<tr>
<td>SecurityException</td>
<td>Any problem with static methods in the Crypto utility class. For more</td>
</tr>
<tr>
<td></td>
<td>information, see <a href="#">Crypto Class</a>.</td>
</tr>
<tr>
<td>SerializationException</td>
<td>Any problem with the serialization of data. This exception is used with</td>
</tr>
<tr>
<td></td>
<td>Visualforce pages. For more information on Visualforce, see the [Visualforce</td>
</tr>
<tr>
<td></td>
<td>Developer's Guide](#).</td>
</tr>
<tr>
<td>SObjectException</td>
<td>Any problem with sObject records, such as attempting to change a field in</td>
</tr>
<tr>
<td></td>
<td>an update statement that can only be changed during insert.</td>
</tr>
<tr>
<td>StringException</td>
<td>Any problem with Strings, such as a String that is exceeding your heap size.</td>
</tr>
<tr>
<td>TypeException</td>
<td>Any problem with type conversions, such as attempting to convert the String</td>
</tr>
<tr>
<td></td>
<td>'a' to an Integer using the valueOf method.</td>
</tr>
<tr>
<td>UnexpectedException</td>
<td>A non-recoverable internal error within Salesforce has occurred. This</td>
</tr>
<tr>
<td></td>
<td>exception causes execution to halt. If necessary, contact Salesforce</td>
</tr>
<tr>
<td></td>
<td>Customer Support for more information.</td>
</tr>
<tr>
<td>VisualforceException</td>
<td>Any problem with a Visualforce page. For more information on Visualforce,</td>
</tr>
<tr>
<td></td>
<td>see the <a href="#">Visualforce Developer's Guide</a>.</td>
</tr>
<tr>
<td>XmlException</td>
<td>Any problem with the XmlStream classes, such as failing to read or write</td>
</tr>
<tr>
<td></td>
<td>XML.</td>
</tr>
</tbody>
</table>

The following is an example using the DmlException exception:
```java
Account[] accts = new Account[] {new Account(billingcity = 'San Jose')};
try {
    insert accts;
} catch (System.DmlException e) {
    for (Integer i = 0; i < e.getNumDml(); i++) {
        // Process exception here
        System.debug(e.getDmlMessage(i));
    }
}
```

For exceptions in other namespaces, see:
- [Cache Exceptions](#)
Common Exception Methods

Exception methods are all called by and operate on an instance of an exception. This table describes all instance exception methods. All types of exceptions have these methods in common.

<table>
<thead>
<tr>
<th>Name</th>
<th>Arguments</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getCause</td>
<td></td>
<td>Exception</td>
<td>Returns the cause of the exception as an exception object.</td>
</tr>
<tr>
<td>getLineNumber</td>
<td>Integer</td>
<td>Integer</td>
<td>Returns the line number from where the exception was thrown.</td>
</tr>
<tr>
<td>getMessage</td>
<td>String</td>
<td>String</td>
<td>Returns the error message that displays for the user.</td>
</tr>
<tr>
<td>getStackTraceString</td>
<td></td>
<td>String</td>
<td>Returns the stack trace of a thrown exception as a string.</td>
</tr>
<tr>
<td>getTypeName</td>
<td>String</td>
<td>String</td>
<td>Returns the type of exception, such as DmlException, ListException, MathException, and so on.</td>
</tr>
<tr>
<td>initCause</td>
<td>Exception cause</td>
<td>Void</td>
<td>Sets the cause for this exception, if one hasn’t already been set.</td>
</tr>
<tr>
<td>setMessage</td>
<td>String s</td>
<td>Void</td>
<td>Sets the error message that displays for the user.</td>
</tr>
</tbody>
</table>

DMLException and EmailException Methods

In addition to the common exception methods, DMLException and EmailException have these methods:

<table>
<thead>
<tr>
<th>Name</th>
<th>Arguments</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getDmlFieldName i</td>
<td>Integer i</td>
<td>String []</td>
<td>Returns the names of the field or fields that caused the error described by the $i^{th}$ failed row.</td>
</tr>
<tr>
<td>getDmlFields i</td>
<td>Integer i</td>
<td>Schema.sObjectField []</td>
<td>Returns the field token or tokens for the field or fields that caused the error described by the $i^{th}$ failed row. For more information on field tokens, see Dynamic Apex.</td>
</tr>
<tr>
<td>getDmlId i</td>
<td>Integer i</td>
<td>String</td>
<td>Returns the ID of the failed record that caused the error described by the $i^{th}$ failed row.</td>
</tr>
<tr>
<td>getDmlIndex i</td>
<td>Integer i</td>
<td>Integer</td>
<td>Returns the original row position of the $i^{th}$ failed row.</td>
</tr>
<tr>
<td>getDmlMessage i</td>
<td>Integer i</td>
<td>String</td>
<td>Returns the user message for the $i^{th}$ failed row.</td>
</tr>
<tr>
<td>getDmlStatusCode i</td>
<td>Integer i</td>
<td>String</td>
<td>Deprecated. Use getDmlType instead. Returns the Apex failure code for the $i^{th}$ failed row.</td>
</tr>
</tbody>
</table>
### Description

Returns the value of the System.StatusCode enum. For example:

```java
try {
    insert new Account();
} catch (System.DmlException ex) {
    System.assertEquals(System.StatusCode.REQUIRED_FIELD_MISSING, ex.getDmlType(0));
}
```

For more information about System.StatusCode, see Enums.

### getNumDml

<table>
<thead>
<tr>
<th>Name</th>
<th>Arguments</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getNumDml</td>
<td>Integer</td>
<td>Integer</td>
<td>Returns the number of failed rows for DML exceptions.</td>
</tr>
</tbody>
</table>

### QueryException Method

In addition to the common exception methods, QueryException has this method.

<table>
<thead>
<tr>
<th>Name</th>
<th>Arguments</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getInaccessibleFields</td>
<td>Map on page 3198&lt;String,Set&lt;String&gt;&gt;</td>
<td>Returns a map in which each key is an sObjectType and its corresponding value is the set of inaccessible field names in fully qualified format (Namespace__FieldName__c). Use this method to determine the cause of the QueryException. The returned map contains data only if the method that threw the QueryException is running in user mode (as opposed to the default system mode). In this code sample, it’s assumed that the user doesn’t have field level security access to the Contact.Email and Account.Website fields.</td>
<td></td>
</tr>
</tbody>
</table>

```java
try {
    List<Account> accounts = [SELECT Website, (SELECT Email FROM Contacts) FROM Account WITH USER_MODE];
} catch (QueryException qe) {
    // Handle inaccessible fields
    Map<String, Set<String>> inaccessible = qe.getInaccessibleFields();
    Set<String> accountFields = inaccessible.get('Account');
    Set<String> contactFields = inaccessible.get('Contact');
}
```
FlexQueue Class

Contains methods that reorder batch jobs in the Apex flex queue.

Namespace

System

Usage

You can place up to 100 batch jobs in a holding status for future execution. When system resources become available, the jobs are taken from the top of the Apex flex queue and moved to the batch job queue. Up to five queued or active jobs can be processed simultaneously for each org. When a job is moved out of the flex queue for processing, its status changes from Holding to Queued. Queued jobs are executed when the system is ready to process new jobs.

Use this class's methods to reorder your Holding jobs in the flex queue. As best practice and for safe usage, a FlexQueue reorder method must be the final statement in a transaction.

Example

This example moves a job to the front of the flex queue so that it's executed immediately. The job is moved by calling the System.FlexQueue.moveJobToFront() method with the high priority job ID as the parameter.

```java
ID highPriorityJobId = Database.executeBatch(new HighPriorityBatchClass(), 200);
boolean jobMovedToFrontOfQueue = FlexQueue.moveJobToFront(highPriorityJobId);
```

IN THIS SECTION:

FlexQueue Methods

SEE ALSO:

Monitoring the Apex Flex Queue

Apex Developer Guide: Using Batch Apex

FlexQueue Methods

The following are methods for FlexQueue.

IN THIS SECTION:

moveAfterJob(jobToMoveId, jobInQueueId)

Moves the job with the ID jobToMoveId immediately after the job with the ID jobInQueueId in the flex queue. You can move jobToMoveId forward or backward in the queue. If either job isn't in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if jobToMoveId is already immediately after jobInQueueId, so no change is made.
moveBeforeJob(jobToMoveId, jobInQueueId)
Moves the job with the ID jobToMoveId immediately before the job with the ID jobInQueueId in the flex queue. You can move jobToMoveId forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if jobToMoveId is already immediately before jobInQueueId, so no change is made.

moveJobToEnd(jobId)
Moves the specified job to the end of the flex queue, to index position (size - 1). All jobs after the job’s starting position move one spot forward. If the job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if the job is already at the end of the queue, so no change is made.

moveJobToFront(jobId)
Moves the specified job to the front of the flex queue, to index position 0. All other jobs move back one spot. If the job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if the job is already at the front of the queue, so no change is made.

moveAfterJob (jobToMoveId, jobInQueueId)
Moves the job with the ID jobToMoveId immediately after the job with the ID jobInQueueId in the flex queue. You can move jobToMoveId forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if jobToMoveId is already immediately after jobInQueueId, so no change is made.

Signature
public static Boolean moveAfterJob(Id jobToMoveId, Id jobInQueueId)

Parameters

jobToMoveId
Type: Id
The ID of the job to move.

jobInQueueId
Type: Id
The ID of the job to move after.

Return Value
Type: Boolean

moveBeforeJob (jobToMoveId, jobInQueueId)
Moves the job with the ID jobToMoveId immediately before the job with the ID jobInQueueId in the flex queue. You can move jobToMoveId forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if jobToMoveId is already immediately before jobInQueueId, so no change is made.

Signature
public static Boolean moveBeforeJob(Id jobToMoveId, Id jobInQueueId)
Parameters

jobToMoveId
Type: Id
The ID of the job to move.

jobInQueueId
Type: Id
The ID of the job to use as a reference point.

Return Value
Type: Boolean

moveJobToEnd (jobId)
Moves the specified job the end of the flex queue, to index position \( \text{size} - 1 \). All jobs after the job’s starting position move one spot forward. If the job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if the job is already at the end of the queue, so no change is made.

Signature
public static Boolean moveJobToEnd(Id jobId)

Parameters

jobId
Type: Id
The ID of the job to move.

Return Value
Type: Boolean

moveJobToFront (jobId)
Moves the specified job to the front of the flex queue, to index position 0. All other jobs move back one spot. If the job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if the job is already at the front of the queue, so no change is made.

Signature
public static Boolean moveJobToFront(Id jobId)

Parameters

jobId
Type: Id
The ID of the job to move.
Return Value
Type: Boolean

FeatureManagement Class
Use the methods in the System.FeatureManagement class to check and modify the values of feature parameters, and to show or hide custom objects and custom permissions in your subscribers’ orgs.

Namespace
System

Usage
For information about feature parameters, see Manage Features in Second Generation Managed Packages in the Second-Generation Managed Packaging Developer Guide, or Manage Features in First-Generation Managed Packages in the First-Generation Managed Packaging Developer Guide.

The set methods (setPackageBooleanValue, setPackageDateValue, setPackageIntegerValue) use DML operations on setup sObjects. To learn more about mixing operations in a test, see Mixed DML Operations in Test Methods.

IN THIS SECTION:
FeatureManagement Methods

FeatureManagement Methods
The following are methods for FeatureManagement.

IN THIS SECTION:
changeProtection(apiName, typeApiName, protection)
Hides or reveals custom permissions, or reveals custom objects, in your subscriber’s org.

checkPackageBooleanValue(apiName)
Checks the value__c value of the FeatureParameterBoolean__c record for a feature parameter in your subscriber’s org. You set the record’s value using setPackageBooleanValue(apiName, value).

checkPackageDateValue(apiName)
Checks the value__c value of the FeatureParameterDate__c record for a feature parameter in your subscriber’s org. You can set the record’s value using setPackageDateValue(apiName, value).

checkPackageIntegerValue(apiName)
Checks the value__c value of the FeatureParameterInteger__c record for a feature parameter in your subscriber’s org. You can set the record’s value using setPackageIntegerValue(apiName, value).

checkPermission(apiName)
Checks whether a custom permission is enabled.

setPackageBooleanValue(apiName, value)
Sets the value__c value of the FeatureParameterBoolean__c record for a subscriber-to-LMO feature parameter in your subscriber’s org. You can check the record’s value using checkPackageBooleanValue(apiName).
setPackageDateValue(apiName, value)
Sets the value__c value of the FeatureParameterDate__c record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using checkPackageDateValue(apiName).

setPackageIntegerValue(apiName, value)
Sets the value__c value of the FeatureParameterInteger__c record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using checkPackageIntegerValue(apiName).

changeProtection(apiName, typeApiName, protection)
Hides or reveals custom permissions, or reveals custom objects, in your subscriber's org.

Signature

```
public static void changeProtection(String apiName, String typeApiName, String protection)
```

Parameters

apiName
Type: String
The API name of the custom object or custom permission to show or hide—for example, 'MyCustomObject__c' or 'MyCustomPermission'.

typeApiName
Type: String
The API name of the type that you want to show or hide: 'CustomObject' or 'CustomPermission'.

protection
Type: String
To show a custom object or custom permission, 'Unprotected'.
To hide a custom permission, 'Protected'.

Return Value
Type: void

Usage

⚠️ Warning: For custom permissions, you can toggle the protected value indefinitely. However, after you've released unprotected objects to subscribers, you can't set visibility to Protected. Be sure to protect any custom objects that you want to hide before you release the first package version that contains them.

To hide custom permissions in released packages:

```
FeatureManagement.changeProtection('YourCustomPermissionName', 'CustomPermission', 'Protected');
```
To unhide custom permissions and custom objects in released packages:

```aplex
FeatureManagement.changeProtection('YourCustomPermissionName', 'CustomPermission', 'Unprotected');
FeatureManagement.changeProtection('YourCustomObjectName__c', 'CustomObject', 'Unprotected');
```

### checkPackageBooleanValue(apiName)

Checks the value__c value of the FeatureParameterBoolean__c record for a feature parameter in your subscriber’s org. You set the record’s value using setPackageBooleanValue(apiName, value).

**Signature**

```aplex
public static Boolean checkPackageBooleanValue(String apiName)
```

**Parameters**

- **apiName**
  - Type: String
  - The fullName__c value of the feature parameter whose value you want to check—for example, 'SpecialAccessAvailable'.

**Return Value**

- Type: Boolean
  - The value that’s currently assigned to the value__c field on the FeatureParameterBoolean__c record that associates the feature parameter with its related license.

### checkPackageDateValue(apiName)

Checks the value__c value of the FeatureParameterDate__c record for a feature parameter in your subscriber’s org. You can set the record’s value using setPackageDateValue(apiName, value).

**Signature**

```aplex
public static Date checkPackageDateValue(String apiName)
```

**Parameters**

- **apiName**
  - Type: String
  - The fullName__c value of the feature parameter whose value you want to check—for example, 'TrialExpirationDate'.

**Return Value**

- Type: Date
The value that’s currently assigned to the value__c field on the FeatureParameterDate__c record that associates the feature parameter with its related license.

**checkPackageIntegerValue (apiName)**

Checks the value__c value of the FeatureParameterInteger__c record for a feature parameter in your subscriber’s org. You can set the record’s value using setPackageIntegerValue(apiName, value).

**Signature**

```java
public static Integer checkPackageIntegerValue(String apiName)
```

**Parameters**

- **apiName**
  - Type: String
  - The fullName__c value of the feature parameter whose value you want to check—for example, 'NumberOfLicenses'.

**Return Value**

- Type: Integer
- The value that’s currently assigned to the value__c field on the FeatureParameterInteger__c record that associates the feature parameter with its related license.

**checkPermission (apiName)**

Checks whether a custom permission is enabled.

**Signature**

```java
public static Boolean checkPermission(String apiName)
```

**Parameters**

- **apiName**
  - Type: String
  - The API name of the custom permission to check the value of—for example, 'MyCustomPermission'.

**Return Value**

- Type: Boolean
- Shows whether the permission is enabled (true) or disabled (false).

**setPackageBooleanValue (apiName, value)**

Sets the value__c value of the FeatureParameterBoolean__c record for a subscriber-to-LMO feature parameter in your subscriber’s org. You can check the record’s value using checkPackageBooleanValue (apiName).
setPackageBooleanValue(String apiName, Boolean value)

Parameters

apiName
   Type: String
      The fullName__c value of the feature parameter whose value you want to set—for example, 'SpecialAccessAvailable'.

value
   Type: Boolean
      The value to assign to the value__c field on the FeatureParameterBoolean__c record that associates the feature parameter with its related license.

Return Value

Type: void

setPackageDateValue(String apiName, Date value)

Sets the value__c value of the FeatureParameterDate__c record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using checkPackageDateValue(apiName).

setPackageIntegerValue(String apiName, Integer value)

Sets the value__c value of the FeatureParameterInteger__c record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using checkPackageIntegerValue(apiName).
Signature

public static void setPackageIntegerValue(String apiName, Integer value)

Parameters

apiName
Type: String
The fullName__c value of the feature parameter whose value you want to set—for example, 'NumberOfLicenses'.

value
Type: Integer
The value to assign to the value__c field on the FeatureParameterInteger__c record that associates the feature parameter with its related license.

Return Value
Type: void

Formula Class

Contains the recalculateFormulas method that updates (recalculates) all formula fields on the input SObjects.

Namespace

System

Usage

Recalculate formula fields on new or queried SObjects. If all data is present on the SObjects, SOQL limits are not affected. If the data required to evaluate a formula field is missing, that data is loaded and limits are changed accordingly.

The new formula values are stored in the SObjects themselves and overwrite previous values of formula fields.

Example

Account a = new Account();
a.Name = 'Salesforce';
a.BillingCity = 'San Francisco';
List<Account> accounts = new List<Account>{a};

List<FormulaRecalcResult> results = Formula.recalculateFormulas(accounts);
System.assert(results[0].isSuccess());
// Option 1
System.debug('New value: ' + accounts[0].get('My_Formula_Field__c'));
// Option 2
System.debug('New value: ' + results[0].getSObject().get('My_Formula_Field__c'));
Formula Methods
The following are methods for Formula.

IN THIS SECTION:
recalculateFormulas(sobjects)
Updates (recalculates) all formula fields on the input SObjects.

**recalculateFormulas(sobjects)**
Updates (recalculates) all formula fields on the input SObjects.

**Signature**
```
public static List<System.FormulaRecalcResult> recalculateFormulas(List<SObject> sobjects)
```

**Parameters**

- **sobjects**
  - Type: List<SObject>
  - List of sObjects whose formula fields are to be recalculated.

**Return Value**
Type: List<FormulaRecalcResult Class>

---

**FormulaRecalcFieldError Class**
The return type of the FormulaRecalcResult.getErrors method.

**Namespace**
System

IN THIS SECTION:
FormulaRecalcFieldError Methods

**FormulaRecalcFieldError Methods**
The following are methods for FormulaRecalcFieldError.

IN THIS SECTION:
get Fehler() Returns a message describing the errors encountered during formula recalculation.
getFieldName()
Returns the name of the formula recalculation error field.

getFieldError()
Returns a message describing the errors encountered during formula recalculation.

Signature
public String getFieldName()

Return Value
Type: String

getFieldError()
Returns a message describing the errors encountered during formula recalculation.

Signature
public String getFieldName()

Return Value
Type: String

FormulaRecalcResult Class
The return type of the Formula.recalculateFormulas method.

Namespace
System

Usage
Indicates the result and status of recalculating formulas on a single sObject. Holds a reference to the sObject and a list of all the fields that were recalculated.

Example
This example assumes that you have a formula field called divide__c with formula “1 / LEN(Name).

```java
List<Account> accounts = [SELECT Name FROM Account WHERE Name='Acme'];
accounts[0].Name = '';
List<FormulaRecalcResult> results = Formula.recalculateFormulas(accounts);
FormulaRecalcResult result0 = results[0];
FormulaRecalcFieldError fieldError = result0.getErrors()[0];
```
**FormulaRecalcResult Methods**

The following are methods for `FormulaRecalcResult`.

### getErrors()

If an error occurs during formula recalculation, an array of one or more database error objects, along with error codes and descriptions, is returned.

**Signature**

```java
public List<System.FormulaRecalcFieldError> getErrors()
```

**Return Value**

Type: `List<FormulaRecalcFieldError>`

### getSObject()

Returns the sObject with formulas recalculated.

**Signature**

```java
public SObject getSObject()
```

**Return Value**

Type: `SObject`

### isSuccess()

Returns a Boolean value that is set to `true` if the formula recalculation process completed successfully; otherwise, it is set to `false`.

**Signature**

```java
public boolean isSuccess()
```
Http Class
Use the Http class to initiate an HTTP request and response.

Namespace
System

Http Methods
The following are methods for Http. All are instance methods.

IN THIS SECTION:
- send(request)
  Sends an HttpRequest and returns the response.
- toString()
  Returns a string that displays and identifies the object’s properties.

**send(request)**
Sends an HttpRequest and returns the response.

**Signature**
```
public HttpResponse send(HttpRequest request)
```

**Parameters**
requests

**Request**
Type: System.HttpRequest

**Return Value**
Type: System.HttpResponse

**toString()**
Returns a string that displays and identifies the object’s properties.
HttpCalloutMock Interface

Enables sending fake responses when testing HTTP callouts.

Namespace

System

Usage

For an implementation example, see Testing HTTP Callouts by Implementing the HttpCalloutMock Interface.

HttpCalloutMock Methods

The following are methods for HttpCalloutMock.

IN THIS SECTION:

- respond(request)

Returns an HTTP response for the given request. The implementation of this method is called by the Apex runtime to send a fake response when an HTTP callout is made after Test.setMock has been called.

**respond(request)**

Returns an HTTP response for the given request. The implementation of this method is called by the Apex runtime to send a fake response when an HTTP callout is made after Test.setMock has been called.

**Signature**

public HttpResponse respond(HttpRequest request)

**Parameters**

- request
  Type: System.HttpRequest

**Return Value**

Type: System.HttpResponse
HttpRequest Class

Use the HttpRequest class to programmatically create HTTP requests like GET, POST, PATCH, PUT, and DELETE.

Namespace

System

Usage

Use the XML classes or JSON classes to parse XML or JSON content in the body of a request created by HttpRequest.

Example

The following example illustrates how you can use an authorization header with a request and handle the response.

```java
public class AuthCallout {

    public void basicAuthCallout() {
        HttpRequest req = new HttpRequest();
        req.setEndpoint('http://www.yahoo.com');
        req.setMethod('GET');

        // Specify the required user name and password to access the endpoint
        // As well as the header and header information
        String username = 'myname';
        String password = 'mypwd';

        Blob headerValue = Blob.valueOf(username + ':' + password);
        String authorizationHeader = 'Basic ' + EncodingUtil.base64Encode(headerValue);
        req.setHeader('Authorization', authorizationHeader);

        // Create a new http object to send the request object
        // A response object is generated as a result of the request
        Http http = new Http();
        HTTPResponse res = http.send(req);
        System.debug(res.getBody());
    }
}
```

Note: You can set the endpoint as a named credential URL. A named credential URL contains the scheme `callout://`, the name of the named credential, and an optional path. For example: `callout://My_Named_Credential/some_path`. A named credential specifies the URL of a callout endpoint and its required authentication parameters in one definition. Salesforce manages all authentication for Apex callouts that specify a named credential as the callout endpoint so that your code doesn’t have to. See Named Credentials as Callout Endpoints.
Compression

To compress the data you send, use setCompressed.

```java
HttpRequest req = new HttpRequest();
req.setEndPoint('my_endpoint');
req.setCompressed(true);
req.setBody('some post body');
```

If a response comes back in compressed format, `getBody` recognizes the format, uncompresses it, and returns the uncompressed value.

SEE ALSO:
- Apex Developer Guide: JSON Support
- Apex Developer Guide: XML Support

HttpRequest Constructors

The following are constructors for `HttpRequest`.

IN THIS SECTION:
- HttpRequest()
  - Creates a new instance of the `HttpRequest` class.

HttpRequest()

Creates a new instance of the `HttpRequest` class.

Signature

```java
public HttpRequest()
```

HttpRequest Methods

The following are methods for `HttpRequest`. All are instance methods.

IN THIS SECTION:
- getBody()
  - Retrieves the body of this request.
- getBodyAsBlob()
  - Retrieves the body of this request as a Blob.
getBodyDocument()  
Retrieves the body of this request as a DOM document.

getCompressed()  
If true, the request body is compressed, false otherwise.

getEndpoint()  
Retrieves the URL for the endpoint of the external server for this request.

getHeader(key)  
Retrieves the contents of the request header.

getMethod()  
Returns the type of method used by HttpRequest.

setBody(body)  
Sets the contents of the body for this request.

setBodyAsBlob(body)  
Sets the contents of the body for this request using a Blob.

setBodyDocument(document)  
Sets the contents of the body for this request. The contents represent a DOM document.

setClientCertificate(clientCert, password)  
This method is deprecated. Use setClientCertificateName instead.

setClientCertificateName(certDevName)  
If the external service requires a client certificate for authentication, set the certificate name.

setCompressed(flag)  
If true, the data in the body is delivered to the endpoint in the gzip compressed format. If false, no compression format is used.

setEndpoint(endpoint)  
Specifies the endpoint for this request.

setHeader(key, value)  
Sets the contents of the request header.

setMethod(method)  
Sets the type of method to be used for the HTTP request.

setTimeout(timeout)  
Sets a timeout for the request between 1 and 120,000 milliseconds. The timeout is the maximum time to wait for establishing the HTTP connection. The same timeout is used for waiting for the request to start. When the request is executing, such as retrieving or posting data, the connection is kept alive until the request finishes.

toString()  
Returns a string containing the URL for the endpoint of the external server for this request and the method used, for example, Endpoint=http://YourServer, Method=POST

getBody()  
Retrieves the body of this request.
Signature
public String getBody()

Return Value
Type: String

getBodyAsBlob()
Retrieves the body of this request as a Blob.

Signature
public Blob getBodyAsBlob()

Return Value
Type: Blob

getBodyDocument()
Retrieves the body of this request as a DOM document.

Signature
public Dom.Document getBodyDocument()

Return Value
Type: Dom.Document

Example
Use this method as a shortcut for:

```java
String xml = httpRequest.getBody();
Dom.Document domDoc = new Dom.Document(xml);
```

getCompressed()
If true, the request body is compressed, false otherwise.

Signature
public Boolean getCompressed()

Return Value
Type: Boolean
getEndpoint()
Retrieves the URL for the endpoint of the external server for this request.

Signature
public String getEndpoint()

Return Value
Type: String

getHeader(key)
Retrieves the contents of the request header.

Signature
public String getHeader(String key)

Parameters
key
Type: String

Return Value
Type: String

getMethod()
Returns the type of method used by HttpRequest.

Signature
public String getMethod()

Return Value
Type: String

Usage
Examples of return values:
- DELETE
- GET
- HEAD
- PATCH
- POST
- PUT
setBody (body)
Sets the contents of the body for this request.

Signature
public Void setBody(String body)

Parameters
body
Type: String

Return Value
Type: Void

Usage
Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.
The HTTP request and response sizes count towards the total heap size.

setBodyAsBlob (body)
Sets the contents of the body for this request using a Blob.

Signature
public Void setBodyAsBlob(Blob body)

Parameters
body
Type: Blob

Return Value
Type: Void

Usage
Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.
The HTTP request and response sizes count towards the total heap size.

setBodyDocument (document)
Sets the contents of the body for this request. The contents represent a DOM document.
null

null

null
Parameters

certDevName
Type: String

Return Value
Type: Void

Usage
See Using Certificates with HTTP Requests.

setCompressed(flag)
If true, the data in the body is delivered to the endpoint in the gzip compressed format. If false, no compression format is used.

Signature

class HttpRequest

public Void setCompressed(Boolean flag)

Parameters

flag
Type: Boolean

Return Value
Type: Void

setEndpoint(endpoint)
Specifies the endpoint for this request.

Signature

class HttpRequest

public Void setEndpoint(String endpoint)

Parameters

endpoint
Type: String

Possible values for the endpoint:

- Endpoint URL

  https://my_endpoint.example.com/some_path

- Named credential URL, which contains the scheme callout, the name of the named credential, and, optionally, an appended path

  callout:My_Named_Credential/some_path
Return Value
Type: Void

SEE ALSO:
 Apex Developer Guide: Named Credentials as Callout Endpoints

**setHeader(key, value)**
Sets the contents of the request header.

**Signature**

```java
public Void setHeader(String key, String value)
```

**Parameters**

- **key**
  Type: String
- **value**
  Type: String

**Return Value**
Type: Void

**Usage**
Limit 100 KB.

**setMethod(method)**
Sets the type of method to be used for the HTTP request.

**Signature**

```java
public Void setMethod(String method)
```

**Parameters**

- **method**
  Type: String
  Possible values for the method type include:
  - DELETE
  - GET
  - HEAD
  - PATCH
  - POST
PUT

TRACE

Return Value
Type: Void

Usage
You can also use this method to set any required options.

setTimeout(timeout)
Sets a timeout for the request between 1 and 120,000 milliseconds. The timeout is the maximum time to wait for establishing the HTTP connection. The same timeout is used for waiting for the request to start. When the request is executing, such as retrieving or posting data, the connection is kept alive until the request finishes.

Signature
public Void setTimeout(Integer timeout)

Parameters
timeout
  Type: Integer

Return Value
Type: Void

toString()
Returns a string containing the URL for the endpoint of the external server for this request and the method used, for example, Endpoint=http://YourServer, Method=POST

Signature
public String toString()

Return Value
Type: String

HttpResponse Class
Use the HttpResponse class to handle the HTTP response returned by the Http class.

Namespace
System
Usage

Use the XML classes or JSON Classes to parse XML or JSON content in the body of a response accessed by HttpResponse.

Example

In the following getXmlStreamReader example, content is retrieved via an HTTP callout, then the XML is parsed using the XmlStreamReader class.

```java
public class ReaderFromCalloutSample {
    public void getAndParse() {

        // Get the XML document from the endpoint
        Http http = new Http();
        HttpRequest req = new HttpRequest();
        req.setEndpoint(URL.getOrgDomainUrl().toExternalForm() + '/services/data');
        req.setMethod('GET');
        req.setHeader('Accept', 'application/xml');
        HttpResponse res = http.send(req);

        // Log the XML content
        System.debug(res.getBody());

        // Generate the HTTP response as an XML stream
        XmlStreamReader reader = res.getXmlStreamReader();

        // Read through the XML
        while(reader.hasNext()) {
            System.debug('Event Type:' + reader.getEventType());
            if (reader.getEventType() == XmlTag.START_ELEMENT) {
                System.debug(reader.getLocalName());
            }
            reader.next();
        }
    }
}
```

SEE ALSO:

Apex Developer Guide: JSON Support
Apex Developer Guide: XML Support

HttpResponse Methods

The following are methods for HttpResponse. All are instance methods.

IN THIS SECTION:

getBody()
Retrieves the body returned in the response.
getBodyAsBlob()
Retrieves the body returned in the response as a Blob.

getBodyDocument()
Retrieves the body returned in the response as a DOM document.

getHeader(key)
Retrieves the contents of the response header.

getHeaderKeys()
Retrieves an array of header keys returned in the response.

getStatus()
Retrieves the status message returned for the response.

getStatusCode()
Retrieves the value of the status code returned in the response.

getXmlStreamReader()
Returns an `XmlStreamReader` that parses the body of the callout response.

setBody(body)
Specifies the body returned in the response.

setBodyAsBlob(body)
Specifies the body returned in the response using a Blob.

setHeader(key, value)
Specifies the contents of the response header.

setStatus(status)
Specifies the status message returned in the response.

setStatusCode(statusCode)
Specifies the value of the status code returned in the response.

toString()
Returns the status message and status code returned in the response, for example:

得到体()  
Retrieves the body returned in the response.

**Signature**

```java
public String getBody()
```

**Return Value**

Type: String

**Usage**

Limit 6 MB for synchronous Apex or 12 MB for asynchronous Apex. The HTTP request and response sizes count towards the total heap size.
getBodyAsBlob()  
Retrieves the body returned in the response as a Blob.

Signature

```java
public Blob getBodyAsBlob()
```

Return Value

Type: Blob

Usage

Limit 6 MB for synchronous Apex or 12 MB for asynchronous Apex. The HTTP request and response sizes count towards the total heap size.

g gotBodyDocument()  
Retrieves the body returned in the response as a DOM document.

Signature

```java
public Dom.Document getBodyDocument()
```

Return Value

Type: Dom.Document

Example

Use it as a shortcut for:

```java
String xml = httpResponse.getBody();
Dom.Document domDoc = new Dom.Document(xml);
```

g getHeader(key)  
Retrieves the contents of the response header.

Signature

```java
public String getHeader(String key)
```

Parameters

```java
key
  Type: String
```

Return Value

Type: String
**getHeaderKeys()**
Retrieves an array of header keys returned in the response.

**Signature**

```java
public String[] getHeaderKeys()
```

**Return Value**
Type: String[]

**getStatus()**
Retrieves the status message returned for the response.

**Signature**

```java
public String getStatus()
```

**Return Value**
Type: String

**getStatusCode()**
Retrieves the value of the status code returned in the response.

**Signature**

```java
public Integer getStatusCode()
```

**Return Value**
Type: Integer

**getXmlStreamReader()**
Returns an XmlStreamReader that parses the body of the callout response.

**Signature**

```java
public XmlStreamReader getXmlStreamReader()
```

**Return Value**
Type: System.XmlStreamReader
Usage

Use it as a shortcut for:

```java
String xml = httpResponse.getBody();
XmlStreamReader xsr = new XmlStreamReader(xml);
```

**setBody (body)**

Specifies the body returned in the response.

**Signature**

```java
public Void setBody(String body)
```

**Parameters**

- `body`
  - Type: String

**Return Value**

Type: Void

**setBodyAsBlob (body)**

Specifies the body returned in the response using a Blob.

**Signature**

```java
public Void setBodyAsBlob(Blob body)
```

**Parameters**

- `body`
  - Type: Blob

**Return Value**

Type: Void

**setHeader (key, value)**

Specifies the contents of the response header.

**Signature**

```java
public Void setHeader(String key, String value)
```
Parameters

key
  Type: String
value
  Type: String

Return Value
Type: Void

**setStatus (status)**
Specifies the status message returned in the response.

**Signature**

```
public Void setStatus(String status)
```

Parameters

status
  Type: String

Return Value
Type: Void

**setStatusCode (statusCode)**
Specifies the value of the status code returned in the response.

**Signature**

```
public Void setStatusCode(Integer statusCode)
```

Parameters

statusCode
  Type: Integer

Return Value
Type: Void

**toString()**
Returns the status message and status code returned in the response, for example:
Apex Reference Guide

Id Class

Signature
public String toString()

Return Value
Type: String

Example
Status=OK, StatusCode=200

Id Class
Contains methods for the ID primitive data type.

Namespace
System

Example: Getting an sObject Token From an ID
This sample shows how to use the getSObjectType method to obtain an sObject token from an ID. The updateOwner method
in this sample accepts a list of IDs of the sObjects to update the ownerId field of. This list contains IDs of sObjects of the same type. The
second parameter is the new owner ID. Note that since it is a future method, it doesn’t accept sObject types as parameters; this is why
it accepts IDs of sObjects. This method gets the sObject token from the first ID in the list, then does a describe to obtain the object name
and constructs a query dynamicallly. It then queries for all sObjects and updates their owner ID fields to the new owner ID.
public class MyDynamicSolution {
@future
public static void updateOwner(List<ID> objIds, ID newOwnerId) {
// Validate input
System.assert(objIds != null);
System.assert(objIds.size() > 0);
System.assert(newOwnerId != null);
// Get the sObject token from the first ID
// (the List contains IDs of sObjects of the same type).
Schema.SObjectType token = objIds[0].getSObjectType();
// Using the token, do a describe
// and construct a query dynamically.
Schema.DescribeSObjectResult dr = token.getDescribe();
String queryString = 'SELECT ownerId FROM ' + dr.getName() +
' WHERE ';
for(ID objId : objIds) {
queryString += 'Id=\'' + objId + '\' OR ';
}
// Remove the last ' OR'
queryString = queryString.subString(0, queryString.length() - 4);
sObject[] objDBList = Database.query(queryString);

3111


System.assert(objDBList.size() > 0);

// Update the owner ID on the sObjects
for(Integer i=0;i<objDBList.size();i++) {
  objDBList[i].put('ownerId', newOwnerId);
}

Database.SaveResult[] srList = Database.update(objDBList, false);
for(Database.SaveResult sr : srList) {
  if (sr.isSuccess()) {
    System.debug('Updated owner ID successfully for ' +
    dr.getName() + ' ID ' + sr.getId());
  }
  else {
    System.debug('Updating ' + dr.getName() + ' returned the following errors.');
    for(Database.Error e : sr.getErrors()) {
      System.debug(e.getMessage());
    }
  }
}

Id Methods
The following are methods for Id.

IN THIS SECTION:
  addError(errorMsg)
  Marks a trigger record with a custom error message and prevents any DML operation from occurring.
  addError(errorMsg, escape)
  Marks a trigger record with a custom error message, specifies if the error message should be escaped, and prevents any DML operation from occurring.
  addError(exceptionError)
  Marks a trigger record with a custom error message and prevents any DML operation from occurring.
  addError(exceptionError, escape)
  Marks a trigger record with a custom error message and prevents any DML operation from occurring.
  getSObjectType()
  Returns the token for the sObject corresponding to this ID. This method is primarily used with describe information.
  to15(Id)
  Converts an 18-character Id value to a 15-character case-sensitive string.
  valueOf(toID)
  Converts the specified String into an ID and returns the ID.
  valueOf(str, restoreCasing)
  Converts the specified string into an ID and returns the ID. If restoreCasing is true, and the string represents an 18-character ID that has incorrect casing, the method returns an 18-character ID that is correctly aligned with its encoded casing.
addError(errorMsg)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature
public Void addError(String errorMsg)

Parameters
errorMsg
Type: String
The error message to mark the record with.

Return Value
Type: Void

Usage
This method is similar to the addError(errorMsg) sObject method.

Note: This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &", \, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

Example
Trigger.new[0].Id.addError('bad');

addError(errorMsg, escape)
Marks a trigger record with a custom error message, specifies if the error message should be escaped, and prevents any DML operation from occurring.

Signature
public Void addError(String errorMsg, Boolean escape)

Parameters
errorMsg
Type: String
The error message to mark the record with.

escape
Type: Boolean
Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false). This parameter is ignored in both Lightning Experience and the Salesforce mobile app, and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.
Return Value
Type: Void

Usage
The escaped characters are: \n, <, >, &", \, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

⚠️ Warning: Be cautious if you specify false for the escape argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a false escape argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify true for the escape argument or call addError(String errorMsg) instead.

Example
Trigger.new[0].Id.addError('Fix & resubmit', false);

addError(exceptionError)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature
public Void addError(Exception exceptionError)

Parameters
exceptionError
Type: System.Exception
An Exception object or a custom exception object that contains the error message to mark the record with.

Return Value
Type: Void

Usage
This method is similar to the addError(exceptionError) sObject method.
This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &", \, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

Example
public class MyException extends Exception{}
Trigger.new[0].Id.addError(new MyException('Invalid Id'));
addError(exceptionError, escape)
 Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature

```java
class MyException extends Exception{}
```n
account a = new account();
a.addError(new MyException('Invalid Id & other issues'), false);

getSObjectType()

Returns the token for the sObject corresponding to this ID. This method is primarily used with describe information.

Signature

```java
public Schema.SObjectType getSObjectType()
```
Return Value
Type: Schema.SObjectType

Usage
For more information about describes, see Understanding Apex Describe Information.

Example
```java
account a = new account(name = 'account');
insert a;
Id myId = a.id;
system.assertEquals(Schema.Account.SObjectType, myId.getSobjectType());
```

tol5(Id)
Converts an 18-character Id value to a 15-character case-sensitive string.

Signature
```java
public static string to15()
```

Return Value
Type: String

Example
```java
String Id_15_char = '0D5B000001DVM9t';
String Id_18_char = '0D5B000001DVM9tkAh';
ID testId = Id_18_char;
System.assertEquals(testId.to15(),Id_15_char);
```

valueOf(toID)
Converts the specified String into an ID and returns the ID.

Signature
```java
public static ID valueOf(String toID)
```

Parameters
```java
toID
  Type: String
```

Return Value
Type: ID
Example

Id myId = Id.valueOf('001xa00003D1lo');

Versioned Behavior Changes
In API version 54.0 and later, assignment of an invalid 15 or 18 character ID to a variable results in a System.StringException exception.

valueOf(str, restoreCasing)
Converts the specified string into an ID and returns the ID. If restoreCasing is true, and the string represents an 18-character ID that has incorrect casing, the method returns an 18-character ID that is correctly aligned with its encoded casing.

Signature
public static Id valueOf(String str, Boolean restoreCasing)

Parameters
str
Type: String
String to be converted to an ID
restoreCasing
Type: Boolean
If set to true, and str represents an 18-character ID that has incorrect casing, the method returns an 18-character ID that is correctly aligned with its casing.

Return Value
Type: Id
The return value depends on both the str and the restoreCasing parameter values.

⚠️ Note: If the str is invalid, the method throws a System.StringException exception.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>restoreCasing=true</th>
<th>restoreCasing=false</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid 15-character str value</td>
<td>Because the 15-character input value can't be encoded for casing, the method throws a System.StringException.</td>
<td>The method returns a 15-character ID.</td>
</tr>
<tr>
<td>Valid 18-character str value</td>
<td>The method returns an 18-character ID that is correctly aligned with its encoded casing.</td>
<td>The method doesn't attempt to correctly align the casing of the 18-character ID and returns an 18-character ID.</td>
</tr>
</tbody>
</table>

Ideas Class
Represents zone ideas.
Namespace

System

Usage

Ideas is a zone of users who post, vote for, and comment on ideas. An Ideas zone provides an online, transparent way for you to attract, manage, and showcase innovation.

A set of recent replies (returned by methods, see below) includes ideas that a user posted or commented on that already have comments posted by another user. The returned ideas are listed based on the time of the last comment made by another user, with the most recent ideas appearing first.

The userID argument is a required argument that filters the results so only the ideas that the specified user has posted or commented on are returned.

The communityID argument filters the results so only the ideas within the specified zone are returned. If this argument is the empty string, then all recent replies for the specified user are returned regardless of the zone.

For more information on ideas, see “Using Ideas” in the Salesforce online help.

Example

The following example finds ideas in a specific zone that have similar titles as a new idea:

```java
public class FindSimilarIdeasController {

    public static void test() {
        // Instantiate a new idea
        Idea idea = new Idea();

        // Specify a title for the new idea
        idea.Title = 'Increase Vacation Time for Employees';

        // Specify the communityID (INTERNAL_IDEAS) in which to find similar ideas.
        Community community = [ SELECT Id FROM Community WHERE Name = 'INTERNAL_IDEAS' ];

        idea.CommunityId = community.Id;

        ID[] results = Ideas.findSimilar(idea);
    }
}
```

The following example uses a Visualforce page in conjunction with a custom controller, that is, a special Apex class. For more information on Visualforce, see the Visualforce Developer’s Guide.

This example creates an Apex method in the controller that returns unread recent replies. You can leverage this same example for the getAllRecentReplies and getReadRecentReplies methods. For this example to work, there must be ideas posted to the zone. In addition, at least one zone member must have posted a comment to another zone member’s idea or comment.

```java
// Create an Apex method to retrieve the recent replies marked as unread in all communities
public Idea[] getUnreadRecentReplies() {
    Idea[] recentReplies;
    if (recentReplies == null) {
```
Id[] recentRepliesIds = Ideas.getUnreadRecentReplies(UserInfo.getUserId(), '');

recentReplies = [SELECT Id, Title FROM Idea WHERE Id IN :recentRepliesIds];

return recentReplies;

The following is the markup for a Visualforce page that uses the above custom controller to list unread recent replies.

```
<apex:page controller="IdeasController" showHeader="false">
    <apex:dataList value="{!unreadRecentReplies}" var="recentReplyIdea">
        <a href="/apex/viewIdea?id={!recentReplyIdea.Id}"
            <apex:outputText value="{!recentReplyIdea.Title}" escape="true"/>
    </apex:dataList>
</apex:page>
```

The following example uses a Visualforce page in conjunction with a custom controller to list ideas. Then, a second Visualforce page and custom controller is used to display a specific idea and mark it as read. For this example to work, there must be ideas posted to the zone.

```
// Create a controller to use on a VisualForce page to list ideas
public class IdeaListController {
    public final Idea[] ideas {get; private set;}

    public IdeaListController() {
        Integer i = 0;
        ideas = new Idea[10];
        for (Idea tmp : Database.query
            ('SELECT Id, Title FROM Idea WHERE Id != null AND parentIdeaId = null LIMIT 10')) {
            i++;
            ideas.add(tmp);
        }
    }
}
```

The following is the markup for a Visualforce page that uses the above custom controller to list ideas:

```
<apex:page controller="IdeaListController" tabStyle="Idea" showHeader="false">
    <apex:dataList value="{!ideas}" var="idea" id="ideaList">
        <a href="/apex/viewIdea?id={!idea.id}"
            <apex:outputText value="{!idea.title}" escape="true"/>
    </apex:dataList>
</apex:page>
```

The following example also uses a Visualforce page and custom controller, this time, to display the idea that is selected on the above idea list page. In this example, the markRead method marks the selected idea and associated comments as read by the user that is currently logged in. Note that the markRead method is in the constructor so that the idea is marked read immediately when the user

3119
goes to a page that uses this controller. For this example to work, there must be ideas posted to the zone. In addition, at least one zone member must have posted a comment to another zone member's idea or comment.

```java
// Create an Apex method in the controller that marks all comments as read for the
// selected idea
public class ViewIdeaController {
    private final String id = System.currentPage().getParameters().get('id');

    public ViewIdeaController(ApexPages.StandardController controller) {
        Ideas.markRead(id);
    }
}
```

The following is the markup for a Visualforce page that uses the above custom controller to display the idea as read.

```xml
<apex:page standardController="Idea" extensions="ViewIdeaController" showHeader="false">
    <h2><apex:outputText value="{!idea.title}" /></h2>
    <apex:outputText value="{!idea.body}" />
</apex:page>
```

### Ideas Methods

The following are methods for Ideas. All methods are static.

**IN THIS SECTION:**
- **findSimilar(idea)**
  - Returns a list of similar ideas based on the title of the specified idea.
- **getAllRecentReplies(userID, communityID)**
  - Returns ideas that have recent replies for the specified user or zone. This includes all read and unread replies.
- **getReadRecentReplies(userID, communityID)**
  - Returns ideas that have recent replies marked as read.
- **getUnreadRecentReplies(userID, communityID)**
  - Returns ideas that have recent replies marked as unread.
- **markRead(ideaID)**
  - Marks all comments as read for the user that is currently logged in.

#### findSimilar(idea)

Returns a list of similar ideas based on the title of the specified idea.

**Signature**

```java
public static ID[] findSimilar(Idea idea)
```
Parameters

idea
    Type: Idea

Return Value

Type: ID[]

Usage

Each findSimilar call counts against the SOSL query limits. See Execution Governors and Limits.

getAllRecentReplies(userID, communityID)

Returns ideas that have recent replies for the specified user or zone. This includes all read and unread replies.

Signature

public static ID[] getAllRecentReplies(String userID, String communityID)

Parameters

userID
    Type: String

communityID
    Type: String

Return Value

Type: ID[]

Usage

Each getAllRecentReplies call counts against the SOQL query limits. See Execution Governors and Limits.

getReadRecentReplies(userID, communityID)

Returns ideas that have recent replies marked as read.

Signature

public static ID[] getReadRecentReplies(String userID, String communityID)

Parameters

userID
    Type: String

communityID
    Type: String
Return Value
Type: ID[]

Usage
Each `getReadRecentReplies` call counts against the SOQL query limits. See Execution Governors and Limits.

`getUnreadRecentReplies(userID, communityID)`
Returns ideas that have recent replies marked as unread.

Signature
```java
public static ID[] getUnreadRecentReplies(String userID, String communityID)
```

Parameters
- `userID`
  Type: String
- `communityID`
  Type: String

Return Value
Type: ID[]

Usage
Each `getUnreadRecentReplies` call counts against the SOQL query limits. See Execution Governors and Limits.

`markRead(ideaID)`
Marks all comments as read for the user that is currently logged in.

Signature
```java
public static Void markRead(String ideaID)
```

Parameters
- `ideaID`
  Type: String

Return Value
Type: Void

InstallHandler Interface
Enables custom code to run after a managed package installation or upgrade.
App developers can implement this interface to specify Apex code that runs automatically after a subscriber installs or upgrades a managed package. The package install or upgrade can be customized based on details of the subscriber's organization. For instance, you can use the script to populate custom settings, create sample data, send an email to the installer, notify an external system, or kick off a batch operation to populate a new field across a large set of data.

The post install script is invoked after tests have been run, and is subject to default governor limits. It runs as a special system user that represents your package, so all operations performed by the script appear to be done by your package. You can access this user by using UserInfo. You only see this user at runtime, not while running tests.

If the script fails, the install or upgrade is aborted. Any errors in the script are emailed to the user specified in the Notify on Apex Error field of the package. If no user is specified, the install or upgrade details are unavailable.

The post install script has the following additional properties.

- It can initiate batch, scheduled, and future jobs.
- It can’t access Session IDs.
- It can only perform callouts using an async operation. The callout occurs after the script is run and the install is complete and committed.
- It can’t call another Apex class in the package if that Apex class uses the with sharing keyword. This keyword can prevent the package from successfully installing. See the Apex Developer Guide to learn more.

The InstallHandler interface has a single method called onInstall, which specifies the actions to be performed on install or upgrade.

```java
public interface InstallHandler {
    void onInstall(InstallContext context);
}
```

The onInstall method takes a context object as its argument, which provides the following information.

- The org ID of the organization in which the installation takes place.
- The user ID of the user who initiated the installation.
- The version number of the previously installed package (specified using the Version class). The version is always a three-part number, such as 1.2.0.
- Whether the installation is an upgrade.
- Whether the installation is a push.

The context argument is an object whose type is the InstallContext interface. This interface is automatically implemented by the system. The following definition of the InstallContext interface shows the methods you can call on the context argument.

```java
public interface InstallContext {
    ID organizationId();
    ID installerId();
    Boolean isUpgrade();
    Boolean isPush();
    Version previousVersion();
}
```
InstallHandler Methods

The following are methods for InstallHandler.

onInstall(context)
Specifies the actions to be performed on install/upgrade.

Signature
public Void onInstall(InstallContext context)

Parameters
context
Type: System.InstallContext

Return Value
Type: Void

InstallHandler Example Implementation

The following sample post install script performs these actions on package install/upgrade.

• If the previous version is null, that is, the package is being installed for the first time, the script:
  – Creates a new Account called Newco and verifies that it was created.
  – Creates a new instance of the custom object Survey, called Client Satisfaction Survey.
  – Sends an email message to the subscriber confirming installation of the package.

• If the previous version is 1.0, the script creates a new instance of Survey called "Upgrading from Version 1.0".

• If the package is an upgrade, the script creates a new instance of Survey called "Sample Survey during Upgrade".

• If the upgrade is being pushed, the script creates a new instance of Survey called "Sample Survey during Push".

```java
public class PostInstallClass implements InstallHandler {
    global void onInstall(InstallContext context) {
        if(context.previousVersion() == null) {
            Account a = new Account(name='Newco');
            insert(a);
        }
    }
}
```
You can test a post install script using the new testInstall method of the Test class. This method takes the following arguments.

- A class that implements the InstallHandler interface.
- A Version object that specifies the version number of the existing package.
- An optional Boolean value that is true if the installation is a push. The default is false.

This sample shows how to test a post install script implemented in the PostInstallClass Apex class.

```apex
@isTest
static void testInstallScript() {
    PostInstallClass postinstall = new PostInstallClass();
    Test.testInstall(postinstall, null);
    Test.testInstall(postinstall, new Version(1,0), true);
    List<Account> a = [Select id, name from Account where name ='Newco'];
    System.assertEquals(a.size(), 1, 'Account not found');
}
```

**Integer Class**

Contains methods for the Integer primitive data type.
Namespace

System

Usage

For more information on integers, see Integer Data Type.

Integer Methods

The following are methods for Integer.

IN THIS SECTION:

format()
Returns the integer as a string using the locale of the context user.

valueOf(stringToInteger)
Returns an Integer that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal integer.

valueOf(fieldValue)
Converts the specified object to an Integer. Use this method to convert a history tracking field value or an object that represents an Integer value.

format()
Returns the integer as a string using the locale of the context user.

Signature

public String format()

Return Value

Type: String

Example

integer myInt = 22;
system.assertEquals('22', myInt.format());

valueOf(stringToInteger)
Returns an Integer that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal integer.

Signature

public static Integer valueOf(String stringToInteger)
Parameters

`stringToInteger`
Type: `String`

Return Value
Type: `Integer`

Example
```
Integer myInt = Integer.valueOf('123');
```

`valueOf(fieldValue)`
Converts the specified object to an Integer. Use this method to convert a history tracking field value or an object that represents an Integer value.

Signature
```
public static Integer valueOf(Object fieldValue)
```

Parameters

`fieldValue`
Type: `Object`

Return Value
Type: `Integer`

Usage
Use this method with the `OldValue` or `NewValue` fields of history sObjects, such as `AccountHistory`, when the field type corresponds to an Integer type, like a number field.

Example:
```
List<AccountHistory> ahlist =
    [SELECT Field, OldValue, NewValue
     FROM AccountHistory];
for(AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'NumberOfEmployees') {
        Integer oldValue =
            Integer.valueOf(ah.OldValue);
        Integer newValue =
            Integer.valueOf(ah.NewValue);
    }
}
JSON Class

Contains methods for serializing Apex objects into JSON format and deserializing JSON content that was serialized using the `serialize` method in this class.

Namespace

`System`

Usage

Use the methods in the `System.JSON` class to perform round-trip JSON serialization and deserialization of Apex objects.

SEE ALSO:

* Apex Developer Guide: Roundtrip Serialization and Deserialization*

JSON Methods

The following are methods for JSON. All methods are static.

IN THIS SECTION:

- `createGenerator(prettyPrint)`
  Returns a new JSON generator.
- `createParser(jsonString)`
  Returns a new JSON parser.
- `deserialize(jsonString, apexType)`
  Deserializes the specified JSON string into an Apex object of the specified type.
- `deserializeStrict(jsonString, apexType)`
  Deserializes the specified JSON string into an Apex object of the specified type.
- `deserializeUntyped(jsonString)`
  Deserializes the specified JSON string into collections of primitive data types.
- `serialize(objectToSerialize)`
  Serializes Apex objects into JSON content.
- `serialize(objectToSerialize, suppressApexObjectNulls)`
  Suppresses `null` values when serializing Apex objects into JSON content.
- `serializePretty(objectToSerialize)`
  Serializes Apex objects into JSON content and generates indented content using the pretty-print format.
- `serializePretty(objectToSerialize, suppressApexObjectNulls)`
  Suppresses `null` values when serializing Apex objects into JSON content and generates indented content using the pretty-print format.

**createGenerator (prettyPrint)**

Returns a new JSON generator.
JSON Class

**Signature**

```java
public static System.JSONGenerator createGenerator(Boolean prettyPrint)
```

**Parameters**

- `prettyPrint`
  - **Type**: `Boolean`
  - Determines whether the JSON generator creates JSON content in pretty-print format with the content indented. Set to `true` to create indented content.

**Return Value**

- **Type**: `System.JSONGenerator`

---

**createParser(jsonString)**

Returns a new JSON parser.

**Signature**

```java
public static System.JSONParser createParser(String jsonString)
```

**Parameters**

- `jsonString`
  - **Type**: `String`
  - The JSON content to parse.

**Return Value**

- **Type**: `System.JSONParser`

---

**deserialize(jsonString, apexType)**

Deserializes the specified JSON string into an Apex object of the specified type.

**Signature**

```java
public static Object deserialize(String jsonString, System.Type apexType)
```

**Parameters**

- `jsonString`
  - **Type**: `String`
  - The JSON content to deserialize.

- `apexType`
  - **Type**: `System.Type`
  - The Apex type of the object that this method creates after deserializing the JSON content.
Return Value
Type: Object

Usage
If the JSON content contains attributes not present in the System.Type argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content into a custom object or an sObject using Salesforce API version 34.0 or earlier, this method throws a runtime exception when passed extraneous attributes. When deserializing JSON content into an Apex class in any API version, or into an object in API version 35.0 or later, no exception is thrown. When no exception is thrown, this method ignores extraneous attributes and parses the rest of the JSON content.

Example
The following example deserializes a Decimal value.

```java
Decimal n = (Decimal)JSON.deserialize('100.1', Decimal.class);
System.assertEquals(n, 100.1);
```

`deserializeStrict(jsonString, apexType)`
Deserializes the specified JSON string into an Apex object of the specified type.

Signature
```
public static Object deserializeStrict(String jsonString, System.Type apexType)
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>jsonString</code></td>
<td>String</td>
<td>The JSON content to deserialize.</td>
</tr>
<tr>
<td><code>apexType</code></td>
<td>System.Type</td>
<td>The Apex type of the object that this method creates after deserializing the JSON content.</td>
</tr>
</tbody>
</table>

Return Value
Type: Object

Usage
All attributes in the JSON string must be present in the specified type. If the JSON content contains attributes not present in the System.Type argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content with extraneous attributes into an Apex class, this method throws an exception in all API versions. However, no exception is thrown when you use this method to deserialize JSON content into a custom object or an sObject.
Example
The following example deserializes a JSON string into an object of a user-defined type represented by the `Car` class, which this example also defines.

```java
class Car {
    public String make;
    public String year;
}

public void parse() {
    Car c = JSON.deserializeStrict(
        '{"make":"SFDC","year":"2020"}',
        Car.class);
    System.assertEquals(c.make, 'SFDC');
    System.assertEquals(c.year, '2020');
}
```

deserializeUntyped(String jsonString)
Deserializes the specified JSON string into collections of primitive data types.

**Signature**

```java
public static Object deserializeUntyped(String jsonString)
```

**Parameters**

`jsonString`
Type: `String`
The JSON content to deserialize.

**Return Value**
Type: Object

Example
The following example deserializes a JSON representation of an appliance object into a map that contains primitive data types and further collections of primitive types. It then verifies the deserialized values.

```java
String jsonInput = '{
    "description":"An appliance",
    "accessories": [{"right":"door handle1", "left":"door handle2" }],
    "dimensions": {
        "height": 5.5,
        "width": 3.0,
        "depth": 2.2
    },
    "type": null,
    "inventory": 2000,
    "price": 1023.45
}'
```
Map<String, Object> m =
  (Map<String, Object>)
  JSON.deserializeUntyped(jsonInput);

System.assertEquals(
  'An appliance', m.get('description'));

List<Object> a =
  (List<Object>)m.get('accessories');
System.assertEquals('powerCord', a[0]);
Map<String, Object> a2 =
  (Map<String, Object>)a[1];
System.assertEquals(
  'door handle1', a2.get('right'));
System.assertEquals(
  'door handle2', a2.get('left'));

Map<String, Object> dim =
  (Map<String, Object>)m.get('dimensions');
System.assertEquals(5.5, dim.get('height'));
System.assertEquals(3.0, dim.get('width'));
System.assertEquals(2.2, dim.get('depth'));

System.assertEquals(null, m.get('type'));
System.assertEquals(2000, m.get('inventory'));
System.assertEquals(1023.45, m.get('price'));
System.assertEquals(true, m.get('isShipped'));
System.assertEquals('123', m.get('modelNumber'));

**serialize(objectToSerialize)**

Serializes Apex objects into JSON content.

**Signature**

```
public static String serialize(Object objectToSerialize)
```

**Parameters**

**objectToSerialize**

Type: Object

The Apex object to serialize.
Return Value
Type: String

Example
The following example serializes a new DateTime value.

```java
Datetime dt = Datetime.newInstance(
    Date.newInstance(
        2011, 3, 22),
    Time.newInstance(
        1, 15, 18, 0));
String str = JSON.serialize(dt);
System.assertEquals(
    "2011-03-22T08:15:18.000Z",
    str);
```

`serialize(objectToSerialize, suppressApexObjectNulls)`
Suppresses null values when serializing Apex objects into JSON content.

Signature
```
public static String serialize(Object objectToSerialize, Boolean suppressApexObjectNulls)
```

Parameters
- `objectToSerialize`  
  Type: Object  
  The Apex object to serialize.
- `suppressApexObjectNulls`  
  Type: Boolean  
  If true, remove null values before serializing the JSON object.

Note: This parameter doesn’t apply to sObjects retrieved via SOQL.

Return Value
Type: String

Usage
This method allows you to specify whether to suppress null values when serializing Apex objects into JSON content.

`serializePretty(objectToSerialize)`
Serializes Apex objects into JSON content and generates indented content using the pretty-print format.
**Signature**

```java
public static String serializePretty(Object objectToSerialize)
```

**Parameters**

- `objectToSerialize`  
  Type: Object  
  The Apex object to serialize.

**Return Value**

Type: String

**serializePretty(objectToSerialize, suppressApexObjectNulls)**

Suppresses null values when serializing Apex objects into JSON content and generates indented content using the pretty-print format.

**Signature**

```java
public static String serializePretty(Object objectToSerialize, Boolean suppressApexObjectNulls)
```

**Parameters**

- `objectToSerialize`  
  Type: Object  
  The Apex object to serialize.

- `suppressApexObjectNulls`  
  Type: Boolean  
  If true, remove null values before serializing the JSON object.

**Note:** This parameter doesn't apply to sObjects retrieved via SOQL.

**Return Value**

Type: String

**JSONGenerator Class**

Contains methods used to serialize objects into JSON content using the standard JSON encoding.

**Namespace**

`System`
Usage
The `System.JSONGenerator` class is provided to enable the generation of standard JSON-encoded content and gives you more control on the structure of the JSON output.

SEE ALSO:
   * Apex Developer Guide: JSON Generator

**JSONGenerator Methods**

The following are methods for `JSONGenerator`. All are instance methods.

**IN THIS SECTION:**
- `close()`: Closes the JSON generator.
- `getAsString()`: Returns the generated JSON content.
- `isClosed()`: Returns `true` if the JSON generator is closed; otherwise, returns `false`.
- `writeBlob(blobValue)`: Writes the specified `Blob` value as a base64-encoded string.
- `write BlobField(fieldName, blobValue)`: Writes a field name and value pair using the specified field name and BLOB value.
- `writeBoolean(blobValue)`: Writes the specified Boolean value.
- `writeBooleanField(fieldName, booleanValue)`: Writes a field name and value pair using the specified field name and Boolean value.
- `writeDate(dateValue)`: Writes the specified date value in the ISO-8601 format.
- `writeDateField(fieldName, dateValue)`: Writes a field name and value pair using the specified field name and date value. The date value is written in the ISO-8601 format.
- `writeDateTime(datetimeValue)`: Writes the specified date and time value in the ISO-8601 format.
- `writeDateTimeField(fieldName, datetimeValue)`: Writes a field name and value pair using the specified field name and date and time value. The date and time value is written in the ISO-8601 format.
- `writeEndArray()`: Writes the ending marker of a JSON array (`'['`).
- `writeEndObject()`: Writes the ending marker of a JSON object (`']`).
- `writeFieldName(fieldName)`: Writes a field name.
writeId(identifier)
Writes the specified ID value.

writeIdField(fieldName, identifier)
Writes a field name and value pair using the specified field name and identifier value.

writeNull()
Writes the JSON null literal value.

writeNullField(fieldName)
Writes a field name and value pair using the specified field name and the JSON null literal value.

writeNumber(number)
Writes the specified decimal value.

writeNumber(number)
Writes the specified double value.

writeNumber(number)
Writes the specified integer value.

writeNumber(number)
Writes the specified long value.

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and decimal value.

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and double value.

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and integer value.

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and long value.

writeObject(anyObject)
Writes the specified Apex object in JSON format.

writeObjectField(fieldName, value)
Writes a field name and value pair using the specified field name and Apex object.

writeStartArray()
Writes the starting marker of a JSON array ('[').

writeStartObject()
Writes the starting marker of a JSON object ('{').

writeString(stringValue)
Writes the specified string value.

writeStringField(fieldName, stringValue)
Writes a field name and value pair using the specified field name and string value.

writeTime(timeValue)
Writes the specified time value in the ISO-8601 format.

writeTimeField(fieldName, timeValue)
Writes a field name and value pair using the specified field name and time value in the ISO-8601 format.
**close()**  
Closes the JSON generator.

**Signature**  
```java
public Void close()
```  

**Return Value**  
Type: Void

**Usage**  
No more content can be written after the JSON generator is closed.

**getAsString()**  
Returns the generated JSON content.

**Signature**  
```java
public String getAsString()
```  

**Return Value**  
Type: String

**Usage**  
This method closes the JSON generator if it isn't closed already.

**isClosed()**  
Returns **true** if the JSON generator is closed; otherwise, returns **false**.

**Signature**  
```java
public Boolean isClosed()
```  

**Return Value**  
Type: Boolean

**writeBlob(blobValue)**  
Writes the specified **Blob** value as a base64-encoded string.

**Signature**  
```java
public Void writeBlob(Blob blobValue)
```
Parameters
blobValue
Type: Blob

Return Value
Type: Void

writeBlobField(fieldName, blobValue)
Writes a field name and value pair using the specified field name and BLOB value.

Signature
public Void writeBlobField(String fieldName, Blob blobValue)

Parameters
fieldName
Type: String
blobValue
Type: Blob

Return Value
Type: Void

writeBoolean(blobValue)
Writes the specified Boolean value.

Signature
public Void writeBoolean(Boolean blobValue)

Parameters
blobValue
Type: Boolean

Return Value
Type: Void

writeBooleanField(fieldName, booleanValue)
Writes a field name and value pair using the specified field name and Boolean value.
**Signature**

```java
public Void writeBooleanField(String fieldName, Boolean booleanValue)
```

**Parameters**

- **fieldName**
  - Type: `String`

- **booleanValue**
  - Type: `Boolean`

**Return Value**

Type: `Void`

**writeDate(dateValue)**

Writes the specified date value in the ISO-8601 format.

**Signature**

```java
public Void writeDate(Date dateValue)
```

**Parameters**

- **dateValue**
  - Type: `Date`

**Return Value**

Type: `Void`

**writeDateField(fieldName, dateValue)**

Writes a field name and value pair using the specified field name and date value. The date value is written in the ISO-8601 format.

**Signature**

```java
public Void writeDateField(String fieldName, Date dateValue)
```

**Parameters**

- **fieldName**
  - Type: `String`

- **dateValue**
  - Type: `Date`

**Return Value**

Type: `Void`
writeDateTime(datetimeValue)

Writes the specified date and time value in the ISO-8601 format.

Signature

public Void writeDateTime(Datetime datetimeValue)

Parameters

datetimeValue
  Type: Datetime

Return Value

Type: Void

writeDateTimeField(fieldName, datetimeValue)

Writes a field name and value pair using the specified field name and date and time value. The date and time value is written in the ISO-8601 format.

Signature

public Void writeDateTimeField(String fieldName, Datetime datetimeValue)

Parameters

fieldName
  Type: String
datetimeValue
  Type: Datetime

Return Value

Type: Void

writeEndArray()

Writes the ending marker of a JSON array (']').

Signature

public Void writeEndArray()

Return Value

Type: Void
writeEndObject()  
Writes the ending marker of a JSON object (').

Signature  
public Void writeEndObject()

Return Value  
Type: Void

writeFieldName(fieldName)  
Writes a field name.

Signature  
public Void writeFieldName(String fieldName)

Parameters  
fieldName  
Type: String

Return Value  
Type: Void

writeId(identifier)  
Writes the specified ID value.

Signature  
public Void writeId(ID identifier)

Parameters  
identifier  
Type: ID

Return Value  
Type: Void

writeIdField(fieldName, identifier)  
Writes a field name and value pair using the specified field name and identifier value.
Signature
public Void writeIdField(String fieldName, Id identifier)

Parameters
fieldName
  Type: String
identifier
  Type: ID

Return Value
Type: Void

writeNull()
Writes the JSON null literal value.

Signature
public Void writeNull()

Return Value
Type: Void

writeNullField(fieldName)
Writes a field name and value pair using the specified field name and the JSON null literal value.

Signature
public Void writeNullField(String fieldName)

Parameters
fieldName
  Type: String

Return Value
Type: Void

writeNumber(number)
Writes the specified decimal value.

Signature
public Void writeNumber(Decimal number)
Parameters

number
Type: Decimal

Return Value
Type: Void

writeNumber(number)
Writes the specified double value.

Signature
public Void writeNumber(Double number)

Parameters

number
Type: Double

Return Value
Type: Void

writeNumber(number)
Writes the specified integer value.

Signature
public Void writeNumber(Integer number)

Parameters

number
Type: Integer

Return Value
Type: Void

writeNumber(number)
Writes the specified long value.

Signature
public Void writeNumber(Long number)
Parameters

number
Type: Long

Return Value
Type: Void

`writeNumberField(fieldName, number)`
Writes a field name and value pair using the specified field name and decimal value.

**Signature**

```java
public Void writeNumberField(String fieldName, Decimal number)
```

**Parameters**

- `fieldName`
  Type: String

- `number`
  Type: Decimal

Return Value
Type: Void

`writeNumberField(fieldName, number)`
Writes a field name and value pair using the specified field name and double value.

**Signature**

```java
public Void writeNumberField(String fieldName, Double number)
```

**Parameters**

- `fieldName`
  Type: String

- `number`
  Type: Double

Return Value
Type: Void

`writeNumberField(fieldName, number)`
Writes a field name and value pair using the specified field name and integer value.
Signature
public Void writeNumberField(String fieldName, Integer number)

Parameters
fieldName
  Type: String
number
  Type: Integer

Return Value
Type: Void

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and long value.

Signature
public Void writeNumberField(String fieldName, Long number)

Parameters
fieldName
  Type: String
number
  Type: Long

Return Value
Type: Void

writeObject(anyObject)
Writes the specified Apex object in JSON format.

Signature
public Void writeObject(Object anyObject)

Parameters
anyObject
  Type: Object

Return Value
Type: Void
**writeObjectField(fieldName, value)**
Writes a field name and value pair using the specified field name and Apex object.

**Signature**
```
public Void writeObjectField(String fieldName, Object value)
```

**Parameters**
- `fieldName`
  - Type: String
- `value`
  - Type: Object

**Return Value**
Type: Void

**writeStartArray()**
Writes the starting marker of a JSON array ('[').

**Signature**
```
public Void writeStartArray()
```

**Return Value**
Type: Void

**writeStartObject()**
Writes the starting marker of a JSON object ('{').

**Signature**
```
public Void writeStartObject()
```

**Return Value**
Type: Void

**writeString(stringValue)**
Writes the specified string value.

**Signature**
```
public Void writeString(String stringValue)
```
Parameters

\[ \text{stringValue} \]
Type: String

Return Value
Type: Void

\textbf{writeStringField(fieldName, stringValue)}

Writes a field name and value pair using the specified field name and string value.

Signature

\textbf{public Void writeStringField(String fieldName, String stringValue)}

Parameters

\[ \text{fieldName} \]
Type: String

\[ \text{stringValue} \]
Type: String

Return Value
Type: Void

\textbf{writeTime(timeValue)}

Writes the specified time value in the ISO-8601 format.

Signature

\textbf{public Void writeTime(Time timeValue)}

Parameters

\[ \text{timeValue} \]
Type: Time

Return Value
Type: Void

\textbf{writeTimeField(fieldName, timeValue)}

Writes a field name and value pair using the specified field name and time value in the ISO-8601 format.
Signature

```java
public Void writeTimeField(String fieldName, Time timeValue)
```

Parameters

- **fieldName**
  - Type: `String`
- **timeValue**
  - Type: `Time`

Return Value

Type: `Void`

JSONParser Class

Represents a parser for JSON-encoded content.

Namespace

`System`

Usage

Use the `System.JSONParser` methods to parse a response that’s returned from a call to an external service that is in JSON format, such as a JSON-encoded response of a Web service callout.

SEE ALSO:

*Apex Developer Guide: JSON Parsing*

JSONParser Methods

The following are methods for `JSONParser`. All are instance methods.

IN THIS SECTION:

- `clearCurrentToken()`
  - Removes the current token.
- `getBlobValue()`
  - Returns the current token as a BLOB value.
- `getBooleanValue()`
  - Returns the current token as a Boolean value.
- `getCurrentName()`
  - Returns the name associated with the current token.
- `getCurrentToken()`
  - Returns the token that the parser currently points to or `null` if there's no current token.
getDatetimeValue()
Returns the current token as a date and time value.

getDateValue()
Returns the current token as a date value.

getDecimalValue()
Returns the current token as a decimal value.

getDoubleValue()
Returns the current token as a double value.

getIdValue()
Returns the current token as an ID value.

getIntegerValue()
Returns the current token as an integer value.

getLastClearedToken()
Returns the last token that was cleared by the clearCurrentToken method.

getLongValue()
Returns the current token as a long value.

getText()
Returns the textual representation of the current token or null if there’s no current token.

getTimeValue()
Returns the current token as a time value.

hasCurrentToken()
Returns true if the parser currently points to a token; otherwise, returns false.

nextToken()
Returns the next token or null if the parser has reached the end of the input stream.

nextValue()
Returns the next token that is a value type or null if the parser has reached the end of the input stream.

readValueAs(apexType)
Deserializes JSON content into an object of the specified Apex type and returns the deserialized object.

readValueAsStrict(apexType)
Deserializes JSON content into an object of the specified Apex type and returns the deserialized object. All attributes in the JSON content must be present in the specified type.

skipChildren()
Skips all child tokens of type JSONToken.START_ARRAY and JSONToken.START_OBJECT that the parser currently points to.

clearCurrentToken()
Removes the current token.

Signature

public Void clearCurrentToken()
## Return Value

**Type:** Void

**Usage**

After this method is called, a call to `hasCurrentToken` returns `false` and a call to `getCurrentToken` returns `null`. You can retrieve the cleared token by calling `getLastClearedToken`.

### `getBlobValue()`

Returns the current token as a BLOB value.

**Signature**

```java
public Blob getBlobValue()
```

**Return Value**

**Type:** Blob

**Usage**

The current token must be of type `JSONToken.VALUE_STRING` and must be Base64-encoded.

### `getBooleanValue()`

Returns the current token as a Boolean value.

**Signature**

```java
public Boolean getBooleanValue()
```

**Return Value**

**Type:** Boolean

**Usage**

The current token must be of type `JSONToken.VALUE_TRUE` or `JSONToken.VALUE_FALSE`.

The following example parses a sample JSON string and retrieves a Boolean value.

```java
String JSONContent = '{"isActive":true}';
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the Boolean value.
Boolean isActive = parser.getBooleanValue();
```
getCurrentName()  
Returns the name associated with the current token.

Signature  
public String getCurrentName()  

Return Value  
Type: String  

Usage  
If the current token is of type JSONToken.FIELD_NAME, this method returns the same value as getText. If the current token is a value, this method returns the field name that precedes this token. For other values such as array values or root-level values, this method returns null.  
The following example parses a sample JSON string. It advances to the field value and retrieves its corresponding field name.

Example  
```java  
String JSONContent = '{"firstName":"John"}';  
JSONParser parser =  
    JSON.createParser(JSONContent);  
// Advance to the start object marker.  
parser.nextToken();  
// Advance to the next value.  
parser.nextValue();  
// Get the field name for the current value.  
String fieldName = parser.getCurrentName();  
// Get the textual representation  
// of the value.  
String fieldValue = parser.getText();  
```

getCurrentToken()  
Returns the token that the parser currently points to or null if there’s no current token.

Signature  
public System.JSONToken getCurrentToken()  

Return Value  
Type: System.JSONToken  

Usage  
The following example iterates through all the tokens in a sample JSON string.

Example  
```java  
String JSONContent = '{"firstName":"John"}';  
JSONParser parser =  
```
getDatetimeValue()

Returns the current token as a date and time value.

Signature

public Datetime getDatetimeValue()

Return Value

Type: Datetime

Usage

The current token must be of type JSONToken.VALUE_STRING and must represent a Datetime value in the ISO-8601 format.

The following example parses a sample JSON string and retrieves a Datetime value.

```java
String JSONContent = '{"transactionDate":"2011-03-22T13:01:23"}';
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parsed.nextValue();
// Get the transaction date.
Datetime transactionDate = parser.getDatetimeValue();
```

generateValue()

Returns the current token as a date value.

Signature

public Date getDateValue()

Return Value

Type: Date

Usage

The current token must be of type JSONToken.VALUE_STRING and must represent a Date value in the ISO-8601 format.

```java
String JSONContent = '{"transactionDate":"2011-03-22T13:01:23"}';
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the start object marker.
parsed.nextToken();
// Advance to the next value.
parsed.nextValue();
// Get the transaction date.
Datetime transactionDate = parsed.getDatetimeValue();
```
The following example parses a sample JSON string and retrieves a Date value.

```java
String JSONContent = 
   "{"dateOfBirth":"2011-03-22"};
JSONParser parser = 
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the date of birth.
Date dob = parser.getDateValue();
```

**getDecimalValue()**

Returns the current token as a decimal value.

**Signature**

```java
public Decimal getDecimalValue()
```

**Return Value**

Type: Decimal

**Usage**

The current token must be of type `JSONToken.VALUE_NUMBER_FLOAT` or `JSONToken.VALUE_NUMBER_INT` and is a numerical value that can be converted to a value of type `Decimal`.

The following example parses a sample JSON string and retrieves a Decimal value.

```java
String JSONContent = 
   "{"GPA":3.8}";
JSONParser parser = 
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the GPA score.
Decimal gpa = parser.getDecimalValue();
```

**getDoubleValue()**

Returns the current token as a double value.

**Signature**

```java
public Double getDoubleValue()
```
Return Value

Type: **Double**

Usage

The current token must be of type `JSONToken.VALUE_NUMBER_FLOAT` and is a numerical value that can be converted to a value of type **Double**.

The following example parses a sample JSON string and retrieves a Double value.

```java
String JSONContent = '
  "GPA":3.8"
';
JSONParser parser =
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the GPA score.
Double gpa = parser.getDoubleValue();
```

**getIdValue()**

Returns the current token as an ID value.

**Signature**

```java
public ID getIdValue()
```

**Return Value**

Type: **ID**

Usage

The current token must be of type `JSONToken.VALUE_STRING` and must be a valid **ID**.

The following example parses a sample JSON string and retrieves an ID value.

```java
String JSONContent = '
  "recordId":"001R0000002nO6H"
';
JSONParser parser =
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the record ID.
ID recordID = parser.getIdValue();
```

**getIntegerValue()**

Returns the current token as an integer value.
Signature

```java
public Integer getIntegerValue()
```

Return Value

Type: `Integer`

Usage

The current token must be of type `JSONToken.VALUE_NUMBER_INT` and must represent an `Integer`.

The following example parses a sample JSON string and retrieves an Integer value.

```java
String JSONContent = 
    '{"recordCount":10}';
JSONParser parser = 
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the record count.
Integer count = parser.getIntegerValue();
```

`getLastClearedToken()`

Returns the last token that was cleared by the `clearCurrentToken` method.

Signature

```java
public System.JSONToken getLastClearedToken()
```

Return Value

Type: `System.JSONToken`

`getLongValue()`

Returns the current token as a long value.

Signature

```java
public Long getLongValue()
```

Return Value

Type: `Long`

Usage

The current token must be of type `JSONToken.VALUE_NUMBER_INT` and is a numerical value that can be converted to a value of type `Long`. 
The following example parses a sample JSON string and retrieves a Long value.

```java
String JSONContent = 
    '{"recordCount":2097531021}';
JSONParser parser = 
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the record count.
Long count = parser.getLongValue();
```

**getText()**

Returns the textual representation of the current token or `null` if there's no current token.

**Signature**

```java
public String getText()
```

**Return Value**

Type: `String`

**Usage**

No current token exists, and therefore this method returns `null`, if `nextToken` has not been called yet for the first time or if the parser has reached the end of the input stream.

**getTimeValue()**

Returns the current token as a time value.

**Signature**

```java
public Time getTimeValue()
```

**Return Value**

Type: `Time`

**Usage**

The current token must be of type `JSONToken.VALUE_STRING` and must represent a `Time` value in the ISO-8601 format.

The following example parses a sample JSON string and retrieves a Datetime value.

```java
String JSONContent = 
    '{"arrivalTime":"18:05"}';
JSONParser parser = 
    JSON.createParser(JSONContent);
// Advance to the start object marker.
```
```java
token;
// Advance to the next value.
parser.nextValue();
// Get the arrival time.
Time arrivalTime = parser.getTimeValue();
```

**hasCurrentToken()**

Returns `true` if the parser currently points to a token; otherwise, returns `false`.

**Signature**

```java
public Boolean hasCurrentToken()
```

**Return Value**

Type: `Boolean`

**nextToken()**

Returns the next token or `null` if the parser has reached the end of the input stream.

**Signature**

```java
public System.JSONToken nextToken()
```

**Return Value**

Type: `System.JSONToken`

**Usage**

Advances the stream enough to determine the type of the next token, if any.

**nextValue()**

Returns the next token that is a value type or `null` if the parser has reached the end of the input stream.

**Signature**

```java
public System.JSONToken nextValue()
```

**Return Value**

Type: `System.JSONToken`

**Usage**

Advances the stream enough to determine the type of the next token that is of a value type, if any, including a JSON array and object start and end markers.
**readValueAs (apexType)**

Deserializes JSON content into an object of the specified Apex type and returns the deserialized object.

**Signature**

```java
public Object readValueAs(System.Type apexType)
```

**Parameters**

- **apexType**
  - Type: `System.Type`
  - The `apexType` argument specifies the type of the object that this method returns after deserializing the current value.

**Return Value**

Type: `Object`

**Usage**

If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content into a custom object or an sObject using Salesforce API version 34.0 or earlier, this method throws a runtime exception when passed extraneous attributes. When deserializing JSON content into an Apex class in any API version, or into an object in API version 35.0 or later, no exception is thrown. When no exception is thrown, this method ignores extraneous attributes and parses the rest of the JSON content.

**Example**

The following example parses a sample JSON string and retrieves a Datetime value. Before being able to run this sample, you must create a new Apex class as follows:

```java
public class Person {
    public String name;
    public String phone;
}
```

Next, insert the following sample in a class method:

```java
// JSON string that contains a Person object.
String JSONContent =
    '{"person":{
        "name":"John Smith",
        "phone":"555-1212")};
JSONParser parser =
    JSON.createParser(JSONContent);
// Make calls to nextToken()
// to point to the second
// start object marker.
parser.nextToken();
parser.nextToken();
parser.nextToken();
// Retrieve the Person object
// from the JSON string.
```
Person obj = (Person)parser.readValueAs(Person.class);
System.assertEquals(obj.name, 'John Smith');
System.assertEquals(obj.phone, '555-1212');

**readValueAsStrict(apexType)**

Deserializes JSON content into an object of the specified Apex type and returns the deserialized object. All attributes in the JSON content must be present in the specified type.

**Signature**

```java
public Object readValueAsStrict(System.Type apexType)
```

**Parameters**

`apexType`

Type: `System.Type`

The `apexType` argument specifies the type of the object that this method returns after deserializing the current value.

**Return Value**

Type: Object

**Usage**

If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content with extraneous attributes into an Apex class, this method throws an exception in all API versions. However, no exception is thrown when you use this method to deserialize JSON content into a custom object or an sObject.

The following example parses a sample JSON string and retrieves a Datetime value. Before being able to run this sample, you must create a new Apex class as follows:

```java
public class Person {
    public String name;
    public String phone;
}
```

Next, insert the following sample in a class method:

```java
// JSON string that contains a Person object.
String JSONContent = '{"person":{"name":"John Smith","phone":"555-1212"}}';
JSONParser parser = JSON.createParser(JSONContent);
// Make calls to nextToken()
// to point to the second
```
// start object marker.
parser.nextToken();
parser.nextToken();
parser.nextToken();

// Retrieve the Person object
// from the JSON string.
Person obj =
    (Person)parser.readValueAsStrict(
            Person.class);
System.assertEquals(
    obj.name, 'John Smith');
System.assertEquals(
    obj.phone, '555-1212');

skipChildren()

Skips all child tokens of type JSONToken.START_ARRAY and JSONToken.START_OBJECT that the parser currently points to.

Signature

public Void skipChildren()

Return Value

Type: Void

JSONToken Enum

Contains all token values used for parsing JSON content.

Namespace

System

<table>
<thead>
<tr>
<th>Enum Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>END_ARRAY</td>
<td>The ending of an array value. This token is returned when ']' is encountered.</td>
</tr>
<tr>
<td>END_OBJECT</td>
<td>The ending of an object value. This token is returned when '}' is encountered.</td>
</tr>
<tr>
<td>FIELD_NAME</td>
<td>A string token that is a field name.</td>
</tr>
<tr>
<td>NOT_AVAILABLE</td>
<td>The requested token isn't available.</td>
</tr>
<tr>
<td>START_ARRAY</td>
<td>The start of an array value. This token is returned when '[' is encountered.</td>
</tr>
<tr>
<td>START_OBJECT</td>
<td>The start of an object value. This token is returned when '{' is encountered.</td>
</tr>
</tbody>
</table>

3160
<table>
<thead>
<tr>
<th>Enum Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_EMBEDDED_OBJECT</td>
<td>An embedded object that isn’t accessible as a typical object structure that includes the start and end object tokens START_OBJECT and END_OBJECT but is represented as a raw object.</td>
</tr>
<tr>
<td>VALUE_FALSE</td>
<td>The literal &quot;false&quot; value.</td>
</tr>
<tr>
<td>VALUE_NULL</td>
<td>The literal &quot;null&quot; value.</td>
</tr>
<tr>
<td>VALUE_NUMBER_FLOAT</td>
<td>A float value.</td>
</tr>
<tr>
<td>VALUE_NUMBER_INT</td>
<td>An integer value.</td>
</tr>
<tr>
<td>VALUE_STRING</td>
<td>A string value.</td>
</tr>
<tr>
<td>VALUE_TRUE</td>
<td>A value that corresponds to the &quot;true&quot; string literal.</td>
</tr>
</tbody>
</table>

**Label Class**

Provides methods to retrieve a custom label or to check if translation exists for a label in a specific language and namespace. Label names are dynamically resolved at run time, overriding the user’s current language if a translation exists for the requested language. You can’t access labels that are protected in a different namespace.

**Namespace**

*System*

**Usage**

Custom labels enable developers to create multilingual applications by automatically presenting information (for example, help text or error messages) in a user’s native language. Custom labels have a limit of 1000 characters and can be accessed from Apex classes, Visualforce pages, Lightning pages, or Lightning components. For more information on custom labels, see Custom Labels in Salesforce Help. The label values can be translated into any language Salesforce supports. For supported languages, see Supported Languages in Salesforce Help.

- To define custom labels, from Setup, in the Quick Find box, enter *Custom Labels*, and then select *Custom Labels*.
- To assign translated values, turn on Translation Workbench and add translation mappings.
- To retrieve the label for a default language setting or for a language and namespace, use `System.Label.get(namespace, label, language)`.
- To check if translation exists for a label and language in a namespace, use `Label.translationExists(namespace, label, language)`.

In Apex code, you can refer to or instantiate a Label like this:

```
System.Label.myLabelName
```

For information on passing in labels into Aura components, see Getting Labels in Apex in the Lightning Aura Components Developer Guide.
Examples

This example returns True if an English label called "MyLabel" exists in the "MyNamespace" namespace.

```java
boolean exists = Label.translationExists('MyNamespace', 'MyLabel', 'en')
```

This example retrieves the custom label translation text for "MyLabel" in French.

```java
String value = Label.get('MyNamespace', 'MyLabel', 'fr')
```

IN THIS SECTION:

Label Methods

The following are methods for Label.

IN THIS SECTION:

get(namespace, label)
Retrieve a custom label for the specified namespace and a default language setting.

get(namespace, label, language)
Retrieve a custom label for the specified namespace and language.

translationExists(namespace, label, language)
Check if translation exists for a label and language in a namespace.

**get(namespace, label)**

Retrieve a custom label for the specified namespace and a default language setting.

**Signature**

```java
public static String get(String namespace, String label)
```

**Parameters**

- `namespace`
  - Type: `String`
    - If the namespace name is null, it defaults to the package namespace. If the namespace name is an empty string, it implies the org namespace.

- `label`
  - Type: `String`
    - The label name cannot be null or an empty string.

**Return Value**

- Type: `String`
**get(namespace, label, language)**
Retrieve a custom label for the specified namespace and language.

**Signature**
```java
public static String get(String namespace, String label, String language)
```

**Parameters**
- **namespace**
  - Type: `String`
  - If the namespace name is null, it defaults to the package namespace. If the namespace name is an empty string, it implies the org namespace.
- **label**
  - Type: `String`
  - The label name cannot be null or an empty string.
- **language**
  - Type: `String`
  - This parameter must be a valid language ISO code. See the Platform-Only Languages section in Supported Languages in Salesforce Help.

**Return Value**
- Type: `String`

**translationExists(namespace, label, language)**
Check if translation exists for a label and language in a namespace.

**Signature**
```java
public static Boolean translationExists(string namespace, string label, string language)
```

**Parameters**
- **namespace**
  - Type: `String`
  - If the namespace name is null, it defaults to the package namespace. If the namespace name is an empty string, it implies the org namespace.
- **label**
  - Type: `String`
  - The label name cannot be null or an empty string.
- **language**
  - Type: `String`
  - This parameter must be a valid language ISO code. See the Platform-Only Languages section in Supported Languages in Salesforce Help.
Return Value
Type: Boolean

Limits Class
Contains methods that return limit information for specific resources.

Namespace
System

Usage
The Limits methods return the specific limit for the particular governor, such as the number of calls of a method or the amount of heap size remaining.

Because Apex runs in a multitenant environment, the Apex runtime engine strictly enforces a number of limits to ensure that runaway Apex doesn’t monopolize shared resources.

None of the Limits methods require an argument. The format of the limits methods is as follows:

```
myDMLLimit = Limits.getDMLStatements();
```

There are two versions of every method: the first returns the amount of the resource that has been used while the second version contains the word limit and returns the total amount of the resource that is available.

See Execution Governors and Limits.

Limits Methods
The following are methods for Limits. All methods are static.

IN THIS SECTION:
- `getAggregateQueries()`: Returns the number of aggregate queries that have been processed with any SOQL query statement.
- `getLimitAggregateQueries()`: Returns the total number of aggregate queries that can be processed with SOQL query statements.
- `getAsynCalls()`: Reserved for future use.
- `getLimitAsynCalls()`: Reserved for future use.
- `getCallouts()`: Returns the number of Web service statements that have been processed.
- `getChildRelationshipsDescribes()`: Deprecated. Returns the number of child relationship objects that have been returned.
- `getLimitCallouts()`: Returns the total number of Web service statements that can be processed.
getCpuTime()  
Returns the CPU time (in milliseconds) that has been used in the current transaction.

gLimitCpuTime()  
Returns the maximum CPU time (in milliseconds) that can be used in a transaction.

gDMLRows()  
Returns the number of records that have been processed with any statement that counts against DML limits, such as DML statements, the Database.emptyRecycleBin method, and other methods.

gLimitDMLRows()  
Returns the total number of records that can be processed with any statement that counts against DML limits, such as DML statements, the database.EmptyRecycleBin method, and other methods.

gDMLStatements()  
Returns the number of DML statements (such as insert, update or the database.EmptyRecycleBin method) that have been called.

gLimitDMLStatements()  
Returns the total number of DML statements or the database.EmptyRecycleBin methods that can be called.

gEmailInvocations()  
Returns the number of email invocations (such as sendEmail) that have been called.

gLimitEmailInvocations()  
Returns the total number of email invocation (such as sendEmail) that can be called.

gFindSimilarCalls()  
Deprecated. Returns the same value as getSoslQueries. The number of findSimilar methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

gLimitFindSimilarCalls()  
Deprecated. Returns the same value as getLimitSoslQueries. The number of findSimilar methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

gFutureCalls()  
Returns the number of methods with the future annotation that have been executed (not necessarily completed).

gLimitFutureCalls()  
Returns the total number of methods with the future annotation that can be executed (not necessarily completed).

gHeapSize()  
Returns the approximate amount of memory (in bytes) that has been used for the heap.

gLimitHeapSize()  
Returns the total amount of memory (in bytes) that can be used for the heap.

gMobilePushApexCalls()  
Returns the number of Apex calls that have been used by mobile push notifications during the current metering interval.

gLimitMobilePushApexCalls()  
Returns the total number of Apex calls that are allowed per transaction for mobile push notifications.

gPublishImmediateDML()  
Returns the number of EventBus.publish calls that have been made for platform events configured to publish immediately.
getLimitPublishImmediateDML()
Returns the total number of EventBus.publish statements that can be called for platform events configured to publish immediately.

getQueries()
Returns the number of SOQL queries that have been issued.

gGetLimitQueries()
Returns the total number of SOQL queries that can be issued.

ggetQueryLocatorRows()
Returns the number of records that have been returned by the Database.getQueryLocator method.

gGetLimitQueryLocatorRows()
Returns the total number of records that can be returned by the Database.getQueryLocator method.

ggetQueryRows()
Returns the number of records that have been returned by issuing SOQL queries.

gGetLimitQueryRows()
Returns the total number of records that can be returned by issuing SOQL queries.

gQueueableJobs()
Returns the number of queueable jobs that have been added to the queue per transaction. A queueable job corresponds to a class that implements the Queueable interface.

gGetLimitQueueableJobs()
Returns the maximum number of queueable jobs that can be added to the queue per transaction. A queueable job corresponds to a class that implements the Queueable interface.

gerunAs()
Deprecated. Returns the same value as getDMLStatements.

gerunAs()
Deprecated. Returns the same value as getLimitDMLStatements.

gSavepointRollbacks()
Deprecated. Returns the same value as getDMLStatements.

gGetSavepointRollbacks()
Deprecated. Returns the same value as getLimitDMLStatements.

gSavepoints()
Deprecated. Returns the same value as getDMLStatements.

gGetSavepoints()
Deprecated. Returns the same value as getLimitDMLStatements.

gSoslQueries()
Returns the number of SOSL queries that have been issued.

gGetLimitSoslQueries()
Returns the total number of SOSL queries that can be issued.

gAgggregateQueries()
Returns the number of aggregate queries that have been processed with any SOQL query statement.
Signature

public static Integer getAggregateQueries()

Return Value
Type: Integer

getLimitAggregateQueries()
Returns the total number of aggregate queries that can be processed with SOQL query statements.

Signature

public static Integer getLimitAggregateQueries()

Return Value
Type: Integer

getAsynccalls()
Reserved for future use.

Signature

public static Integer getAsynccalls()

Return Value
Type: Integer

getLimitAsynccalls()
Reserved for future use.

Signature

public static Integer getLimitAsynccalls()

Return Value
Type: Integer

getCallouts()
Returns the number of Web service statements that have been processed.

Signature

public static Integer getCallouts()
Return Value
Type: Integer

getchildrelationshipsdescribes()
Deprecated. Returns the number of child relationship objects that have been returned.

Signature
public static Integer getchildrelationshipsdescribes()

Return Value
Type: Integer

Usage
Note: Because describe limits are no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is available but is deprecated.

gelimitcallouts()
Returns the total number of Web service statements that can be processed.

Signature
public static Integer gelimitcallouts()

Return Value
Type: Integer

gecputime()
Returns the CPU time (in milliseconds) that has been used in the current transaction.

Signature
public static Integer gecputime()

Return Value
Type: Integer

gelimitcputime()
Returns the maximum CPU time (in milliseconds) that can be used in a transaction.
Signature

```java
public static Integer getLimitCpuTime()
```

Return Value

Type: Integer

**getDMLRows()**

Returns the number of records that have been processed with any statement that counts against DML limits, such as DML statements, the `Database.emptyRecycleBin` method, and other methods.

Signature

```java
public static Integer getDMLRows()
```

Return Value

Type: Integer

**getLimitDMLRows()**

Returns the total number of records that can be processed with any statement that counts against DML limits, such as DML statements, the `database.EmptyRecycleBin` method, and other methods.

Signature

```java
public static Integer getLimitDMLRows()
```

Return Value

Type: Integer

**getDMLStatements()**

Returns the number of DML statements (such as `insert`, `update` or the `database.EmptyRecycleBin` method) that have been called.

Signature

```java
public static Integer getDMLStatements()
```

Return Value

Type: Integer

**getLimitDMLStatements()**

Returns the total number of DML statements or the `Database.EmptyRecycleBin` methods that can be called.
Signature
public static Integer getLimitDMLStatements()

Return Value
Type: Integer

getEmailInvocations()
Returns the number of email invocations (such as sendEmail) that have been called.

Signature
public static Integer getEmailInvocations()

Return Value
Type: Integer

getLimitEmailInvocations()
Returns the total number of email invocation (such as sendEmail) that can be called.

Signature
public static Integer getLimitEmailInvocations()

Return Value
Type: Integer

getFindSimilarCalls()
Deprecated. Returns the same value as getSoslQueries. The number of findSimilar methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

Signature
public static Integer getFindSimilarCalls()

Return Value
Type: Integer

getLimitFindSimilarCalls()
Deprecated. Returns the same value as getLimitSoslQueries. The number of findSimilar methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.
Signature

```
public static Integer getLimitFindSimilarCalls()
```

Return Value
Type: Integer

**getFutureCalls()**
Returns the number of methods with the `future` annotation that have been executed (not necessarily completed).

Signature

```
public static Integer getFutureCalls()
```

Return Value
Type: Integer

**getLimitFutureCalls()**
Returns the total number of methods with the `future` annotation that can be executed (not necessarily completed).

Signature

```
public static Integer getLimitFutureCalls()
```

Return Value
Type: Integer

**getHeapSize()**
Returns the approximate amount of memory (in bytes) that has been used for the heap.

Signature

```
public static Integer getHeapSize()
```

Return Value
Type: Integer

**getLimitHeapSize()**
Returns the total amount of memory (in bytes) that can be used for the heap.

Signature

```
public static Integer getLimitHeapSize()
```
Return Value
Type: Integer

getMobilePushApexCalls()
Returns the number of Apex calls that have been used by mobile push notifications during the current metering interval.

Signature
public static Integer getMobilePushApexCalls()

Return Value
Type: Integer

gLimitMobilePushApexCalls()
Returns the total number of Apex calls that are allowed per transaction for mobile push notifications.

Signature
public static Integer getLimitMobilePushApexCalls()

Return Value
Type: Integer

getPublishImmediateDML()
Returns the number of EventBus.publish calls that have been made for platform events configured to publish immediately.

Signature
public static Integer getPublishImmediateDML()

Return Value
Type: Integer

getLimitPublishImmediateDML()
Returns the total number of EventBus.publish statements that can be called for platform events configured to publish immediately.

Signature
public static Integer getLimitPublishImmediateDML()

Return Value
Type: Integer
getQueries()
Returns the number of SOQL queries that have been issued.

Signature
public static Integer getQueries()

Return Value
Type: Integer

genLimitQueries()
Returns the total number of SOQL queries that can be issued.

Signature
public static Integer getLimitQueries()

Return Value
Type: Integer

getQueryLocatorRows()
Returns the number of records that have been returned by the Database.getQueryLocator method.

Signature
public static Integer getQueryLocatorRows()

Return Value
Type: Integer

getLimitQueryLocatorRows()
Returns the total number of records that can be returned by the Database.getQueryLocator method.

Signature
public static Integer getLimitQueryLocatorRows()

Return Value
Type: Integer

getQueryRows()
Returns the number of records that have been returned by issuing SOQL queries.
### getQueryRows()

Returns the total number of records that can be returned by issuing SOQL queries.

**Signature**

```java
generate public static Integer getQueryRows()
```

**Return Value**

Type: `Integer`

### getLimitQueryRows()

Returns the maximum number of records that can be returned by issuing SOQL queries.

**Signature**

```java
generate public static Integer getLimitQueryRows()
```

**Return Value**

Type: `Integer`

### getQueueableJobs()

Returns the number of queueable jobs that have been added to the queue per transaction. A queueable job corresponds to a class that implements the `Queueable` interface.

**Signature**

```java
generate public static Integer getQueueableJobs()
```

**Return Value**

Type: `Integer`

### getLimitQueueableJobs()

Returns the maximum number of queueable jobs that can be added to the queue per transaction. A queueable job corresponds to a class that implements the `Queueable` interface.

**Signature**

```java
generate public static Integer getLimitQueueableJobs()
```

**Return Value**

Type: `Integer`

### getRunAs()

Deprecated. Returns the same value as `getDMLStatements`.

**Signature**

```java
generate public static Integer getRunAs()
```

**Return Value**

Type: `Integer`
Signature

```java
public static Integer getRunAs()
```

Return Value

Type: Integer

Usage

The number of `RunAs` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

```java
getLimitRunAs()
```

Deprecated. Returns the same value as `getLimitDMLStatements`.

Signature

```java
public static Integer getLimitRunAs()
```

Return Value

Type: Integer

Usage

The number of `RunAs` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

```java
getSavepointRollbacks()
```

Deprecated. Returns the same value as `getDMLStatements`.

Signature

```java
public static Integer getSavepointRollbacks()
```

Return Value

Type: Integer

Usage

The number of `Rollback` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

```java
getLimitSavepointRollbacks()
```

Deprecated. Returns the same value as `getLimitDMLStatements`.

Signature

```java
public static Integer getLimitSavepointRollbacks()
```
Return Value
Type: Integer

Usage
The number of Rollback methods is no longer a separate limit, but is tracked as the number of DML statements issued.

getsavepoints()
Deprecated. Returns the same value as getDMLStatements.

Signature
public static Integer getsavepoints()

Return Value
Type: Integer

Usage
The number of setSavepoint methods is no longer a separate limit, but is tracked as the number of DML statements issued.

getLimitsavepoints()
Deprecated. Returns the same value as getLimitDMLStatements.

Signature
public static Integer getLimitsavepoints()

Return Value
Type: Integer

Usage
The number of setSavepoint methods is no longer a separate limit, but is tracked as the number of DML statements issued.

getSoslQueries()
Returns the number of SOSL queries that have been issued.

Signature
public static Integer getSoslQueries()

Return Value
Type: Integer
**getLimitSoslQueries()**

Returns the total number of SOSL queries that can be issued.

**Signature**

```java
public static Integer getLimitSoslQueries()
```

**Return Value**

*Type:* Integer

**List Class**

Contains methods for the List collection type.

**Namespace**

*System*

**Usage**

The list methods are all instance methods, that is, they operate on a particular instance of a list. For example, the following removes all elements from `myList`:

```java
myList.clear();
```

Even though the `clear` method does not include any parameters, the list that calls it is its implicit parameter.

![Note:](https://example.com)

- When using a custom type for the list elements, provide an `equals` method in your class. Apex uses this method to determine equality and uniqueness for your objects. For more information on providing an `equals` method, see [Using Custom Types in Map Keys and Sets](https://www.salesforce.com/

- If the list contains String elements, the elements are case-sensitive. Two list elements that differ only by case are considered distinct.

For more information on lists, see [Lists](https://www.salesforce.com/).

**IN THIS SECTION:**

- List Constructors
- List Methods

**List Constructors**

The following are constructors for List.
IN THIS SECTION:

List<T>()
Creates a new instance of the List class. A list can hold elements of any data type T.

List<T>(listToCopy)
Creates a new instance of the List class by copying the elements from the specified list. T is the data type of the elements in both lists and can be any data type.

List<T>(setToCopy)
Creates a new instance of the List class by copying the elements from the specified set. T is the data type of the elements in the set and list and can be any data type.

List<T>()
Creates a new instance of the List class. A list can hold elements of any data type T.

Signature
public List<T>()

Example

```java
// Create a list
List<Integer> ls1 = new List<Integer>();
// Add two integers to the list
ls1.add(1);
ls1.add(2);
```

List<T>(listToCopy)
Creates a new instance of the List class by copying the elements from the specified list. T is the data type of the elements in both lists and can be any data type.

Signature
public List<T>(List<T> listToCopy)

Parameters

listToCopy
Type: List<T>
The list containing the elements to initialize this list from. T is the data type of the list elements.

Example

```java
List<Integer> ls1 = new List<Integer>();
ls1.add(1);
ls1.add(2);
// Create a list based on an existing one
List<Integer> ls2 = new List<Integer>(ls1);
```
List\langle T\rangle (setToCopy)

Creates a new instance of the List class by copying the elements from the specified set. T is the data type of the elements in the set and list and can be any data type.

Signature

\textbf{public} List\langle T\rangle (Set\langle T\rangle setToCopy)

Parameters

setToCopy

Type: Set\langle T\rangle

The set containing the elements to initialize this list with. T is the data type of the set elements.

Example

```java
Set<Integer> s1 = new Set<Integer>();
set.add(1);
set.add(2);
// Create a list based on a set
List<Integer> ls = new List<Integer>(s1);
// ls elements are copied from s1
System.debug(ls);// DEBUG\langle 1, 2\rangle
```

List Methods

The following are methods for List. All are instance methods.

\textbf{IN THIS SECTION:}

\begin{itemize}
\item \textbf{add(listElement)}
\end{itemize}

Adds an element to the end of the list.

\begin{itemize}
\item \textbf{add(index, listElement)}
\end{itemize}

Inserts an element into the list at the specified index position.

\begin{itemize}
\item \textbf{addAll(fromList)}
\end{itemize}

Adds all of the elements in the specified list to the list that calls the method. Both lists must be of the same type.

\begin{itemize}
\item \textbf{addAll(fromSet)}
\end{itemize}

Add all of the elements in specified set to the list that calls the method. The set and the list must be of the same type.

\begin{itemize}
\item \textbf{clear()}
\end{itemize}

Removes all elements from a list, consequently setting the list’s length to zero.

\begin{itemize}
\item \textbf{clone()}
\end{itemize}

Makes a duplicate copy of a list.
contains(listElement)
Returns true if the list contains the specified element.

deepClone(preserveId, preserveReadonlyTimestamps, preserveAutonumber)
Makes a duplicate copy of a list of sObject records, including the sObject records themselves.
equals(list2)
Compares this list with the specified list and returns true if both lists are equal; otherwise, returns false.

get(index)
Returns the list element stored at the specified index.

getSObjectType()
Returns the token of the sObject type that makes up a list of sObjects.

hashCode()
Returns the hashcode corresponding to this list and its contents.

indexOf(listElement)
Returns the index of the first occurrence of the specified element in this list. If this list does not contain the element, returns -1.

isEmpty()
Returns true if the list has zero elements.

iterator()
Returns an instance of an iterator for this list.

remove(index)
Removes the list element stored at the specified index, returning the element that was removed.

set(index, listElement)
Sets the specified value for the element at the given index.

size()
Returns the number of elements in the list.

sort()
Sorts the items in the list in ascending order.

toString()
Returns the string representation of the list.

**add(listElement)**
Adds an element to the end of the list.

**Signature**

```java
public Void add(Object listElement)
```

**Parameters**

`listElement`
Type: Object
Return Value
Type: Void

Example
```
List<Integer> myList = new List<Integer>(){
    myList.add(47);
    Integer myNumber = myList.get(0);
    system.assertEquals(47, myNumber);
}
```

add(index, listElement)
Inserts an element into the list at the specified index position.

Signature
```
public Void add(Integer index, Object listElement)
```

Parameters
- index
  Type: Integer
- listElement
  Type: Object

Return Value
Type: Void

Example
In the following example, a list with six elements is created, and integers are added to the first and second index positions.
```
List<Integer> myList = new Integer[6];
myList.add(0, 47);
myList.add(1, 52);
system.assertEquals(52, myList.get(1));
```

addAll(fromList)
Adds all of the elements in the specified list to the list that calls the method. Both lists must be of the same type.

Signature
```
public Void addAll(List fromList)
```

Parameters
- fromList
  Type: List
Return Value
Type: Void

**addAll(fromSet)**
Add all of the elements in specified set to the list that calls the method. The set and the list must be of the same type.

**Signature**

```java
public Void addAll(Set fromSet)
```

**Parameters**

*fromSet*
Type: Set

**Return Value**
Type: Void

**clear()**
Removes all elements from a list, consequently setting the list’s length to zero.

**Signature**

```java
public Void clear()
```

**Return Value**
Type: Void

**clone()**
Makes a duplicate copy of a list.

**Signature**

```java
public List<Object> clone()
```

**Return Value**
Type: List<Object>

**Usage**
The cloned list is of the same type as the current list.
Note that if this is a list of sObject records, the duplicate list will only be a shallow copy of the list. That is, the duplicate will have references to each object, but the sObject records themselves will not be duplicated. For example:
To also copy the sObject records, you must use the `deepClone` method.
Example

```java
Account a = new Account(Name='Acme', BillingCity='New York');
Account b = new Account();
Account[] q1 = new Account[]{a, b};
Account[] q2 = q1.clone();
q1[0].BillingCity = 'San Francisco';

System.assertEquals('San Francisco', q1[0].BillingCity);
System.assertEquals('San Francisco', q2[0].BillingCity);
```

`contains(listElement)`

Returns `true` if the list contains the specified element.

Signature

```java
public Boolean contains(Object listElement)
```

Parameters

`listElement`
Type: `Object`

Return Value

Type: `Boolean`

Example

```java
List<String> myStrings = new List<String>{'a', 'b'};
Boolean result = myStrings.contains('z');
System.assertEquals(false, result);
```

deepClone(preserveId, preserveReadonlyTimestamps, preserveAutonumber)

Makes a duplicate copy of a list of sObject records, including the sObject records themselves.

Signature

```java
public List<Object> deepClone(Boolean preserveId, Boolean preserveReadonlyTimestamps, Boolean preserveAutonumber)
```
Parameters

*preserveId*
Type: Boolean
The optional *preserveId* argument determines whether the IDs of the original objects are preserved or cleared in the duplicates. If set to *true*, the IDs are copied to the cloned objects. The default is *false*, that is, the IDs are cleared.

*preserveReadonlyTimestamps*
Type: Boolean
The optional *preserveReadonlyTimestamps* argument determines whether the read-only timestamp and user ID fields are preserved or cleared in the duplicates. If set to *true*, the read-only fields CreatedById, CreatedDate, LastModifiedById, and LastModifiedDate are copied to the cloned objects. The default is *false*, that is, the values are cleared.

*preserveAutonumber*
Type: Boolean
The optional *preserveAutonumber* argument determines whether the autonumber fields of the original objects are preserved or cleared in the duplicates. If set to *true*, auto number fields are copied to the cloned objects. The default is *false*, that is, auto number fields are cleared.

Return Value
Type: List<Object>

Usage
The returned list is of the same type as the current list.

Note:
- `deepClone` only works with lists of sObjects, not with lists of primitives.
- For Apex saved using Salesforce API version 22.0 or earlier, the default value for the *preserve_id* argument is *true*, that is, the IDs are preserved.

To make a shallow copy of a list without duplicating the sObject records it contains, use the `clone` method.

Example
This example performs a deep clone for a list with two accounts.

```java
Account a = new Account(Name='Acme', BillingCity='New York');
Account b = new Account(Name='Salesforce');
Account[] q1 = new Account[]{a,b};
Account[] q2 = q1.deepClone();
q1[0].BillingCity = 'San Francisco';
System.assertEquals('San Francisco', q1[0].BillingCity);
```
This example is based on the previous example and shows how to clone a list with preserved read-only timestamp and user ID fields.

```
insert q1;

List<Account> accts = [SELECT CreatedById, CreatedDate, LastModifiedById, LastModifiedDate, BillingCity
FROM Account
WHERE Name='Acme' OR Name='Salesforce'];

// Clone list while preserving timestamp and user ID fields.
Account[] q3 = accts.deepClone(false, true, false);

// Verify timestamp fields are preserved for the first list element.
System.assertEquals(accts[0].CreatedById, q3[0].CreatedById);
System.assertEquals(accts[0].CreatedDate, q3[0].CreatedDate);
System.assertEquals(accts[0].LastModifiedById, q3[0].LastModifiedById);
System.assertEquals(accts[0].LastModifiedDate, q3[0].LastModifiedDate);
```

### equals(list2)

Compares this list with the specified list and returns `true` if both lists are equal; otherwise, returns `false`.

**Signature**

```
public Boolean equals(List list2)
```

**Parameters**

- **list2**
  - Type: `List`
  - The list to compare this list with.

**Return Value**

- Type: `Boolean`

**Usage**

Two lists are equal if their elements are equal and are in the same order. The `==` operator is used to compare the elements of the lists.
The `==` operator is equivalent to calling the `equals` method, so you can call `list1.equals(list2)` instead of `list1 == list2`.

**get(index)**

Returns the list element stored at the specified index.

**Signature**

```java
public Object get(Integer index)
```

**Parameters**

- `index`
  
  Type: `Integer`

**Return Value**

Type: `Object`

**Usage**

To reference an element of a one-dimensional list of primitives or sObjects, you can also follow the name of the list with the element’s index position in square brackets as shown in the example.

**Example**

```java
List<Integer> myList = new List<Integer>();
myList.add(47);
Integer myNumber = myList.get(0);
system.assertEquals(47, myNumber);
```

```java
List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
```

**getSObjectType()**

Returns the token of the sObject type that makes up a list of sObjects.

**Signature**

```java
public Schema.SObjectType getSObjectType()
```

**Return Value**

Type: `Schema.SObjectType`
Usage

Use this method with describe information to determine if a list contains sObjects of a particular type. Note that this method can only be used with lists that are composed of sObjects. For more information, see Understanding Apex Describe Information.

Example

```java
// Create a generic sObject variable.
SObject sObj = Database.query('SELECT Id FROM Account LIMIT 1');

// Verify if that sObject variable is an Account token.
System.assertEquals(Account.sObjectType, sObj.getSObjectType());

// Create a list of generic sObjects.
List<sObject> q = new Account[]{};

// Verify if the list of sObjects contains Account tokens.
System.assertEquals(Account.sObjectType, q.getSObjectType());
```

hashCode()

Returns the hashcode corresponding to this list and its contents.

Signature

```java
public Integer hashCode()
```

Return Value

Type: Integer

indexOf(listElement)

Returns the index of the first occurrence of the specified element in this list. If this list does not contain the element, returns -1.

Signature

```java
public Integer indexOf(Object listElement)
```

Parameters

```java
listElement
    Type: Object
```
Return Value
Type: Integer

Example
```
List<String> myStrings = new List<String>{'a', 'b', 'a'};
Integer result = myStrings.indexOf('a');
System.assertEquals(0, result);
```

isEmpty()
Returns true if the list has zero elements.

Signature
```
public Boolean isEmpty()
```

Return Value
Type: Boolean

iterator()
Returns an instance of an iterator for this list.

Signature
```
public Iterator iterator()
```

Usage
From the returned iterator, you can use the iterable methods hasNext and next to iterate through the list.

Note: You don’t have to implement the iterable interface to use the iterable methods with a list.

See Custom Iterators.

Example
```
public class CustomIterator
    implements Iterator<Account>{

    private List<Account> accounts;
    private Integer currentIndex;

    public CustomIterator(List<Account> accounts){
        this.accounts = accounts;
```
this.currentIndex = 0;

public Boolean hasNext(){
    return currentIndex < accounts.size();
}

public Account next(){
    if(hasNext()) {
        return accounts[currentIndex++];
    } else {
        throw new NoSuchElementException('Iterator has no more elements.');
    }
}

remove(index)
Removes the list element stored at the specified index, returning the element that was removed.

Signature
public Object remove(Integer index)

Parameters
index
Type: Integer

Return Value
Type: Object

Example
List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
String s1 = colors.remove(2);
System.assertEquals('Green', s1);

set(index, listElement)
Sets the specified value for the element at the given index.

Signature
public Void set(Integer index, Object listElement)
Parameters

*index*
  Type: Integer
  The index of the list element to set.

*listElement*
  Type: Object
  The value of the list element to set.

Return Value
Type: Void

Usage
To set an element of a one-dimensional list of primitives or sObjects, you can also follow the name of the list with the element’s index position in square brackets.

Example

```java
List<Integer> myList = new Integer[6];
myList.set(0, 47);
myList.set(1, 52);
system.assertEquals(52, myList.get(1));

List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
```

`size()`

Returns the number of elements in the list.

Signature

```java
public Integer size()
```

Return Value
Type: Integer

Example

```java
List<Integer> myList = new List<Integer>();
Integer size = myList.size();
system.assertEquals(0, size);

List<Integer> myList2 = new Integer[6];
```
sort()
Sorts the items in the list in ascending order.

Signature
public Void sort()

Return Value
Type: Void

Usage
Using this method, you can sort primitive types, SelectOption elements, and sObjects (standard objects and custom objects). For more information on the sort order used for sObjects, see Sorting Lists of sObjects. You can sort custom types (your Apex classes) if they implement the Comparable interface. Alternatively, a class implementing the Comparator interface can be passed as a parameter to the List.sort method.

When you use sort() methods on List<Id>s that contain both 15-character and 18-character IDs, IDs for the same record sort together in API version 35.0 and later.

Example
In the following example, the list has three elements. When the list is sorted, the first element is null because it has no value assigned. The second element and third element have values of 5 and 10.

```java
List<Integer> q1 = new Integer[3];

// Assign values to the first two elements.
q1[0] = 10;
q1[1] = 5;

q1.sort();

// Verify sorted list. Elements are sorted in nulls-first order: null, 5, and 10
system.assertEquals(null, q1.get(0));
system.assertEquals(5, q1.get(1));
system.assertEquals(10, q1.get(2));
```
**toString()**

Returns the string representation of the list.

**Signature**

```java
public String toString()
```

**Return Value**

Type: String

**Usage**

When used in cyclic references, the output is truncated to prevent infinite recursion. When used with large collections, the output is truncated to avoid exceeding total heap size and maximum CPU time.

- Up to 10 items per collection are included in the output, followed by an ellipsis (...).
- If the same object is included multiple times in a collection, it’s shown in the output only once; subsequent references are shown as (already output).

**Location Class**

Contains methods for accessing the component fields of geolocation compound fields.

**Namespace**

`system`

**Usage**

Each of these methods is also equivalent to a read-only property. For each getter method you can access the property using dot notation. For example, `myLocation.getLatitude()` is equivalent to `myLocation.latitude`.

You can’t use dot notation to access compound fields’ subfields directly on the parent field. Instead, assign the parent field to a variable of type `Location`, and then access its components.

```java
Location loc = myAccount.MyLocation__c;
Double lat = loc.latitude;
```

**Important:** “Location” in Salesforce can also refer to the Location standard object. When referencing the Location object in your Apex code, always use `Schema.Location` instead of `Location` to prevent confusion with the standard Location compound field. If referencing both the location object and the Location field in the same snippet, you can differentiate between the two by using `System.Location` for the field and `Schema.Location` for the object.

**Example**

```java
// Select and access the Location field. MyLocation__c is the name of a geolocation field on Account.
Account[] records = [SELECT id, MyLocation__c FROM Account LIMIT 10];
```
for (Account acct : records) {
    Location loc = acct.MyLocation__c;
    Double lat = loc.latitude;
    Double lon = loc.longitude;
}

// Instantiate new Location objects and compute the distance between them in different ways.
Location loc1 = Location.newInstance(28.635308,77.22496);
Location loc2 = Location.newInstance(37.7749295,-122.4194155);
Double dist = Location.getDistance(loc1, loc2, 'mi');
Double dist2 = loc1.getDistance(loc2, 'mi');

IN THIS SECTION:
Location Methods

The following are methods for Location.

IN THIS SECTION:
getDistance(toLocation, unit)
Calculates the distance between this location and the specified location, using an approximation of the haversine formula and the specified unit.

getDistance(firstLocation, secondLocation, unit)
Calculates the distance between the two specified locations, using an approximation of the haversine formula and the specified unit.

getLatitude()
Returns the latitude field of this location.

getLongitude()
Returns the longitude field of this location.

newInstance(latitude, longitude)
Creates an instance of the Location class, with the specified latitude and longitude.

getDistance(toLocation, unit)
Calculates the distance between this location and the specified location, using an approximation of the haversine formula and the specified unit.

Signature
public Double getDistance(Location toLocation, String unit)

Parameters
toLocation
Type: Location
The Location to which you want to calculate the distance from the current Location.

unit
Type: String
The distance unit you want to use: mi or km.

Return Value
Type: Double

gDistance(firstLocation, secondLocation, unit)
Calculates the distance between the two specified locations, using an approximation of the haversine formula and the specified unit.

Signature
public static Double getDistance(Location firstLocation, Location secondLocation, String unit)

Parameters
firstLocation
Type: Location
The first of two locations used to calculate distance.

secondLocation
Type: Location
The second of two locations used to calculate distance.

unit
Type: String
The distance unit you want to use: mi or km.

Return Value
Type: Double

gLatitude()
Returns the latitude field of this location.

Signature
public Double getLatitude()

Return Value
Type: Double
**getLongitude()**

Returns the longitude field of this location.

**Signature**

```java
public Double getLongitude()
```

**Return Value**

Type: Double

**newInstance(latitude, longitude)**

Creates an instance of the `Location` class, with the specified latitude and longitude.

**Signature**

```java
public static Location newInstance(Decimal latitude, Decimal longitude)
```

**Parameters**

- `latitude`
  Type: Decimal
- `longitude`
  Type: Decimal

**Return Value**

Type: Location

---

**LoggingLevel Enum**

Specifies the logging level for the `System.debug` method.

**Enum Values**

The following are the values of the `System.LoggingLevel` enum, listed from the lowest to the highest levels. The level is cumulative, that is, if you select FINE, the log also includes all events logged at the DEBUG, INFO, WARN, and ERROR levels.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NONE</td>
<td>No logging.</td>
</tr>
<tr>
<td>ERROR</td>
<td>Error and exception logging.</td>
</tr>
<tr>
<td>WARN</td>
<td>Warning logging.</td>
</tr>
<tr>
<td>INFO</td>
<td>Informational logging.</td>
</tr>
<tr>
<td>DEBUG</td>
<td>User-specified debug logging.</td>
</tr>
</tbody>
</table>
### Usage

Log levels are cumulative. For example, if the lowest level, ERROR, is specified for Apex code, only `System.debug` methods with the log level of ERROR are logged. If the next log level, WARN, is specified, `System.debug` methods specified with either ERROR or WARN levels are logged.

In this example, if the log level is set to ERROR, the string `MsgTxt` isn't written to the debug log because the `debug` method has a level of INFO.

```java
System.debug(logginglevel.INFO, 'MsgTxt');
```

For more information on log levels, see [Debug Log Levels](https://help.salesforce.com) in Salesforce Help.

## Long Class

Contains methods for the Long primitive data type.

### Namespace

`System`

### Usage

For more information on Long, see [Long Data Type](https://help.salesforce.com).

### Long Methods

The following are methods for `Long`.

**IN THIS SECTION:**

- `format()`: Returns the String format for this Long using the locale of the context user.
- `intValue()`: Returns the Integer value for this Long.
- `valueOf(stringToLong)`: Returns a Long that contains the value of the specified String. As in Java, the string is interpreted as representing a signed decimal Long.
**format()**
Returns the String format for this Long using the locale of the context user.

**Signature**

```java
public String format()
```

**Return Value**
Type: String

**Example**

```java
Long myLong = 4271990;
system.assertEquals('4,271,990', myLong.format());
```

**intValue()**
Returns the Integer value for this Long.

**Signature**

```java
public Integer intValue()
```

**Return Value**
Type: Integer

**Example**

```java
Long myLong = 7191991;
Integer value = myLong.intValue();
system.assertEquals(7191991, myLong.intValue());
```

**valueOf(stringToLong)**
Returns a Long that contains the value of the specified String. As in Java, the string is interpreted as representing a signed decimal Long.

**Signature**

```java
public static Long valueOf(String stringToLong)
```

**Parameters**

- **stringToLong**
  Type: String

**Return Value**
Type: Long
Example

```java
Long l1 = Long.valueOf('123456789');
```

**Map Class**

Contains methods for the Map collection type.

**Namespace**

*System*

**Usage**

The Map methods are all instance methods, that is, they operate on a particular instance of a map. The following are the instance methods for maps.

**Note:**

- Map keys and values can be of any data type—primitive types, collections, sObjects, user-defined types, and built-in Apex types.
- Uniqueness of map keys of user-defined types is determined by the `equals` and `hashCode` methods, which you provide in your classes. Uniqueness of keys of all other non-primitive types, such as sObject keys, is determined by comparing the objects’ field values.
- Map keys of type String are case-sensitive. Two keys that differ only by the case are considered unique and have corresponding distinct Map entries. Subsequently, the Map methods, including `put`, `get`, `containsKey`, and `remove` treat these keys as distinct.

For more information on maps, see Maps.

**IN THIS SECTION:**

- Map Constructors
- Map Methods

**Map Constructors**

The following are constructors for Map.

**IN THIS SECTION:**

- `Map<T1,T2>()` Creates a new instance of the `Map` class. T1 is the data type of the keys and T2 is the data type of the values.
- `Map<T1,T2>(mapToCopy)` Creates a new instance of the `Map` class and initializes it by copying the entries from the specified map. T1 is the data type of the keys and T2 is the data type of the values.
- `Map<ID,sObject>(recordList)` Creates a new instance of the `Map` class and populates it with the passed-in list of sObject records. The keys are populated with the sObject IDs and the values are the sObjects.
**Map<T1,T2>()**

Creates a new instance of the `Map` class. T1 is the data type of the keys and T2 is the data type of the values.

**Signature**

```java
public Map<T1,T2>()
```

**Example**

```java
Map<Integer, String> m1 = new Map<Integer, String>();
m1.put(1, 'First item');
m1.put(2, 'Second item');
```

**Map<T1,T2>(mapToCopy)**

Creates a new instance of the `Map` class and initializes it by copying the entries from the specified map. T1 is the data type of the keys and T2 is the data type of the values.

**Signature**

```java
public Map<T1,T2>(Map<T1,T2> mapToCopy)
```

**Parameters**

`mapToCopy`

Type: `Map<T1, T2>`

The map to initialize this map with. T1 is the data type of the keys and T2 is the data type of the values. All map keys and values are copied to this map.

**Example**

```java
Map<Integer, String> m1 = new Map<Integer, String>();
m1.put(1, 'First item');
m1.put(2, 'Second item');
Map<Integer, String> m2 = new Map<Integer, String>(m1);
// The map elements of m2 are copied from m1
System.debug(m2);
```

**Map<ID,sObject>(recordList)**

Creates a new instance of the `Map` class and populates it with the passed-in list of `sObject` records. The keys are populated with the `sObject` IDs and the values are the `sObjects`.

**Signature**

```java
public Map<ID,sObject>(List<sObject> recordList)
```
Parameters

recordList

Type: List<sObject>

The list of sObjects to populate the map with.

Example

List<Account> ls = [select Id, Name from Account];
Map<Id, Account> m = new Map<Id, Account>(ls);

Map Methods

The following are methods for Map. All are instance methods.

IN THIS SECTION:

clear()
Removes all of the key-value mappings from the map.

copy()
Makes a duplicate copy of the map.

containsKey(key)
Returns true if the map contains a mapping for the specified key.

depthClone()
Makes a duplicate copy of a map, including sObject records if this is a map with sObject record values.

equals(map2)
Compares this map with the specified map and returns true if both maps are equal; otherwise, returns false.

get(key)
Returns the value to which the specified key is mapped, or null if the map contains no value for this key.

getSObjectType()
Returns the token of the sObject type that makes up the map values.

hashCode()
Returns the hashcode corresponding to this map.

isEmpty()
Returns true if the map has zero key-value pairs.

keySet()
Returns a set that contains all of the keys in the map.

put(key, value)
Associates the specified value with the specified key in the map.

putAll(fromMap)
Copies all of the mappings from the specified map to the original map.

putAll(sobjectArray)
Adds the list of sObject records to a map declared as Map<ID, sObject> or Map<String, sObject>. 
remove(key)
Removes the mapping for the specified key from the map, if present, and returns the corresponding value.

size()
Returns the number of key-value pairs in the map.

toString()
Returns the string representation of the map.

values()
Returns a list that contains all the values in the map.

clear()
Removes all of the key-value mappings from the map.

**Signature**

```
public Void clear()
```

**Return Value**

Type: Void

clone()
Makes a duplicate copy of the map.

**Signature**

```
public Map<Object, Object> clone()
```

**Return Value**

Type: Map (of same type)

**Usage**

If this is a map with sObject record values, the duplicate map will only be a shallow copy of the map. That is, the duplicate will have references to each sObject record, but the records themselves are not duplicated. For example:

To also copy the sObject records, you must use the `deepClone` method.

**Example**

```java
Account a = new Account(
    Name='Acme',
    BillingCity='New York');

Map<Integer, Account> map1 = new Map<Integer, Account> {};
map1.put(1, a);

Map<Integer, Account> map2 = map1.clone();
```
map1.get(1).BillingCity = 'San Francisco';

System.assertEquals('San Francisco',
    map1.get(1).BillingCity);

System.assertEquals('San Francisco',
    map2.get(1).BillingCity);

**containsKey(key)**

Returns true if the map contains a mapping for the specified key.

**Signature**

```java
public Boolean containsKey(Object key)
```

**Parameters**

- **key**
  Type: Object

**Return Value**

Type: Boolean

**Usage**

If the key is a string, the key value is case-sensitive.

**Example**

```java
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

Boolean contains = colorCodes.containsKey('Blue');
System.assertEquals(true, contains);
```

**deepClone()**

Makes a duplicate copy of a map, including sObject records if this is a map with sObject record values.

**Signature**

```java
public Map<Object, Object> deepClone()
```
Return Value
Type: Map (of the same type)

Usage
To make a shallow copy of a map without duplicating the sObject records it contains, use the clone() method.

Example

```java
Account a = new Account(
    Name='Acme',
    BillingCity='New York');

Map<Integer, Account> map1 = new Map<Integer, Account>{};
map1.put(1, a);

Map<Integer, Account> map2 = map1.deepClone();

// Update the first entry of map1
map1.get(1).BillingCity = 'San Francisco';
// Verify that the BillingCity is updated in map1 but not in map2
System.assertEquals('San Francisco', map1.get(1).BillingCity);
System.assertEquals('New York', map2.get(1).BillingCity);
```

equals(map2)
Compares this map with the specified map and returns true if both maps are equal; otherwise, returns false.

Signature
public Boolean equals(Map map2)

Parameters
map2
Type: Map
The map2 argument is the map to compare this map with.

Return Value
Type: Boolean

Usage
Two maps are equal if their key/value pairs are identical, regardless of the order of those pairs. The == operator is used to compare the map keys and values.

The == operator is equivalent to calling the equals method, so you can call map1.equals(map2); instead of map1 == map2;.
**get (key)**

Returns the value to which the specified key is mapped, or `null` if the map contains no value for this key.

**Signature**

```java
public Object get(Object key)
```

**Parameters**

`key`

Type: Object

**Return Value**

Type: Object

**Usage**

If the key is a string, the key value is case-sensitive.

**Example**

```java
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');
String code = colorCodes.get('Blue');
System.assertEquals('0000A0', code);
// The following is not a color in the map
String code2 = colorCodes.get('Magenta');
System.assertEquals(null, code2);
```

**getSObjectType ()**

Returns the token of the sObject type that makes up the map values.

**Signature**

```java
public Schema.SObjectType getSObjectType()
```

**Return Value**

Type: `Schema.SObjectType`

**Usage**

Use this method with describe information, to determine if a map contains sObjects of a particular type.
Note that this method can only be used with maps that have sObject values.
For more information, see Understanding Apex Describe Information.

Example

```java
// Create a generic sObject variable.
SObject sObj = Database.query('SELECT Id FROM Account LIMIT 1');

// Verify if that sObject variable is an Account token.
System.assertEquals(Account.sObjectType, sObj.getSObjectType());

// Create a map of generic sObjects
Map<Integer, Account> m = new Map<Integer, Account>();

// Verify if the map contains Account tokens.
System.assertEquals(Account.sObjectType, m.getSObjectType());
```

**hashCode()**

Returns the hashcode corresponding to this map.

**Signature**

```
public Integer hashCode()
```

**Return Value**

Type: Integer

**isEmpty()**

Returns true if the map has zero key-value pairs.

**Signature**

```
public Boolean isEmpty()
```

**Return Value**

Type: Boolean

Example

```java
Map<String, String> colorCodes = new Map<String, String>();
Boolean empty = colorCodes.isEmpty();
System.assertEquals(true, empty);
```
**keySet()**

Returns a set that contains all of the keys in the map.

**Signature**

```java
public Set<Object> keySet()
```

**Return Value**

Type: Set (of key type)

**Example**

```java
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');
Set<String> colorSet = new Set<String>();
colorSet = colorCodes.keySet();
```

**put(key, value)**

Associates the specified value with the specified key in the map.

**Signature**

```java
public Object put(Object key, Object value)
```

**Parameters**

- `key`
  - Type: Object
- `value`
  - Type: Object

**Return Value**

Type: Object

**Usage**

If the map previously contained a mapping for this key, the old value is returned by the method and then replaced.

If the key is a string, the key value is case-sensitive.

**Example**

```java
Map<String, String> colorCodes = new Map<String, String>();
```
colorCodes.put('Red', 'ff0000');
colorCodes.put('Red', '#FF0000');
// Red is now #FF0000

**putAll(fromMap)**

Copies all of the mappings from the specified map to the original map.

**Signature**

```java
public Void putAll(Map fromMap)
```

**Parameters**

`fromMap`

Type: Map

**Return Value**

Type: Void

**Usage**

The new mappings from `fromMap` replace any mappings that the original map had.

**Example**

```java
Map<String, String> map1 = new Map<String, String>();
map1.put('Red', 'FF0000');
Map<String, String> map2 = new Map<String, String>();
map2.put('Blue', '0000FF');
// Add map1 entries to map2
map2.putAll(map1);
System.assertEquals(2, map2.size());
```

**putAll(subjectArray)**

Adds the list of sObject records to a map declared as Map<ID, sObject> or Map<String, sObject>.

**Signature**

```java
public Void putAll(sObject[] subjectArray)
```

**Parameters**

`subjectArray`

Type: sObject[]

**Return Value**

Type: Void
Usage
This method is similar to calling the Map constructor with the same input.

Example

```java
List<Account> accts = new List<Account>();
accts.add(new Account(Name='Account1'));
accts.add(new Account(Name='Account2'));
// Insert accounts so their IDs are populated.
insert accts;
Map<Id, Account> m = new Map<Id, Account>();
// Add all the records to the map.
m.putAll(accts);
System.assertEquals(2, m.size());
```

**remove(key)**

Removes the mapping for the specified key from the map, if present, and returns the corresponding value.

**Signature**

```
public Object remove(Key key)
```

**Parameters**

- `key`
  
  Type: Key

**Return Value**

Type: Object

**Usage**

If the key is a string, the key value is case-sensitive.

**Example**

```java
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

String myColor = colorCodes.remove('Blue');
String code2 = colorCodes.get('Blue');
System.assertEquals(null, code2);
```

**size()**

Returns the number of key-value pairs in the map.
Signature

public Integer size()

Return Value

Type: Integer

Example

Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

Integer mSize = colorCodes.size();

system.assertEquals(2, mSize);

toString()

Returns the string representation of the map.

Signature

public String toString()

Return Value

Type: String

Usage

When used in cyclic references, the output is truncated to prevent infinite recursion. When used with large collections, the output is truncated to avoid exceeding total heap size and maximum CPU time.

- Up to 10 items per collection are included in the output, followed by an ellipsis (...).
- If the same object is included multiple times in a collection, it’s shown in the output only once; subsequent references are shown as (already output).

values()

Returns a list that contains all the values in the map.

Signature

public List<Object> values()

Return Value

Type: List<Object>
Usage

The order of map elements is deterministic. You can rely on the order being the same in each subsequent execution of the same code. For example, suppose the `values()` method returns a list containing `value1` and index 0 and `value2` and index 1. Subsequent runs of the same code result in those values being returned in the same order.

Example

```java
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

List<String> colors = new List<String>();
colors = colorCodes.values();
```

Matcher Class

Matchers use Patterns to perform match operations on a character string.

Namespace

System

Matcher Methods

The following are methods for `Matcher`.

IN THIS SECTION:

- `end()`: Returns the position after the last matched character.
- `end(groupIndex)`: Returns the position after the last character of the subsequence captured by the group index during the previous match operation. If the match was successful but the group itself did not match anything, this method returns -1.
- `find()`: Attempts to find the next subsequence of the input sequence that matches the pattern. This method returns true if a subsequence of the input sequence matches this Matcher object’s pattern.
- `find(group)`: Resets the Matcher object and then tries to find the next subsequence of the input sequence that matches the pattern. This method returns `true` if a subsequence of the input sequence matches this Matcher object’s pattern.
- `group()`: Returns the input subsequence returned by the previous match.
- `group(groupIndex)`: Returns the input subsequence captured by the specified group index during the previous match operation. If the match was successful but the specified group failed to match any part of the input sequence, `null` is returned.
groupCount()
Returns the number of capturing groups in this Matching object’s pattern. Group zero denotes the entire pattern and is not included in this count.

hasAnchoringBounds()
Returns true if the Matcher object has anchoring bounds, false otherwise. By default, a Matcher object uses anchoring bounds regions.

hasTransparentBounds()
Returns true if the Matcher object has transparent bounds, false if it uses opaque bounds. By default, a Matcher object uses opaque region boundaries.

hitEnd()
Returns true if the end of input was found by the search engine in the last match operation performed by this Matcher object. When this method returns true, it is possible that more input would have changed the result of the last search.

lookingAt()
Attempts to match the input sequence, starting at the beginning of the region, against the pattern.

matches()
Attempts to match the entire region against the pattern.

pattern()
Returns the Pattern object from which this Matcher object was created.

quoteReplacement(inputString)
Returns a literal replacement string for the specified string inputString. The characters in the returned string match the sequence of characters in inputString.

region(start, end)
Sets the limits of this Matcher object’s region. The region is the part of the input sequence that is searched to find a match.

regionEnd()
Returns the end index (exclusive) of this Matcher object’s region.

regionStart()
Returns the start index (inclusive) of this Matcher object’s region.

replaceAll(replacementString)
Replaces every subsequence of the input sequence that matches the pattern with the replacement string.

replaceFirst(replacementString)
Replaces the first subsequence of the input sequence that matches the pattern with the replacement string.

requireEnd()
Returns true if more input could change a positive match into a negative one.

reset()
Resets this Matcher object. Resetting a Matcher object discards all of its explicit state information.

reset(inputSequence)
Resets this Matcher object with the new input sequence. Resetting a Matcher object discards all of its explicit state information.

start()
Returns the start index of the first character of the previous match.
start(groupIndex)
Returns the start index of the subsequence captured by the group specified by the group index during the previous match operation. Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression m.start(0) is equivalent to m.start().

useAnchoringBounds(anchoringBounds)
Sets the anchoring bounds of the region for the Matcher object. By default, a Matcher object uses anchoring bounds regions.

usePattern(pattern)
Changes the Pattern object that the Matcher object uses to find matches. This method causes the Matcher object to lose information about the groups of the last match that occurred. The Matcher object's position in the input is maintained.

useTransparentBounds(transparentBounds)
Sets the transparency bounds for this Matcher object. By default, a Matcher object uses anchoring bounds regions.

end()
Returns the position after the last matched character.

Signature
public Integer end()

Return Value
Type: Integer

end(groupIndex)
Returns the position after the last character of the subsequence captured by the group index during the previous match operation. If the match was successful but the group itself did not match anything, this method returns -1.

Signature
public Integer end(Integer groupIndex)

Parameters

<table>
<thead>
<tr>
<th>groupIndex</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type: Integer</td>
</tr>
</tbody>
</table>

Return Value
Type: Integer

Usage
Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression m.end(0) is equivalent to m.end().
See Understanding Capturing Groups.
**find()**
Attempts to find the next subsequence of the input sequence that matches the pattern. This method returns true if a subsequence of the input sequence matches this Matcher object's pattern.

**Signature**
```
public Boolean find()
```

**Return Value**
Type: Boolean

**Usage**
This method starts at the beginning of this Matcher object's region, or, if a previous invocation of the method was successful and the Matcher object has not since been reset, at the first character not matched by the previous match.

If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.

For more information, see Using Regions.

**find(group)**
Resets the Matcher object and then tries to find the next subsequence of the input sequence that matches the pattern. This method returns true if a subsequence of the input sequence matches this Matcher object's pattern.

**Signature**
```
public Boolean find(Integer group)
```

**Parameters**
- `group`
  Type: Integer

**Return Value**
Type: Boolean

**Usage**
If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.

**group()**
Returns the input subsequence returned by the previous match.

**Signature**
```
public String group()
```
Return Value
Type: String

Usage
Note that some groups, such as `(a*)`, match the empty string. This method returns the empty string when such a group successfully matches the empty string in the input.

group(groupIndex)
Returns the input subsequence captured by the specified group index during the previous match operation. If the match was successful but the specified group failed to match any part of the input sequence, `null` is returned.

Signature
public String group(Integer groupIndex)

Parameters

  groupIndex
    Type: Integer

Return Value
Type: String

Usage
Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression `m.group(0)` is equivalent to `m.group()`.

Note that some groups, such as `(a*)`, match the empty string. This method returns the empty string when such a group successfully matches the empty string in the input.

See Understanding Capturing Groups.

groupCount()
Returns the number of capturing groups in this Matching object’s pattern. Group zero denotes the entire pattern and is not included in this count.

Signature
public Integer groupCount()

Return Value
Type: Integer

Usage
See Understanding Capturing Groups.
hasAnchoringBounds()
Returns true if the Matcher object has anchoring bounds, false otherwise. By default, a Matcher object uses anchoring bounds regions.

Signature
public Boolean hasAnchoringBounds()

Return Value
Type: Boolean

Usage
If a Matcher object uses anchoring bounds, the boundaries of this Matcher object’s region match start and end of line anchors such as ^ and $.
For more information, see Using Bounds.

hasTransparentBounds()
Returns true if the Matcher object has transparent bounds, false if it uses opaque bounds. By default, a Matcher object uses opaque region boundaries.

Signature
public Boolean hasTransparentBounds()

Return Value
Type: Boolean

Usage
For more information, see Using Bounds.

hitEnd()
Returns true if the end of input was found by the search engine in the last match operation performed by this Matcher object. When this method returns true, it is possible that more input would have changed the result of the last search.

Signature
public Boolean hitEnd()

Return Value
Type: Boolean

lookingAt()
Attempts to match the input sequence, starting at the beginning of the region, against the pattern.
Signature

public Boolean lookingAt()

Return Value

Type: Boolean

Usage

Like the matches method, this method always starts at the beginning of the region; unlike that method, it does not require the entire region be matched.

If the match succeeds, more information can be obtained using the start, end, and group methods.

See Using Regions.

matches()

Attempts to match the entire region against the pattern.

Signature

public Boolean matches()

Return Value

Type: Boolean

Usage

If the match succeeds, more information can be obtained using the start, end, and group methods.

See Using Regions.

pattern()

Returns the Pattern object from which this Matcher object was created.

Signature

public Pattern object pattern()

Return Value

Type: System.Pattern

quoteReplacement(inputString)

Returns a literal replacement string for the specified string inputString. The characters in the returned string match the sequence of characters in inputString.
**Signature**

```java
public static String quoteReplacement(String inputString)
```

**Parameters**

`inputString`
Type: String

**Return Value**

Type: String

**Usage**

Metacharacters (such as $ or ^) and escape sequences in the input string are treated as literal characters with no special meaning.

**region(start, end)**

Sets the limits of this Matcher object’s region. The region is the part of the input sequence that is searched to find a match.

**Signature**

```java
public Matcher object region(Integer start, Integer end)
```

**Parameters**

`start`
Type: Integer

`end`
Type: Integer

**Return Value**

Type: Matcher

**Usage**

This method first resets the Matcher object, then sets the region to start at the index specified by `start` and end at the index specified by `end`.

Depending on the transparency boundaries being used, certain constructs such as anchors may behave differently at or around the boundaries of the region.

See Using Regions and Using Bounds.

**regionEnd()**

Returns the end index (exclusive) of this Matcher object’s region.
Signature

```
public Integer regionEnd()
```

Return Value

Type: Integer

Usage

See Using Regions.

`regionStart()`

Returns the start index (inclusive) of this Matcher object’s region.

Signature

```
public Integer regionStart()
```

Return Value

Type: Integer

Usage

See Using Regions.

`replaceAll(replacementString)`

Replaces every subsequence of the input sequence that matches the pattern with the replacement string.

Signature

```
public String replaceAll(String replacementString)
```

Parameters

- `replacementString`
  Type: String

Return Value

Type: String

Usage

This method first resets the Matcher object, then scans the input sequence looking for matches of the pattern. Characters that are not part of any match are appended directly to the result string; each match is replaced in the result by the replacement string. The replacement string may contain references to captured subsequences.
Note that backslashes (\) and dollar signs ($) in the replacement string may cause the results to be different than if the string was treated as a literal replacement string. Dollar signs may be treated as references to captured subsequences, and backslashes are used to escape literal characters in the replacement string.

Invoking this method changes this Matcher object’s state. If the Matcher object is to be used in further matching operations it should first be reset.

Given the regular expression *a+b*, the input "aabxyzaabxyzabxyzb", and the replacement string "-", an invocation of this method on a Matcher object for that expression would yield the string "-xyz-xyz-xyz-".

**replaceFirst(replacementString)**
Replaces the first subsequence of the input sequence that matches the pattern with the replacement string.

**Signature**
`public String replaceFirst(String replacementString)`

**Parameters**
- `replacementString`
  Type: String

**Return Value**
Type: String

**Usage**
Note that backslashes (\) and dollar signs ($) in the replacement string may cause the results to be different than if the string was treated as a literal replacement string. Dollar signs may be treated as references to captured subsequences, and backslashes are used to escape literal characters in the replacement string.

Invoking this method changes this Matcher object’s state. If the Matcher object is to be used in further matching operations it should first be reset.

Given the regular expression *dog*, the input "zzzdogzzzdogzzz", and the replacement string "cat", an invocation of this method on a Matcher object for that expression would return the string "zzzcatzzzdogzzz".

**requireEnd()**
Returns true if more input could change a positive match into a negative one.

**Signature**
`public Boolean requireEnd()`

**Return Value**
Type: Boolean
Usage
If this method returns true, and a match was found, then more input could cause the match to be lost.
If this method returns false and a match was found, then more input might change the match but the match won’t be lost.
If a match was not found, then requireEnd has no meaning.

reset()
Resets this Matcher object. Resetting a Matcher object discards all of its explicit state information.

Signature
public Matcher object reset()

Return Value
Type: Matcher

Usage
This method does not change whether the Matcher object uses anchoring bounds. You must explicitly use the useAnchoringBounds method to change the anchoring bounds.
For more information, see Using Bounds.

reset(inputSequence)
Resets this Matcher object with the new input sequence. Resetting a Matcher object discards all of its explicit state information.

Signature
public Matcher reset(String inputSequence)

Parameters
inputSequence
Type: String

Return Value
Type: Matcher

start()
Returns the start index of the first character of the previous match.

Signature
public Integer start()
Return Value
Type: Integer

**start(groupIndex)**

Returns the start index of the subsequence captured by the group specified by the group index during the previous match operation. Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression `m.start(0)` is equivalent to `m.start()`.

**Signature**

```
public Integer start(Integer groupIndex)
```

**Parameters**

- `groupIndex`
  Type: Integer

**Return Value**

Type: Integer

**Usage**

See Understanding Capturing Groups.

**useAnchoringBounds(anchoringBounds)**

Sets the anchoring bounds of the region for the Matcher object. By default, a Matcher object uses anchoring bounds regions.

**Signature**

```
public Matcher object useAnchoringBounds(Boolean anchoringBounds)
```

**Parameters**

- `anchoringBounds`
  Type: Boolean
  If you specify `true`, the Matcher object uses anchoring bounds. If you specify `false`, non-anchoring bounds are used.

**Return Value**

Type: Matcher

**Usage**

If a Matcher object uses anchoring bounds, the boundaries of this Matcher object’s region match start and end of line anchors such as `^` and `$.

For more information, see Using Bounds.
**usePattern (pattern)**
Changes the Pattern object that the Matcher object uses to find matches. This method causes the Matcher object to lose information about the groups of the last match that occurred. The Matcher object’s position in the input is maintained.

**Signature**
```java
public Matcher object usePattern(Pattern pattern)
```

**Parameters**
- `pattern`  
  Type: `System.Pattern`

**Return Value**
Type: `Matcher`

---

**useTransparentBounds (transparentBounds)**
Sets the transparency bounds for this Matcher object. By default, a Matcher object uses anchoring bounds regions.

**Signature**
```java
public Matcher object useTransparentBounds(Boolean transparentBounds)
```

**Parameters**
- `transparentBounds`  
  Type: `Boolean`

  If you specify `true`, the Matcher object uses transparent bounds. If you specify `false`, opaque bounds are used.

**Return Value**
Type: `Matcher`

**Usage**
For more information, see `Using Bounds`.

---

**Math Class**
Contains methods for mathematical operations.

**Namespace**
`System`
Math Fields

The following are fields for Math.

IN THIS SECTION:

E
Returns the mathematical constant e, which is the base of natural logarithms.

PI
Returns the mathematical constant pi, which is the ratio of the circumference of a circle to its diameter.

E
Returns the mathematical constant e, which is the base of natural logarithms.

Signature

public static final Double E

Property Value

Type: Double

PI
Returns the mathematical constant pi, which is the ratio of the circumference of a circle to its diameter.

Signature

public static final Double PI

Property Value

Type: Double

Math Methods

The following are methods for Math. All methods are static.

IN THIS SECTION:

abs(decimalValue)
Returns the absolute value of the specified Decimal.

abs(doubleValue)
Returns the absolute value of the specified Double.

abs(integerValue)
Returns the absolute value of the specified Integer.

abs(longValue)
Returns the absolute value of the specified Long.
acos(decimalAngle)
Returns the arc cosine of an angle, in the range of 0.0 through pi.
acos(doubleAngle)
Returns the arc cosine of an angle, in the range of 0.0 through pi.

asin(decimalAngle)
Returns the arc sine of an angle, in the range of -pi/2 through pi/2.
asin(doubleAngle)
Returns the arc sine of an angle, in the range of -pi/2 through pi/2.

atan(decimalAngle)
Returns the arc tangent of an angle, in the range of -pi/2 through pi/2.
atan(doubleAngle)
Returns the arc tangent of an angle, in the range of -pi/2 through pi/2.

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates (xCoordinate and yCoordinate) to polar (r and theta). This method computes the phase theta by computing an arc tangent of xCoordinate/yCoordinate in the range of -pi to pi.

ctb(decimalValue)
Returns the cube root of the specified Decimal. The cube root of a negative value is the negative of the cube root of that value's magnitude.
ctb(doubleValue)
Returns the cube root of the specified Double. The cube root of a negative value is the negative of the cube root of that value's magnitude.

ceil(decimalValue)
Returns the smallest (closest to negative infinity) Decimal that is not less than the argument and is equal to a mathematical integer.
ceil(doubleValue)
Returns the smallest (closest to negative infinity) Double that is not less than the argument and is equal to a mathematical integer.

cos(decimalAngle)
Returns the trigonometric cosine of the angle specified by decimalAngle.
cos(doubleAngle)
Returns the trigonometric cosine of the angle specified by doubleAngle.

cosh(decimalAngle)
Returns the hyperbolic cosine of decimalAngle. The hyperbolic cosine of d is defined to be \((e^d + e^{-d})/2\) where e is Euler's number.
cosh(doubleAngle)
Returns the hyperbolic cosine of doubleAngle. The hyperbolic cosine of d is defined to be \((e^d + e^{-d})/2\) where e is Euler's number.

exp(exponentDecimal)
Returns Euler's number e raised to the power of the specified Decimal.
exp(exponentDouble)
Returns Euler's number e raised to the power of the specified Double.
floor(decimalValue)
Returns the largest (closest to positive infinity) Decimal that is not greater than the argument and is equal to a mathematical integer.

floor(doubleValue)
Returns the largest (closest to positive infinity) Double that is not greater than the argument and is equal to a mathematical integer.

log(decimalValue)
Returns the natural logarithm (base $e$) of the specified Decimal.

log(doubleValue)
Returns the natural logarithm (base $e$) of the specified Double.

log10(decimalValue)
Returns the logarithm (base 10) of the specified Decimal.

log10(doubleValue)
Returns the logarithm (base 10) of the specified Double.

max(decimalValue1, decimalValue2)
Returns the larger of the two specified Decimals.

max(doubleValue1, doubleValue2)
Returns the larger of the two specified Doubles.

max(integerValue1, integerValue2)
Returns the larger of the two specified Integers.

max(longValue1, longValue2)
Returns the larger of the two specified Longs.

min(decimalValue1, decimalValue2)
Returns the smaller of the two specified Decimals.

min(doubleValue1, doubleValue2)
Returns the smaller of the two specified Doubles.

min(integerValue1, integerValue2)
Returns the smaller of the two specified Integers.

min(longValue1, longValue2)
Returns the smaller of the two specified Longs.

mod(integerValue1, integerValue2)
Returns the remainder of integerValue1 divided by integerValue2.

mod(longValue1, longValue2)
Returns the remainder of longValue1 divided by longValue2.

pow(doubleValue, exponent)
Returns the value of the first Double raised to the power of exponent.

random()
Returns a positive Double that is greater than or equal to 0.0 and less than 1.0.

rint(decimalValue)
Returns the value that is closest in value to decimalValue and is equal to a mathematical integer.

rint(doubleValue)
Returns the value that is closest in value to doubleValue and is equal to a mathematical integer.
round(doubleValue)
Do not use. This method is deprecated as of the Winter '08 release. Instead, use Math.roundToLong. Returns the closest Integer to the specified Double. If the result is less than -2,147,483,648 or greater than 2,147,483,647, Apex generates an error.

round(decimalValue)
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

roundToLong(decimalValue)
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

roundToLong(doubleValue)
Returns the closest Long to the specified Double.

signum(decimalValue)
Returns the signum function of the specified Decimal, which is 0 if `decimalValue` is 0, 1.0 if `decimalValue` is greater than 0, -1.0 if `decimalValue` is less than 0.

signum(doubleValue)
Returns the signum function of the specified Double, which is 0 if `doubleValue` is 0, 1.0 if `doubleValue` is greater than 0, -1.0 if `doubleValue` is less than 0.

sin(decimalAngle)
Returns the trigonometric sine of the angle specified by `decimalAngle`.

sin(doubleAngle)
Returns the trigonometric sine of the angle specified by `doubleAngle`.

sinh(decimalAngle)
Returns the hyperbolic sine of `decimalAngle`. The hyperbolic sine of `decimalAngle` is defined to be \((e^x - e^{-x})/2\) where \(e\) is Euler's number.

sinh(doubleAngle)
Returns the hyperbolic sine of `doubleAngle`. The hyperbolic sine of `doubleAngle` is defined to be \((e^x - e^{-x})/2\) where \(e\) is Euler's number.

sqrt(decimalValue)
Returns the correctly rounded positive square root of `decimalValue`.

sqrt(doubleValue)
Returns the correctly rounded positive square root of `doubleValue`.

tan(decimalAngle)
Returns the trigonometric tangent of the angle specified by `decimalAngle`.

tan(doubleAngle)
Returns the trigonometric tangent of the angle specified by `doubleAngle`.

tanh(decimalAngle)
Returns the hyperbolic tangent of `decimalAngle`. The hyperbolic tangent of `decimalAngle` is defined to be \((e^x - e^{-x})/(e^x + e^{-x})\) where \(e\) is Euler's number. In other words, it is equivalent to \(\sinh(x)/\cosh(x)\). The absolute value of the exact `tanh` is always less than 1.
tanh(doubleAngle)
Returns the hyperbolic tangent of doubleAngle. The hyperbolic tangent of doubleAngle is defined to be \((e^x - e^{-x})/(e^x + e^{-x})\) where \(e\) is Euler’s number. In other words, it is equivalent to \(\sinh(x)/\cosh(x)\). The absolute value of the exact \(\tanh\) is always less than 1.

abs (decimalValue)
Returns the absolute value of the specified Decimal.

**Signature**

```java
public static Decimal abs(Decimal decimalValue)
```

**Parameters**

decimalValue
Type: Decimal

**Return Value**

Type: Decimal

abs (doubleValue)
Returns the absolute value of the specified Double.

**Signature**

```java
public static Double abs(Double doubleValue)
```

**Parameters**

doubleValue
Type: Double

**Return Value**

Type: Double

abs (integerValue)
Returns the absolute value of the specified Integer.

**Signature**

```java
public static Integer abs(Integer integerValue)
```

**Parameters**

integerValue
Type: Integer
Return Value
Type: Integer

Example

```java
Integer i = -42;
Integer i2 = math.abs(i);
system.assertEquals(i2, 42);
```

`abs(longValue)`
Returns the absolute value of the specified Long.

**Signature**

```java
public static Long abs(Long longValue)
```

**Parameters**

`longValue`  
Type: Long

Return Value  
Type: Long

`acos(decimalAngle)`
Returns the arc cosine of an angle, in the range of 0.0 through \( \pi \).

**Signature**

```java
public static Decimal acos(Decimal decimalAngle)
```

**Parameters**

`decimalAngle`  
Type: Decimal

Return Value  
Type: Decimal

`acos(doubleAngle)`
Returns the arc cosine of an angle, in the range of 0.0 through \( \pi \).

**Signature**

```java
public static Double acos(Double doubleAngle)
```
Parameters

\textit{doubleAngle}

Type: \textit{Double}

Return Value

Type: \textit{Double}

\textbf{asin(decimalAngle)}

Returns the arc sine of an angle, in the range of \(-\pi/2 \text{ through } \pi/2\).

Signature

\texttt{public static Decimal asin(Decimal decimalAngle)}

Parameters

\textit{decimalAngle}

Type: \textit{Decimal}

Return Value

Type: \textit{Decimal}

\textbf{asin(doubleAngle)}

Returns the arc sine of an angle, in the range of \(-\pi/2 \text{ through } \pi/2\).

Signature

\texttt{public static Double asin(Double doubleAngle)}

Parameters

\textit{doubleAngle}

Type: \textit{Double}

Return Value

Type: \textit{Double}

\textbf{atan(decimalAngle)}

Returns the arc tangent of an angle, in the range of \(-\pi/2 \text{ through } \pi/2\).

Signature

\texttt{public static Decimal atan(Decimal decimalAngle)}
Parameters

decimalAngle
   Type: Decimal

Return Value
   Type: Decimal

atan(doubleAngle)
Returns the arc tangent of an angle, in the range of -pi/2 through pi/2.

Signature
public static Double atan(Double doubleAngle)

Parameters

doubleAngle
   Type: Double

Return Value
   Type: Double

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates (xCoordinate and yCoordinate) to polar (r and theta). This method computes the phase theta by computing an arc tangent of xCoordinate/yCoordinate in the range of -pi to pi.

Signature
public static Decimal atan2(Decimal xCoordinate, Decimal yCoordinate)

Parameters

xCoordinate
   Type: Decimal

yCoordinate
   Type: Decimal

Return Value
   Type: Decimal

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates (xCoordinate and yCoordinate) to polar (r and theta). This method computes the phase theta by computing an arc tangent of xCoordinate/yCoordinate in the range of -pi to pi.
Signature

```
public static Double atan2(Double xCoordinate, Double yCoordinate)
```

Parameters

- **xCoordinate**
  - Type: Double
- **yCoordinate**
  - Type: Double

Return Value

Type: Double

cbrt(decimalValue)

Returns the cube root of the specified Decimal. The cube root of a negative value is the negative of the cube root of that value’s magnitude.

Signature

```
public static Decimal cbrt(Decimal decimalValue)
```

Parameters

- **decimalValue**
  - Type: Decimal

Return Value

Type: Decimal

cbrt(doubleValue)

Returns the cube root of the specified Double. The cube root of a negative value is the negative of the cube root of that value’s magnitude.

Signature

```
public static Double cbrt(Double doubleValue)
```

Parameters

- **doubleValue**
  - Type: Double

Return Value

Type: Double
**ceil(decimalValue)**

Returns the smallest (closest to negative infinity) Decimal that is not less than the argument and is equal to a mathematical integer.

**Signature**

```java
public static Decimal ceil(Decimal decimalValue)
```

**Parameters**

- `decimalValue`
  - Type: Decimal

**Return Value**

- Type: Decimal

**ceil(doubleValue)**

Returns the smallest (closest to negative infinity) Double that is not less than the argument and is equal to a mathematical integer.

**Signature**

```java
public static Double ceil(Double doubleValue)
```

**Parameters**

- `doubleValue`
  - Type: Double

**Return Value**

- Type: Double

**cos(decimalAngle)**

Returns the trigonometric cosine of the angle specified by `decimalAngle`.

**Signature**

```java
public static Decimal cos(Decimal decimalAngle)
```

**Parameters**

- `decimalAngle`
  - Type: Decimal

**Return Value**

- Type: Decimal
cos(doubleAngle)
Returns the trigonometric cosine of the angle specified by doubleAngle.

Signature
public static Double cos(Double doubleAngle)

Parameters
doubleAngle
   Type: Double

Return Value
Type: Double

cosh(decimalAngle)
Returns the hyperbolic cosine of decimalAngle. The hyperbolic cosine of \( d \) is defined to be \( (e^d + e^{-d})/2 \) where \( e \) is Euler's number.

Signature
public static Decimal cosh(Decimal decimalAngle)

Parameters
decimalAngle
   Type: Decimal

Return Value
Type: Decimal

cosh(doubleAngle)
Returns the hyperbolic cosine of doubleAngle. The hyperbolic cosine of \( d \) is defined to be \( (e^d + e^{-d})/2 \) where \( e \) is Euler's number.

Signature
public static Double cosh(Double doubleAngle)

Parameters
doubleAngle
   Type: Double

Return Value
Type: Double
**exp (exponentDecimal)**
Returns Euler’s number $e$ raised to the power of the specified Decimal.

**Signature**
```
public static Decimal exp(Decimal exponentDecimal)
```

**Parameters**
- `exponentDecimal`
  Type: `Decimal`

**Return Value**
Type: `Decimal`

**exp (exponentDouble)**
Returns Euler’s number $e$ raised to the power of the specified Double.

**Signature**
```
public static Double exp(Double exponentDouble)
```

**Parameters**
- `exponentDouble`
  Type: `Double`

**Return Value**
Type: `Double`

**floor (decimalValue)**
Returns the largest (closest to positive infinity) Decimal that is not greater than the argument and is equal to a mathematical integer.

**Signature**
```
public static Decimal floor(Decimal decimalValue)
```

**Parameters**
- `decimalValue`
  Type: `Decimal`

**Return Value**
Type: `Decimal`
**floor(doubleValue)**
Returns the largest (closest to positive infinity) Double that is not greater than the argument and is equal to a mathematical integer.

**Signature**
```
public static Double floor(Double doubleValue)
```

**Parameters**
-doubleValue
  Type: Double

**Return Value**
Type: Double

**log(decimalValue)**
Returns the natural logarithm (base $e$) of the specified Decimal.

**Signature**
```
public static Decimal log(Decimal decimalValue)
```

**Parameters**
-decimalValue
  Type: Decimal

**Return Value**
Type: Decimal

**log(doubleValue)**
Returns the natural logarithm (base $e$) of the specified Double.

**Signature**
```
public static Double log(Double doubleValue)
```

**Parameters**
-doubleValue
  Type: Double

**Return Value**
Type: Double
log10(decimalValue)
Returns the logarithm (base 10) of the specified Decimal.

Signature
public static Decimal log10(Decimal decimalValue)

Parameters
decimalValue
Type: Decimal

Return Value
Type: Decimal

log10(doubleValue)
Returns the logarithm (base 10) of the specified Double.

Signature
public static Double log10(Double doubleValue)

Parameters
doubleValue
Type: Double

Return Value
Type: Double

max(decimalValue1, decimalValue2)
Returns the larger of the two specified Decimals.

Signature
public static Decimal max(Decimal decimalValue1, Decimal decimalValue2)

Parameters
decimalValue1
Type: Decimal
decimalValue2
Type: Decimal
Return Value
Type: Decimal

Example
```
Decimal larger = math.max(12.3, 156.6);
system.assertEquals(larger, 156.6);
```

max(doubleValue1, doubleValue2)
Returns the larger of the two specified Doubles.

Signature
```
public static Double max(Double doubleValue1, Double doubleValue2)
```

Parameters
```
doubleValue1  
  Type: Double

doubleValue2  
  Type: Double
```

Return Value
Type: Double

max(integerValue1, integerValue2)
Returns the larger of the two specified Integers.

Signature
```
public static Integer max(Integer integerValue1, Integer integerValue2)
```

Parameters
```
integerValue1  
  Type: Integer

integerValue2  
  Type: Integer
```

Return Value
Type: Integer

max(longValue1, longValue2)
Returns the larger of the two specified Longs.
**max(longValue1, longValue2)**

**Parameters**
- `longValue1`
  - Type: `Long`
- `longValue2`
  - Type: `Long`

**Return Value**
- Type: `Long`

**min(decimalValue1, decimalValue2)**

Returns the smaller of the two specified Decimals.

**Signature**

```
public static Decimal min(Decimal decimalValue1, Decimal decimalValue2)
```

**Parameters**
- `decimalValue1`
  - Type: `Decimal`
- `decimalValue2`
  - Type: `Decimal`

**Return Value**
- Type: `Decimal`

**Example**

```java
Decimal smaller = math.min(12.3, 156.6);
system.assertEquals(smaller, 12.3);
```

**min(doubleValue1, doubleValue2)**

Returns the smaller of the two specified Doubles.

**Signature**

```
public static Double min(Double doubleValue1, Double doubleValue2)
```
Parameters

doubleValue1
Type: Double

doubleValue2
Type: Double

Return Value
Type: Double

\texttt{min(integerValue1, integerValue2)}
Returns the smaller of the two specified Integers.

Signature

\texttt{public static Integer min(Integer integerValue1, Integer integerValue2)}

Parameters

integerValue1
Type: Integer

integerValue2
Type: Integer

Return Value
Type: Integer

\texttt{min(longValue1, longValue2)}
Returns the smaller of the two specified Longs.

Signature

\texttt{public static Long min(Long longValue1, Long longValue2)}

Parameters

longValue1
Type: Long

longValue2
Type: Long

Return Value
Type: Long
mod(integerValue1, integerValue2)

Returns the remainder of integerValue1 divided by integerValue2.

Signature

public static Integer mod(Integer integerValue1, Integer integerValue2)

Parameters

integerValue1
Type: Integer

integerValue2
Type: Integer

Return Value

Type: Integer

Example

```java
Integer remainder = math.mod(12, 2);
system.assertEquals(remainder, 0);

Integer remainder2 = math.mod(8, 3);
system.assertEquals(remainder2, 2);
```

mod(longValue1, longValue2)

Returns the remainder of longValue1 divided by longValue2.

Signature

public static Long mod(Long longValue1, Long longValue2)

Parameters

longValue1
Type: Long

longValue2
Type: Long

Return Value

Type: Long

pow(doubleValue, exponent)

Returns the value of the first Double raised to the power of exponent.
public static Double pow(Double doubleValue, Double exponent)

Parameters

doubleValue
  Type: Double

exponent
  Type: Double

Return Value
Type: Double

random()
Returns a positive Double that is greater than or equal to 0.0 and less than 1.0.

signature
public static Double random()

Return Value
Type: Double

rint(decimalValue)
Returns the value that is closest in value to decimalValue and is equal to a mathematical integer.

Signature
public static Decimal rint(Decimal decimalValue)

Parameters

decimalValue
  Type: Decimal

Return Value
Type: Decimal

rint(doubleValue)
Returns the value that is closest in value to doubleValue and is equal to a mathematical integer.

Signature
public static Double rint(Double doubleValue)
Parameters

doubleValue
Type: Double

Return Value
Type: Double

**round (doubleValue)**
Do not use. This method is deprecated as of the Winter '08 release. Instead, use Math.roundToLong. Returns the closest Integer to the specified Double. If the result is less than -2,147,483,648 or greater than 2,147,483,647, Apex generates an error.

Signature

```
public static Integer round(Double doubleValue)
```

Parameters

doubleValue
Type: Double

Return Value
Type: Integer

**round (decimalValue)**
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

Signature

```
public static Integer round(Decimal decimalValue)
```

Parameters

decimalValue
Type: Decimal

Return Value
Type: Integer

Usage
Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.
**Example**

```java
Decimal d1 = 4.5;
Integer i1 = Math.round(d1);
System.assertEquals(4, i1);

Decimal d2 = 5.5;
Integer i2 = Math.round(d2);
System.assertEquals(6, i2);
```

**roundToLong(decimalValue)**

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the "nearest neighbor" unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

**Signature**

```java
public static Long roundToLong(Decimal decimalValue)
```

**Parameters**

decimalValue

Type: Decimal

**Return Value**

Type: Long

**Usage**

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

**Example**

```java
Decimal d1 = 4.5;
Long i1 = Math.roundToLong(d1);
System.assertEquals(4, i1);

Decimal d2 = 5.5;
Long i2 = Math.roundToLong(d2);
System.assertEquals(6, i2);
```

**roundToLong(doubleValue)**

Returns the closest Long to the specified Double.

**Signature**

```java
public static Long roundToLong(Double doubleValue)
```
Parameters

doubleValue
   Type: Double

Return Value
Type: Long

**signum(decimalValue)**

Returns the signum function of the specified Decimal, which is 0 if `decimalValue` is 0, 1.0 if `decimalValue` is greater than 0, -1.0 if `decimalValue` is less than 0.

Signature

`public static Decimal signum(Decimal decimalValue)`

Parameters

decimalValue
   Type: Decimal

Return Value
Type: Decimal

**signum(doubleValue)**

Returns the signum function of the specified Double, which is 0 if `doubleValue` is 0, 1.0 if `doubleValue` is greater than 0, -1.0 if `doubleValue` is less than 0.

Signature

`public static Double signum(Double doubleValue)`

Parameters

doubleValue
   Type: Double

Return Value
Type: Double

**sin(decimalAngle)**

Returns the trigonometric sine of the angle specified by `decimalAngle`. 
Signature
public static Decimal sin(Decimal decimalAngle)

Parameters
decimalAngle
  Type: Decimal

Return Value
Type: Decimal

\textbf{sin(doubleAngle)}

Returns the trigonometric sine of the angle specified by doubleAngle.

Signature
public static Double sin(Double doubleAngle)

Parameters
doubleAngle
  Type: Double

Return Value
Type: Double

\textbf{sinh(decimalAngle)}

Returns the hyperbolic sine of decimalAngle. The hyperbolic sine of decimalAngle is defined to be \((e^x - e^{-x})/2\) where \(e\) is Euler's number.

Signature
public static Decimal sinh(Decimal decimalAngle)

Parameters
decimalAngle
  Type: Decimal

Return Value
Type: Decimal
\textbf{sinh(\textit{doubleAngle})}

Returns the hyperbolic sine of \textit{doubleAngle}. The hyperbolic sine of \textit{doubleAngle} is defined to be \((e^x - e^{-x})/2\) where \(e\) is Euler's number.

**Signature**

\texttt{public static Double sinh(Double doubleAngle)}

**Parameters**

- \textit{doubleAngle}
  - Type: Double

**Return Value**

- Type: Double

\textbf{sqrt(\textit{decimalValue})}

Returns the correctly rounded positive square root of \textit{decimalValue}.

**Signature**

\texttt{public static Decimal sqrt(Decimal decimalValue)}

**Parameters**

- \textit{decimalValue}
  - Type: Decimal

**Return Value**

- Type: Decimal

\textbf{sqrt(\textit{doubleValue})}

Returns the correctly rounded positive square root of \textit{doubleValue}.

**Signature**

\texttt{public static Double sqrt(Double doubleValue)}

**Parameters**

- \textit{doubleValue}
  - Type: Double

**Return Value**

- Type: Double
**tan (decimalAngle)**

Returns the trigonometric tangent of the angle specified by `decimalAngle`.

**Signature**

```java
public static Decimal tan(Decimal decimalAngle)
```

**Parameters**

- `decimalAngle`
  Type: `Decimal`

**Return Value**

Type: `Decimal`

**tan (doubleAngle)**

Returns the trigonometric tangent of the angle specified by `doubleAngle`.

**Signature**

```java
public static Double tan(Double doubleAngle)
```

**Parameters**

- `doubleAngle`
  Type: `Double`

**Return Value**

Type: `Double`

**tanh (decimalAngle)**

Returns the hyperbolic tangent of `decimalAngle`. The hyperbolic tangent of `decimalAngle` is defined to be `(e^x - e^{-x})/(e^x + e^{-x})` where `e` is Euler's number. In other words, it is equivalent to `sinh (x) / cosh (x)`. The absolute value of the exact `tanh` is always less than 1.

**Signature**

```java
public static Decimal tanh(Decimal decimalAngle)
```

**Parameters**

- `decimalAngle`
  Type: `Decimal`
Return Value
Type: Decimal

tanh(doubleAngle)
Returns the hyperbolic tangent of doubleAngle. The hyperbolic tangent of doubleAngle is defined to be \((e^x - e^{-x})/(e^x + e^{-x})\) where \(e\) is Euler's number. In other words, it is equivalent to \(\sinh(x)/\cosh(x)\). The absolute value of the exact \(\tanh\) is always less than 1.

Signature
public static Double tanh(Double doubleAngle)

Parameters
doubleAngle
Type: Double

Return Value
Type: Double

Messaging Class
Contains messaging methods used when sending a single or mass email.

Namespace
System

Messaging Methods
The following are methods for Messaging. All are instance methods.

IN THIS SECTION:

extractInboundEmail(source, includeForwardedAttachments)
Use this method in your email service code to control how to parse and process forwarded or attached emails. Returns an instance of Messaging.InboundEmail from a stream of data that is in RFC822 format. The data stream can be a forwarded email in an attachment to an existing InboundEmail, or a stream from another source.

reserveMassEmailCapacity(amountReserved)
Reserves email capacity to send mass email to the specified number of email addresses, after the current transaction commits.

reserveSingleEmailCapacity(amountReserved)
Reserves email capacity to send single email to the specified number of email addresses, after the current transaction commits.
sendEmail(emails, allOrNothing)
Sends the list of emails instantiated with either SingleEmailMessage or MassEmailMessage and returns a list of SendEmailResult objects. When org preferences are set to save EmailMessage objects and a trigger is defined for EmailMessage objects, the trigger is fired for each SingleEmailMessage individually. The sendEmail method can be called 10 times per Apex transaction and each method invocation can include up to 100 "To", 25 "Cc", and 25 "Bcc" recipients.

sendEmailMessage(emailMessageIds, allOrNothing)
Sends draft email messages as defined by the specified email message IDs and returns a list of SendEmailResult objects.

renderEmailTemplate(whoId, whatId, bodies)
Replaces merge fields in text bodies of email templates with values from Salesforce records. Returns an array of RenderEmailTemplateBodyResult objects, each of which corresponds to an element in the supplied array of text bodies. Each RenderEmailTemplateBodyResult provides a success or failure indication, along with either an error code or the rendered text.

renderStoredEmailTemplate(templateId, whoId, whatId)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of Messaging.SingleEmailMessage. Includes all attachment content in the returned email message.

renderStoredEmailTemplate(templateId, whoId, whatId, attachmentRetrievalOption)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of Messaging.SingleEmailMessage. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

renderStoredEmailTemplate(templateId, whoId, whatId, attachmentRetrievalOption, updateEmailTemplateUsage)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of Messaging.SingleEmailMessage. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

extractInboundEmail(source, includeForwardedAttachments)
Use this method in your email service code to control how to parse and process forwarded or attached emails. Returns an instance of Messaging.InboundEmail from a stream of data that is in RFC822 format. The data stream can be a forwarded email in an attachment to an existing InboundEmail, or a stream from another source.

Signature
public static Messaging.InboundEmail extractInboundEmail(Object source, Boolean includeForwardedAttachments)

Parameters

source
Type: Object
An instance of Messaging.InboundEmail.BinaryAttachment whose MimeTypeSubtype is message/rfc822 or a Blob. If source is a Blob, then supply a byte array in RFC822 format.

includeForwardedAttachments
Type: Boolean
This parameter controls how attachments to embedded or forwarded emails are handled. Set to true to provide all attachments, even attachments in embedded emails in the binaryAttachments and textAttachments properties of the returned value. Set to false to provide only the attachments that are at the top level of the source email.
Return Value
Type: Messaging.InboundEmail

reserveMassEmailCapacity(amountReserved)
Reserves email capacity to send mass email to the specified number of email addresses, after the current transaction commits.

Signature
public Void reserveMassEmailCapacity(Integer amountReserved)

Parameters
amountReserved
Type: Integer

Return Value
Type: Void

Usage
This method can be called when you know in advance how many addresses emails will be sent to as a result of the transaction. If the transaction would cause the organization to exceed its daily email limit, using this method results in the following error:
System.HandledException: The daily limit for the org would be exceeded by this request.
If the organization doesn’t have permission to send API or mass email, using this method results in the following error:
System.NoAccessException: The organization is not permitted to send email.

reserveSingleEmailCapacity(amountReserved)
Reserves email capacity to send single email to the specified number of email addresses, after the current transaction commits.

Signature
public Void reserveSingleEmailCapacity(Integer amountReserved)

Parameters
amountReserved
Type: Integer

Return Value
Type: Void

Usage
This method can be called when you know in advance how many addresses emails will be sent to as a result of the transaction. If the transaction would cause the organization to exceed its daily email limit, using this method results in the following error:
System.HandledException: The daily limit for the org would be exceeded by this request.
If the organization doesn’t have permission to send API or mass email, using this method results in the following error:
System.NoAccessException: The organization is not permitted to send email.
the organization doesn’t have permission to send API or mass email, using this method results in the following error:
System.NoAccessException: The organization is not permitted to send email.

**sendEmail(emails, allOrNothing)**

Sends the list of emails instantiated with either SingleEmailMessage or MassEmailMessage and returns a list of SendEmailResult objects. When org preferences are set to save EmailMessage objects and a trigger is defined for EmailMessage objects, the trigger is fired for each SingleEmailMessage individually. The sendEmail method can be called 10 times per Apex transaction and each method invocation can include up to 100 "To", 25 "Cc", and 25 "Bcc" recipients.

**Signature**

```java
public Messaging.SendEmailResult[] sendEmail(Messaging.Email[] emails, Boolean allOrNothing)
```

**Parameters**

- `emails`
  - Type: Messaging.Email[]
- `allOrNothing`
  - Type: Boolean

  The optional `opt_allOrNone` parameter specifies whether sendEmail prevents delivery of all other messages when any of the messages fail due to an error (true), or whether it allows delivery of the messages that don’t have errors (false). The default is true.

**Return Value**

Type: Messaging.SendEmailResult[]

**sendEmailMessage(emailMessageIds, allOrNothing)**

Sends draft email messages as defined by the specified email message IDs and returns a list of SendEmailResult objects.

**Signature**

```java
public Messaging.SendEmailResult[] sendEmailMessage(List<ID> emailMessageIds, Boolean allOrNothing)
```

**Parameters**

- `emailMessageIds`
  - Type: List<ID>
- `allOrNothing`
  - Type: Boolean

**Return Value**

Type: Messaging.SendEmailResult[]

If the `emailMessageIds` parameter is null, the method throws a System.IllegalArgumentException exception.
Usage

The sendEmailMessage method assumes that the optional allOrNothing parameter is always false and ignores the value you set. Delivery of all messages is attempted even if some messages fail due to an error.

The email address of the user calling the sendEmailMessage method is inserted in the From Address field of the email header and the Email Message record.

Example

This example shows how to send a draft email message. It creates a case and a new email message associated with the case. Next, the example sends a draft email message and checks the results. Before running this example, make sure to replace the email address with a valid address.

```apex
Case c = new Case();
insert c;

EmailMessage e = new EmailMessage();
e.parentid = c.id;
// Set to draft status.
// This status is required
// for sendEmailMessage().
e.Status = '5';
e.TextBody = 'Sample email message.';
e.Subject = 'Apex sample';
e.ToAddress = 'customer@email.com';
insert e;
List<Messaging.SendEmailResult> results = Messaging.sendEmailMessage(new ID[]
{ e.id });
System.assertEquals(1, results.size());
System.assertEquals(true,
results[0].success);
```

Versioned Behavior Changes

In API version 54.0 and later, a null emailMessageIds parameter results in a System.IllegalArgumentException exception. In API version 53.0 and earlier, a null emailMessageIds parameter results in an error.

renderEmailTemplate(whoId, whatId, bodies)

Replaces merge fields in text bodies of email templates with values from Salesforce records. Returns an array of RenderEmailTemplateBodyResult objects, each of which corresponds to an element in the supplied array of text bodies. Each RenderEmailTemplateBodyResult provides a success or failure indication, along with either an error code or the rendered text.
Signature

```
public static List<Messaging.RenderEmailTemplateBodyResult> renderEmailTemplate(String whoId, String whatId, List<String> bodies)
```

Parameters

**whoId**
- Type: String
  - The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

**whatId**
- Type: String
  - Identifies an object in the database like an account or opportunity. The record for that object is read and used in merge field processing.

**bodies**
- Type: List<String>
  - An array of strings that are examined for merge field references. The corresponding data from the object referenced by the `whoId` or `whatId` replaces the merge field reference.

Return Value

Type: List<Messaging.RenderEmailTemplateBodyResult>

Usage

Use this method in situations in which you want to dynamically compose blocks of text that are enriched with data from the database. You can then use the the rendered blocks of text to compose and send an email or update a text value in another database record.

Executing the `renderEmailTemplate` method counts toward the SOQL governor limit. The number of SOQL queries that this method consumes is the number of elements in the list of strings passed in the `bodies` parameter.

SEE ALSO:
- Execution Governors and Limits

**renderStoredEmailTemplate(templateId, whoId, whatId)**

Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of `Messaging.SingleEmailMessage`. Includes all attachment content in the returned email message.

Signature

```
public static Messaging.SingleEmailMessage renderStoredEmailTemplate(String templateId, String whoId, String whatId)
```

Parameters

**templateId**
- Type: String
  - An email template that exists in the database, such as text, HTML, custom, and Visualforce templates.
whoId
Type: String
The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

whatId
Type: String
Identifies an object in the database, like an account or opportunity. The record for that object is read and used in merge field processing.

Return Value
Type: Messaging.SingleEmailMessage

Usage
Executing the renderStoredEmailTemplate method counts toward the SOQL governor limit as one query.

SEE ALSO:
Execution Governors and Limits

renderStoredEmailTemplate(templateId, whoId, whatId, attachmentRetrievalOption)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of Messaging.SingleEmailMessage. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

Signature
public static Messaging.SingleEmailMessage renderStoredEmailTemplate(String templateId, String whoId, String whatId, Messaging.AttachmentRetrievalOption attachmentRetrievalOption)

Parameters

templateId
Type: String
An email template that exists in the database, such as text, HTML, custom, and Visualforce templates.

whoId
Type: String
The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

whatId
Type: String
Identifies an object in the database, like an account or opportunity. The record for that object is read and used in merge field processing.
attachmentRetrievalOption
Type: Messaging.AttachmentRetrievalOption

Specifies options for including attachments in the fileAttachments property of the returned Messaging.SingleEmailMessage. Set to one of the Messaging.AttachmentRetrievalOption values to include attachment metadata only, attachment metadata and content, or to exclude attachments.

Note: When the attachmentRetrievalOption parameter is not set to NONE, the entityAttachments property of Messaging.SingleEmailMessage contains the ID of the Salesforce content objects to attach (ContentVersion or Document). The fileAttachments property contains the IDs of attachments, in addition to all the IDs in the entityAttachments property. As a result, the ID values in entityAttachments are duplicates of the IDs in the fileAttachments property. If you call renderStoredEmailTemplate() by passing the METADATA_WITH_BODY option, and send the rendered email message, the email will contain duplicate attachments. Before using the returned email message with sendEmail(emails, allOrNothing), you can remove attachments from fileAttachments that are duplicated in entityAttachments.

Return Value
Type: Messaging.SingleEmailMessage

Usage
Executing the renderStoredEmailTemplate method counts toward the SOQL governor limit as one query.

renderStoredEmailTemplate(templateId, whoId, whatId, attachmentRetrievalOption, updateEmailTemplateUsage)

Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of Messaging.SingleEmailMessage. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

Signature
public static Messaging.SingleEmailMessage renderStoredEmailTemplate(String templateId, String whoId, String whatId, Messaging.AttachmentRetrievalOption attachmentRetrievalOption, Boolean updateEmailTemplateUsage)

Parameters

templateId
Type: String

An email template that exists in the database, such as text, HTML, custom, and Visualforce templates.

whoId
Type: String

The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

whatId
Type: String

3255
Identifies an object in the database, like an account or opportunity. The record for that object is read and used in merge field processing.

attachmentRetrievalOption
Type: Messaging.AttachmentRetrievalOption

Specifies options for including attachments in the fileAttachments property of the returned Messaging.SingleEmailMessage. Set to one of the Messaging.AttachmentRetrievalOption values to include attachment metadata only, attachment metadata and content, or to exclude attachments.

Note: When the attachmentRetrievalOption parameter is not set to NONE, the entityAttachments property of Messaging.SingleEmailMessage contains the ID of the Salesforce content objects to attach (ContentVersion or Document). The fileAttachments property contains the IDs of attachments, in addition to all the IDs in the entityAttachments property. As a result, the ID values in entityAttachments are duplicates of the IDs in the fileAttachments property. If you call renderStoredEmailTemplate() by passing the METADATA_WITH_BODY option, and send the rendered email message, the email will contain duplicate attachments. Before using the returned email message with sendEmail(emails, allOrNothing), you can remove attachments from fileAttachments that are duplicated in entityAttachments.

updateEmailTemplateUsage
Type: Boolean

Specifies whether the usage field in the EmailTemplate record is updated upon successful rendering.

Return Value
Type: Messaging.SingleEmailMessage

Usage
Executing the renderStoredEmailTemplate method counts toward the SOQL governor limit as one query.

MultiStaticResourceCalloutMock Class
Utility class used to specify a fake response using multiple resources for testing HTTP callouts.

Namespace
System

Usage
Use the methods in this class to set the response properties for testing HTTP callouts. You can specify a resource for each endpoint.

IN THIS SECTION:
MultiStaticResourceCalloutMock Constructors
MultiStaticResourceCalloutMock Methods

MultiStaticResourceCalloutMock Constructors
The following are constructors for MultiStaticResourceCalloutMock.
MultiStaticResourceCalloutMock() creates a new instance of the System.MultiStaticResourceCalloutMock class.

**Signature**

```java
public MultiStaticResourceCalloutMock()
```

**MultiStaticResourceCalloutMock Methods**

The following are methods for MultiStaticResourceCalloutMock. All are instance methods.

**setHeader(headerName, headerValue)**

Sets the specified header name and value for the fake response.

**setStaticResource(endpoint, resourceName)**

Sets the specified static resource corresponding to the endpoint. The static resource contains the response body.

**setStatus(httpStatus)**

Sets the specified HTTP status for the response.

**setStatusCode(httpStatusCode)**

Sets the specified HTTP status code for the response.

**setHeader(headerName, headerValue)**

Sets the specified header name and value for the fake response.

**Signature**

```java
public Void setHeader(String headerName, String headerValue)
```

**Parameters**

- **headerName**
  - Type: String
- **headerValue**
  - Type: String

**Return Value**

- Type: Void
**setStaticResource(endpoint, resourceName)**

Sets the specified static resource corresponding to the endpoint. The static resource contains the response body.

**Signature**

```java
public Void setStaticResource(String endpoint, String resourceName)
```

**Parameters**

- `endpoint`  
  Type: `String`
- `resourceName`  
  Type: `String`

**Return Value**

Type: Void

**setStatus(httpStatus)**

Sets the specified HTTP status for the response.

**Signature**

```java
public Void setStatus(String httpStatus)
```

**Parameters**

- `httpStatus`  
  Type: `String`

**Return Value**

Type: Void

**setStatusCode(httpStatusCode)**

Sets the specified HTTP status code for the response.

**Signature**

```java
public Void setStatusCode(Integer httpStatusCode)
```

**Parameters**

- `httpStatusCode`  
  Type: `Integer`
Return Value
Type: Void

Network Class
Manage Experience Cloud sites.

Namespace
System

IN THIS SECTION:
Network Constructors
Create an instance of the System.Network class.

Network Methods
Get the default landing page, login page, and self-registration page of a site. Asynchronously create site users and records. Get the login and logout URLs for a site. Get a user’s current site. Map dashboards and Insights reports.

Network Constructors
Create an instance of the System.Network class.
The following are constructors for Network.

IN THIS SECTION:
Network()
Creates a new instance of the System.Network class.

public Network()

Network Methods
Get the default landing page, login page, and self-registration page of a site. Asynchronously create site users and records. Get the login and logout URLs for a site. Get a user’s current site. Map dashboards and Insights reports.
The following are methods for Network. All methods are static.

IN THIS SECTION:
communitiesLanding()
Returns a Page Reference to the default landing page for the Experience Cloud site. This is the first tab of the site.
createExternalUserAsync(user, contact, account)
Asynchronously creates an Experience Cloud site user for the given account or contact and associates it with the site. This method processes requests in batches and then sends an email with login information to the user.

createRecordAsync(processType, mbObject)
Asynchronously creates case, lead, and custom object records. This method collects record creation requests and processes them in batches.

forwardToAuthPage(startURL)
Returns a Page Reference to the default login page. StartURL is included as a query parameter for where to redirect after a successful login.

getLoginUrl(networkId)
Returns the absolute URL of the login page used by the Experience Cloud site.

getLogoutUrl(networkId)
Returns the absolute URL of the logout page used by the Experience Cloud site.

getNetworkId()
Returns the user’s current Experience Cloud site.

getSelfRegUrl(networkId)
Returns the absolute URL of the self-registration page used by the Experience Cloud site.

loadAllPackageDefaultNetworkDashboardSettings()
Maps the dashboards from the Salesforce Communities Management package onto each Experience Cloud site’s unconfigured dashboard settings. Returns the number of settings it configures.

loadAllPackageDefaultNetworkPulseSettings()
Maps the Insights reports from the Salesforce Communities Management package onto each Experience Cloud site’s unconfigured Insights settings. Returns the number of settings it configures.

communitiesLanding()
Returns a Page Reference to the default landing page for the Experience Cloud site. This is the first tab of the site.

Signature
public static String communitiesLanding()

Return Value
Type: PageReference

Usage
If digital experiences isn’t enabled for the user’s org or the user is currently in the internal org, returns null.

createExternalUserAsync(user, contact, account)
Asynchronously creates an Experience Cloud site user for the given account or contact and associates it with the site. This method processes requests in batches and then sends an email with login information to the user.
Signature

```java
public static String createExternalUserAsync(SObject user, SObject contact, SObject account)
```

Parameters

**user**
Type: `SObject` (optional)
Information required to create a user.

**contact**
Type: `SObject` (optional)
The contact you want to associate the user with.

**account**
Type: `SObject`
The account you want to associate the user with.

Return Value

Type: `String`
Returns the UUID for the site user.

---

**createRecordAsync**

Asynchronously creates case, lead, and custom object records. This method collects record creation requests and processes them in batches.

Signature

```java
public static String createRecordAsync(String processType, SObject mbObject)
```

Parameters

**processType**
Type: `String`
The process you use to create records.

**mbObject**
Type: `SObject`
The records created for objects. Objects must be supported by the high-volume record creation.

Return Value

Type: `String`
Returns the UUID for the record created.
**forwardToAuthPage(startURL)**

Returns a Page Reference to the default login page. StartURL is included as a query parameter for where to redirect after a successful login.

**Signature**

```java
public static PageReference forwardToAuthPage(String startURL)
```

**Parameters**

- `startURL`
  - Type: `String`

**Return Value**

- Type: `PageReference`

**Usage**

If digital experiences isn’t enabled for the user’s org or the user is currently in the internal org, returns `null`.

**getLoginUrl(networkId)**

Returns the absolute URL of the login page used by the Experience Cloud site.

**Signature**

```java
public static String getLoginUrl(String networkId)
```

**Parameters**

- `networkId`
  - Type: `String`
    - The ID of the Experience Cloud site you’re retrieving this information for.

**Return Value**

- Type: `String`

**Usage**

Returns the full URL for the Lightning Platform or Experience Builder page used as the login page in the Experience Cloud site.

**getLogoutUrl(networkId)**

Returns the absolute URL of the logout page used by the Experience Cloud site.

**Signature**

```java
public static String getLogoutUrl(String networkId)
```
Parameters

networkId
Type: String

The ID of the Experience Cloud site you’re retrieving this information for.

Return Value
Type: String

Usage

Returns the full URL for the Lightning Platform page, Experience Builder page, or Web page used as the logout page in the Experience Cloud site.

getNetworkId()

Returns the user’s current Experience Cloud site.

Signature

public static String getNetworkId()

Return Value
Type: String

Usage

If digital experiences isn’t enabled for the user’s org or the user is currently in the internal org, returns null.

getSelfRegUrl(networkId)

Returns the absolute URL of the self-registration page used by the Experience Cloud site.

Signature

public static String getSelfRegUrl(String networkId)

Parameters

networkId
Type: String

The ID of the Experience Cloud site you’re retrieving this information for.

Return Value
Type: String
Usage

Returns the full URL for the Lightning Platform or Experience Builder page used as the self-registration page in the Experience Cloud site.

`loadAllPackageDefaultNetworkDashboardSettings()`

Maps the dashboards from the Salesforce Communities Management package onto each Experience Cloud site's unconfigured dashboard settings. Returns the number of settings it configures.

Signature

`public static Integer loadAllPackageDefaultNetworkDashboardSettings()`

Return Value

Type: Integer

Usage

If digital experiences is enabled, and the Salesforce Communities Management package is installed, maps the dashboards provided in the package onto each Experience Cloud site's unconfigured dashboard settings. Returns the number of settings it configures. This method is invoked automatically during site creation and package installation, but isn't typically invoked manually.

If digital experiences isn't enabled for the user's org or the user is in the internal org, returns 0.

`loadAllPackageDefaultNetworkPulseSettings()`

Maps the Insights reports from the Salesforce Communities Management package onto each Experience Cloud site's unconfigured Insights settings. Returns the number of settings it configures.

Signature

`public static Integer loadAllPackageDefaultNetworkPulseSettings()`

Return Value

Type: Integer

Usage

If digital experiences is enabled, and the Salesforce Communities Management package is installed, maps the Insights reports provided in the package onto each Experience Cloud site's unconfigured Insights settings. Returns the number of settings it configures. This method is invoked automatically during site creation and package installation, but isn't typically invoked manually.

If digital experiences isn't enabled for the user's org or the user is in the internal org, returns 0.

OrgLimit Class

Contains methods that provide the name, maximum value, and current value of an org limit.
Namespace

System

Usage

Use the System.OrgLimits getAll and getMap methods to obtain either a list or a map of all your org limits. To get details on each limit, use instance methods from System.OrgLimit.

For comparison, the Limits Class returns Apex governor limits and not Salesforce API limits.

Note: Limit values are updated asynchronously, in near-real-time.

IN THIS SECTION:

OrgLimit Methods

OrgLimit Methods

The following are methods for OrgLimit.

IN THIS SECTION:

getLimit()

Returns the maximum allowed limit value.

getName()

Returns the limit’s name.

getValue()

Returns the limit usage value.

toString()

Returns the string representation of the org limit.

getLimit() Returns the maximum allowed limit value.

Signature

public Integer getLimit()

Return Value

Type: Integer

Example

List<System.OrgLimit> limits = OrgLimits.getAll();
for (System.OrgLimit aLimit: limits) {
    System.debug('Limit: ' + aLimit.getName());
System.debug('Max Limit is: ' + aLimit.getLimit());
}

getName()

Returns the limit’s name.

Signature
public String getName()

Return Value
Type: String

Example
List<System.OrgLimit> limits = OrgLimits.getAll();
for (System.OrgLimit aLimit: limits) {
    System.debug('Limit: ' + aLimit.getName());
    System.debug('Max Limit is: ' + aLimit.getLimit());
}

getValue()

Returns the limit usage value.

Signature
public Integer getValue()

Return Value
Type: Integer

Example
List<System.OrgLimit> limits = OrgLimits.getAll();
for (System.OrgLimit aLimit: limits) {
    System.debug('Limit: ' + aLimit.getName());
    System.debug('Usage Value is: ' + aLimit.getValue());
}

toString()

Returns the string representation of the org limit.

Signature
public String toString()
Return Value
Type: String
String denoting the name, current consumption, and maximum value of the org limit. For example:

```
OrgLimit[DailyBulkApiBatches: consumed 25 of 15000]
```

OrgLimits Class
Contains methods that provide a list or map of all OrgLimit instances for Salesforce your org, such as SOAP API requests, Bulk API requests, and Streaming API limits.

Namespace
System

Usage
Use the `System.OrgLimits.getAll` and `getMap` methods to obtain either a list or a map of all your org limits. To get details on each limit, use instance methods from `System.OrgLimit`.
For comparison, the `Limits Class` returns Apex governor limits and not Salesforce API limits.

Note: Limit values are updated asynchronously, in near-real-time.

IN THIS SECTION:
OrgLimits Methods

SEE ALSO:
`REST API Developer Guide: Limits`

OrgLimits Methods
The following are methods for `OrgLimits`.

IN THIS SECTION:
`getAll`
`getMap`

`getAll()`
Returns a list of OrgLimit instances.

`getMap()`
Returns a map of all OrgLimit instances with the limit name as key.

`getAll()`
Returns a list of OrgLimit instances.
Signature

```java
public static List<System.OrgLimit> getAll()
```

Return Value

Type: `List<System.OrgLimit>`

```java
getMap()
```

Returns a map of all OrgLimit instances with the limit name as key.

Signature

```java
public static Map<String, System.OrgLimit> getMap()
```

Return Value

Type: `Map<String, System.OrgLimit>`

Example

```java
Map<String, System.OrgLimit> limitsMap = OrgLimits.getMap();
System.OrgLimit apiRequestsLimit = limitsMap.get('DailyApiRequests');
System.debug('Limit Name: ' + apiRequestsLimit.getName());
System.debug('Usage Value: ' + apiRequestsLimit.getValue());
System.debug('Maximum Limit: ' + apiRequestsLimit.getLimit());
```

**PageReference Class**

A PageReference is a reference to an instantiation of a page. Among other attributes, PageReferences consist of a URL and a set of query parameter names and values.

**Namespace**

`System`

Use a PageReference object:

- To view or set query string parameters and values for a page
- To navigate the user to a different page as the result of an action method

**Instantiation**

In a custom controller or controller extension, you can refer to or instantiate a PageReference in one of the following ways:
PageReference Class

- **Page.**existingPageName

Refers to a PageReference for a Visualforce page that has already been saved in your organization. By referring to a page in this way, the platform recognizes that this controller or controller extension is dependent on the existence of the specified page and will prevent the page from being deleted while the controller or extension exists.

```object
PageReference pageRef = new PageReference('partialURL');
```

Creates a PageReference to any page that is hosted on the Lightning platform. For example, setting 'partialURL' to '/apex/HelloWorld' refers to the Visualforce page located at http://mySalesforceInstance/apex/HelloWorld. Likewise, setting 'partialURL' to '/' + 'recordID' refers to the detail page for the specified record.

This syntax is less preferable for referencing other Visualforce pages than **Page.**existingPageName because the PageReference is constructed at runtime, rather than referenced at compile time. Runtime references are not available to the referential integrity system. Consequently, the platform doesn’t recognize that this controller or controller extension is dependent on the existence of the specified page and won’t issue an error message to prevent user deletion of the page.

```object
PageReference pageRef = new PageReference('fullURL');
```

Creates a PageReference for an external URL. For example:

```object
PageReference pageRef = new PageReference('http://www.google.com');
```

You can also instantiate a PageReference object for the current page with the currentPage ApexPages method. For example:

```object
PageReference pageRef = ApexPages.currentPage();
```

### Request Headers

The following table is a non-exhaustive list of headers that are set on requests.

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>The host name requested in the request URL. This header is always set on Lightning Platform Site requests and My Domain requests. This header is optional on other requests when HTTP/1.0 is used instead of HTTP/1.1.</td>
</tr>
<tr>
<td>Referer</td>
<td>The URL that is either included or linked to the current request’s URL. This header is optional.</td>
</tr>
<tr>
<td>User-Agent</td>
<td>The name, version, and extension support of the program that initiated this request, such as a web browser. This header is optional and can be overridden in most browsers to be a different value. Therefore, this header should not be relied upon.</td>
</tr>
<tr>
<td>CipherSuite</td>
<td>If this header exists and has a non-blank value, this means that the request is using HTTPS. Otherwise, the request is using HTTP. The contents of a non-blank value are not defined by this API, and can be changed without notice.</td>
</tr>
<tr>
<td>X-Salesforce-SIP</td>
<td>The source IP address of the request. This header is always set on HTTP and HTTPS requests that are initiated outside of Salesforce’s data centers.</td>
</tr>
</tbody>
</table>

**Note:** If a request passes through a content delivery network (CDN) or proxy server, the source IP address might be altered, and no longer the original client IP address.
Example: Retrieving Query String Parameters

The following example shows how to use a PageReference object to retrieve a query string parameter in the current page URL. In this example, the `getAccount` method references the `id` query string parameter:

```java
public with sharing class MyController {
    public Account getAccount() {
        return [SELECT Id, Name FROM Account WITH SECURITY_ENFORCED
            WHERE Id = :ApexPages.currentPage().getParameters().get('Id')];
    }
}
```

The following page markup calls the `getAccount` method from the controller above:

```xml
<apex:page controller="MyController">
    <apex:pageBlock title="Retrieving Query String Parameters">
        You are viewing the {!account.name} account.
    </apex:pageBlock>
</apex:page>
```

Note: For this example to render properly, you must associate the Visualforce page with a valid account record in the URL. For example, if 001D000000IRt53 is the account ID, the resulting URL should be:

```
https://Salesforce_instance/apex/MyFirstPage?id=001D000000IRt53
```

The `getAccount` method uses an embedded SOQL query to return the account specified by the `id` parameter in the URL of the page. To access `id`, the `getAccount` method uses the `ApexPages` namespace:

- First the `currentPage` method returns the `PageReference` instance for the current page. `PageReference` returns a reference to a Visualforce page, including its query string parameters.
- Using the page reference, use the `getParameters` method to return a map of the specified query string parameter names and values.
- Then a call to the `get` method specifying `id` returns the value of the `id` parameter itself.

Example: Navigating to a New Page as the Result of an Action Method

Any action method in a custom controller or controller extension can return a PageReference object as the result of the method. If the `redirect` attribute on the PageReference is set to `true`, the user navigates to the URL specified by the PageReference.

The following example shows how this can be implemented with a `save` method. In this example, the PageReference returned by the `save` method redirects the user to the detail page for the account record that was just saved:

```java
public class mySecondController {
    Account account;

    public Account getAccount() {
        if(account == null) account = new Account();
        return account;
    }
}
```
public PageReference save() {
    // Add the account to the database.
    insert account;
    // Send the user to the detail page for the new account.
    acctPage.setRedirect(true);
    return acctPage;
}

The following page markup calls the `save` method from the controller above. When a user clicks `Save`, he or she is redirected to the detail page for the account just created:

```apex
<apex:page controller="mySecondController" tabStyle="Account">
    <apex:sectionHeader title="New Account Edit Page" />
    <apex:form>
        <apex:pageBlock title="Create a New Account">
            <apex:pageBlockButtons location="bottom">
                <apex:commandButton action="{!save}" value="Save"/>
            </apex:pageBlockButtons>
            <apex:pageBlockSection title="Account Information">
                <apex:inputField id="accountName" value="{!account.name}"/>
                <apex:inputField id="accountSite" value="{!account.site}"/>
            </apex:pageBlockSection>
        </apex:pageBlock>
    </apex:form>
</apex:page>
```

**Example: Redirect Users to a Replacement Experience Cloud Site**

The following example shows how to redirect a user attempting to access a retired feedback site to a self-service help site. If the `redirect` attribute is set to `true` on the PageReference for the feedback site, the user navigates to the URL specified by the PageReference. The `redirectCode` attribute defines the redirection type for search engine optimization in public Experience Cloud sites.

```apex
public class RedirectController {
    // Redirect users to the self-service help site
    public PageReference redirect() {
        final PageReference target = new PageReference(Site.getBaseSecureUrl() + '/SiteLogin');
        target.setRedirect(true);
        // This is a permanent redirection
        target.setRedirectCode(301);
        return target;
    }
}
```

The following example shows how to call the RedirectController class from the retired site page.

```apex
<apex:page controller="RedirectController" action="{!redirect}"/>
```
IN THIS SECTION:

PageReference Constructors
PageReference Methods

PageReference Constructors
The following are constructors for PageReference.

IN THIS SECTION:

PageReference(partialURL)
Creates a new instance of the PageReference class using the specified URL.

PageReference(record)
Generate a new instance of the PageReference class for the specified sObject record.

PageReference (partialURL)
Creates a new instance of the PageReference class using the specified URL.

Signature
public PageReference(String partialURL)

Parameters
partialURL
Type: String

The partial URL of a page hosted on the Lightning Platform or a full external URL. The following are some examples of the partialURL parameter values:
- /recordID: refers to the detail page of a specified record.
- http://www.google.com: refers to an external URL.

PageReference (record)
Generate a new instance of the PageReference class for the specified sObject record.

Signature
public PageReference(SObject record)

Parameters
record
Type: SObject
The sObject record that references the ApexPage. The reference must be an ApexPage.

SEE ALSO:

Visualforce Developer Guide: apexpage
SOAP API Developer Guide: ApexPage

PageReference Methods
The following are methods for PageReference. All are instance methods.

IN THIS SECTION:

forResource(resourceName, path)
Create a PageReference for nested content inside a zip static resource, by name and path.

forResource(resourceName)
Create a PageReference for a static resource, by name.

getAnchor()
Returns the name of the anchor referenced in the page’s URL. That is, the part of the URL after the hashtag (#).

getContent()
Returns the output of the page, as displayed to a user in a web browser.

getContentAsPDF()
Returns the page in PDF, regardless of the <apex:page> component’s renderAs attribute.

getCookies()
Returns a map of cookie names and cookie objects, where the key is a String of the cookie name and the the value contains the cookie object with that name.

getHeaders()
Returns a map of the request headers, where the key string contains the name of the header, and the value string contains the value of the header.

getParameters()
Returns a map of the query string parameters for the PageReference; both POST and GET parameters are included. The key string contains the name of the parameter, while the value string contains the value of the parameter.

getRedirect()
Returns the current value of the PageReference object’s redirect attribute.

getRedirectCode()
Returns the HTTP redirect code used when getRedirect() is set to true for the PageReference object.

getUrl()
Returns the relative URL associated with the PageReference when it was originally defined, including any query string parameters and anchors.

setAnchor(ANCHOR)
Sets the URL’s anchor reference to the specified string.

setCookies(cookies)
Creates a list of cookie objects. Used in conjunction with the Cookie class.
setRedirect(redirect)
Sets the value of the PageReference object's `redirect` attribute. If set to `true`, a redirect is performed through a client side redirect.

setRedirectCode(redirectCode)
Sets the HTTP redirect code to use for the PageReference object when `setRedirect(redirect)` is set to `true`.

**forResource(resourceName, path)**
Create a PageReference for nested content inside a zip static resource, by name and path.

**Signature**

```java
public static System.PageReference forResource(String resourceName, String path)
```

**Parameters**

- `resourceName`
  - Type: `String`
  - The resource name

- `path`
  - Type: `String`
  - The resource path

**Return Value**

Type: `System.PageReference`

**forResource(resourceName)**
Create a PageReference for a static resource, by name.

**Signature**

```java
public static System.PageReference forResource(String resourceName)
```

**Parameters**

- `resourceName`
  - Type: `String`
  - The resource name

**Return Value**

Type: `System.PageReference`

**getAnchor()**
Returns the name of the anchor referenced in the page's URL. That is, the part of the URL after the hashtag (`#`).
Signature

```java
public String getAnchor()
```

Return Value

Type: String

⚠️ Note: Instances of PageReference returned by ApexPages.currentPage() have a null anchor attribute, because URL fragments are not sent to the Salesforce server during a request.

**getContent()**

Returns the output of the page, as displayed to a user in a web browser.

Signature

```java
public Blob getContent()
```

Return Value

Type: Blob

**Usage**

The content of the returned Blob depends on how the page is rendered. If the page is rendered as a PDF file, it returns the PDF document. If the page is not rendered as PDF, it returns HTML. To access the content of the returned HTML as a string, use the `toString Blob` method.

⚠️ Note: If you use `getContent` in a test method, the test method fails. `getContent` is treated as a callout in API version 34.0 and later.

This method can’t be used in:

- Triggers
- Test methods
- Apex email services

If the Visualforce page has an error, an `ExecutionException` is thrown.

**getContentAsPDF()**

Returns the page in PDF, regardless of the `<apex:page>` component’s `renderAs` attribute.

Signature

```java
public Blob getContentAsPDF()
```

Return Value

Type: Blob
Usage

Note: If you use `getContentAsPDF` in a test method, the test method fails. `getContentAsPDF` is treated as a callout in API version 34.0 and later.

This method can’t be used in:
- Triggers
- Test methods
- Apex email services

**getCookies()**

Returns a map of cookie names and cookie objects, where the key is a String of the cookie name and the the value contains the cookie object with that name.

**Signature**

```java
public Map<String, System.Cookie> getCookies()
```

**Return Value**

Type: `Map<String, System.Cookie>`

**Usage**

Used in conjunction with the `Cookie` class. Only returns cookies with the “apex__” prefix set by the `setCookies` method.

**getHeaders()**

Returns a map of the request headers, where the key string contains the name of the header, and the value string contains the value of the header.

**Signature**

```java
public Map<String, String> getHeaders()
```

**Return Value**

Type: `Map<String, String>`

**Usage**

This map can be modified and remains in scope for the PageReference object. For instance, you could do:

```java
PageReference.getHeaders().put('Date', '9/9/99');
```

For a description of request headers, see Request Headers.

**getParameters()**

Returns a map of the query string parameters for the PageReference; both POST and GET parameters are included. The key string contains the name of the parameter, while the value string contains the value of the parameter.
Signature

public Map<String, String> getParameters()

Return Value

Type: Map<String, String>

Usage

This map can be modified and remains in scope for the PageReference object. For instance, you could do:

```java
PageReference.getParameters().put('id', myID);
```

Parameter keys are case-insensitive. For example:

```java
System.assert(
    ApexPages.currentPage().getParameters().get('myParamName') ==
    ApexPages.currentPage().getParameters().get('myparamname'));
```

getRedirect()

Returns the current value of the PageReference object's redirect attribute.

Signature

public Boolean getRedirect()

Return Value

Type: Boolean

Usage

Note that if the URL of the PageReference object is set to a website outside of the salesforce.com domain, the redirect always occurs, regardless of whether the redirect attribute is set to true or false.

getRedirectCode()

Returns the HTTP redirect code used when getRedirect() is set to true for the PageReference object.

Signature

public Integer getRedirectCode()

Return Value

Type: Integer

Possible Values:

- 0 — Redirect using the default redirect action for this PageReference. Typically a JavaScript-based redirection or HTTP 302.
Note: Site URL Rewriter Interface implementations pointing to a PageReference with a redirectCode of 0 are not redirected.

- **301** — Moved Permanently. Redirect users by sending an HTTP GET request to the target location. Includes instructions to update any references to the requested URL with the target location.
- **302** — Moved Temporarily. Redirect users by sending an HTTP GET request to the target location. Because the redirection is temporary, it doesn’t include update instructions.
- **303** — See Other. Redirect users by sending an HTTP GET request to the target location. Not commonly used. Useful when the client sends a POST request and you want the client to call the new web page using a GET request instead of a POST request.
- **307** — Temporary Redirect. Send the same HTTP request, regardless of the HTTP method, to the target location. Because the redirection is temporary, it doesn’t include update instructions.
- **308** — Permanent Redirect. Send the same HTTP request, regardless of the HTTP method, to the target location. Includes instructions to update any references to the requested URL with the target location.

**getUrl()**

Returns the relative URL associated with the PageReference when it was originally defined, including any query string parameters and anchors.

**Signature**

```java
public String getUrl()
```

**Return Value**

Type: `String`

**setAnchor(anchor)**

Sets the URL’s anchor reference to the specified string.

**Signature**

```java
public System.PageReference setAnchor(String anchor)
```

**Parameters**

- `anchor`
  
  Type: `String`

**Return Value**

Type: `System.PageReference`

**setCookies(cookies)**

Creates a list of cookie objects. Used in conjunction with the `Cookie` class.
**setCookies(cookies)**

*Signature*

```java
public Void setCookies(Cookie[] cookies)
```

*Parameters*

- `cookies`  
  Type: `System.Cookie[]`

*Return Value*

Type: Void

*Usage*

**Important:**

- Cookie names and values set in Apex are URL encoded, that is, characters such as @ are replaced with a percent sign and their hexadecimal representation.
- The `setCookies` method adds the prefix "apex__" to the cookie names.
- Setting a cookie's value to `null` sends a cookie with an empty string value instead of setting an expired attribute.
- After you create a cookie, the properties of the cookie can't be changed.
- Be careful when storing sensitive information in cookies. Pages are cached regardless of a cookie value. If you use a cookie value to generate dynamic content, you should disable page caching. For more information, see Configure Site Caching in Salesforce Help.

**setRedirect(redirect)**

Sets the value of the `PageReference` object's `redirect` attribute. If set to `true`, a redirect is performed through a client side redirect.

*Signature*

```java
public System.PageReference setRedirect(Boolean redirect)
```

*Parameters*

- `redirect`  
  Type: `Boolean`

*Return Value*

Type: `System.PageReference`

*Usage*

This type of redirect performs an HTTP GET request, and flushes the view state, which uses POST. If set to `false`, the redirect is a server-side forward that preserves the view state if and only if the target page uses the same controller and contains the proper subset of extensions used by the source page.
Note that if the URL of the PageReference object is set to a website outside of the salesforce.com domain, or to a page with a different controller or controller extension, the redirect always occurs, regardless of whether the redirect attribute is set to true or false.

```java
setRedirectCode(redirectCode)
```

Sets the HTTP redirect code to use for the PageReference object when setRedirect(redirect) is set to true.

**Signature**

```java
```

**Parameters**

- **redirectCode**
  - Type: Integer
  - Valid values:
    - 0 — Redirect using the default redirect action for this PageReference. Typically a JavaScript-based redirection or HTTP 302.
      
      ※ **Note:** Site URLRewriter Interface implementations pointing to a PageReference with a redirectCode of 0 are not redirected.
    
    - 301 — Moved Permanently. Redirect users by sending an HTTP GET request to the target location. Includes instructions to update any references to the requested URL with the target location.
    
    - 302 — Moved Temporarily. Redirect users by sending an HTTP GET request to the target location. Because the redirection is temporary, it doesn't include update instructions.
    
    - 303 — See Other. Redirect users by sending an HTTP GET request to the target location. Not commonly used. Useful when the client sends a POST request and you want the client to call the new web page using a GET request instead of a POST request.
    
    - 307 — Temporary Redirect. Send the same HTTP request, regardless of the HTTP method, to the target location. Because the redirection is temporary, it doesn't include update instructions.
    
    - 308 — Permanent Redirect. Send the same HTTP request, regardless of the HTTP method, to the target location. Includes instructions to update any references to the requested URL with the target location.
      
      If the redirect code contains an invalid integer, an error message is displayed when PageReference is used by Salesforce for redirection.

**Return Value**

- Type: System.PageReference

### Packaging Class

Contains a method for obtaining information about managed and unlocked packages.

**Namespace**

System
Usage
In the context of a package, use the getCurrentPackageId method to retrieve the packageId.

Packaging Methods
The following are methods for Packaging.

getCurrentPackageId()
Returns the context packageId in managed and unlocked packages.

Signature
public String getCurrentPackageId()

Return Value
Type: String

Usage
For managed packages, this method can be combined with isCurrentUserLicensedForPackage(packageId) to retrieve the packageId at runtime. Then, use packageId to confirm that the contextual user is licensed to use that managed package.

Pattern Class
Represents a compiled representation of a regular expression.

Namespace
System

Pattern Methods
The following are methods for Pattern.
matcher(stringToMatch)
Creates a Matcher object that matches the input string *stringToMatch* against this Pattern object.

matches(regExp, stringToMatch)
Compiles the regular expression *regExp* and tries to match it against the specified string. This method returns *true* if the specified string matches the regular expression, *false* otherwise.

pattern()
Returns the regular expression from which this Pattern object was compiled.

quote(yourString)
Returns a string that can be used to create a pattern that matches the string *yourString* as if it were a literal pattern.

split(regExp)
Returns a list that contains each substring of the String that matches this pattern.

split(regExp, limit)
Returns a list that contains each substring of the String that is terminated either by the regular expression *regExp* that matches this pattern, or by the end of the String.

**compile(regExp)**
Compiles the regular expression into a Pattern object.

**Signature**

```java
public static Pattern compile(String regExp)
```

**Parameters**

*regExp*
Type: *String*

**Return Value**

Type: *System.Pattern*

**matcher(stringToMatch)**
Creates a Matcher object that matches the input string *stringToMatch* against this Pattern object.

**Signature**

```java
public Matcher matcher(String stringToMatch)
```

**Parameters**

*stringToMatch*
Type: *String*

**Return Value**

Type: *Matcher*
matches(regExp, stringtoMatch)
Compiles the regular expression `regExp` and tries to match it against the specified string. This method returns `true` if the specified string matches the regular expression, `false` otherwise.

**Signature**
```
public static Boolean matches(String regExp, String stringtoMatch)
```

**Parameters**
- `regExp`
  Type: `String`
- `stringtoMatch`
  Type: `String`

**Return Value**
Type: `Boolean`

**Usage**
If a pattern is to be used multiple times, compiling it once and reusing it is more efficient than invoking this method each time.

**Example**
Note that the following code example:
```
Pattern.matches(regExp, input);
```
produces the same result as this code example:
```
Pattern.compile(regex).matcher(input).matches();
```

pattern()
Returns the regular expression from which this Pattern object was compiled.

**Signature**
```
public String pattern()
```

**Return Value**
Type: `String`

quote(yourString)
Returns a string that can be used to create a pattern that matches the string `yourString` as if it were a literal pattern.
public static String quote(String yourString)

Parameters

yourString
  Type: String

Return Value

Type: String

Usage

Metacharacters (such as $ or ^) and escape sequences in the input string are treated as literal characters with no special meaning.

split(regExp)

Returns a list that contains each substring of the String that matches this pattern.

Signature

public String[] split(String regExp)

Parameters

regExp
  Type: String

Return Value

Type: String[]

Note: In API version 34.0 and earlier, a zero-width regExp value produces an empty list item at the beginning of the method’s output.

Usage

The substrings are placed in the list in the order in which they occur in the String. If regExp does not match the pattern, the resulting list has just one element containing the original String.

split(regExp, limit)

Returns a list that contains each substring of the String that is terminated either by the regular expression regExp that matches this pattern, or by the end of the String.

Signature

public String[] split(String regExp, Integer limit)
Parameters

- **regExp**
  - Type: String

- **limit**
  - Type: Integer
  
  (Optional) Controls the number of times the pattern is applied and therefore affects the length of the list.
  
  - If `limit` is greater than zero:
    - The pattern is applied a maximum of `(limit - 1)` times.
    - The list's length is no greater than `limit`.
    - The list's last entry contains all input beyond the last matched delimiter.
  
  - If `limit` is non-positive, the pattern is applied as many times as possible, and the list can have any length.
  
  - If `limit` is zero, the pattern is applied as many times as possible, the list can have any length, and trailing empty strings are discarded.

Return Value

- Type: String[]

**Note:** In API version 34.0 and earlier, a zero-width `regExp` value produces an empty list item at the beginning of the method's output.

Queueable Interface

Enables the asynchronous execution of Apex jobs that can be monitored.

Namespace

- System

Usage

To execute Apex as an asynchronous job, implement the **Queueable** interface and add the processing logic in your implementation of the `execute` method.

To implement the **Queueable** interface, you must first declare a class with the `implements` keyword as follows:

```java
public class MyQueueableClass implements Queueable {

    // Your code here
}
```

Next, your class must provide an implementation for the following method:

```java
public void execute(QueueableContext context) {
    // Your code here
}
```

Your class and method implementation must be declared as `public` or `global`.

To submit your class for asynchronous execution, call the `System.enqueueJob` by passing it an instance of your class implementation of the **Queueable** interface as follows:

```java
ID jobID = System.enqueueJob(new MyQueueableClass());
```
Queueable Methods

The following are methods for Queueable.

IN THIS SECTION:

execute(context)
Executes the queueable job.

**execute (context)**
Executes the queueable job.

**Signature**

```
public void execute(QueueableContext context)
```

**Parameters**

- `context`
  - Type: QueueableContext
  - Contains the job ID.

**Return Value**

Type: Void

Queueable Example Implementation

This example is an implementation of the Queueable interface. The `execute` method in this example inserts a new account.

```
public class AsyncExecutionExample implements Queueable {
    public void execute(QueueableContext context) {
        Account a = new Account(Name='Acme',Phone='(415) 555-1212');
        insert a;
    }
}
```

To add this class as a job on the queue, call this method:

```
ID jobID = System.enqueueJob(new AsyncExecutionExample());
```
After you submit your queueable class for execution, the job is added to the queue and will be processed when system resources become available. You can monitor the status of your job programmatically by querying AsyncApexJob or through the user interface in Setup by entering Apex Jobs in the Quick Find box, then selecting Apex Jobs.

To query information about your submitted job, perform a SOQL query on AsyncApexJob by filtering on the job ID that the System.enqueueJob method returns. This example uses the jobID variable that was obtained in the previous example.

```apex
AsyncApexJob jobInfo = [SELECT Status,NumberOfErrors FROM AsyncApexJob WHERE Id=:jobID];
```

Similar to future jobs, queueable jobs don’t process batches, and so the number of processed batches and the number of total batches are always zero.

### Testing Queueable Jobs

This example shows how to test the execution of a queueable job in a test method. A queueable job is an asynchronous process. To ensure that this process runs within the test method, the job is submitted to the queue between the Test.startTest and Test.stopTest block. The system executes all asynchronous processes started in a test method synchronously after the Test.stopTest statement. Next, the test method verifies the results of the queueable job by querying the account that the job created.

```apex
@isTest
class AsyncExecutionExampleTest {
    static testmethod void test1() {
        // startTest/stopTest block to force async processes
        // to run in the test.
        Test.startTest();
        System.enqueueJob(new AsyncExecutionExample());
        Test.stopTest();

        // Validate that the job has run
        // by verifying that the record was created.
        // This query returns only the account created in test context by the
        // Queueable class method.
        Account acct = [SELECT Name,Phone FROM Account WHERE Name='Acme' LIMIT 1];
        System.assertNotEquals(null, acct);
        System.assertEquals('(415) 555-1212', acct.Phone);
    }
}
```

**Note:** The ID of a queueable Apex job isn’t returned in test context—System.enqueueJob returns null in a running test.

---

### QueueableContext Interface

Represents the parameter type of the `execute()` method in a class that implements the Queueable interface and contains the job ID. This interface is implemented internally by Apex.

**Namespace**

System
QueueableContext Methods

The following are methods for QueueableContext.

IN THIS SECTION:

**getJobId()**
Returns the ID of the submitted job that uses the Queueable interface.

**getJobId()**
Returns the ID of the submitted job that uses the Queueable interface.

**Signature**

```java
public ID getJobId()
```

**Return Value**
Type: ID
The ID of the submitted job.

QueueableDuplicateSignature Class

Used in the AsyncOptions class to store the queueable job signature in the DuplicateSignature property.

**Namespace**

System

**In This Section:**

QueueableDuplicateSignature Methods

QueueableDuplicateSignature Methods

The following are methods for QueueableDuplicateSignature.

IN THIS SECTION:

**toString()**
Returns the duplicate signature as a string value.

**toString()**
Returns the duplicate signature as a string value.
Signature

public String toString()

Return Value

Type: String

QueueableDuplicateSignature.Builder Class

Build a unique signature for your queueable job using this inner builder class. The build() class method builds a QueueableDuplicateSignature object with input from the addId(), addInteger(), and addString() methods. Use the DuplicateSignature property in the AsyncOptions class to store the queueable job signature. Enqueue your job by using the System.enqueueJob() with the AsyncOptions parameter.

Namespace

System

Examples

This example builds the async job signature with UserId and the string MyQueueable.

```java
AsyncOptions options = new AsyncOptions();
options.DuplicateSignature = new System.QueueableDuplicateSignature.Builder()
    .addId(UserInfo.getUserId())
    .addString('MyQueueable')
    .build();
try {
    System.enqueueJob(new MyQueueable(), options);
} catch (DuplicateMessageException ex) {
    //Exception is thrown if there is already an enqueued job with the same signature
    Assert.areEqual('Attempt to enqueue job with duplicate queueable signature', ex.getMessage());
}
```

This example builds the async job signature using ApexClass Id and the hash value of an sObject.

```java
AsyncOptions options = new AsyncOptions();
options.DuplicateSignature = new QueueableDuplicateSignature.Builder()
    .addInteger(System.hashCode(someAccount))
    .addId([SELECT Id FROM ApexClass
            WHERE Name='MyQueueable'].Id)
    .build();
System.enqueueJob(new MyQueueable(), options);
```

IN THIS SECTION:

QueueableDuplicateSignature.Builder Methods
QueueableDuplicateSignature.Builder Methods

The following are methods for QueueableDuplicateSignature.Builder.

IN THIS SECTION:

addId(inputId)
Adds an ID to build a unique signature for a queueable job. You can then enqueue the job by using the signature as the AsyncOptions parameter to System.enqueueJob().

addInteger(inputInteger)
Adds an integer to build a unique signature for a queueable job. You can then enqueue the job by using the signature as the AsyncOptions parameter to System.enqueueJob().

addString(inputString)
Adds a string to build a unique signature for a queueable job. You can then enqueue the job by using the signature as the AsyncOptions parameter to System.enqueueJob().

build()
Builds a unique signature for a queueable job. You can then enqueue the job by using the signature as the AsyncOptions parameter to System.enqueueJob().

getMaxSize()
Gets the maximum size of the queueable job signature in bytes.

getRemainingSize()
Gets the remaining size of the queueable job signature in bytes, after subtracting what is already used by the signature from the maximum allowed number.

getSize()
Gets the size of the queueable job signature in bytes.

addId (inputId)
Adds an ID to build a unique signature for a queueable job. You can then enqueue the job by using the signature as the AsyncOptions parameter to System.enqueueJob().

Signature

public System.QueueableDuplicateSignature.Builder addId(Id id)

Parameters

inputId
Type: Id

Return Value

Type: QueueableDuplicateSignature.Builder
addInteger(inputInteger)

Adds an integer to build a unique signature for a queueable job. You can then enqueue the job by using the signature as the AsyncOptions parameter to System.enqueueJob().

Signature

public System.QueueableDuplicateSignature.Builder addInteger(Integer i)

Parameters

inputInteger
Type: Integer

Return Value
Type: QueueableDuplicateSignature.Builder

addString(inputString)

Adds a string to build a unique signature for a queueable job. You can then enqueue the job by using the signature as the AsyncOptions parameter to System.enqueueJob().

Signature

public System.QueueableDuplicateSignature.Builder addString(String s)

Parameters

inputString
Type: String

Return Value
Type: QueueableDuplicateSignature.Builder

build()

Builds a unique signature for a queueable job. You can then enqueue the job by using the signature as the AsyncOptions parameter to System.enqueueJob().

Signature

public System.QueueableDuplicateSignature build()

Return Value
Type: QueueableDuplicateSignature Class
getMaxSize()
Gets the maximum size of the queueable job signature in bytes.

Signature
public Integer getMaxSize()

Return Value
Type: Integer

getRemainingSize()
Gets the remaining size of the queueable job signature in bytes, after subtracting what is already used by the signature from the maximum allowed number.

Signature
public Integer getRemainingSize()

Return Value
Type: Integer

getSize()
Gets the size of the queueable job signature in bytes.

Signature
public Integer getSize()

Return Value
Type: Integer

QuickAction Class
Use Apex to request and process actions on objects that allow custom fields, on objects that appear in a Chatter feed, or on objects that are available globally.

Namespace
System
**Example**

In this sample, the trigger determines if the new contacts to be inserted are created by a quick action. If so, it sets the `WhereFrom__c` custom field to a value that depends on whether the quick action is global or local to the contact. Otherwise, if the inserted contacts don’t originate from a quick action, the `WhereFrom__c` field is set to 'NoAction'.

```apex
trigger accTrig2 on Contact (before insert) {
    for (Contact c : Trigger.new) {
        if (c.getQuickActionName() == QuickAction.CreateContact) {
            c.WhereFrom__c = 'GlobalAction1';
        } else if (c.getQuickActionName() == Schema.Account.QuickAction.CreateContact) {
            c.WhereFrom__c = 'AccountAction';
        } else if (c.getQuickActionName() == null) {
            c.WhereFrom__c = 'NoAction';
        } else {
            System.assert(false);
        }
    }
}
```

This sample performs a global action—QuickAction.CreateContact—on the passed-in contact object.

```apex
public Id globalCreate(Contact c) {
    QuickAction.QuickActionRequest req = new QuickAction.QuickActionRequest();
    req.quickActionName = QuickAction.CreateContact;
    req.record = c;
    QuickAction.QuickActionResult res = QuickAction.performQuickAction(req);
    return c.id;
}
```

**SEE ALSO:**
- QuickActionRequest Class
- QuickActionResult Class

**QuickAction Methods**

The following are methods for QuickAction. All methods are static.

**IN THIS SECTION:**
- `describeAvailableQuickActions(parentType)`
  Returns metadata information for the available quick actions of the provided parent object.
- `describeAvailableQuickActions(sObjectNames)`
  Returns the metadata information for the provided quick actions.
- `performQuickAction(quickActionRequest)`
  Performs the quick action specified in the quick action request and returns the action result.
- `performQuickAction(quickActionRequest, allOrNothing)`
  Performs the quick action specified in the quick action request with the option for partial success, and returns the result.
- `performQuickActions(quickActionRequests)`
  Performs the quick actions specified in the quick action request list and returns action results.
performQuickActions(quickActionRequests, allOrNothing)
Performs the quick actions specified in the quick action request list with the option for partial success, and returns action results.

describeAvailableQuickActions(\texttt{parentType})
Returns metadata information for the available quick actions of the provided parent object.

\textbf{Signature}
\begin{verbatim}
public static List\<QuickAction.DescribeAvailableQuickActionResult\> describeAvailableQuickActions(\texttt{String parentType})
\end{verbatim}

\textbf{Parameters}
\begin{verbatim}
parentType
Type: String
\end{verbatim}

The parent object type. This can be an object type name (\texttt{Account}) or \texttt{Global} (meaning that this method is called at a global level and not an entity level).

\textbf{Return Value}
Type: \texttt{List<QuickAction.DescribeAvailableQuickActionResult>}
The metadata information for the available quick actions of the parent object.

\textbf{Example}
\begin{verbatim}
// Called for Account entity.
List<QuickAction.DescribeAvailableQuickActionResult> result1 =
QuickAction.DescribeAvailableQuickActions('Account');

// Called at global level, not entity level.
List<QuickAction.DescribeAvailableQuickActionResult> result2 =
QuickAction.DescribeAvailableQuickActions('Global');
\end{verbatim}

describeAvailableQuickActions(\texttt{sObjectNames})
Returns the metadata information for the provided quick actions.

\textbf{Signature}
\begin{verbatim}
public static List\<QuickAction.DescribeQuickActionResult\> describeAvailableQuickActions(List\<String\> sObjectNames)
\end{verbatim}

\textbf{Parameters}
\begin{verbatim}
sObjectNames
Type: List\<String\>
\end{verbatim}

The names of the quick actions. The quick action name can contain the entity name if it is at the entity level ('Account.QuickCreateContact'), or 'Global' if used for the action at the global level ('Global.CreateNewContact').
Return Value
Type: List<QuickAction.DescribeQuickActionResult>
The metadata information for the provided quick actions.

Example

```java
// First 3 parameter values are for actions at the entity level.
// Last parameter is for an action at the global level.
List<QuickAction.DescribeQuickActionResult> result =
    QuickAction.DescribeQuickActions(new List<String> {
        'Account.QuickCreateContact', 'Opportunity.Update1',
        'Contact.Create1', 'Global.CreateNewContact' });
```

`performQuickAction(quickActionRequest)`
Performs the quick action specified in the quick action request and returns the action result.

Signature
```
public static QuickAction.QuickActionResult performQuickAction(QuickAction.QuickActionRequest quickActionRequest)
```

Parameters
`quickActionRequest`
Type: QuickAction.QuickActionRequest

Return Value
Type: QuickAction.QuickActionResult

`performQuickAction(quickActionRequest, allOrNothing)`
Performs the quick action specified in the quick action request with the option for partial success, and returns the result.

Signature
```
public static QuickAction.QuickActionResult performQuickAction(QuickAction.QuickActionRequest quickActionRequest, Boolean allOrNothing)
```

Parameters
`quickActionRequest`
Type: QuickAction.QuickActionRequest
`allOrNothing`
Type: Boolean
Specifies whether this operation allows partial success. If you specify false for this argument and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value
Type: QuickAction.QuickActionResult

**performQuickActions(quickActionRequests)**
Performs the quick actions specified in the quick action request list and returns action results.

**Signature**
```java
public static List<QuickAction.QuickActionResult> performQuickActions(List<QuickAction.QuickActionRequest> quickActionRequests)
```

**Parameters**
- `quickActionRequests`
  Type: List<QuickAction.QuickActionRequest>

**Return Value**
Type: List<QuickAction.QuickActionResult>

**performQuickActions(quickActionRequests, allOrNothing)**
Performs the quick actions specified in the quick action request list with the option for partial success, and returns action results.

**Signature**
```java
public static List<QuickAction.QuickActionResult> performQuickActions(List<QuickAction.QuickActionRequest> quickActionRequests, Boolean allOrNothing)
```

**Parameters**
- `quickActionRequests`
  Type: List<QuickAction.QuickActionRequest>
- `allOrNothing`
  Type: Boolean
  Specifies whether this operation allows partial success. If you specify false for this argument and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

**Return Value**
Type: List<QuickAction.QuickActionResult>
Quiddity Enum

Specifies a Quiddity value used by the methods in the System.Request class

Enum Values

The following are the values of the System.Quiddity enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANONYMOUS</td>
<td>Execution event is an anonymous Apex block.</td>
</tr>
<tr>
<td>AURA</td>
<td>Execution event is an Aura component.</td>
</tr>
<tr>
<td>BATCH_ACS</td>
<td>Execution event is an API Query Cursor driven batch Apex.</td>
</tr>
<tr>
<td>BATCH_APEX</td>
<td>Execution event is a batch Apex job.</td>
</tr>
<tr>
<td>BATCH_CHUNK_PARALLEL</td>
<td>Execution event is chunks of a batch Apex job running in parallel.</td>
</tr>
<tr>
<td>BATCH_CHUNK_SERIAL</td>
<td>Execution event is chunks of a batch Apex job running in serial.</td>
</tr>
<tr>
<td>BULK_API</td>
<td>Execution event is a bulk API request.</td>
</tr>
<tr>
<td>COMMERCE_INTEGRATION</td>
<td>Execution event is an Apex integration for B2B Commerce.</td>
</tr>
<tr>
<td>DISCOVERABLE_LOGIN</td>
<td>Execution event is Login Discoverable login page used by external users to log in to an Experience Cloud site.</td>
</tr>
<tr>
<td>FUNCTION_CALLBACK</td>
<td>Execution event is a callback function.</td>
</tr>
<tr>
<td>FUTURE</td>
<td>Execution event is a future method.</td>
</tr>
<tr>
<td>INBOUND_EMAIL_SERVICE</td>
<td>Execution event is an Apex inbound email service.</td>
</tr>
<tr>
<td>INVOCABLE_ACTION</td>
<td>Execution event is an invocable action.</td>
</tr>
<tr>
<td>PLATFORM_EVENT_PUBLISH_CALLBACK</td>
<td>Execution event is an Apex publish callback for platform events.</td>
</tr>
<tr>
<td>POST_INSTALL_SCRIPT</td>
<td>Execution event is a managed package install or upgrade.</td>
</tr>
<tr>
<td>QUEUEABLE</td>
<td>Execution event is a queueable Apex operation.</td>
</tr>
<tr>
<td>QUICK_ACTION</td>
<td>Execution event is a quick action.</td>
</tr>
<tr>
<td>REMOTE_ACTION</td>
<td>Execution event is a remote action.</td>
</tr>
<tr>
<td>REST</td>
<td>Execution event is an Apex RESTful Web service.</td>
</tr>
<tr>
<td>RUNTEST_ASYNC</td>
<td>Execution event is Apex tests running asynchronously.</td>
</tr>
<tr>
<td>RUNTEST_DEPLOY</td>
<td>Execution event is Apex tests run during deployment.</td>
</tr>
<tr>
<td>RUNTEST_SYNC</td>
<td>Execution event is Apex tests running synchronously.</td>
</tr>
<tr>
<td>SCHEDULED</td>
<td>Execution event is a scheduled Apex job.</td>
</tr>
<tr>
<td>SOAP</td>
<td>Execution event is an Apex SOAP Web service.</td>
</tr>
<tr>
<td>SYNCHRONOUS</td>
<td>Execution event is a synchronous Apex operation.</td>
</tr>
</tbody>
</table>
RemoteObjectController

Use RemoteObjectController to access the standard Visualforce Remote Objects operations in your Remote Objects override methods.

Namespace

System

Usage

RemoteObjectController is supported only for use within Remote Objects methods. See *Overriding Default Remote Objects Operations* in the Visualforce Developer’s Guide for examples of how to use RemoteObjectController with your Visualforce pages.

RemoteObjectController Methods

The following are methods for RemoteObjectController. All methods are static.

IN THIS SECTION:

  - create(type, fields)
    Create a record in the database.
  - del(type, recordIds)
    Delete records from the database.
  - retrieve(type, fields, criteria)
    Retrieve records from the database.
  - updat(type, recordIds, fields)
    Update records in the database.

create(type, fields)

Create a record in the database.

Signature

```java
public static Map<String, Object> create(String type, Map<String, Object> fields)
```

Parameters

- **type**
  Type: String
The sObject type on which create is being called.

fields
Type: Map<String, Object>
The fields and values to set on the new record.

Return Value
Type: Map<String, Object>
The return value is a map that represents the result of the Remote Objects operation. What is returned depends on the results of the call.

Success
A map that contains a single element with the ID of the record created. For example, `{ id: 'recordId' }`.

Failure
A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

del(type, recordIds)
Delete records from the database.

Signature
public static Map<String, Object> del(String type, List<String> recordIds)

Parameters
type
Type: String
The sObject type on which delete is being called.

recordIds
Type: List<String>
The IDs of the records to be deleted.

Return Value
Type: Map<String, Object>
The return value is a map that represents the result of the Remote Objects operation. What is returned depends on how the method was called and the results of the call.

Single Delete—Success
A map that contains a single element with the ID of the record that was deleted. For example, `{ id: 'recordId' }`.

Batch Delete—Success
A map that contains a single element, an array of Map<String, Object> elements. Each element contains the ID of a record that was deleted and an array of errors, if there were any, for that record’s individual delete. For example, `{ results: [ { id: 'recordId', errors: ['errorMessage'], ... } ], ... ] }.
Single and Batch Delete—Failure

A map that contains a single element with the error message for the overall operation. For example, 

```json
{ error: 'errorMessage' }
```

**retrieve(type, fields, criteria)**

Retrieve records from the database.

**Signature**

```java
public static Map<String,Object> retrieve(String type, List<String> fields, Map<String,Object> criteria)
```

**Parameters**

- **type**
  - Type: String
  - The sObject type on which retrieve is being called.

- **fields**
  - Type: List<String>
  - The fields to retrieve for each record.

- **criteria**
  - Type: Map<String,Object>
  - The criteria to use when performing the query.

**Return Value**

Type: Map<String,Object>

The return value is a map that represents the result of the Remote Objects operation. What is returned depends on the results of the call.

**Success**

A map that contains the following elements.

- **records**: An array of records that match the query conditions.
- **type**: A string that indicates the type of the sObject that was retrieved.
- **size**: The number of records in the response.

**Failure**

A map that contains a single element with the error message for the overall operation. For example, 

```json
{ error: 'errorMessage' }
```

**updat(type, recordIds, fields)**

Update records in the database.
Signature

```java
public static Map<String, Object> updat(String type, List<String> recordIds, Map<String, Object> fields)
```

Parameters

type
Type: String
The sObject type on which update is being called.

recordIds
Type: List<String>
The IDs of the records to be updated.

fields
Type: Map<String, Object>
The fields to update, and the value to update each field with.

Return Value
Type: Map<String, Object>
The return value is a map that represents the result of the Remote Objects operation. What is returned depends on how the method was called and the results of the call.

Single Update—Success
A map that contains a single element with the ID of the record that was updated. For example, `{ id: 'recordId' }`.

Batch Update—Success
A map that contains a single element, an array of Map<String, Object> elements. Each element contains the ID of the record updated and an array of errors, if there were any, for that record's individual update. For example, `{ results: [ { id: 'recordId', errors: ['errorMessage', ...]}, ...] }`.

Single and Batch Update—Failure
A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

Request Class
Contains methods to obtain the request ID and Quiddity value of the current Salesforce request.

Namespace
System

Usage
Use the Request class to detect the current Apex context at runtime. The methods in the Request class obtain a unique request ID and the Quiddity value that represent the current Apex execution type. These values can also be used to correlate with debug and event logs:

- The request ID is universally unique and present in the debug logs that are triggered by the request.
The request ID and Quiddity values are the same as in the event log files of the Apex Execution event type used in Event Monitoring.

Example

This example code shows how to obtain current Apex code context by retrieving the request ID and Quiddity value of the current request.

```java
//Get info about the current request
Request reqInfo = Request.getCurrent();

//Get the identifier for this request, which is universally unique
//Same as requestId in splunk or REQUEST_ID in event monitoring
String currentRequestId = reqInfo.getRequestId();

//Enum representing how Apex is running. e.g. BULK_API vs LIGHTNING
Quiddity currentType = reqInfo.getQuiddity();

//Use this with a switch statement,
//instead of checking System.isFuture() || System.isQueueable() || ...
```

Request Methods

The following are methods for Request.

:getCurrent()

Returns the current Request object that contains the request ID and Quiddity value.

:getQuiddity()

Returns the Quiddity value of the current Request object.

:getRequestId()

Returns the request ID of the current Request object.

:getCurrent()

Returns the current Request object that contains the request ID and Quiddity value.

**Signature**

```
public static System.Request getCurrent()
```

**Return Value**

Type: System.Request

:getQuiddity()

Returns the Quiddity value of the current Request object.
Signature

```java
public System.Quiddity getQuiddity()
```

Return Value

Type: `System.Quiddity`

Uses the values from the Quiddity enum. This value identifies the type of execution event associated with the current request.

```java
getRequestId()
```

Returns the request ID of the current Request object.

Signature

```java
public String getRequestId()
```

Return Value

Type: `String`

### ResetPasswordResult Class

Represents the result of a password reset.

#### Namespace

`System`

#### ResetPasswordResult Methods

The following are instance methods for `ResetPasswordResult`.

**IN THIS SECTION:**

- `getPassword()`: Returns the password generated by the `System.resetPassword` method call.

**getPassword()**

Returns the password generated by the `System.resetPassword` method call.

Signature

```java
public String getPassword()
```

Return Value

Type: `String`
RestContext Class

Contains the RestRequest and RestResponse objects.

Namespace

System

Usage

Use the System.RestContext class to access the RestRequest and RestResponse objects in your Apex REST methods.

Sample

The following example shows how to use RestContext to access the RestRequest and RestResponse objects in an Apex REST method.

```java
@RestResource(urlMapping='/MyRestContextExample/*')
global with sharing class MyRestContextExample {
    @HttpGet
    global static Account doGet() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
        String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
        Account result = [SELECT Id, Name, Phone, Website FROM Account WHERE Id = :accountId];
        return result;
    }
}
```

RestContext Properties

The following are properties for RestContext.

IN THIS SECTION:

- request
  - Returns the RestRequest for your Apex REST method.
- response
  - Returns the RestResponse for your Apex REST method.

**request**

Returns the RestRequest for your Apex REST method.

**Signature**

```java
public RestRequest request {get; set;}
```
Property Value
Type: System.RestRequest

**response**
Returns the RestResponse for your Apex REST method.

**Signature**

```java
public RestResponse response {get; set;}
```

Property Value
Type: System.RestResponse

---

**RestRequest Class**

Use the System.RestRequest class to access and pass request data in a RESTful Apex method.

**Namespace**

System

**Usage**
An Apex RESTful Web service method is defined using one of the REST annotations. For more information about Apex RESTful Web service, see Exposing Apex Classes as REST Web Services.

**Example: An Apex Class with REST Annotated Methods**
The following example shows you how to implement the Apex REST API in Apex. This class exposes three methods that each handle a different HTTP request: GET, DELETE, and POST. You can call these annotated methods from a client by issuing HTTP requests.

```java
@RestResource(urlMapping='/Account/*')
global with sharing class MyRestResource {

    @HttpDelete
global static void doGet() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
        String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
        Account account = [SELECT Id FROM Account WHERE Id = :accountId];
        delete account;
    }

    @HttpGet
global static Account doGet() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
        String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/'))+1);
```
Account result = [SELECT Id, Name, Phone, Website FROM Account WHERE Id = :accountId];
            return result;
        }
        
        @HttpPost
        global static String doPost(String name, String phone, String website) {
            Account account = new Account();
            account.Name = name;
            account.phone = phone;
            account.website = website;
            insert account;
            return account.Id;
        }

IN THIS SECTION:

  RestRequest Constructors
  RestRequest Properties
  RestRequest Methods

RestRequest Constructors

The following are constructors for RestRequest.

IN THIS SECTION:

  RestRequest()

  Creates a new instance of the System.RestRequest class.

RestRequest ()

Creates a new instance of the System.RestRequest class.

Signature

public RestRequest ()

RestRequest Properties

The following are properties for RestRequest.

Note: While the RestRequest List and Map properties are read-only, their contents are read-write. You can modify them by calling the collection methods directly or you can use the associated RestRequest methods shown in the previous table.
IN THIS SECTION:

headers
Returns the headers that are received by the request.

httpMethod
Returns one of the supported HTTP request methods.

params
Returns the parameters that are received by the request.

remoteAddress
Returns the IP address of the client making the request.

requestBody
Returns or sets the body of the request.

requestURI
Returns or sets everything after the host in the HTTP request string.

resourcePath
Returns the REST resource path for the request.

headers

Returns the headers that are received by the request.

Signature

public Map<String, String> headers {get; set;}

Property Value

Type: Map<String, String>

httpMethod

Returns one of the supported HTTP request methods.

Signature

public String httpMethod {get; set;}

Property Value

Type: String

Possible values returned:

- DELETE
- GET
- HEAD
- PATCH
- POST
• PUT

**params**

Returns the parameters that are received by the request.

**Signature**

```java
public Map<String, String> params {get; set;}
```

**Property Value**

Type: `Map<String, String>`

**remoteAddress**

Returns the IP address of the client making the request.

**Signature**

```java
public String remoteAddress {get; set;}
```

**Property Value**

Type: `String`

**requestBody**

Returns or sets the body of the request.

**Signature**

```java
public Blob requestBody {get; set;}
```

**Property Value**

Type: `Blob`

**Usage**

If the Apex method has no parameters, then Apex REST copies the HTTP request body into the `RestRequest.requestBody` property. If there are parameters, then Apex REST attempts to deserialize the data into those parameters and the data won't be deserialized into the `RestRequest.requestBody` property.

**requestURI**

Returns or sets everything after the host in the HTTP request string.

**Signature**

```java
public String requestURI {get; set;}
```
Property Value
Type: String

Example
For example, if the request string is https://instance.salesforce.com/services/apexrest/Account/ then the requestURI is /Account/.

resourcePath
Returns the REST resource path for the request.

Signature
public String resourcePath {get; set;}

Property Value
Type: String

Example
For example, if the Apex REST class defines a urlMapping of /MyResource/*, the resourcePath property returns /services/apexrest/MyResource/*.

RestRequest Methods
The following are methods for RestRequest. All are instance methods.

Note: At runtime, you typically don’t need to add a header or parameter to the RestRequest object because they are automatically deserialized into the corresponding properties. The following methods are intended for unit testing Apex REST classes. You can use them to add header or parameter values to the RestRequest object without having to recreate the REST method call.

IN THIS SECTION:
- addHeader(name, value)
  Adds a header to the request header map in an Apex test.
- addParameter(name, value)
  Adds a parameter to the request params map in an Apex test.

addHeader(name, value)
Adds a header to the request header map in an Apex test.

Signature
public Void addHeader(String name, String value)
Parameters

name
    Type: String
value
    Type: String

Return Value
Type: Void

Usage
This method is intended for unit testing of Apex REST classes.
The following headers aren't allowed:
• cookie
• set-cookie
• set-cookie2
• content-length
• authorization
If any of these headers are used, an Apex exception is thrown.

addParameter(name, value)
Adds a parameter to the request params map in an Apex test.

Signature
public Void addParameter(String name, String value)

Parameters

name
    Type: String
value
    Type: String

Return Value
Type: Void

Usage
This method is intended for unit testing of Apex REST classes.

RestResponse Class
Represents an object used to pass data from an Apex RESTful Web service method to an HTTP response.
Namespace

System

Usage

Use the `System.RestResponse` class to pass response data from an Apex RESTful web service method that is defined using one of the REST annotations.

IN THIS SECTION:
- RestResponse Constructors
- RestResponse Properties
- RestResponse Methods

RestResponse Constructors

The following are constructors for `RestResponse`.

IN THIS SECTION:
- `RestResponse()`
  - Creates a new instance of the `System.RestResponse` class.

RestResponse() Creates a new instance of the `System.RestResponse` class.

Signature

```java
public RestResponse()
```

RestResponse Properties

The following are properties for `RestResponse`.

**Note:** While the `RestResponse.List` and `Map` properties are read-only, their contents are read-write. You can modify them by calling the collection methods directly or you can use the associated `RestResponse` methods shown in the previous table.

IN THIS SECTION:
- `responseBody`
  - Returns or sets the body of the response.
- `headers`
  - Returns the headers to be sent to the response.
- `statusCode`
  - Returns or sets the response status code.
**responseBody**

Returns or sets the body of the response.

**Signature**

```java
public Blob responseBody {get; set;}
```

**Property Value**

Type: Blob

**Usage**

The response is either the serialized form of the method return value or it's the value of the `responseBody` property based on the following rules:

- If the method returns void, then Apex REST returns the response in the `responseBody` property.
- If the method returns a value, then Apex REST serializes the return value as the response. If the return value contains fields with null value, those fields are not serialized in the response.

**headers**

Returns the headers to be sent to the response.

**Signature**

```java
public Map<String, String> headers {get; set;}
```

**Property Value**

Type: `Map<String, String>`

**statusCode**

Returns or sets the response status code.

**Signature**

```java
public Integer statusCode {get; set;}
```

**Property Value**

Type: Integer

**Status Codes**

The following are valid response status codes. The status code is returned by the `RestResponse.statusCode` property.

- **Note:** If you set the `RestResponse.statusCode` property to a value that's not listed in the table, then an HTTP status of 500 is returned with the error message "Invalid status code for HTTP response: nnn" where nnn is the invalid status code value.

**RestResponse Methods**

The following are instance methods for `RestResponse`.

**Note:** At runtime, you typically don’t need to add a header to the `RestResponse` object because it’s automatically deserialized into the corresponding properties. The following methods are intended for unit testing Apex REST classes. You can use them to add header or parameter values to the `RestRequest` object without having to recreate the REST method call.
IN THIS SECTION:

addHeader(name, value)
Adds a header to the response header map.

addHeader(name, value)
Adds a header to the response header map.

**Signature**

```java
public Void addHeader(String name, String value)
```

**Parameters**

- `name`
  Type: `String`

- `value`
  Type: `String`

**Return Value**

Type: `Void`

**Usage**

The following headers aren't allowed:

- cookie
- set-cookie
- set-cookie2
- content-length
- authorization
- Header names that aren't RFC 7230 compliant

If any of these headers are used, an Apex exception is thrown.

---

**SandboxPostCopy Interface**

To make your sandbox environment business ready, automate data manipulation or business logic tasks. Extend this interface and add methods to perform post-copy tasks, then specify the class during sandbox creation.

**Namespace**

`System`

**Usage**

Create an Apex class that implements this interface. Specify your class during sandbox creation. After your sandbox is created, the `runApexClass(context)` method in your class runs using the automated process user's permissions.
**Important:** The SandboxPostCopy Apex class is executed at the end of the sandbox copy using a special Automated Process user that isn’t visible within the org. This user doesn’t have access to all object and features; therefore, the Apex script cannot access all objects and features. If the script fails, run the script after sandbox activation as a user with appropriate permissions.

**IN THIS SECTION:**
- SandboxPostCopy Methods
- SandboxPostCopy Example Implementation

These examples show a simple implementation of the SandboxPostCopy interface and a test for that implementation. To test your SandboxPostCopy implementation, use the `System.Test.testSandboxPostCopyScript()` method.

**SEE ALSO:**
- Tooling API: SandboxInfo
- Tooling API: SandboxInfo

### SandboxPostCopy Methods

The following method is for SandboxPostCopy.

**IN THIS SECTION:**
- `runApexClass(context)`

Executes actions in a new sandbox to prepare it for use. For example, add logic to this method to create users, run sanitizing code on records, and perform other setup tasks.

**runApexClass(context)**

Executes actions in a new sandbox to prepare it for use. For example, add logic to this method to create users, run sanitizing code on records, and perform other setup tasks.

**Signature**

```java
public void runApexClass(System.SandboxContext context)
```

**Parameters**

- `context`
  - Type: System.SandboxContext
  - The org ID, sandbox ID, and sandbox name for your sandbox. To work with these values, reference `context.organizationId()`, `context.sandboxId()`, and `context.sandboxName()` in your code.

**Return Value**

Type: void
SandboxPostCopy Example Implementation

These examples show a simple implementation of the SandboxPostCopy interface and a test for that implementation. To test your SandboxPostCopy implementation, use the `System.Test.testSandboxPostCopyScript()` method.

**Important:** The SandboxPostCopy Apex class is executed at the end of the sandbox copy using a special Automated Process user that isn’t visible within the org. This user doesn’t have access to all object and features; therefore, the Apex script can’t access all objects and features. If the script fails, run the script after sandbox activation as a user with appropriate permissions.

This example implements the `System.SandboxPostCopy` interface.

```java
global class PrepareMySandbox implements SandboxPostCopy {
    global PrepareMySandbox() {
        //Implementations of SandboxPostCopy must have a no-arg constructor.
        //This constructor is used during the sandbox copy process.
        //You can also implement constructors with arguments, but be aware that
        //they won’t be used by the sandbox copy process (unless as part of the
        //no-arg constructor).
        this(some_args);
    }

    global PrepareMySandbox(String some_args) {
        //Logic for constructor.
    }

    global void runApexClass(SandboxContext context) {
        System.debug('Org ID: ' + context.organizationId());
        System.debug('Sandbox ID: ' + context.sandboxId());
        System.debug('Sandbox Name: ' + context.sandboxName());

        // Insert logic here to prepare the sandbox for use.
    }
}
```

The following example tests the implementation using the `System.Test.testSandboxPostCopyScript()` method. This method takes four parameters: a reference to a class that implements the SandboxPostCopy interface, and the three fields on the context object that you pass to the `runApexClass(context)` method. An overload on the method takes an optional Boolean parameter to indicate if the test should be performed as the Automated Process user.

```java
@isTest
class PrepareMySandboxTest {

    @isTest
    static void testMySandboxPrep() {
        // Insert logic here to create records of the objects that the class you’re testing
        // manipulates.
        Test.startTest();

        //Execute test script with RunAsAutoProcUser set to true
        Test.testSandboxPostCopyScript(
            new PrepareMySandbox(), UserInfo.getOrganizationId(),
            ...
        );
    }
}
```
UserInfo.getOrganizationId(), UserInfo.getOrganizationName(), true);

Test.stopTest();

// Insert assert statements here to check that the records you created above have
// the values you expect.

For more information on testing, see Testing Apex.

**Scheduled Interface**

The class that implements this interface can be scheduled to run at different intervals.

**Namespace**

*System*

SEE ALSO:

*Apex Developer Guide: Scheduler*

**Scheduled Methods**

The following are methods for *Scheduled*.

**IN THIS SECTION:**

*execute(context)*

Executes the scheduled Apex job.

```
execute(context)
```

Executes the scheduled Apex job.

**Signature**

```
public Void execute(SchedulableContext context)
```

**Parameters**

*context*

Type: *System.SchedulableContext*

Contains the job ID.

**Return Value**

Type: Void
ScheduledContext Interface

Represents the parameter type of a method in a class that implements the `Scheduled` interface and contains the scheduled job ID. This interface is implemented internally by Apex.

Namespace

`System`

SEE ALSO:

`Scheduled Interface`

ScheduledContext Methods

The following are methods for `ScheduledContext`.

IN THIS SECTION:

`getTriggerId()`

Returns the ID of the CronTrigger scheduled job.

```java
public Id getTriggerId()
```

Return Value

Type: `ID`

Schema Class

Contains methods for obtaining schema describe information.

Namespace

`System`

Schema Methods

The following are methods for `Schema`. All methods are static.
IN THIS SECTION:

getGlobalDescribe()
Returns a map of all sObject names (keys) to sObject tokens (values) for the standard and custom objects defined in your organization.

describeDataCategoryGroups(sObjectName)
Returns a list of the category groups associated with the specified objects.

describeSObjects(sObjectTypes)
Describes metadata (field list and object properties) for the specified sObject or array of sObjects.

describeSObjects(SObjectTypes, SObjectDescribeOptions)
Describes metadata such as field list and object properties for the specified list of SObjects. The default describe option for this method is SObjectDescribeOptions.DEFERRED, which indicates lazy initialization of describe attributes on first use.

describeTabs()
Returns information about the standard and custom apps available to the running user.

describeDataCategoryGroupStructures(pairs, topCategoriesOnly)
Returns available category groups along with their data category structure for objects specified in the request.

globalDescribe()

Returns a map of all sObject names (keys) to sObject tokens (values) for the standard and custom objects defined in your organization.

**Signature**

```
public static Map<String, Schema.SObjectType> getGlobalDescribe()
```

**Return Value**

Type: `Map<String, Schema.SObjectType>`

**Usage**

For more information on accessing SObjects, see Accessing All sObjects.

**Example**

```
Map<String, Schema.SObjectType> gd = Schema.getGlobalDescribe();
```

describeDataCategoryGroups(sObjectName)

Returns a list of the category groups associated with the specified objects.

**Signature**

```
public static List<Schema.DescribeDataCategoryGroupResult> describeDataCategoryGroups(List<String> sObjectNames)
```
Parameters

sObjectName
Type: List<String>

Return Value
Type: List<Schema.DescribeDataCategoryGroupResult>

Usage
You can specify one of the following sObject names:
• KnowledgeArticleVersion—to retrieve category groups associated with article types.
• Question—to retrieve category groups associated with questions.
For more information and code examples using describeDataCategoryGroups, see Accessing All Data Categories Associated with an sObject.
For additional information about articles and questions, see "Work with Articles and Translations" in the Salesforce online help.

describeSObjects (sObjectTypes)
Describes metadata (field list and object properties) for the specified sObject or array of sObjects.

Signature
public static List<Schema.DescribeSObjectResult> describeSObjects(List<String> sObjectTypes)

Parameters

sObjectTypes
Type: List<String>
The sObjectTypes argument is a list of sObject type names you want to describe.

Return Value
Type: List<Schema.DescribeSObjectResult>

Usage
This method is similar to the getDescribe method on the Schema.sObjectType token. Unlike the getDescribe method, this method allows you to specify the sObject type dynamically and describe more than one sObject at a time.
You can first call getGlobalDescribe to retrieve a list of all objects for your organization, then iterate through the list and use describeSObjects to obtain metadata about individual objects.

Example
Schema.DescribeSObjectResult[] descResult = Schema.describeSObjects(new String[]{'Account','Contact'});
**describeSObjects(SObjectTypes, SObjectDescribeOptions)**

Describes metadata such as field list and object properties for the specified list of SObjects. The default describe option for this method is SObjectDescribeOptions.DEFERRED, which indicates lazy initialization of describe attributes on first use.

**Signature**

```java
public static List<Schema.DescribeSObjectResult> describeSObjects(List<String> SObjectTypes, Object SObjectDescribeOptions)
```

**Parameters**

*SObjectTypes*

Type: List<String>

The list of SObject types to describe.

*SObjectDescribeOptions*

Type: Object

The effective describe option used for the SObject.

**Return Value**

Type: List<Schema.DescribeSObjectResult>

**describeTabs()**

Returns information about the standard and custom apps available to the running user.

**Signature**

```java
public static List<Schema.DescribeTabSetResult> describeTabs()
```

**Return Value**

Type: List<Schema.DescribeTabSetResult>

**Usage**

An app is a group of tabs that works as a unit to provide application functionality. For example, two of the standard Salesforce apps are “Sales” and “Service.”

The `describeTabs` method returns the minimum required metadata that can be used to render apps in another user interface. Typically, this call is used by partner applications to render Salesforce data in another user interface, such as in a mobile or connected app.

In the Salesforce user interface, users have access to standard apps (and can also have access to custom apps) as listed in the Salesforce app menu at the top of the page. Selecting an app name in the menu allows the user to switch between the listed apps at any time.

**Note:** The “All Tabs” tab isn’t included in the list of described tabs.
Example

This example shows how to call the describeTabs method.

```java
Schema.DescribeTabSetResult[] tabSetDesc = Schema.describeTabs();
```

This longer example shows how to obtain describe metadata information for the Sales app. For each tab, the example gets describe information, such as the icon URL, whether the tab is custom or not, and colors. The describe information is written to the debug output.

```java
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set describe for each app and display the info
for (DescribeTabSetResult tsr : tabSetDesc) {
    String appLabel = tsr.getLabel();
    System.debug('Label: ' + appLabel);
    System.debug('Logo URL: ' + tsr.getLogoUrl());
    System.debug('isSelected: ' + tsr.isSelected());
    String ns = tsr.getNamespace();
    if (ns == '') {
        System.debug('The ' + appLabel + ' app has no namespace defined.');
    } else {
        System.debug('Namespace: ' + ns);
    }

    // Display tab info for the Sales app
    if (appLabel == 'Sales') {
        List<Schema.DescribeTabResult> tabDesc = tsr.getTabs();
        System.debug('-- Tab information for the Sales app --');
        for (Schema.DescribeTabResult tr : tabDesc) {
            System.debug('getLabel: ' + tr.getLabel());
            System.debug('getColors: ' + tr.getColors());
            System.debug('getIconUrl: ' + tr.getIconUrl());
            System.debug('getIcons: ' + tr.getIcons());
            System.debug('getMiniIconUrl: ' + tr.getMiniIconUrl());
            System.debug('getSobjectName: ' + tr.getSobjectName());
            System.debug('getUrl: ' + tr.getUrl());
            System.debug('isCustom: ' + tr.isCustom());
        }
    }
}
```

// Example debug statement output
// DEBUG|Label: Sales
// DEBUG|Logo URL: https://MyDomainName.my.salesforce.com/img/seasonLogos/2014_winter_aloha.png
// DEBUG|isSelected: true
// DEBUG|The Sales app has no namespace defined.// DEBUG|-- Tab information for the Sales app --
// (This is an example debug output for the Accounts tab.)
// DEBUG|getLabel: Accounts
// DEBUG|getColors:
// (Schema.DescribeColorResult[getColor=236FBD;getContext=primary;getTheme=theme4;],
// Schema.DescribeColorResult[getColor=236FBD;getContext=primary;getTheme=theme3;],
// ...)
describeDataCategoryGroupStructures (pairs, topCategoriesOnly)

Returns available category groups along with their data category structure for objects specified in the request.

Signature

public static List<Schema.DescribeDataCategoryGroupStructureResult> describeDataCategoryGroupStructures(List<Schema.DataCategoryGroupSobjectTypePair> pairs, Boolean topCategoriesOnly)

Parameters

pairs

Type: List<Schema.DataCategoryGroupSobjectTypePair>

The pairs argument is one or more category groups and objects to query Schema.DataCategoryGroupSobjectTypePairs. Visible data categories are retrieved for the specified object. For more information on data category group visibility, see “Data Category Visibility” in Salesforce Help.

topCategoriesOnly

Type: Boolean

Use true to return only the top visible category and false to return all the visible categories, depending on the user’s data category group visibility settings. For more information on data category group visibility, see Data Category Visibility in Salesforce Help.

Return Value

Type: List<Schema.DescribeDataCategoryGroupStructureResult>

Search Class

Use the methods of the Search class to perform dynamic SOSL queries.

Namespace

System
Search Methods

The following are static methods for Search.

IN THIS SECTION:

find(searchQuery)
Performs a dynamic SOSL query that can include the SOSL WITH SNIPPET clause. Snippets provide more context for users in Salesforce Knowledge article search results.

find(searchQuery, accessLevel)
Performs a dynamic SOSL query that can include the SOSL WITH SNIPPET clause. Snippets provide more context for users in Salesforce Knowledge article search results.

query(query)
Performs a dynamic SOSL query.

query(query, accessLevel)
Performs a dynamic SOSL query.

suggest(searchQuery, sObjectType, suggestions)
Returns a list of records or Salesforce Knowledge articles whose names or titles match the user’s search query string. Use this method to provide users with shortcuts to navigate to relevant records or articles before they perform a search.

suggest(searchQuery, sObjectType, suggestions, accessLevel)
Returns a list of records or Salesforce Knowledge articles whose names or titles match the user’s search query string. Use this method to provide users with shortcuts to navigate to relevant records or articles before they perform a search.

find(searchQuery)
Performs a dynamic SOSL query that can include the SOSL WITH SNIPPET clause. Snippets provide more context for users in Salesforce Knowledge article search results.

Signature

public static Search.SearchResults find(String searchQuery)

Parameters

searchQuery
Type: String
A SOSL query string.

Return Value

Type: Search.SearchResults

Usage

Use this method wherever a static SOSL query can be used, such as in regular assignment statements and for loops.
See Use Dynamic SOSL to Return Snippets.

SEE ALSO:
get(sObjectType)
Apex Developer Guide: Dynamic SOSL

**find(searchQuery, accessLevel)**

Performs a dynamic SOSL query that can include the SOSL WITH SNIPPET clause. Snippets provide more context for users in Salesforce Knowledge article search results.

**Signature**

```java
public static Search.SearchResults find(String searchQuery, System.AccessLevel accessLevel)
```

**Parameters**

- **searchQuery**
  - Type: String
  - A SOSL query string.
- **accessLevel**
  - Type: System.AccessLevel
  - (Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**

- Type: Search.SearchResults

**Usage**

Use this method wherever a static SOSL query can be used, such as in regular assignment statements and for loops.
See Use Dynamic SOSL to Return Snippets.

**query(query)**

Performs a dynamic SOSL query.

**Signature**

```java
public static sObject[] query(String query)
```
Parameters

query
  Type: String
  A SOSL query string.
  To create a SOSL query that includes the WITH SNIPPET clause, use the Search.find(String searchQuery) method instead.

Return Value
Type: sObject[sObject[]]

Usage
This method can be used wherever a static SOSL query can be used, such as in regular assignment statements and for loops.
For more information, see Dynamic SOSL.

query(query, accessLevel)
Performs a dynamic SOSL query.

Signature
public static List<List<SObject>> query(String query, System.AccessLevel accessLevel)

Parameters
query
  Type: String
  A SOSL query string.
  To create a SOSL query that includes the WITH SNIPPET clause, use the Search.find(String searchQuery) method instead.

accessLevel
  Type: System.AccessLevel
  (Optional) The accessLevel parameter specifies whether the method runs in system mode (AccessLevel.SYSTEM_MODE) or user mode (AccessLevel.USER_MODE). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

Return Value
Type: sObject[sObject[]]

Usage
This method can be used wherever a static SOSL query can be used, such as in regular assignment statements and for loops.
For more information, see Dynamic SOSL.
suggest(searchQuery, sObjectType, suggestions)

Returns a list of records or Salesforce Knowledge articles whose names or titles match the user's search query string. Use this method to provide users with shortcuts to navigate to relevant records or articles before they perform a search.

Signature

public static Search.SuggestionResults suggest(String searchQuery, String sObjectType, Search.SuggestionOption suggestions)

Parameters

searchQuery
  Type: String
  A SOSL query string.

sObjectType
  Type: String
  An sObject type.

options
  Type: Search.SuggestionOption
  This object contains options that change the suggestion results.

  If the searchQuery returns KnowledgeArticleVersion objects, pass an options parameter with a Search.SuggestionOption object that contains a language KnowledgeSuggestionFilter and a publish status KnowledgeSuggestionFilter.

  For suggestions for all other record types, the only supported option is a limit, which sets the maximum number of suggestions returned.

Return Value

Type: SuggestionResults

Usage

Use this method to return:

Suggestions for Salesforce Knowledge articles (KnowledgeArticleVersion)

  Salesforce Knowledge must be enabled in your organization. The user must have the “View Articles” permission enabled.

  The articles suggested include only the articles the user can access, based on the data categories and article types the user has permissions to view.

Suggestions for other record types

  The records suggested include only the records the user can access.

  This method returns a record if its name field starts with the text in the search string. This method automatically appends an asterisk wildcard (*) at the end of the search string. Records that contain the search string within a word aren’t considered a match.

  Records are suggested if the entire search string is found in the record name, in the same order as specified in the search string. For example, the text string national u is treated as national u* and returns “National Utility” and “National Urban Company” but not “National Company Utility” or “Urban National Company”.

3327
Note: If the user’s search query contains quotation marks or wildcards, those symbols are automatically removed from the query string in the URI.

SEE ALSO:

* Apex Developer Guide: Suggest Salesforce Knowledge Articles*

**suggest**(searchQuery, sObjectType, suggestions, accessLevel)

Returns a list of records or Salesforce Knowledge articles whose names or titles match the user’s search query string. Use this method to provide users with shortcuts to navigate to relevant records or articles before they perform a search.

**Signature**

```java
public static Search.SuggestionResults suggest(String searchQuery, String sObjectType, Search.SuggestionOption suggestions, System.AccessLevel accessLevel)
```

**Parameters**

- **searchQuery**
  - Type: `String`
  - A SOSL query string.

- **sObjectType**
  - Type: `String`
  - An sObject type.

- **suggestions**
  - Type: `Search.SuggestionOption`
  - This object contains options that change the suggestion results.
  - If the `searchQuery` returns KnowledgeArticleVersion objects, pass an `options` parameter with a Search.SuggestionOption object that contains a language KnowledgeSuggestionFilter and a publish status KnowledgeSuggestionFilter.
  - For suggestions for all other record types, the only supported option is a limit, which sets the maximum number of suggestions returned.

- **accessLevel**
  - Type: `System.AccessLevel`
  - (Optional) The `accessLevel` parameter specifies whether the method runs in system mode (`AccessLevel.SYSTEM_MODE`) or user mode (`AccessLevel.USER_MODE`). In system mode, the object and field-level permissions of the current user are ignored, and the record sharing rules are controlled by the class sharing keywords. In user mode, the object permissions, field-level security, and sharing rules of the current user are enforced. System mode is the default.

**Return Value**

- Type: `SuggestionResults`

**Usage**

Use this method to return:
Suggestions for Salesforce Knowledge articles (KnowledgeArticleVersion)

Salesforce Knowledge must be enabled in your organization. The user must have the “View Articles” permission enabled.

The articles suggested include only the articles the user can access, based on the data categories and article types the user has permissions to view.

Suggestions for other record types

The records suggested include only the records the user can access.

This method returns a record if its name field starts with the text in the search string. This method automatically appends an asterisk wildcard (*) at the end of the search string. Records that contain the search string within a word aren’t considered a match.

Records are suggested if the entire search string is found in the record name, in the same order as specified in the search string. For example, the text string national u is treated as national u* and returns “National Utility” and “National Urban Company” but not “National Company Utility” or “Urban National Company”.

Note: If the user’s search query contains quotation marks or wildcards, those symbols are automatically removed from the query string in the URI.

Security Class

Contains methods to securely implement Apex applications.

Namespace

System

Usage

In the context of the current user’s create, read, update, or upsert access permission, use the Security class methods to:

- Strip fields that aren’t visible from query and subquery results
- Remove inaccessible fields before a DML operation without causing an exception
- Sanitize SObjects that have been deserialized from an untrusted source

IN THIS SECTION:

Security Methods

Security Methods

The following are methods for Security.

IN THIS SECTION:

stripInaccessible(accessCheckType, sourceRecords, enforceRootObjectCRUD)

Creates a list of sObjects from the source records, which are stripped of fields that fail the field-level security checks for the current user. The method also provides an option to enforce an object-level access check.

stripInaccessible(accessCheckType, sourceRecords)

Creates a list of sObjects from the source records, which are stripped of fields that fail the field-level security checks for the current user.
stripInaccessible(accessCheckType, sourceRecords, enforceRootObjectCRUD)

Creates a list of sObjects from the source records, which are stripped of fields that fail field-level and object-level access checks. Apex enforces field-level security (FLS) and object permissions as per the specified permission set, in addition to the running user’s permissions.

**stripInaccessible(accessCheckType, sourceRecords, enforceRootObjectCRUD)**

Creates a list of sObjects from the source records, which are stripped of fields that fail the field-level security checks for the current user. The method also provides an option to enforce an object-level access check.

**Signature**

```java
public static System.SObjectAccessDecision stripInaccessible(System.AccessType accessCheckType, List<SObject> sourceRecords, Boolean enforceRootObjectCRUD)
```

**Parameters**

- **accessCheckType**
  
  Type: `System.AccessType`

  Uses values from the `AccessType` enum. This parameter determines the type of field-level access check to be performed. To check the current user's field-level access, use the `Schema.DescribeFieldResult` methods — `isCreatable()`, `isAccessible()`, or `isUpdatable()`.

- **sourceRecords**
  
  Type: `List<SObject>`

  A list of sObjects to be checked for fields that aren’t accessible in the context of the current user’s operation.

- **enforceRootObjectCRUD**
  
  Type: `Boolean`

  Indicates whether an object-level access check is performed. If this parameter is set to `true` and the access check fails, the method throws an exception. The default value of this optional parameter is `true`.

**Return Value**

Type: `System.SObjectAccessDecision`

**Example**

In this example, the user doesn’t have permission to create the `Probability` field of an Opportunity.

```java
List<Opportunity> opportunities = new List<Opportunity>(
    new Opportunity(Name='Opportunity1'),
    new Opportunity(Name='Opportunity2', Probability=95)
);

// Strip fields that are not creatable
SObjectAccessDecision decision = Security.stripInaccessible(
    AccessType.CREATABLE,
    opportunities);

// Print stripped records
```
for (SObject strippedOpportunity : decision.getRecords()) {
    System.debug(strippedOpportunity);
}

// Print modified indexes
System.debug(decision.getModifiedIndexes());

// Print removed fields
System.debug(decision.getRemovedFields());

//Lines from output log
///|DEBUG|Opportunity:{Name=Opportunity1}
///|DEBUG|Opportunity:{Name=Opportunity2}
///|DEBUG|{1}
///|DEBUG|{Opportunity={Probability}}

stripInaccessible(accessCheckType, sourceRecords)

Creates a list of sObjects from the source records, which are stripped of fields that fail the field-level security checks for the current user.

**Signature**

public static System.SObjectAccessDecision stripInaccessible(System.AccessType accessCheckType, List<SObject> sourceRecords)

**Parameters**

*accessCheckType*
- Type: System.AccessType
  - Uses values from the AccessType enum. This parameter determines the type of field-level access check to be performed. To check the current user's field-level access, use the Schema.DescribeFieldResult methods — isCreatable(), isAccessible(), or isUpdatable().

*sourceRecords*
- Type: List<SObject>
  - A list of sObjects to be checked for fields that aren't accessible in the context of the current user's operation.

**Return Value**

Type: System.SObjectAccessDecision

**Example**

In this example, the user doesn't have permission to read the ActualCost field of a Campaign.

List<Campaign> campaigns = new List<Campaign>{
    new Campaign(Name='Campaign1', BudgetedCost=1000, ActualCost=2000),
    new Campaign(Name='Campaign2', BudgetedCost=4000, ActualCost=1500)
};
insert campaigns;

// Strip fields that are not readable
SObjectAccessDecision decision = Security.stripInaccessible(
    AccessType.READABLE,
    [SELECT Name, BudgetedCost, ActualCost from Campaign]);

// Print stripped records
for (SObject strippedCampaign : decision.getRecords()) {
    System.debug(strippedCampaign); // Does not display ActualCost
}

// Print modified indexes
System.debug(decision.getModifiedIndexes());

// Print removed fields
System.debug(decision.getRemovedFields());

//Lines from output log
///|DEBUG|Campaign:{Name=Campaign1, BudgetedCost=1000, Id=701xx00000011nhAAA}
///|DEBUG|Campaign:{Name=Campaign2, BudgetedCost=4000, Id=701xx00000011niAAA}
///|DEBUG|{0, 1}
///|DEBUG|{ActualCost}

stripInaccessible(accessCheckType, sourceRecords, enforceRootObjectCRUD, permissionSetId)(Developer Preview)

Creates a list of sObjects from the source records, which are stripped of fields that fail field-level and object-level access checks. Apex enforces field-level security (FLS) and object permissions as per the specified permission set, in addition to the running user's permissions.

Note: Feature is available as a developer preview. Feature isn’t generally available unless or until Salesforce announces its general availability in documentation or in press releases or public statements. All commands, parameters, and other features are subject to change or deprecation at any time, with or without notice. Don’t implement functionality developed with these commands or tools in a production environment. You can provide feedback and suggestions for the “Permission Sets with User Mode” feature in the Trailblazer Community.

This feature is available in scratch orgs where the ApexUserModeWithPermset feature is enabled. If the feature isn’t enabled, Apex code with this feature can be compiled but not executed.

Signature

```
public static System.SObjectAccessDecision stripInaccessible(System.AccessType accessCheckType, List<SObject> sourceRecords, Boolean enforceRootObjectCRUD, Id permissionSetId)
```

Parameters

accessCheckType
Type: System.AccessType

Uses values from the AccessType enum. This parameter determines the type of field-level access check to be performed. To check the current user’s field-level access, use the Schema.DescribeFieldResult methods — isCreatable(), isAccessible(), or isUpdatable().

sourceRecords
Type: List<SObject>
enforceRootObjectCRUD
Type: Boolean
Indicates whether an object-level access check is performed. If this parameter is set to true and the access check fails, the method throws an exception. The default value of this optional parameter is true.

permissionSetId
Type: Id
Permissions in the specified permission set are enforced in addition to the running user’s permissions.

Return Value
Type: System.SObjectAccessDecision

SelectOption Class
A SelectOption object specifies one of the possible values for a Visualforce selectCheckboxes, selectList, or selectRadio component.

Namespace
System
SelectOption consists of a label that is displayed to the end user, and a value that is returned to the controller if the option is selected. A SelectOption can also be displayed in a disabled state, so that a user cannot select it as an option, but can still view it.

Instantiation
In a custom controller or controller extension, you can instantiate a SelectOption in one of the following ways:

* `SelectOption option = new SelectOption(value, label, isDisabled);`

  where value is the String that is returned to the controller if the option is selected by a user, label is the String that is displayed to the user as the option choice, and isDisabled is a Boolean that, if true, specifies that the user cannot select the option, but can still view it.

* `SelectOption option = new SelectOption(value, label);`

  where value is the String that is returned to the controller if the option is selected by a user, and label is the String that is displayed to the user as the option choice. Because a value for isDisabled is not specified, the user can both view and select the option.

Example
The following example shows how a list of SelectOptions objects can be used to provide possible values for a selectCheckboxes component on a Visualforce page. In the following custom controller, the getItems method defines and returns the list of possible SelectOption objects:

public class sampleCon {
String[] countries = new String[]{};

public PageReference test() {
    return null;
}

public List<SelectOption> getItems() {
    List<SelectOption> options = new List<SelectOption>();
    options.add(new SelectOption('US', 'US'));
    options.add(new SelectOption('CANADA', 'Canada'));
    options.add(new SelectOption('MEXICO', 'Mexico'));
    return options;
}

public String[] getCountries() {
    return countries;
}

public void setCountries(String[] countries) {
    this.countries = countries;
}

In the following page markup, the <apex:selectOptions> tag uses the getItems method from the controller above to retrieve the list of possible values. Because <apex:selectOptions> is a child of the <apex:selectCheckboxes> tag, the options are displayed as checkboxes:

```apex
<apex:page controller="sampleCon">
    <apex:form>
        <apex:selectCheckboxes value="{!countries}">
            <apex:selectOptions value="{!items}"/>
        </apex:selectCheckboxes>
        <apex:commandButton value="Test" action="{!test}" rerender="out" status="status"/>
    </apex:form>
    <apex:outputPanel id="out">
        <apex:actionstatus id="status" startText="testing...">
            <apex:facet name="stop">
                <apex:outputPanel>
                    <p>You have selected:</p>
                    <apex:datalist value="{!countries}" var="c">{!c}</apex:datalist>
                </apex:outputPanel>
            </apex:facet>
        </apex:actionstatus>
    </apex:outputPanel>
</apex:page>
```

IN THIS SECTION:

SelectOption Constructors
SelectOption Methods
SelectOption Constructors

The following are constructors for SelectOption.

IN THIS SECTION:

SelectOption(value, label)
Creates a new instance of the SelectOption class using the specified value and label.

SelectOption(value, label, isDisabled)
Creates a new instance of the SelectOption class using the specified value, label, and disabled setting.

SelectOption(value, label)
Creates a new instance of the SelectOption class using the specified value and label.

Signature

public SelectOption(String value, String label)

Parameters

value
  Type: String
  The string that is returned to the Visualforce controller if the option is selected by a user.

label
  Type: String
  The string that is displayed to the user as the option choice.

SelectOption(value, label, isDisabled)
Creates a new instance of the SelectOption class using the specified value, label, and disabled setting.

Signature

public SelectOption(String value, String label, Boolean isDisabled)

Parameters

value
  Type: String
  The string that is returned to the Visualforce controller if the option is selected by a user.

label
  Type: String
  The string that is displayed to the user as the option choice.

isDisabled
  Type: Boolean
  If set to true, the option can’t be selected by the user but can still be viewed.
SelectOption Methods

The following are methods for SelectOption. All are instance methods.

IN THIS SECTION:

getDisabled()
Returns the current value of the SelectOption object’s isDisabled attribute.

getEscapeItem()
Returns the current value of the SelectOption object’s itemEscaped attribute.

getLabel()
Returns the option label that is displayed to the user.

getValue()
Returns the option value that is returned to the controller if a user selects the option.

setDisabled(isDisabled)
Sets the value of the SelectOption object’s isDisabled attribute.

setEscapeItem(itemsEscaped)
Sets the value of the SelectOption object’s itemEscaped attribute.

setLabel(label)
Sets the value of the option label that is displayed to the user.

setValue(value)
Sets the value of the option value that is returned to the controller if a user selects the option.

getDisabled()
Returns the current value of the SelectOption object’s isDisabled attribute.

Signature

public Boolean getDisabled()

Return Value

Type: Boolean

Usage

If isDisabled is set to true, the user can view the option, but cannot select it. If isDisabled is set to false, the user can both view and select the option.

getEscapeItem()
Returns the current value of the SelectOption object’s itemEscaped attribute.

Signature

public Boolean getEscapeItem()
Return Value
Type: Boolean

Usage
If `itemEscaped` is set to `true`, sensitive HTML and XML characters are escaped in the HTML output generated by this component. If `itemEscaped` is set to `false`, items are rendered as written.

`getLabel()`
Returns the option label that is displayed to the user.

Signature
```
public String getLabel()
```

Return Value
Type: String

`getValue()`
Returns the option value that is returned to the controller if a user selects the option.

Signature
```
public String getValue()
```

Return Value
Type: String

`setDisabled(isDisabled)`
Sets the value of the SelectOption object's `isDisabled` attribute.

Signature
```
public Void setDisabled(Boolean isDisabled)
```

Parameters
`isDisabled`
Type: Boolean

Return Value
Type: Void
Usage
If `isDisabled` is set to `true`, the user can view the option, but cannot select it. If `isDisabled` is set to `false`, the user can both view and select the option.

`setEscapeItem(itemsEscaped)`
Sets the value of the SelectOption object's `itemEscaped` attribute.

Signature
```java
public Void setEscapeItem(Boolean itemsEscaped)
```

Parameters
- `itemsEscaped`
  Type: `Boolean`

Return Value
Type: Void

Usage
If `itemEscaped` is set to `true`, sensitive HTML and XML characters are escaped in the HTML output generated by this component. If `itemEscaped` is set to `false`, items are rendered as written.

`setLabel(label)`
Sets the value of the option label that is displayed to the user.

Signature
```java
public Void setLabel(String label)
```

Parameters
- `label`
  Type: `String`

Return Value
Type: Void

`setValue(value)`
Sets the value of the option value that is returned to the controller if a user selects the option.

Signature
```java
public Void setValue(String value)
```
Parameters

value
Type: String

Return Value
Type: Void

Set Class

Represents a collection of unique elements with no duplicate values.

Namespace

System

Usage

The Set methods work on a set, that is, an unordered collection of elements that was initialized using the set keyword. Set elements can be of any data type—primitive types, collections, sObjects, user-defined types, and built-in Apex types. Set methods are all instance methods, that is, they all operate on a particular instance of a Set. The following are the instance methods for sets.

Note:

- Uniqueness of set elements of user-defined types is determined by the equals and hashCode methods, which you provide in your classes. Uniqueness of all other non-primitive types is determined by comparing the objects' fields.
- If the set contains String elements, the elements are case-sensitive. Two set elements that differ only by case are considered distinct.

For more information on sets, see Sets.

IN THIS SECTION:

Set Constructors

Set Methods

Set Constructors

The following are constructors for Set.

IN THIS SECTION:

Set<T>()

Creates a new instance of the Set class. A set can hold elements of any data type T.

Set<T>(setToCopy)

Creates a new instance of the Set class by copying the elements of the specified set. T is the data type of the elements in both sets and can be any data type.
Set<T>(listToCopy)
Creates a new instance of the Set class by copying the list elements. T is the data type of the elements in the set and list and can be any data type.

Set<T>()
Creates a new instance of the Set class. A set can hold elements of any data type T.

Signature
public Set<T>()

Example
// Create a set of strings
Set<String> s1 = new Set<String>();
// Add two strings to it
s1.add('item1');
s1.add('item2');

Set<T>(setToCopy)
Creates a new instance of the Set class by copying the elements of the specified set. T is the data type of the elements in both sets and can be any data type.

Signature
public Set<T>(Set<T> setToCopy)

Parameters
setToCopy
Type: Set<T>
The set to initialize this set with.

Example
Set<String> s1 = new Set<String>();
s1.add('item1');
s1.add('item2');
Set<String> s2 = new Set<String>(s1);
// The set elements in s2 are copied from s1
System.debug(s2);

Set<T>(listToCopy)
Creates a new instance of the Set class by copying the list elements. T is the data type of the elements in the set and list and can be any data type.
Signature

```java
public Set<T>(List<T> listToCopy)
```

Parameters

`listToCopy`

Type: `Integer`

The list to copy the elements of into this set.

Example

```java
List<Integer> ls = new List<Integer>();
ls.add(1);
ls.add(2);
// Create a set based on a list
Set<Integer> s1 = new Set<Integer>(ls);
// Elements are copied from the list to this set
System.debug(s1);// DEBUG|{1, 2}
```

Set Methods

The following are methods for `Set`. All are instance methods.

**IN THIS SECTION:**

- `add(setElement)`
  Adds an element to the set if it is not already present.
- `addAll(fromList)`
  Adds all of the elements in the specified list to the set if they are not already present.
- `addAll(fromSet)`
  Adds all of the elements in the specified set to the set that calls the method if they are not already present.
- `clear()`
  Removes all of the elements from the set.
- `clone()`
  Makes a duplicate copy of the set.
- `contains(setElement)`
  Returns `true` if the set contains the specified element.
- `containsAll(listToCompare)`
  Returns `true` if the set contains all of the elements in the specified list. The list must be of the same type as the set that calls the method.
- `containsAll(setToCompare)`
  Returns `true` if the set contains all of the elements in the specified set. The specified set must be of the same type as the original set that calls the method.
- `equals(set2)`
  Compares this set with the specified set and returns `true` if both sets are equal; otherwise, returns `false`.
hashCode()
Returns the hashcode corresponding to this set and its contents.

isEmpty()
Returns true if the set has zero elements.

remove(setElement)
Removes the specified element from the set if it is present.

removeAll(listOfElementsToRemove)
Removes the elements in the specified list from the set if they are present.

removeAll(setOfElementsToRemove)
Removes the elements in the specified set from the original set if they are present.

retainAll(listOfElementsToRetain)
Retains only the elements in this set that are contained in the specified list.

retainAll(setOfElementsToRetain)
Retains only the elements in the original set that are contained in the specified set.

size()
Returns the number of elements in the set (its cardinality).

toString()
Returns the string representation of the set.

add(setElement)
Adds an element to the set if it is not already present.

**Signature**

```java
public Boolean add(Object setElement)
```

**Parameters**

setElement
Type: Object

**Return Value**

Type: Boolean

**Usage**

This method returns true if the original set changed as a result of the call. For example:

```java
Set<String> myString = new Set<String>{'a', 'b', 'c'};
Boolean result = myString.add('d');
System.assertEquals(true, result);
```

addAll(fromList)
Adds all of the elements in the specified list to the set if they are not already present.
**Signature**

public Boolean addAll(List<Object> fromList)

**Parameters**

*fromList*

  Type: List

**Return Value**

Type: Boolean

Returns true if the original set changed as a result of the call.

**Usage**

This method results in the union of the list and the set. The list must be of the same type as the set that calls the method.

**addAll(fromSet)**

Adds all of the elements in the specified set to the set that calls the method if they are not already present.

**Signature**

public Boolean addAll(Set<Object> fromSet)

**Parameters**

*fromSet*

  Type: Set<Object>

**Return Value**

Type: Boolean

This method returns true if the original set changed as a result of the call.

**Usage**

This method results in the union of the two sets. The specified set must be of the same type as the original set that calls the method.

**Example**

```java
Set<String> myString = new Set<String>{'a', 'b'};
Set<String> sString = new Set<String>{'c'};
Boolean result1 = myString.addAll(sString);
System.assertEquals(true, result1);
```

**clear()**

Removes all of the elements from the set.
Signature
public Void clear()

Return Value
Type: Void

close()
Makes a duplicate copy of the set.

Signature
public Set<Object> close()

Return Value
Type: Set (of same type)

contains(setElement)
Returns true if the set contains the specified element.

Signature
public Boolean contains(Object setElement)

Parameters
setElement
Type: Object

Return Value
Type: Boolean

Example
Set<String> myString = new Set<String>{'a', 'b'};
Boolean result = myString.contains('z');
System.assertEquals(false, result);

containsAll(listToCompare)
Returns true if the set contains all of the elements in the specified list. The list must be of the same type as the set that calls the method.

Signature
public Boolean containsAll(List<Object> listToCompare)
Parameters

listToCompare
Type: List<Object>

Return Value
Type: Boolean

containsAll(setToCompare)
Returns true if the set contains all of the elements in the specified set. The specified set must be of the same type as the original set that calls the method.

Signature
public Boolean containsAll(Set<Object> setToCompare)

Parameters

setToCompare
Type: Set<Object>

Return Value
Type: Boolean

Example

```java
Set<String> myString = new Set<String>{'a', 'b'};
Set<String> sString = new Set<String>{'c'};
Set<String> rString = new Set<String>{'a', 'b', 'c'};

Boolean result1, result2;
result1 = myString.addAll(sString);
system.assertEquals(true, result1);

result2 = myString.containsAll(rString);
System.assertEquals(true, result2);
```

equals(set2)
Compares this set with the specified set and returns true if both sets are equal; otherwise, returns false.

Signature
public Boolean equals(Set<Object> set2)

Parameters

set2
Type: Set<Object>
The `set2` argument is the set to compare this set with.

**Return Value**
Type: Boolean

**Usage**
Two sets are equal if their elements are equal, regardless of their order. The `==` operator is used to compare the elements of the sets. The `==` operator is equivalent to calling the `equals` method, so you can call `set1.equals(set2);` instead of `set1 == set2;`.

**hashCode()**
Returns the hashcode corresponding to this set and its contents.

**Signature**
```
public Integer hashCode()
```

**Return Value**
Type: Integer

**isEmpty()**
Returns `true` if the set has zero elements.

**Signature**
```
public Boolean isEmpty()
```

**Return Value**
Type: Boolean

**Example**
```java
Set<Integer> mySet = new Set<Integer>();
Boolean result = mySet.isEmpty();
System.assertEquals(true, result);
```

**remove(setElement)**
Removes the specified element from the set if it is present.

**Signature**
```
public Boolean remove(Object setElement)
```
Parameters

setElement
Type: Object

Return Value
Type: Boolean
Returns true if the original set changed as a result of the call.

removeAll(listOfElementsToRemove)
Removes the elements in the specified list from the set if they are present.

Signature
public Boolean removeAll(List<Object> listOfElementsToRemove)

Parameters

listOfElementsToRemove
Type: List<Object>

Return Value
Type: Boolean
Returns true if the original set changed as a result of the call.

Usage
This method results in the relative complement of the two sets. The list must be of the same type as the set that calls the method.

Example
```
Set<Integer> mySet = new Set<Integer>{1, 2, 3};
List<Integer> myList = new List<Integer>{1, 3};
Boolean result = mySet.removeAll(myList);
System.assertEquals(true, result);
Integer result2 = mySet.size();
System.assertEquals(1, result2);
```

removeAll(setOfElementsToRemove)
Removes the elements in the specified set from the original set if they are present.

Signature
public Boolean removeAll(Set<Object> setOfElementsToRemove)
Parameters

setOfElementsToRemove

Type: Set<Object>

Return Value

Type: Boolean

This method returns true if the original set changed as a result of the call.

Usage

This method results in the relative complement of the two sets. The specified set must be of the same type as the original set that calls the method.

retainAll(listOfElementsToRetain)

Retains only the elements in this set that are contained in the specified list.

Signature

public Boolean retainAll(List<Object> listOfElementsToRetain)

Parameters

listOfElementsToRetain

Type: List<Object>

Return Value

Type: Boolean

This method returns true if the original set changed as a result of the call.

Usage

This method results in the intersection of the list and the set. The list must be of the same type as the set that calls the method.

Example

Set<Integer> mySet = new Set<Integer>{1, 2, 3};
List<Integer> myList = new List<Integer>{1, 3};
Boolean result = mySet.retainAll(myList);
System.assertEquals(true, result);

retainAll(setOfElementsToRetain)

Retains only the elements in the original set that are contained in the specified set.
Signature

public Boolean retainAll(Set setOfElementsToRetain)

Parameters

setOfElementsToRetain
Type: Set

Return Value

Type: Boolean

Returns true if the original set changed as a result of the call.

Usage

This method results in the intersection of the two sets. The specified set must be of the same type as the original set that calls the method.

size()

Returns the number of elements in the set (its cardinality).

Signature

public Integer size()

Return Value

Type: Integer

Example

```java
Set<Integer> mySet = new Set<Integer>{1, 2, 3};
List<Integer> myList = new List<Integer>{1, 3};
Boolean result = mySet.retainAll(myList);
System.assertEquals(true, result);

Integer result2 = mySet.size();
System.assertEquals(2, result2);
```

toString()

Returns the string representation of the set.

Signature

public String toString()
Return Value
Type: String

Usage
When used in cyclic references, the output is truncated to prevent infinite recursion. When used with large collections, the output is truncated to avoid exceeding total heap size and maximum CPU time.

- Up to 10 items per collection are included in the output, followed by an ellipsis (…).
- If the same object is included multiple times in a collection, it’s shown in the output only once; subsequent references are shown as (already output).

Site Class
Use the Site Class to manage your sites. Change, reset, validate, and check the expiration of passwords. Create site users, person accounts, and portal users. Get the admin email and ID. Get various URLs, the path prefix, the ID, the template, and the type of the site. Log in to the site.

Namespace
System

Site Methods
The following are methods for Site. All methods are static.

IN THIS SECTION:

changePassword(newPassword, verifyNewPassword, oldPassword)
Changes the password of the current user.
createExternalUser(user, accountId)
Creates a Salesforce Site or Experience Cloud site user for the given account and associates it with the site.
createExternalUser(user, accountId, password)
Creates a Salesforce Site or Experience Cloud site user for the given account and associates it with the site. This method sends an email with the specified password to the user.
createExternalUser(user, accountId, password, sendEmailConfirmation)
Creates a Salesforce Site or Experience Cloud site user and associates it with the given account. This method sends the user an email with the specified password and a new user confirmation email.
createPersonAccountPortalUser(user, ownerId, password)
Creates a person account using the default record type defined on the guest user’s profile, then enables it for the site’s portal.
createPersonAccountPortalUser(user, ownerId, recordTypeId, password)
Creates a person account using the specified recordTypeID, then enables it for the site’s portal.
createPortalUser(user, accountId, password, sendEmailConfirmation)
Creates a portal user for the given account and associates it with the site’s portal.
forgotPassword(username, emailTemplateName)
Resets the user's password and sends an email to the user with the user's new password. You can specify a custom email template or use the default email template. Returns a value indicating whether the password reset was successful.

forgotPassword(username)
Resets the user's password and sends an email to the user with the user's new password. Returns a value indicating whether the password reset was successful.

getAdminEmail()
Returns the email address of the site administrator.

getAdminId()
Returns the user ID of the site administrator.

getAnalyticsTrackingCode()
The tracking code associated with your site. Services such as Google Analytics can use this code to track page request data for your site.

gGetCurrentSiteUrl()
Deprecated. This method was replaced by getBaseUrl() in API version 30.0. Returns the base URL of the current site that references and links should use.

getBaseCustomUrl()
Returns a base URL for the current site that doesn’t use a force.com subdomain. The returned URL uses the same protocol (HTTP or HTTPS) as the current request if at least one non-Force.com custom URL that supports HTTPS exists on the site. The returned value never ends with a / character. If all the custom URLs in this site end in Force.com or this site has no custom URLs, then this returns an empty string. If the current request is not a site request, then this method returns an empty string. This method replaced getCustomWebAddress and includes the custom URL's path prefix.

getBaseInsecureUrl()
Deprecated. Returns a base URL for the current site that uses HTTP instead of HTTPS. The current request’s domain is used. The returned value includes the path prefix and never ends with a / character. If the current request is not a site request, then this method returns an empty string.

gBaseUrl()
Deprecated. Returns a base URL for the current site that uses HTTPS instead of HTTP. The current request’s domain is preferred if it supports HTTPS. Domains that are not Force.com subdomains are preferred over Force.com subdomains. A Force.com subdomain, if associated with the site, is used if no other HTTPS domains exist in the current site. If no HTTPS custom URLs exist in the site, then this method returns an empty string. The returned value includes the path prefix and never ends with a / character. If the current request is not a site request, then this method returns an empty string.

gBaseUrl()
Returns the base URL of the current site that references and links should use. Note that this field may return the referring page's URL instead of the current request's URL. The returned value includes the path prefix and never ends with a / character. If the current request is not a site request, then this field returns an empty string. This field replaces getCurrentSiteUrl.

gCustomWebAddress()
Deprecated. This method was replaced by getBaseCustomUrl() in API version 30.0.

gDomain()
Returns your Salesforce Sites based URL.
getErrorDescription()
Returns the error description for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

getErrorMessage()
Returns an error message for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

getExperienceId()
Returns the value of the experience ID (expid). This expid value comes from a cookie in the user’s web browser.

getMasterLabel()
Returns the value of the Master Label field for the current site. If the current request is not a site request, then this field returns null.

getName()
Returns the API name of the current site.

getOriginalUrl()
Returns the original URL for this page if it’s a designated error page for the site; otherwise, returns null.

getPasswordPolicyStatement()
Returns the password requirements for a Salesforce Site or Experience Cloud site created with the Customer Service template.

getPathPrefix()
Returns the URL path prefix of the current site or an empty string if none. For example, if the requested site URL is https://myco.my.salesforce-sites.com/partners, then /partners is the path prefix. If the current request is not a site request, then this method returns an empty string. This method replaced getPrefix in API version 30.0.

getPrefix()
Deprecated. This method was replaced by getPathPrefix() in API version 30.0.

getSiteId()
Returns the ID of the current site. If the current request is not a site request, then this field returns null.

getTemplate()
Returns the template name associated with the current site; returns the default template if no template has been designated.

getSiteType()
Returns the API value of the site type field for the current site. This can be Visualforce for a Salesforce site, Siteforce for a Site.com site, ChatterNetwork for an Experience Cloud site, or ChatterNetworkPicasso for an Experience Cloud site. If the current request is not a site request, then this method returns null.

getSiteTypeLabel()
Returns the value of the Site Type field's label for the current site. If the current request is not a site request, then this method returns null.

isLoginEnabled()
Returns true if the current site is associated with an active login-enabled portal; otherwise returns false.

isPasswordExpired()
For authenticated users, returns true if the currently logged-in user's password is expired. For non-authenticated users, returns false.

isRegistrationEnabled()
Returns true if the current site is associated with an active self-registration-enabled Customer Portal; otherwise returns false.

isValidUsername(username)
Returns true if the given username is valid; otherwise, returns false.
login(username, password, startUrl)
Allows users to log in to the current site with the given username and password, then takes them to the startUrl. If startUrl is not a relative path, it defaults to the site’s designated index page.

passwordlessLogin(userId, methods, startUrl)
Logs in a user to a Salesforce Site or Experience Cloud site using an identity verification method, such as email or text, instead of a password. Passwordless login is a convenient, mobile-centric way to welcome users into your site. Let your users log in with something other than their password, like their email address or phone number.

setExperienceId(expIdValue)
Sets the experience ID for the current user. Use this method to populate the value of the experience ID (expid) cookie in the user’s web browser.

setPortalUserAsAuthProvider(user, contactId)
Sets the specified user information within the site’s portal via an authentication provider.

validatePassword(user, password, confirmPassword)
Indicates whether a given password meets the requirements specified by org-wide or profile-based password policies in the current user’s org.

**changePassword(newPassword, verifyNewPassword, oldPassword)**
Changes the password of the current user.

**Signature**

```java
public static System.PageReference changePassword(String newPassword, String verifyNewPassword, String oldPassword)
```

**Parameters**

- `newPassword`
  Type: `String`

- `verifyNewPassword`
  Type: `String`

- `oldPassword`
  Type: `String`

  Optional only if the current user’s password has expired; otherwise, required.

**Return Value**

Type: `System.PageReference`

**Usage**

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

**createExternalUser(user, accountId)**
Creates a Salesforce Site or Experience Cloud site user for the given account and associates it with the site.
Signature

public static Id createExternalUser(SObject user, String accountId)

Parameters

user
  Type: SObject
  Information required to create a user.
  The email address of the user is used to look for matching contacts associated with the specified accountId. If a matching contact is found and is already used by an external user, self-registration isn’t successful. If a matching contact is found but isn’t used by an external user, it is used for the new external user. If there is no matching contact, a new contact is created for the new external user.

accountId
  Type: String
  The ID of the account you want to associate the user with.

Return Value

Type: Id
The ID of the user that this method creates.

Usage

This method throws Site.ExternalUserCreateException when user creation fails.

The nickname field is required for the User sObject when using the createExternalUser method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

createExternalUser(user, accountId, password)

Creates a Salesforce Site or Experience Cloud site user for the given account and associates it with the site. This method sends an email with the specified password to the user.

Signature

public static Id createExternalUser(SObject user, String accountId, String password)

Parameters

user
  Type: SObject
  Information required to create a user.
  The email address of the user is used to look for matching contacts associated with the specified accountId. If a matching contact is found and is already used by an external user, self-registration isn’t successful. If a matching contact is found but isn’t used by an external user, it is used for the new external user. If there is no matching contact, a new contact is created for the new external user.
accountID
Type: String
The ID of the account you want to associate the user with.

password
Type: String
The password of the Salesforce Site or Experience Cloud site user. If not specified, or if set to null or an empty string, this method sends a new password email to the portal user.

Return Value
Type: Id
The ID of the user that this method creates.

Usage
This method throws Site.ExternalUserCreateException when user creation fails.
The nickname field is required for the User sObject when using the createExternalUser method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

createExternalUser(user, accountId, password, sendEmailConfirmation)
Creates a Salesforce Site or Experience Cloud site user and associates it with the given account. This method sends the user an email with the specified password and a new user confirmation email.

Signature
public static Id createExternalUser(SObject user, String accountId, String password, Boolean sendEmailConfirmation)

Parameters
user
Type: SObject
Information required to create a user.
The email address of the user is used to look for matching contacts associated with the specified accountId. If a matching contact is found and is already used by an external user, self-registration isn’t successful. If a matching contact is found but isn’t used by an external user, it is used for the new external user. If there is no matching contact, a new contact is created for the new external user.

accountId
Type: String
The ID of the account you want to associate the user with.

password
Type: String
The password of the Salesforce Site or Experience Cloud site user. If not specified, or if set to `null` or an empty string, this method sends a new password email to the portal user.

`sendEmailConfirmation`  
Type: Boolean  
Determines whether a new user email is sent to the portal user. Set it to `true` to send a new user email to the portal user. The default is `false`, that is, the new user email isn’t sent.

Return Value  
Type: Id  
The ID of the user that this method creates.

Usage  
This method throws `Site.ExternalUserCreateException` when user creation fails.  
The `nickname` field is required for the `User` sObject when using the `createExternalUser` method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

`createPersonAccountPortalUser(user, ownerId, password)`  
Creates a person account using the default record type defined on the guest user’s profile, then enables it for the site’s portal.

Signature  
```java  
public static ID createPersonAccountPortalUser(sObject user, String ownerId, String password)  
```

Parameters  
- `user`  
  Type: `sObject`  
- `ownerId`  
  Type: `String`  
- `password`  
  Type: `String`

Return Value  
Type: ID

Usage  
Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.
createPersonAccountPortalUser(user, ownerId, recordTypeId, password)

Creates a person account using the specified `recordTypeId`, then enables it for the site's portal.

**Signature**

```
public static ID createPersonAccountPortalUser(sObject user, String ownerId, String recordTypeId, String password)
```

**Parameters**

- **user**
  - Type: `sObject`
- **ownerId**
  - Type: `String`
- **recordTypeId**
  - Type: `String`
- **password**
  - Type: `String`

**Return Value**

Type: `ID`

**Usage**

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

**Note:** This method is only valid when a site is associated with a Customer Portal, and when the user license for the default new user profile is a high-volume portal user.

createPortalUser(user, accountId, password, sendEmailConfirmation)

Creates a portal user for the given account and associates it with the site's portal.

**Signature**

```
public static ID createPortalUser(sObject user, String accountId, String password, Boolean sendEmailConfirmation)
```

**Parameters**

- **user**
  - Type: `sObject`
accountId
Type: String

password
Type: String
(Optional) The password of the portal user. If not specified, or if set to null or an empty string, this method sends a new password email to the portal user.

sendEmailConfirmation
Type: Boolean
(Optional) Determines whether a new user email is sent to the portal user. Set it to true to send a new user email to the portal user. The default is false, that is, the new user email isn’t sent.

Return Value
Type: ID

Usage
If you’re using API version 34.0 or later, we recommend using the createExternalUser() methods because they offer better error handling than this method.

The nickname field is required for the user sObject when using the createPortalUser method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

forgotPassword(username, emailTemplateName)
Resets the user’s password and sends an email to the user with the user’s new password. You can specify a custom email template or use the default email template. Returns a value indicating whether the password reset was successful.

Signature
public static Boolean forgotPassword(String username, String emailTemplateName)

Parameters
username
Type: String

emailTemplateName
Type: String
If provided, the method applies the template to the email. Otherwise, the method applies the default system template. If an email template that doesn’t exist is provided, the system logs an exception.

Return Value
Type: Boolean
forgotPassword(username)

Resets the user’s password and sends an email to the user with the user’s new password. Returns a value indicating whether the password reset was successful.

Signature

```
public static Boolean forgotPassword(String username)
```

Parameters

- **username**
  Type: String

Return Value

Type: Boolean

Note: The return value is always true unless it's called outside of a Visualforce page.

Usage

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

Note: Site.forgotPassword cannot be used with the @future method, which enables asynchronous execution.

getAdminEmail()

Returns the email address of the site administrator.

Signature

```
public static String getAdminEmail()
```

Return Value

Type: String

Usage

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

Note: Site.forgotPassword cannot be used with the @future method, which enables asynchronous execution.
**getAdminId()**

Returns the user ID of the site administrator.

Signature

```java
public static ID getAdminId()
```

Return Value

Type: ID

**getAnalyticsTrackingCode()**

The tracking code associated with your site. Services such as Google Analytics can use this code to track page request data for your site.

Signature

```java
public static String getAnalyticsTrackingCode()
```

Return Value

Type: String

**getCurrentSiteUrl()**

Deprecated. This method was replaced by `getBaseUrl()` in API version 30.0. Returns the base URL of the current site that references and links should use.

Note that this may return the referring page's URL instead of the current request's URL. The returned value includes the path prefix and always ends with a `/` character. If the current request is not a site request, then this method returns `null`. If the current request is not a site request, then this method returns `null`. This method was replaced by `getBaseUUrl` in API version 30.0.

Signature

```java
public static String getCurrentSiteUrl()
```

Return Value

Type: String

Usage

Use `getBaseUrl()` instead.

**getBaseCustomUrl()**

Returns a base URL for the current site that doesn’t use a `force.com` subdomain. The returned URL uses the same protocol (HTTP or HTTPS) as the current request if at least one non-Force.com custom URL that supports HTTPS exists on the site. The returned value never ends with a `/` character. If all the custom URLs in this site end in `Force.com` or this site has no custom URLs, then this returns an empty string. If the current request is not a site request, then this method returns an empty string. This method replaced `getCustomWebAddress` and includes the custom URL’s path prefix.
**Signature**

```java
public static String getBaseCustomUrl()
```

**Return Value**

Type: String

**Usage**

This method replaces `getCustomWebAddress()` and includes the custom URL's path prefix.

**getBaseInsecureUrl()**

Deprecated. Returns a base URL for the current site that uses HTTP instead of HTTPS. The current request's domain is used. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

**Signature**

```java
public static String getBaseInsecureUrl()
```

**Return Value**

Type: String

**getBaseRequestUrl()**

Returns the base URL of the current site for the requested URL. This isn't influenced by the referring page's URL. The returned URL uses the same protocol (HTTP or HTTPS) as the current request. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

**Signature**

```java
public static String getBaseRequestUrl()
```

**Return Value**

Type: String

**getBaseSecureUrl()**

Returns a base URL for the current site that uses HTTPS instead of HTTP. The current request's domain is preferred if it supports HTTPS. Domains that are not Force.com subdomains are preferred over Force.com subdomains. A Force.com subdomain, if associated with the site, is used if no other HTTPS domains exist in the current site. If no HTTPS custom URLs exist in the site, then this method returns an empty string. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

**Signature**

```java
public static String getBaseSecureUrl()
```
Return Value
Type: String

**getBaseUrl()**
Returns the base URL of the current site that references and links should use. Note that this field may return the referring page's URL instead of the current request's URL. The returned value includes the path prefix and never ends with a / character. If the current request is not a site request, then this field returns an empty string. This field replaces getCurrentSiteUrl.

Signature

```java
public static String getBaseUrl()
```

Return Value
Type: String

Usage
This method replaces `getCurrentSiteUrl()`.

**getCustomWebAddress()**
Deprecated. This method was replaced by `getBaseCustomUrl()` in API version 30.0.
Returns the request's custom URL if it doesn't end in Lightning Platform or returns the site's primary custom URL. If neither exist, then this returns null. Note that the URL's path is always the root, even if the request's custom URL has a path prefix. If the current request is not a site request, then this method returns null. The returned value always ends with a / character.

Signature

```java
public static String getCustomWebAddress()
```

Return Value
Type: String

Usage
Use `getBaseCustomUrl()` instead.

**getDomain()**
Returns your Salesforce Sites based URL.

Signature

```java
public static String getDomain()
```
Return Value
Type: String

**getErrorDescription()**
Returns the error description for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

**Signature**

```java
public static String getErrorDescription()
```

Return Value
Type: String

**getErrorMessage()**
Returns an error message for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

**Signature**

```java
public static String getErrorMessage()
```

Return Value
Type: String

**getExperienceId()**
Returns the value of the experience ID (expid). This expid value comes from a cookie in the user’s web browser.

**Signature**

```java
public static String getExperienceId()
```

Return Value
Type: String

**Usage**
Use the `getExperienceId` and `setExperienceId` methods to implement dynamic login experiences. You can set the experience ID with `setExperienceId` or by extending the following endpoints with `expid_value`:

- `community-url/services/oauth2/authorize/expid_value`
- `community-url/idp/endpoint/HttpPost/expid_value`
- `community-url/idp/endpoint/HttpRedirect/expid_value`
- `community-url_login_page/expid={value}`
The cookie is set when the browser loads the URLs with the expid values.

**getMasterLabel()**

Returns the value of the Master Label field for the current site. If the current request is not a site request, then this field returns `null`.

**Signature**

```java
public static String getMasterLabel()
```

**Return Value**

Type: `String`

**getName()**

Returns the API name of the current site.

**Signature**

```java
public static String getName()
```

**Return Value**

Type: `String`

**getOriginalUrl()**

Returns the original URL for this page if it’s a designated error page for the site; otherwise, returns `null`.

**Signature**

```java
public static String getOriginalUrl()
```

**Return Value**

Type: `String`

**getPasswordPolicyStatement()**

Returns the password requirements for a Salesforce Site or Experience Cloud site created with the Customer Service template.

**Signature**

```java
public static String getPasswordPolicyStatement()
```
Return Value
Type: String

getPathPrefix()
Returns the URL path prefix of the current site or an empty string if none. For example, if the requested site URL is https://myco.my.salesforce-sites.com/partners, then /partners is the path prefix. If the current request is not a site request, then this method returns an empty string. This method replaced getPrefix in API version 30.0.

Signature
public static String getPathPrefix()

Return Value
Type: String

getPrefix()
Deprecated. This method was replaced by getPathPrefix() in API version 30.0.
Returns the URL path prefix of the current site. For example, if your site URL is MyDomainName.my.salesforce-sites.com/partners, /partners is the path prefix. Returns null if the prefix isn’t defined. If the current request is not a site request, then this method returns a null.

Signature
public static String getPrefix()

Return Value
Type: String

getSiteId()
Returns the ID of the current site. If the current request is not a site request, then this field returns null.

Signature
public static String getSiteId()

Return Value
Type: Id

getTemplate()
Returns the template name associated with the current site; returns the default template if no template has been designated.
**Signature**

```java
public static System.PageReference getTemplate()
```

**Return Value**
Type: `System.PageReference`

---

**getSiteType()**

Returns the API value of the site type field for the current site. This can be Visualforce for a Salesforce site, Siteforce for a Site.com site, ChatterNetwork for an Experience Cloud site, or ChatterNetworkPicasso for an Experience Cloud site. If the current request is not a site request, then this method returns `null`.

**Signature**

```java
public static String getSiteType()
```

**Return Value**
Type: `String`

---

**getSiteTypeLabel()**

Returns the value of the Site Type field's label for the current site. If the current request is not a site request, then this method returns `null`.

**Signature**

```java
public static String getSiteTypeLabel()
```

**Return Value**
Type: `String`

---

**isLoginEnabled()**

Returns `true` if the current site is associated with an active login-enabled portal; otherwise returns `false`.

**Signature**

```java
public static Boolean isLoginEnabled()
```

**Return Value**
Type: `Boolean`

---

**isPasswordExpired()**

For authenticated users, returns `true` if the currently logged-in user's password is expired. For non-authenticated users, returns `false`.

---

3366
Signature
public static Boolean isPasswordExpired()

Return Value
Type: Boolean

isRegistrationEnabled()
Returns true if the current site is associated with an active self-registration-enabled Customer Portal; otherwise returns false.

Signature
public static Boolean isRegistrationEnabled()

Return Value
Type: Boolean

isValidUsername(username)
Returns true if the given username is valid; otherwise, returns false.

Signature
public static Boolean isValidUsername(String username)

Parameters
username
Type: String
The username to test for validity.

Return Value
Type: Boolean

login(username, password, startUrl)
Allows users to log in to the current site with the given username and password, then takes them to the startUrl. If startUrl is not a relative path, it defaults to the site's designated index page.

Signature
public static System.PageReference login(String username, String password, String startUrl)
Parameters

- **username**
  Type: String

- **password**
  Type: String

- **startUrl**
  Type: String

Return Value

Type: System.PageReference

Usage

All DML statements before the call to Site.login get committed. It's not possible to roll back to a save point that was created before a call to Site.login.

暄Note: Do not include http:// or https:// in the startURL.

passwordlessLogin(userId, methods, startUrl)

Logs in a user to a Salesforce Site or Experience Cloud site using an identity verification method, such as email or text, instead of a password. Passwordless login is a convenient, mobile-centric way to welcome users into your site. Let your users log in with something other than their password, like their email address or phone number.

Signature

```
public static System.PageReference passwordlessLogin(Id userId, List<Auth.VerificationMethod> methods, String startUrl)
```

Parameters

- **userId**
  Type: Id
  ID of the user to log in.

- **methods**
  Type: List<Auth.VerificationMethod>
  List of identity verification methods available to the user for passwordless login.

- **startUrl**
  Type: String
  Path to the page that users see after they log in.

Return Value

Type: System.PageReference
Usage
Include this method in the Apex controller of a custom login page implementation.

PasswordlessLogin Example
This simple code example of an Apex controller contains the passwordlessLogin method. The PageReference returned by passwordlessLogin redirects the user to the Salesforce Verify page. When the user enters the correct code, the user is redirected to the site page specified by the start URL.

```java
global with sharing class MFILoginController
{
    // Input variables
    global String input {get; set;}
    public String startURL {get; set;}
    public List<Auth.VerificationMethod> methods;
    public String error;

    global MFILoginController()
    {
        // Add verification methods in priority order
        methods = new List<Auth.VerificationMethod>();
        methods.add(Auth.VerificationMethod.SMS);
        methods.add(Auth.VerificationMethod.EMAIL);
        methods.add(Auth.VerificationMethod.U2F);
        methods.add(Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
        methods.add(Auth.VerificationMethod.TOTP);
    }

    global PageReference login() {
        List<User> users = null;
        // Empty input
        if(input == null || input == '')
        {
            error = 'Enter Username';
            return null;
        }
        users = [select name, id, email from User where username=:input];
        if(users == null || users.isEmpty())
        {
            error = 'Can\'t find a user';
            return null;
        }
        if (startURL == null) startURL = '/';
        return Site.passwordlessLogin(users[0].id, methods, startURL);
    }
}
```
setExperienceId(expIdValue)

Sets the experience ID for the current user. Use this method to populate the value of the experience ID (expid) cookie in the user’s web browser.

**Signature**

```java
public static void setExperienceId(String expIdValue)
```

**Parameters**

`expIdValue`

Type: String

A value that indicates the user's login experience.

The value must contain alphanumeric characters only, up to 30 characters.

**Usage**

Use `setExperienceId` when you’re implementing dynamic login experiences. A login experience refers to a login page plus any secondary pages associated with the login page (such as multi-factor authentication (MFA) or a login flow). You define different login experiences depending on who users are or where they’re logging in from. For example, you can require a different registration process based on the user’s location. In this case, `expIdValue` includes a state or country code. When the user logs in, the URL contains the experience ID parameter, `{expid}`. The `{expid}` parameter is replaced by the value stored in `expIdValue`, such as `.jp`. Then the user is redirected to the Japanese login experience.

**Example**

```java
String expid = ApexPages.currentPage().getParameters().get('expid');
if (expId != null) {
    Site.setExperienceId(expId);
}
```

setPortalUserAsAuthProvider(user, contactId)

Sets the specified user information within the site’s portal via an authentication provider.

**Signature**

```java
public static Void setPortalUserAsAuthProvider(sObject user, String contactId)
```

**Parameters**

`user`

Type: sObject

`contactId`

Type: String

**Return Value**

Type: Void
Usage

- This method is only valid when a site is associated with a Customer Portal.
- Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.
- For more information on an authentication provider, see RegistrationHandler.

validatePassword(user, password, confirmPassword)

Indicates whether a given password meets the requirements specified by org-wide or profile-based password policies in the current user’s org.

Signature

public static void validatePassword(SObject user, String password, String confirmPassword)

Parameters

user
Type: SObject
The user attempting to create a password during self-registration for a Salesforce Site or Experience Cloud site.

password
Type: String
The password entered by the user.

confirmPassword
Type: String
The password reentered by the user to confirm the password.

Return Value

Type: void

Usage

If validation fails when the method is run in a Lightning controller, this method throws an Apex exception describing the failed validation.
If validation fails when the method is run in a Visualforce controller, the method provides Visualforce error messages.

SObject Class

Contains methods for the sObject data type.

Namespace

System
Usage

SObject methods are all instance methods: they are called by and operate on an sObject instance such as an account or contact. The following are the instance methods for sObjects.

For more information on sObjects, see Working with sObjects.

SObject Methods

The following are methods for SObject. All are instance methods.

IN THIS SECTION:

addError(errorMsg)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

addError(errorMsg, escape)
Marks a trigger record with a custom error message, specifies if the error message should be escaped, and prevents any DML operation from occurring.

addError(exceptionError)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

addError(exceptionError, escape)
Marks a trigger record with a custom exception error message, specifies whether or not the exception error message should be escaped, and prevents any DML operation from occurring.

addError(fieldName, errorMsg)
Dynamically add errors to fields of an SObject associated with the specified field name.

addError(fieldToken, errorMsg)
Dynamically add errors to an SObject instance associated with the specified field.

addError(fieldName, errorMsg, escape)
Dynamically add errors to fields of an SObject associated with the specified field name.

addError(fieldToken, errorMsg, escape)
Dynamically add errors to an SObject instance associated with the specified field.

clear()
Clears all field values

clone(preserveId, isDeepClone, preserveReadOnlyTimestamps, preserveAutonumber)
Creates a copy of the SObject record.

get(fieldName)
Returns the value for the field specified by fieldName, such as AccountNumber.
get(field)
Returns the value for the field specified by the field token Schema.sObjectField such as, Schema.Account.AccountNumber.

getCloneSourceId()
Returns the ID of the entity from which an object was cloned. You can use it for objects cloned through the Salesforce user interface. You can also use it for objects created using the System.SObject.clone(preserveId, isDeepClone, preserveReadOnlyTimestamps, preserveAutonumber) method, provided that the preserveId parameter wasn't used or was set to false. The getCloneSourceId() method can only be used within the transaction where the entity is cloned, as clone information doesn't persist in subsequent transactions.

getErrors()
Returns a list of Database.Error objects for an SObject instance. If the SObject has no errors, an empty list is returned.

getOptions()
Returns the database.DMLOptions object for the SObject.

getPopulatedFieldsAsMap()
Returns a map of populated field names and their corresponding values. The map contains only the fields that have been populated in memory for the SObject instance.

getSObject(fieldName)
Returns the value for the specified field. This method is primarily used with dynamic DML to access values for external IDs.

getSObject(field)
Returns the value for the field specified by the field token Schema.sObjectField such as, Schema.MyObj.MyExternalId. This method is primarily used with dynamic DML to access values for external IDs.

getSObjects(fieldName)
Returns the values for the specified field. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

getSObjects(field)
Returns the value for the field specified by the field token Schema.fieldName, such as, Schema.Account.Contact. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

getSObjectType()
Returns the token for this SObject. This method is primarily used with describe information.

getQuickActionName()
Retrieves the name of a quick action associated with this SObject. Typically used in triggers.

hasErrors()
Returns true if an SObject instance has associated errors. The error message can be associated to the SObject instance by using SObject.addError(), validation rules, or by other means.

isClone()
Returns true if an entity is cloned from something, even if the entity hasn't been saved. The method can only be used within the transaction where the entity is cloned, as clone information doesn't persist in subsequent transactions.

isSet(fieldName)
Returns information about the queried SObject field. Returns true if the SObject field is populated, either by direct assignment or by inclusion in a SOQL query. Returns false if the SObject field is not set. If an invalid field is specified, an SObjectException is thrown.
isSet(field)
Returns information about the queried sObject field. Returns true if the sObject field is populated, either by direct assignment or by inclusion in a SOQL query. Returns false if the sObject field is not set. If an invalid field is specified, an SObjectException is thrown.

put(fieldName, value)
Sets the value for the specified field and returns the previous value for the field.

put(field, value)
Sets the value for the field specified by the field token Schema.sObjectField, such as, Schema.Account.AccountNumber and returns the previous value for the field.

putSObject(fieldName, value)
Sets the value for the specified field. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

putSObject(field, value)
Sets the value for the field specified by the token Schema.SObjectType. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

recalculateFormulas()
Deprecated as of API version 57.0. Use the recalculateFormulas() method in the System.Formula class instead.

setOptions(DMLOptions)
Sets the DMLOptions object for the SObject.

addError(errorMsg)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature
public Void addError(String errorMsg)

Parameters
errorMsg
  Type: String
  The error message to mark the record with.

Return Value
Type: Void

Usage
When used on Trigger.new in before insert and before update triggers, and on Trigger.old in before delete triggers, the error message is displayed in the application interface.
See Triggers and Trigger Exceptions.
**Note:** This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &, "", \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

When used in Visualforce controllers, the generated message is added to the collection of errors for the page. For more information, see Validation Rules and Standard Controllers in the Visualforce Developer’s Guide.

**Example**

```java
Trigger.new[0].addError('bad');
```

### addError(errorMsg, escape)

Marks a trigger record with a custom error message, specifies if the error message should be escaped, and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(String errorMsg, Boolean escape)
```

**Parameters**

- **errorMsg**
  - Type: `String`
  - The error message to mark the record with.

- **escape**
  - Type: `Boolean`
  - Indicates whether any HTML markup in the custom error message should be escaped (`true`) or not (`false`). This parameter is ignored in both Lightning Experience and the Salesforce mobile app, and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

**Return Value**

Type: Void

**Usage**

The escaped characters are: \n, <, >, &, "", \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

**Warning:** Be cautious if you specify `false` for the `escape` argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false escape` argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify `true` for the `escape` argument or call `addError(String errorMsg)` instead.

**Example**

```java
Trigger.new[0].addError('Fix & resubmit', false);
```
**addError(exceptionError)**
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(Exception exceptionError)
```

**Parameters**

`exceptionError`
Type: `System.Exception`
An Exception object or a custom exception object that contains the error message to mark the record with.

**Return Value**
Type: Void

**Usage**
When used on `Trigger.new` in `before insert` and `before update` triggers, and on `Trigger.old` in `before delete` triggers, the error message is displayed in the application interface.

See [Triggers and Trigger Exceptions](#).

**Note:** This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &", \", \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

When used in Visualforce controllers, the generated message is added to the collection of errors for the page. For more information, see [Validation Rules and Standard Controllers](#) in the Visualforce Developer's Guide.

**Example**

```java
public class MyException extends Exception {
}
Trigger.new[0].addError(new MyException('Invalid Id'));
```

**addError(exceptionError, escape)**
Marks a trigger record with a custom exception error message, specifies whether or not the exception error message should be escaped, and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(Exception exceptionError, Boolean escape)
```

**Parameters**

`exceptionError`
Type: `System.Exception`
An Exception object or a custom exception object that contains the error message to mark the record with.
escape
Type: Boolean
Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false). This parameter is ignored in both Lightning Experience and the Salesforce mobile app, and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value
Type: Void

Usage
The escaped characters are: \n, <, >, &. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

⚠️ Warning: Be cautious if you specify false for the escape argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a false escape argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify true for the escape argument or call addError(Exception e) instead.

Example
```java
public class MyException extends Exception {}
Trigger.new[0].addError(new myException('Invalid Id & other issues', false));
```

addError(errorMsg)
Places the specified error message on a trigger record field in the Salesforce user interface and prevents any DML operation from occurring.

Signature
```java
public Void addError(String errorMsg)
```

Parameters
```java
errorMsg
Type: String
```

Return Value
Type: Void

Usage
Note:
- When used on Trigger.new in before insert and before update triggers, and on Trigger.old in before delete triggers, the error appears in the application interface.
• When used in Visualforce controllers, if there is an `inputField` component bound to field, the message is attached to the component. For more information, see Validation Rules and Standard Controllers in the Visualforce Developer's Guide.

• This method is highly specialized because the field identifier is not actually the invoking object—the sObject record is the invoker. The field is simply used to identify the field that should be used to display the error.

See Triggers and Trigger Exceptions.

Note: This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &, "", \, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

Example

```java
Trigger.new[0].myField__c.addError('bad');
```

`addError(errorMsg, escape)`

Places the specified error message, which can be escaped or unescaped, on a trigger record field in the Salesforce user interface, and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(String errorMsg, Boolean escape)
```

**Parameters**

- `errorMsg`
  Type: `String`
  The error message to mark the record with.

- `escape`
  Type: `Boolean`
  Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false). This parameter is ignored in both Lightning Experience and the Salesforce mobile app, and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

**Return Value**

Type:

**Usage**

The escaped characters are: \n, <, >, &, "", \, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

⚠️ **Warning**: Be cautious if you specify `false` for the `escape` argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false` `escape` argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify `true` for the `escape` argument or call `field.addError(String errorMsg)` instead.
Example

```
Trigger.new[0].myField__c.addError('Fix & resubmit', false);
```

addError(fieldName, errorMsg)
Dynamically add errors to fields of an SObject associated with the specified field name.

Signature
```
public void addError(String fieldName, String errorMsg)
```

Parameters

fieldName
Type: String
The field name of the SObject.

errorMsg
Type: String
The error message to be added. HTML special characters in the error message string are always escaped.

Return Value
Type: void

Usage
If the field name is an empty string or null, the error is associated with the SObject and not with a specific field.

Example

```
// Add an error to an SObject field using the addError() method.
Account acct = new Account(name = 'TestAccount');
acct.addError('name', 'error in name field');
// Use the hasErrors() method to verify that the error is added, and then the getErrors() method to validate the error.
System.Assert(acct.hasErrors());
List<Database.Error> errors = acct.getErrors();
System.AssertEquals(1, errors.size());
```

addError(fieldToken, errorMsg)
Dynamically add errors to an SObject instance associated with the specified field.

Signature
```
public void addError(Schema.SObjectField fieldToken, String errorMsg)
```

Usage
If the field name is an empty string or null, the error is associated with the SObject and not with a specific field.
Parameters

`fieldToken`
- **Type:** Schema.SObjectField
- The field of the SObject instance.

`errorMsg`
- **Type:** String
- The error message to be added. HTML special characters in the error message string are always escaped.

Return Value

**Type:** void

Usage

Use this method to add errors to the specified field token of a standard or custom object. If `fieldToken` is null, the error is associated with the SObject and not with a specific field.

Example

```java
// Add an error to a field of an SObject instance using the addError() method.
Account acct = new Account(name = 'TestAccount');
Schema.DescribeFieldResult nameDesc = Account.name.getDescribe();
Schema.sObjectField nameField = nameDesc.getSObjectField();
acct.addError(nameField, 'error is name field');
// Use the hasErrors() method to verify that the error is added, and then the getErrors() method to validate the error.
System.Assert(acct.hasErrors());
List<Database.Error> errors = acct.getErrors();
System.AssertEquals(1, errors.size());
```

`addError(fieldName, errorMsg, escape)`

Dynamically add errors to fields of an SObject associated with the specified field name.

**Signature**

```java
public void addError(String fieldName, String errorMsg, Boolean escape)
```

**Parameters**

`fieldName`
- **Type:** String
  - The field name of the SObject.

`errorMsg`
- **Type:** String
  - The error message to be added.

`escape`
- **Type:** Boolean
Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false). This parameter is ignored in both Lightning Experience and the Salesforce mobile app, and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value
Type: void

Usage
If the field name is an empty string or null, the error is associated with the SObject and not with a specific field.

The escaped characters are: \n, <, >, &", \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

⚠️ Warning:
- The escape parameter cannot be disabled in Lightning Experience and in the Salesforce mobile app, and will be ignored.
- Be cautious if you specify false for the escape argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a false escape argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify true for the escape argument or call addError(String fieldName, String errorMsg) instead.

Example

```java
// Add an error to an SObject field using the addError() method.
Account acct = new Account(name = 'TestAccount');
acct.addError('name', 'error in name field', false);
// Use the hasErrors() method to verify that the error is added, and then the getErrors() method to validate the error.
System.Assert(acct.hasErrors());
List<Database.Error> errors = acct.getErrors();
System.AssertEquals(1, errors.size());
```

addError(fieldToken, errorMsg, escape)
Dynamically add errors to an SObject instance associated with the specified field.

Signature
```
public void addError(Schema.SObjectField fieldToken, String errorMsg, Boolean escape)
```

Parameters

- **fieldToken**
  Type: Schema.SObjectField
  The field of the SObject instance.

- **errorMsg**
  Type: String
The error message to be added.

escape
Type: Boolean
Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false). This parameter is ignored in both Lightning Experience and the Salesforce mobile app, and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value
Type: void

Usage
Use this method to add errors to the specified field token of a standard or custom object. If fieldToken is null, the error is associated with the SObject and not with a specific field.

The escaped characters are: \n, <, >, &, \, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

Warning:
- The escape parameter cannot be disabled in Lightning Experience and in the Salesforce mobile app, and will be ignored.
- Be cautious if you specify false for the escape argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a false escape argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify true for the escape argument or call addError(Schema.SObjectField fieldToken, String errorMsg) instead.

Example
```
// Add an error to a field of an SObject instance using the addError() method.
Account acct = new Account(name = 'TestAccount');
Schema.DescribeFieldResult nameDesc = Account.name.getDescribe();
Schema.sObjectField nameField = nameDesc.getSObjectField();
acct.addError(nameField, 'error is name field', false);
// Use the hasErrors() method to verify that the error is added, and then the getErrors() method to validate the error.
System.Assert(acct.hasErrors());
List<Database.Error> errors = acct.getErrors();
System.AssertEquals(1, errors.size());
```

clear()
Clears all field values

Signature
```
public Void clear()
```
Return Value
Type: Void

Example

```java
Account acc = new account(Name = 'Acme');
acc.clear();
Account expected = new Account();
system.assertEquals(expected, acc);
```

colors.map Ön, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber)

Creates a copy of the SObject record.

Signature

```java
public SObject clone(Boolean preserveId, Boolean isDeepClone, Boolean preserveReadonlyTimestamps, Boolean preserveAutonumber)
```

Parameters

**preserveId**
Type: Boolean

(Optional) Determines whether the ID of the original object is preserved or cleared in the duplicate. If set to true, the ID is copied to the duplicate. The default is false, that is, the ID is cleared.

**isDeepClone**
Type: Boolean

(Optional) Determines whether the method creates a full copy of the SObject field or just a reference:

- If set to true, the method creates a full copy of the SObject. All fields on the SObject are duplicated in memory, including relationship fields. Consequently, if you change a field on the cloned SObject, the original SObject isn’t affected.
- If set to false, the method performs a shallow copy of the SObject fields. All copied relationship fields reference the original SObjects. Consequently, if you change a relationship field on the cloned SObject, the corresponding field on the original SObject is also affected, and vice versa. The default is false.

**preserveReadonlyTimestamps**
Type: Boolean

(Optional) Determines whether the read-only timestamp fields are preserved or cleared in the duplicate. If set to true, the read-only fields CreatedById, CreatedDate, LastModifiedById, and LastModifiedDate are copied to the duplicate. The default is false, that is, the values are cleared.

Tip: Audit field values won’t be persisted to the database via DML on the cloned SObject instance.

**preserveAutonumber**
Type: Boolean

(Optional) Determines whether auto number fields of the original object are preserved or cleared in the duplicate. If set to true, auto number fields are copied to the cloned object. The default is false, that is, auto number fields are cleared.
Return Value
Type: SObject (of the same type)

Usage
Note: For Apex saved using Salesforce API version 22.0 or earlier, the default value for the preserveId argument is true, that is, the ID is preserved.

Example
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
Account clonedAcc = acc.clone(false, false, false, false);
System.assertEquals(acc, clonedAcc);

get(fieldName)
Returns the value for the field specified by fieldName, such as AccountNumber.

Signature
public Object get(String fieldName)

Parameters
fieldName
Type: String

Return Value
Type: Object

Usage
For more information, see Dynamic SOQL.

Example
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
String description = (String)acc.get('Description');
System.assertEquals('Acme Account', description);

Versioned Behavior Changes
In API version 34.0 and later, you must include the namespace name to retrieve a field from a field Map using this method. For example, to get the account__c field in the MyNamespace namespace from a fields field Map, use:
fields.get('MyNamespace__account__c').
get(field)
Returns the value for the field specified by the field token `Schema.sObjectField` such as, `Schema.Account.AccountNumber`.

Signature
```
public Object get(Schema.sObjectField field)
```

Parameters
- `field`
  Type: `Schema.SObjectField`

Return Value
Type: `Object`

Usage
For more information, see Dynamic SOQL.

Note: Field tokens aren’t available for person accounts. If you access `Schema.Account.fieldname`, you get an exception error. Instead, specify the field name as a string.

Example
```
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
String description = (String)acc.get(Schema.Account.Description);
System.assertEquals('Acme Account', description);
```

getCloneSourceId()
Returns the ID of the entity from which an object was cloned. You can use it for objects cloned through the Salesforce user interface. You can also use it for objects created using the `System.SObject.clone(preserveId, isDeepClone, preserveReadOnlyTimestamps, preserveAutonumber)` method, provided that the `preserveId` parameter wasn’t used or was set to `false`. The `getCloneSourceId()` method can only be used within the transaction where the entity is cloned, as clone information doesn’t persist in subsequent transactions.

Signature
```
public Id getCloneSourceId()
```

Return Value
Type: `Id`

Usage
If A is cloned to B, B is cloned to C, and C is cloned to D, then B, C, and D all point back to A as their clone source.

Example

```java
Account acc0 = new Account(Name = 'Acme');
insert acc0;
Account acc1 = acc0.clone();
Account acc2 = acc1.clone();
Account acc3 = acc2.clone();
Account acc4 = acc3.clone();
System.assert(acc0.Id != null);
System.assertEquals(acc0.Id, acc1.getCloneSourceId());
System.assertEquals(acc0.Id, acc2.getCloneSourceId());
System.assertEquals(acc0.Id, acc3.getCloneSourceId());
System.assertEquals(acc0.Id, acc4.getCloneSourceId());
System.assertEquals(null, acc0.getCloneSourceId());
```

getErrors()

Returns a list of `Database.Error` objects for an SObject instance. If the SObject has no errors, an empty list is returned.

**Signature**

```java
public List<Database.Error> getErrors()
```

**Return Value**

Type: `List<Database.Error>`

getOptions()

Returns the `Database.DMLOptions` object for the SObject.

**Signature**

```java
public Database.DMLOptions getOptions()
```

**Return Value**

Type: `Database.DMLOptions`

Example

```java
Database.DMLOptions dmo = new Database.dmlOptions();
dmo.assignmentRuleHeader.useDefaultRule = true;

Account acc = new Account(Name = 'Acme');
acc.setOptions(dmo);
Database.DMLOptions accDmo = acc.getOptions();
```

getPopulatedFieldsAsMap()

Returns a map of populated field names and their corresponding values. The map contains only the fields that have been populated in memory for the SObject instance.
signature

public Map<String, Object> getPopulatedFieldsAsMap()

return value

Type: Map<String, Object>

A map of field names and their corresponding values.

usage

The returned map contains only the fields that have been populated in memory for the SObject instance, which makes it easy to iterate over those fields. A field is populated in memory in the following cases.

• The field has been queried by a SOQL statement.
• The field has been explicitly set before the call to the getPopulatedFieldsAsMap() method.

Fields on related objects that are queried or set are also returned in the map.

The following example iterates over the map returned by the getPopulatedFieldsAsMap() method after a SOQL query.

```java
Account a = new Account();
a.name = 'TestMapAccount1';
insert a;
a = [select Id, Name from Account where id=:a.Id];
Map<String, Object> fieldsToValue = a.getPopulatedFieldsAsMap();

for (String fieldName : fieldsToValue.keySet()) {
    System.debug('field name is ' + fieldName + ', value is ' + fieldsToValue.get(fieldName));
}

// Example debug statement output:
// DEBUG|field name is Id, value is 001R0000003EPPkIAO
// DEBUG|field name is Name, value is TestMapAccount1
```

This example iterates over the map returned by the getPopulatedFieldsAsMap() method after fields on the SObject are explicitly set.

```java
Account a = new Account();
a.name = 'TestMapAccount2';
a.phone = '123-4567';
insert a;
Map<String, Object> fieldsToValue = a.getPopulatedFieldsAsMap();

for (String fieldName : fieldsToValue.keySet()) {
    System.debug('field name is ' + fieldName + ', value is ' + fieldsToValue.get(fieldName));
}

// Example debug statement output:
// DEBUG|field name is Name, value is TestMapAccount2
// DEBUG|field name is Phone, value is 123-4567
// DEBUG|field name is Id, value is 001R0000003EPPpIAO
```
The following example shows how to use the `getPopulatedFieldsAsMap()` method with related objects.

```java
Account a = new Account();
a.name='TestMapAccount3';
insert a;

Contact c = new Contact();
c.firstname='TestContactFirstName';
c.lastName = 'TestContactLastName';
c.accountid = a.id;
insert c;

c = [SELECT id, Contact.Firstname, Contact.Account.Name FROM Contact
    where id=:c.id limit 1];
Map<String, Object> fieldsToValue = c.getPopulatedFieldsAsMap();

// To get the fields on Account, get the Account object
// and call getMapPopulatedFieldsAsMap() on that object.

a = (Account)fieldsToValue.get('Account');
fieldsToValue = a.getPopulatedFieldsAsMap();

for (String fieldName : fieldsToValue.keySet()) {
    System.debug('field name is ' + fieldName + ', value is ' + fieldsToValue.get(fieldName));
}

// Example debug statement output:
// DEBUG|field name is Id, value is 001R0000003EPPuIAO
// DEBUG|field name is Name, value is TestMapAccount3
```

**Versioned Behavior Changes**

In API version 39.0 and later, `getPopulatedFieldsAsMap` returns all values set on the SObject, even if values were set after the record was queried. This behavior is dependent on the version of the apex class calling this method and not on the version of the class that generated the SObject. If you query an SObject at API version 20.0, and then call this method in a class with API version 40.0, you will get the full set of fields.

**getSObject** *(fieldName)*

Returns the value for the specified field. This method is primarily used with dynamic DML to access values for external IDs.

**Signature**

```java
public SObject getSObject(String fieldName)
```

**Parameters**

`fieldName`

Type: `String`

**Return Value**

Type: `SObject`
Example

Account acc = new account(Name = 'Acme', Description = 'Acme Account');
insert acc;
Contact con = new Contact(Lastname = 'AcmeCon', AccountId = acc.id);
insert con;

SObject contactDB =
[SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1];
Account a = (Account)contactDB.getSObject('Account');
System.assertEquals('Acme', a.name);

**getSObject(field)**

Returns the value for the field specified by the field token `Schema.sObjectField` such as, `Schema.MyObj.MyExternalId`. This method is primarily used with dynamic DML to access values for external IDs.

**Signature**

```java
public SObject getSObject(Schema.SObjectField field)
```

**Parameters**

`field`

Type: `Schema.SObjectField`

**Return Value**

Type: `SObject`

**Usage**

If the method references polymorphic fields, a `Name object` is returned. Use the `TYPEOF` clause in the SOQL SELECT statement to directly get results that depend on the runtime object type referenced by the polymorphic field. See [Working with Polymorphic Relationships in SOQL Queries](#).

Example

Account acc = new account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;

Schema.DescribeFieldResult fieldResult = Contact.AccountId.getDescribe();
Schema.SObjectField field = fieldResult.getSObjectField();

SObject contactDB =
[SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1];
Account a = (Account)contactDB.getSObject(field);
System.assertEquals('Acme', a.name);
**getSObjects(fieldName)**

Returns the values for the specified field. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

**Signature**

```
public SObject[] getSObjects(String fieldName)
```

**Parameters**

- `fieldName`
  
  Type: String

**Return Value**

Type: SObject[]

**Usage**

For more information, see Dynamic DML.

**Example**

```
Account acc = new account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;
SObject[] a = [SELECT id, (SELECT Name FROM Contacts LIMIT 1) FROM Account WHERE id = :acc.id];
SObject[] contactsDB = a.get(0).getSObjects('Contacts');
String fieldValue = (String)contactsDB.get(0).get('Name');
System.assertEquals('AcmeCon', fieldValue);
```

---

**getSObjects(fieldToken)**

Returns the value for the field specified by the field token `Schema.fieldName`, such as, `Schema.Account.Contact`. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

**Signature**

```
public SObject[] getSObjects(Schema.SObjectType fieldName)
```

**Parameters**

- `fieldName`
  
  Type: Schema.SObjectType

**Return Value**

Type: SObject[]
**getSObjectType()**

Returns the token for this SObject. This method is primarily used with describe information.

**Signature**

```java
public Schema.SObjectType getSObjectType()
```

**Return Value**

Type: `Schema.SObjectType`

**Usage**

For more information, see `apex_dynamic_describe_objects_understanding`.

**Example**

```java
Account acc = new Account(name = 'Acme', description = 'Acme Account');
Schema.SObjectType expected = Schema.Account.getSObjectType();
System.assertEquals(expected, acc.getSObjectType());
```

**getQuickActionName()**

Retrieves the name of a quick action associated with this SObject. Typically used in triggers.

**Signature**

```java
public String getQuickActionName()
```

**Return Value**

Type: `String`

**Example**

```java
trigger accTrig2 on Contact (before insert) {
    for (Contact c : Trigger.new) {
        if (c.getQuickActionName() == QuickAction.CreateContact) {
            c.WhereFrom__c = 'GlobaActionl';
        } else if (c.getQuickActionName() == Schema.Account.QuickAction.CreateContact) {
            c.WhereFrom__c = 'AccountAction';
        } else if (c.getQuickActionName() == null) {
            c.WhereFrom__c = 'NoAction';
        } else {
            System.assert(false);
        }
    }
}
```
hasErrors()

Returns true if an SObject instance has associated errors. The error message can be associated to the SObject instance by using SObject.addError(), validation rules, or by other means.

Signature

```
public Boolean hasErrors()
```

Return Value

Type: Boolean

isClone()

Returns true if an entity is cloned from something, even if the entity hasn’t been saved. The method can only be used within the transaction where the entity is cloned, as clone information doesn’t persist in subsequent transactions.

Signature

```
public Boolean isClone()
```

Return Value

Type: Boolean

Example

```
Account acc = new Account(Name = 'Acme');
insert acc;
Account acc2 = acc.clone();
// Test before saving
System.assertEquals(true, acc2.isClone());
insert acc2;
// Test after saving
System.assertEquals(true, acc2.isClone());
```

isSet(fieldName)

Returns information about the queried sObject field. Returns true if the sObject field is populated, either by direct assignment or by inclusion in a SOQL query. Returns false if the sObject field is not set. If an invalid field is specified, an SObjectException is thrown.

Signature

```
public Void isSet(String fieldName)
```

Parameters

```
fieldName
 Type: String
```
Return Value
Type: Boolean

Usage
The `isSet` method doesn't check if a field is accessible to a specific user via org permissions or other specialized access permissions.

Example
```
Contact c = new Contact(LastName = 'Joyce');
System.assertEquals(true, c.isSet('LastName'));
System.assertEquals(false, c.isSet('FirstName')); // FirstName field is not written to
System.assertEquals(true, c.isSet('FirstName')); // FirstName field is written to
```

`isSet(field)`
Returns information about the queried sObject field. Returns `true` if the sObject field is populated, either by direct assignment or by inclusion in a SOQL query. Returns `false` if the sObject field is not set. If an invalid field is specified, an SObjectException is thrown.

Signature
```
public Void isSet(Schema.SObjectField field)
```

Parameters
`field`
Type: `SObjectField Class`

Return Value
Type: Boolean

Usage
The `isSet` method doesn't check if a field is accessible to a specific user via org permissions or other specialized access permissions.

Example
```
Contact newContact = new Contact(LastName = 'Joyce');
insert(newContact); // Insert a new contact with last name Joyce
Contact c = [SELECT FirstName FROM Contact WHERE Id = :newContact.Id];
System.assertEquals(true, c.isSet(Contact.FirstName)); // FirstName field in query
System.assertEquals(false, c.isSet(Contact.LastName)); // LastName field not in query
```

`put(fieldName, value)`
Sets the value for the specified field and returns the previous value for the field.
**Signature**

```java
public Object put(String fieldName, Object value)
```

**Parameters**

- **fieldName**
  - Type: `String`
- **value**
  - Type: `Object`

**Return Value**

Type: `Object`

**Example**

```java
Account acc = new Account(name = 'test', description = 'old desc');
String oldDesc = (String)acc.put('description', 'new desc');
System.assertEquals('old desc', oldDesc);
System.assertEquals('new desc', acc.description);
```

**put(field, value)**

Sets the value for the field specified by the field token `Schema.sObjectField`, such as, `Schema.Account.AccountNumber` and returns the previous value for the field.

**Signature**

```java
public Object put(Schema.SObjectField field, Object value)
```

**Parameters**

- **field**
  - Type: `Schema.SObjectField`
- **value**
  - Type: `Object`

**Return Value**

Type: `Object`

**Example**

```java
Account acc = new Account(name = 'test', description = 'old desc');
String oldDesc = (String)acc.put(Schema.Account.Description, 'new desc');
System.assertEquals('old desc', oldDesc);
System.assertEquals('new desc', acc.description);
```
Note: Field tokens aren't available for person accounts. If you access Schema.Account.\textit{fieldName}, you get an exception error. Instead, specify the field name as a string.

\texttt{\textbf{putSObject(fieldName, value)}}

Sets the value for the specified field. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

\textbf{Signature}

\begin{verbatim}
public SObject putSObject(String fieldName, SObject value)
\end{verbatim}

\textbf{Parameters}

\begin{itemize}
  \item \textit{fieldName}
    \begin{itemize}
      \item Type: String
    \end{itemize}
  \item \textit{value}
    \begin{itemize}
      \item Type: SObject
    \end{itemize}
\end{itemize}

\textbf{Return Value}

Type: SObject

\textbf{Example}

\begin{verbatim}
Account acc = new Account(name = 'Acme', description = 'Acme Account');
    insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
    insert con;
Account acc2 = new account(name = 'Not Acme');

    Contact contactDB =
        (Contact)[SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1];
    Account a = (Account)contactDB.putSObject('Account', acc2);
    System.assertEquals('Acme', a.name);
    System.assertEquals('Not Acme', contactDB.Account.name);
\end{verbatim}

\texttt{\textbf{putSObject(fieldName, value)}}

Sets the value for the field specified by the token Schema.SObjectType. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

\textbf{Signature}

\begin{verbatim}
public SObject putSObject(Schema.SObjectType fieldName, SObject value)
\end{verbatim}

\textbf{Parameters}

\begin{itemize}
  \item \textit{fieldName}
    \begin{itemize}
      \item Type: Schema.SObjectType
    \end{itemize}
\end{itemize}
value
  Type: SObject

Return Value
Type: SObject

recalculateFormulas()
Deprecated as of API version 57.0. Use the recalculateFormulas() method in the System.Formula class instead.

Signature
public Void recalculateFormulas()

Return Value
Type: Void

Usage
This method doesn’t recalculate cross-object formulas. If you call this method on objects that have both cross-object and non-cross-object formula fields, only the non-cross-object formula fields are recalculated.

Each recalculateFormulas call counts against the SOQL query limits. See Execution Governors and Limits.

SEE ALSO:
  recalculateFormulas(sobjects)
  What Is a Cross-Object Formula?

setOptions(DMLOptions)
Sets the DMLOptions object for the SObject.

Signature
public Void setOptions(database.DMLOptions DMLOptions)

Parameters
  DMLOptions
    Type: Database.DMLOptions

Return Value
Type: Void
Example

```java
Database.DMLOptions dmo = new Database.dmlOptions();
dmo.assignmentRuleHeader.useDefaultRule = true;

Account acc = new Account(Name = 'Acme');
acc.setOptions(dmo);
```

**SObjectAccessDecision Class**

Contains the results of a call to the `Security.stripInaccessible` method and methods to retrieve those results.

**Namespace**

*System*

**IN THIS SECTION:**

SObjectAccessDecision Methods

**SObjectAccessDecision Methods**

The following are methods for `SObjectAccessDecision`.

**IN THIS SECTION:**

- `getModifiedIndexes()`
  - Returns the indexes of sObjects that are modified by the `stripInaccessible` method.
- `getRecords()`
  - Returns a list of new sObjects that are identical to the source records, except that they are stripped of fields that fail the field-level security check for the current user.
- `getRemovedFields()`
  - Returns a map of sObject types to their corresponding inaccessible fields. The map key is a string representation of the sObject type. The map value is a set of strings, which denote the fields names that are inaccessible.

**getModifiedIndexes()**

Returns the indexes of sObjects that are modified by the `stripInaccessible` method.

**Signature**

```java
public Set<Integer> getModifiedIndexes()
```

**Return Value**

Type: `Set<Integer>`

A set of unsigned integers that represent the row indexes of the modified sObjects.
Example

In this example, the user doesn’t have permission to update the `AnnualRevenue` field of an `Account`.

```java
List<Account> accounts = new List<Account>{{
    new Account(Name='Account1', AnnualRevenue=1000),
    new Account(Name='Account2')
}};

// Strip fields that are not updatable
SObjectAccessDecision decision = Security.stripInaccessible(
   AccessType.UPDATABLE,
    accounts);

// Print stripped records
for (SObject strippedAccount : decision.getRecords()) {
    System.debug(strippedAccount);
}

// Print modified indexes
System.debug(decision.getModifiedIndexes());
```

### getRecords()

Returns a list of new sObjects that are identical to the source records, except that they are stripped of fields that fail the field-level security check for the current user.

### Usage

The `stripInaccessible` method performs field-level access check for the source records in the context of the current user’s operation. The `getRecords()` method returns the new records that contain only the fields that the current user has access to.

### Signature

```java
public List<SObject> getRecords()
```

### Return Value

Type: `List<SObject>`

Even if the result list contains only one sObject, the return type is still a list (of size one).

### Example

In this example, the user doesn’t have permission to update the `AnnualRevenue` field of an `Account`.

```java
List<Account> accounts = new List<Account>{{
    new Account(Name='Account1', AnnualRevenue=1000),
    new Account(Name='Account2')
}};

// Strip fields that are not updatable
SObjectAccessDecision decision = Security.stripInaccessible(
   AccessType.UPDATABLE,
```
accounts;

// Print stripped records
for (SObject strippedAccount : decision.getRecords()) {
    System.debug(strippedAccount);
}

getRemovedFields()

Returns a map of sObject types to their corresponding inaccessible fields. The map key is a string representation of the sObject type. The map value is a set of strings, which denote the fields names that are inaccessible.

**Signature**

```
public Map<String,Set<String>> getRemovedFields()
```

**Return Value**

Type: `Map<String,Set<String>>`

**Example**

In this example, the user doesn’t have permission to update the `AnnualRevenue` field of an Account.

```
List<Account> accounts = new List<Account>{
    new Account(Name='Account1', AnnualRevenue=1000),
    new Account(Name='Account2')
};

// Strip fields that are not updatable
SObjectAccessDecision decision = Security.stripInaccessible(
    AccessType.UPDATABLE,
    accounts);

// Print stripped records
for (SObject strippedAccount : decision.getRecords()) {
    System.debug(strippedAccount);
}
// Print removed fields
System.debug(decision.getRemovedFields());
```

**StaticResourceCalloutMock Class**

Utility class used to specify a fake response for testing HTTP callouts.

**Namespace**

```
System
```
**Usage**

Use the methods in this class to set the response properties for testing HTTP callouts.

**StaticResourceCalloutMock Constructors**

The following are constructors for StaticResourceCalloutMock.

**StaticResourceCalloutMock()**

Creates a new instance of the StaticResourceCalloutMock class.

**Signature**

```
public StaticResourceCalloutMock()
```

**StaticResourceCalloutMock Methods**

The following are methods for StaticResourceCalloutMock. All are instance methods.

**setHeader(headerName, headerValue)**

Sets the specified header name and value for the fake response.

**setStaticResource(resourceName)**

Sets the specified static resource, which contains the response body.

**setStatus(httpStatus)**

Sets the specified HTTP status for the response.

**setStatusCode(httpStatusCode)**

Sets the specified HTTP status for the response.

**setHeader(headerName, headerValue)**

Sets the specified header name and value for the fake response.

**Signature**

```
public Void setHeader(String headerName, String headerValue)
```
Parameters

headerName
  Type: String

headerValue
  Type: String

Return Value
  Type: Void

**setStaticResource(resourceName)**
Sets the specified static resource, which contains the response body.

Signature

```java
public Void setStaticResource(String resourceName)
```

Parameters

resourceName
  Type: String

Return Value
  Type: Void

**setStatus(httpStatus)**
Sets the specified HTTP status for the response.

Signature

```java
public Void setStatus(String httpStatus)
```

Parameters

httpStatus
  Type: String

Return Value
  Type: Void

**getStatusCode(httpStatusCode)**
Sets the specified HTTP status for the response.
Signature

```java
public Void setStatusCode(Integer httpStatusCode)
```

Parameters

`httpStatusCode`
Type: Integer

Return Value

Type: Void

String Class
Contains methods for the String primitive data type.

Namespace

`System`

Usage

For more information on Strings, see String Data Type.

String Methods

The following are methods for String.

IN THIS SECTION:

- `abbreviate(maxWidth)`
  Returns an abbreviated version of the String, of the specified length and with ellipses appended if the current String is longer than the specified length; otherwise, returns the original String without ellipses.

- `abbreviate(maxWidth, offset)`
  Returns an abbreviated version of the String, starting at the specified character offset and of the specified length. The returned String has ellipses appended at the start and the end if characters have been removed at these locations.

- `capitalize()`
  Returns the current String with the first letter changed to title case.

- `center(size)`
  Returns a version of the current String of the specified size padded with spaces on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without added spaces.

- `center(size, paddingString)`
  Returns a version of the current String of the specified size padded with the specified String on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without padding.

- `charAt(index)`
  Returns the value of the character at the specified index.
codePointAt(index)
Returns the Unicode code point value at the specified index.

codePointBefore(index)
Returns the Unicode code point value that occurs before the specified index.

codePointCount(beginIndex, endIndex)
Returns the number of Unicode code points within the specified text range.

compareTo(secondString)
Compares two strings lexicographically, based on the Unicode value of each character in the Strings.

contains(substring)
Returns true if and only if the String that called the method contains the specified sequence of characters in substring.

containsAny(inputString)
Returns true if the current String contains any of the characters in the specified String; otherwise, returns false.

containsIgnoreCase(substring)
Returns true if the current String contains the specified sequence of characters without regard to case; otherwise, returns false.

containsNone(inputString)
Returns true if the current String doesn’t contain any of the characters in the specified String; otherwise, returns false.

containsOnly(inputString)
Returns true if the current String contains characters only from the specified sequence of characters and not any other characters; otherwise, returns false.

containsWhitespace()
Returns true if the current String contains any white space characters; otherwise, returns false.

countMatches(substring)
Returns the number of times the specified substring occurs in the current String.

deleteWhitespace()
Returns a version of the current String with all white space characters removed.

difference(secondString)
Returns the difference between the current String and the specified String.

endsWith(suffix)
Returns true if the String that called the method ends with the specified suffix.

endsWithIgnoreCase(suffix)
Returns true if the current String ends with the specified suffix; otherwise, returns false.

equals(secondString)
Deprecated. This method is replaced by equals(stringOrId). Returns true if the passed-in string is not null and represents the same binary sequence of characters as the current string. Use this method to perform case-sensitive comparisons.

equals(stringOrId)
Returns true if the passed-in object is not null and represents the same binary sequence of characters as the current string. Use this method to compare a string to an object that represents a string or an ID.

equalsIgnoreCase(secondString)
Returns true if the secondString isn’t null and represents the same sequence of characters as the String that called the method, ignoring case.
escapeCsv()
Returns a String for a CSV column enclosed in double quotes, if required.

escapeEcmaScript()
Escapes the characters in the String using EcmaScript String rules.

escapeHtml3()
Escapes the characters in a String using HTML 3.0 entities.

escapeHtml4()
Escapes the characters in a String using HTML 4.0 entities.

escapeJava()
Returns a String whose characters are escaped using Java String rules. Characters escaped include quotes and control characters, such as tab, backslash, and carriage return characters.

escapeSingleQuotes(stringToEscape)
Returns a String with the escape character (\) added before any single quotation marks in the String s.

escapeUnicode()
Returns a String whose Unicode characters are escaped to a Unicode escape sequence.

escapeXml()
Escapes the characters in a String using XML entities.

format(stringToFormat, formattingArguments)
Treat the first argument as a pattern and return a string using the second argument for substitution and formatting. The substitution and formatting are the same as apex:outputText and the Java MessageFormat class. Non-string types in the second argument’s List are implicitly converted to strings, respecting the toString() method overrides that exist on the type.

fromCharArray(charArray)
Returns a String from the values of the list of integers.

getChars()
Returns an array of character values that represent the characters in this string.

getCommonPrefix(strings)
Returns the initial sequence of characters as a String that is common to all the specified Strings.

getLevenshteinDistance(stringToCompare)
Returns the Levenshtein distance between the current String and the specified String.

getLevenshteinDistance(stringToCompare, threshold)
Returns the Levenshtein distance between the current String and the specified String if it is less than or equal than the given threshold; otherwise, returns -1.

hashCode()
Returns a hash code value for this string.

indexOf(substring)
Returns the index of the first occurrence of the specified substring. If the substring does not occur, this method returns -1.

indexOf(substring, index)
Returns the zero-based index of the first occurrence of the specified substring from the point of the given index. If the substring does not occur, this method returns -1.
indexOfAny(substring)
Returns the zero-based index of the first occurrence of any character specified in the substring. If none of the characters occur, returns -1.

indexOfAnyBut(substring)
Returns the zero-based index of the first occurrence of a character that is not in the specified substring. Otherwise, returns -1.

indexOfChar(character)
Returns the index of the first occurrence of the character that corresponds to the specified character value.

indexOfChar(character, startIndex)
Returns the index of the first occurrence of the character that corresponds to the specified character value, starting from the specified index.

indexOfDifference(stringToCompare)
Returns the zero-based index of the character where the current String begins to differ from the specified String.

indexOfIgnoreCase(substring)
Returns the zero-based index of the first occurrence of the specified substring without regard to case. If the substring does not occur, this method returns -1.

indexOfIgnoreCase(substring, startPosition)
Returns the zero-based index of the first occurrence of the specified substring from the point of index startPosition, without regard to case. If the substring does not occur, this method returns -1.

isAllLowerCase()
Returns true if all characters in the current String are lowercase; otherwise, returns false.

isAllUpperCase()
Returns true if all characters in the current String are uppercase; otherwise, returns false.

isAlpha()
Returns true if all characters in the current String are Unicode letters only; otherwise, returns false.

isAlphaSpace()
Returns true if all characters in the current String are Unicode letters or spaces only; otherwise, returns false.

isAlphanumeric()
Returns true if all characters in the current String are Unicode letters or numbers only; otherwise, returns false.

isAlphanumericSpace()
Returns true if all characters in the current String are Unicode letters, numbers, or spaces only; otherwise, returns false.

isAsciiPrintable()
Returns true if the current String contains only ASCII printable characters; otherwise, returns false.

isBlank(inputString)
Returns true if the specified String is white space, empty (""), or null; otherwise, returns false.

isEmpty(inputString)
Returns true if the specified String is empty (") or null; otherwise, returns false.

isNotBlank(inputString)
Returns true if the specified String is not whitespace, not empty (""), and not null; otherwise, returns false.

isNotEmpty(inputString)
Returns true if the specified String is not empty (") and not null; otherwise, returns false.
isNumeric() Returns true if the current String contains only Unicode digits; otherwise, returns false.

isNumericSpace() Returns true if the current String contains only Unicode digits or spaces; otherwise, returns false.

isWhitespace() Returns true if the current String contains only white space characters or is empty; otherwise, returns false.

join(iterableObj, separator) Joins the elements of the specified iterable object, such as a List, into a single String separated by the specified separator.

lastIndexOf(substring) Returns the index of the last occurrence of the specified substring. If the substring does not occur, this method returns -1.

lastIndexOf(substring, endPosition) Returns the index of the last occurrence of the specified substring, starting from the character at index 0 and ending at the specified index.

lastIndexOfChar(character) Returns the index of the last occurrence of the character that corresponds to the specified character value.

lastIndexOfChar(character, endIndex) Returns the index of the last occurrence of the character that corresponds to the specified character value, starting from the specified index.

lastIndexOfIgnoreCase(substring) Returns the index of the last occurrence of the specified substring regardless of case.

lastIndexOfIgnoreCase(substring, endPosition) Returns the index of the last occurrence of the specified substring regardless of case, starting from the character at index 0 and ending at the specified index.

left(length) Returns the leftmost characters of the current String of the specified length.

leftPad(length) Returns the current String padded with spaces on the left and of the specified length.

leftPad(length, padStr) Returns the current String padded with String padStr on the left and of the specified length.

length() Returns the number of 16-bit Unicode characters contained in the String.

mid(startIndex, length) Returns a new String that begins with the character at the specified zero-based startIndex with the number of characters specified by length.

normalizeSpace() Returns the current String with leading, trailing, and repeating white space characters removed.

offsetByCodePoints(index, codePointOffset) Returns the index of the Unicode code point that is offset by the specified number of code points, starting from the given index.

remove(substring) Removes all occurrences of the specified substring and returns the String result.
removeEnd(substring)
Removes the specified substring only if it occurs at the end of the String.

removeEndIgnoreCase(substring)
Removes the specified substring only if it occurs at the end of the String using a case-insensitive match.

removeStart(substring)
Removes the specified substring only if it occurs at the beginning of the String.

removeStartIgnoreCase(substring)
Removes the specified substring only if it occurs at the beginning of the String using a case-insensitive match.

repeat(numberOfTimes)
Returns the current String repeated the specified number of times.

repeat(separator, numberOfTimes)
Returns the current String repeated the specified number of times using the specified separator to separate the repeated Strings.

replace(target, replacement)
Replaces each substring of a string that matches the literal target sequence target with the specified literal replacement sequence replacement.

replaceAll(regExp, replacement)
Replaces each substring of a string that matches the regular expression regExp with the replacement sequence replacement.

replaceFirst(regExp, replacement)
Replaces the first substring of a string that matches the regular expression regExp with the replacement sequence replacement.

reverse()
Returns a String with all the characters reversed.

right(length)
Returns the rightmost characters of the current String of the specified length.

rightPad(length)
Returns the current String padded with spaces on the right and of the specified length.

rightPad(length, padStr)
Returns the current String padded with String padStr on the right and of the specified length.

split(regExp)
Returns a list that contains each substring of the String that is terminated by either the regular expression regExp or the end of the String.

split(regExp, limit)
Returns a list that contains each substring of the String that is terminated by either the regular expression regExp or the end of the String.

splitByCharacterType()
Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens.

splitByCharacterTypeCamelCase()
Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens, with the following exception: the uppercase character, if any, immediately preceding a lowercase character token belongs to the following character token rather than to the preceding.

startsWith(prefix)
Returns true if the String that called the method begins with the specified prefix.
startsWithIgnoreCase(prefix)
Returns true if the current String begins with the specified prefix regardless of the prefix case.

stripHtmlTags()
Removes HTML markup and returns plain text.

substring(startIndex)
Returns a new String that begins with the character at the specified zero-based startIndex and extends to the end of the String.

substring(startIndex, endIndex)
Returns a new String that begins with the character at the specified zero-based startIndex and extends to the character at endIndex - 1.

substringAfter(separator)
Returns the substring that occurs after the first occurrence of the specified separator.

substringAfterLast(separator)
Returns the substring that occurs after the last occurrence of the specified separator.

substringBefore(separator)
Returns the substring that occurs before the first occurrence of the specified separator.

substringBeforeLast(separator)
Returns the substring that occurs before the last occurrence of the specified separator.

substringBetween(tag)
Returns the substring that occurs between two instances of the specified tag String.

substringBetween(open, close)
Returns the substring that occurs between the two specified Strings.

swapCase()
Swaps the case of all characters and returns the resulting String by using the default (English US) locale.

toLowerCase()
Converts all of the characters in the String to lowercase using the rules of the default (English US) locale.

toLowerCase(locale)
Converts all of the characters in the String to lowercase using the rules of the specified locale.

toUpperCase()
Converts all of the characters in the String to uppercase using the rules of the default (English US) locale.

toUpperCase(locale)
Converts all of the characters in the String to uppercase using the rules of the specified locale.

trim()
Returns a copy of the string that no longer contains any leading or trailing white space characters.

uncapitalize()
Returns the current String with the first letter in lowercase.

unescapeCsv()
Returns a String representing an unescaped CSV column.

unescapeEcmaScript()
Unescapes any EcmaScript literals found in the String.
unescapeHtml3()  
Unescapes the characters in a String using HTML 3.0 entities.

unescapeHtml4()  
Unescapes the characters in a String using HTML 4.0 entities.

unescapeJava()  
Returns a String whose Java literals are unescaped. Literals unescaped include escape sequences for quotes (""), and control characters, such as tab (\t), and carriage return (\n).

unescapeUnicode()  
Returns a String whose escaped Unicode characters are unescaped.

unescapeXml()  
Unescapes the characters in a String using XML entities.

valueOf(dateToConvert)  
Returns a String that represents the specified Date in the standard “yyyy-MM-dd” format.

valueOf(datetimeToConvert)  
Returns a String that represents the specified Datetime in the standard “yyyyy-MM-dd HH:mm:ss” format for the local time zone.

valueOf(decimalToConvert)  
Returns a String that represents the specified Decimal.

valueOf(doubleToConvert)  
Returns a String that represents the specified Double.

valueOf(integerToConvert)  
Returns a String that represents the specified Integer.

valueOf(longToConvert)  
Returns a String that represents the specified Long.

valueOf(toConvert)  
Returns a string representation of the specified object argument.

valueOfGmt(datetimeToConvert)  
Returns a String that represents the specified Datetime in the standard “yyyy-MM-dd HH:mm:ss” format for the GMT time zone.

---

**abbreviate(maxWidth)**

Returns an abbreviated version of the String, of the specified length and with ellipses appended if the current String is longer than the specified length; otherwise, returns the original String without ellipses.

**Signature**

public String abbreviate(Integer maxWidth)

**Parameters**

*maxWidth*  
Type: ```Integer```  

If *maxWidth* is less than four, this method throws a run-time exception.
Return Value
Type: String

Example
```java
String s = 'Hello Maximillian';
String s2 = s.abbreviate(8);
System.assertEquals('Hello...', s2);
System.assertEquals(8, s2.length());
```

**abbreviate (maxWidth, offset)**
Returns an abbreviated version of the String, starting at the specified character offset and of the specified length. The returned String has ellipses appended at the start and the end if characters have been removed at these locations.

**Signature**
```java
public String abbreviate(Integer maxWidth, Integer offset)
```

**Parameters**
- **maxWidth**
  Type: Integer
  Note that the offset is not necessarily the leftmost character in the returned String or the first character following the ellipses, but it appears somewhere in the result. Regardless, abbreviate won't return a String of length greater than maxWidth. If maxWidth is too small, this method throws a run-time exception.

- **offset**
  Type: Integer

**Return Value**
Type: String

Example
```java
String s = 'Hello Maximillian';
// Start at M
String s2 = s.abbreviate(9,6);
System.assertEquals('...Max...', s2);
System.assertEquals(9, s2.length());
```

**capitalize()**
Returns the current String with the first letter changed to title case.

**Signature**
```java
public String capitalize()
```
Return Value
Type: String

Usage
This method is based on the Character.toTitleCase(char) Java method.

Example
```java
String s = 'hello maximillian';
String s2 = s.capitalize();
System.assertEquals('Hello maximillian', s2);
```

center(size)
Returns a version of the current String of the specified size padded with spaces on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without added spaces.

Signature
public String center(Integer size)

Parameters
size
Type: Integer

Return Value
Type: String

Example
```java
String s = 'hello';
String s2 = s.center(9);
System.assertEquals(
   ' hello ',
   s2);
```

center(size, paddingString)
Returns a version of the current String of the specified size padded with the specified String on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without padding.

Signature
public String center(Integer size, String paddingString)
Parameters

size
  Type: Integer

paddingString
  Type: String

Return Value
Type: String

Example

```java
String s = 'hello';
String s2 = s.center(9, '-');
System.assertEquals('--hello--', s2);
```

**charAt(index)**

Returns the value of the character at the specified index.

**Signature**

```java
public Integer charAt(Integer index)
```

**Parameters**

index
  Type: Integer
  The index of the character to get the value of.

**Return Value**

Type: Integer
  The integer value of the character.

**Usage**

The `charAt` method returns the value of the character pointed to by the specified index. If the index points to the beginning of a surrogate pair (the high-surrogate code point), this method returns only the high-surrogate code point. To return the supplementary code point corresponding to a surrogate pair, call `codePointAt` instead.

**Example**

This example gets the value of the first character at index 0.

```java
String str = 'Ω is Omega.';
System.assertEquals(937, str.charAt(0));
```
This example shows the difference between `charAt` and `codePointAt`. The example calls these methods on escaped supplementary Unicode characters. `charAt(0)` returns the high surrogate value, which corresponds to \uD835. `codePointAt(0)` returns the value for the entire surrogate pair.

```java
String str = '\uD835\uDD0A';
System.assertEquals(55349, str.charAt(0),
  'charAt(0) didn\'t return the high surrogate.');
System.assertEquals(120074, str.codePointAt(0),
  'codePointAt(0) didn\'t return the entire two-character supplementary value.');
```

codePointAt(index)

Returns the Unicode code point value at the specified index.

**Signature**

```java
public Integer codePointAt(Integer index)
```

**Parameters**

- `index`  
  Type: Integer  
  The index of the characters (Unicode code units) in the string. The index range is from zero to the string length minus one.

**Return Value**

- Type: Integer  
  The Unicode code point value at the specified index.

**Usage**

If the `index` points to the beginning of a surrogate pair (the high-surrogate code point), and the character value at the following index points to the low-surrogate code point, this method returns the supplementary code point corresponding to this surrogate pair. Otherwise, this method returns the character value at the given index.

For more information on Unicode and surrogate pairs, see [The Unicode Consortium](https://www.unicode.org/).

**Example**

This example gets the code point value of the first character at index 0, which is the escaped Omega character. Also, the example gets the code point at index 20, which corresponds to the escaped supplementary Unicode characters (a pair of characters). Finally, it verifies that the escaped and unescaped forms of Omega have the same code point values.

The supplementary characters in this example (\uD835\uDD0A) correspond to mathematical fraktur capital G: \u03A9

```java
String str = '\u03A9 is Ω (Omega), and \uD835\uDD0A \n  is Fraktur Capital G..GeneratedValue=';
System.assertEquals(937, str.codePointAt(0));
System.assertEquals(120074, str.codePointAt(20));
// Escaped or unescaped forms of the same character have the same code point
System.assertEquals(str.codePointAt(0), str.codePointAt(5));
```
**codePointBefore(index)**

Returns the Unicode code point value that occurs before the specified index.

**Signature**

```java
public Integer codePointBefore(Integer index)
```

**Parameters**

*index*

Type: `Integer`

The index before the Unicode code point that is to be returned. The index range is from one to the string length.

**Return Value**

Type: `Integer`

The character or Unicode code point value that occurs before the specified index.

**Usage**

If the character value at index -1 is the low-surrogate code point, and index -2 is not negative and the character at this index location is the high-surrogate code point, this method returns the supplementary code point corresponding to this surrogate pair. If the character value at index -1 is an unpaired low-surrogate or high-surrogate code point, the surrogate value is returned.

For more information on Unicode and surrogate pairs, see The Unicode Consortium.

**Example**

This example gets the code point value of the first character (before index 1), which is the escaped Omega character. Also, the example gets the code point at index 20, which corresponds to the escaped supplementary characters (the two characters before index 22).

```java
String str = '\u03A9 is Ω (Omega), and \uD835\uDD0A ' +
            ' is Fraktur Capital G.';
System.assertEquals(937, str.codePointBefore(1));
System.assertEquals(120074, str.codePointBefore(22));
```

**codePointCount(beginIndex, endIndex)**

Returns the number of Unicode code points within the specified text range.

**Signature**

```java
public Integer codePointCount(Integer beginIndex, Integer endIndex)
```

**Parameters**

*beginIndex*

Type: `Integer`

The index of the first character in the range.
endIndex
Type: Integer
The index after the last character in the range.

Return Value
Type: Integer
The number of Unicode code points within the specified range.

Usage
The specified range begins at beginIndex and ends at endIndex–1. Unpaired surrogates within the text range count as one code point each.

Example
This example writes the count of code points in a substring that contains an escaped Unicode character and another substring that contains Unicode supplementary characters, which count as one code point.

```java
String str = '\u03A9 and \uD835\uDD0A characters.\';
System.debug('Count of code points for ' + str.substring(0,1) + ': ' + str.codePointCount(0,1));
System.debug('Count of code points for ' + str.substring(6,8) + ': ' + str.codePointCount(6,8));
```

// Output:
// Count of code points for Ω: 1
// Count of code points for ☯: 1

compareTo(secondString)
Compares two strings lexicographically, based on the Unicode value of each character in the Strings.

Signature
public Integer compareTo(String secondString)

Parameters
secondString
Type: String

Return Value
Type: Integer

Usage
The result is:
- A negative Integer if the String that called the method lexicographically precedes secondString
- A positive Integer if the String that called the method lexicographically follows `compsecondStringString`
- Zero if the Strings are equal

If there is no index position at which the Strings differ, then the shorter String lexicographically precedes the longer String.

Note that this method returns 0 whenever the `equals` method returns true.

**Example**

```java
String myString1 = 'abcde';
String myString2 = 'abcd';
Integer result =
    myString1.compareTo(myString2);
System.assertEquals(result, 1);
```

### contains(substring)

Returns `true` if and only if the String that called the method contains the specified sequence of characters in `substring`.

**Signature**

```java
public Boolean contains(String substring)
```

**Parameters**

- **substring**
  - Type: `String`

**Return Value**

- Type: `Boolean`

**Example**

```java
String myString1 = 'abcde';
String myString2 = 'abcd';
Boolean result =
    myString1.contains(myString2);
System.assertEquals(result, true);
```

### containsAny(inputString)

Returns `true` if the current String contains any of the characters in the specified String; otherwise, returns `false`.

**Signature**

```java
public Boolean containsAny(String inputString)
```

**Parameters**

- **inputString**
  - Type: `String`
Return Value
Type: Boolean

Example

```java
String s = 'hello';
Boolean b1 = s.containsAny('hx');
Boolean b2 = s.containsAny('x');
System.assertEquals(true, b1);
System.assertEquals(false, b2);
```

containsIgnoreCase(substring)
Returns true if the current String contains the specified sequence of characters without regard to case; otherwise, returns false.

Signature

```java
public Boolean containsIgnoreCase(String substring)
```

Parameters

substring
Type: String

Return Value
Type: Boolean

Example

```java
String s = 'hello';
Boolean b = s.containsIgnoreCase('HE');
System.assertEquals(true, b);
```

containsNone(inputString)
Returns true if the current String doesn’t contain any of the characters in the specified String; otherwise, returns false.

Signature

```java
public Boolean containsNone(String inputString)
```

Parameters

inputString
Type: String

If inputString is an empty string or the current String is empty, this method returns true. If inputString is null, this method returns a run-time exception.
Return Value
Type: Boolean

Example
```java
String s1 = 'abcde';
System.assert(s1.containsNone('fg'));
```

**containsOnly**(inputString)
Returns `true` if the current String contains characters only from the specified sequence of characters and not any other characters; otherwise, returns `false`.

Signature
```java
public Boolean containsOnly(String inputString)
```

Parameters
- `inputString`
  Type: String

Return Value
Type: Boolean

Example
```java
String s1 = 'abba';
String s2 = 'abba xyz';
Boolean b1 =
    s1.containsOnly('abcd');
System.assertEquals(
    true,
    b1);
Boolean b2 =
    s2.containsOnly('abcd');
System.assertEquals(
    false,
    b2);
```

**containsWhitespace()**
Returns `true` if the current String contains any white space characters; otherwise, returns `false`.

Signature
```java
public Boolean containsWhitespace()
```
Return Value
Type: Boolean

Example
```java
String s = 'Hello Jane';
System.assert(s.containsWhitespace()); //true
s = 'HelloJane ';
System.assert(s.containsWhitespace()); //true
s = 'HelloJane';
System.assert(s.containsWhitespace()); //true
s = 'HelloJane';
System.assert(!s.containsWhitespace()); //false
```

countMatches(substring)
Returns the number of times the specified substring occurs in the current String.

Signature
```java
public Integer countMatches(String substring)
```

Parameters
substring
Type: String

Return Value
Type: Integer

Example
```java
String s = 'Hello Jane';
System.assertEquals(1, s.countMatches('Hello'));
s = 'Hello Hello';
System.assertEquals(2, s.countMatches('Hello'));
s = 'Hello hello';
System.assertEquals(1, s.countMatches('Hello'));
```

deleteWhitespace()
Returns a version of the current String with all white space characters removed.

Signature
```java
public String deleteWhitespace()
```

Return Value
Type: String
Example

```java
String s1 = 'Hello Jane';
String s2 = 'HelloJane';
System.assertEquals(s2, s1.deleteWhitespace());
```

difference(secondString)

Returns the difference between the current String and the specified String.

Signature

```java
public String difference(String secondString)
```

Parameters

secondString

Type: String

- If `secondString` is an empty string, this method returns an empty string.
- If `secondString` is null, this method throws a run-time exception.

Return Value

Type: String

Example

```java
String s = 'Hello Jane';
String d1 = s.difference('Hello Max');
System.assertEquals('Max', d1);
String d2 = s.difference('Goodbye');
System.assertEquals('Goodbye', d2);
```

endsWith(suffix)

Returns `true` if the String that called the method ends with the specified `suffix`.

Signature

```java
public Boolean endsWith(String suffix)
```

Parameters

suffix

Type: String
Return Value
Type: Boolean

Example
```java
String s = 'Hello Jason';
System.assert(s.endsWith('Jason'));
```

`endsWithIgnoreCase(suffix)`

Returns `true` if the current String ends with the specified suffix; otherwise, returns `false`.

Signature
```java
public Boolean endsWithIgnoreCase(String suffix)
```

Parameters
- `suffix`
  Type: String

Return Value
Type: Boolean

Example
```java
String s = 'Hello Jason';
System.assert(s.endsWithIgnoreCase('jason'));
```

`equals(secondString)`

Deprecated. This method is replaced by `equals(stringOrId)`. Returns `true` if the passed-in string is not null and represents the same binary sequence of characters as the current string. Use this method to perform case-sensitive comparisons.

Signature
```java
public Boolean equals(String secondString)
```

Parameters
- `secondString`
  Type: String

Return Value
Type: Boolean
Usage

This method returns `true` when the `compareTo` method returns 0.

Use this method to perform case-sensitive comparisons. In contrast, the `==` operator performs case-insensitive string comparisons to match Apex semantics.

Example

```java
String myString1 = 'abcde';
String myString2 = 'abcd';
Boolean result = myString1.equals(myString2);
System.assertEquals(result, false);
```

`equals(stringOrId)`

Returns `true` if the passed-in object is not null and represents the same binary sequence of characters as the current string. Use this method to compare a string to an object that represents a string or an ID.

Signature

```java
public Boolean equals(Object stringOrId)
```

Parameters

`stringOrId`

Type: Object

Return Value

Type: Boolean

Usage

If you compare ID values, the lengths of IDs don't need to be equal. For example, if you compare a 15-character ID string to an object that represents the equivalent 18-character ID value, this method returns `true`. For more information about 15-character and 18-character IDs, see the ID Data Type.

Use this method to perform case-sensitive comparisons. In contrast, the `==` operator performs case-insensitive string comparisons to match Apex semantics.

Example

These examples show comparisons between different types of variables with both equal and unequal values. The examples also show how Apex automatically converts certain values before comparing them.

```java
// Compare a string to an object containing a string
Object obj1 = 'abc';
String str = 'abc';
Boolean result1 = str.equals(obj1);
System.assertEquals(result1, true);

// Compare a string to an object containing a number
```
```java
Integer obj2 = 100;
Boolean result2 = str.equals(obj2);
System.assertEquals(false, result2);

// Compare a string to an ID of the same length.
// 15-character ID
Id idValue15 = '001D000000Ju1zH';
// 15-character ID string value
String stringValue15 = '001D000000Ju1zH';
Boolean result3 = stringValue15.equals(IdValue15);
System.assertEquals(true, result3);

// Compare two equal ID values of different lengths:
// 15-character ID and 18-character ID
Id idValue18 = '001D000000Ju1zHIAR';
Boolean result4 = stringValue15.equals(IdValue18);
System.assertEquals(true, result4);
```

**equalsIgnoreCase(secondString)**

Returns `true` if the `secondString` isn’t null and represents the same sequence of characters as the String that called the method, ignoring case.

**Signature**

```java
public Boolean equalsIgnoreCase(String secondString)
```

**Parameters**

- **secondString**
  
  Type: **String**

**Return Value**

Type: **Boolean**

**Usage**

The `String.equalsIgnoreCase()` method ignores the locale of the context user. If you want the string comparison to be performed according to the locale, use the `==` operator instead. The `String.equalsIgnoreCase()` method typically executes faster than the operator because the method ignores the locale.

**Example**

```java
String myString1 = 'abcd';
String myString2 = 'ABCD';
Boolean result =
myString1.equalsIgnoreCase(myString2);
System.assertEquals(result, true);
```
**escapeCsv()**

Returns a String for a CSV column enclosed in double quotes, if required.

**Signature**

```java
public String escapeCsv()
```

**Return Value**

Type: String

**Usage**

If the String contains a comma, newline or double quote, the returned String is enclosed in double quotes. Also, any double quote characters in the String are escaped with another double quote.

If the String doesn’t contain a comma, newline or double quote, it is returned unchanged.

**Example**

```java
String s1 = 'Max1, "Max2"';
String s2 = s1.escapeCsv();
System.assertEquals("Max1, "Max2"", s2);
```

**escapeEcmaScript()**

Escapes the characters in the String using EcmaScript String rules.

**Signature**

```java
public String escapeEcmaScript()
```

**Return Value**

Type: String

**Usage**

The only difference between Apex strings and EcmaScript strings is that in EcmaScript, a single quote and forward-slash (/) are escaped.

**Example**

```java
String s1 = "grade": 3.9/4.0;
String s2 = s1.escapeEcmaScript();
System.debug(s2);
// Output is:
// "grade": 3.9\/4.0
System.assertEquals("'\"grade\": 3.9\/4.0', s2);
```
**escapeHtml3()**
Escapes the characters in a String using HTML 3.0 entities.

**Signature**

```java
public String escapeHtml3()
```

**Return Value**
Type: **String**

**Example**

```java
String s1 = '
"<Black&White>"';
String s2 = s1.escapeHtml3();
System.debug(s2);
// Output:
// &quot;&lt;Black&amp;
// White&gt;&quot;
```

**escapeHtml4()**
Escapes the characters in a String using HTML 4.0 entities.

**Signature**

```java
public String escapeHtml4()
```

**Return Value**
Type: **String**

**Example**

```java
String s1 = '
"<Black&White>"';
String s2 = s1.escapeHtml4();
System.debug(s2);
// Output:
// &quot;&lt;Black&amp;
// White&gt;&quot;
```

**escapeJava()**
Returns a String whose characters are escaped using Java String rules. Characters escaped include quotes and control characters, such as tab, backslash, and carriage return characters.
Apex Reference Guide

String Class

Signature
public String escapeJava()

Return Value
Type: String
The escaped string.

Example
// Input string contains quotation marks
String s = 'Company: "Salesforce.com"';
String escapedStr = s.escapeJava();
// Output string has the quotes escpaded
System.assertEquals('Company: \\"Salesforce.com\\"', escapedStr);

escapeSingleQuotes(stringToEscape)
Returns a String with the escape character (\) added before any single quotation marks in the String s.

Signature
public static String escapeSingleQuotes(String stringToEscape)

Parameters
stringToEscape

Type: String

Return Value
Type: String

Usage
This method is useful when creating a dynamic SOQL statement, to help prevent SOQL injection. For more information on dynamic
SOQL, see Dynamic SOQL.

Example
String s = '\'Hello Jason\'';
system.debug(s); // Outputs 'Hello Jason'
String escapedStr = String.escapeSingleQuotes(s);
// Outputs \'Hello Jason\'
system.debug(escapedStr);
// Escapes the string \\\' to string \'
system.assertEquals('\\\'Hello Jason\\\'', escapedStr);

3426


**escapeUnicode()**
Returns a String whose Unicode characters are escaped to a Unicode escape sequence.

**Signature**
```
public String escapeUnicode()
```

**Return Value**
Type: `String`
The escaped string.

**Example**
```
String s = 'De onde você é?';
String escapedStr = s.escapeUnicode();
System.assertEquals('De onde voc\u00E9?', escapedStr);
```

**escapeXml()**
Escapes the characters in a String using XML entities.

**Signature**
```
public String escapeXml()
```

**Return Value**
Type: `String`

**Usage**
Supports only the five basic XML entities (gt, lt, quot, amp, apos). Does not support DTDs or external entities. Unicode characters greater than 0x7f are not escaped.

**Example**
```
String s1 = "<Black&White>";
String s2 = s1.escapeXml();
System.debug(s2);
// Output:
// &quot;&lt;Black&amp;White&gt;";
```
format(stringToFormat, formattingArguments)

Treat the first argument as a pattern and return a string using the second argument for substitution and formatting. The substitution and formatting are the same as apex:outputText and the Java MessageFormat class. Non-string types in the second argument’s List are implicitly converted to strings, respecting the toString() method overrides that exist on the type.

Signature

public static String format(String stringToFormat, List<Object> formattingArguments)

Parameters

stringToFormat
Type: String

formattingArguments
Type: List<Object>

Return Value
Type: String

Versioned Behavior Changes

From version 51.0 and later, the format() method supports single quotes in the stringToFormat parameter and returns a formatted string using the formattingArguments parameter. In version 50.0 and earlier, single quotes weren’t supported.

Example

String template = '{0} was last updated {1}';
List<Object> parameters = new List<Object> {'Universal Containers',
DateTime.newInstance(2018, 11, 15) };
String formatted = String.format(template, parameters);
System.debug ('Newly formatted string is:' + formatted);

fromCharArray(charArray)

Returns a String from the values of the list of integers.

Signature

public static String fromCharArray(List<Integer> charArray)

Parameters

charArray
Type: List<Integer>

Return Value
Type: String
Example

```java
List<Integer> charArr = new Integer[]{74};
String convertedChar = String.fromCharCode(charArr);
System.assertEquals('J', convertedChar);
```

getChars()

Returns an array of character values that represent the characters in this string.

Signature

```java
public List<Integer> getChars()
```

Return Value

Type: `List<Integer>`

A list of integers, each corresponding to a character value in the string.

Example

This sample converts a string to a character array and then gets the first array element, which corresponds to the value of 'J'.

```java
String str = 'Jane goes fishing.';
Integer[] chars = str.getChars();
// Get the value of 'J'
System.assertEquals(74, chars[0]);
```

getCommonPrefix(strings)

Returns the initial sequence of characters as a String that is common to all the specified Strings.

Signature

```java
public static String getCommonPrefix(List<String> strings)
```

Parameters

`strings`
Type: `List<String>`

Return Value

Type: `String`

Example

```java
List<String> ls = new List<String>{'SFDCApex', 'SFDCVisualforce'};
String prefix = String.getCommonPrefix(ls);
System.assertEquals('SFDC', prefix);
```
getLevenshteinDistance(stringToCompare)

Returns the Levenshtein distance between the current String and the specified String.

Signature

```java
public Integer getLevenshteinDistance(String stringToCompare)
```

Parameters

- `stringToCompare`
  Type: `String`

Return Value

Type: `Integer`

Usage

The Levenshtein distance is the number of changes needed to change one String into another. Each change is a single character modification (deletion, insertion or substitution).

Example

```java
String s = 'Hello Joe';
Integer i = s.getLevenshteinDistance('Hello Max');
System.assertEquals(3, i);
```

getLevenshteinDistance(stringToCompare, threshold)

Returns the Levenshtein distance between the current String and the specified String if it is less than or equal than the given threshold; otherwise, returns -1.

Signature

```java
public Integer getLevenshteinDistance(String stringToCompare, Integer threshold)
```

Parameters

- `stringToCompare`
  Type: `String`
- `threshold`
  Type: `Integer`

Return Value

Type: `Integer`
Usage

The Levenshtein distance is the number of changes needed to change one String into another. Each change is a single character modification (deletion, insertion or substitution).

Example:

In this example, the Levenshtein distance is 3, but the threshold argument is 2, which is less than the distance, so this method returns -1.

Example

```java
String s = 'Hello Jane';
Integer i = s.getLevenshteinDistance('Hello Max', 2);
System.assertEquals(-1, i);
```

hashCode()

Returns a hash code value for this string.

Signature

```java
public Integer hashCode()
```

Return Value

Type: Integer

Usage

This value is based on the hash code computed by the Java `String.hashCode` counterpart method.

You can use this method to simplify the computation of a hash code for a custom type that contains String member variables. You can compute your type's hash code value based on the hash code of each String variable. For example:

For more details about the use of hash code methods with custom types, see Using Custom Types in Map Keys and Sets.

Example

```java
public class MyCustomClass {
    String x, y;
    // Provide a custom hash code
    public Integer hashCode() {
        return (31*x.hashCode())^y.hashCode();
    }
}
```

indexOf(substring)

Returns the index of the first occurrence of the specified substring. If the substring does not occur, this method returns -1.
Signature

public Integer indexOf(String substring)

Parameters

substring
  Type: String

Return Value

Type: Integer

Example

String myString1 = 'abcde';
String myString2 = 'cd';
Integer result = myString1.indexOf(myString2);
System.assertEquals(2, result);

indexOf(substring, index)

Returns the zero-based index of the first occurrence of the specified substring from the point of the given index. If the substring does not occur, this method returns -1.

Signature

public Integer indexOf(String substring, Integer index)

Parameters

substring
  Type: String

index
  Type: Integer

Return Value

Type: Integer

Example

String myString1 = 'abcdabcd';
String myString2 = 'ab';
Integer result = myString1.indexOf(myString2, 1);
System.assertEquals(4, result);

indexOfAny(substring)

Returns the zero-based index of the first occurrence of any character specified in the substring. If none of the characters occur, returns -1.

Signature

public Integer indexOfAny(String substring)
Signature

downloads\.indexOfAny(String substring)

Parameters

substring
  Type: String

Return Value

Type: Integer

Example

String s1 = 'abcd';
String s2 = 'xc';
Integer result = s1.indexOfAny(s2);
System.assertEquals(2, result);

indexOfAnyBut(substring)

Returns the zero-based index of the first occurrence of a character that is not in the specified substring. Otherwise, returns -1.

Signature

public Integer indexOfAnyBut(String substring)

Parameters

substring
  Type: String

Return Value

Type: Integer

Example

String s1 = 'abcd';
String s2 = 'xc';
Integer result = s1.indexOfAnyBut(s2);
System.assertEquals(0, result);

indexOfChar(character)

Returns the index of the first occurrence of the character that corresponds to the specified character value.

Signature

public Integer indexOfChar(Integer character)
Parameters

character
Type: Integer
The integer value of the character in the string.

Return Value

Type: Integer
The index of the first occurrence of the specified character, -1 if the character is not found.

Usage

The index that this method returns is in Unicode code units.

Example

```java
String str = '\u03A9 is Ω (Omega)';
// Returns 0, which is the first character.
System.debug('indexOfChar(937)=' + str.indexOfChar(937));
// Output:
// indexOfChar(937)=0
```

`indexOfChar(character, startIndex)`

Returns the index of the first occurrence of the character that corresponds to the specified character value, starting from the specified index.

Signature

```
public Integer indexOfChar(Integer character, Integer startIndex)
```

Parameters

character
Type: Integer
The integer value of the character to look for.

startIndex
Type: Integer
The index to start the search from.

Return Value

Type: Integer
The index, starting from the specified start index, of the first occurrence of the specified character, -1 if the character is not found.
Usage
The index that this method returns is in Unicode code units.

Example
This example shows different ways of searching for the index of the Omega character. The first call to `indexOfChar` doesn’t specify a start index and therefore the returned index is 0, which is the first occurrence of Omega in the entire string. The subsequent calls specify a start index to find the occurrence of Omega in substrings that start at the specified index.

```java
String str = 'Ω and \u03A9 and Ω';
System.debug('indexOfChar(937)= ' + str.indexOfChar(937));
System.debug('indexOfChar(937,1)= ' + str.indexOfChar(937,1));
System.debug('indexOfChar(937,10)= ' + str.indexOfChar(937,10));
```

// Output:
// indexOfChar(937)=0
// indexOfChar(937,1)=6, (corresponds to the escaped form \u03A9)
// indexOfChar(937,10)=12

`indexOfDifference(stringToCompare)`
Returns the zero-based index of the character where the current String begins to differ from the specified String.

Signature
```
public Integer indexOfDifference(String stringToCompare)
```

Parameters

- `stringToCompare`  
  Type: String

Return Value

Type: Integer

Example

```java
String s1 = 'abcd';
String s2 = 'abxc';
Integer result = s1.indexOfDifference(s2);
System.assertEquals(2, result);
```

`indexOfIgnoreCase(substring)`
Returns the zero-based index of the first occurrence of the specified substring without regard to case. If the substring does not occur, this method returns -1.

Signature
```
public Integer indexOfIgnoreCase(String substring)
```

3435
Parameters

substring
Type: String

Return Value
Type: Integer

Example

```java
String s1 = 'abcd';
String s2 = 'BC';
Integer result = s1.indexOfIgnoreCase(s2, 0);
System.assertEquals(1, result);
```

`indexOfIgnoreCase(substring, startPosition)`

Returns the zero-based index of the first occurrence of the specified substring from the point of index `i`, without regard to case. If the substring does not occur, this method returns -1.

Signature

```java
public Integer indexOfIgnoreCase(String substring, Integer startPosition)
```

Parameters

substring
Type: String

startPosition
Type: Integer

Return Value
Type: Integer

`isAllLowerCase()`

Returns `true` if all characters in the current String are lowercase; otherwise, returns `false`.

Signature

```java
public Boolean isAllLowerCase()
```

Return Value
Type: Boolean
**Example**

```java
String allLower = 'abcde';
System.assert(allLower.isAllLowerCase());
```

**isAllUpperCase()**

Returns `true` if all characters in the current String are uppercase; otherwise, returns `false`.

**Signature**

```java
public Boolean isAllUpperCase()
```

**Return Value**

Type: `Boolean`

**Example**

```java
String allUpper = 'ABCDE';
System.assert(allUpper.isAllUpperCase());
```

**isAlpha()**

Returns `true` if all characters in the current String are Unicode letters only; otherwise, returns `false`.

**Signature**

```java
public Boolean isAlpha()
```

**Return Value**

Type: `Boolean`

**Example**

```java
// Letters only
String s1 = 'abc';
// Returns true
Boolean b1 =
    s1.isAlpha();
System.assertEquals(
    true, b1);

// Letters and numbers
String s2 = 'abc 21';
// Returns false
Boolean b2 =
    s2.isAlpha();
System.assertEquals(
    false, b2);
```
**isAlphaSpace()**

Returns `true` if all characters in the current String are Unicode letters or spaces only; otherwise, returns `false`.

**Signature**

```java
public Boolean isAlphaSpace()
```

**Return Value**

Type: `Boolean`

**Example**

```java
String alphaSpace = 'aA Bb';
System.assert(alphaSpace.isAlphaSpace());
String notAlphaSpace = 'ab 12';
System.assert(!notAlphaSpace.isAlphaSpace());
notAlphaSpace = 'aA$Bb';
System.assert(!notAlphaSpace.isAlphaSpace());
```

**isAlphanumeric()**

Returns `true` if all characters in the current String are Unicode letters or numbers only; otherwise, returns `false`.

**Signature**

```java
public Boolean isAlphanumeric()
```

**Return Value**

Type: `Boolean`

**Example**

```java
// Letters only
String s1 = 'abc';
// Returns true
Boolean b1 = s1.isAlphanumeric();
System.assertEquals(true, b1);
// Letters and numbers
String s2 = 'abc021';
// Returns true
Boolean b2 = s2.isAlphanumeric();
System.assertEquals(true, b2);
```
**isAlphanumericSpace()**

Returns **true** if all characters in the current String are Unicode letters, numbers, or spaces only; otherwise, returns **false**.

**Signature**

```java
public Boolean isAlphanumericSpace()
```

**Return Value**

Type: Boolean

**Example**

```java
String alphanumSpace = 'AE 86';
System.assert(alphanumSpace.isAlphanumericSpace());
String notAlphanumSpace = 'aA$12';
System.assert(!notAlphanumSpace.isAlphanumericSpace());
```

**isAsciiPrintable()**

Returns **true** if the current String contains only ASCII printable characters; otherwise, returns **false**.

**Signature**

```java
public Boolean isAsciiPrintable()
```

**Return Value**

Type: Boolean

**Example**

```java
String ascii = 'abcd1234!#$^&*()~--+={[]}|:<,.?';
System.assert(ascii.isAsciiPrintable());
String notAscii = '√';
System.assert(!notAscii.isAsciiPrintable());
```

**isBlank(inputString)**

Returns **true** if the specified String is white space, empty (""), or null; otherwise, returns **false**.

**Signature**

```java
public static Boolean isBlank(String inputString)
```

**Parameters**

`inputString`

Type: String
Return Value
Type: Boolean

Example
```
String blank = '';
String nullString = null;
String whitespace = ' ';
System.assert(String.isBlank(blank));
System.assert(String.isBlank(nullString));
System.assert(String.isBlank(whitespace));
String alpha = 'Hello';
System.assert(!String.isBlank(alpha));
```

isEmpty(inputString)
Returns true if the specified String is empty ("") or null; otherwise, returns false.

Signature
```
public static Boolean isEmpty(String inputString)
```

Parameters
- inputString
  Type: String

Return Value
Type: Boolean

Example
```
String empty = '';
String nullString = null;
System.assert(String.isEmpty(empty));
System.assert(String.isEmpty(nullString));
String whitespace = ' ';
String alpha = 'Hello';
System.assert(!String.isEmpty(whitespace));
System.assert(!String.isEmpty(alpha));
```

isNotBlank(inputString)
Returns true if the specified String is not whitespace, not empty (""), and not null; otherwise, returns false.

Signature
```
public static Boolean isNotBlank(String inputString)
```

Example
```
```
Parameters

inputString
Type: String

Return Value

Type: Boolean

Example

```java
String alpha = 'Hello world!';
System.assert(String.isNotBlank(alpha));
String blank = '';
String nullString = null;
String whitespace = ' ';
System.assert(!String.isNotBlank(blank));
System.assert(!String.isNotBlank(nullString));
System.assert(!String.isNotBlank(whitespace));
```

isEmpty(inputString)

Returns true if the specified String is not empty ("") and not null; otherwise, returns false.

Signature

```java
public static Boolean isEmpty(String inputString)
```

Parameters

inputString
Type: String

Return Value

Type: Boolean

Example

```java
String whitespace = ' ';
String alpha = 'Hello world!';
System.assert(String.isNotEmpty(whitespace));
System.assert(String.isNotEmpty(alpha));
String empty = '';  
String nullString = null;
System.assert(!String.isNotEmpty(empty));
System.assert(!String.isNotEmpty(nullString));
```

isNumeric()

Returns true if the current String contains only Unicode digits; otherwise, returns false.
Signature

public Boolean isNumeric()

Return Value

Type: Boolean

Usage

A decimal point (1.2) is not a Unicode digit.

Example

```java
String numeric = '1234567890';
System.assert(numeric.isNumeric());
String alphanumeric = 'R32';
String decimalPoint = '1.2';
System.assert(!alphanumeric.isNumeric());
System.assert(!decimalPoint.isNumeric());
```

isNumericSpace()

Returns true if the current String contains only Unicode digits or spaces; otherwise, returns false.

Signature

public Boolean isNumericSpace()

Return Value

Type: Boolean

Usage

A decimal point (1.2) is not a Unicode digit.

Example

```java
String numericSpace = '1 2 3';
System.assert(numericSpace.isNumericSpace());
String notNumericspace = 'FD3S FC3S';
System.assert(!notNumericspace.isNumericspace());
```

isWhitespace()

Returns true if the current String contains only white space characters or is empty; otherwise, returns false.

Signature

public Boolean isWhitespace()
Return Value
Type: Boolean

Example
```java
String whitespace = ' ';
String blank = '';  
System.assert(whitespace.isWhitespace());
System.assert(blank.isWhitespace());
String alphanum = 'SIL80';
System.assert(!alphanum.isWhitespace());
```

**join(iterableObj, separator)**
Joins the elements of the specified iterable object, such as a List, into a single String separated by the specified separator.

**Signature**
```java
public static String join(Object iterableObj, String separator)
```

**Parameters**
- **iterableObj**
  Type: Object
- **separator**
  Type: String

**Return Value**
Type: String

**Usage**
```java
List<Integer> li = new List<Integer>{10, 20, 30};
String s = String.join(li, '/');
System.assertEquals('10/20/30', s);
```

**lastIndexOf(substring)**
Returns the index of the last occurrence of the specified substring. If the substring does not occur, this method returns -1.

**Signature**
```java
public Integer lastIndexOf(String substring)
```
Parameters

substring
Type: String

Return Value
Type: Integer

Example

```java
String s1 = 'abcdefgc';
Integer i1 = s1.lastIndexOf('c');
System.assertEquals(7, i1);
```

`lastIndexOf(substring, endPosition)`

Returns the index of the last occurrence of the specified substring, starting from the character at index 0 and ending at the specified index.

Signature

```java
public Integer lastIndexOf(String substring, Integer endPosition)
```

Parameters

substring
Type: String

definition

Type: Integer

Usage

If the substring doesn't occur or `endPosition` is negative, this method returns -1. If `endPosition` is larger than the last index in the current String, the entire String is searched.

Example

```java
String s1 = 'abcdaacd';
Integer i1 = s1.lastIndexOf('c', 7);
System.assertEquals(6, i1);
Integer i2 = s1.lastIndexOf('c', 3);
System.assertEquals(2, i2);
```

`lastIndexOfChar(character)`

Returns the index of the last occurrence of the character that corresponds to the specified character value.
Signature
public Integer lastIndexOfChar(Integer character)

Parameters
character
Type: Integer
The integer value of the character in the string.

Return Value
Type: Integer
The index of the last occurrence of the specified character, -1 if the character is not found.

Usage
The index that this method returns is in Unicode code units.

Example
String str = '\u03A9 is Ω (Omega)';
// Get the last occurrence of Omega.
System.assertEquals(5, str.lastIndexOfChar(937));

lastIndexOfChar(character, endIndex)
Returns the index of the last occurrence of the character that corresponds to the specified character value, starting from the specified index.

Signature
public Integer lastIndexOfChar(Integer character, Integer endIndex)

Parameters
character
Type: Integer
The integer value of the character to look for.
endIndex
Type: Integer
The index to end the search at.

Return Value
Type: Integer
The index, starting from the specified start index, of the last occurrence of the specified character. -1 if the character is not found.
Usage

The index that this method returns is in Unicode code units.

Example

This example shows different ways of searching for the index of the last occurrence of the Omega character. The first call to `lastIndexOfChar` doesn’t specify an end index and therefore the returned index is 12, which is the last occurrence of Omega in the entire string. The subsequent calls specify an end index to find the last occurrence of Omega in substrings.

```java
String str = 'Ω and \u03A9 and Ω';
System.assertEquals(12, str.lastIndexOfChar(937));
System.assertEquals(6, str.lastIndexOfChar(937,11));
System.assertEquals(0, str.lastIndexOfChar(937,5));
```

`lastIndexOfIgnoreCase(substring)`

Returns the index of the last occurrence of the specified substring regardless of case.

Signature

```java
public Integer lastIndexOfIgnoreCase(String substring)
```

Parameters

`substring`
Type: `String`

Return Value

Type: `Integer`

Usage

If the substring doesn’t occur, this method returns -1.

Example

```java
String s1 = 'abcdaacd';
Integer i1 = s1.lastIndexOfIgnoreCase('DAAC');
System.assertEquals(3, i1);
```

`lastIndexOfIgnoreCase(substring, endPosition)`

Returns the index of the last occurrence of the specified substring regardless of case, starting from the character at index 0 and ending at the specified index.

Signature

```java
public Integer lastIndexOfIgnoreCase(String substring, Integer endPosition)
```
Parameters

substring
Type: String

denPosition
Type: Integer

Return Value
Type: Integer

Usage
If the substring doesn't occur or endPosition is negative, this method returns -1. If endPosition is larger than the last index in the current String, the entire String is searched.

Example

```java
String s1 = 'abcdaacd';
Integer i1 = s1.lastIndexOfIgnoreCase('C', 7);
System.assertEquals(6, i1);
```

left(length)

Returns the leftmost characters of the current String of the specified length.

Signature

```java
public String left(Integer length)
```

Parameters

length
Type: Integer

Return Value
Type: String

Usage
If length is greater than the String size, the entire String is returned.

Example

```java
String s1 = 'abcdaacd';
String s2 = s1.left(3);
System.assertEquals('abc', s2);
```
**leftPad(length)**

Returns the current String padded with spaces on the left and of the specified length.

**Signature**

```java
public String leftPad(Integer length)
```

**Parameters**

- `length`
  
  Type: `Integer`

**Usage**

If `length` is less than or equal to the current String size, the entire String is returned without space padding.

**Return Value**

Type: `String`

**Example**

```java
String s1 = 'abc';
String s2 = s1.leftPad(5);
System.assertEquals(' abc', s2);
```

**leftPad(length, padStr)**

Returns the current String padded with String `padStr` on the left and of the specified length.

**Signature**

```java
public String leftPad(Integer length, String padStr)
```

**Parameters**

- `length`
  
  Type: `Integer`

- `padStr`
  
  Type: `String`

  String to pad with; if null or empty treated as single blank.

**Usage**

If `length` is less than or equal to the current String size, the entire String is returned without space padding.

**Return Value**

Type: `String`
Example

```java
String s1 = 'abc';
String s2 = 'xy';
String s3 = s1.leftPad(7, s2);
System.assertEquals('xyxyabc', s3);
```

length()

Returns the number of 16-bit Unicode characters contained in the String.

Signature

```java
public Integer length()
```

Return Value

Type: Integer

Example

```java
String myString = 'abcd';
Integer result = myString.length();
System.assertEquals(result, 4);
```

mid(startIndex, length)

Returns a new String that begins with the character at the specified zero-based `startIndex` with the number of characters specified by `length`.

Signature

```java
public String mid(Integer startIndex, Integer length)
```

Parameters

- `startIndex`
  - Type: `Integer`
  - If `startIndex` is negative, it is considered to be zero.

- `length`
  - Type: `Integer`
  - If `length` is negative or zero, an empty String is returned. If `length` is greater than the remaining characters, the remainder of the String is returned.

Return Value

Type: `String`
Usage

This method is similar to the `substring(startIndex)` and `substring(startIndex, endIndex)` methods, except that the second argument is the number of characters to return.

Example

```java
String s = 'abcde';
String s2 = s.mid(2, 3);
System.assertEquals('cde', s2);
```

**normalizeSpace()**

Returns the current String with leading, trailing, and repeating white space characters removed.

**Signature**

```java
public String normalizeSpace()
```

**Return Value**

Type: String

**Usage**

This method normalizes the following white space characters: space, tab (\t), new line (\n), carriage return (\r), and form feed (\f).

**Example**

```java
String s1 = 'Salesforce \t force.com';
String s2 = s1.normalizeSpace();
System.assertEquals('Salesforce force.com', s2);
```

**offsetByCodePoints(index, codePointOffset)**

Returns the index of the Unicode code point that is offset by the specified number of code points, starting from the given index.

**Signature**

```java
public Integer offsetByCodePoints(Integer index, Integer codePointOffset)
```

**Parameters**

- `index`  
  Type: Integer  
  The start index in the string.
**codePointOffset**

Type: `Integer`

The number of code points to be offset.

**Return Value**

Type: `Integer`

The index that corresponds to the start index that is added to the offset.

**Usage**

Unpaired surrogates within the text range that is specified by `index` and `codePointOffset` count as one code point each.

**Example**

This example calls `offsetByCodePoints` on a string with a start index of 0 (to start from the first character) and an offset of three code points. The string contains one sequence of supplementary characters in escaped form (a pair of characters). After an offset of three code points when counting from the beginning of the string, the returned code point index is four.

```java
String str = 'A \uD835\uDD0A BC';
System.assertEquals(4, str.offsetByCodePoints(0,3));
```

**remove(substring)**

Removes all occurrences of the specified substring and returns the String result.

**Signature**

```java
public String remove(String substring)
```

**Parameters**

- `substring`
  
  Type: `String`

**Return Value**

Type: `String`

**Example**

```java
String s1 = 'Salesforce and force.com';
String s2 =
  s1.remove('force');
System.assertEquals(
  'Sales and .com', s2);
```

**removeEnd(substring)**

Removes the specified substring only if it occurs at the end of the String.
Signature

public String removeEnd(String substring)

Parameters

substring
Type: String

Return Value
Type: String

Example

```java
String s1 = 'Salesforce and force.com';
String s2 =
    s1.removeEnd('.com');
System.assertEquals(
    'Salesforce and force', s2);
```

removeEndIgnoreCase(substring)
Removes the specified substring only if it occurs at the end of the String using a case-insensitive match.

Signature

public String removeEndIgnoreCase(String substring)

Parameters

substring
Type: String

Return Value
Type: String

Example

```java
String s1 = 'Salesforce and force.com';
String s2 = s1.removeEndIgnoreCase('.COM');
System.assertEquals('Salesforce and force', s2);
```

removeStart(substring)
Removes the specified substring only if it occurs at the beginning of the String.

Signature

public String removeStart(String substring)
Parameters

substring
Type: String

Return Value
Type: String

Example

```java
String s1 = 'Salesforce and force.com';
String s2 =
    s1.removeStart('Sales');
System.assertEquals(
    'force and force.com', s2);
```

**removeStartIgnoreCase(substring)**

Removes the specified substring only if it occurs at the beginning of the String using a case-insensitive match.

Signature

```java
public String removeStartIgnoreCase(String substring)
```

Parameters

substring
Type: String

Return Value
Type: String

Example

```java
String s1 = 'Salesforce and force.com';
String s2 =
    s1.removeStartIgnoreCase('SALES');
System.assertEquals(
    'force and force.com', s2);
```

**repeat(numberOfTimes)**

Returns the current String repeated the specified number of times.

Signature

```java
public String repeat(Integer numberOfTimes)
```
Parameters

numberOfTimes
Type: Integer

Return Value
Type: String

Example

```java
String s1 = 'SFDC';
String s2 = s1.repeat(2);
System.assertEquals('SFDCSFDC', s2);
```

**repeat(separator, numberOfTimes)**

Returns the current String repeated the specified number of times using the specified separator to separate the repeated Strings.

**Signature**

```java
public String repeat(String separator, Integer numberOfTimes)
```

**Parameters**

separator
Type: String

numberOfTimes
Type: Integer

**Return Value**
Type: String

**Example**

```java
String s1 = 'SFDC';
String s2 = s1.repeat('-', 2);
System.assertEquals('SFDC-SFDC', s2);
```

**replace(target, replacement)**

Replaces each substring of a string that matches the literal target sequence `target` with the specified literal replacement sequence `replacement`.

**Signature**

```java
public String replace(String target, String replacement)
```
Parameters

target
  Type: String

replacement
  Type: String

Return Value
  Type: String

Example

```java
String s1 = 'abcdbca';
String target = 'bc';
String replacement = 'xy';
String s2 = s1.replace(target, replacement);
System.assertEquals('axydxya', s2);
```

`replaceAll(regExp, replacement)`

Replaces each substring of a string that matches the regular expression `regExp` with the replacement sequence `replacement`.

Signature

```java
public String replaceAll(String regExp, String replacement)
```

Parameters

`regExp`
  Type: String

`replacement`
  Type: String

Return Value
  Type: String

Usage

See the Java `Pattern` class for information on regular expressions.

Example

```java
String s1 = 'a b c 5 xyz';
String regExp = '[a-zA-Z]';
String replacement = '1';
String s2 = s1.replaceAll(regExp, replacement);
System.assertEquals('1 1 1 5 111', s2);
```
**replaceFirst(regExp, replacement)**

Replaces the first substring of a string that matches the regular expression `regExp` with the replacement sequence `replacement`.

**Signature**

```java
public String replaceFirst(String regExp, String replacement)
```

**Parameters**

- `regExp`
  - Type: `String`
- `replacement`
  - Type: `String`

**Return Value**

Type: `String`

**Usage**

See the Java `Pattern` class for information on regular expressions.

**Example**

```java
String s1 = 'a b c 11 xyz';
String regExp = '[a-zA-Z]{2}';
String replacement = '2';
String s2 = s1.replaceFirst(regExp, replacement);
System.assertEquals('a b c 11 2z', s2);
```

**reverse()**

Returns a String with all the characters reversed.

**Signature**

```java
public String reverse()
```

**Return Value**

Type: `String`

**right(length)**

Returns the rightmost characters of the current String of the specified length.

**Signature**

```java
public String right(Integer length)
```
Parameters

\( \text{length} \)
Type: Integer

If \( \text{length} \) is greater than the String size, the entire String is returned.

Return Value
Type: String

Example

```java
String s1 = 'Hello Max';
String s2 =  
s1.right(3);
System.assertEquals(
 'Max', s2);
```

**rightPad(length)**

Returns the current String padded with spaces on the right and of the specified length.

**Signature**

```
public String rightPad(Integer length)
```

Parameters

\( \text{length} \)
Type: Integer

If \( \text{length} \) is less than or equal to the current String size, the entire String is returned without space padding.

Return Value
Type: String

Example

```java
String s1 = 'abc';
String s2 =  
s1.rightPad(5);
System.assertEquals(
 'abc ', s2);
```

**rightPad(length, padStr)**

Returns the current String padded with String \( \text{padStr} \) on the right and of the specified length.
Signature

public String rightPad(Integer length, String padStr)

Parameters

length
Type: Integer

padStr
Type: String
String to pad with; if null or empty treated as single blank.

Usage

If length is less than or equal to the current String size, the entire String is returned without space padding.

Return Value

Type: String

Example

```java
String s1 = 'abc';
String s2 = 'xy';
String s3 = s1.rightPad(7, s2);
System.assertEquals('abcxyxy', s3);
```

split(regExp)

Returns a list that contains each substring of the String that is terminated by either the regular expression regExp or the end of the String.

Signature

public String[] split(String regExp)

Parameters

regExp
Type: String

Return Value

Type: String[]

Note: In API version 34.0 and earlier, a zero-width regExp value produces an empty list item at the beginning of the method's output.

Usage

See the Java Pattern class for information on regular expressions.
The substrings are placed in the list in the order in which they occur in the String. If \textit{regExp} does not match any part of the String, the resulting list has just one element containing the original String.

\textbf{Example}

In the following example, a string is split using a backslash as a delimiter.

\begin{verbatim}
public String splitPath(String filename) {
    if (filename == null)
        return null;
    List<String> parts = filename.split("\\");
    filename = parts[parts.size()-1];
    return filename;
}
\end{verbatim}

// For example, if the file path is e:\\processed\\PPDSF100111.csv
// This method splits the path and returns the last part.
// Returned filename is PPDSF100111.csv

\textbf{split}(\textit{regExp}, \textit{limit})

Returns a list that contains each substring of the String that is terminated by either the regular expression \textit{regExp} or the end of the String.

\textbf{Signature}

\begin{verbatim}
public String[] split(String regExp, Integer limit)
\end{verbatim}

\textbf{Parameters}

\begin{itemize}
    \item \textit{regExp} \\
        Type: \textit{String} \\
        A regular expression.
    \item \textit{limit} \\
        Type: \textit{Integer}
\end{itemize}

\textbf{Return Value}

Type: \textit{String[]}

\begin{itemize}
    \item \textbf{Note:} In API version 34.0 and earlier, a zero-width \textit{regExp} value produces an empty list item at the beginning of the method’s output.
\end{itemize}

\textbf{Usage}

The optional \textit{limit} parameter controls the number of times the pattern is applied and therefore affects the length of the list.

- If \textit{limit} is greater than zero:
  - The pattern is applied a maximum of \((\textit{limit} - 1)\) times.
  - The list’s length is no greater than \textit{limit}.
  - The list’s last entry contains all input beyond the last matched delimiter.
• If \( \text{limit} \) is non-positive, the pattern is applied as many times as possible, and the list can have any length.
• If \( \text{limit} \) is zero, the pattern is applied as many times as possible, the list can have any length, and trailing empty strings are discarded.

Example
For example, for `String s = 'boo:and:moo'`:

- `s.split(';', 2)` results in `{'boo', 'and:moo'}`
- `s.split(';', 5)` results in `{'boo', 'and', 'moo'}`
- `s.split(';', -2)` results in `{'boo', 'and', 'moo'}`
- `s.split('o', 5)` results in `{'b', '', ':and:m', '', ''}`
- `s.split('o', -2)` results in `{'b', '', ':and:m', '', ''}`
- `s.split('o', 0)` results in `{'b', '', ':and:m'}`

splitByCharacterType()
Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens.

Signature
```
public List<String> splitByCharacterType()
```

Return Value
Type: `List<String>`

Usage
For more information about the character types used, see `java.lang.Character.getType(char)`.

Example
```
String s1 = 'Lightning.platform';
List<String> ls =
    s1.splitByCharacterType();
System.debug(ls);
// Writes this output:
// (L, ightning, ., platform)
```

splitByCharacterTypeCamelCase()
Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens, with the following exception: the uppercase character, if any, immediately preceding a lowercase character token belongs to the following character token rather than to the preceding.

Signature
```
public List<String> splitByCharacterTypeCamelCase()
```
Return Value
Type: List<String>

Usage
For more information about the character types used, see java.lang.Character.getType(char).

Example
```java
String s1 = 'Lightning.platform';
List<String> ls =
    s1.splitByCharacterTypeCamelCase();
System.debug(ls);
// Writes this output:
// (Lightning, ., platform)
```

**startsWith (prefix)**

Returns true if the String that called the method begins with the specified prefix.

**Signature**
```
public Boolean startsWith(String prefix)
```

**Parameters**
```
prefix
  Type: String
```

Return Value
Type: Boolean

**Example**
```java
String s1 = 'AE86 vs EK9';
System.assert(s1.startsWith('AE86'));
```

**startsWithIgnoreCase (prefix)**

Returns true if the current String begins with the specified prefix regardless of the prefix case.

**Signature**
```
public Boolean startsWithIgnoreCase(String prefix)
```

**Parameters**
```
prefix
  Type: String
```

**Example**
```java
String s1 = 'AE86 vs EK9';
System.assert(s1.startsWithIgnoreCase('AE86'));
```
Return Value
Type: Boolean

Example

```java
String s1 = 'AE86 vs EK9';
System.assert(s1.startsWithIgnoreCase('ae86'));
```

stripHtmlTags()
Removes HTML markup and returns plain text.

Signature

```java
public String stripHtmlTags(String htmlInput)
```

Return Value
Type: String

Usage

⚠️ **Warning:** The stripHtmlTags function does not recursively strip tags; therefore, tags may still exist in the returned string. Do not use the stripHtmlTags function to sanitize input for inclusion as a raw HTML page. The unescaped output is not considered safe to include in an HTML document. The function will be deprecated in a future release.

Example

```java
String s1 = '<b>hello world</b>';  
String s2 = s1.stripHtmlTags();  
System.assertEquals('hello world', s2);
```

substring(startIndex)
Returns a new String that begins with the character at the specified zero-based startIndex and extends to the end of the String.

Signature

```java
public String substring(Integer startIndex)
```

Parameters

startIndex
Type: Integer

Return Value
Type: String
Example

```java
String s1 = 'hamburger';
System.assertEquals('burger', s1.substring(3));
```

**substring**(startIndex, endIndex)

Returns a new String that begins with the character at the specified zero-based `startIndex` and extends to the character at `endIndex` - 1.

**Signature**

```java
public String substring(Integer startIndex, Integer endIndex)
```

**Parameters**

- **startIndex**
  - Type: Integer
- **endIndex**
  - Type: Integer

**Return Value**

Type: String

**Example**

```java
'hamburger'.substring(4, 8);
// Returns "urge"

'smiles'.substring(1, 5);
// Returns "mile"
```

**substringAfter**(separator)

Returns the substring that occurs after the first occurrence of the specified separator.

**Signature**

```java
public String substringAfter(String separator)
```

**Parameters**

- **separator**
  - Type: String

**Return Value**

Type: String
Example

```java
String s1 = 'Salesforce.Lightning.platform';
String s2 =
    s1.substringAfter('.');
System.assertEquals('Lightning.platform', s2);
```

`substringAfterLast(separator)`

Returns the substring that occurs after the last occurrence of the specified separator.

Signature

```java
public String substringAfterLast(String separator)
```

Parameters

`separator`

Type: `String`

Return Value

Type: `String`

Example

```java
String s1 = 'Salesforce.Lightning.platform';
String s2 =
    s1.substringAfterLast('.');
System.assertEquals('platform', s2);
```

`substringBefore(separator)`

Returns the substring that occurs before the first occurrence of the specified separator.

Signature

```java
public String substringBefore(String separator)
```

Parameters

`separator`

Type: `String`

Return Value

Type: `String`
Example

```java
String s1 = 'Salesforce.Lightning.platform';
String s2 =
    s1.substringBefore('.');
System.assertEquals('Salesforce', s2);
```

**substringBeforeLast(separator)**

Returns the substring that occurs before the last occurrence of the specified separator.

**Signature**

```java
public String substringBeforeLast(String separator)
```

**Parameters**

- `separator`
  - Type: `String`

**Return Value**

- Type: `String`

Example

```java
String s1 = 'Salesforce.Lightning.platform';
String s2 =
    s1.substringBeforeLast('.');
System.assertEquals('Salesforce.Lightning', s2);
```

**substringBetween(tag)**

Returns the substring that occurs between two instances of the specified `tag` `String`.

**Signature**

```java
public String substringBetween(String tag)
```

**Parameters**

- `tag`
  - Type: `String`

**Return Value**

- Type: `String`
Example

```java
String s1 = 'tagYellowtag';
String s2 = s1.substringBetween('tag');
System.assertEquals('Yellow', s2);
```

`substringBetween(open, close)`

Returns the substring that occurs between the two specified Strings.

Signature

```java
public String substringBetween(String open, String close)
```

Parameters

- `open`
  - Type: String

- `close`
  - Type: String

Return Value

Type: String

Example

```java
String s1 = 'xYellowy';
String s2 =
    s1.substringBetween('x','y');
System.assertEquals('Yellow', s2);
```

`swapCase()`

Swaps the case of all characters and returns the resulting String by using the default (English US) locale.

Signature

```java
public String swapCase()
```

Return Value

Type: String

Usage

Upper case and title case converts to lower case, and lower case converts to upper case.
Example

```java
String s1 = 'Force.com';
String s2 = s1.swapCase();
System.assertEquals('fORCE.COM', s2);
```

toLowerCase()

Converts all of the characters in the String to lowercase using the rules of the default (English US) locale.

**Signature**

```java
public String toLowerCase()
```

**Return Value**

Type: `String`

**Example**

```java
String s1 = 'This is hard to read';
System.assertEquals('this is hard to read',
                   s1.toLowerCase());
```

toLowerCase(locale)

Converts all of the characters in the String to lowercase using the rules of the specified locale.

**Signature**

```java
public String toLowerCase(String locale)
```

**Parameters**

- `locale`
  Type: `String`

**Return Value**

Type: `String`

**Example**

```java
// Example in Turkish
// An uppercase dotted "i", \u0304, which is İ
// Note this contains both a İ as well as a I
String s1 = 'KIYMETLİ';
String s1Lower = s1.toLowerCase('tr');
// Dotless lowercase "i", \u0131, which is ı
// Note this has both a i and ı
String expected = 'kıymetli';
```
System.assertEquals(expected, s1Lower);
// Note if this was done in toLowerCase('en'), it would output 'kiymetli'

toUpperCase()

Converts all of the characters in the String to uppercase using the rules of the default (English US) locale.

**Signature**

```java
public String toUpperCase()
```

**Return Value**

Type: String

**Example**

```java
String myString1 = 'abcd';
String myString2 = 'ABCD';
myString1 =
    myString1.toUpperCase();
Boolean result =
    myString1.equals(myString2);
System.assertEquals(result, true);
```

toUpperCase(locale)

Converts all of the characters in the String to the uppercase using the rules of the specified locale.

**Signature**

```java
public String toUpperCase(String locale)
```

**Parameters**

locale
Type: String

**Return Value**

Type: String

**Example**

```java
// Example in Turkish
// Dotless lowercase "i", \u0131, which is ı
// Note this has both a i and ı
String s1 = 'imkansız';
String s1Upper = s1.toUpperCase('tr');
// An uppercase dotted "i", \u0304, which is İ
// Note this contains both a İ as well as a I
```
trim()

Returns a copy of the string that no longer contains any leading or trailing white space characters.

Signature

public String trim()

Return Value

Type: String

Usage

Leading and trailing ASCII control characters such as tabs and newline characters are also removed. White space and control characters that aren’t at the beginning or end of the sentence aren’t removed.

Example

String s1 = ' Hello! ';
String trimmed = s1.trim();
System.assertEquals('Hello!', trimmed);

uncapitalize()

Returns the current String with the first letter in lowercase.

Signature

public String uncapitalize()

Return Value

Type: String

Example

String s1 = 'Hello max';
String s2 = s1.uncapitalize();
System.assertEquals('hello max', s2);
unescapeCsv()

Returns a String representing an unescaped CSV column.

Signature

public String unescapeCsv()

Return Value

Type: String

Usage

If the String is enclosed in double quotes and contains a comma, newline or double quote, quotes are removed. Also, any double quote escaped characters (a pair of double quotes) are unescaped to just one double quote.

If the String is not enclosed in double quotes, or is and does not contain a comma, newline or double quote, it is returned unchanged.

Example

```java
String s1 = "Max1, "Max2"");
String s2 = s1.unescapeCsv();
System.assertEquals('Max1, "Max2"', s2);
```

unescapeEcmaScript()

Unescapes any EcmaScript literals found in the String.

Signature

public String unescapeEcmaScript()

Return Value

Type: String

Example

```java
String s1 = "'3.8',"3.9"';
String s2 = s1.unescapeEcmaScript();
System.assertEquals('"3.8","3.9"', s2);
```
unescapeHtml3()
Unescapes the characters in a String using HTML 3.0 entities.

Signature
public String unescapeHtml3()

Return Value
Type: String

Example
String s1 = '
&quot;&lt;Black&lt;White&gt;&quot;&
String s2 =
  s1.unescapeHtml3();
System.assertEquals(""<&Black&White>"",
  s2);

unescapeHtml4()
Unescapes the characters in a String using HTML 4.0 entities.

Signature
public String unescapeHtml4()

Return Value
Type: String

Usage
If an entity isn’t recognized, it is kept as is in the returned string.

Example
String s1 = '
&quot;&lt;Black&amp;White&gt;&quot;
String s2 =
  s1.unescapeHtml4();
System.assertEquals(""<&Black&White>"",
  s2);
unescapeJava()  
Returns a String whose Java literals are unescaped. Literals unescaped include escape sequences for quotes (\") and control characters, such as tab (\t), and carriage return (\n).

Signature  
public String unescapeJava()

Return Value  
Type: String
The unescaped string.

Example  
```java
String s = 'Company: \"Salesforce.com\"';
String unescapedStr = s.unescapeJava();
System.assertEquals('Company: "Salesforce.com"', unescapedStr);
```

unescapeUnicode()  
Returns a String whose escaped Unicode characters are unescaped.

Signature  
public String unescapeUnicode()

Return Value  
Type: String
The unescaped string.

Example  
```java
String s = 'De onde você é?';
String unescapedStr = s.unescapeUnicode();
System.assertEquals('De onde você é?', unescapedStr);
```

unescapeXml()  
Unescapes the characters in a String using XML entities.

Signature  
public String unescapeXml()

Return Value  
Type: String
Usage
Supports only the five basic XML entities (gt, lt, quot, amp, apos). Does not support DTDs or external entities.

Example
```
String s1 =
    '"&quot;&amp;Black&amp;White&gt;&amp;quot;';
String s2 =
    s1.unescapeXml();
System.assertEquals(
    '"&lt;Black&amp;White&gt;"',
    s2);
```

valueOf(dateToConvert)
Returns a String that represents the specified Date in the standard "yyyy-MM-dd" format.

Signature
```
public static String valueOf(Date dateToConvert)
```

Parameters
dateToConvert
Type: Date

Return Value
Type: String

Example
```
Date myDate = Date.Today();
String sDate = String.valueOf(myDate);
```

valueOf(datetimeToConvert)
Returns a String that represents the specified Datetime in the standard "yyyy-MM-dd HH:mm:ss" format for the local time zone.

Signature
```
public static String valueOf(Datetime datetimeToConvert)
```

Parameters
datetimeToConvert
Type: Datetime
Return Value
Type: String

Example
```
DateTime dt = datetime.newInstance(1996, 6, 23);
String sDateTime = String.valueOf(dt);
System.assertEquals('1996-06-23 00:00:00', sDateTime);
```

valueOf(decimalToConvert)
Returns a String that represents the specified Decimal.

Signature
```
public static String valueOf(Decimal decimalToConvert)
```

Parameters
```
decimalToConvert
  Type: Decimal
```

Return Value
Type: String

Example
```
Decimal dec = 3.14159265;
String sDecimal = String.valueOf(dec);
System.assertEquals('3.14159265', sDecimal);
```

valueOf(doubleToConvert)
Returns a String that represents the specified Double.

Signature
```
public static String valueOf(Double doubleToConvert)
```

Parameters
```
doubleToConvert
  Type: Double
```

Return Value
Type: String
Example

```java
Double myDouble = 12.34;
String myString = String.valueOf(myDouble);
System.assertEquals('12.34', myString);
```

**valueOf(integerToConvert)**

Returns a String that represents the specified Integer.

**Signature**

```java
public static String valueOf(Integer integerToConvert)
```

**Parameters**

- `integerToConvert`  
  Type: `Integer`

**Return Value**

Type: `String`

**Example**

```java
Integer myInteger = 22;
String sInteger = String.valueOf(myInteger);
System.assertEquals('22', sInteger);
```

**valueOf(longToConvert)**

Returns a String that represents the specified Long.

**Signature**

```java
public static String valueOf(Long longToConvert)
```

**Parameters**

- `longToConvert`  
  Type: `Long`

**Return Value**

Type: `String`
Example

```java
Long myLong = 123456789;
String sLong = String.valueOf(myLong);
System.assertEquals('123456789', sLong);
```

**valueOf(toConvert)**

Returns a string representation of the specified object argument.

**Signature**

```java
public static String valueOf(Object toConvert)
```

**Parameters**

`toConvert`

Type: Object

**Return Value**

Type: String

**Usage**

If the argument is not a String, the `valueOf` method converts it into a String by calling the `toString` method on the argument, if available, or any overridden `toString` method if the argument is a user-defined type. Otherwise, if no `toString` method is available, it returns a String representation of the argument.

Example

```java
List<Integer> ls =
    new List<Integer>();
ls.add(10);
ls.add(20);
String strList =
    String.valueOf(ls);
System.assertEquals(
    '(10, 20)', strList);
```

**valueOfGmt(datetimeToConvert)**

Returns a String that represents the specified Datetime in the standard "yyyy-MM-dd HH:mm:ss" format for the GMT time zone.

**Signature**

```java
public static String valueOfGmt(Datetime datetimeToConvert)
```
Parameters

datetimeToConvert
  Type: Datetime

Return Value
  Type: String

Example

```java
// For a PST timezone:
DateTime dt = datetime.newInstance(2001, 9, 14);
String sDateTime = String.valueOfGmt(dt);
System.assertEquals('2001-09-14 07:00:00', sDateTime);
```

StubProvider Interface

StubProvider is a callback interface that you can use as part of the Apex stub API to implement a mocking framework. Use this interface with the Test.createStub() method to create stubbed Apex objects for testing.

Namespace

System

Usage

The StubProvider interface allows you to define the behavior of a stubbed Apex class. The interface specifies a single method that requires implementing: handleMethodCall(). You specify the behavior of each method of the stubbed class in the handleMethodCall() method.

In your Apex test, you create a stubbed object using the Test.createStub() method. When you invoke methods on the stubbed object, StubProvider.handleMethodCall() is called, which performs the behavior that you've specified for each method.

IN THIS SECTION:
  StubProvider Methods

SEE ALSO:
  Apex Developer Guide: Build a Mocking Framework with the Stub API
  createStub(parentType, stubProvider)

StubProvider Methods

The following are methods for StubProvider.
handleMethodCall(stubbedObject, stubbedMethodName, returnType, listOfParamTypes, listOfParamNames, listOfArgs)
Use this method to define the behavior of each method of a stubbed class.

handleMethodCall(stubbedObject, stubbedMethodName, returnType, listOfParamTypes, listOfParamNames, listOfArgs)
Use this method to define the behavior of each method of a stubbed class.

Signature

public Object handleMethodCall(Object stubbedObject, String stubbedMethodName, System.Type returnType, List<System.Type> listOfParamTypes, List<String> listOfParamNames, List<Object> listOfArgs)

Parameters

stubbedObject
Type: Object
The stubbed object.

stubbedMethodName
Type: String
The name of the invoked method.

returnType
Type: System.Type
The return type of the invoked method.

listOfParamTypes
Type: ListYSTEM.Type>
A list of the parameter types of the invoked method.

listOfParamNames
Type: List<String>
A list of the parameter names of the invoked method.

listOfArgs
Type: List<Object>
The actual argument values passed into this method at runtime.

Return Value
Type: Object
Usage
You can use the parameters passed into this method to identify which method on the stubbed object was invoked. Then you can define the behavior for each identified method.

SEE ALSO:
Apex Developer Guide: Build a Mocking Framework with the Stub API

System Class
Contains methods for system operations, such as writing debug messages and scheduling jobs.

Namespace
System

System Methods
The following are methods for System. All methods are static.

IN THIS SECTION:
abortJob(jobId)
Stops the specified job. The stopped job is still visible in the job queue in the Salesforce user interface.
assert(condition, msg)
Asserts that the specified condition is true. If it isn’t, a fatal error is returned that causes code execution to halt.
assertEquals(expected, actual, msg)
Asserts that the first two arguments are the same. If they aren’t, a fatal error is returned that causes code execution to halt.
assertNotEquals(expected, actual, msg)
Asserts that the first two arguments are different. If they’re the same, a fatal error is returned that causes code execution to halt.
currentPageReference()
Returns a reference to the current page. This is used with Visualforce pages.
currentTimeMillis()
Returns the current time in milliseconds, which is expressed as the difference between the current time and midnight, January 1, 1970 UTC.
debug(msg)
Writes the specified message, in string format, to the execution debug log. The DEBUG log level is used.
debug(logLevel, msg)
Writes the specified message, in string format, to the execution debug log with the specified log level.
enqueueJob(queueableObj)
Adds a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID.
enqueueJob(queueable, delay)
Adds a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID. The job is scheduled with a specified minimum delay (0–10 minutes). The delay is ignored during Apex testing.
enqueueJob(queueable, asyncOptions)
Add a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID. Specify a unique signature for your queueable job, the maximum stack depth or the minimum queue delay in the asyncOptions parameter.

equals(obj1, obj2)
Returns true if both arguments are equal. Otherwise, returns false.

getAddressReadWriteMode()
Returns the read write mode set for an organization during Salesforce.com upgrades and downtimes.

getQuiddityShortCode(QuiddityValue)
Returns the short code for the Quiddity value of the current Request object.

hashCode(obj)
Returns the hash code of the specified object.

isBatch()
Returns true if a batch Apex job invoked the executing code, or false if not. In API version 35.0 and earlier, also returns true if a queueable Apex job invoked the code.

isFunctionCallback()
Returns true if an asynchronous Salesforce Function callback invoked the executing code, or false if not. Available in API version 51.0 and later.

isFuture()
Returns true if the currently executing code is invoked by code contained in a method annotated with future; false otherwise.

isQueueable()
Returns true if a queueable Apex job invoked the executing code. Returns false if not, including if a batch Apex job or a future method invoked the code.

isRunningElasticCompute()
Reserved for future use.

isScheduled()
Returns true if the currently executing code is invoked by a scheduled Apex job; false otherwise.

movePassword(targetUserId,sourceUserId)
Moves the specified user’s password to a different user.

now()
Returns the current date and time in the GMT time zone.

process(workItemIds, action, comments, nextApprover)
Processes the list of work item IDs.

purgeOldAsyncJobs(dt)
Deletes asynchronous Apex job records for jobs that have finished execution before the specified date with a Completed, Aborted, or Failed status, and returns the number of records deleted.

requestVersion()
Returns a two-part version that contains the major and minor version numbers of a package.

resetPassword(userId, sendUserEmail)
Resets the password for the specified user.
resetPasswordWithEmailTemplate(userId, sendUserEmail, emailTemplateName)
Resets the user’s password and sends an email to the user with their new password. You specify the email template that is sent to the specified user. Use this method for external users of Experience Cloud sites.

runAs(version)
Changes the current package version to the package version specified in the argument.

runAs(userSObject)
Changes the current user to the specified user.

schedule(jobName, cronExpression, schedulableClass)
Use schedule with an Apex class that implements the Schedulable interface to schedule the class to run at the time specified by a Cron expression.

scheduleBatch(batchable, jobName, minutesFromNow)
Schedules a batch job to run once in the future after the specified time interval and with the specified job name.

scheduleBatch(batchable, jobName, minutesFromNow, scopeSize)
Schedules a batch job to run once in the future after the specified the time interval, with the specified job name and scope size. Returns the scheduled job ID (CronTrigger ID).

setPassword(userId, password)
Sets the password for the specified user.

submit(workItemIds, comments, nextApprover)
Submits the processed approvals. The current user is the submitter and the entry criteria is evaluated for all processes applicable to the current user.

today()
Returns the current date in the current user’s time zone.

abortJob(jobId)

Stop the specified job. The stopped job is still visible in the job queue in the Salesforce user interface.

**Signature**

```java
public static Void abortJob(String jobId)
```

**Parameters**

`jobId`
Type: String

The `jobId` is the ID associated with either AsyncApexJob or CronTrigger.

**Return Value**

Type: Void

**Usage**

The following methods return the job ID that can be passed to `abortJob`.

- **System.schedule method**—returns the CronTrigger object ID associated with the scheduled job as a string.
• **SchedulableContext.getTriggerId method**—returns the CronTrigger object ID associated with the scheduled job as a string.

• **getJobId method**—returns the AsyncApexJob object ID associated with the batch job as a string.

• **Using Batch Apex**
  - **Database.executeBatch method**—returns the AsyncApexJob object ID associated with the batch job as a string.

---

**assert(condition, msg)**

Asserts that the specified condition is true. If it isn’t, a fatal error is returned that causes code execution to halt.

**Important:** We recommend that you use the methods of the Assert Class rather than this method. The System.Assert class provides methods that handle all types of logical assertions and comparisons, which improve the clarity of your Apex code.

**Signature**

```
public static Void assert(Boolean condition, Object msg)
```

**Parameters**

- **condition**
  - Type: Boolean

- **msg**
  - Type: Object
  - (Optional) Custom message returned as part of the error message.

**Return Value**

Type: Void

**Usage**

You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

---

**assertEquals(expected, actual, msg)**

Asserts that the first two arguments are the same. If they aren’t, a fatal error is returned that causes code execution to halt.

**Important:** We recommend that you use the methods of the Assert Class rather than this method. The System.Assert class provides methods that handle all types of logical assertions and comparisons, which improve the clarity of your Apex code.

**Signature**

```
public static Void assertEquals(Object expected, Object actual, Object msg)
```

**Parameters**

- **expected**
  - Type: Object
  - Specifies the expected value.
actual
  Type: Object
  Specifies the actual value.

msg
  Type: Object
  (Optional) Custom message returned as part of the error message.

Return Value
Type: Void

Usage
You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.

assertNotEquals(expected, actual, msg)
Asserts that the first two arguments are different. If they’re the same, a fatal error is returned that causes code execution to halt.

Important: We recommend that you use the methods of the Assert Class rather than this method. The System.Assert class provides methods that handle all types of logical assertions and comparisons, which improve the clarity of your Apex code.

Signature
public static Void assertNotEquals(Object expected, Object actual, Object msg)

Parameters
expected
  Type: Object
  Specifies the expected value.

actual
  Type: Object
  Specifies the actual value.

msg
  Type: Object
  (Optional) Custom message returned as part of the error message.

Return Value
Type: Void

Usage
You can’t catch an assertion failure using a try/catch block even though it’s logged as an exception.
currentPageReference()
Returns a reference to the current page. This is used with Visualforce pages.

Signature
public static System.PageReference currentPageReference()

Return Value
Type: System.PageReference

Usage
For more information, see PageReference Class.

currentTimeMillis()
Returns the current time in milliseconds, which is expressed as the difference between the current time and midnight, January 1, 1970 UTC.

Signature
public static Long currentTimeMillis()

Return Value
Type: Long

debug (msg)
Writes the specified message, in string format, to the execution debug log. The DEBUG log level is used.

Signature
public static Void debug(Object msg)

Parameters
msg
  Type: Object

Return Value
Type: Void

Usage
If the msg argument is not a string, the debug method calls String.valueOf to convert it into a string. The String.valueOf method calls the toString method on the argument, if available, or any overridden toString method if the argument is a user-defined type. Otherwise, if no toString method is available, it returns a string representation of the argument.
If the log level for Apex Code is set to `DEBUG` or higher, the message of this debug statement will be written to the debug log.

Note that when a map or set is printed, the output is sorted in key order and is surrounded with square brackets (```[]```). When an array or list is printed, the output is enclosed in parentheses (```()```).

Note: Calls to `System.debug` are not counted as part of Apex code coverage.

For more information on log levels, see Debug Log Levels in the Salesforce online help.

`debug(logLevel, msg)`

Writes the specified message, in string format, to the execution debug log with the specified log level.

**Signature**

```java
public static Void debug(LoggingLevel logLevel, Object msg)
```

**Parameters**

- `logLevel`
  - Type: `LoggingLevel Enum`
  - The logging level to set for this method.

- `msg`
  - Type: Object
  - The message or object to write in string format to the execution debug log.

**Return Value**

Type: Void

**Usage**

If the `msg` argument is not a string, the `debug` method calls `String.valueOf` to convert it into a string. The `String.valueOf` method calls the `toString` method on the argument, if available, or any overridden `toString` method if the argument is a user-defined type. Otherwise, if no `toString` method is available, it returns a string representation of the argument.

Note: Calls to `System.debug` are not counted as part of Apex code coverage.

For more information on log levels, see Debug Log Levels in the Salesforce online help.

`enqueueJob(queueableObj)`

Adds a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID.

**Signature**

```java
public static ID enqueueJob(Object queueableObj)
```
**Parameters**

`queueableObj`

*Type: Object*

An instance of the class that implements the Queueable Interface.

**Return Value**

*Type: ID*

The job ID, which corresponds to the ID of an AsyncApexJob record.

**Usage**

To add a job for asynchronous execution, call `System.enqueueJob` by passing in an instance of your class implementation of the Queueable Interface for execution as follows:

```java
ID jobID = System.enqueueJob(new MyQueueableClass());
```

For more information about Queueable Apex, including information about limits, see Queueable Apex.

**enqueueJob(queueable, delay)**

Adds a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID. The job is scheduled with a specified minimum delay (0–10 minutes). The delay is ignored during Apex testing.

**Signature**

```java
public static Id enqueueJob(Object queueable, Integer delay)
```

**Parameters**

`queueable`

*Type: Object*

An instance of the class that implements the Queueable Interface.

`delay`

*Type: Integer*

The minimum delay (0–10 minutes) before the queueable job is scheduled for execution.

The delay is ignored during Apex testing.

⚠️ **Warning:** When you set the delay to 0 (zero), the Queueable job is run as quickly as possible. With chained queueable jobs, implement a mechanism to slow down or halt the job if necessary. Without such a fail-safe mechanism in place, you can rapidly reach the daily async Apex limit.

**Return Value**

*Type: Id*

The job ID, which corresponds to the ID of an AsyncApexJob record.
Example

This example adds a job for delayed asynchronous execution by passing in an instance of your class implementation of the Queueable interface for execution. There's a minimum delay of 5 minutes before the job is executed.

```
Integer delayInMinutes = 5;
ID jobID = System.enqueueJob(new MyQueueableClass(), delayInMinutes);
```

For more information about Queueable Apex, including information about limits, see Queueable Apex.

enqueueJob (queueable, asyncOptions)

Adds a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID. Specify a unique signature for your queueable job, the maximum stack depth or the minimum queue delay in the asyncOptions parameter.

Signature

```
public static Id enqueueJob(Object queueable, Object asyncOptions)
```

Parameters

- **queueable**
  - Type: Object
  - An instance of the class that implements the Queueable Interface.

- **asyncOptions**
  - Type: AsyncOptions
  - Specify a unique signature for your queueable job, the maximum stack depth, or a minimum queue delay in the AsyncOptions class properties.

Return Value

Type: Id

The job ID, which corresponds to the ID of an AsyncApexJob record.

Usage

The System.AsyncInfo class methods help you determine if maximum stack depth is set in your Queueable request and get the stack depths and queue delay for queueables that are currently running. Use information about the current queueable execution to make decisions on adjusting delays on subsequent calls.

These are methods in the System.AsyncInfo class.

- hasMaxStackDepth()
- getCurrentQueueableStackDepth()
- getMaximumQueueableStackDepth()
- getMinimumQueueableDelayInMinutes()

For more information about Queueable Apex, including information about limits, see Queueable Apex.
equals(obj1, obj2)

Returns true if both arguments are equal. Otherwise, returns false.

Signature

public static Boolean equals(Object obj1, Object obj2)

Parameters

obj1
Type: Object
Object being compared.

obj2
Type: Object
Object to compare with the first argument.

Return Value

Type: Boolean

Usage

obj1 and obj2 can be of any type. They can be values, or object references, such as sObjects and user-defined types.

The comparison rules for System.equals are identical to the ones for the == operator. For example, string comparison is case insensitive. For information about the comparison rules, see the == operator.

getApplicationReadWriteMode()

Returns the read write mode set for an organization during Salesforce.com upgrades and downtimes.

Signature

public static System.ApplicationReadWriteMode getApplicationReadWriteMode()

Return Value

Type: System.ApplicationReadWriteMode

Valid values are:

- DEFAULT
- READ_ONLY

Using the System.ApplicationReadWriteMode Enum

Use the System.ApplicationReadWriteMode enum returned by the getApplicationReadWriteMode to programmatically determine if the application is in read-only mode during Salesforce upgrades and downtimes.

Valid values for the enum are:

- DEFAULT
public class myClass {
    public static void execute() {
        ApplicationReadWriteMode mode = System.getApplicationReadWriteMode();

        if (mode == ApplicationReadWriteMode.READ_ONLY) {
            // Do nothing. If DML operation is attempted in readonly mode,
            // InvalidReadOnlyUserDmlException will be thrown.
        } else if (mode == ApplicationReadWriteMode.DEFAULT) {
            Account account = new Account(name = 'my account');
            insert account;
        }
    }
}

getQuiddityShortCode(QuiddityValue)
Returns the short code for the Quiddity value of the current Request object.

Signature
public String getQuiddityShortCode(System.Quiddity QuiddityValue)

Parameters
QuiddityValue
    Type: System.Quiddity
    The Quiddity enum value that has an associated short code. This short code is used in Event Monitoring logs. For more information, see Apex Execution Event Type.

Return Value
Type: String

hashCode(obj)
Returns the hash code of the specified object.

Signature
public static Integer hashCode(Object obj)

Parameters
obj
    Type: Object
    The object to get the hash code for. This parameter can be of any type, including values or object references, such as sObjects or user-defined types.
Return Value
Type: Integer

Versioned Behavior Changes
In API version 51.0 and later, the `hashCode()` method returns the same hashCode for identical Id values. In API version 50.0 and earlier, identical Id values didn't always generate the same hashCode value.

`isBatch()`
Returns `true` if a batch Apex job invoked the executing code, or `false` if not. In API version 35.0 and earlier, also returns `true` if a queueable Apex job invoked the code.

Signature
`public static Boolean isBatch()`

Return Value
Type: Boolean

Usage
A batch Apex job can't invoke a future method. Before invoking a future method, use `isBatch()` to check whether the executing code is a batch Apex job.

`isFunctionCallback()`
Returns `true` if an asynchronous Salesforce Function callback invoked the executing code, or `false` if not. Available in API version 51.0 and later.

Signature
`public static Boolean isFunctionCallback()`

Return Value
Type: Boolean

Usage
Use this method to determine if the Apex code is being invoked as part of a callback from an asynchronous Salesforce Functions invocation. For more details on invoking Salesforce Functions from Apex, see Functions Namespace.

`isFuture()`
Returns `true` if the currently executing code is invoked by code contained in a method annotated with `future`; `false` otherwise.
**Signature**

```
public static Boolean isFuture()
```

**Return Value**

Type: Boolean

**Usage**

Since a future method can’t be invoked from another future method, use this method to check if the current code is executing within the context of a future method before you invoke a future method.

**isQueueable()**

Returns true if a queueable Apex job invoked the executing code. Returns false if not, including if a batch Apex job or a future method invoked the code.

**Signature**

```
public static Boolean isQueueable()
```

**Return Value**

Type: Boolean

**Usage**

```java
public class SimpleQueueable implements Queueable {

    String name;

    public SimpleQueueable(String name) {
        this.name = name;
        System.assert(!System.isQueueable()); //Should return false
    }

    public void execute(QueueableContext ctx) {
        Account testAccount = new Account();
        testAccount.name = 'testAcc';
        insert(testAccount);
        System.assert(System.isQueueable()); //Should return true
    }
}
```

```java
global class ComplexBatch implements Database.Batchable<SObject> {

    global Database.QueryLocator start(Database.BatchableContext info) {
        System.assert(!System.isQueueable()); //Should return false
        return Database.getQueryLocator(([SELECT Id, Name FROM Account LIMIT 1]);
    }

    global void execute(Database.BatchableContext info, SObject[] scope) {
```
isRunningElasticCompute()
Reserved for future use.

Signature
public static Boolean isRunningElasticCompute()

Return Value
Type: Boolean

isScheduled()
Returns true if the currently executing code is invoked by a scheduled Apex job; false otherwise.

Signature
public static Boolean isScheduled()

Return Value
Type: Boolean

movePassword(targetUserId, sourceUserId)
Moves the specified user's password to a different user.

Signature
public static Void movePassword(ID targetUserId, ID sourceUserId)

Parameters

targetUserId
Type: ID
The user that the password is moved to.

sourceUserId
Type: ID
The user that the password is moved from.
Return Value
Type: Void

Usage
Moving a password simplifies converting a user to another type of user, such as when converting an external user to a user with less restrictive access. If you require access to the movePassword method, contact Salesforce.

Keep in mind these requirements.
- The targetUserId, sourceUserId, and user performing the move operation must all belong to the same Salesforce org.
- The targetUserId and the sourceUserId cannot be the same as the user performing the move operation.
- A user without a password can't be specified as the sourceUserId. For example, a source user who has already had their password moved is left without a password. That user can’t be a source user again.

After the password is moved:
- The target user can log in with the password.
- The source user no longer has a password. To enable logins for this user, a password reset is required.

now()
Returns the current date and time in the GMT time zone.

Signature
public static Datetime now()

Return Value
Type: Datetime

process(workItemIds, action, comments, nextApprover)
Processes the list of work item IDs.

Signature
public static List<Id> process(List<Id> workItemIds, String action, String comments, String nextApprover)

Parameters
workItemIds
  Type: List<Id>
action
  Type: String
comments
  Type: String
nextApprover
  Type: String
Return Value
Type: List<Id>

**purgeOldAsyncJobs (dt)**
Deletes asynchronous Apex job records for jobs that have finished execution before the specified date with a Completed, Aborted, or Failed status, and returns the number of records deleted.

**Signature**

```java
public static Integer purgeOldAsyncJobs(Date dt)
```

**Parameters**

dt
  Type: Date
  Specifies the date up to which old records are deleted. The date comparison is based on the `CompletedDate` field of `AsyncApexJob`, which is in the GMT time zone.

**Return Value**
Type: Integer

**Usage**
Asynchronous Apex job records are records in `AsyncApexJob`.
The system cleans up asynchronous job records for jobs that have finished execution and are older than seven days. You can use this method to further reduce the size of `AsyncApexJob` by cleaning up more records.
Each execution of this method counts as a single row against the governor limit for DML statements.

**Example**
This example shows how to delete all job records for jobs that have finished before today’s date.

```java
Integer count = System.purgeOldAsyncJobs(Date.today());
System.debug('Deleted ' + count + ' old jobs.);
```

**requestVersion()**
Returns a two-part version that contains the major and minor version numbers of a package.

**Signature**

```java
public static System.Version requestVersion()
```

**Return Value**
Type: System.Version
Usage
Using this method, you can determine the version of an installed instance of your package from which the calling code is referencing your package. Based on the version that the calling code has, you can customize the behavior of your package code.

The requestVersion method isn’t supported for unmanaged packages. If you call it from an unmanaged package, an exception will be thrown.

```
resetPassword(userId, sendUserEmail)
```

Resets the password for the specified user.

**Signature**

```
public static System.ResetPasswordResult resetPassword(ID userId, Boolean sendUserEmail)
```

**Parameters**

- `userId` 
  Type: ID

- `sendUserEmail` 
  Type: Boolean

**Return Value**

Type: System.ResetPasswordResult

**Usage**

When the user logs in with the new password, they are prompted to enter a new password, and to select a security question and answer if they haven’t already. If you specify `true` for `sendUserEmail`, the user is sent an email notifying them that their password was reset. A link to sign onto Salesforce using the new password is included in the email. Use `setPassword(userId, password)` if you don’t want the user to be prompted to enter a new password when they log in.

⚠️ **Warning**: Be careful with this method, and do not expose this functionality to end-users.

```
resetPasswordWithEmailTemplate(userId, sendUserEmail, emailTemplateName)
```

Resets the user’s password and sends an email to the user with their new password. You specify the email template that is sent to the specified user. Use this method for external users of Experience Cloud sites.

**Signature**

```
public static System.ResetPasswordResult resetPasswordWithEmailTemplate(Id userId, Boolean sendUserEmail, String emailTemplateName)
```

**Parameters**

- `userId` 
  Type: Id

  The ID of the user whose password was reset.
sendUserEmail
    Type: Boolean

templateName
    Type: String

Return Value
    Type: System.ResetPasswordResult

Usage
If you specify true for sendUserEmail, specify the email template that is sent to the user notifying them that their password was
reset. When the user logs in with the new password in the email, they are prompted to enter a new password. A link to sign onto
Salesforce using the new password is included in the email. Use setPassword(userId, password) if you don’t want the user
to be prompted to enter a new password when they log in.

⚠️ Warning: Be careful with this method, and do not expose this functionality to end-users.

runAs(version)
Changes the current package version to the package version specified in the argument.

Signature
    public static Void runAs(System.Version version)

Parameters
    version
        Type: System.Version

Return Value
    Type: Void

Usage
A package developer can use Version methods to continue to support existing behavior in classes and triggers in previous package
versions while continuing to evolve the code. Apex classes and triggers are saved with the version settings for each installed managed
package that the class or trigger references.

This method is used for testing your component behavior in different package versions that you upload to the AppExchange. This method
effectively sets a two-part version consisting of major and minor numbers in a test method so that you can test the behavior for different
package versions.

You can only use runAs in a test method. There is no limitation to the number of calls to this method in a transaction. For sample
usage of this method, see Testing Behavior in Package Versions.
**runAs (userSObject)**
Changes the current user to the specified user.

**Signature**
```
public static Void runAs(User userSObject)
```

**Parameters**
- **userSObject**
  Type: User

**Return Value**
Type: Void

**Usage**
All of the specified user’s record sharing is enforced during the execution of `runAs`. You can only use `runAs` in a test method. For more information, see Using the `runAs()` Method.

**Note:** The `runAs` method ignores user license limits. You can create new users with `runAs` even if your organization has no additional user licenses.

The `runAs` method implicitly inserts the user that is passed in as parameter if the user has been instantiated, but not inserted yet. You can also use `runAs` to perform mixed DML operations in your test by enclosing the DML operations within the `runAs` block. In this way, you bypass the mixed DML error that is otherwise returned when inserting or updating setup objects together with other sObjects. See sObjects That Cannot Be Used Together in DML Operations.

**Note:** Every call to `runAs` counts against the total number of DML statements issued in the process.

**schedule(jobName, cronExpression, schedulableClass)**
Use `schedule` with an Apex class that implements the `Schedulable` interface to schedule the class to run at the time specified by a Cron expression.

**Signature**
```
public static String schedule(String jobName, String cronExpression, Object schedulableClass)
```

**Parameters**
- **jobName**
  Type: String
- **cronExpression**
  Type: String
- **schedulableClass**
  Type: Object
Return Value
Type: String
Returns the scheduled job ID (CronTrigger ID).

Usage
Use extreme care if you’re planning to schedule a class from a trigger. You must be able to guarantee that the trigger won’t add more scheduled classes than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time. Use the abortJob method to stop the job after it has been scheduled.

Note: Salesforce schedules the class for execution at the specified time. Actual execution may be delayed based on service availability.

Using the System.Schedule Method
After you implement a class with the Schedulable interface, use the System.Schedule method to execute it. The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.

Note: Use extreme care if you’re planning to schedule a class from a trigger. You must be able to guarantee that the trigger won’t add more scheduled classes than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time.

The System.Schedule method takes three arguments: a name for the job, an expression used to represent the time and date the job is scheduled to run, and the name of the class. This expression has the following syntax:

Seconds Minutes Hours Day_of_month Month Day_of_week Optional_year

Note: Salesforce schedules the class for execution at the specified time. Actual execution may be delayed based on service availability.

The System.Schedule method uses the user’s timezone for the basis of all schedules.

The following are the values for the expression:

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Special Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seconds</td>
<td>0–59</td>
<td>None</td>
</tr>
<tr>
<td>Minutes</td>
<td>0–59</td>
<td>None</td>
</tr>
<tr>
<td>Hours</td>
<td>0–23</td>
<td>, - * /</td>
</tr>
<tr>
<td>Month</td>
<td>1–12 or the following:</td>
<td>, - * /</td>
</tr>
<tr>
<td></td>
<td>• JAN</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• FEB</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• MAR</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• APR</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• MAY</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• JUN</td>
<td></td>
</tr>
</tbody>
</table>
## Special Characters

### Values

- JAN
- MAR
- APR
- MAY
- JUN
- JUL
- AUG
- SEP
- OCT
- NOV
- DEC

### Special Characters

- \,
- -
- *
- ?
- / (starting on the first of the month)
- L
- #

### Description

1. **\,** Delimits values. For example, use JAN, MAR, APR to specify more than one month.
2. **-** Specifies a range. For example, use JAN-MAR to specify more than one month.
3. ***\*** Specifies all values. For example, if Month is specified as *, the job is scheduled for every month.
4. **?** Specifies no specific value. This is only available for Day_of_month and Day_of_week, and is generally used when specifying a value for one and not the other.
5. **/** Specifies increments. The number before the slash specifies when the intervals will begin, and the number after the slash is the interval amount. For example, if you specify 1/5 for Day_of_month, the Apex class runs every fifth day of the month, starting on the first of the month.
6. **L** Specifies the end of a range (last). This is only available for Day_of_month and Day_of_week. When used with Day_of_month, L always means the last day of the month, such as January 31, February 29 for leap years, and so on. When used with Day_of_week by itself, it always means 7 or SAT. When used with a Day_of_week value, it means the last of that type of day in the month. For example, if you specify 2L, you are specifying the last Monday of the month. Do not use a range of values with L as the results might be unexpected.
<table>
<thead>
<tr>
<th>Special Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>W</td>
<td>Specifies the nearest weekday (Monday-Friday) of the given day. This is only available for <code>Day_of_month</code>. For example, if you specify 20W, and the 20th is a Saturday, the class runs on the 19th. If you specify 1W, and the first is a Saturday, the class does not run in the previous month, but on the third, which is the following Monday.</td>
</tr>
</tbody>
</table>

**Tip:** Use the L and W together to specify the last weekday of the month.

| #                 | Specifies the `n`th day of the month, in the format `weekday#day_of_month`. This is only available for `Day_of_week`. The number before the # specifies weekday (SUN-SAT). The number after the # specifies the day of the month. For example, specifying 2#1 means the class runs on the first Monday of every month. |

The following are some examples of how to use the expression.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0 13 * * ?</td>
<td>Class runs every day at 1 PM.</td>
</tr>
<tr>
<td>0 0 22 ? * 6L</td>
<td>Class runs the last Friday of every month at 10 PM.</td>
</tr>
<tr>
<td>0 0 10 ? * MON-FRI</td>
<td>Class runs Monday through Friday at 10 AM.</td>
</tr>
<tr>
<td>0 0 20 * * ? 2010</td>
<td>Class runs every day at 8 PM during the year 2010.</td>
</tr>
</tbody>
</table>

In the following example, the class `proschedule` implements the `Schedulable` interface. The class is scheduled to run at 8 AM, on the 13 February.

```java
proschedule p = new proschedule();
   String sch = '0 0 8 13 2 ?';
   system.schedule('One Time Pro', sch, p);
```

**scheduleBatch(batchable, jobName, minutesFromNow)**

Schedules a batch job to run once in the future after the specified time interval and with the specified job name.

**Signature**

```java
public static String scheduleBatch(Database.Batchable batchable, String jobName, Integer minutesFromNow)
```

**Parameters**

- **batchable**
  
  Type: `Database.Batchable`
  
  An instance of a class that implements the `Database.Batchable` interface.

- **jobName**
  
  Type: `String`
The name if the job that this method will start.

`minutesFromNow`
Type: `Integer`

The time interval in minutes after which the job should start executing. This argument must be greater than zero.

**Return Value**
Type: `String`
The scheduled job ID (CronTrigger ID).

**Usage**

**Note:** Some things to note about `System.scheduleBatch`:

- When you call `System.scheduleBatch`, Salesforce schedules the job for execution at the specified time. Actual execution occurs at or after that time, depending on service availability.
- The scheduler runs as system—all classes are executed, whether the user has permission to execute the class, or not.
- When the job’s schedule is triggered, the system queues the batch job for processing. If Apex flex queue is enabled in your org, the batch job is added at the end of the flex queue. For more information, see Holding Batch Jobs in the Apex Flex Queue.
- All scheduled Apex limits apply for batch jobs scheduled using `System.scheduleBatch`. After the batch job is queued (with a status of Holding or Queued), all batch job limits apply and the job no longer counts toward scheduled Apex limits.
- After calling this method and before the batch job starts, you can use the returned scheduled job ID to abort the scheduled job using the `System.abortJob` method.

For an example, see Using Batch Apex.

```plaintext
scheduleBatch(batchable, jobName, minutesFromNow, scopeSize)
```

Schedules a batch job to run once in the future after the specified the time interval, with the specified job name and scope size. Returns the scheduled job ID (CronTrigger ID).

**Signature**

```plaintext
public static String scheduleBatch(Database.Batchable batchable, String jobName, Integer minutesFromNow, Integer scopeSize)
```

**Parameters**

- `batchable`
  Type: `Database.Batchable`
  The batch class that implements the `Database.Batchable` interface.

- `jobName`
  Type: `String`
  The name of the job that this method will start.

- `minutesFromNow`
  Type: `Integer`
The time interval in minutes after which the job should start executing.

`scopeSize`
Type: `Integer`

The number of records that should be passed to the batch `execute` method.

**Return Value**
Type: `String`

**Usage**

*Note:* Some things to note about `System.scheduleBatch`:
- When you call `System.scheduleBatch`, Salesforce schedules the job for execution at the specified time. Actual execution occurs at or after that time, depending on service availability.
- The scheduler runs as system— all classes are executed, whether the user has permission to execute the class, or not.
- When the job’s schedule is triggered, the system queues the batch job for processing. If Apex flex queue is enabled in your org, the batch job is added at the end of the flex queue. For more information, see Holding Batch Jobs in the Apex Flex Queue.
- All scheduled Apex limits apply for batch jobs scheduled using `System.scheduleBatch`. After the batch job is queued (with a status of `Holding` or `Queued`), all batch job limits apply and the job no longer counts toward scheduled Apex limits.
- After calling this method and before the batch job starts, you can use the returned scheduled job ID to abort the scheduled job using the `System.abortJob` method.

For an example, see Using the `System.scheduleBatch` Method.

**setPassword(userId, password)**

Sets the password for the specified user.

**Signature**

```java
public static Void setPassword(ID userId, String password)
```

**Parameters**

`userId`
Type: `ID`

`password`
Type: `String`

**Return Value**
Type: `Void`

**Usage**

- If a security question hasn’t been previously configured, a user who logs in with a new password that was set using `setPassword` is redirected to the “Change Your Password” page.
• Use `resetPassword(userId, sendUserEmail)` if you want the user to go through the reset process and create their own password.

⚠️ **Warning:** Be careful with this method, and don’t expose this functionality to end users.

### submit(workItemIds, comments, nextApprover)

Submits the processed approvals. The current user is the submitter and the entry criteria is evaluated for all processes applicable to the current user.

**Signature**

```java
public static List<ID> submit(List<ID> workItemIds, String comments, String nextApprover)
```

**Parameters**

- `workItemIds`  
  Type: `List<ID>`
- `comments`  
  Type: `String`
- `nextApprover`  
  Type: `String`

**Return Value**

Type: `List<ID>`

**Usage**

For enhanced submit and evaluation features, see the `ProcessSubmitRequest` class.

### today()

Returns the current date in the current user’s time zone.

**Signature**

```java
public static Date today()
```

**Return Value**

Type: `Date`

---

**Test Class**

Contains methods related to Apex tests.
Namespace

System

Test Methods

The following are methods for Test. All methods are static.

IN THIS SECTION:

- **calculatePermissionSetGroup(psgIds)**
  Calculates aggregate permissions in specified permission set groups for testing.

- **calculatePermissionSetGroup(psgId)**
  Calculates aggregate permissions in a specified permission set group for testing.

- **clearApexPageMessages()**
  Clear the messages on a Visualforce page while executing Apex test methods.

- **createStub(parentType, stubProvider)**
  Creates a stubbed version of an Apex class that you can use for testing. This method is part of the Apex stub API. You can use it with the System.StubProvider interface to create a mocking framework.

- **enableChangeDataCapture()**
  Use this method in an Apex test so that change event notifications are generated for all supported Change Data Capture entities. Call this method at the beginning of your test before performing DML operations and calling Test.getEventBus().deliver();.

- **enqueueBatchJobs(numberOfJobs)**
  Adds the specified number of jobs with no-operation contents to the test-context queue. It first fills the test batch queue, up to the maximum 5 jobs, and then places jobs in the test flex queue. It throws a limit exception when the number of jobs in the test flex queue exceeds the allowed limit of 100 jobs.

- **getEventBus()**
  Returns an instance of the test event bus broker, which lets you operate on platform event or change event messages in an Apex test. For example, you can call Test.getEventBus().deliver() to deliver event messages.

- **getFlexQueueOrder()**
  Returns an ordered list of job IDs for jobs in the test-context flex queue. The job at index 0 is the next job slated to run. This method returns only test-context results, even if it’s annotated with @IsTest(SeeAllData=true).

- **getStandardPricebookId()**
  Returns the ID of the standard price book in the organization.

- **invokeContinuationMethod(controller, request)**
  Invokes the callback method for the specified controller and continuation in a test method.

- **isRunningTest()**
  Returns true if the currently executing code was called by code contained in a test method, false otherwise. Use this method if you need to run different code depending on whether it was being called from a test.

- **loadData(sObjectToken, resourceName)**
  Inserts test records from the specified static resource .csv file and for the specified sObject type, and returns a list of the inserted sObjects.
newSendEmailQuickActionDefaults(contextId, replyToId)
Creates a new QuickAction.SendEmailQuickActionDefaults instance for testing a class implementing the QuickActionQuickActionDefaultsHandler interface.

setContinuationResponse(requestLabel, mockResponse)
Sets a mock response for a continuation HTTP request in a test method.

setCreatedDate(recordId, createdDatetime)
Sets CreatedDate for a test-context sObject.

setCurrentPage(page)
A Visualforce test method that sets the current PageReference for the controller.

setCurrentPageReference(page)
A Visualforce test method that sets the current PageReference for the controller.

setFixedSearchResults(fixedSearchResults)
Defines a list of fixed search results to be returned by all subsequent SOSL statements in a test method.

setMock(interfaceType, instance)
Sets the response mock mode and instructs the Apex runtime to send a mock response whenever a callout is made through the HTTP classes or the auto-generated code from WSDLs.

setReadOnlyApplicationMode(applicationMode)
Sets the application mode for an organization to read-only in an Apex test to simulate read-only mode during Salesforce upgrades and downtimes. The application mode is reset to the default mode at the end of each Apex test run.

startTest()
Marks the point in your test code when your test actually begins. Use this method when you are testing governor limits.

stopTest()
Marks the point in your test code when your test ends. Use this method in conjunction with the startTest method.

testInstall(installImplementation, version, isPush)
Tests the implementation of the InstallHandler interface, which is used for specifying a post install script in packages. Tests run as the test initiator in the development environment.

testSandboxPostCopyScript(script, organizationId, sandboxId, sandboxName)
Tests the implementation of the SandboxPostCopy Interface, which is used for specifying a script to run at the completion of a Sandbox copy. Tests run as the test initiator in the development environment.

testSandboxPostCopyScript(script, organizationId, sandboxId, sandboxName, RunAsAutoProcUser)
Tests the implementation of the SandboxPostCopy Interface, which is used for specifying a script to run at the completion of a Sandbox copy. When RunAsAutoProcUser is true, tests run as Automated Process user in the development environment.

testUninstall(uninstallImplementation)
Tests the implementation of the UninstallHandler interface, which is used for specifying an uninstall script in packages. Tests run as the test initiator in the development environment.

calculatePermissionSetGroup(psgIds)
Calculates aggregate permissions in specified permission set groups for testing.

**Signature**

```java
public static void calculatePermissionSetGroup(List<String> psgIds)
```
Parameters

*psgIds*
  Type: `List<String>`
  A list of IDs for permission set groups.

Return Value

Type: `void`

`calculatePermissionSetGroup(psgId)`
Calculates aggregate permissions in a specified permission set group for testing.

Signature

```java
public static void calculatePermissionSetGroup(String psgId)
```

Parameters

*psgId*
  Type: `String`
  A single ID for a specified permission set group.

Return Value

Type: `void`

`clearApexPageMessages()`
Clear the messages on a Visualforce page while executing Apex test methods.

Signature

```java
public static void clearApexPageMessages()
```

Return Value

Type: `void`

Usage

This method may only be used in tests.

Example:

```java
@isTest
static void clearMessagesTest() {
    Test.setCurrentPage(new PageReference('/'));
    ApexPages.addMessage(
        new ApexPages.Message(ApexPages.Severity.WARNING, 'Sample Warning'))
```
createStub(parentType, stubProvider)

Creates a stubbed version of an Apex class that you can use for testing. This method is part of the Apex stub API. You can use it with the System.StubProvider interface to create a mocking framework.

Signature

public static Object createStub(System.Type parentType, System.StubProvider stubProvider)

Parameters

parentType
Type: System.Type
The type of the Apex class to be stubbed.

stubProvider
System.StubProvider
An implementation of the StubProvider interface.

Return Value

Type: Object
Returns the stubbed object to use in testing.

Usage

The createStub() method works together with the System.StubProvider interface. You define the behavior of the stubbed object by implementing the StubProvider interface. Then you create a stubbed object using the createStub() method. When you invoke methods on the stubbed object, the handleMethodCall() method of the StubProvider interface is called to perform the behavior of the stubbed method.

SEE ALSO:
Apex Developer Guide: Build a Mocking Framework with the Stub API

enableChangeDataCapture()

Use this method in an Apex test so that change event notifications are generated for all supported Change Data Capture entities. Call this method at the beginning of your test before performing DML operations and calling Test.getEventBus().deliver();.

Signature

public static void enableChangeDataCapture()
**Return Value**

Type: void

**Usage**

The `enableChangeDataCapture()` method ensures that Apex tests can fire change event triggers regardless of the entities selected in Setup in the Change Data Capture page. The `enableChangeDataCapture()` method doesn't affect the entities selected in Setup.

SEE ALSO:

*Change Data Capture Developer Guide*

---

**enqueueBatchJobs(numberOfJobs)**

Adds the specified number of jobs with no-operation contents to the test-context queue. It first fills the test batch queue, up to the maximum 5 jobs, and then places jobs in the test flex queue. It throws a limit exception when the number of jobs in the test flex queue exceeds the allowed limit of 100 jobs.

**Signature**

```java
public static List<Id> enqueueBatchJobs(Integer numberOfJobs)
```

**Parameters**

`numberOfJobs`

Type: `Integer`

Number of test jobs to enqueue.

**Return Value**

Type: `List<Id>`

A list of IDs of enqueued test jobs.

**Usage**

Use this method to reduce testing time. Instead of using your org's real batch jobs for testing, you can use this method to simulate batch-job enqueueing. Using `enqueueBatchJobs(numberOfJobs)` is faster than enqueuing real batch jobs.

---

**getEventBus()**

Returns an instance of the test event bus broker, which lets you operate on platform event or change event messages in an Apex test. For example, you can call `Test.getEventBus().deliver()` to deliver event messages.

**Signature**

```java
public static EventBus.TestBroker getEventBus()
```
Return Value
Type: `EventBus.TestBroker`
A broker for the test event bus.

Usage
Enclose `Test.getEventBus().deliver()` within the `Test.startTest()` and `Test.stopTest()` statement block.

```java
Test.startTest();
// Create test events
// ...
// Publish test events with EventBus.publish()
// ...
// Deliver test events
Test.getEventBus().deliver();
// Perform validation
// ...
Test.stopTest();
```

SEE ALSO:
Platform Events Developer Guide

---

### getFlexQueueOrder()

Returns an ordered list of job IDs for jobs in the test-context flex queue. The job at index 0 is the next job slated to run. This method returns only test-context results, even if it’s annotated with `@IsTest(SeeAllData=true)`.

**Signature**

```java
public static List<Id> getFlexQueueOrder()
```

**Return Value**

Type: `List<Id>`
An ordered list of IDs of the jobs in the test’s flex queue.

---

### getStandardPricebookId()

Returns the ID of the standard price book in the organization.

**Signature**

```java
public static Id getStandardPricebookId()
```

**Return Value**

Type: `Id`
The ID of the standard price book.
Usage

This method returns the ID of the standard price book in your organization regardless of whether the test can query organization data. By default, tests can’t query organization data unless they’re annotated with \@isTest(SeeAllData=true).

Creating price book entries with a standard price requires the ID of the standard price book. Use this method to get the standard price book ID so that you can create price book entries in your tests.

Example

This example creates some test data for price book entries. The test method in this example gets the standard price book ID and uses this ID to create a price book entry for a product with a standard price. Next, the test creates a custom price book and uses the ID of this custom price book to add a price book entry with a custom price.

```java
@isTest
class PriceBookTest {
    // Utility method that can be called by Apex tests to create price book entries.
    static testmethod void addPricebookEntries() {
        // First, set up test price book entries.
        // Insert a test product.
        Product2 prod = new Product2(Name = 'Laptop X200',
            Family = 'Hardware');
        insert prod;

        // Get standard price book ID.
        // This is available irrespective of the state of SeeAllData.
        Id pricebookId = Test.getStandardPricebookId();

        // 1. Insert a price book entry for the standard price book.
        PricebookEntry standardPrice = new PricebookEntry(
            Pricebook2Id = pricebookId, Product2Id = prod.Id,
            UnitPrice = 10000, IsActive = true);
        insert standardPrice;

        // Create a custom price book
        Pricebook2 customPB = new Pricebook2(Name='Custom Pricebook', isActive=true);
        insert customPB;

        // 2. Insert a price book entry with a custom price.
        PricebookEntry customPrice = new PricebookEntry(
            Pricebook2Id = customPB.Id, Product2Id = prod.Id,
            UnitPrice = 12000, IsActive = true);
        insert customPrice;

        // Next, perform some tests with your test price book entries.
    }
}
```

`invokeContinuationMethod(controller, request)`

Invokes the callback method for the specified controller and continuation in a test method.
Signature

public static Object invokeContinuationMethod(Object controller, Continuation request)

Parameters

controller
  Type: Object
  An instance of the controller class that invokes the continuation request.

request
  Type: Continuation
  The continuation that is returned by an action method in the controller class.

Return Value

Type: Object
The response of the continuation callback method.

Usage

Use the Test.setContinuationResponse and Test.invokeContinuationMethod methods to test continuations. In test context, callouts of continuations aren’t sent to the external service. By using these methods, you can set a mock response and cause the runtime to call the continuation callback method to process the mock response.

Call Test.setContinuationResponse before you call Test.invokeContinuationMethod. When you call Test.invokeContinuationMethod, the runtime executes the callback method that is associated with the continuation. The callback method processes the mock response that is set by Test.setContinuationResponse.

isRunningTest()

Returns true if the currently executing code was called by code contained in a test method, false otherwise. Use this method if you need to run different code depending on whether it was being called from a test.

Signature

public static Boolean isRunningTest()

Return Value

Type: Boolean

loadData(sObjectToken, resourceName)

Inserts test records from the specified static resource .csv file and for the specified sObject type, and returns a list of the inserted sObjects.

Signature

public static List<sObject> loadData(Schema.SObjectType sObjectToken, String resourceName)
Parameters

sObjectToken
Type: Schema.SObjectType
The sObject type for which to insert test records.

resourceName
Type: String
The static resource that corresponds to the .csv file containing the test records to load. The name is case insensitive.

Return Value
Type: List<sObject>

Usage
You must create the static resource prior to calling this method. The static resource is a comma-delimited file ending with a .csv extension. The file contains field names and values for the test records. The first line of the file must contain the field names and subsequent lines are the field values. To learn more about static resources, see "Defining Static Resources" in the Salesforce online help.

Once you create a static resource for your .csv file, the static resource will be assigned a MIME type. Supported MIME types are:

- text/csv
- application/vnd.ms-excel
- application/octet-stream
- text/plain

newSendEmailQuickActionDefaults(contextId, replyToId)
Creates a new QuickAction.SendEmailQuickActionDefaults instance for testing a class implementing the QuickAction.QuickActionDefaultsHandler interface.

Signature
public static QuickAction.SendEmailQuickActionDefaults newSendEmailQuickActionDefaults(ID contextId, ID replyToId)

Parameters

contextId
Type: Id
Parent record of the email message.

replyToId
Type: Id
Previous email message ID if this email message is a reply.

Return Value
Type: SendEmailQuickActionDefaults Class
The default values used for an email message quick action.
setContinuationResponse(requestLabel, mockResponse)
Sets a mock response for a continuation HTTP request in a test method.

Signature

```java
public static void setContinuationResponse(String requestLabel, System.HttpResponse mockResponse)
```

Parameters

- **requestLabel**
  - Type: `String`
  - The unique label that corresponds to the continuation HTTP request. This label is returned by `Continuation.addHttpRequest`.

- **mockResponse**
  - Type: `HttpResponse`
  - The fake response to be returned by `Test.invokeContinuationMethod`.

Return Value

Type: `void`

Usage

Use the `Test.setContinuationResponse` and `Test.invokeContinuationMethod` methods to test continuations. In test context, callouts of continuations aren’t sent to the external service. By using these methods, you can set a mock response and cause the runtime to call the continuation callback method to process the mock response.

Call `Test.setContinuationResponse` before you call `Test.invokeContinuationMethod`. When you call `Test.invokeContinuationMethod`, the runtime executes the callback method that is associated with the continuation. The callback method processes the mock response that is set by `Test.setContinuationResponse`.

setCreatedDate(recordId, createdDatetime)
Sets CreatedDate for a test-context sObject.

Signature

```java
public static void setCreatedDate(Id recordId, Datetime createdDatetime)
```

Parameters

- **recordId**
  - Type: `Id`
  - The ID of an sObject.

- **createdDatetime**
  - Type: `Datetime`
  - The value to assign to the sObject’s CreatedDate field.
Return Value
Type: void

Usage
All database changes are rolled back at the end of a test. You can’t use this method on records that existed before your test executed. You also can’t use setCreatedDate in methods annotated with @isTest(SeeAllData=true), because those methods have access to all data in your org. If you set CreatedDate to a future value, it can cause unexpected results. This method takes two parameters—an sObject ID and a Datetime value—neither of which can be null.

Insert your test record before you set its CreatedDate, as shown in this example.

```apex
@isTest
private class SetCreatedDateTest {
    static testMethod void testSetCreatedDate() {
        Account a = new Account(name='myAccount');
        insert a;
        Test.setCreatedDate(a.Id, DateTime.newInstance(2012,12,12));
        Test.startTest();
        Account myAccount = [SELECT Id, Name, CreatedDate FROM Account WHERE Name='myAccount' limit 1];
        System.assertEquals(myAccount.CreatedDate, DateTime.newInstance(2012,12,12));
        Test.stopTest();
    }
}
```

**setCurrentPage(page)**
A Visualforce test method that sets the current PageReference for the controller.

**Signature**
```apex```
public static Void setCurrentPage(PageReference page)
```apex```

**Parameters**
```apex```
page
Type: System.PageReference
```apex```

**Return Value**
Type: Void

**setCurrentPageReference(page)**
A Visualforce test method that sets the current PageReference for the controller.

**Signature**
```apex```
public static Void setCurrentPageReference(PageReference page)
```apex```
Parameters

page
Type: System.PageReference

Return Value
Type: Void

setFixedSearchResults(fixedSearchResults)
Defines a list of fixed search results to be returned by all subsequent SOSL statements in a test method.

Signature
public static Void setFixedSearchResults(ID[] fixedSearchResults)

Parameters

fixedSearchResults
Type: ID[]
The list of record IDs specified by opt_set_search_results replaces the results that would normally be returned by the SOSL queries if they were not subject to any WHERE or LIMIT clauses. If these clauses exist in the SOSL queries, they are applied to the list of fixed search results.

Return Value
Type: Void

Usage
If opt_set_search_results is not specified, all subsequent SOSL queries return no results.
For more information, see Dynamic SOSL.

setMock(interfaceType, instance)
Sets the response mock mode and instructs the Apex runtime to send a mock response whenever a callout is made through the HTTP classes or the auto-generated code from WSDLs.

Signature
public static Void setMock(Type interfaceType, Object instance)

Parameters

interfaceType
Type: System.Type

instance
Type: Object
Return Value
Type: Void

Usage

Note: To mock a callout if the code that performs the callout is in a managed package, call Test.setMock from a test method in the same package with the same namespace.

**setReadOnlyApplicationMode** *(applicationMode)*

Sets the application mode for an organization to read-only in an Apex test to simulate read-only mode during Salesforce upgrades and downtimes. The application mode is reset to the default mode at the end of each Apex test run.

**Signature**

```java
public static Void setReadOnlyApplicationMode(Boolean applicationMode)
```

**Parameters**

*applicationMode*

Type: Boolean

**Return Value**

Type: Void

Usage

Also see the `getApplicationReadWriteMode()` System method.

Do not use `setReadOnlyApplicationMode` for purposes unrelated to Read-Only Mode testing, such as simulating DML exceptions.

Example

The following example sets the application mode to read-only and attempts to insert a new account record, which results in the exception. It then resets the application mode and performs a successful insert.

```java
@isTest
private class ApplicationReadOnlyModeTestClass {
    public static testmethod void test() {
        // Create a test account that is used for querying later.
        Account testAccount = new Account(Name = 'TestAccount');
        insert testAccount;

        // Set the application read only mode.
        Test.setReadOnlyApplicationMode(true);

        // Verify that the application is in read-only mode.
        System.assertEquals( ApplicationReadWriteMode.READ_ONLY, System.getApplicationReadWriteMode() );
    }
}
```
// Create a new account object.
Account testAccount2 = new Account(Name = 'TestAccount2');

try {
    // Get the test account created earlier. Should be successful.
    Account testAccountFromDb = [
        SELECT Id, Name FROM Account WHERE Name = 'TestAccount'
    ];
    System.assertEquals(testAccount.Id, testAccountFromDb.Id);

    // Inserts should result in the InvalidReadOnlyUserDmlException
    // being thrown.
    insert testAccount2;
    System.assertEquals(false, true);
} catch (System.InvalidReadOnlyUserDmlException e) {
    // Expected
}

// Insertion should work after read only application mode gets disabled.
Test.setReadOnlyApplicationMode(false);
insert testAccount2;
Account testAccount2FromDb = [
    SELECT Id, Name FROM Account WHERE Name = 'TestAccount2'
];
System.assertEquals(testAccount2.Id, testAccount2FromDb.Id);
}

startTest()
Marks the point in your test code when your test actually begins. Use this method when you are testing governor limits.

Signature
public static Void startTest()

Return Value
Type: Void

Usage
You can also use this method with stopTest to ensure that all asynchronous calls that come after the startTest method are run before doing any assertions or testing. Each test method is allowed to call this method only once. All of the code before this method should be used to initialize variables, populate data structures, and so on, allowing you to set up everything you need to run your test. Any code that executes after the call to startTest and before stopTest is assigned a new set of governor limits.

stopTest()
Marks the point in your test code when your test ends. Use this method in conjunction with the startTest method.
stopTest()

public static Void stopTest()

Return Value
Type: Void

Usage
Each test method is allowed to call this method only once. Any code that executes after the stopTest method is assigned the original limits that were in effect before startTest was called. All asynchronous calls made after the startTest method are collected by the system. When stopTest is executed, all asynchronous processes are run synchronously.

Note: Asynchronous calls, such as @future or executeBatch, called in a startTest, stopTest block, do not count against your limits for the number of queued jobs.

testInstall(installImplementation, version, isPush)
Tests the implementation of the InstallHandler interface, which is used for specifying a post install script in packages. Tests run as the test initiator in the development environment.

Signature
public static Void testInstall(InstallHandler installImplementation, Version version, Boolean isPush)

Parameters
installImplementation
Type: System.InstallHandler
A class that implements the InstallHandler interface.

version
Type: System.Version
The version number of the existing package installed in the subscriber organization.

isPush
Type: Boolean
(Optional) Specifies whether the upgrade is a push. The default value is false.

Return Value
Type: Void

Usage
This method throws a run-time exception if the test install fails.
Example

```java
@isTest static void test() {
    PostInstallClass postinstall = 
        new PostInstallClass();
    Test.testInstall(postinstall, 
        new Version(1,0));
}
```

testSandboxPostCopyScript(script, organizationId, sandboxId, sandboxName)

Tests the implementation of the SandboxPostCopy Interface, which is used for specifying a script to run at the completion of a Sandbox copy. Tests run as the test initiator in the development environment.

Signature

```java
public static void testSandboxPostCopyScript(System.SandboxPostCopy script, Id organizationId, Id sandboxId, String sandboxName)
```

Parameters

- **script**
  - Type: `System.SandboxPostCopy`
  - A class that implements the SandboxPostCopy interface.

- **organizationId**
  - Type: `Id`
  - The sandbox organization ID

- **sandboxId**
  - Type: `Id`
  - The sandbox ID to be provided to the SandboxPostCopy script.

- **sandboxName**
  - Type: `String`
  - The sandbox name to be provided to the SandboxPostCopy script.

Return Value

Type: `void`

Usage

This method throws a run-time exception if the test install fails.

**Note:** Salesforce recommends that you use the `testSandboxPostCopyScript(script, organizationId, sandboxId, sandboxName, isRunAsAutoProcUser)` overload instead of this method. When `isRunAsAutoProcUser` is true, the SandboxPostCopy script is tested with the same user access permissions as used by post-copy tasks during sandbox creation. Using the same permissions enables the test to better simulate the actual usage of the class, and to uncover potential issues.
Example

See SandboxPostCopy Example Implementation

testSandboxPostCopyScript(script, organizationId, sandboxId, sandboxName, RunAsAutoProcUser)
Tests the implementation of the SandboxPostCopy Interface, which is used for specifying a script to run at the completion of a Sandbox copy. When RunAsAutoProcUser is true, tests run as Automated Process user in the development environment.

Signature

public static void testSandboxPostCopyScript(System.SandboxPostCopy script, Id organizationId, Id sandboxId, String sandboxName, Boolean RunAsAutoProcUser)

Parameters

script
Type: System.SandboxPostCopy
A class that implements the SandboxPostCopy interface.

organizationId
Type: Id
The sandbox organization ID.

sandboxId
Type: Id
The sandbox ID to be provided to the SandboxPostCopy script.

sandboxName
Type: String
The sandbox name to be provided to the SandboxPostCopy script.

RunAsAutoProcUser
Type: Boolean
When true, the SandboxPostCopy script is tested with the same user access permissions as used by post-copy tasks during sandbox creation. Using the same permissions enables the test to better simulate the actual usage of the class, and to uncover potential issues.
When false, the test runs as the test initiator. This option can alter the permissions with which the script is tested, such as the ability to access objects and features.

Return Value

Type: void

Usage

This method throws a run-time exception if the test install fails.
Example
See SandboxPostCopy Example Implementation

testUninstall(uninstallImplementation)
Tests the implementation of the UninstallHandler interface, which is used for specifying an uninstall script in packages. Tests run as the test initiator in the development environment.

Signature
public static Void testUninstall(UninstallHandler uninstallImplementation)

Parameters
uninstallImplementation
Type: System.UninstallHandler
A class that implements the UninstallHandler interface.

Return Value
Type: Void

Usage
This method throws a run-time exception if the test uninstall fails.

Example
@isTest static void test() {
    UninstallClass uninstall =
    new UninstallClass();
    Test.testUninstall(uninstall);
}

Time Class
Contains methods for the Time primitive data type.

Namespace
System

Usage
For more information on time, see Time Data Type.

Time Methods
The following are methods for Time.
IN THIS SECTION:

- `addHours(additionalHours)`
  Adds the specified number of hours to a Time.
- `addMilliseconds(additionalMilliseconds)`
  Adds the specified number of milliseconds to a Time.
- `addMinutes(additionalMinutes)`
  Adds the specified number of minutes to a Time.
- `addSeconds(additionalSeconds)`
  Adds the specified number of seconds to a Time.
- `hour()`
  Returns the hour component of a Time.
- `millisecond()`
  Returns the millisecond component of a Time.
- `minute()`
  Returns the minute component of a Time.
- `newInstance(hour, minutes, seconds, milliseconds)`
  Constructs a Time from Integer representations of the specified hour, minutes, seconds, and milliseconds. (UTC is assumed.)
- `second()`
  Returns the second component of a Time.

### addHours (additionalHours)

Adds the specified number of hours to a Time.

**Signature**

```java
public Time addHours(Integer additionalHours)
```

**Parameters**

- `additionalHours`  
  Type: `Integer`

**Return Value**

Type: `Time`

**Example**

```java
Time myTime = Time.newInstance(1, 2, 3, 4);
Time expected = Time.newInstance(4, 2, 3, 4);
System.assertEquals(expected, myTime.addHours(3));
```

### addMilliseconds (additionalMilliseconds)

Adds the specified number of milliseconds to a Time.

```java
public Time addMilliseconds(Integer additionalMilliseconds)
```
Signature
public Time addMilliseconds(Integer additionalMilliseconds)

Parameters
additionalMilliseconds
Type: Integer

Return Value
Type: Time

Example
Time myTime = Time.newInstance(1, 2, 3, 0);
Time expected = Time.newInstance(1, 2, 4, 400);
System.assertEquals(expected, myTime.addMilliseconds(1400));

addMinutes(additionalMinutes)
Adds the specified number of minutes to a Time.

Signature
public Time addMinutes(Integer additionalMinutes)

Parameters
additionalMinutes
Type: Integer

Return Value
Type: Time

Example
Time myTime = Time.newInstance(18, 30, 2, 20);
Integer myMinutes = myTime.minute();
myMinutes = myMinutes + 5;
System.assertEquals(myMinutes, 35);

addSeconds(additionalSeconds)
Adds the specified number of seconds to a Time.

Signature
public Time addSeconds(Integer additionalSeconds)
Parameters

`additionalSeconds`
Type: Integer

Return Value
Type: Time

Example

```java
Time myTime = Time.newInstance(1, 2, 55, 0);
Time expected = Time.newInstance(1, 3, 5, 0);
System.assertEquals(expected, myTime.addSeconds(10));
```

`hour()`

Returns the hour component of a Time.

Signature

```java
public Integer hour()
```

Return Value
Type: Integer

Example

```java
Time myTime = Time.newInstance(18, 30, 2, 20);
myTime = myTime.addHours(2);
Integer myHour = myTime.hour();
System.assertEquals(myHour, 20);
```

`millisecond()`

Returns the millisecond component of a Time.

Signature

```java
public Integer millisecond()
```

Return Value
Type: Integer

Example

```java
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(926, myTime.millisecond());
```
minute()  
Returns the minute component of a Time.  

Signature  
public Integer minute()  

Return Value  
Type: Integer  

Example  
Time myTime = Time.newInstance(3, 14, 15, 926);  
System.assertEquals(14, myTime.minute());  

newInstance(hour, minutes, seconds, milliseconds)  
Constructs a Time from Integer representations of the specified hour, minutes, seconds, and milliseconds. (UTC is assumed.)  

Signature  
public static Time newInstance(Integer hour, Integer minutes, Integer seconds, Integer milliseconds)  

Parameters  
hour  
Type: Integer  

minutes  
Type: Integer  

seconds  
Type: Integer  

milliseconds  
Type: Integer  

Return Value  
Type: Time  

Example  
The following example creates a time of 18:30:2:20 (UTC).  
Time myTime =  
Time.newInstance(18, 30, 2, 20);
second()
Returns the second component of a Time.

Signature
public Integer second()

Return Value
Type: Integer

Example
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(15, myTime.second());

TimeZone Class
Represents a time zone. Contains methods for creating a new time zone and obtaining time zone properties, such as the time zone ID, offset, and display name.

Namespace
System

Usage
You can use the methods in this class to get properties of a time zone, such as the properties of the time zone returned by UserInfo.getTimeZone, or the time zone returned by getTimeZone of this class.

Example
This example shows how to get properties of the current user's time zone and displays them to the debug log.

TimeZone tz = UserInfo.getTimeZone();
System.debug('Display name: ' + tz.getDisplayName());
System.debug('ID: ' + tz.getID());
// During daylight saving time for the America/Los_Angeles time zone
System.debug('Offset: ' + tz.getOffset(DateTime.newInstance(2012,10,23,12,0,0)));
// Not during daylight saving time for the America/Los_Angeles time zone
System.debug('Offset: ' + tz.getOffset(DateTime.newInstance(2012,11,23,12,0,0)));
System.debug('String format: ' + tz.toString());

The output of this sample varies based on the user's time zone. This is an example output if the user's time zone is America/Los_Angeles. For this time zone, daylight saving time is -7 hours from GMT (-25200000 milliseconds) and standard time is -8 hours from GMT (-28800000 milliseconds).

Display name: Pacific Standard Time
ID: America/Los_Angeles
Offset: -25200000
This second example shows how to create a time zone for the New York time zone and get the offset of this time zone to the GMT time zone. The example uses two dates to get the offset from. One date is before DST (Daylight Saving Time), and one is after DST. In 2000, DST ended on Sunday, October 29 for the New York time zone. Because the date occurs after DST ends, the offset on the first date is –5 hours to GMT. In 2012, DST ended on Sunday, November 4. Because the date is within DST, the offset on the second date is –4 hours.

```java
// Get the New York time zone
Timezone tz = Timezone.getTimeZone('America/New_York');

// Create a date before the 2007 shift of DST into November
DateTime dtpre = DateTime.newInstanceGMT(2000, 11, 1, 0, 0, 0);
system.debug(tz.getOffset(dtpre)); // -18000000 (= -5 hours = EST)

// Create a date after the 2007 shift of DST into November
DateTime dtpost = DateTime.newInstanceGMT(2012, 11, 1, 0, 0, 0);
system.debug(tz.getOffset(dtpost)); // -14400000 (= -4 hours = EDT)
```

This next example is similar to the previous one except that it gets the offset around the boundary of DST. In 2014, DST ended on Sunday, November 2 at 2:00 AM local time for the New York time zone. The first offset is obtained right before DST ends, and the second offset is obtained right after DST ends. The dates are created by using the `DateTime.newInstanceGMT` method. This method expects the passed-in date values to be based on the GMT time zone.

```java
// Get the New York time zone
Timezone tz = Timezone.getTimeZone('America/New_York');

// Before DST ends
DateTime dtpre = DateTime.newInstanceGMT(2014, 11, 2, 5, 59, 59); // 1:59:59AM local EDT
system.debug(tz.getOffset(dtpre)); // -14400000 (= -4 hours = still on DST)

// After DST ends
DateTime dtpost = DateTime.newInstanceGMT(2014, 11, 2, 6, 0, 0); // 1:00:00AM local EST
system.debug(tz.getOffset(dtpost)); // -18000000 (= -5 hours = back one hour)
```

**TimeZone Methods**

The following are methods for `TimeZone`.

**IN THIS SECTION:**
- `getDisplayName()`
  - Returns this time zone’s display name.
- `getID()`
  - Returns this time zone’s ID.
- `getOffset(date)`
  - Returns the time zone offset, in milliseconds, of the specified date to the GMT time zone.
- `getTimeZone(timeZoneIdString)`
  - Returns the time zone corresponding to the specified time zone ID.
- `toString()`
  - Returns the string representation of this time zone.
**getDisplayName()**
Returns this time zone's display name.

**Signature**
```
public String getDisplayName()
```

**Return Value**
Type: String

**Versioned Behavior Changes**
In API version 45.0 and later, getDisplayName displays Daylight Savings Time appropriately when daylight savings are in effect. For example, British Summer Time is displayed for Europe/London and Pacific Daylight Time for America/Los_Angeles.

**getID()**
Returns this time zone's ID.

**Signature**
```
public String getID()
```

**Return Value**
Type: String

**getOffset(date)**
Returns the time zone offset, in milliseconds, of the specified date to the GMT time zone.

**Signature**
```
public Integer getOffset(Datetime date)
```

**Parameters**
```

date
    Type: Datetime
    The date argument is the date and time to evaluate.
```

**Return Value**
Type: Integer

**Usage**

*Note:* The returned offset is adjusted for daylight saving time if the date argument falls within daylight saving time for this time zone.
getTimeZone(timeZoneIdString)
Returns the time zone corresponding to the specified time zone ID.

Signature
public static TimeZone getTimeZone(String timeZoneIdString)

Parameters
timeZoneIdString
Type: String
The time zone values you can use for the Id argument are any valid time zone values that the Java TimeZone class supports.

Return Value
Type: TimeZone

Example
TimeZone tz = TimeZone.getTimeZone('America/Los_Angeles');
String tzName = tz.getDisplayName();
System.assert(tzName.equals('(GMT-08:00) Pacific Standard Time (America/Los_Angeles)') ||
        tzName.equals('(GMT-07:00) Pacific Daylight Time (America/Los_Angeles)'));

toString()
Returns the string representation of this time zone.

Signature
public String toString()

Return Value
Type: String

Trigger Class
Use the Trigger class to access run-time context information in a trigger, such as the type of trigger or the list of sObject records that the trigger operates on.

Namespace
System

Trigger Context Variables
The Trigger class provides the following context variables.
<table>
<thead>
<tr>
<th><strong>Variable</strong></th>
<th><strong>Usage</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>isExecuting</code></td>
<td>Returns true if the current context for the Apex code is a trigger, not a Visualforce page, a Web service, or an <code>executeAnonymous()</code> API call.</td>
</tr>
<tr>
<td><code>isInsert</code></td>
<td>Returns <code>true</code> if this trigger was fired due to an insert operation, from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td><code>isUpdate</code></td>
<td>Returns <code>true</code> if this trigger was fired due to an update operation, from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td><code>isDelete</code></td>
<td>Returns <code>true</code> if this trigger was fired due to a delete operation, from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td><code>isBefore</code></td>
<td>Returns <code>true</code> if this trigger was fired before any record was saved.</td>
</tr>
<tr>
<td><code>isAfter</code></td>
<td>Returns <code>true</code> if this trigger was fired after all records were saved.</td>
</tr>
<tr>
<td><code>isUndelete</code></td>
<td>Returns <code>true</code> if this trigger was fired after a record is recovered from the Recycle Bin. This recovery can occur after an undelete operation from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td><code>new</code></td>
<td>Returns a list of the new versions of the sObject records. This sObject list is only available in <code>insert</code>, <code>update</code>, and <code>undelete</code> triggers, and the records can only be modified in <code>before</code> triggers.</td>
</tr>
<tr>
<td><code>newMap</code></td>
<td>A map of IDs to the new versions of the sObject records. This map is only available in <code>before update</code>, <code>after insert</code>, <code>after update</code>, and <code>after undelete</code> triggers.</td>
</tr>
<tr>
<td><code>old</code></td>
<td>Returns a list of the old versions of the sObject records. This sObject list is only available in <code>update</code> and <code>delete</code> triggers.</td>
</tr>
<tr>
<td><code>oldMap</code></td>
<td>A map of IDs to the old versions of the sObject records. This map is only available in <code>update</code> and <code>delete</code> triggers.</td>
</tr>
<tr>
<td><code>operationType</code></td>
<td>Returns an enum of type <code>System.TriggerOperation</code> corresponding to the current operation. Possible values of the <code>System.TriggerOperation</code> enum are: <code>BEFORE_INSERT</code>, <code>BEFORE_UPDATE</code>, <code>BEFORE_DELETE</code>, <code>AFTER_INSERT</code>, <code>AFTER_UPDATE</code>, <code>AFTER_DELETE</code>, and <code>AFTER_UNDELETE</code>. If you vary your programming logic based on different trigger types, consider using the <code>switch</code> statement with different permutations of unique trigger execution enum states.</td>
</tr>
<tr>
<td><code>size</code></td>
<td>The total number of records in a trigger invocation, both old and new.</td>
</tr>
</tbody>
</table>

**Note:** The record firing a trigger can include an invalid field value, such as a formula that divides by zero. In this case, the field value is set to `null` in these variables:

- `new`
- `newMap`
- `old`
- `oldMap`
### Example

For example, in this simple trigger, `Trigger.new` is a list of sObjects and can be iterated over in a `for` loop. It can also be used as a bind variable in the `IN` clause of a SOQL query.

```apex
Trigger simpleTrigger on Account (after insert) {
    for (Account a : Trigger.new) {
        // Iterate over each sObject
    }

    // This single query finds every contact that is associated with any of the
    // triggering accounts. Note that although Trigger.new is a collection of
    // records, when used as a bind variable in a SOQL query, Apex automatically
    // transforms the list of records into a list of corresponding Ids.
    Contact[] cons = [SELECT LastName FROM Contact
                     WHERE AccountId IN :Trigger.new];
}
```

This trigger uses Boolean context variables like `Trigger.isBefore` and `Trigger.isDelete` to define code that only executes for specific trigger conditions:

```apex
trigger myAccountTrigger on Account(before delete, before insert, before update,
                                    after delete, after insert, after update) {
    if (Trigger.isBefore) {
        if (Trigger.isDelete) {
            // In a before delete trigger, the trigger accesses the records that will be
            // deleted with the Trigger.old list.
            for (Account a : Trigger.old) {
                if (a.name != 'okToDelete') {
                    a.addError('You can\'t delete this record!');
                }
            }
        } else {
            // In before insert or before update triggers, the trigger accesses the new records
            // with the Trigger.new list.
            for (Account a : Trigger.new) {
                if (a.name == 'bad') {
                    a.name.addError('Bad name');
                }
            }
        }
    } else {
        if (Trigger.isInsert) {
            List<Contact> contacts = new List<Contact>();

            for (Account a : Trigger.new) {
                System.assertEquals('xxx', a.accountNumber);
                System.assertEquals('industry', a.industry);
                System.assertEquals(100, a.numberofemployees);
                System.assertEquals(100.0, a.annualrevenue);
                a.accountNumber = 'yyy';
            }
        }
    }
}
```

// If the trigger is not a before trigger, it must be an after trigger.
for (Account a : Trigger.new) {
    if(a.Name == 'makeContact') {
        contacts.add(new Contact (LastName = a.Name, AccountId = a.Id));
    }
    insert contacts;
}
}}

TriggerOperation Enum

System.TriggerOperation enum values are associated with trigger events.

Enum Values

The following are the values of the System.TriggerOperation enum:

- AFTER_DELETE
- AFTER_INSERT
- AFTER_UNDELETE
- AFTER_UPDATE
- BEFORE_DELETE
- BEFORE_INSERT
- BEFORE_UPDATE

Type Class

Contains methods for getting the Apex type that corresponds to an Apex class and for instantiating new types.

Namespace

System

Usage

Use the forName methods to retrieve the type of an Apex class, which can be a built-in or a user-defined class. You can use these methods to retrieve the type of public and global classes, and not private classes even if the context user has access. Also, use the newInstance method if you want to instantiate a Type that implements an interface and call its methods while letting someone else, such as a subscriber of your package, provide the methods' implementations.

Note: A call to Type.forName() can cause the class to be compiled.

Example: Instantiating a Type Based on Its Name

The following sample shows how to use the Type methods to instantiate a Type based on its name. A typical application of this scenario is when a package subscriber provides a custom implementation of an interface that is part of an installed package. The package can
get the name of the class that implements the interface through a custom setting in the subscriber’s org. The package can then instantiate the type that corresponds to this class name and invoke the methods that the subscriber implemented.

In this sample, Vehicle represents the interface that the VehicleImpl class implements. The last class contains the code sample that invokes the methods implemented in VehicleImpl.

This is the Vehicle interface.

```apex
global interface Vehicle {
    Long getMaxSpeed();
    String getType();
}
```

This is the implementation of the Vehicle interface.

```apex
global class VehicleImpl implements Vehicle {
    global Long getMaxSpeed() { return 100; }
    global String getType() { return 'Sedan'; }
}
```

The method in this class gets the name of the class that implements the Vehicle interface through a custom setting value. It then instantiates this class by getting the corresponding type and calling the newInstance method. Next, it invokes the methods implemented in VehicleImpl. This sample requires that you create a public list custom setting named CustomImplementation with a text field named className. Create one record for this custom setting with a data set name of Vehicle and a class name value of VehicleImpl.

```apex
public class CustomerImplInvocationClass {

    public static void invokeCustomImpl() {
        // Get the class name from a custom setting.
        // This class implements the Vehicle interface.
        CustomImplementation__c cs = CustomImplementation__c.getInstance('Vehicle');

        // Get the Type corresponding to the class name
        Type t = Type.forName(cs.className__c);

        // Instantiate the type.
        // The type of the instantiated object
        // is the interface.
        Vehicle v = (Vehicle)t.newInstance();

        // Call the methods that have a custom implementation
        System.debug('Max speed: ' + v.getMaxSpeed());
        System.debug('Vehicle type: ' + v.getType());
    }
}
```

Class Property

The class property returns the System.Type of the type it is called on. It’s exposed on all Apex built-in types including primitive data types and collections, sObject types, and user-defined classes. This property can be used instead of forName methods.

Call this property on the type name. For example:

```apex
System.Type t = Integer.class;
```
You can use this property for the second argument of JSON.deserialize, deserializeStrict, JSONParser.readValueAs, and readValueAsStrict methods to get the type of the object to deserialize. For example:

```java
Decimal n = (Decimal)JSON.deserialize('100.1', Decimal.class);
```

### Type Methods

The following are methods for `Type`.

**IN THIS SECTION:**

- `equals(typeToCompare)`: Returns `true` if the specified type is equal to the current type; otherwise, returns `false`.
- `forName(fullyQualifiedName)`: Returns the type that corresponds to the specified fully qualified class name.
- `forName(namespace, name)`: Returns the type that corresponds to the specified namespace and class name.
- `getName()`: Returns the name of the current type.
- `hashCode()`: Returns a hash code value for the current type.
- `isAssignableFrom(sourceType)`: Returns `true` if an object reference of the specified type can be assigned from the child type; otherwise, returns `false`.
- `newInstance()`: Creates an instance of the current type and returns this new instance.
- `toString()`: Returns a string representation of the current type, which is the type name.

**equals(typeToCompare)**

Returns `true` if the specified type is equal to the current type; otherwise, returns `false`.

**Signature**

```java
public Boolean equals(Object typeToCompare)
```

**Parameters**

- `typeToCompare`  
  Type: `Object`  
  The type to compare with the current type.

**Return Value**

Type: `Boolean`
Example

```java
Type t1 = Account.class;
Type t2 = Type.forName('Account');
System.assert(t1.equals(t2));
```

**forName(fullyQualifiedName)**

Returns the type that corresponds to the specified fully qualified class name.

**Signature**

```java
public static System.Type forName(String fullyQualifiedName)
```

**Parameters**

`fullyQualifiedName`  
Type: String  
The fully qualified name of the class to get the type of. The fully qualified class name contains the namespace name, for example, `MyNamespace.ClassName`.

**Return Value**

Type: `System.Type`

**Usage**

⚠️ **Note:**

- This method returns `null` if called outside a managed package to get the type of a non-global class in a managed package. This is because the non-global class isn’t visible outside the managed package. For Apex saved using Salesforce API version 27.0 and earlier, this method does return the corresponding class type for the non-global managed package class.
- When called from an installed managed package to get the name of a local type in an organization with no defined namespace, the `forName(fullyQualifiedName)` method returns `null`. Instead, use the `forName(namespace, name)` method and specify an empty string or `null` for the namespace argument.
- A call to `Type.forName()` can cause the class to be compiled.

**forName(namespace, name)**

Returns the type that corresponds to the specified namespace and class name.

**Signature**

```java
public static System.Type forName(String namespace, String name)
```

**Parameters**

`namespace`  
Type: String  
The namespace of the class. If the class doesn’t have a namespace, set the `namespace` argument to `null` or an empty string.
name
Type: String
The name of the class.

Return Value
Type: System.Type

Usage
Note:
• This method returns null if called outside a managed package to get the type of a non-global class in a managed package. This is because the non-global class isn’t visible outside the managed package. For Apex saved using Salesforce API version 27.0 and earlier, this method does return the corresponding class type for the non-global managed package class.
• Use this method instead of forName(fullyQualifiedName) if it’s called from a managed package installed in an organization with no defined namespace. To get the name of a local type, set the namespace argument to an empty string or null. For example, Type t = Type.forName('', 'ClassName');
• A call to Type.forName() can cause the class to be compiled.

Example
This example shows how to get the type that corresponds to the ClassName class and the MyNamespace namespace.

Type myType =
    Type.forName('MyNamespace', 'ClassName');

getName()
Returns the name of the current type.

Signature
public String getName()

Return Value
Type: String

Example
This example shows how to get a Type’s name. It first obtains a Type by calling forName, then calls getName on the Type object.

Type t =
    Type.forName('MyClassName');

String typeName =
    t.getName();
System.assertEquals('MyClassName',
    typeName);
hashCode()
Returns a hash code value for the current type.

Signature
public Integer hashCode()

Return Value
Type: Integer

Usage
The returned hash code value corresponds to the type name hash code that String.hashCode returns.

isAssignableFrom(sourceType)
Returns true if an object reference of the specified type can be assigned from the child type; otherwise, returns false.

Signature
public Boolean isAssignableFrom(Type sourceType)

Parameters
sourceType
The type of the object with which you are checking compatibility.

Return Value
Type: Boolean
The method returns true when the method is invoked as parentType.isAssignableFrom(childType). When invoked in any of the following ways, the method returns false:
- childType.isAssignableFrom(parentType)
- typeA.isAssignableFrom(TypeB) where TypeB is a sibling of TypeA
- typeA.isAssignableFrom(TypeB) where TypeB and TypeA are unrelated

Note: A childType is the child of a parentType when it implements an interface, extends a virtual or abstract class, or is the same System.Type as the parentType.

Usage
Unlike the instanceof operator, this method allows you to check type compatibility without having to create a class instance. This method eliminates static compile-time dependencies that instanceof requires.

The following code demonstrates how a typical ISV customer can use isAssignableFrom() to check compatibility between a customer-defined type (customerProvidedPluginType) and a valid plugin type.

//Scenario: Managed package code loading a “plugin” class that implements a managed interface; the implementation done outside of the package
String pluginNameStr = Config__c.getInstance().PluginApexType__c;
Type customerProvidedPluginType = Type.forName(pluginNameStr);
Type pluginInterface = ManagedPluginInterface.class;

// Constructors may have side-effects, including potentially unsafe DML/callouts.
// We want to make sure the class is really designed to be a valid plugin before we
// instantiate it
Boolean validPlugin = pluginInterface.isAssignableFrom(customerProvidedPluginType); //
// validate that it implements the right interface

if(!validPlugin){
    throw new SecurityException('Cannot create instance of '+customerProvidedPluginType+'.
Does not implement ManagedPluginInterface');
} else{
    return Type.newInstance(validPlugin);
}

Example

The following code snippet first defines sibling classes A and B that both implement the Callable interface and an unrelated class C.
Then, it explores several type comparisons using isAssignableFrom().

//Define classes A, B, and C

global class A implements Database.Batchable<String>, Callable {
    global Iterable<String> start(Database.BatchableContext context) { return null; }
    global void execute(Database.BatchableContext context, String[] scope) { }
    global void finish(Database.BatchableContext context) { }
    global Object call(String action, Map<String, Object> args) { return null; }
}

global class B implements Callable {
    global Object call(String action, Map<String, Object> args) { return null; }
}

global class C {
}

Type listOfStrings = Type.forName('List<String>');
Type listOfIntegers = Type.forName('List<Integer>');
boolean flagListTypes = listOfIntegers.isAssignableFrom(listOfStrings); // false

//Examples with stringType and idType
Type stringType = Type.forName('String');
Type idType = Type.forName('Id');
boolean isId_assignableFromString = idType.isAssignableFrom(stringType); // true
//isAssignableFrom respects that String can be assigned to Id without an explicit cast

//Examples with typeA, typeB, and typeC
Type typeA = Type.forName('A');
Type typeB = Type.forName('B');
Type typeC = Type.forName('C');
boolean isTypeB_ofTypeA = typeB.isAssignableFrom(typeA); // false - siblings
boolean isTypeA_ofTypeC = typeA.isAssignableFrom(typeC); // false - unrelated types
boolean isTypeA_ofTypeA = typeA.isAssignableFrom(typeA); // true - identity

//Examples with callableType and batchableType
Type callableType = Type.forName('Callable');
Type batchableType = Type.forName('Database.Batchable');
boolean isTypeA_Callable = callableType.isAssignableFrom(typeA); // true - type A is a child of Callable type
boolean isTypeA_Batchable = batchableType.isAssignableFrom(typeA); // true - type A is a child of Batchable type
boolean isCallableOfTypeA = typeA.isAssignableFrom(callableType); // false - Callable type is not a child of type A
boolean isBatchableOfTypeA = typeA.isAssignableFrom(batchableType); // false - Batchable type is not a child of type A

newInstance()

Creates an instance of the current type and returns this new instance.

Signature

public Object newInstance()

Return Value

Type: Object

Usage

Because newInstance returns the generic object type, you should cast the return value to the type of the variable that will hold this value.

This method enables you to instantiate a Type that implements an interface and call its methods while letting someone else provide the methods’ implementation. For example, a package developer can provide an interface that a subscriber who installs the package can implement. The code in the package calls the subscriber’s implementation of the interface methods by instantiating the subscriber’s Type.

Example

This example shows how to create an instance of a Type. It first gets a Type by calling forName with the name of a class (ShapeImpl), then calls newInstance on this Type object. The newObj instance is declared with the interface type (Shape) that the ShapeImpl class implements. The return value of the newInstance method is cast to the Shape type.

Type t =
    Type.forName('ShapeImpl');

Shape newObj =
    (Shape)t.newInstance();

toString()

Returns a string representation of the current type, which is the type name.
Signature

```
public String toString()
```

Return Value

Type: String

Usage

This method returns the same value as `getName`. `String.valueOf` and `System.debug` use this method to convert their `Type` argument into a String.

Example

This example calls `toString` on the `Type` corresponding to a list of Integers.

```
Type t = List<Integer>.class;
String s = t.toString();
System.assertEquals('List<Integer>', s);
```

UninstallHandler Interface

Enables custom code to run after a managed package is uninstalled.

Namespace

`System`

Usage

App developers can implement this interface to specify Apex code that runs automatically after a subscriber uninstalls a managed package. This makes it possible to perform cleanup and notification tasks based on details of the subscriber’s organization.

The uninstall script is subject to default governor limits. It runs as a special system user that represents your package, so all operations performed by the script will appear to be done by your package. You can access this user by using `UserInfo`. You will only see this user at runtime, not while running tests.

If the script fails, the uninstall continues but none of the changes performed by the script are committed. Any errors in the script are emailed to the user specified in the `Notify on Apex Error` field of the package. If no user is specified, the uninstall details will be unavailable.

The uninstall script has the following restrictions. You can’t use it to initiate batch, scheduled, and future jobs, to access Session IDs, or to perform callouts.

The `UninstallHandler` interface has a single method called `onUninstall`, which specifies the actions to be performed on uninstall.

```
global interface UninstallHandler {
    void onUninstall(UninstallContext context);
}
```

The `onUninstall` method takes a context object as its argument, which provides the following information:

- The org ID of the organization in which the uninstall takes place.
• The user ID of the user who initiated the uninstall.

The context argument is an object whose type is the UninstallContext interface. This interface is automatically implemented by the system. The following definition of the UninstallContext interface shows the methods you can call on the context argument.

global interface UninstallContext {
  ID organizationId();
  ID uninstallerId();
}

IN THIS SECTION:
  UninstallHandler Methods
  UninstallHandler Example Implementation

UninstallHandler Methods

The following are methods for UninstallHandler.

IN THIS SECTION:
  onUninstall(context)
    Specifies the actions to be performed on uninstall.

onUninstall(context)

Specifies the actions to be performed on uninstall.

Signature

public Void onUninstall(UninstallContext context)

Parameters

  context
    Type: UninstallContext

Return Value

Type: Void

UninstallHandler Example Implementation

Example of an Uninstall Script

This sample uninstall script performs the following actions on package uninstall.

• Inserts an entry in the feed describing which user did the uninstall and in which organization
• Creates and sends an email message confirming the uninstall to that user

```apex
global class UninstallClass implements UninstallHandler {
    global void onUninstall(UninstallContext ctx) {
        FeedItem feedPost = new FeedItem();
        feedPost.parentId = ctx.uninstallerID();
        feedPost.body = 'Thank you for using our application!';
        insert feedPost;

        User u = [Select Id, Email from User where Id =:ctx.uninstallerID()];
        String toAddress= u.Email;
        String[] toAddresses = new String[] {toAddress};
        Messaging.SingleEmailMessage mail = new Messaging.SingleEmailMessage();
        mail.setToAddresses(toAddresses);
        mail.setReplyTo('support@package.dev');
        mail.setSenderDisplayName('My Package Support');
        mail.setSubject('Package uninstall successful');
        mail.setPlainTextBody('Thanks for uninstalling the package.');
        Messaging.sendEmail(new Messaging.Email[] { mail });
    }
}
```

You can test an uninstall script using the `testUninstall` method of the `Test` class. This method takes as its argument a class that implements the `UninstallHandler` interface.

This sample shows how to test an uninstall script implemented in the `UninstallClass` Apex class.

```apex
@isTest
static void testUninstallScript() {
    Id UninstallerId = UserInfo.getUserId();
    List<FeedItem> feedPostsBefore =
        [SELECT Id FROM FeedItem WHERE parentId=:UninstallerId AND CreatedDate=TODAY];
    Test.testUninstall(new UninstallClass());
    List<FeedItem> feedPostsAfter =
        [SELECT Id FROM FeedItem WHERE parentId=:UninstallerId AND CreatedDate=TODAY];
    System.assertEquals(feedPostsBefore.size() + 1, feedPostsAfter.size(),
                        'Post to uninstaller failed.');
}
```

**URL Class**

Represents a uniform resource locator (URL) and provides access to parts of the URL. Enables access to the base URL used to access your Salesforce org.

**Namespace**

System
Usage

Use the methods of the `System.URL` class to create links to objects in your organization. Such objects can be files, images, logos, or records that you want to include in external emails, in activities, or in Chatter posts. For example, you can create a link to a file uploaded as an attachment to a Chatter post by concatenating the Salesforce base URL with the file ID:

```java
// Get a file uploaded through Chatter.
ContentDocument doc = [SELECT Id FROM ContentDocument WHERE Title = 'myfile'];
// Create a link to the file.
String fullFileURL = URL.getOrgDomainURL().toExternalForm() + '/' + doc.id;
system.debug(fullFileURL);
```

The following example creates a link to a Salesforce record. The full URL is created by concatenating the Salesforce base URL with the record ID.

```java
Account acct = [SELECT Id FROM Account WHERE Name = 'Acme' LIMIT 1];
String fullRecordURL = URL.getOrgDomainURL().toExternalForm() + '/' + acct.Id;
```

Example

In this example, the base URL and the full request URL of the current Salesforce server instance are retrieved. Next, a URL pointing to a specific account object is created. Finally, components of the base and full URL are obtained. This example prints out all the results to the debug log output.

```java
// Create a new account called Acme that we will create a link for later.
Account myAccount = new Account(Name='Acme');
insert myAccount;
// Get the base URL.
String sfdcBaseURL = URL.getOrgDomainURL().toExternalForm();
System.debug('Base URL: ' + sfdcBaseURL);
// Get the URL for the current request.
String currentRequestURL = URL.getCurrentRequestUrl().toExternalForm();
System.debug('Current request URL: ' + currentRequestURL);
// Create the account URL from the base URL.
String accountURL = URL.getOrgDomainURL().toExternalForm() + '/' + myAccount.Id;
System.debug('URL of a particular account: ' + accountURL);
// Get some parts of the base URL.
System.debug('Host: ' + URL.getOrgDomainURL().getHost());
System.debug('Protocol: ' + URL.getOrgDomainURL().getProtocol());
// Get the query string of the current request.
System.debug('Query: ' + URL.getCurrentRequestUrl().getQuery());
```

Versioned Behavior Changes

In API version 41.0 and later, Apex URL objects are represented by the `java.net.URI` type, not the `java.net.URL` type. The API version in which the URL object was instantiated determines the behavior of subsequent method calls to the specific instance.
Salesforce strongly encourages you to use API 41.0 and later versions for fully RFC-compliant URL parsing that includes proper handling of edge cases of complex URL structures. API 41.0 and later versions also enforce that inputs are valid, RFC-compliant URL or URI strings.

IN THIS SECTION:
- URL Constructors
- URL Methods

### URL Constructors

The following are constructors for `URL`.

IN THIS SECTION:
- `Url(spec)`
  - Creates a new instance of the `URL` class using the specified string representation of the URL.
- `Url(context, spec)`
  - Creates a new instance of the `URL` class by parsing the specified spec within the specified context.
- `Url(protocol, host, file)`
  - Creates a new instance of the `URL` class using the specified protocol, host, and file on the host. The default port for the specified protocol is used.
- `Url(protocol, host, port, file)`
  - Creates a new instance of the `URL` class using the specified protocol, host, port, and file on the host.

#### `Url(spec)`

Creates a new instance of the `URL` class using the specified string representation of the URL.

**Signature**

```java
public URL(String spec)
```

**Parameters**

- `spec`
  - Type: `String`
  - The string to parse as a URL.

#### `Url(context, spec)`

Creates a new instance of the `URL` class by parsing the specified spec within the specified context.

**Signature**

```java
public URL(Url context, String spec)
```
Parameters

context
  Type: URL on page 3542
  The context in which to parse the specification.

spec
  Type: String
  The string to parse as a URL.

Usage

The new URL is created from the given context URL and the spec argument as described in RFC2396 "Uniform Resource Identifiers: Generic Syntax":

```
<scheme>://<authority><path>?<query>#<fragment>
```

For more information about the arguments of this constructor, see the corresponding URL(java.net.URL, java.lang.String) constructor for Java.

Url(protocol, host, file)

Creates a new instance of the URL class using the specified protocol, host, and file on the host. The default port for the specified protocol is used.

Signature

```
public Url(String protocol, String host, String file)
```

Parameters

protocol
  Type: String
  The protocol name for this URL.

host
  Type: String
  The host name for this URL.

file
  Type: String
  The file name for this URL.

Url(protocol, host, port, file)

Creates a new instance of the URL class using the specified protocol, host, port, and file on the host.

Signature

```
public Url(String protocol, String host, Integer port, String file)
```
Parameters

**protocol**
Type: *String*
The protocol name for this URL.

**host**
Type: *String*
The host name for this URL.

**port**
Type: *Integer*
The port number for this URL.

**file**
Type: *String*
The file name for this URL.

URL Methods

The following are methods for URL.

IN THIS SECTION:

- `getAuthority()`
  Returns the authority portion of the current URL.

- `getCurrentRequestUrl()`
  Returns the URL of an entire request on a Salesforce instance.

- `getDefaultPort()`
  Returns the default port number of the protocol associated with the current URL.

- `getFile()`
  Returns the file name of the current URL.

- `getFileFieldURL(entityId, fieldName)`
  Returns the download URL for a file attachment.

- `getHost()`
  Returns the host name of the current URL.

- `getOrgDomainUrl()`
  Returns the canonical URL for your org. For example, https://MyDomainName.my.salesforce.com.

- `getPath()`
  Returns the path portion of the current URL.

- `getPort()`
  Returns the port of the current URL.

- `getProtocol()`
  Returns the protocol name of the current URL, such as, https.

- `getQuery()`
  Returns the query portion of the current URL.
getRef()
Returns the anchor of the current URL.

getSalesforceBaseUrl()
In API version 59.0 and later, this method is deprecated and versioned out. Use getOrgDomainUrl() to get the canonical URL for your org or use getCurrentRequestUrl() to get the URL of an entire request on a Salesforce instance. Returns the URL of the current connection to the Salesforce org.

getUserInfo()
Gets the UserInfo portion of the current URL.
sameFile(URLToCompare)
Compares the current URL with the specified URL object, excluding the fragment component.
toExternalForm()
Returns a string representation of the current URL.

getAuthority()
Returns the authority portion of the current URL.

Signature
public String getAuthority()

Return Value
Type: String

getCurrentRequestUrl()
Returns the URL of an entire request on a Salesforce instance.

Signature
public static System.URL getCurrentRequestUrl()

Return Value
Type: System.URL

Usage
An example of a URL for an entire request is https://yourInstance.salesforce.com/apex/myVfPage.apexp.

defaultPort()
Returns the default port number of the protocol associated with the current URL.

Signature
public Integer getDefaultPort()
Return Value
Type: Integer

Usage
Returns -1 if the URL scheme or the stream protocol handler for the URL doesn’t define a default port number.

getFileSize()
Returns the file name of the current URL.

Signature
public String getFile()

Return Value
Type: String

ggetFileFieldURL(entityId, fieldName)
Returns the download URL for a file attachment.

Signature
public static String getFileFieldURL(String entityId, String fieldName)

Parameters
entityId
Type: String
Specifies the ID of the entity that holds the file data.

fieldName
Type: String
Specifies the API name of a file field component, such as AttachmentBody.

Return Value
Type: String

Usage
Example:

Example
String fileURL =
URL.getFileFieldURL( 
getHost()

Returns the host name of the current URL.

Signature

public String getHost()

Return Value

Type: String

getOrgDomainUrl()

Returns the canonical URL for your org. For example, https://MyDomainName.my.salesforce.com.

Signature

public static System.Url getOrgDomainUrl()

Return Value

Type: System.URL

getOrgDomainUrl() always returns the login URL for your org, regardless of context. Use that URL when making API calls to your org.

Usage

Use getOrgDomainUrl() to interact with Salesforce REST and SOAP APIs in Apex code. Get endpoints for User Interface API calls, for creating and customizing picklist value sets and custom fields, and more.

getOrgDomainUrl() can access the domain URL only for the org in which the Apex code is running.

You don’t need a RemoteSiteSetting for your org to interact with the Salesforce APIs using domain URLs retrieved with this method.

Example

This example uses the Salesforce REST API to get organization limit values. For information on limits, see Limits in the REST API Developer Guide.

```java
Http h = new Http();
HttpRequest req = new HttpRequest();
req.setEndpoint(Url.getOrgDomainUrl().toExternalForm() + '/services/data/v44.0/limits');
req.setMethod('GET');
```
req.setHeader('Authorization', 'Bearer ' + UserInfo.getSessionId());
HttpResponse res = h.send(req);

Lightning Aura Components Developer Guide: Making API Calls from Apex
User Interface API Developer Guide: Get Default Values to Clone a Record
User Interface API Developer Guide: Get Values for a Picklist Field
User Interface API Developer Guide: User Inteface API Resources

**getPath()**

Returns the path portion of the current URL.

**Signature**

```java
public String getPath()
```

**Return Value**

Type: String

**getPort()**

Returns the port of the current URL.

**Signature**

```java
public Integer getPort()
```

**Return Value**

Type: Integer

**getProtocol()**

Returns the protocol name of the current URL, such as, https.

**Signature**

```java
public String getProtocol()
```

**Return Value**

Type: String

**getQuery()**

Returns the query portion of the current URL.
**Signature**

```java
public String getQuery()
```

**Return Value**

Type: `String`

**Usage**

Returns `null` if no query portion exists.

**getRef()**

Retruns the anchor of the current URL.

**Signature**

```java
public String getRef()
```

**Return Value**

Type: `String`

**Usage**

Returns `null` if no query portion exists.

**getSalesforceBaseUrl()**

In API version 59.0 and later, this method is deprecated and versioned out. Use `getOrgDomainUrl()` to get the canonical URL for your org or use `getCurrentRequestUrl()` to get the URL of an entire request on a Salesforce instance. Returns the URL of the current connection to the Salesforce org.

**Signature**

```java
public static System.URL getSalesforceBaseUrl()
```

**Return Value**

Type: `System.URL`

**SEE ALSO:**

- `getOrgDomainUrl()`

**getUserInfo()**

Gets the UserInfo portion of the current URL.
Signature
public String getUserInfo()

Return Value
Type: String

Usage
Returns null if no UserInfo portion exists.

**sameFile(URLToCompare)**
Compares the current URL with the specified URL object, excluding the fragment component.

Signature
public Boolean sameFile(System.URL URLToCompare)

Parameters
URLToCompare
  Type: System.URL

Return Value
Type: Boolean
Returns true if both URL objects reference the same remote resource; otherwise, returns false.

Usage
For more information about the syntax of URIs and fragment components, see RFC3986.

toExternalForm()
Returns a string representation of the current URL.

Signature
public String toExternalForm()

Return Value
Type: String

UserInfo Class
Contains methods for obtaining information about the context user.
Namespace

System

UserInfo Methods

The following are methods for UserInfo. All methods are static.

IN THIS SECTION:

- `getDefaultCurrency()`: Returns the context user’s default currency code for multiple currency organizations or the organization’s currency code for single currency organizations.
- `getFirstName()`: Returns the context user’s first name
- `getLanguage()`: Returns the context user’s language
- `getLastName()`: Returns the context user’s last name
- `getLocale()`: Returns the context user’s locale.
- `getName()`: Returns the context user’s full name. The format of the name depends on the language preferences specified for the organization.
- `getOrganizationId()`: Returns the context organization’s ID.
- `getOrganizationName()`: Returns the context organization’s company name.
- `getProfileId()`: Returns the context user’s profile ID.
- `getSessionId()`: Returns the session ID for the current session.
- `getTimeZone()`: Returns the current user’s local time zone.
- `getUiTheme()`: Returns the preferred theme for the current user. Use `getUiThemeDisplayed` to determine the theme actually displayed to the current user.
- `getUiThemeDisplayed()`: Returns the theme being displayed for the current user.
- `getUserEmail()`: Returns the current user’s email address.
- `getUserId()`: Returns the context user’s ID
getUserName()  
Returns the context user's login name.

getUserRoleId()  
Returns the context user's role ID.

getUserType()  
Returns the context user's type.

hasPackageLicense(packageId)  
Returns true if the context user has a license to the managed package via a package license only. Otherwise, returns false.

isCurrentUserLicensed(namespace)  
Returns true if the context user has a license to any managed package denoted by the namespace. Otherwise, returns false.

isCurrentUserLicensedForPackage(packageId)  
Returns true if the context user has a license to the managed package denoted by the package ID. Otherwise, returns false. If the context user has access, it's determined either via the package license or a namespace permission set license for the package namespace.

isMultiCurrencyOrganization()  
Specifies whether the organization uses multiple currencies.

getDefaultCurrency()  
Returns the context user's default currency code for multiple currency organizations or the organization's currency code for single currency organizations.

**Signature**

```
public static String getDefaultCurrency()
```

**Return Value**

Type: String

**Usage**

Note: For Apex saved using Salesforce API version 22.0 or earlier, `getDefaultCurrency` returns null for single currency organizations.

getFirstName()  
Returns the context user's first name.

**Signature**

```
public static String getFirstName()
```

**Return Value**

Type: String
**getLanguage()**

Returns the context user's language

**Signature**

```java
public static String getLanguage()
```

**Return Value**

Type: String

**getLastName()**

Returns the context user's last name

**Signature**

```java
public static String getLastName()
```

**Return Value**

Type: String

**getLocale()**

Returns the context user's locale.

**Signature**

```java
public static String getLocale()
```

**Return Value**

Type: String

**Example**

```java
String result = UserInfo.getLocale();
System.assertEquals('en_US', result);
```

**getName()**

Returns the context user's full name. The format of the name depends on the language preferences specified for the organization.

**Signature**

```java
public static String getName()
```
Return Value
Type: String

Usage
The format is one of the following:

- FirstName LastName
- LastName, FirstName

getOrganizationId()
Returns the context organization’s ID.

Signature
public static String getOrganizationId()

Return Value
Type: String

getOrganizationName()
Returns the context organization’s company name.

Signature
public static String getOrganizationName()

Return Value
Type: String

getProfileId()
Returns the context user’s profile ID.

Signature
public static String getProfileId()

Return Value
Type: String

getSessionId()
Returns the session ID for the current session.
**Signature**

```java
public static String getSessionId()
```

**Return Value**

Type: String

**Usage**

You can use `getSessionId()` both synchronously and asynchronously. In asynchronous Apex (Batch, Future, Queueable, or Scheduled Apex), this method returns the session ID only when the code is run by an active, valid user. When the code is run by an internal user, such as the automated process user or a proxy user, the method returns `null`.

As a best practice, ensure that your code handles both cases: when a session ID is or is not available.

**getTimeZone()**

Returns the current user’s local time zone.

**Signature**

```java
public static System.TimeZone getTimeZone()
```

**Return Value**

Type: System.TimeZone

**Example**

```java
TimeZone tz = UserInfo.getTimeZone();
System.debug('Display name: ' + tz.getDisplayName());
System.debug('ID: ' + tz.getID());
```

**getUiTheme()**

Returns the preferred theme for the current user. Use `getUiThemeDisplayed` to determine the theme actually displayed to the current user.

**Signature**

```java
public static String getUiTheme()
```

**Return Value**

Type: String

The preferred theme for the current user.
Valid values include:

- Theme1—Obsolete Salesforce theme
- Theme2—Salesforce Classic 2005 user interface theme
- Theme3—Salesforce Classic 2010 user interface theme
- Theme4d—Modern "Lightning Experience" Salesforce theme
- Theme4t—Salesforce mobile app theme
- Theme4u—Lightning Console theme
- PortalDefault—Salesforce Customer Portal theme that applies to Customer Portals only and not to Experience Builder sites
- Webstore—AppExchange theme

**getUiThemeDisplayed()**

Returns the theme being displayed for the current user.

**Signature**

```java
public static String getUiThemeDisplayed()
```

**Return Value**

Type: **String**

The theme being displayed for the current user

Valid values include:

- Theme1—Obsolete Salesforce theme
- Theme2—Salesforce Classic 2005 user interface theme
- Theme3—Salesforce Classic 2010 user interface theme
- Theme4d—Modern "Lightning Experience" Salesforce theme
- Theme4t—Salesforce mobile app theme
- Theme4u—Lightning Console theme
- PortalDefault—Salesforce Customer Portal theme that applies to Customer Portals only and not to Experience Builder sites
- Webstore—AppExchange theme

**getUserEmail()**

Returns the current user’s email address.

**Signature**

```java
public static String getUserEmail()
```

**Return Value**

Type: **String**
Example

```java
String emailAddress = UserInfo.getUserEmail();
System.debug('Email address: ' + emailAddress);
```

**getUserId()**
Returns the context user's ID

**Signature**

```java
public static String getUserId()
```

**Return Value**
Type: String

**getUserName()**
Returns the context user's login name.

**Signature**

```java
public static String getUserName()
```

**Return Value**
Type: String

**getUserRoleId()**
Returns the context user's role ID.

**Signature**

```java
public static String getUserRoleId()
```

**Return Value**
Type: String

**getUserType()**
Returns the context user's type.

**Signature**

```java
public static String getUserType()
```
Return Value
Type: String

**hasPackageLicense(packageId)**
Returns `true` if the context user has a license to the managed package via a package license only. Otherwise, returns `false`.

**Signature**
```
public static Boolean hasPackageLicense(ID packageID)
```

**Parameters**
`packageID`  
Type: String

**Return Value**
Type: Boolean

**isCurrentUserLicensed(namespace)**
Returns `true` if the context user has a license to any managed package denoted by the namespace. Otherwise, returns `false`.

**Signature**
```
public static Boolean isCurrentUserLicensed(String namespace)
```

**Parameters**
`namespace`  
Type: String

**Return Value**
Type: Boolean

**Usage**
A `TypeException` is thrown if `namespace` is an invalid type.

**isCurrentUserLicensedForPackage(packageID)**
Returns `true` if the context user has a license to the managed package denoted by the package ID. Otherwise, returns `false`. If the context user has access, it’s determined either via the package license or a namespace permission set license for the package namespace.

**Signature**
```
public static Boolean isCurrentUserLicensedForPackage(ID packageID)
```
Parameters

`packageId`

Type: `String`

Return Value

Type: `Boolean`

Usage

Retrieve `packageId` at runtime, with the `getCurrentPackageId()` method. Then, use `packageId` to confirm that the contextual user is licensed to use that managed package.

A `TypeException` is thrown if `packageId` is an invalid type. A `SystemException` is thrown if `packageId` is the ID of an unlocked or unmanaged package, or if the contextual user doesn’t have a license to the managed package.

`isMultiCurrencyOrganization()`

Specifies whether the organization uses multiple currencies.

Signature

`public static Boolean isMultiCurrencyOrganization()`

Return Value

Type: `Boolean`

UserManagement Class

Contains methods to manage end users, for example, to register their verification methods, verify their identity, or remove their personal information.

Namespace

`System`

Usage

Let users register and deregister identity verification methods. Create custom Login and Verify pages for passwordless login and self-registration. Convert mobile phone numbers to the proper format before registering users. Scramble user data when users request that Salesforce remove their personal information.

This class is available in API version 43.0 and later.

IN THIS SECTION:

UserManagement Methods
UserManagement Methods

The following are methods for UserManagement.

IN THIS SECTION:

clone()

deregisterVerificationMethod(userId, method)
Deregisters an identity verification method. Use this method to let users delete an existing verification method.

formatPhoneNumber(countryCode, phoneNumber)
Formats a mobile phone number for a user. Call this method to ensure that the phone number is formatted properly before updating a user’s mobile phone number.

initPasswordlessLogin(userId, method)
Invokes a verification challenge for passwordless login when creating custom (Visualforce) Login and Verify pages for customers and partners.

initRegisterVerificationMethod(method)
Invokes a verification challenge for registering identity verification methods with a custom (Visualforce) page. Users can register either their email address or phone number.

initSelfRegistration(method, user)
Invokes a verification challenge for self-registration when creating a custom (Visualforce) Verify page for Experience Cloud self-registration.

initVerificationMethod(method)
Initiates a verification service for email, phone (SMS), and the Salesforce Authenticator verification methods.

initVerificationMethod(method, actionName, extras)
Initiates a verification service for email, phone (SMS), and the Salesforce Authenticator verification methods.

obfuscateUser(userId, username)
Scrambles users’ data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it. Use this method to set the username to a specific value after it’s scrambled.

obfuscateUser(userId)
Scrambles users’ data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it.

registerVerificationMethod(method, startUrl)
 Registers an identity verification method. Verification methods can be a time-based one-time password (TOTP), email or text verification code, Salesforce Authenticator, or U2F-compatible security key. End users register verification methods for themselves.

sendAsyncEmailConfirmation(userId, emailTemplateId, networkId, startUrl)
Send an email message to a user’s email address for verification. The message contains a verification link (URL) that the user clicks to verify the email address later on. You can send email verifications in bulk.

verifyPasswordlessLogin(userId, method, identifier, code, startUrl)
Completes a verification challenge during a passwordless login that uses a custom Verify page (Visualforce only). If the user who is trying to log in enters the verification code successfully, the user is logged in.
verifyRegisterVerificationMethod(code, method)
Completes registering a user’s email address or phone number as a verification method when customizing the identity verification process.

verifySelfRegistration(method, identifier, code, startUrl)
Completes a verification challenge when creating a custom (Visualforce) Verify page for Experience Cloud site self-registration. If the person who is attempting to register enters the verification code successfully, the user is created and logged in.

verifyVerificationMethod(identifier, code, method)
Completes the verification service for email, phone (SMS), Salesforce Authenticator, password, or time-based one-time password (TOTP) verification methods.

clonE()

Signature
custom Object clone()

Return Value
Type: User Management
deregisterVerificationMethod(userId, method)
Deregisters an identity verification method. Use this method to let users delete an existing verification method.

Signature
custom static void deregisterVerificationMethod(Id userId, Auth.VerificationMethod method)

Parameters
userId
Type: Id
User ID of the user deregistering the verification method.

method
Type: Auth.VerificationMethod
Verification method used to verify the identity of the user.

Return Value
Type: void
Usage

Use this method to deregister an existing identity verification method. For example, your users can deregister a phone number when their phone number changes. While only end users can register an identity verification method, you and your users can deregister one. Keep this behavior in mind when you implement a custom registration page.

This method is available in API version 43.0 and later.

ℹ️ Note: This method doesn’t support deregistering built-in authenticators.

`formatPhoneNumber(countryCode, phoneNumber)`

Formats a mobile phone number for a user. Call this method to ensure that the phone number is formatted properly before updating a user’s mobile phone number.

**Signature**

```
global static String formatPhoneNumber(String countryCode, String phoneNumber)
```

**Parameters**

- `countryCode`
  - Type: String
  - A valid country code.

- `phoneNumber`
  - Type: String
  - A mobile number that contains from 3 through 49 numeric characters, without the country code. For example, (415) 555-1234.

**Return Value**

- Type: String
  - Returns a user’s mobile phone number in the proper format.

Usage

Use this method to ensure a user’s mobile phone number is formatted as required by Salesforce. Then use the method’s return value to update the mobile field of the user’s record. This mobile number is used for SMS-based device activation. For example, mobile phone numbers are stored along with other identity verification methods in `Auth.VerificationMethod` enum. This method is introduced in API version 43.0. It isn’t available in earlier versions.

Here are some acceptable ways that users can enter their mobile number:

- +1, (415) 555-1234 (with plus signs, parentheses, and dashes)
- 1, 4155551234 (only numbers, no symbols)
- 1, 415-555-1234 (extra spaces)

Now, consider the following examples.

- Correct examples:
  - `formatPhoneNumber('1', '4155551234');`
  - `formatPhoneNumber('+1', '(415) 555-1234');`
- `formatPhoneNumber('1', '415-555-1234');`

  - Incorrect example, because the country code and mobile number aren’t separated:
    - `formatPhoneNumber(null, '+1 415-555-1234');`

  - Example that doesn’t generate an error, but likely won’t work as intended:
    - `formatPhoneNumber('+1', '+1 (415) 555-1234');`

### Format Phone Number Code Example

Here’s a code example that uses the `formatPhoneNumber` method. It gets the mobile number from the user and converts it to the format required by Salesforce. Then it updates the user’s record with the formatted mobile number.

```apex
global with sharing class PhoneRegistrationController {
    // Input variables
    global String countryCode {get; set;}
    global String phoneNumber {get; set;}

    global String addPhoneNumber() {
        if(countryCode == null) return 'Country code is required';
        if(phoneNumber == null) return 'Phone number is required';

        String userId = UserInfo.getUserId();
        User u = [SELECT Id FROM User WHERE Id=:userId LIMIT 1];
        String formatNum = System.UserManagement.formatPhoneNumber(countryCode, phoneNumber);

        u.MobilePhone = formatNum;
        update u;
        return null;
    }
}
```

As long as the country code and phone number are separated, `formatPhoneNumber` returns a value in the proper format.

### `initPasswordlessLogin(userId, method)`

Invokes a verification challenge for passwordless login when creating custom (Visualforce) Login and Verify pages for customers and partners.

#### Signature

`public static String initPasswordlessLogin(Id userId, Auth.VerificationMethod method)`

#### Parameters

- **userId**
  
  Type: `Id`
  
  ID of the user who’s logging in.

- **method**
  
  Type: `Auth.VerificationMethod`
Method used to verify the user’s identity, which can be EMAIL or SMS.

Return Value
Type: String
Identifier of the verification attempt.

Usage
Use this method along with its paired verifyPasswordlessLogin to customize the login experience with your own Visualforce Login and Verify pages. Invoke initPasswordlessLogin from the Login page where the user enters an email address or phone number.

Note: An alternative to using this combination of methods is to use Site.passwordlessLogin. Both approaches let you customize the Login page in Visualforce. With the paired methods, you can create custom Login and Verify pages. With Site.passwordlessLogin, Salesforce supplies the Verify page.

First call the initPasswordlessLogin method to initiate an authentication challenge. This method:
• Gets the user ID and verification method, such as EMAIL or SMS, from the Login page.
• Looks up the user and checks that the user is unique and active.
• Sends a verification code to the user.
• Adds an entry for the verification attempt to the Identity Verification History log, assigning an identifier to the verification attempt and setting the status to User challenged, waiting for response.
• Adds an entry for the Passwordless Login to the Login History log.
• Returns the identifier to verifyPasswordlessLogin to link the transactions.

Then call verifyPasswordlessLogin, which, if the user enters the verification code correctly, logs in the user.

Note: Users must verify their identity by email address or phone number before they can log in without a password. You can check whether the user is verified from the user’s detail page in Setup. Or you can check programmatically with TwoFactorMethodsInfo.

initRegisterVerificationMethod(method)
Invokes a verification challenge for registering identity verification methods with a custom (Visualforce) page. Users can register either their email address or phone number.

Signature
public static String initRegisterVerificationMethod(Auth.VerificationMethod method)

Parameters
method
Type: Auth.VerificationMethod
Method used to verify the user’s identity, which can be EMAIL or SMS.

Return Value
Type: String
The method returns an error message if the phone number is already registered, the user isn’t a customer or partner, or if the context isn’t an Experience Cloud site.

**Usage**

Use this method along with its paired `verifyRegisterVerificationMethod` on page 3576 to customize the process for registering a user’s verification method using a Visualforce Verify page.

First call the `initRegisterVerificationMethod` method to get the verification code sent to the user as input, and validate it. If the verification code isn’t valid, it returns an error message.

**Example**

Here’s a code example that registers a user’s phone number as a verification method. When the user enters a verification code on the Visualforce page, it invokes `registerUser()`. The method gets the User ID of the user who’s registering the verification method and the user’s phone number. It also gets the user’s registration status to check whether the phone number is verified already. If the user is registered with a different phone number, the number is updated.

```apex
public void registerUser() {
    try {
        exceptionText = ''; 
        String userId = UserInfo.getUserId();
        User u = [Select MobilePhone, Id from User Where Id=:userId];
        currPhone = u.MobilePhone;
        mobilePhone = getFormattedSms(mobilePhone);
        if (mobilePhone != null && mobilePhone != '') {
            u.MobilePhone = mobilePhone;
            update u;
            // We're updating the email and phone number before verifying. Roll back
            // the change in the verify API if it is unsuccessful.
            exceptionText = System.
            UserManagement.initRegisterVerificationMethod(Auth.VerificationMethod.SMS);
            if(exceptionText!= null && exceptionText!='') {
                isInit = false;
                showInitException = true;
            } else {
                isInit = false;
                isVerify = true;
            }
        } else {
            showInitException = true;
        }
    } catch (Exception e) {
        exceptionText = e.getMessage();
        isInit = false;
        showInitException = true;
    }
}

public void verifyUser() {
    // Take the user’s input for the code sent to their phone number
    exceptionText = System.
    UserManagement.
    verifyRegisterVerificationMethod(code, Auth.VerificationMethod.SMS);
    if(exceptionText != null && exceptionText!=''){
        isVerify = false;
        showInitException = true;
    }
}
```
showInitException = true;
} else {
    //Success
}

initSelfRegistration(method, user)
Invokes a verification challenge for self-registration when creating a custom (Visualforce) Verify page for Experience Cloud self-registration.

Signature
public static String initSelfRegistration(Auth.VerificationMethod method, User user)

Parameters
method
Type: Auth.VerificationMethod
Method used to verify the identity of the user, which can be EMAIL or SMS.

user
Type: User
User object to insert after successful registration.

Return Value
Type: String
Identifier of the registration attempt.

Usage
By default, when users sign up for your Experience Cloud site with an email address or phone number, Salesforce sends them a verification code. At the same time, it generates a Verify page for users to confirm their identity. You can replace the default Salesforce Verify page with your own Visualforce page and then invoke the verification process.

Call this method to initiate the authentication challenge, and include a User object to insert if the registration is successful. The method returns the identifier for the self-registration attempt.

Note: If you specify a language in the LanguageLocaleKey field on the User object, Salesforce uses this language for verification email and SMS messages.

Then call verifySelfRegistration, which, if the user enters the verification code correctly, logs in the user.

Example
This code contains the result of a verification challenge that registers a new user.

```java
String id = System.UserManagement.initSelfRegistration
(Auth.VerificationMethod.SMS, user);
Auth.VerificationResult res = System.UserManagement.verifySelfRegistration
(Auth.VerificationMethod.SMS, id, '123456', null);
if(res.success == true){
```
initVerificationMethod (method)

Initiates a verification service for email, phone (SMS), and the Salesforce Authenticator verification methods.

**Signature**

```java
public static String initVerificationMethod(Auth.VerificationMethod method)
```

**Parameters**

- `method`
  - Type: `Auth.VerificationMethod`
  - Method used to initiate a verification service for EMAIL, SMS, or SALESFORCE_AUTHENTICATOR verification methods.

**Return Value**

- Type: `String`
  - The returned identifier must be passed into `verifyVerificationMethod`.

**Usage**

Use this method along with its paired `verifyVerificationMethod` to customize a verification service for EMAIL, SMS, or SALESFORCE_AUTHENTICATOR verification methods. The returned identifier from `initVerificationMethod` must be passed into `verifyVerificationMethod`.

First invoke the `initVerificationMethod` method to send a verification code to the user’s email or phone number, or to send a push notification to the Salesforce Authenticator. The user then enters the code or approves the push notification. If the verification code isn’t valid or the push notification isn’t approved, the service returns an error message.

**Email Example**

This example shows multi-factor authentication using email.

```java
public void initVerification() {
    // user will receive code on their registered verified email
    identifier = UserManagement.initVerificationMethod(Auth.VerificationMethod.EMAIL);
}

public Auth.VerificationResult verifyVerification() {
    // requiring identifier from the initVerification
    // the code will need to be entered in this method
    return UserManagement.verifyVerificationMethod(identifier, code ,
        Auth.VerificationMethod.EMAIL);
}
```

initVerificationMethod (method, actionName, extras)

Initiates a verification service for email, phone (SMS), and the Salesforce Authenticator verification methods.
Signature

public static String initVerificationMethod(Auth.VerificationMethod method, String actionName, Map<String,String> extras)

Parameters

method
Type: Auth.VerificationMethod
Method used to initiate a verification service for EMAIL, SMS, or SALESFORCE_AUTHENTICATOR verification methods.

actionName
Type: String
For the SALESFORCE_AUTHENTICATOR verification method only, the name of the action to display on the Salesforce Authenticator, such as Connect to My Salesforce Org. The default action name is Apex-Defined Activity.

extras
Type: Map<String,String>
For the SALESFORCE_AUTHENTICATOR verification method only, the following extra settings.

- secure_device_required--If set to true, the user’s device must be secured. For example, the user must enter the device’s passcode to approve the request. Default setting is false.
- challenge_required--If set to true, the user must complete a biometric challenge, such as face recognition, on the device to approve the request. Default setting is false.

Return Value

Type: String
The returned identifier must be passed into verifyVerificationMethod method.

Usage

Use this method along with its paired verifyVerificationMethod to customize a verification service for EMAIL, SMS, or SALESFORCE_AUTHENTICATOR verification methods. The returned identifier from initVerificationMethod must be passed into verifyVerificationMethod method.

First invoke the initVerificationMethod method to send a verification code to the user’s email or phone number, or to send a push notification to the Salesforce Authenticator. The user then enters the code or approves the push notification. If the verification code isn’t valid or the push notification isn’t approved, the service returns an error message.

Salesforce Authenticator Example

This example shows multi-factor authentication (MFA) using the Salesforce Authenticator mobile app. In this example, the actionName parameter is set to the default setting and the extra parameter settings are set to false.

```java
public void initVerification() {
    // user will receive push notification on their registered MFA devices
    identifier = UserManagement.initVerificationMethod(Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
}

public Auth.VerificationResult verifyVerification() {
```
This example shows multi-factor authentication using Salesforce Authenticator. In this example, the `actionName` parameter is set to `Connect to My Salesforce Org` and the `challenge_required` extra parameter is set to `true`.

```apex
public void initVerification() {
    Map<String, String> extras = new Map<String, String>();
    extras.put('challenge_required', 'true');
    // user will receive push notification in their registered MFA devices
    identifier = UserManagement.initVerificationMethod(Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR, 'Connect to My Salesforce Org', extras);
}

public Auth.VerificationResult verifyVerification() {
    // requiring identifier from the initVerification
    // user will need to take the action on their registered MFA devices
    return UserManagement.verifyVerificationMethod(identifier, '', Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
}
```

**obfuscateUser(userId, username)**

Scrambles users’ data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it. Use this method to set the username to a specific value after it’s scrambled.

**Signature**

```apex
public static void obfuscateUser(Id userId, String username)
```

**Parameters**

- **userId**
  - Type: Id
  - ID of the user whose data this method scrambles.

- **username**
  - Type: String
  - The username after the user’s data is scrambled. Sets the value of the scrambled username to a specific string.

**Return Value**

Type: void

**Usage**

This method is introduced in API version 43.0. It isn't available in earlier versions.
You can use the `obfuscateUser` method to protect the personal information of your org's users. When invoked, Salesforce permanently scrambles the user’s object data and replaces it with random character strings. The user’s detail page exists, but the fields contain meaningless strings of characters. Salesforce merely obfuscates (scrambles) personal data because you can’t delete a user in Salesforce; you can only disable or deactivate a user. In other words, the user record remains in the database and this method performs a soft delete.

**Note:** Take care when using this method. The users’ data becomes anonymous and can never be recovered.

### Considerations
- This method requires that the org’s User Management setting, *Scramble Specific Users' Data*, is enabled from Setup.
- This method affects the standard fields of the user object—excluding a few fields such as the user ID, timezone, locale, and profile.
- It is recommended that you note the user’s ID and other attributes for post processing, such as the email address, if you want to send the user a confirmation.
- This method changes only the user object. The association between the user and other objects is removed, but no other objects are changed. For example, contact, ThirdPartyAccountLink (TPAL), and user password authentication (UPA) objects remain unchanged.

**Note:** Assure your admins that invoking this method doesn’t trigger an email change notification.

This method is part of our effort to protect users’ personal data and privacy. For more information on what you can do to actively protect user data, see Data Protection and Privacy in Salesforce Help.

**obfuscateUser** *(userId)*

Scrambles users’ data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it.

### Signature

```java
public static void obfuscateUser(Id userId)
```

### Parameters

- **userId**
  - Type: `Id`
  - ID of the user whose data this method scrambles.

### Return Value

- Type: `void`

### Usage

This method is introduced in API version 43.0. It isn’t available in earlier versions.

You can use the `obfuscateUser` method to protect the personal information of your org’s users. When invoked, Salesforce permanently scrambles the user’s object data and replaces it with random character strings. The user’s detail page exists, but the fields contain meaningless strings of characters. Salesforce merely obfuscates (scrambles) personal data because you can’t delete a user in Salesforce; you can only disable or deactivate a user. In other words, the user record remains in the database and this method performs a soft delete.

**Note:** Take care when using this method. The users’ data becomes anonymous and can never be recovered.
Considerations

- This method requires that the org’s User Management setting, Scramble Specific Users’ Data, is enabled from Setup.
- This method affects the standard fields of the user object—excluding a few fields such as the user ID, timezone, locale, and profile.
- If you want to send the user a confirmation, it’s recommended that you note the user’s ID and other attributes for post processing, such as the email address.
- This method changes only the user object. The association between the user and other objects is removed, but no other objects are changed. For example, contact, ThirdPartyAccountLink (TPAL), and user password authentication (UPA) objects remain unchanged.

Note: Assure your admins that invoking this method doesn’t trigger an email change notification.

This method is part of our effort to protect users’ personal data and privacy. For more information on what you can do to actively protect user data, see Data Protection and Privacy in Salesforce Help.

ObfuscateUser Code Example

```java
public class UserManagementController{
    public List<User> users {get; set;}

    public UserManagementController()
    {
        Profile p = [select id from profile where name = 'Customer Community User'];
        users = [select username, id from User where profileId=:p.id AND isactive=true];
    }

    //Use method with extreme caution. Data can’t be recovered.
    @InvocableMethod(label='User Management' description='Obfuscate User data and more')
    static public void obfuscate(List<User> users)
    {
        String uid = ApexPages.currentPage().getParameters().get('uid');
        if(uid == null)
            return;
        User u = [select contactId from user where id=:uid];
        System.UserManagement.obfuscateUser(uid);
    }
}
```

**registerVerificationMethod(method, startUrl)**

Registers an identity verification method. Verification methods can be a time-based one-time password (TOTP), email or text verification code, Salesforce Authenticator, or U2F-compatible security key. End users register verification methods for themselves.

**Signature**

```java
```
Parameters

method
  Type: Auth.VerificationMethod
  Verification method used to verify the identity of the user.

startUrl
  Type: String
  Path to the page that users see after they log in.

Return Value

Type: System.PageReference

Usage

Use this method to enable users to complete identity verification, such as multi-factor authentication (MFA), or to log in to their Experience Cloud site without a password. Users register these methods to verify their identity when logging in. You create a custom registration page when implementing mobile-centric passwordless logins. See VerifyPasswordlessLogin.

The PageReference returned by registerVerificationMethod redirects the user to the Salesforce Verify page. If the user enters the correct code, the user is redirected to the Experience Cloud site page specified by the start URL. For example:

```java
PageReference pr = System.UserManagement.registerVerificationMethod(Auth.VerificationMethod.TOTP, startUrl);
PageReference p = System.UserManagement.deregisterVerificationMethod(userId, Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
```

This method is available in API version 43.0 and later.

Note: As a security measure, when users add or update mobile numbers in their detail page, they must log in again to verify their identity. As a result, unsaved changes in the app are lost. To disable this security measure, contact Salesforce Support.

sendAsyncEmailConfirmation(userId, emailTemplateId, networkId, startUrl)

Send an email message to a user's email address for verification. The message contains a verification link (URL) that the user clicks to verify the email address later on. You can send email verifications in bulk.

Signature

public static Boolean sendAsyncEmailConfirmation(String userId, String emailTemplateId, String networkId, String startUrl)

Parameters

userId
  Type: String
  ID of the user to receive the email confirmation.
emailTemplateId
Type: String
ID of the email template in which the verification link is defined.

networkId
Type: String
ID of the Experience Cloud site.

startUrl
Type: String
The user is redirected to this page after verification, with a success or error message as the parameter. If null, the user is redirected to the login page.

Return Value
Type: Boolean
Indicates whether sending the email message succeeded or failed.

Usage
Sending an async email message is good practice to ensure that users are registered with a valid email address that they truly own. To determine which users receive an email with the verification link, check whether the User Verified Email field in the User detail page is set to true. You can also get this information from the TwoFactorMethodsInfo API.
Send async email verification to customers and partners to verify their email address. These users must verify their email address before they can log in with email OTP (passwordless login).
The error code and description are passed as query parameters so that you can process any errors when building a custom landing page.

Example
```
System.UserManagement.sendAsyncEmailConfirmation('005RM000001a0Ox',
'00XRM000000hxnG','0DBRM000000015i', '/s/contactsupport');
```

verifyPasswordlessLogin(userId, method, identifier, code, startUrl)
Completes a verification challenge during a passwordless login that uses a custom Verify page (Visualforce only). If the user who is trying to log in enters the verification code successfully, the user is logged in.

Signature
```
public static Auth.VerificationResult verifyPasswordlessLogin(Id userId,
Auth.VerificationMethod method, String identifier, String code, String startUrl)
```

Parameters
userId
Type: Id
ID of the user who’s logging in.
method
Type: Auth.VerificationMethod
Method used to verify the identity of the user, which can be either EMAIL or SMS.

identifier
Type: String
ID of the verification attempt received from the initPasswordlessLogin method.

code
Type: String
Code used to verify the identity of the user.

startUrl
Type: String
The page where the user is directed after successful login.

Return Value
Type: Auth.VerificationResult
Result of the verification challenge, which includes the message displayed, and where the user is directed if they enter the verification code correctly.

Usage
Call this method to complete the passwordless login authentication process. It validates the verification method and verification code. It also checks that the identifier is the same as the one returned by initPasswordlessLogin on page 3565.

Example
For an example, see Auth.VerificationResult.

`verifyRegisterVerificationMethod(code, method)`
Completes registering a user’s email address or phone number as a verification method when customizing the identity verification process.

Signature
`public static String verifyRegisterVerificationMethod(String code, Auth.VerificationMethod method)`

Parameters
`code`
Type: String
Code used to verify the identity of the user.

`method`
Type: Auth.VerificationMethod
Method used to verify the identity of the user, which can be either EMAIL or SMS.
Return Value

Type: String

If the user enters an incorrect verification code, the method returns an error message.

Usage

Call verifyRegisterVerificationMethod to complete the process of registering a user's verification method. This method checks whether the user entered the correct verification code. If the verification code is correct, the method

• Confirms that the user entered the correct verification code
• From the user's detail page, updates the user's verification method status (sets the verification bit)
• Sends an email to the user confirming that a verification method has been added to their record

If the verification code is incorrect, an error message is returned.

Note: If users want to change their email address after registering one, don’t use the initRegisterVerificationMethod and verify RegisterVerificationMethod methods. To enable automatic identity verification for email address changes, from the Identity Verification Setup page, select the field Require email confirmations for email address changes (applies to users in Experience Builder sites).

Example

Here’s a code example that registers a user's phone number as a verification method. When the user enters a verification code on the Visualforce page, it invokes registerUser(). The method gets the User ID of the user who’s registering the verification method and the user’s phone number. It also gets the user’s registration status to check whether the phone number is verified already. If the user is registered with a different phone number, the number is updated.

```apex
public void registerUser() {
    try {
        exceptionText = ''; 
        String userId = UserInfo.getUserId();
        User u = [Select MobilePhone, Id from User Where Id=:userId];
        currPhone = u.MobilePhone;
        mobilePhone = getFormattedSms(mobilePhone);
        if (mobilePhone != null && mobilePhone != '') {
            u.MobilePhone = mobilePhone;
            update u;
            // We're updating the email and phone number before verifying. Roll back // the change in the verify API if it is unsuccessful.
            exceptionText = System.
            UserManagement.initRegisterVerificationMethod(Auth.VerificationMethod.SMS);
            if(exceptionText!= null && exceptionText!=''){
                isInit = false;
                showInitException = true;
            } else {
                isInit = false;
                isVerify = true;
            }
        } else {
            showInitException = true;
        }
    } catch (Exception e) {
        exceptionText = e.getMessage();
    }
} 
```

3577
isInit = false;
showInitException = true;
}
}

public void verifyUser() {
    // Take the user’s input for the code sent to their phone number
    exceptionText = System.UserManagement.
    verifyRegisterVerificationMethod(code, Auth.VerificationMethod.SMS);
    if(exceptionText != null && exceptionText !=''){showInitException = true;
    } else {
        //Success
    }
}

**verifySelfRegistration(method, identifier, code, startUrl)**

Completes a verification challenge when creating a custom (Visualforce) Verify page for Experience Cloud site self-registration. If the person who is attempting to register enters the verification code successfully, the user is created and logged in.

**Signature**

public static Auth.VerificationResult verifySelfRegistration(Auth.VerificationMethod method, String identifier, String code, String startUrl)

**Parameters**

**method**

Type: Auth.VerificationMethod

Method used to verify the identity of the user, which can be either EMAIL or SMS.

**identifier**

Type: String

The unique identifier received from the initSelfRegistration method.

**code**

Type: String

Code used to verify the identity of the user.

**startUrl**

Type: String

The page where the user is directed after successful self-registration.

**Return Value**

Type: Auth.VerificationResult

Result of the verification challenge, which includes the message displayed, and where the user is directed when they enter the verification code correctly.
Usage

By default, when users sign up for your Experience Cloud site with an email address or phone number, Salesforce sends them a verification code and generates a Verify page. This Verify page is where users enter the verification code to confirm their identity. You can replace this Salesforce-generated Verify page with a custom Verify page that you create with Visualforce. Then you invoke the verification process with Apex methods.

First, call the `initSelfRegistration` method, which returns the identifier of the user to create. Then call this `verifySelfRegistration` method to complete the verification process. If the user enters the verification code correctly, the user is created and directed to the page specified in the `startURL`.

This method returns the verification result, which contains the verification status and, if the user is created, the session ID. If the verification method is SMS, the User object must contain a properly formatted mobile number, which is country code, space, and then phone number, for example, +1 1234567890. Use `System.UserManagement.formatPhoneNumber` to ensure that the phone number is formatted correctly.

Example

This code contains the result of a verification challenge that registers a new user.

```java
String id = System.UserManagement.initSelfRegistration
(Auth.VerificationMethod.SMS, user);
Auth.VerificationResult res = System.UserManagement.verifySelfRegistration
(Auth.VerificationMethod.SMS, id, '123456', null);
if(res.success == true){
    //redirect
}
```

`verifyVerificationMethod(identifier, code, method)`

Completes the verification service for email, phone (SMS), Salesforce Authenticator, password, or time-based one-time password (TOTP) verification methods.

Signature

```java
public static VerificationResult verifyVerificationMethod(String identifier, String code, Auth.VerificationMethod method)
```

Parameters

- **identifier**
  - Type: `String`
  - Identifier returned from `initVerificationMethod` for EMAIL, SMS, and SALESFORCE_AUTHENTICATOR.

- **code**
  - Type: `String`
  - Code used to verify the user's identity for EMAIL, SMS, or PASSWORD.

- **method**
  - Type: `Auth.VerificationMethod`
  - Method used to verify the user's identity, which can be EMAIL, PASSWORD, SALESFORCE_AUTHENTICATOR, SMS, or TOTP.
Return Value
Type: VerificationResult

Usage
Use this method along with its paired initVerificationMethod to customize a verification service for EMAIL, SMS, or SALESFORCE_AUTHENTICATOR verification methods. Or use this method alone to provide a complete verification service for PASSWORD and TOTP verification methods.

This method checks whether the user entered the correct verification code or password. If the verification code or password is correct, the method verifies the user’s identity.

If the verification code or password isn’t valid, the service returns an error message.

Examples
This example shows multi-factor authentication using email.

```java
public void initVerification() {
    // user will receive code on their registered verified email
    identifier = UserManagement.initVerificationMethod(Auth.VerificationMethod.EMAIL);
}

public Auth.VerificationResult verifyVerification() {
    // requiring identifier from the initVerification
    // the code will need to be entered in this method
    return UserManagement.verifyVerificationMethod(identifier, code ,
        Auth.VerificationMethod.EMAIL);
}
```

The next two examples show multi-factor authentication using only the verifyVerificationMethod for password and TOTP verifications.

```java
public Auth.VerificationResult verifyVerification() {
    // user will enter their password as a param in the verifyVerificationMethod for password verification method
    return UserManagement.verifyVerificationMethod('', password ,
        Auth.VerificationMethod.PASSWORD);
}

public Auth.VerificationResult verifyVerification() {
    // user will enter their registered time-based one-time password (TOTP) code (token)
    return UserManagement.verifyVerificationMethod('', code ,
        Auth.VerificationMethod.TOTP);
}
```

Version Class
Use the Version methods to get the version of a first-generation managed package, and to compare package versions.

Namespace
System
Usage

A package version is a number that identifies the set of components uploaded in a package. The version number has the format `majorNumber.minorNumber.patchNumber` (for example, 2.1.3). The major and minor numbers increase to a chosen value during every major release. The `patchNumber` is generated and updated only for a patch release.

A called component can check the version against which the caller was compiled using the `System.requestVersion` method and behave differently depending on the caller’s expectations. This allows you to continue to support existing behavior in classes and triggers in previous package versions while continuing to evolve the code.

The value returned by the `System.requestVersion` method is an instance of this class with a two-part version number containing a major and a minor number. Since the `System.requestVersion` method doesn’t return a patch number, the patch number in the returned `Version` object is null.

The `System.Version` class can also hold also a three-part version number that includes a patch number.

Example

This example shows how to use the methods in this class, along with the `requestVersion` method, to determine the managed package version of the code that is calling your package.

```java
if (System.requestVersion() == new Version(1,0))
{
    // Do something
}
if ((System.requestVersion().major() == 1)
    && (System.requestVersion().minor() > 0)
    && (System.requestVersion().minor() <=9))
{
    // Do something different for versions 1.1 to 1.9
}
else if (System.requestVersion().compareTo(new Version(2,0)) >= 0)
{
    // Do something completely different for versions 2.0 or greater
}
```

IN THIS SECTION:

- Version Constructors
- Version Methods

Version Constructors

The following are constructors for `Version`.

IN THIS SECTION:

- `Version(major, minor)`
  Creates a new instance of the `Version` class as a two-part package version using the specified major and minor version numbers.
- `Version(major, minor, patch)`
  Creates a new instance of the `Version` class as a three-part package version using the specified major, minor, and patch version numbers.
**Version(major, minor)**

Creates a new instance of the `Version` class as a two-part package version using the specified major and minor version numbers.

**Signature**

```java
public Version(Integer major, Integer minor)
```

**Parameters**

- **major**
  - Type: `Integer`
  - The major version number.

- **minor**
  - Type: `Integer`
  - The minor version number.

**Version(major, minor, patch)**

Creates a new instance of the `Version` class as a three-part package version using the specified major, minor, and patch version numbers.

**Signature**

```java
public Version(Integer major, Integer minor, Integer patch)
```

**Parameters**

- **major**
  - Type: `Integer`
  - The major version number.

- **minor**
  - Type: `Integer`
  - The minor version number.

- **patch**
  - Type: `Integer`
  - The patch version number.

**Version Methods**

The following are methods for `Version`. All are instance methods.

**IN THIS SECTION:**

- `compareTo(version)`
  - Compares the current version with the specified version.
major()
Returns the major package version of the calling code.

minor()
Returns the minor package version of the calling code.

patch()
Returns the patch package version of the calling code or `null` if there is no patch version.

**compareTo(version)**
Compares the current version with the specified version.

**Signature**
```
public Integer compareTo(System.Version version)
```

**Parameters**

- `version`
  Type: `System.Version`

**Return Value**
Type: `Integer`
Returns one of the following values:
- zero if the current package version is equal to the specified package version
- an Integer value greater than zero if the current package version is greater than the specified package version
- an Integer value less than zero if the current package version is less than the specified package version

**Usage**
If a two-part version is being compared to a three-part version, the patch number is ignored and the comparison is based only on the major and minor numbers.

**major()**
Returns the major package version of the calling code.

**Signature**
```
public Integer major()
```

**Return Value**
Type: `Integer`

**minor()**
Returns the minor package version of the calling code.
Signature
public Integer minor()

Return Value
Type: Integer

patch()
Returns the patch package version of the calling code or null if there is no patch version.

Signature
public Integer patch()

Return Value
Type: Integer

WebServiceCallout Class
Enables making callouts to SOAP operations on an external Web service. This class is used in the Apex stub class that is auto-generated from a WSDL.

Namespace
System

IN THIS SECTION:
WebServiceCallout Methods

SEE ALSO:
Apex Developer Guide: SOAP Services: Defining a Class from a WSDL Document

WebServiceCallout Methods
The following is the static method for WebServiceCallout.

IN THIS SECTION:
invoke(stub, request, response, infoArray)
Invokes an external SOAP web service operation based on an Apex class that is auto-generated from a WSDL.

invoke(stub, request, response, infoArray)
Invokes an external SOAP web service operation based on an Apex class that is auto-generated from a WSDL.
Signature

```java
public static void invoke(Object stub, Object request, Map<String, Object> response,
List<String> infoArray)
```

Parameters

**stub**

Type: Object

An instance of the Apex class that is auto-generated from a WSDL (the stub class).

**request**

Type: Object

The request to the external service. The request is an instance of a type that is created as part of the auto-generated stub class.

**response**

Type: `Map<String, Object>`

A map of key-value pairs that represent the response that the external service sends after receiving the request. In each pair, the key is a response identifier. The value is the response object, which is an instance of a type that is created as part of the auto-generated stub class.

**infoArray**

Type: `String[]`

An array of strings that contains information about the callout—web service endpoint, SOAP action, request, and response. The order of the elements in the array matters.

- Element at index 0 ([0]): One of the following options for identifying the URL of the external web service.
  - Endpoint URL. For example: 'http://YourServer/YourService'
  - Named credential URL, which contains the scheme `callout`, the name of the named credential, and optionally, an appended path. For example: 'callout:MyNamedCredential/some/path'
- Element at index 1 ([1]): The SOAP action. For example: 'urn:dotnet.callouttest.soap.sforce.com/EchoString'
- Element at index 2 ([2]): The request namespace. For example: 'http://doc.sample.com/docSample'
- Element at index 3 ([3]): The request name. For example: 'EchoString'
- Element at index 4 ([4]): The response namespace. For example: 'http://doc.sample.com/docSample'
- Element at index 5 ([5]): The response name. For example: 'EchoStringResponse'
- Element at index 6 ([6]): The response type. For example: 'docSample.EchoStringResponse_element'

Return Value

Type: Void

SEE ALSO:

*Apex Developer Guide: Named Credentials as Callout Endpoints*

**WebServiceMock Interface**

Enables sending fake responses when testing Web service callouts of a class auto-generated from a WSDL.
Namespace

System

Usage

For an implementation example, see Test Web Service Callouts.

WebServiceMock Methods

The following are methods for WebServiceMock.

IN THIS SECTION:

    doInvoke(stub, soapRequest, responseMap, endpoint, soapAction, requestName, responseNamespace, responseName, responseType)

    The implementation of this method is called by the Apex runtime to send a fake response when a Web service callout is made after Test.setMock has been called.

    doInvoke(stub, soapRequest, responseMap, endpoint, soapAction, requestName, responseNamespace, responseName, responseType)

    The implementation of this method is called by the Apex runtime to send a fake response when a Web service callout is made after Test.setMock has been called.

Signature

public Void doInvoke(Object stub, Object soapRequest, Map<String, Object> responseMap, String endpoint, String soapAction, String requestName, String responseNamespace, String responseName, String responseType)

Parameters

stub

    Type: Object
    An instance of the auto-generated class.

soapRequest

    Type: Object
    The SOAP Web service request being invoked.

responseMap

    Type: Map<String, Object>
    A collection of key/value pairs representing the response to send for the request.
    When implementing this interface, set the responseMap argument to a key/value pair representing the response desired.

endpoint

    Type: String
    The endpoint URL for the request.
soapAction
   Type: String
   The requested SOAP operation.

requestName
   Type: String
   The requested SOAP operation name.

responseNamespace
   Type: String
   The response namespace.

responseName
   Type: String
   The name of the response element as defined in the WSDL.

responseType
   Type: String
   The class for the response as defined in the auto-generated class.

Return Value
   Type: Void

Usage

**XmlStreamReader Class**

The XmlStreamReader class provides methods for forward, read-only access to XML data. You can pull data from XML or skip unwanted events. You can parse nested XML content that’s up to 50 nodes deep.

Namespace

System

Usage

The XmlStreamReader class is similar to the XMLStreamReader utility class from StAX (Streaming API for XML). StAX is an API to read and write XML documents, originating from the Java programming language community.

**Note:** The XmlStreamReader class in Apex is based on its counterpart in Java. See [Java XMLStreamReader class](#).

IN THIS SECTION:

XmlStreamReader Constructors
XmlStreamReader Methods

SEE ALSO:
Apex Developer Guide: Reading XML Using Streams

XmlStreamReader Constructors

The following are constructors for XmlStreamReader.

IN THIS SECTION:
XmlStreamReader(xmlInput)
Creates a new instance of the XmlStreamReader class for the specified XML input.

XmlStreamReader(xmlInput)
Creates a new instance of the XmlStreamReader class for the specified XML input.

Signature
public XmlStreamReader(String xmlInput)

Parameters
xmlInput:
Type: String
The XML string input.

XmlStreamReader Methods

The following are methods for XmlStreamReader. All are instance methods.

IN THIS SECTION:
getAttributeCount()
Returns the number of attributes on the start element, excluding namespace definitions.
getAttributeLocalName(index)
Returns the local name of the attribute at the specified index.
getAttributeNamespace(index)
Returns the namespace URI of the attribute at the specified index.
getAttributePrefix(index)
Returns the prefix of this attribute at the specified index.
getAttributeType(index)
Returns the XML type of the attribute at the specified index.
getAttributeValue(namespaceUri, localName)
Returns the value of the attribute in the specified localName at the specified URI.
getAttributeValueAt(index)
Returns the value of the attribute at the specified index.

getEventType()
Returns the type of XML event the cursor is pointing to.

getLocalName()
Returns the local name of the current event.

getLocation()
Return the current location of the cursor.

getNamespace()
If the current event is a start element or end element, this method returns the URI of the prefix or the default namespace.

getNamespaceCount()
Returns the number of namespaces declared on a start element or end element.

getNamespacePrefix(index)
Returns the prefix for the namespace declared at the index.

getNamespaceURI(prefix)
Return the URI for the given prefix.

getNamespaceURIAt(index)
Returns the URI for the namespace declared at the index.

getPIData()
Returns the data section of a processing instruction.

getPITarget()
Returns the target section of a processing instruction.

getPrefix()
Returns the prefix of the current XML event or null if the event does not have a prefix.

getText()
Returns the current value of the XML event as a string.

getVersion()
Returns the XML version specified on the XML declaration. Returns null if none was declared.

hasName()
Returns true if the current XML event has a name. Returns false otherwise.

hasNext()
Returns true if there are more XML events and false if there are no more XML events.

hasText()
Returns true if the current event has text, false otherwise.

isCharacters()
Returns true if the cursor points to a character data XML event. Otherwise, returns false.

isEndElement()
Returns true if the cursor points to an end tag. Otherwise, it returns false.

isStartElement()
Returns true if the cursor points to a start tag. Otherwise, it returns false.
isWhiteSpace()  
Returns true if the cursor points to a character data XML event that consists of all white space. Otherwise it returns false.

next()  
Reads the next XML event. A processor may return all contiguous character data in a single chunk, or it may split it into several chunks. Returns an integer which indicates the type of event.

nextTag()  
Skips any white space (the isWhiteSpace method returns true), comment, or processing instruction XML events, until a start element or end element is reached. Returns the index for that XML event.

setCoalescing(returnAsSingleBlock)  
If you specify true for returnAsSingleBlock, text is returned in a single block, from a start element to the first end element or the next start element, whichever comes first. If you specify it as false, the parser may return text in multiple blocks.

setNamespaceAware(isNamespaceAware)  
If you specify true for isNamespaceAware, the parser recognizes namespace. If you specify it as false, the parser does not. The default value is true.

toString()  
Returns a string containing the length of the input XML given to XmlStreamReader and the first 50 characters of the input XML.

getAttributeCount()  
Returns the number of attributes on the start element, excluding namespace definitions.

**Signature**

public Integer getAttributeCount()  

**Return Value**

Type: Integer

**Usage**

This method is only valid on a start element or attribute XML events. The count for the number of attributes for an attribute XML event starts with zero.

getAttributeLocalName(index)  
Returns the local name of the attribute at the specified index.

**Signature**

public String getAttributeLocalName(Integer index)

**Parameters**

index  
Type: Integer
Return Value
Type: String

Usage
If there is no name, an empty string is returned. This method is only valid with start element or attribute XML events.

getAttributeNamespace(index)
Returns the namespace URI of the attribute at the specified index.

Signature
public String getAttributeNamespace(Integer index)

Parameters
index
Type: Integer

Return Value
Type: String

Usage
If no namespace is specified, null is returned. This method is only valid with start element or attribute XML events.

getAttributePrefix(index)
Returns the prefix of this attribute at the specified index.

Signature
public String getAttributePrefix(Integer index)

Parameters
index
Type: Integer

Return Value
Type: String

Usage
If no prefix is specified, null is returned. This method is only valid with start element or attribute XML events.
**getAttributeType(index)**
Returns the XML type of the attribute at the specified index.

**Signature**
```
public String getAttributeType(Integer index)
```

**Parameters**
- **index**
  Type: Integer

**Return Value**
Type: String

**Usage**
For example, `id` is an attribute type. This method is only valid with start element or attribute XML events.

**getAttributeValue(namespaceUri, localName)**
Returns the value of the attribute in the specified `localName` at the specified URI.

**Signature**
```
public String getAttributeValue(String namespaceUri, String localName)
```

**Parameters**
- **namespaceUri**
  Type: String
- **localName**
  Type: String

**Return Value**
Type: String

**Usage**
Returns `null` if the value is not found. You must specify a value for `localName`. This method is only valid with start element or attribute XML events.

**getAttributeValueAt(index)**
Returns the value of the attribute at the specified index.
Signature

```java
public String getAttributeValueAt(Integer index)
```

Parameters

```java
index
Type: Integer
```

Return Value

Type: String

Usage

This method is only valid with start element or attribute XML events.

`getEventType()`

Returns the type of XML event the cursor is pointing to.

Signature

```java
public System.XmlTag getEventType()
```

Return Value

Type: System.XmlTag

**XmlTag Enum**

The values for XmlTag are:

- ATTRIBUTE
- CDATA
- CHARACTERS
- COMMENT
- DTD
- END_DOCUMENT
- END_ELEMENT
- ENTITY_DECLARATION
- ENTITY_REFERENCE
- NAMESPACE
- NOTATION_DECLARATION
- PROCESSING_INSTRUCTION
- SPACE
- START_DOCUMENT
- START_ELEMENT
**getLocalName()**

Returns the local name of the current event.

**Signature**

```java
public String getLocalName()
```

**Return Value**

Type: String

**Usage**

For start element or end element XML events, it returns the local name of the current element. For the entity reference XML event, it returns the entity name. The current XML event must be start element, end element, or entity reference.

**getLocation()**

Return the current location of the cursor.

**Signature**

```java
public String getLocation()
```

**Return Value**

Type: String

**Usage**

If the location is unknown, returns -1. The location information is only valid until the next method is called.

**getNamespace()**

If the current event is a start element or end element, this method returns the URI of the prefix or the default namespace.

**Signature**

```java
public String getNamespace()
```

**Return Value**

Type: String

**Usage**

Returns null if the XML event does not have a prefix.
getNamespaceCount()
Returns the number of namespaces declared on a start element or end element.

Signature
public Integer getNamespaceCount()

Return Value
Type: Integer

Usage
This method is only valid on a start element, end element, or namespace XML event.

getNamespacePrefix(index)
Returns the prefix for the namespace declared at the index.

Signature
public String getNamespacePrefix(Integer index)

Parameters
index
  Type: Integer

Return Value
Type: String

Usage
Returns null if this is the default namespace declaration. This method is only valid on a start element, end element, or namespace XML event.

getNamespaceURI(prefix)
Return the URI for the given prefix.

Signature
public String getNamespaceURI(String prefix)

Parameters
prefix
  Type: String
Return Value
Type: String

Usage
The returned URI depends on the current state of the processor.

**getNamespaceURIAt(index)**
Returns the URI for the namespace declared at the index.

**Signature**
```java
public String getNamespaceURIAt(Integer index)
```

**Parameters**
- **index**
  Type: Integer

**Return Value**
Type: String

Usage
This method is only valid on a start element, end element, or namespace XML event.

**getPIData()**
Returns the data section of a processing instruction.

**Signature**
```java
public String getPIData()
```

**Return Value**
Type: String

**getPITarget()**
Returns the target section of a processing instruction.

**Signature**
```java
public String getPITarget()
```

**Return Value**
Type: String
getPrefix()  
Returns the prefix of the current XML event or null if the event does not have a prefix.

**Signature**  
```java
public String getPrefix()
```

**Return Value**  
Type: `String`

getText()  
Returns the current value of the XML event as a string.

**Signature**  
```java
public String getText()
```

**Return Value**  
Type: `String`

**Usage**  
The valid values for the different events are:
- The string value of a character XML event
- The string value of a comment
- The replacement value for an entity reference. For example, assume `getText` reads the following XML snippet:

```xml
<!ENTITY Title "Salesforce For Dummies" >
<moo a="b">Name &Title;</moo>'
```

The `getText` method returns `Salesforce for Dummies`, not `&Title`.
- The string value of a CDATA section
- The string value for a space XML event
- The string value of the internal subset of the DTD

getVersion()  
Returns the XML version specified on the XML declaration. Returns `null` if none was declared.

**Signature**  
```java
public String getVersion()
```
Return Value
Type: String

**hasName()**

Returns `true` if the current XML event has a name. Returns `false` otherwise.

**Signature**
`public Boolean hasName()`

**Return Value**
Type: Boolean

**Usage**
This method is only valid for start element and stop element XML events.

**hasNext()**

Returns `true` if there are more XML events and `false` if there are no more XML events.

**Signature**
`public Boolean hasNext()`

**Return Value**
Type: Boolean

**Usage**
This method returns `false` if the current XML event is end document.

**hasText()**

Returns `true` if the current event has text, `false` otherwise.

**Signature**
`public Boolean hasText()`

**Return Value**
Type: Boolean

**Usage**
The following XML events have text: characters, entity reference, comment and space.
isCharacters()
Returns true if the cursor points to a character data XML event. Otherwise, returns false.

Signature
public Boolean isCharacters()

Return Value
Type: Boolean

isEndElement()
Returns true if the cursor points to an end tag. Otherwise, it returns false.

Signature
public Boolean isEndElement()

Return Value
Type: Boolean

isStartElement()
Returns true if the cursor points to a start tag. Otherwise, it returns false.

Signature
public Boolean isStartElement()

Return Value
Type: Boolean

isWhiteSpace()
Returns true if the cursor points to a character data XML event that consists of all white space. Otherwise it returns false.

Signature
public Boolean isWhiteSpace()

Return Value
Type: Boolean
**next ()**
Reads the next XML event. A processor may return all contiguous character data in a single chunk, or it may split it into several chunks. Returns an integer which indicates the type of event.

**Signature**
`public Integer next()`

**Return Value**
Type: Integer

**nextTag ()**
Skips any white space (the `isWhiteSpace` method returns `true`), comment, or processing instruction XML events, until a start element or end element is reached. Returns the index for that XML event.

**Signature**
`public Integer nextTag()`

**Return Value**
Type: Integer

**Usage**
This method throws an error if elements other than white space, comments, processing instruction, start elements or stop elements are encountered.

**setCoalescing (returnAsSingleBlock)**
If you specify `true` for `returnAsSingleBlock`, text is returned in a single block, from a start element to the first end element or the next start element, whichever comes first. If you specify it as `false`, the parser may return text in multiple blocks.

**Signature**
`public Void setCoalescing(Boolean returnAsSingleBlock)`

**Parameters**
`returnAsSingleBlock`
Type: `Boolean`

**Return Value**
Type: Void
setNamespaceAware(isNamespaceAware)

If you specify true for isNamespaceAware, the parser recognizes namespace. If you specify it as false, the parser does not. The default value is true.

Signature

```java
public Void setNamespaceAware(Boolean isNamespaceAware)
```

Parameters

isNamespaceAware
Type: Boolean

Return Value

Type: Void

toString()

Returns a string containing the length of the input XML given to XmlStreamReader and the first 50 characters of the input XML.

Signature

```java
public String toString()
```

Return Value

Type: String

XmlStreamWriter Class

The XmlStreamWriter class provides methods for writing XML data.

Namespace

System

Usage

You can use the XmlStreamWriter class to programmatically construct an XML document, then use HTTP classes to send the document to an external server.

The XmlStreamWriter class is similar to the XMLStreamWriter utility class from StAX (Streaming API for XML). StAX is an API to read and write XML documents, originating from the Java programming language community.

Note: The XmlStreamWriter class in Apex is based on its counterpart in Java. See Java XMLStreamWriter class.

IN THIS SECTION:

XmlStreamWriter Constructors
XmlStreamWriter Methods

SEE ALSO:
- Http Class
- HttpRequest Class
- HttpResponse Class

XmlStreamWriter Constructors
The following are constructors for XmlStreamWriter.

IN THIS SECTION:
- XmlStreamWriter()
  Creates a new instance of the XmlStreamWriter class.

XmlStreamWriter()
Creates a new instance of the XmlStreamWriter class.

Signature

public XmlStreamWriter()

XmlStreamWriter Methods
The following are methods for XmlStreamWriter. All are instance methods.

IN THIS SECTION:
- close()
  Closes this instance of an XmlStreamWriter and free any resources associated with it.
- getXmlString()
  Returns the XML written by the XmlStreamWriter instance.
- setDefaultNamespace(uri)
  Binds the specified URI to the default namespace. This URI is bound in the scope of the current START_ELEMENT – END_ELEMENT pair.
- writeAttribute(prefix, namespaceUri, localName, value)
  Writes an attribute to the output stream.
- writeCData(data)
  Writes the specified CData to the output stream.
- writeCharacters(text)
  Writes the specified text to the output stream.
- writeComment(comment)
  Writes the specified comment to the output stream.
writeDefaultNamespace(namespaceUri)
Writes the specified namespace to the output stream.

writeEmptyElement(prefix, localName, namespaceUri)
Writes an empty element tag to the output stream.

writeEndElement()
Closes any start tags and writes corresponding end tags to the output stream.

writeEndDocument()
Writes an end tag to the output stream, relying on the internal state of the writer to determine the prefix and local name.

writeNamespace(prefix, namespaceUri)
Writes the specified namespace to the output stream.

writeProcessingInstruction(target, data)
Writes the specified processing instruction.

writeStartDocument(encoding, version)
Writes the XML Declaration using the specified XML encoding and version.

writeStartElement(prefix, localName, namespaceUri)
Writes the start tag specified by localName to the output stream.

close()
Closes this instance of an XmlStreamWriter and free any resources associated with it.

Signature
public Void close()

Return Value
Type: Void

getXmlString()
Returns the XML written by the XmlStreamWriter instance.

Signature
public String getXmlString()

Return Value
Type: String

setDefaultNamespace(uri)
Binds the specified URI to the default namespace. This URI is bound in the scope of the current START_ELEMENT – END_ELEMENT pair.
setDefaultNamespace(String uri)

Parameters
uri
Type: String

Return Value
Type: Void

writeAttribute(prefix, namespaceUri, localName, value)

Writes an attribute to the output stream.

writeCData(data)

Writers the specified CData to the output stream.
Return Value
Type: Void

**writeCharacters(text)**
Writes the specified text to the output stream.

**Signature**
```
public Void writeCharacters(String text)
```

**Parameters**
- **text**
  Type: `String`

**Return Value**
Type: Void

**writeComment(comment)**
Writes the specified comment to the output stream.

**Signature**
```
public Void writeComment(String comment)
```

**Parameters**
- **comment**
  Type: `String`

**writeDefaultNamespace(namespaceUri)**
Writes the specified namespace to the output stream.

**Signature**
```
public Void writeDefaultNamespace(String namespaceUri)
```

**Parameters**
- **namespaceUri**
  Type: `String`
**Return Value**
Type: Void

**writeEmptyElement**(prefix, localName, namespaceUri)
Writes an empty element tag to the output stream.

**Signature**
```java
public Void writeEmptyElement(String prefix, String localName, String namespaceUri)
```

**Parameters**
- **prefix**
  Type: String
- **localName**
  Type: String
  Specifies the name of the tag to be written.
- **namespaceUri**
  Type: String

**Return Value**
Type: Void

**writeEndDocument**()
Closes any start tags and writes corresponding end tags to the output stream.

**Signature**
```java
public Void writeEndDocument()
```

**Return Value**
Type: Void

**writeEndElement**()
Writes an end tag to the output stream, relying on the internal state of the writer to determine the prefix and local name.

**Signature**
```java
public Void writeEndElement()
```

**Return Value**
Type: Void
writeNamespace(prefix, namespaceUri)
Writes the specified namespace to the output stream.

Signature
public Void writeNamespace(String prefix, String namespaceUri)

Parameters
prefix
Type: String
namespaceUri
Type: String

Return Value
Type: Void

writeProcessingInstruction(target, data)
Writes the specified processing instruction.

Signature
public Void writeProcessingInstruction(String target, String data)

Parameters
target
Type: String
data
Type: String

Return Value
Type: Void

writeStartDocument(encoding, version)
Writes the XML Declaration using the specified XML encoding and version.

Signature
public Void writeStartDocument(String encoding, String version)

Parameters
encoding
Type: String
version
Type: String

Return Value
Type: Void

**writeStartElement(prefix, localName, namespaceUri)**
Writes the start tag specified by `localName` to the output stream.

**Signature**
```java
public Void writeStartElement(String prefix, String localName, String namespaceUri)
```

**Parameters**
- **prefix**
  Type: String
- **localName**
  Type: String
- **namespaceUri**
  Type: String

**Return Value**
Type: Void

**TerritoryMgmt Namespace**

The **TerritoryMgmt** namespace provides an interface used for territory management.
The following is the interface in the **TerritoryMgmt** namespace.

**IN THIS SECTION:**
- **OpportunityTerritory2AssignmentFilter Global Interface**
  Apex interface that allows an implementing class to assign a single territory to an opportunity.

**OpportunityTerritory2AssignmentFilter Global Interface**

Apex interface that allows an implementing class to assign a single territory to an opportunity.

**Namespace**

**TerritoryMgmt**
Usage

Method called by Opportunity Territory Assignment job to assign territory to opportunity. Input is a list of (up to 1000) opportunityIds that have IsExcludedFromTerritory2Filter=false. Returns a map of OpportunityId to Territory2Id, which is used to update the Territory2Id field on the Opportunity object.

OpportunityTerritory2AssignmentFilter Methods

The following are methods for OpportunityTerritory2AssignmentFilter.

getOpportunityTerritory2Assignments(opportunityIds)

Returns the mapping of opportunities to territory IDs. When Salesforce invokes this method, it supplies the list of opportunity IDs, except for opportunities that have been excluded from territory assignment (IsExcludedFromTerritory2Filter=false).

Signature

public Map<Id,Id> getOpportunityTerritory2Assignments(List<Id> opportunityIds)

Parameters

opportunityIds

Type: List<Id>
Opportunity IDs.

Return Value

Type: Map<Id,Id>
A key value pair associating each Territory ID to an Opportunity ID.

OpportunityTerritory2AssignmentFilter Example Implementation

This is an example implementation of the TerritoryMgmt.OpportunityTerritory2AssignmentFilter interface.

```apex
/**
 * Apex version of the default logic.
 * If opportunity's assigned account is assigned to
 * Case 1: 0 territories in active model
 * then set territory2Id = null
 * Case 2: 1 territory in active model
 */
```
then set territory2Id = account's territory2Id

Case 3: 2 or more territories in active model
then set territory2Id = account’s territory2Id that is of highest priority.
But if multiple territories have same highest priority, then set territory2Id = null

*/
global class OppTerrAssignDefaultLogicFilter implements TerritoryMgmt.OpportunityTerritory2AssignmentFilter {
/**
* No-arg constructor.
*/
global OppTerrAssignDefaultLogicFilter() {}

/**
* Get mapping of opportunity to territory2Id. The incoming list of opportunityIds contains only those with IsExcludedFromTerritory2Filter=false.
* If territory2Id = null in result map, clear the opportunity.territory2Id if set.
* If opportunity is not present in result map, its territory2Id remains intact.
*/
global Map<Id,Id> getOpportunityTerritory2Assignments(List<Id> opportunityIds) {
    Map<Id, Id> OppIdTerritoryIdResult = new Map<Id, Id>();

    // Get the active territory model Id
    Id activeModelId = getActiveModelId();

    if(activeModelId != null){
        List<Opportunity> opportunities =
            [Select Id, AccountId, Territory2Id from Opportunity where Id IN :opportunityIds];
        Set<Id> accountIds = new Set<Id>();
        // Create set of parent accountIds
        for(Opportunity opp:opportunities){
            if(opp.AccountId != null){
                accountIds.add(opp.AccountId);
            }
        }

        Map<Id,Territory2Priority> accountMaxPriorityTerritory =
            getAccountMaxPriorityTerritory(activeModelId, accountIds);

        // For each opportunity, assign the highest priority territory if there is no conflict, else assign null.
        for(Opportunity opp: opportunities){
            Territory2Priority tp = accountMaxPriorityTerritory.get(opp.AccountId);
            // Assign highest priority territory if there is only 1.
            if((tp != null) && (tp.moreTerritoriesAtPriority == false) && (tp.territory2Id != opp.Territory2Id)){
                OppIdTerritoryIdResult.put(opp.Id, tp.territory2Id);
            }else{
                OppIdTerritoryIdResult.put(opp.Id, null);
            }
        }
    }
    return OppIdTerritoryIdResult;
}
private Map<Id, Territory2Priority> getAccountMaxPriorityTerritory(Id activeModelId, Set<Id> accountIds){
    Map<Id, Territory2Priority> accountMaxPriorityTerritory = new Map<Id, Territory2Priority>();
    for(ObjectTerritory2Association ota:[Select ObjectId, Territory2Id, Territory2.Type.Priority from ObjectTerritory2Association where objectId IN :accountIds and Territory2.Type.ModelId = :activeModelId]){
        Territory2Priority tp = accountMaxPriorityTerritory.get(ota.ObjectId);
        if((tp == null) || (ota.Territory2.Type.Priority > tp.priority)){
            // If this is the first territory examined for account or it has greater priority than current highest priority territory, then set this as new highest priority territory.
            tp = new Territory2Priority(ota.Territory2Id, ota.Territory2.Type.Priority, false);
        } else if(ota.Territory2.Type.priority == tp.priority){
            // The priority of current highest territory is same as this, so set moreTerritoriesAtPriority to indicate multiple highest priority territories seen so far.
            tp.moreTerritoriesAtPriority = true;
        }
        accountMaxPriorityTerritory.put(ota.ObjectId, tp);
    }
    return accountMaxPriorityTerritory;
}

/**
 * Get the Id of the Active Territory Model.
 * If none exists, return null.
 */
private Id getActiveModelId() {
    List<Territory2Model> models = [Select Id from Territory2Model where State = 'Active'];
    Id activeModelId = null;
    if(models.size() == 1){
        activeModelId = models.get(0).Id;
    }
    return activeModelId;
}

/**
 * Helper class to help capture territory2Id, its priority, and whether there are more territories with same priority assigned to the account.
 */
private class Territory2Priority {
    public Id territory2Id { get; set; }
public Integer priority { get; set; }
public Boolean moreTerritoriesAtPriority { get; set; }

Territory2Priority(Id territory2Id, Integer priority, Boolean moreTerritoriesAtPriority)
{
    this.territory2Id = territory2Id;
    this.priority = priority;
    this.moreTerritoriesAtPriority = moreTerritoriesAtPriority;
}
}

TxnSecurity Namespace

The TxnSecurity namespace provides an interface used for transaction security.
The following is the interface and its supporting class in the TxnSecurity namespace.

IN THIS SECTION:

**Event Class**
Contains event information that the `evaluate` method uses to evaluate a transaction security policy.

**EventCondition Interface**
Allows an implementing class to specify whether to take action when certain events occur based on a transaction security policy. This interface is only used for Apex policies created in Real-Time Event Monitoring.

**AsyncCondition Interface**
Allows an implementing class to make asynchronous Apex calls. This interface is used only for transaction security Apex policies created in Real-Time Event Monitoring.

**PolicyCondition Interface**
Apex interface that allows an implementing class to specify actions to take when certain events occur based on a transaction security policy.

**Event Class**
Contains event information that the `evaluate` method uses to evaluate a transaction security policy.

**Namespace**
 TxnSecurity

**Usage**
The Event class contains the information needed to determine if the event triggers a Transaction Security policy. Not all class attributes are used for every type of event.

⚠️ Tip: The `EventClass` interface applies only to Legacy Transaction Security, which is a retired feature as of Summer '20. Use the `EventCondition` interface instead of the `EventClass` interface.
Event Constructors

The following is the constructor for Event.

**Event()**

Creates an instance of the TxnSecurity.Event class.

**Signature**

```java
public Event()
```

Event Properties

The following are properties for Event.

**IN THIS SECTION:**

- `action`
  Specifies the action being taken on the resource for an Entity event. For example, a Login IP resource for an Entity event could have an action of `create`. The `action` attribute is not used by any other event type.

- `data`
  Contains data used by actions. For example, `data` for a login event includes the login history ID. Returns a map whose keys are the type of event data, like `SourceIp`.

- `entityId`
  The ID of any entity associated with the event. For example, the `entityId` of a DataExport event for an Account object contains the Account ID.

- `entityName`
  The name of the object the event acts on.

- `organizationId`
  The ID of the Salesforce org where the event occurred.

- `resourceType`
  The type of resource for the event. For example, an AccessResource event could have a Connected Application as a resource type. Not all event types have resources.

- `timeStamp`
  The time the event occurred.
userId
Identifies the user that caused the event.

**action**

Specifies the action being taken on the resource for an Entity event. For example, a Login IP resource for an Entity event could have an action of create. The action attribute is not used by any other event type.

**Signature**

```java
public String action {get; set;}
```

**Property Value**

Type: String

**data**

Contains data used by actions. For example, data for a login event includes the login history ID. Returns a map whose keys are the type of event data, like SourceIp.

**Signature**

```java
public Map<String,String> data {get; set;}
```

**Property Value**

Type: Map<String, String>

The following table lists all the available data types. Not all types appear with all event types. The data type values are always string representations. For example, the `isApi` value is a string in the map, but is actually a Boolean value. Convert the value from a string to its true type this way: `Boolean.valueOf(event.data.get('isApi'));`

<table>
<thead>

<td>String (IPV4 Address)</td>
<td>AccessResource</td>
</tr>
<tr>
<td>UserName</td>
<td>String</td>
<td>Entity</td>
</tr>
</tbody>
</table>

**entityId**

The ID of any entity associated with the event. For example, the entityId of a DataExport event for an Account object contains the Account ID.

**Signature**

```java
public String entityId {get; set;}
```

**Property Value**

Type: String

**entityName**

The name of the object the event acts on.

**Signature**

```java
public String entityName {get; set;}
```

**Property Value**

Type: String

**organizationId**

The ID of the Salesforce org where the event occurred.

**Signature**

```java
public String organizationId {get; set;}
```
Property Value
Type: String

**resourceType**
The type of resource for the event. For example, an AccessResource event could have a Connected Application as a resource type. Not all event types have resources.

Signature

```java
public String resourceType {get; set;}
```

Property Value
Type: String

**timeStamp**
The time the event occurred.

Signature

```java
public Datetime timeStamp {get; set;}
```

Property Value
Type: Datetime

**userId**
Identifies the user that caused the event.

Signature

```java
public String userId {get; set;}
```

EventCondition Interface

Allows an implementing class to specify whether to take action when certain events occur based on a transaction security policy. This interface is only used for Apex policies created in Real-Time Event Monitoring.

Usage

The `evaluate` method is called upon the occurrence of a real-time event monitored by a transaction security policy. A typical implementation first selects the fields of interest from the event. Then the fields are tested to see if they meet the conditions being monitored. If the conditions are met, the method returns `true`. 
For example, imagine a transaction security policy that triggers when a user queries more than 1,000 lead records. For each API event, the `evaluate` method checks whether the `RowsProcessed` value is greater than 1,000 and the `QueriedEntities` value contains “Lead”. If so, `true` is returned.

We recommend having test classes for the policy condition interface to ensure it works correctly. Testing is required regardless of whether the policy is moved from a sandbox to production, with a change set, or some other way. For example, test your policies in your development environment before moving the policies to production.

For more information about testing Apex transaction security policies, read Transaction Security Apex Testing.

### EventCondition Methods

The following are methods for `EventCondition`.

**IN THIS SECTION:**
- EventCondition Methods
- EventCondition Example Implementation

#### EventCondition Methods

The following are methods for `EventCondition`.

**IN THIS SECTION:**
- `evaluate(event)`

#### `evaluate(event)`

Evaluates an event against a transaction security policy created in Real-Time Event Monitoring. If the event triggers the policy, the method returns `true`.

**Signature**

```
public Boolean evaluate(SObject event)
```

**Parameters**

- `var1`
  - Type: `SObject`
  - The event to check against the transaction security policy.

**Return Value**

- Type: `Boolean`
  - Returns `true` when the policy is triggered. For example, suppose that the policy is to limit users to a single login session. If a user tries to log in a second time, the policy blocks the attempted login, and updates the `Status`, `PolicyId`, and `PolicyOutcome` fields of that `LoginEvent`. The policy also sends an email notification to the Salesforce admin. The `evaluate` method only checks the login event, and returns `true` if it’s the user’s second login attempt.
  - The system performs the action and notification, not the `evaluate` method.
EventCondition Example Implementation

This example shows an implementation of the TxnSecurity.EventCondition interface. The transaction security policy triggers when the user queries an Account object.

```
global class BlockAccountQueriesEventCondition implements TxnSecurity.EventCondition {

    public boolean evaluate(SObject event) {
        switch on event {
            when ApiEvent apiEvent {
                return handleApiEvent(apiEvent);
            }
            when null {
                // Trigger action if event is null
                return true;
            }
            when else {
                // Trigger action for unhandled events
                return true;
            }
        }
    }

    private boolean handleApiEvent(ApiEvent apiEvent) {
        if(apiEvent.QueriedEntities.contains('Account')){
            return true;
        }
        return false;
    }
}
```

For more examples, see Enhanced Apex Transaction Security Implementation Examples.

AsyncCondition Interface

Allows an implementing class to make asynchronous Apex calls. This interface is used only for transaction security Apex policies created in Real-Time Event Monitoring.

Namespace

TxnSecurity

Usage

If you make an Asynchronous Apex call in the class that implements your transaction security policy condition, the class must implement the TxnSecurity.AsyncCondition interface in addition to TxnSecurity.EventCondition. Use Asynchronous Apex instead of Apex callouts and DML statements, neither of which is allowed in transaction security Apex policies.

Apex offers multiple ways to run your Apex code asynchronously and all are supported in the TxnSecurity.AsyncCondition interface.

This interface has no methods.
AsyncCondition Example Implementation

Here's an example implementation of the `TxnSecurity.AsyncCondition` interface. The transaction security policy triggers when a user logs in. In the example, `ExternalValidation__c` is a custom object that contains information from an external validation system. The result of the SOQL query on `ExternalValidation__c` determines whether to block the user from logging in. The policy then queues the `CalloutToExternalValidator` class for asynchronous execution. When it executes, the `CalloutToExternalValidator` class makes an external call to the validation system to update it with information about this log in event. Because `CalloutToExternalValidator` is triggered by Asynchronous Apex, you must implement the `TxnSecurity.AsyncCondition` interface in the `ExternallyValidatedLoginCondition` Apex class along with the usual `TxnSecurity.EventCondition` interface.

```java
global class ExternallyValidatedLoginCondition implements TxnSecurity.EventCondition,
    TxnSecurity.AsyncCondition {
    public boolean evaluate(SObject event) {
        LoginEvent loginEvent = (LoginEvent) event;
        Boolean userBlocked = [select blocked from ExternalValidation__c where loginId =
            loginEvent.UserId][0].Blocked;

        System.enqueueJob(new CalloutToExternalValidator(loginEvent.SourceIp,
            loginEvent.LoginUrl));
        return userBlocked;
    }
}

public class CalloutToExternalValidator implements Queueable {
    private String sourceIp;
    private String loginUrl;

    public CalloutToExternalValidator(String sourceIp, String loginUrl) {
        this.sourceIp = sourceIp;
        this.loginUrl = loginUrl;
    }

    public void execute(QueueableContext context) {
        // callout to external validation service
        // pass sourceIp, loginUrl

        // update ExternalValidation__c
    }
}
```

PolicyCondition Interface

Apex interface that allows an implementing class to specify actions to take when certain events occur based on a transaction security policy.
Namespace

`TxnSecurity`

Usage

⚠️ **Tip:** The PolicyCondition interface applies only to Legacy Transaction Security, which is a retired feature as of Summer '20. Use the EventCondition interface instead of the PolicyCondition interface.

The `evaluate` method is called upon the occurrence of an event monitored by a transaction security policy. A typical implementation first selects the item of interest from the event. Then the item is tested to see if it meets the condition being monitored. If the condition is met, the method returns `true`.

For example, imagine a transaction security policy that checks for the same user logging in more than once. For each login event, the method would check if the user logging in already has a login session in progress, and if so, `true` is returned.

We recommend having test classes for the policy condition interface to ensure it works correctly. Testing is required regardless of whether the policy is moved from a sandbox to production, with a change set, or some other way. For example, test your policies in your development environment before moving the policies to production.

Don't include DML statements in your custom policies because they can cause errors. When you send a custom email via Apex during transaction policy evaluation, you get an error, even if the record isn't explicitly related to another record. For more information, see Apex DML Operations in the Apex Reference Guide.

IN THIS SECTION:

PolicyCondition Methods

PolicyCondition Methods

The following is the method for PolicyCondition.

IN THIS SECTION:

`evaluate(event)`

Evaluates an event against a transaction security policy. If the event triggers the policy, `true` is returned.

**Signature**

```java
public Boolean evaluate(TxnSecurity.Event event)
```

**Parameters**

`event`

Type: `TxnSecurity.Event`

The event to check against the transaction security policy.
Return Value

Type: Boolean

When the policy is triggered, True is returned. For example, let’s suppose the policy is to limit users to a single login session. If anyone tries to log in a second time, the policy’s action requires that they end their current session. The policy also sends an email notification to the Salesforce admin. The evaluate() method only checks the login event, and returns True if it’s the user’s second login. The Transaction Security system performs the action and notification, and not the evaluate() method.

UserProvisioning Namespace

The UserProvisioning namespace provides methods for monitoring outbound user provisioning requests.

The following is the class in the UserProvisioning namespace.

IN THIS SECTION:

ConnectorTestUtil Class
Enables developers to write Apex test classes for connectors used by the connected app provisioning solution. This class simulates provisioning for the associated app.

UserProvisioningLog Class
Provides methods for writing messages to monitor outbound user provisioning requests.

UserProvisioningPlugin Class
The UserProvisioningPlugin base class implements Process.Plugin for programmatic customization of the user provisioning process for connected apps.

ConnectorTestUtil Class

Enables developers to write Apex test classes for connectors used by the connected app provisioning solution. This class simulates provisioning for the associated app.

Namespace

UserProvisioning

Usage

Use this class for connector-based test accelerators. You can invoke it only from within an Apex test.

Example

This example creates an instance of a connected app, gets a value, and checks whether the value is correct. The test is simply a row inserted in the database table.

```apex
@isTest
private class SCIMCreateUserPluginTest {
    public static void callPlugin(Boolean validInputParams) {
        // Code goes here
    }
```
//Create an instance of a connected app
ConnectedApplication capp = UserProvisioning.ConnectorTestUtil.createConnectedApp('TestApp');
Profile p = [SELECT Id FROM Profile WHERE Name='Standard User'];
//Create a user
User user = new User(username='testuser1@scimuserprov.test', FirstName='Test',
LastName='User1', email='testuser1@testemail.com', FederationIdentifier='testuser1@testemail.com', profileId= p.Id,
communityNickName='tuser1', alias='tuser', TimeZoneSidKey='GMT',
LocaleSidKey='en_US', EmailEncodingKey='ISO-8859-1', LanguageLocaleKey='en_US');
//insert user into a row in the database table
 insert user;
//Create a UPR
UserProvisioningRequest upr = new UserProvisioningRequest(appname = capp.name,
connectedAppId=capp.id, operation='Create',
state='New', approvalStatus='NotRequired',salesforceUserId=user.id);
//Insert the UPR to test the flow end to end
 insert upr;
}}

IN THIS SECTION:
ConnectorTestUtil Method

SEE ALSO:
Salesforce Help: User Provisioning for Connected Apps

ConnectorTestUtil Method

The ConnectorTestUtil class has 1 method.

IN THIS SECTION:
createConnectedApp(connectedAppName)
Creates an instance of a connected app to simulate provisioning.

createConnectedApp (connectedAppName)
Creates an instance of a connected app to simulate provisioning.

Signature
public static ConnectedApplication createConnectedApp(String connectedAppName)

Parameters
connectedAppName
Type: String
Name of the connected app to test for provisioning.

Return Value
Type: ConnectedApplication
The instance of the connected app to test for provisioning.

UserProvisioningLog Class
Provides methods for writing messages to monitor outbound user provisioning requests.

Namespace
UserProvisioning

Example
This example writes the user account information sent to a third-party system for a provisioning request to the UserProvisioningLog object.

```java
String inputParamsStr = 'Input parameters: uprId=' + uprId + ',
endpointURL=' + endpointURL + ', adminUsername=' + adminUsername + ',
email=' + email + ', username=' + username + ', defaultPassword=' + defaultPassword + ',
defaultRoles = ' + defaultRoles;
UserProvisioning.UserProvisioningLog.log(uprId, inputParamsStr);
```

IN THIS SECTION:
UserProvisioningLog Methods

UserProvisioningLog Methods
The following are methods for UserProvisioningLog. All methods are static.

IN THIS SECTION:
- `log(userProvisioningRequestId, details)`
  Writes a specific message, such as an error message, to monitor the progress of a user provisioning request.
- `log(userProvisioningRequestId, status, details)`
  Writes a specific status and message, such as a status and detailed error message, to monitor the progress of a user provisioning request.
- `log(userProvisioningRequestId, externalUserId, externalUserName, userId, details)`
  Writes a specific message, such as an error message, to monitor the progress of a user provisioning request associated with a specific user.
- `log(userProvisioningRequestId, details)`
  Writes a specific message, such as an error message, to monitor the progress of a user provisioning request.
Signature

```java
public void log(String userProvisioningRequestId, String details)
```

Parameters

- `userProvisioningRequestId`
  - Type: `String`
  - A unique identifier for the user provisioning request.

- `details`
  - Type: `String`
  - The text for the message.

Return Value

Type: `void`

### log(userProvisioningRequestId, status, details)

Writes a specific status and message, such as a status and detailed error message, to monitor the progress of a user provisioning request.

Signature

```java
public void log(String userProvisioningRequestId, String status, String details)
```

Parameters

- `userProvisioningRequestId`
  - Type: `String`
  - A unique identifier for the user provisioning request.

- `status`
  - Type: `String`
  - A description of the current state. For example, while invoking a third-party API, the status could be `invoke`.

- `details`
  - Type: `String`
  - The text for the message.

Return Value

Type: `void`

### log(userProvisioningRequestId, externalUserId, externalUserName, userId, details)

Writes a specific message, such as an error message, to monitor the progress of a user provisioning request associated with a specific user.
Signature

```java
public void log(String userProvisioningRequestId, String externalUserId, String externalUserName, String userId, String details)
```

**Parameters**

- `userProvisioningRequestId`
  - Type: `String`
  - A unique identifier for the user provisioning request.

- `externalUserId`
  - Type: `String`
  - The unique identifier for the user in the target system.

- `externalUserName`
  - Type: `String`
  - The username for the user in the target system.

- `userId`
  - Type: `String`
  - Salesforce ID of the user making the request.

- `details`
  - Type: `String`
  - The text for the message.

**Return Value**

Type: `void`

**UserProvisioningPlugin Class**

The `UserProvisioningPlugin` base class implements `Process.Plugin` for programmatic customization of the user provisioning process for connected apps.

**Namespace**

`UserProvisioning`

**Usage**

Extending this class gives you a plug-in that can be used Flow Builder as a legacy Apex action, with the following input and output parameters.

<table>
<thead>
<tr>
<th>Input Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>userProvisioningRequestId</code></td>
<td>The unique ID of the request for the plug-in to process.</td>
</tr>
<tr>
<td><code>userId</code></td>
<td>The ID of the associated user for the request.</td>
</tr>
</tbody>
</table>
### Input Parameter Name

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NamedCredDevName</strong></td>
</tr>
<tr>
<td><strong>reconFilter</strong></td>
</tr>
<tr>
<td><strong>reconOffset</strong></td>
</tr>
</tbody>
</table>

### Output Parameter Name

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Status</strong></td>
</tr>
<tr>
<td><strong>Details</strong></td>
</tr>
<tr>
<td><strong>ExternalUserId</strong></td>
</tr>
<tr>
<td><strong>ExternalUsername</strong></td>
</tr>
<tr>
<td><strong>ExternalEmail</strong></td>
</tr>
<tr>
<td><strong>ExternalFirstName</strong></td>
</tr>
<tr>
<td><strong>ExternalLastName</strong></td>
</tr>
<tr>
<td><strong>reconState</strong></td>
</tr>
<tr>
<td><strong>nextReconOffset</strong></td>
</tr>
</tbody>
</table>

If you want to add more custom parameters, use the `buildDescribeCall()` method.
**Example**

The following example uses the `buildDescribeCall()` method to add a new input parameter and a new output parameter. The example also demonstrates how to bypass the limit of the 10,000 records processed in DML statements in an Apex transaction.

```apex
global class SampleConnector extends UserProvisioning.UserProvisioningPlugin {

    // Example of adding more input and output parameters to those defined in the base class
    global override Process.PluginDescribeResult buildDescribeCall() {
        Process.PluginDescribeResult describeResult = new Process.PluginDescribeResult();
        describeResult.inputParameters = new List<Process.PluginDescribeResult.InputParameter>{
        };
        describeResult.outputParameters = new List<Process.PluginDescribeResult.OutputParameter>{
        };
        return describeResult;
    }

    // Example Plugin that demonstrates how to leverage the reconOffset/nextReconOffset/reconState
    // parameters to create more than 10,000 users. (i.e. go beyond the 10,000 DML limit per transaction)
    global override Process.PluginResult invoke(Process.PluginRequest request) {
        Map<String,String> result = new Map<String,String>();
        String uprId = (String) request.inputParameters.get('userProvisioningRequestId');
        UserProvisioning.UserProvisioningLog.log(uprId, 'Inserting Log from test Apex connector');
        UserProvisioningRequest upr = [SELECT id, operation, connectedAppId, state
            FROM userprovisioningrequest WHERE id = :uprId];
        if (upr.operation.equals('Reconcile')) {
            String reconOffsetStr = (String) request.inputParameters.get('reconOffset');
            Integer reconOffset = 0;
            if (reconOffsetStr != null) {
                reconOffset = Integer.valueOf(reconOffsetStr);
            }
            if (reconOffset > 44999) {
                result.put('reconState', 'Completed');
            }
            Integer i = 0;
            List<UserProvAccountStaging> upasList = new List<UserProvAccountStaging>();
            for (i = 0; i < 5000; i++) {
                UserProvAccountStaging upas = new UserProvAccountStaging();
            }
        }
    }
}
```
upas.Name = i + reconOffset + '';
upas.ExternalFirstName = upas.Name;
upas.ExternalEmail = 'externaluser@externalsystem.com';
upas.LinkState = 'Orphaned';
upas.Status = 'Active';
upas.connectedAppId = upr.connectedAppId;
upasList.add(upas);
}
insert upasList;
result.put('nextReconOffset', reconOffset + 5000 + '');
}
return new Process.PluginResult(result);
}

IN THIS SECTION:
UserProvisioningPlugin Methods

UserProvisioningPlugin Methods

The following are methods for UserProvisioningPlugin.

IN THIS SECTION:
buildDescribeCall()
Use this method to add more input and output parameters to those defined in the base class.
describe()
Returns a Process.PluginDescribeResult object that describes this method call.
getPluginClassName()
Returns the name of the class implementing the plugin.
invoke(request)
Primary method that the system invokes when the class that implements the interface is instantiated.

buildDescribeCall()

Use this method to add more input and output parameters to those defined in the base class.

Signature

public Process.PluginDescribeResult buildDescribeCall()

Return Value

Type: Process.PluginDescribeResult
describe()  
Returns a Process.PluginDescribeResult object that describes this method call.

**Signature**  
```java
public Process.PluginDescribeResult describe()
```

**Return Value**  
Type: Process.PluginDescribeResult

getPluginClassName()  
Returns the name of the class implementing the plugin.

**Signature**  
```java
public String getPluginClassName()
```

**Return Value**  
Type: String

invoke(request)  
Primary method that the system invokes when the class that implements the interface is instantiated.

**Signature**  
```java
```

**Parameters**  
```
request  
Type: Process.PluginRequest
```

**Return Value**  
Type: Process.PluginDescribeResult

---

**VisualEditor Namespace**

The **VisualEditor** namespace provides classes and methods for interacting with the Lightning App Builder. The classes and methods in this namespace operate on Lightning components, which include Lightning web components and Aura components. As of Spring ’19 (API version 45.0), you can build Lightning components using two programming models: the Lightning Web Components model, and the original Aura Components model. Lightning web components are custom HTML elements built using HTML and modern JavaScript. Lightning web components and Aura components can coexist and interoperate on a page.
Configure Lightning web components and Aura components to work in Lightning App Builder and Experience Builder. Admins and end users don’t know which programming model was used to develop the components. To them, they’re simply Lightning components.

The following are the classes in the VisualEditor namespace.

IN THIS SECTION:
- **DataRow Class**
  Contains information about one item in a picklist used in a Lightning component on a Lightning page.
- **DesignTimePageContext Class**
  A class that provides context information about a Lightning page. It can be used to help define the values of a picklist in a Lightning component on a Lightning page based on the page’s type and the object with which it’s associated.
- **DynamicPickList Class**
  An abstract class, used to display the values of a picklist in a Lightning component on a Lightning page.
- **DynamicPickListRows Class**
  Contains a list of picklist items in a Lightning component on a Lightning page.

**DataRow Class**

Contains information about one item in a picklist used in a Lightning component on a Lightning page.

**Namespace**

VisualEditor

IN THIS SECTION:
- **DataRow Constructors**
- **DataRow Methods**

**DataRow Constructors**

The following are constructors for DataRow.

IN THIS SECTION:
- **DataRow(label, value, selected)**
  Creates an instance of the VisualEditor.DataRow class using the specified label, value, and selected option.
- **DataRow(label, value)**
  Creates an instance of the VisualEditor.DataRow class using the specified label and value.

**DataRow(label, value, selected)**

Creates an instance of the VisualEditor.DataRow class using the specified label, value, and selected option.

**Signature**

```java
public DataRow(String label, Object value, Boolean selected)
```
Parameters

**label**
Type: String
User-facing label for the picklist item.

**value**
Type: Object
The value of the picklist item.

**selected**
Type: Boolean
Specifies whether the picklist item is selected (true) or not (false).

**DataRow(label, value)**
Creates an instance of the `VisualEditor.DataRow` class using the specified label and value.

**Signature**

```java
public DataRow(String label, Object value)
```

**Parameters**

**label**
Type: String
User-facing label for the picklist item.

**value**
Type: Object
The value of the picklist item.

**DataRow Methods**
The following are methods for `DataRow`.

IN THIS SECTION:

- **clone()**
  Makes a duplicate copy of the `VisualEditor.DataRow` object.

- **compareTo(o)**
  Compares the current `VisualEditor.DataRow` object to the specified one. Returns an integer value that is the result of the comparison.

- **getLabel()**
  Returns the user-facing label of the picklist item.

- **getValue()**
  Returns the value of the picklist item.

- **isSelected()**
  Returns the state of the picklist item, indicating whether it's selected or not.
clone ()
Makes a duplicate copy of the VisualEditor.DataRow object.

Signature
public Object clone()  

Return Value
Type: Object

compareTo (o)
Compares the current VisualEditor.DataRow object to the specified one. Returns an integer value that is the result of the comparison.

Signature
public Integer compareTo(VisualEditor.DataRow o)

Parameters
- o  
  Type: VisualEditor.DataRow
  A single item in a picklist.

Return Value
Type: Integer
Returns one of the following values:
- Zero if the current package version is equal to the specified package version
- An integer value greater than zero if the current package version is greater than the specified package version
- An integer value less than zero if the current package version is less than the specified package version

getLabel ()
Returns the user-facing label of the picklist item.

Signature
public String getLabel()

Return Value
Type: String

getValue ()
Returns the value of the picklist item.
Signature

```java
public Object getValue()
```

Return Value
Type: Object

**isSelected()**
Returns the state of the picklist item, indicating whether it’s selected or not.

Signature

```java
public Boolean isSelected()
```

Return Value
Type: Boolean

### DesignTimePageContext Class
A class that provides context information about a Lightning page. It can be used to help define the values of a picklist in a Lightning component on a Lightning page based on the page’s type and the object with which it’s associated.

### Namespace
VisualEditor

### Usage
To use this class, create a parameterized constructor in the custom Apex class that extends VisualEditor.DynamicPickList.

### Example
Here’s an example of a custom Apex class extending the VisualEditor.DynamicPickList class. It includes VisualEditor.DesignTimePageContext to define a picklist value that is available only if the page type is HomePage.

```java
global class MyCustomPickList extends VisualEditor.DynamicPickList{
    VisualEditor.DesignTimePageContext context;

    global MyCustomPickList(VisualEditor.DesignTimePageContext context) {
        this.context = context;
    }

    global override VisualEditor.DataRow getDefaultValue(){
        VisualEditor.DataRow defaultValue = new VisualEditor.DataRow('red', 'RED');
        return defaultValue;
    }

    global override VisualEditor.DynamicPickListRows getValues() {
        VisualEditor.DataRow value1 = new VisualEditor.DataRow('red', 'RED');
    }
}
```
VisualEditor.DataRow value2 = new VisualEditor.DataRow('yellow', 'YELLOW');
VisualEditor.DynamicPickListRows myValues = new VisualEditor.DynamicPickListRows();
myValues.addRow(value1);
myValues.addRow(value2);
if (context.pageType == 'HomePage') {
    VisualEditor.DataRow value3 = new VisualEditor.DataRow('purple', 'PURPLE');
    myValues.addRow(value3);
}
return myValues;
}

DesignTimePageContext Class

IN THIS SECTION:
DesignTimePageContext Properties
DesignTimePageContext Methods

DesignTimePageContext Properties

The following are properties for DesignTimePageContext.

IN THIS SECTION:

entityName
The API name of the sObject that a Lightning page is associated with, such as Account, Contact, or Custom_object__c. entityType
is available only for object pages, and not all Lightning pages are associated with objects.

pageType
The type of Lightning page, such as HomePage, AppPage, or RecordPage.

entityName

The API name of the sObject that a Lightning page is associated with, such as Account, Contact, or Custom_object__c. entityType
is available only for object pages, and not all Lightning pages are associated with objects.

Signature

public String entityId {get; set;}

Property Value

Type: String

pageType

The type of Lightning page, such as HomePage, AppPage, or RecordPage.
Signature

public String pageType {get; set;}

Property Value

Type: String

DesignTimePageContext Methods

The following are methods for DesignTimePageContext.

IN THIS SECTION:

clone()  

clone()  

Signature

public Object clone()

Return Value

Type: Object

DynamicPickList Class

An abstract class, used to display the values of a picklist in a Lightning component on a Lightning page.

Namespace

VisualEditor

Usage

To use this class as the datasource of a picklist in a Lightning component, it must be extended by a custom Apex class and then that class must be called in the component's design file.

Example

Here's an example of a custom Apex class extending the VisualEditor.DynamicPickList class.

global class MyCustomPickList extends VisualEditor.DynamicPickList{
    
    global override VisualEditor.DataRow getDefaultValue(){
        VisualEditor.DataRow defaultValue = new VisualEditor.DataRow('red', 'RED');
    
}
Here's an example of how the custom Apex class gets called in a design file so that the picklist appears in the Lightning component.

```xml
<design:component>
  <design:attribute name="property1" datasource="apex://MyCustomPickList"/>
</design:component>
```

IN THIS SECTION:
DynamicPickList Methods

DynamicPickList Methods

The following are methods for DynamicPickList.

IN THIS SECTION:
clone()  

global override VisualEditor.DynamicPicklistRows getValues() {
  VisualEditor.DataRow value1 = new VisualEditor.DataRow('red', 'RED');
  VisualEditor.DataRow value2 = new VisualEditor.DataRow('yellow', 'YELLOW');
  VisualEditor.DynamicPicklistRows myValues = new VisualEditor.DynamicPicklistRows();
  myValues.addRow(value1);
  myValues.addRow(value2);
  return myValues;
}

getDefaultValue()  
Returns the picklist item that is set as the default value for the picklist.

getLabel(attributeValue)  
Returns the user-facing label for a specified picklist value.

getValues()  
Returns the list of picklist item values.

isValid(attributeValue)  
Returns the valid state of the picklist item’s value. A picklist value is considered valid if it’s a part of any VisualEditor.DataRow in the VisualEditor.DynamicPicklistRows returned by getValues().

### clone()

**Signature**

```java
public Object clone()
```
Return Value
Type: Object

getDefaultValue()
Returns the picklist item that is set as the default value for the picklist.

Signature
public VisualEditor.DataRow getDefaultValue()

Return Value
Type: VisualEditor.DataRow

getLabel(attributeValue)
Returns the user-facing label for a specified picklist value.

Signature
public String getLabel(Object attributeValue)

Parameters
attributeValue
   Type: Object
   The value of the picklist item.

Return Value
Type: String

getValues()
Returns the list of picklist item values.

Signature
public VisualEditor.DynamicPickListRows getValues()

Return Value
Type: VisualEditor.DynamicPickListRows

isValid(attributeValue)
Returns the valid state of the picklist item's value. A picklist value is considered valid if it's a part of any VisualEditor.DataRow in the VisualEditor.DynamicPickListRows returned by getValues().
Signature

```java
public Boolean isValid(Object attributeValue)
```

Parameters

`attributeValue`

- **Type**: Object
- The value of the picklist item.

Return Value

- **Type**: Boolean

DynamicPickListRows Class

Contains a list of picklist items in a Lightning component on a Lightning page.

Namespace

`VisualEditor`

IN THIS SECTION:

- DynamicPickListRows Constructors
- DynamicPickListRows Methods

DynamicPickListRows Constructors

The following are constructors for DynamicPickListRows.

IN THIS SECTION:

- DynamicPickListRows(rows, containsAllRows)
- DynamicPickListRows(rows)
- DynamicPickListRows()

DynamicPickListRows(rows, containsAllRows)

- Creates an instance of the `VisualEditor.DynamicPickListRows` class using the specified parameters.

DynamicPickListRows(rows)

- Creates an instance of the `VisualEditor.DynamicPickListRows` class using the specified parameter.

DynamicPickListRows()

- Creates an instance of the `VisualEditor.DynamicPickListRows` class. You can then add rows by using the class's `addRow` or `addAllRows` methods.

**DynamicPickListRows(rows, containsAllRows)**

- Creates an instance of the `VisualEditor.DynamicPickListRows` class using the specified parameters.

**Signature**

```java
public DynamicPickListRows(List<VisualEditor.DataRow> rows, Boolean containsAllRows)
```
Parameters

rows
  Type: List VisualEditor.DataRow
  List of picklist items.

containsAllRows
  Type: Boolean
  Indicates if all values of the picklist are included in a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

A picklist in a Lightning component can display only the first 200 values of a list. If containsAllRows is set to false, when a user does a type-ahead search to find values in the picklist, the search will only look at those first 200 values that were displayed, not the complete set of picklist values.

DynamicPickListRows(rows)

Creates an instance of the VisualEditor.DynamicPickListRows class using the specified parameter.

Signature

public DynamicPickListRows(List<VisualEditor.DataRow> rows)

Parameters

rows
  Type: List VisualEditor.DataRow
  List of picklist rows.

DynamicPickListRows()

Creates an instance of the VisualEditor.DynamicPickListRows class. You can then add rows by using the class’s addRow or addAllRows methods.

Signature

public DynamicPickListRows()
containsAllRows()  
Returns a Boolean value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) 
or only those values initially displayed when the list is clicked on (false).

get(i)  
Returns a picklist element stored at the specified index.

dataGetRows()  
Returns a list of picklist items.

setDataRows(containsAllRows)  
Sets the value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only 
those values initially displayed when the list is clicked on (false).

size()  
Returns the size of the list of VisualEditor.DynamicPickListRows.

sort()  
Sorts the list of VisualEditor.DynamicPickListRows.

**addAllRows (rows)**

Adds a list of picklist items to a dynamic picklist rendered in a Lightning component on a Lightning page.

**Signature**

```
public void addAllRows(List<VisualEditor.DataRow> rows)
```

**Parameters**

rows
  Type: List VisualEditor.DataRow
  List of picklist items.

**Return Value**

Type: void

**addRow (row)**

Adds a single picklist item to a dynamic picklist rendered in a Lightning component on a Lightning page.

**Signature**

```
public void addRow(VisualEditor.DataRow row)
```

**Parameters**

row
  Type: VisualEditor.DataRow
  A single picklist item.
Return Value
Type: void

clonel()

Signature
public Object clone()

Return Value
Type: Object

containsAllRows()
Returns a Boolean value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

Signature
public Boolean containsAllRows()

Return Value
Type: Boolean
A picklist in a Lightning component can display only the first 200 values of a list. If `containsAllRows` is set to false, when a user does a type-ahead search to find values in the picklist, the search will only look at those first 200 values that were displayed, not the complete set of picklist values.

geti()
Returns a picklist element stored at the specified index.

Signature
public VisualEditor.DataRow get(Integer i)

Parameters
i
  Type: Integer
  The index.

Return Value
Type: VisualEditor.DataRow
getDataRows ()
Returns a list of picklist items.

Signature
public List<VisualEditor.DataRow> getDataRows ()

Return Value
Type: List VisualEditor.DataRow

setContainsAllRows (containsAllRows)
Sets the value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

Signature
public void setContainsAllRows (Boolean containsAllRows)

Parameters
containsAllRows
Type: Boolean
Indicates if all values of the picklist are included in a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

A picklist in a Lightning component can display only the first 200 values of a list. If containsAllRows is set to false, when a user does a type-ahead search to find values in the picklist, the search will only look at those first 200 values that were displayed, not the complete set of picklist values.

Return Value
Type: void

size ()
Returns the size of the list of VisualEditor.DynamicPickListRows.

Signature
public Integer size ()

Return Value
Type: Integer

sort ()
Sorts the list of VisualEditor.DynamicPickListRows.
Signature

```java
public void sort()
```

Return Value

Type: void

**Wave Namespace**

The classes in the Wave namespace are part of the CRM Analytics Analytics SDK, designed to facilitate querying CRM Analytics data from Apex code.

The following are the classes in the Wave namespace.

IN THIS SECTION:

- **QueryBuilder Class**
  The QueryBuilder class provides methods for constructing well-formed SAQL queries to pass to CRM Analytics.

- **QueryNode Class**
  Define each node of the query - such as projection, groups, order, filters. Execute the query.

- **ProjectionNode Class**
  Add aggregate functions to the query, or define an alias.

- **Templates Class**
  The Templates class provides methods for retrieving CRM Analytics template collections, individual templates, and template configurations.

- **TemplatesSearchOptions Class**
  The TemplatesSearchOptions class provides optional properties to filter the template collection.

**QueryBuilder Class**

The QueryBuilder class provides methods for constructing well-formed SAQL queries to pass to CRM Analytics.

**Namespace**

wave

**Usage**

Use QueryBuilder and its associated classes, Wave.ProjectionNode and Wave.QueryNode, to incrementally build your SAQL statement. For example:

```java
public static void executeApexQuery(String name){
    Wave.ProjectionNode[] projs = new Wave.ProjectionNode[]{
        Wave.QueryBuilder.get('State').alias('State'),
        Wave.QueryBuilder.get('City').alias('City'),
        Wave.QueryBuilder.get('Revenue').avg().alias('avg_Revenue'),
        Wave.QueryBuilder.get('Revenue').sum().alias('sum_Revenue'),
```
Examples

QueryBuilder is the core of this first phase of the CRM Analytics Apex SDK, so let’s take a closer look. Here’s a simple count query.

```
Wave.ProjectionNode[] projs = new
Wave.ProjectionNode[]{Wave.QueryBuilder.count().alias('c')};
String query = Wave.QueryBuilder.load('datasetId',
'datasetVersionId').group().foreach(projs).build('q');
```

The resulting SAQL query looks like this:

```
q = load "datasetId/datasetVersionId";
q = group q by all;
q = foreach q generate count as c;
```

Here’s a more complex example that uses a union statement.

```
Wave.ProjectionNode[] projs = new Wave.ProjectionNode[]{
Wave.QueryBuilder.get('Name'),
Wave.QueryBuilder.get('AnnualRevenue').alias('Revenue')};
Wave.QueryNode nodeOne =
Wave.QueryBuilder.load('datasetOne','datasetVersionOne').foreach(projs);
Wave.QueryNode nodeTwo = Wave.QueryBuilder.load('datasetTwo',
'datasetVersionTwo').foreach(projs);
String query = Wave.QueryBuilder.union(new List<Wave.QueryNode>{nodeOne,
nodeTwo}).build('q');
```

The resulting SAQL query has two projection streams, qa and qb.

```
qa = load "datasetOne/datasetVersionOne";
qa = foreach q generate Name,AnnualRevenue as Revenue;
qb = load "datasetTwo/datasetVersionTwo";
qb = foreach q generate Name,AnnualRevenue as Revenue;
q = union qa, qb;
```

IN THIS SECTION:

QueryBuilder Methods

QueryBuilder Methods

The following are methods for QueryBuilder.
IN THIS SECTION:

load(datasetID, datasetVersionID)
Load a stream from a dataset.

count()
Calculate the number of rows that match the query criteria.

get(projection)
Query by selecting specific attributes.

union(unionNodes)
Combine multiple result sets into one result set.

cogroup(cogroupNodes, groups)
Cogrouping means that two input streams are grouped independently and arranged side by side. Only data that exists in both groups appears in the results.

load(datasetID, datasetVersionID)
Load a stream from a dataset.

**Signature**

```java
public static wave.QueryNode load(String datasetID, String datasetVersionID)
```

**Parameters**

- `datasetID`
  - Type: `String`
  - The ID of the dataset.

- `datasetVersionID`
  - Type: `String`
  - The ID identifying the version of the dataset.

**Return Value**

Type: `wave.QueryNode`

**count()**
Calculate the number of rows that match the query criteria.

**Signature**

```java
public static wave.ProjectionNode count()
```

**Return Value**

Type: `wave.ProjectionNode`
`get (projection)`
Query by selecting specific attributes.

**Signature**
```java
public static wave.ProjectionNode get(String proj)
```

**Parameters**
- `proj`
  - Type: `String`
  - The name of the column to query.

**Return Value**
- Type: `wave.ProjectionNode`

`union (unionNodes)`
Combine multiple result sets into one result set.

**Signature**
```java
global static Wave.QueryNode union(List<Wave.QueryNode> unionNodes)
```

**Parameters**
- `unionNodes`
  - Type: `List<wave.QueryNode>`
  - List of nodes to combine.

**Return Value**
- Type: `wave.QueryNode`

`cogroup (cogroupNodes, groups)`
Cogrouping means that two input streams are grouped independently and arranged side by side. Only data that exists in both groups appears in the results.

**Signature**
```java
global static Wave.QueryNode cogroup(List<Wave.QueryNode> cogroupNodes, List<List<String>> groups)
```

**Parameters**
- `cogroupNodes`
  - Type: `wave.QueryNode`
List of nodes to group.

groups
Type: String
The type of grouping.

Return Value
Type: wave.QueryNode

QueryNode Class
Define each node of the query - such as projection, groups, order, filters. Execute the query.

Namespace
wave

Usage
Refer to the QueryBuilder example.

IN THIS SECTION:
QueryNode Methods

QueryNode Methods
The following are methods for QueryNode.

IN THIS SECTION:
build(streamName)
Build the query string represented by this QueryNode and assign it to a stream name.

foreach(projections)
Applies a set of expressions to every row in a dataset. This action is often referred to as projection.

group(groups)
Groups matched records (group by specific dataset attributes).

group()
Groups matched records (group by all).

order(orders)
Sorts in ascending or descending order on one or more fields.

cap(cap)
Limits the number of results that are returned.

filter(filterCondition)
Selects rows from a dataset based on a filter condition (a predicate).
filter(filterConditions)
Selects rows from a dataset based on multiple filter conditions (predicates).

execute(streamName)
Execute the query and return rows as JSON.

**build(streamName)**
Build the query string represented by this QueryNode and assign it to a stream name.

**Signature**

```
public String build(String streamName)
```

**Parameters**

- **streamName**
  - Type: String
  - The identifier for the stream - for example, "q".

**Return Value**

- Type: String
  - The SAQL query string represented by the QueryNode.

**foreach(projections)**
Applies a set of expressions to every row in a dataset. This action is often referred to as projection.

**Signature**

```
public wave.QueryNode foreach(List<wave.ProjectionNode> projections)
```

**Parameters**

- **projections**
  - Type: List<wave.ProjectionNode>
  - A list of ProjectionNodes to be added to this QueryNode.

**Return Value**

- Type: wave.QueryNode

**group(groups)**
Groups matched records (group by specific dataset attributes).

**Signature**

```
public wave.QueryNode group(List<String> groups)
```
### Parameters

**groups**

Type: `List<String>`

A list of expressions.

### Return Value

Type: `wave.QueryNode`

### Example

```java
Wave.ProjectionNode[] projs = new Wave.ProjectionNode[]{
    Wave.QueryBuilder.get('Name'),
    Wave.QueryBuilder.get('Revenue').sum().alias('REVENUE_SUM')};
ConnectApi.LiteralJson result = Wave.QueryBuilder.load('datasetId',
    'datasetVersionId').group(new String[]{'Name'}).foreach(projs).build('q');
```

### group()

Groups matched records (group by all).

**Signature**

```java
public wave.QueryNode group()
```

### Return Value

Type: `wave.QueryNode`

**Example**

```java
String query = Wave.QueryBuilder.load('datasetId',
    'datasetVersionId').group().foreach(projs).build('q');
```

### order(orders)

Sorts in ascending or descending order on one or more fields.

**Signature**

```java
public wave.QueryNode group(List<String> groups)
```

**Parameters**

**groups**

Type: `List<String>`

A list of column names and associated ascending or descending keywords, for example

```java
List<List<String>>{{'Name', 'asc'}, {'Revenue', 'desc'}}
```
Return Value
Type: `wave.QueryNode`

`cap(cap)`
Limits the number of results that are returned.

Signature
`global Wave.QueryNode cap(Integer cap)`

Parameters
`cap`
Type: `Integer`
The maximum number of rows to return.

Return Value
Type: `wave.QueryNode`

`filter(filterCondition)`
Selects rows from a dataset based on a filter condition (a predicate).

Signature
`public Wave.QueryNode filter(String filterCondition)`

Parameters
`filterCondition`
Type: `String`
For example: `filter('Name != 'My Name')`

Return Value
Type: `wave.QueryNode`

`filter(filterConditions)`
Selects rows from a dataset based on multiple filter conditions (predicates).

Signature
`public Wave.QueryNode filter(List<String> filterCondition)`
Parameters

*filterCondition*
Type: List<String>
A list of filter conditions.

Return Value
Type: wave.QueryNode

**execute(streamName)**
Execute the query and return rows as JSON.

Signature

```java
public ConnectApi.LiteralJson execute(String streamName)
```

Parameters

*streamName*
Type: String
The query stream to execute. For example:

```java
ConnectApi.LiteralJson result = Wave.QueryBuilder.load('datasetId', 'datasetVersionId').group().foreach(projs).execute('q');
```

Return Value
Type: ConnectApi.LiteralJson

**ProjectionNode Class**
Add aggregate functions to the query, or define an alias.

**Namespace**
wave on page 3643

**Usage**
Refer to the QueryBuilder example.

IN THIS SECTION:

ProjectionNode Methods

**ProjectionNode Methods**
The following are methods for ProjectionNode.
IN THIS SECTION:

- **sum()**
  Returns the sum of a numeric field.

- **avg()**
  Returns the average value of a numeric field.

- **min()**
  Returns the minimum value of a field.

- **max()**
  Returns the maximum value of a field.

- **count()**
  Returns the number of rows that match the query criteria.

- **unique()**
  Returns the count of unique values.

- **alias(name)**
  Define output column names.

**sum()**

Returns the sum of a numeric field.

**Signature**

```java
public wave.ProjectionNode sum()
```

**Return Value**

Type: `wave.ProjectionNode`

**avg()**

Returns the average value of a numeric field.

**Signature**

```java
public wave.ProjectionNode avg()
```

**Return Value**

Type: `wave.ProjectionNode`

**min()**

Returns the minimum value of a field.

**Signature**

```java
public wave.ProjectionNode min()
```
Return Value
Type: `wave.ProjectionNode`

```java
public wave.ProjectionNode max()
```

**max()**
Returns the maximum value of a field.

**Signature**
```
public wave.ProjectionNode max()
```

Return Value
Type: `wave.ProjectionNode`

```java
public wave.ProjectionNode count()
```

**count()**
Returns the number of rows that match the query criteria.

**Signature**
```
public wave.ProjectionNode count()
```

Return Value
Type: `wave.ProjectionNode`

```java
public wave.ProjectionNode unique()
```

**unique()**
Returns the count of unique values.

**Signature**
```
public wave.ProjectionNode unique()
```

Return Value
Type: `wave.ProjectionNode`

```java
public wave.ProjectionNode alias(String name)
```

**alias(name)**
Define output column names.

**Signature**
```
public wave.ProjectionNode alias(String name)
```
Parameters

name

Type: String

The name to use for this column. For example, this code defines the alias \( c \):

```java
```

Return Value

Type: \texttt{wave.ProjectionNode}

Templates Class

The Templates class provides methods for retrieving CRM Analytics template collections, individual templates, and template configurations.

Namespace

\texttt{Wave}

Usage

Use Templates and its associated class \texttt{Wave.TemplatesSearchOptions} to get CRM Analytics template information.

Examples

This code sample declares a method that returns a list of the template names.

```java
@AuraEnabled(cacheable=true)
public static void List<String> getTemplateNames() {
    Map<String, Object> o = Wave.Templates.getTemplates(new Wave.TemplatesSearchOptions());

    List<Object> templates = (List<Object>) o.get('templates');
    List<String> names = new List<String>();
    for (Object templateObj : templates) {
        names.add((String) ((Map<String, Object>) templateObj.get('name')));
    }
    return names;
}
```

Adding the \texttt{@AuraEnabled} annotation allows Lightning Web Components to access Templates methods directly.

For example, in the lwc.js file:

```javascript
import getTemplates from '@salesforce/apex/Wave.Templates.getTemplates';
export default class Templates extends LightningElement {
    @wire(getTemplates, {
        // specifying 'options' is optional
        options: {
            // values in TemplatesSearchOptions go here; all optional
            type: 'app'
        }
    }
```
Templates Methods

The following are methods for Templates.

**getTemplate(templateIdOrApiName)**

Gets a CRM Analytics template by the specified ID or API name. The returned template is a map of the template JSON attributes as name/value pairs.

**getTemplateConfig(templateIdOrApiName)**

Gets the CRM Analytics template configuration by the specified ID or API name. The returned template configuration is a map of the JSON attributes as name/value pairs.

**getTemplates(options)**

Get a filtered collection of CRM Analytics templates using search options.

**getTemplates()**

Gets all CRM Analytics templates.

---

**getTemplate(templateIdOrApiName)**

Gets a CRM Analytics template by the specified ID or API name. The returned template is a map of the template JSON attributes as name/value pairs.

**Signature**

```java
public static Map<String, Object> getTemplate(String templateIdOrApiName)
```

**Parameters**

- **templateIdOrApiName**
  - Type: `String`
  - The template ID or API name of the template to retrieve.

**Return Value**

- Type: `Map<String, Object>`
A map of the template JSON attribute name/value pairs, where the name is a string with an object value. For attributes details, see TemplateRepresentation.

Example

```java
String templateName = (String) Wave.Templates.getTemplate(templateId).get('name');
```

**getTemplateConfig(templateIdOrApiName)**

Gets the CRM Analytics template configuration by the specified ID or API name. The returned template configuration is a map of the JSON attributes as name/value pairs.

**Signature**

```java
public static Map<String, Object> getTemplateConfig(String templateIdOrApiName)
```

**Parameters**

- `templateIdOrApiName`  
  Type: `String`  
  The template ID or developer name to retrieve the template configuration for.

**Return Value**

- Type: `Map<String, Object>`  
  A map of template configuration JSON attribute names and the object values. For attribute details, see TemplateConfigurationRepresentation.

Example

```java
Map<String, Object> templateVariables = (Map<String, Object>) Wave.Templates.getTemplateConfig(templateId).get('variables');
```

**getTemplates(options)**

Get a filtered collection of CRM Analytics templates using search options.

**Signature**

```java
public static Map<String, Object> getTemplates(Wave.TemplatesSearchOptions options)
```

**Parameters**

- `options`  
  Type: `Wave.TemplatesSearchOptions` on page 3657  
  The search options to use for filtering the template collection.
Return Value
Type: Map<String,Object>
A map of template names and the template object values. For template collection details, see TemplateCollectionRepresentation.

Example
Map<String, Object> templatesMap = Wave.Templates.getTemplates(new Wave.TemplatesSearchOptions());

getTemplates()
Gets all CRM Analytics templates.

Signature
public static Map<String, Object> getTemplates()

Return Value
Type: Map<String,Object>
A map of template names and the template object values. For template collection details, see TemplateCollectionRepresentation.

Example
Map<String, Object> templatesMap = Wave.Templates.getTemplates();

TemplatesSearchOptions Class
The TemplatesSearchOptions class provides optional properties to filter the template collection.

Namespace
Wave

Usage
Use TemplatesSearchOptions with Wave.Templates class to filter the CRM Analytics template collection returned. For example:

```java
public static void List<String> getAppTemplates() {
    Wave.TemplatesSearchOptions tsOptions = new Wave.TemplatesSearchOptions();
    tsOptions.type = 'app';

    Map<String, Object> o = Wave.Templates.getTemplates(tsOptions);
    List<Object> appTemplates = (List<Object>) o.get('templates');
    List<String> names = new List<String>();
    for (Object templateObj : appTemplates) {
        names.add((String) ((Map<String, Object>) templateObj).get('name'));
    }
}
TemplatesSearchOptions Properties

The following are properties for TemplatesSearchOptions.

filterGroup
Specifies the Connect API filter group for CRM Analytics template search options.

options
Specifies the template visibility option to filter the CRM Analytics template collection by.

type
Sets the template type to filter the CRM Analytics template collection by.

filterGroup

Specifies the Connect API filter group for CRM Analytics template search options.

Signature

public String filterGroup {get; set;}

Property Value

Type: String

Uses the ConnectFilterGroupEnum values.

Example

```
Wave.TemplateSearchOptions tsOptions = new Wave.TemplateSearchOptions();
nullsOptions.filterGroup = 'small';
```

options

Specifies the template visibility option to filter the CRM Analytics template collection by.

Signature

public String options {get; set;}

return names;
}
Property Value
Type: String
Uses the ConnectWaveTemplateVisibilityOptionsEnum values. Valid values are CreateApp, ViewOnly, and ManageableOnly.

Example
Wave.TemplateSearchOptions tsOptions = new Wave.TemplateSearchOptions();
tsOptions.options = 'ViewOnly';

type
Sets the template type to filter the CRM Analytics template collection by.

Signature
public String type {get; set;}

Property Value
Type: String
Uses the ConnectWaveTemplateTypeEnum values. Valid values are app, dashboard, embedded, and lens.

Example
Wave.TemplateSearchOptions tsOptions = new Wave.TemplateSearchOptions();
tsOptions.type = 'app';

Glossary

Shipping Invoice Example
This appendix provides an example of an Apex application. This is a more complex example than the Hello World example.

• Shipping Invoice Walk-Through
• Shipping Invoice Example Code
Shipping Invoice Example Walk-Through

The sample application in this section includes traditional Salesforce functionality blended with Apex. Many of the syntactic and semantic features of Apex, along with common idioms, are illustrated in this application.

**Note:** The Shipping Invoice sample requires custom objects. You can either create these on your own, or download the objects and Apex code as an unmanaged package from the Salesforce AppExchange. To obtain the sample assets in your org, install the Apex Tutorials Package. This package also contains sample code and objects for the Apex Quick Start.

**Scenario**

In this sample application, the user creates a new shipping invoice, or order, and then adds items to the invoice. The total amount for the order, including shipping cost, is automatically calculated and updated based on the items added or deleted from the invoice.

**Data and Code Models**

This sample application uses two new objects: Item and Shipping_invoice.

The following assumptions are made:

- Item A cannot be in both orders shipping_invoice1 and shipping_invoice2. Two customers cannot obtain the same (physical) product.
- The tax rate is 9.25%.
- The shipping rate is 75 cents per pound.
- Once an order is over $100, the shipping discount is applied (shipping becomes free).

The fields in the Item custom object include:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>String</td>
<td>The name of the item</td>
</tr>
<tr>
<td>Price</td>
<td>Currency</td>
<td>The price of the item</td>
</tr>
<tr>
<td>Quantity</td>
<td>Number</td>
<td>The number of items in the order</td>
</tr>
<tr>
<td>Weight</td>
<td>Number</td>
<td>The weight of the item, used to calculate shipping costs</td>
</tr>
<tr>
<td>Shipping_invoice</td>
<td>Master-Detail (shipping_invoice)</td>
<td>The order this item is associated with</td>
</tr>
</tbody>
</table>

The fields in the Shipping_invoice custom object include:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>String</td>
<td>The name of the shipping invoice/order</td>
</tr>
<tr>
<td>Subtotal</td>
<td>Currency</td>
<td>The subtotal</td>
</tr>
</tbody>
</table>
### Table of Key Terms

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GrandTotal</td>
<td>Currency</td>
<td>The total amount, including tax and shipping</td>
</tr>
<tr>
<td>Shipping</td>
<td>Currency</td>
<td>The amount charged for shipping (assumes $0.75 per pound)</td>
</tr>
<tr>
<td>ShippingDiscount</td>
<td>Currency</td>
<td>Only applied once when subtotal amount reaches $100</td>
</tr>
<tr>
<td>Tax</td>
<td>Currency</td>
<td>The amount of tax (assumes 9.25%)</td>
</tr>
<tr>
<td>TotalWeight</td>
<td>Number</td>
<td>The total weight of all items</td>
</tr>
</tbody>
</table>

All of the Apex for this application is contained in triggers. This application has the following triggers:

<table>
<thead>
<tr>
<th>Object</th>
<th>Trigger Name</th>
<th>When Runs</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Item</td>
<td>Calculate</td>
<td>after insert, after update, after delete</td>
<td>Updates the shipping invoice, calculates the totals and shipping</td>
</tr>
<tr>
<td>Shipping_invoice</td>
<td>ShippingDiscount</td>
<td>after update</td>
<td>Updates the shipping invoice, calculating if there is a shipping discount</td>
</tr>
</tbody>
</table>

The following is the general flow of user actions and when triggers run:

**Flow of user action and triggers for the shopping cart application**

1. User clicks **Orders > New**, names the shipping invoice and clicks **Save**.
2. User clicks **New Item**, fills out information, and clicks **Save**.

3. Calculate trigger runs. Part of the Calculate trigger updates the shipping invoice.

4. ShippingDiscount trigger runs.

5. User can then add, delete or change items in the invoice.

In **Shipping Invoice Example Code** both of the triggers and the test class are listed. The comments in the code explain the functionality.

### Testing the Shipping Invoice Application

Before an application can be included as part of a package, 75% of the code must be covered by unit tests. Therefore, one piece of the shipping invoice application is a class used for testing the triggers.

The test class verifies the following actions are completed successfully:

- Inserting items
- Updating items
- Deleting items
- Applying shipping discount
- Negative test for bad input

### Shipping Invoice Example Code

The following triggers and test class make up the shipping invoice example application:

- Calculate trigger
- ShippingDiscount trigger
- Test class

#### Calculate Trigger

```
trigger calculate on Item__c (after insert, after update, after delete) {

// Use a map because it doesn't allow duplicate values
Map<ID, Shipping_Invoice__C> updateMap = new Map<ID, Shipping_Invoice__C>();

// Set this integer to -1 if we are deleting
Integer subtract;

// Populate the list of items based on trigger type
List<Item__c> itemList;
if(trigger.isInsert || trigger.isUpdate) {
    itemList = Trigger.new;
    subtract = 1;
} else if(trigger.isDelete) {
    // Note -- there is no trigger.new in delete
    itemList = trigger.old;
    subtract = -1;
}
```

// Access all the information we need in a single query
// rather than querying when we need it.
// This is a best practice for bulkifying requests

set<Id> AllItems = new set<id>();

for(item__c i :itemList){
    // Assert numbers are not negative.
    // None of the fields would make sense with a negative value
    System.assert(i.quantity__c > 0, 'Quantity must be positive');
    System.assert(i.weight__c >= 0, 'Weight must be non-negative');
    System.assert(i.price__c >= 0, 'Price must be non-negative');

    // If there is a duplicate Id, it won't get added to a set
    AllItems.add(i.Shipping_Invoice__C);
}

// Accessing all shipping invoices associated with the items in the trigger
List<Shipping_Invoice__c> AllShippingInvoices = [SELECT Id, ShippingDiscount__c,
                                                 SubTotal__c, TotalWeight__c, Tax__c, GrandTotal__c
                                                 FROM Shipping_Invoice__c WHERE Id IN :AllItems];

// Take the list we just populated and put it into a Map.
// This will make it easier to look up a shipping invoice
// because you must iterate a list, but you can use lookup for a map,
Map<ID, Shipping_Invoice__c> SIMap = new Map<ID, Shipping_Invoice__c>();

for(Shipping_Invoice__c sc : AllShippingInvoices)
{
    SIMap.put(sc.id, sc);
}

// Process the list of items
if(Trigger.isUpdate)
{
    // Treat updates like a removal of the old item and addition of the
    // revised item rather than figuring out the differences of each field
    // and acting accordingly.
    // Note updates have both trigger.new and trigger.old
    for(Integer x = 0; x < Trigger.old.size(); x++)
    {
        Shipping_Invoice__c myOrder;
        myOrder = SIMap.get(trigger.old[x].Shipping_Invoice__C);

        // Decrement the previous value from the subtotal and weight.
        myOrder.SubTotal__c -= (trigger.old[x].price__c * trigger.old[x].quantity__c);
        myOrder.TotalWeight__c -= (trigger.old[x].weight__c * trigger.old[x].quantity__c);

        // Increment the new subtotal and weight.
        myOrder.SubTotal__c += (trigger.new[x].price__c * trigger.new[x].quantity__c);
    }
}
```apex
trigger.new[x].quantity__c);
myOrder.TotalWeight__c += (trigger.new[x].weight__c *
    trigger.new[x].quantity__c);
}

for(Shipping_Invoice__C myOrder : AllShippingInvoices)
{

    // Set tax rate to 9.25% Please note, this is a simple example.
    // Generally, you would never hard code values.
    // Leveraging Custom Settings for tax rates is a best practice.
    // See Custom Settings in the Apex Developer Guide
    // for more information.
    myOrder.Tax__c = myOrder.Subtotal__c * .0925;

    // Reset the shipping discount
    myOrder.ShippingDiscount__c = 0;

    // Set shipping rate to 75 cents per pound.
    // Generally, you would never hard code values.
    // Leveraging Custom Settings for the shipping rate is a best practice.
    // See Custom Settings in the Apex Developer Guide
    // for more information.
    myOrder.Shipping__c = (myOrder.totalWeight__c * .75);
    myOrder.GrandTotal__c = myOrder.SubTotal__c + myOrder.tax__c +
        myOrder.Shipping__c;

    updateMap.put(myOrder.id, myOrder);
}
else
{
    for(Item__c itemToProcess : itemList)
    {
        Shipping_Invoice__C myOrder;

        // Look up the correct shipping invoice from the ones we got earlier
        myOrder = SIMap.get(itemToProcess.Shipping_Invoice__C);
        myOrder.SubTotal__c += (itemToProcess.price__c *
            itemToProcess.quantity__c * subtract);
        myOrder.TotalWeight__c += (itemToProcess.weight__c *
            itemToProcess.quantity__c * subtract);
    }

    for(Shipping_Invoice__C myOrder : AllShippingInvoices)
    {

        // Set tax rate to 9.25% Please note, this is a simple example.
        // Generally, you would never hard code values.
        // Leveraging Custom Settings for tax rates is a best practice.
        // See Custom Settings in the Apex Developer Guide
        // for more information.
        myOrder.Tax__c = myOrder.Subtotal__c * .0925;

        // Reset shipping discount
```
myOrder.ShippingDiscount__c = 0;

// Set shipping rate to 75 cents per pound.
// Generally, you would never hard code values.
// Leveraging Custom Settings for the shipping rate is a best practice.
// See Custom Settings in the Apex Developer Guide for more information.
myOrder.Shipping__c = (myOrder.totalWeight__c * .75);
myOrder.GrandTotal__c = myOrder.SubTotal__c + myOrder.tax__c +
    myOrder.Shipping__c;

updateMap.put(myOrder.id, myOrder);

// Only use one DML update at the end.
// This minimizes the number of DML requests generated from this trigger.
update updateMap.values();

ShippingDiscount Trigger

trigger ShippingDiscount on Shipping_Invoice__C (before update) {
    // Free shipping on all orders greater than $100
    for(Shipping_Invoice__C myShippingInvoice : Trigger.new)
    {
        if((myShippingInvoice.subtotal__c >= 100.00) &&
           (myShippingInvoice.ShippingDiscount__c == 0))
        {
            myShippingInvoice.ShippingDiscount__c = myShippingInvoice.Shipping__c * -1;
            myShippingInvoice.GrandTotal__c += myShippingInvoice.ShippingDiscount__c;
        }
    }
}

Documentation Typographical Conventions

Apex and Visualforce documentation uses the following typographical conventions.
<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Courier font</td>
<td>In descriptions of syntax, monospace font indicates items that you should type as shown, except for brackets. For example:</td>
</tr>
<tr>
<td></td>
<td><strong>Public class</strong> HelloWorld</td>
</tr>
<tr>
<td>Italics</td>
<td>In descriptions of syntax, italics represent variables. You supply the actual value. In the following example, three values need to be supplied:</td>
</tr>
<tr>
<td></td>
<td><em>datatype</em> <em>variable_name</em> = <em>value</em>;</td>
</tr>
<tr>
<td></td>
<td>If the syntax is bold and italic, the text represents a code element that needs a value supplied by you, such as a class name or variable value:</td>
</tr>
<tr>
<td></td>
<td><strong>public static class</strong> YourClassHere { ... }</td>
</tr>
<tr>
<td>Bold Courier font</td>
<td>In code samples and syntax descriptions, bold courier font emphasizes a portion of the code or syntax.</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>In descriptions of syntax, less-than and greater-than symbols (&lt; &gt;) are typed exactly as shown.</td>
</tr>
<tr>
<td></td>
<td><code>&lt;apex:pageBlockTable value=&quot; {!account.Contacts} &quot; var=&quot;contact&quot;&gt;</code></td>
</tr>
<tr>
<td></td>
<td><code>&lt;apex:column value=&quot; {!contact.Name}&quot;/&gt;</code></td>
</tr>
<tr>
<td></td>
<td><code>&lt;apex:column value=&quot; {!contact.MailingCity}&quot;/&gt;</code></td>
</tr>
<tr>
<td></td>
<td><code>&lt;apex:column value=&quot; {!contact.Phone}&quot;/&gt;</code></td>
</tr>
<tr>
<td></td>
<td><code>&lt;/apex:pageBlockTable&gt;</code></td>
</tr>
<tr>
<td>[]</td>
<td>In descriptions of syntax, braces ({ }) are typed exactly as shown.</td>
</tr>
<tr>
<td></td>
<td><code>&lt;apex:page&gt;</code></td>
</tr>
<tr>
<td></td>
<td>Hello {!$User.FirstName}!</td>
</tr>
<tr>
<td></td>
<td><code>&lt;/apex:page&gt;</code></td>
</tr>
<tr>
<td>[ ]</td>
<td>In descriptions of syntax, anything included in brackets is optional. In the following example, specifying <em>value</em> is optional:</td>
</tr>
<tr>
<td></td>
<td><em>data_type</em> <em>variable_name</em> = <em>value</em>;</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>In the following example, you can create a new unpopulated set in one of two ways, or you can populate the set:</td>
</tr>
<tr>
<td></td>
<td>Set&lt;data_type&gt; <em>set_name</em></td>
</tr>
<tr>
<td></td>
<td>[= new Set&lt;data_type&gt; ()]</td>
</tr>
<tr>
<td></td>
<td>[= new Set&lt;data_type&gt; {value, value2...}]</td>
</tr>
<tr>
<td></td>
<td>;</td>
</tr>
</tbody>
</table>

3673
Administrator (System Administrator)
One or more individuals in your organization who can configure and customize the application. Users assigned to the System Administrator profile have administrator privileges.

AJAX Toolkit
A JavaScript wrapper around the API that allows you to execute any API call and access any object you have permission to view from within JavaScript code. For more information, see the AJAX Toolkit Developer Guide.

Anti-Join
An anti-join is a subquery on another object in a `NOT IN` clause in a SOQL query. You can use anti-joins to create advanced queries. See also Semi-Join.

Anonymous Block, Apex
Apex code that doesn't get stored in Salesforce, but that can be compiled and executed by using the `ExecuteAnonymousResult()` API call, or the equivalent in the AJAX Toolkit.

Ant Migration Tool
A toolkit that allows you to write an Apache Ant build script for migrating Lightning Platform components between a local file system and a Salesforce organization.

Apex
Apex is a strongly typed, object-oriented programming language that allows developers to execute flow and transaction control statements on the Lightning Platform server in conjunction with calls to the Lightning Platform API. Using syntax that looks like Java and acts like database-stored procedures, Apex enables developers to add business logic to most system events, including button clicks, related record updates, and Visualforce pages. Apex code can be initiated by Web service requests and from triggers on objects.

Apex Connector Framework
The Apex Connector Framework is a set of classes and methods in the DataSource namespace for creating a custom adapter for Salesforce Connect. Create a custom adapter to connect to data that's stored outside your Salesforce org when the other available Salesforce Connect adapters aren't suitable for your needs.

Apex-Managed Sharing
Enables developers to programmatically manipulate sharing to support their application’s behavior. Apex-managed sharing is only available for custom objects.

Apex Page
See Visualforce page.

App
Short for “application.” A collection of components such as tabs, reports, dashboards, and Visualforce pages that address a specific business need. Salesforce provides standard apps such as Sales and Service. You can customize the standard apps to match the way you work. In addition, you can package an app and upload it to AppExchange along with related components such as custom fields, custom tabs, and custom objects. Then, you can make the app available to other Salesforce users from AppExchange.

AppExchange
The AppExchange is a sharing interface from Salesforce that allows you to browse and share apps and services for the Lightning Platform.

Application Programming Interface (API)
The interface that a computer system, library, or application provides to allow other computer programs to request services from it and exchange data.

Approval Process
An approval process automates how records are approved in Salesforce. An approval process specifies each step of approval, including who to request approval from and what to do at each point of the process.
Asynchronous Calls
A call that doesn’t return results immediately because the operation can take a long time. Calls in the Metadata API and Bulk API 2.0 are asynchronous.

B
Batch Apex
The ability to perform long, complex operations on many records at a scheduled time using Apex.

Beta, Managed Package
In the context of managed packages, a beta managed package is an early version of a managed package distributed to a sampling of your intended audience to test it.

Bulk API 2.0
The REST-based Bulk API 2.0 is optimized for processing large sets of data. It allows you to query, insert, update, upsert, or delete a large number of records asynchronously by submitting a job that is processed in the background by Salesforce. See also SOAP API.

C
Callout, Apex
An Apex callout enables you to tightly integrate your Apex with an external service by making a call to an external Web service or sending a HTTP request from Apex code and then receiving the response.

Child Relationship
A relationship that has been defined on an sObject that references another sObject as the “one” side of a one-to-many relationship. For example, contacts, opportunities, and tasks have child relationships with accounts.
See also sObject.

Class, Apex
A template or blueprint from which Apex objects are created. Classes consist of other classes, user-defined methods, variables, exception types, and static initialization code. In most cases, Apex classes are modeled on their counterparts in Java.

Client App
An app that runs outside the Salesforce user interface and uses only the Lightning Platform API or Bulk API 2.0. It typically runs on a desktop or mobile device. These apps treat the platform as a data source, using the development model of whatever tool and platform for which they’re designed.

Code Coverage
A way to identify which lines of code are exercised by a set of unit tests, and which aren’t. Code coverage helps you identify sections of code that are untested and therefore at greatest risk of containing a bug or introducing a regression in the future.

Component, Metadata
A component is an instance of a metadata type in the Metadata API. For example, CustomObject is a metadata type for custom objects, and the MyCustomObject__c component is an instance of a custom object. A component is described in an XML file and it can be deployed or retrieved using the Metadata API, or tools built on top of it, such as the Salesforce extensions for Visual Studio Code or the Ant Migration Tool.

Component, Visualforce
Something that can be added to a Visualforce page with a set of tags, for example, `<apex:detail>`. Visualforce includes a number of standard components, or you can create your own custom components.

Component Reference, Visualforce
A description of the standard and custom Visualforce components that are available in your organization. You can access the component library from the development footer of any Visualforce page or the Visualforce Developer’s Guide.
Composite App
An app that combines native platform functionality with one or more external Web services, such as Yahoo! Maps. Composite apps allow for more flexibility and integration with other services, but can require running and managing external code. See also Client App and Native App.

Controller, Visualforce
An Apex class that provides a Visualforce page with the data and business logic it must run. Visualforce pages can use the standard controllers that come by default with every standard or custom object, or they can use custom controllers.

Controller Extension
A controller extension is an Apex class that extends the functionality of a standard or custom controller.

Cookie
Client-specific data used by some Web applications to store user and session-specific information. Salesforce issues a session "cookie" only to record encrypted authentication information for the duration of a specific session.

Custom App
See App.

Custom Controller
A custom controller is an Apex class that implements all of the logic for a page without using a standard controller. Use custom controllers when you want your Visualforce page to run entirely in system mode, which doesn’t enforce the permissions and field-level security of the current user.

Custom Field
A field that can be added in addition to the standard fields to customize Salesforce for your organization’s needs.

Custom Links
Custom links are URLs defined by administrators to integrate your Salesforce data with external websites and back-office systems. Formerly known as Web links.

Custom Object
Custom records that allow you to store information unique to your organization.

Custom Settings
Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data can then be used by formula fields, validation rules, flows, Apex, and SOAP API.
See also Hierarchy Custom Settings and List Custom Settings.

D

Database
An organized collection of information. The underlying architecture of the Lightning Platform includes a database where your data is stored.

Database Table
A list of information, presented with rows and columns, about the person, thing, or concept you want to track. See also Object.

Data Loader
A Lightning Platform tool used to import and export data from your Salesforce organization.

Data Manipulation Language (DML)
An Apex method or operation that inserts, updates, or deletes records.
Data State
The structure of data in an object at a particular point in time.

Date Literal
A keyword in a SOQL or SOSL query that represents a relative range of time such as last month or next year.

Decimal Places
Parameter for number, currency, and percent custom fields that indicates the total number of digits you can enter to the right of a decimal point, for example, 4.98 for an entry of 2. The system rounds the decimal numbers you enter, if necessary. For example, if you enter 4.986 in a field with Decimal Places of 2, the number rounds to 4.99. Salesforce uses the round half-up rounding algorithm. Half-way values are always rounded up. For example, 1.45 is rounded to 1.5. –1.45 is rounded to –1.5.

Dependency
A relationship where one object’s existence depends on that of another. There are a number of different kinds of dependencies including mandatory fields, dependent objects (parent-child), file inclusion (referenced images, for example), and ordering dependencies (when one object must be deployed before another object).

Dependent Field
Any custom picklist or multi-select picklist field that displays available values based on the value selected in its corresponding controlling field.

Deploy
To move functionality from an inactive state to active. For example, when developing new features in the Salesforce user interface, you must select the “Deployed” option to make the functionality visible to other users.

The process by which an application or other functionality is moved from development to production.

To move metadata components from a local file system to a Salesforce organization.

For installed apps, deployment makes any custom objects in the app available to users in your organization. Before a custom object is deployed, it’s only available to administrators and any users with the “Customize Application” permission.

Deprecated Component
Developers can refine the functionality in a managed package over time as the requirements evolve, such as redesign some of the components in the managed package. Developers can’t delete some components in a Managed - Released package, but they can deprecate a component in a later package version so that new subscribers don’t receive the component, while the component continues to function for existing subscribers and API integrations.

Detail
A page that displays information about a single object record. The detail page of a record allows you to view the information, whereas the edit page allows you to modify it.

A term used in reports to distinguish between summary information and inclusion of all column data for all information in a report. You can toggle the Show Details/Hide Details button to view and hide report detail information.

Developer Edition
A free, fully functional Salesforce organization designed for developers to extend, integrate, and develop with the Lightning Platform. Developer Edition accounts are available on developer.salesforce.com.

Salesforce Developers
The Salesforce Developers website at developer.salesforce.com provides a full range of resources for platform developers, including sample code, toolkits, an online developer community, and the ability to obtain limited Lightning Platform environments.

Development Environment
A Salesforce organization where you can make configuration changes that don’t affect users on the production organization. There are two kinds of development environments, sandboxes and Developer Edition organizations.
Email Alert
Email alerts are actions that send emails, using a specified email template, to specified recipients.

Email Template
A form email that communicates a standard message, such as a welcome letter to new employees or an acknowledgment that a customer service request has been received. Email templates can be personalized with merge fields, and can be written in text, HTML, or custom format.

Note: Lightning email templates aren't packageable.

Enterprise Edition
A Salesforce edition designed for larger, more complex businesses.

Enterprise WSDL
A strongly typed WSDL for customers who want to build an integration with their Salesforce organization only, or for partners who are using tools like Tibco or webMethods to build integrations that require strong typecasting. The downside of the Enterprise WSDL is that it only works with the schema of a single Salesforce organization because it's bound to all of the unique objects and fields that exist in that organization's data model.

Entity Relationship Diagram (ERD)
A data modeling tool that helps you organize your data into entities (or objects, as they're called in the Lightning Platform) and define the relationships between them. ERDs for key Salesforce objects are published in the Salesforce Object Reference.

Enumeration Field
An enumeration is the WSDL equivalent of a picklist field. The valid values of the field are restricted to a strict set of possible values, all having the same data type.

Facet
A child of another Visualforce component that allows you to override an area of the rendered parent with the contents of the facet.

Field
A part of an object that holds a specific piece of information, such as a text or currency value.

Field Dependency
A filter that allows you to change the contents of a picklist based on the value of another field.

Field-Level Security
Settings that determine whether fields are hidden, visible, read only, or editable for users. Available in Professional, Enterprise, Unlimited, Performance, and Developer Editions.

Foreign Key
A field whose value is the same as the primary key of another table. You can think of a foreign key as a copy of a primary key from another table. A relationship is made between two tables by matching the values of the foreign key in one table with the values of the primary key in another.

Getter Methods
Methods that enable developers to display database and other computed values in page markup. Methods that return values. See also Setter Methods.
Global Variable
A special merge field that you can use to reference data in your organization.
A method access modifier for any method that must be referenced outside of the application, either in SOAP API or by other Apex code.

Governor Limits
Apex execution limits that prevent developers who write inefficient code from monopolizing the resources of other Salesforce users.

Gregorian Year
A calendar based on a 12-month structure used throughout much of the world.

Hierarchy Custom Settings
A type of custom setting that uses a built-in hierarchical logic that lets you “personalize” settings for specific profiles or users. The hierarchy logic checks the organization, profile, and user settings for the current user and returns the most specific, or “lowest,” value. In the hierarchy, settings for an organization are overridden by profile settings, which, in turn, are overridden by user settings.

HTTP Debugger
An application that can be used to identify and inspect SOAP requests that are sent from the AJAX Toolkit. They behave as proxy servers running on your local machine and allow you to inspect and author individual requests.

ID
See Salesforce Record ID.

IdeaExchange
Salesforce’s always-on feedback platform that connects the Trailblazer Community with Salesforce product managers. It’s the go-to place to post ideas and contribute feedback about how to improve products and experiences. Visit IdeaExchange at ideas.salesforce.com.

Import Wizard
A tool for importing data into your Salesforce organization, accessible from Setup.

Instance
The cluster of software and hardware represented as a single logical server that hosts an organization’s data and runs their applications. The Lightning Platform runs on multiple instances, but data for any single organization is always stored on a single instance.

Integrated Development Environment (IDE)
A software application that provides comprehensive facilities for software developers including a source code editor, testing and debugging tools, and integration with source code control systems.

Integration User
A Salesforce user defined solely for client apps or integrations. Also referred to as the logged-in user in a SOAP API context.

ISO Code
The International Organization for Standardization country code, which represents each country by two letters.
Junction Object

A custom object with two master-detail relationships. Using a custom junction object, you can model a "many-to-many" relationship between two objects. For example, you create a custom object called "Bug" that relates to the standard case object such that a bug could be related to multiple cases and a case could also be related to multiple bugs.

Length

Parameter for custom text fields that specifies the maximum number of characters (up to 255) that a user can enter in the field.

Parameter for number, currency, and percent fields that specifies the number of digits you can enter to the left of the decimal point, for example, 123.98 for an entry of 3.

Lightning Platform

The Salesforce platform for building applications in the cloud. Lightning Platform combines a powerful user interface, operating system, and database to allow you to customize and deploy applications in the cloud for your entire enterprise.

List Custom Settings

A type of custom setting that provides a reusable set of static data that can be accessed across your organization. If you use a particular set of data frequently within your application, putting that data in a list custom setting streamlines access to it. Data in list settings doesn’t vary with profile or user, but is available organization-wide. Examples of list data include two-letter state abbreviations, international dialing prefixes, and catalog numbers for products. Because the data is cached, access is low-cost and efficient: you don’t have to use SOQL queries that count against your governor limits.

List View

A list display of items (for example, accounts or contacts) based on specific criteria. Salesforce provides some predefined views.

In the Agent console, the list view is the top frame that displays a list view of records based on specific criteria. The list views you can select to display in the console are the same list views defined on the tabs of other objects. You can’t create a list view within the console.

Local Name

The value stored for the field in the user’s or account’s language. The local name for a field is associated with the standard name for that field.

Locale

The country or geographic region in which the user is located. The setting affects the format of date and number fields, for example, dates in the English (United States) locale display as 06/30/2000 and as 30/06/2000 in the English (United Kingdom) locale.

In Professional, Enterprise, Unlimited, Performance, and Developer Edition organizations, a user’s individual Locale setting overrides the organization’s Default Locale setting. In Personal and Group Editions, the organization-level locale field is called Locale, not Default Locale.

Long Text Area

Data type of custom field that allows entry of up to 32,000 characters on separate lines.

Lookup Relationship

A relationship between two records so you can associate records with each other. For example, cases have a lookup relationship with assets that lets you associate a particular asset with a case. On one side of the relationship, a lookup field allows users to click a lookup icon and select another record from a window. On the associated record, you can then display a related list to show all of the records that have been linked to it. If a lookup field references a record that has been deleted, by default Salesforce clears the lookup field. Alternatively, you can prevent records from being deleted if they’re in a lookup relationship.
Managed Package
A collection of application components that is posted as a unit on AppExchange and associated with a namespace and possibly a License Management Organization. To support upgrades, a package must be managed. An organization can create a single managed package that can be downloaded and installed by many different organizations. Managed packages differ from unmanaged packages by having some locked components, allowing the managed package to be upgraded later. Unmanaged packages don’t include locked components and can’t be upgraded. In addition, managed packages obfuscate certain components (like Apex) on subscribing organizations to protect the intellectual property of the developer.

Manual Sharing
Record-level access rules that allow record owners to give read and edit permissions to other users who don’t have access to the record any other way.

Many-to-Many Relationship
A relationship where each side of the relationship can have many children on the other side. Many-to-many relationships are implemented through the use of junction objects.

Master-Detail Relationship
A relationship between two different types of records that associates the records with each other. For example, accounts have a master-detail relationship with opportunities. This type of relationship affects record deletion, security, and makes the lookup relationship field required on the page layout.

Metadata
Information about the structure, appearance, and functionality of an organization and any of its parts. Lightning Platform uses XML to describe metadata.

Metadata-Driven Development
An app development model that allows apps to be defined as declarative “blueprints,” with no code required. Apps built on the platform—their data models, objects, forms, workflows, and more—are defined by metadata.

Metadata WSDL
A WSDL for users who want to use the Lightning Platform Metadata API calls.

Multitenancy
An application model where all users and apps share a single, common infrastructure and code base.

MVC (Model-View-Controller)
A design paradigm that deconstructs applications into components that represent data (the model), ways of displaying that data in a user interface (the view), and ways of manipulating that data with business logic (the controller).

Namespace
In a packaging context, a one- to 15-character alphanumeric identifier that distinguishes your package and its contents from packages of other developers on AppExchange, similar to a domain name. Salesforce automatically prepends your namespace prefix, followed by two underscores (“__”), to all unique component names in your Salesforce organization.

Native App
An app that is built exclusively with setup (metadata) configuration on Lightning Platform. Native apps don’t require any external services or infrastructure.
Object
An object allows you to store information in your Salesforce organization. The object is the overall definition of the type of information you're storing. For example, the case object lets you store information regarding customer inquiries. For each object, your organization has multiple records that store the information about specific instances of that type of data. For example, you can have a case record to store the information about Joe Smith’s training inquiry and another case record to store the information about Mary Johnson's configuration issue.

Object-Level Help
Custom help text that you can provide for any custom object. It displays on custom object record home (overview), detail, and edit pages, as well as list views and related lists.

Object-Level Security
Settings that allow an administrator to hide whole objects from users so that they don't know that type of data exists. Object-level security is specified with object permissions.

One-to-Many Relationship
A relationship in which a single object is related to many other objects. For example, an account can have one or more related contacts.

Organization
A deployment of Salesforce with a defined set of licensed users. An organization is the virtual space provided to an individual customer of Salesforce. Your organization includes all of your data and applications, and is separate from all other organizations.

Organization-Wide Defaults
Settings that allow you to specify the baseline level of data access that a user has in your organization. For example, you can set organization-wide defaults so that any user can see any record of a particular object that is enabled via their object permissions, but they need extra permissions to edit one.

Outbound Call
Any call that originates from a user to a number outside of a call center in Salesforce CRM Call Center.

Outbound Message
An outbound message sends information to a designated endpoint, like an external service. Outbound messages are configured from Setup. You must configure the external endpoint and create a listener for the messages using SOAP API.

Owner
Individual user to which a record (for example, a contact or case) is assigned.

P

PaaS
See Platform as a Service.

Package
A group of Lightning Platform components and applications that are made available to other organizations through AppExchange. You use packages to bundle an app along with any related components so that you can upload them to AppExchange together.

Package Dependency
This dependency is created when one component references another component, permission, or preference that is required for the component to be valid. Components can include but aren’t limited to:

- Standard or custom fields
- Standard or custom objects
- Visualforce pages
• Apex code

Permissions and preferences can include but aren’t limited to:
• Divisions
• Multicurrency
• Record types

Package Installation
Installation incorporates the contents of a package into your Salesforce organization. A package on AppExchange can include an app, a component, or a combination of the two. After you install a package, you can deploy components in the package to make it generally available to the users in your organization.

Package Version
A package version is a number that identifies the set of components uploaded in a package. The version number has the format majorNumber.minorNumber.patchNumber (for example, 2.1.3). The major and minor numbers increase to a chosen value during every major release. The patchNumber is generated and updated only for a patch release.

Unmanaged packages aren’t upgradeable, so each package version is simply a set of components for distribution. A package version has more significance for managed packages. Packages can exhibit different behavior for different versions. Publishers can use package versions to evolve the components in their managed packages gracefully by releasing subsequent package versions without breaking existing customer integrations using the package. See also Patch and Patch Development Organization.

Partner WSDL
A loosely typed WSDL for customers, partners, and ISVs who want to build an integration or an AppExchange app that can work across multiple Salesforce organizations. With this WSDL, the developer is responsible for marshaling data in the correct object representation, which typically involves editing the XML. However, the developer is also freed from being dependent on any particular data model or Salesforce organization. Contrast to the Enterprise WSDL, which is strongly typed.

Patch
A patch enables a developer to change the functionality of existing components in a managed package, while ensuring subscribing organizations that there are no visible behavior changes to the package. For example, you can add new variables or change the body of an Apex class, but you can’t add, deprecate, or remove any of its methods. Patches are tracked by a patchNumber appended to every package version. See also Patch Development Organization and Package Version.

Patch Development Organization
The organization where patch versions are developed, maintained, and uploaded. Patch development organizations are created automatically for a developer organization when they request to create a patch. See also Patch and Package Version.

Personal Edition
Product designed for individual sales representatives and single users.

Platform as a Service (PaaS)
An environment where developers use programming tools offered by a service provider to create applications and deploy them in a cloud. The application is hosted as a service and provided to customers via the Internet. The PaaS vendor provides an API for creating and extending specialized applications. The PaaS vendor also takes responsibility for the daily maintenance, operation, and support of the deployed application and each customer’s data. The service alleviates the need for programmers to install, configure, and maintain the applications on their own hardware, software, and related IT resources. Services can be delivered using the PaaS environment to any market segment.

Platform Edition
A Salesforce edition based on Enterprise, Unlimited, or Performance Edition that doesn’t include any of the standard Salesforce apps, such as Sales or Service & Support.
Primary Key
A relational database concept. Each table in a relational database has a field in which the data value uniquely identifies the record. This field is called the primary key. The relationship is made between two tables by matching the values of the foreign key in one table with the values of the primary key in another.

Production Organization
A Salesforce organization that has live users accessing data.

Professional Edition
A Salesforce edition designed for businesses who need full-featured CRM functionality.

Prototype
The classes, methods, and variables that are available to other Apex code.

Query Locator
A parameter returned from the `query()` or `queryMore()` API call that specifies the index of the last result record that was returned.

Query String Parameter
A name-value pair that’s included in a URL, typically after a ‘?’ character. For example:

https://yourInstance.salesforce.com/001/e?name=value

Record
A single instance of a Salesforce object. For example, “John Jones” can be the name of a contact record.

Record ID
The unique identifier for each record.

Record-Level Security
A method of controlling data in which you can allow a particular user to view and edit an object, but then restrict the records that the user is allowed to see.

Record Locking
Record locking prevents users from editing a record, regardless of field-level security or sharing settings. By default, Salesforce locks records that are pending approval. Only admins can edit locked records.

Record Name
A standard field on all Salesforce objects. Whenever a record name is displayed in a Lightning Platform application, the value is represented as a link to a detail view of the record. A record name can be either free-form text or an autonumber field. Record Name doesn’t have to be a unique value.

Recycle Bin
A page that lets you view and restore deleted information. Access the Recycle Bin either by using the link in the sidebar in Salesforce Classic or from the App Launcher in Lightning Experience.

Relationship
A connection between two objects, used to create related lists in page layouts and detail levels in reports. Matching values in a specified field in both objects are used to link related data; for example, if one object stores data about companies and another object stores data about people, a relationship allows you to find out which people work at the company.
Relationship Query
In a SOQL context, a query that traverses the relationships between objects to identify and return results. Parent-to-child and child-to-parent syntax differs in SOQL queries.

Role Hierarchy
A record-level security setting that defines different levels of users such that users at higher levels can view and edit information owned by or shared with users beneath them in the role hierarchy, regardless of the organization-wide sharing model settings.

Roll-Up Summary Field
A field type that automatically provides aggregate values from child records in a master-detail relationship.

Running User
Each dashboard has a running user, whose security settings determine which data to display in a dashboard. If the running user is a specific user, all dashboard viewers see data based on the security settings of that user—regardless of their own personal security settings. For dynamic dashboards, you can set the running user to be the logged-in user, so that each user sees the dashboard according to their own access level.

S
SaaS
See Software as a Service (SaaS).

S-Control

Note: S-controls have been superseded by Visualforce pages. After March 2010 organizations that have never created s-controls, as well as new organizations, won’t be allowed to create them. Existing s-controls remain unaffected, and can still be edited.

Custom Web content for use in custom links. Custom s-controls can contain any type of content that you can display in a browser, for example a Java applet, an Active-X control, an Excel file, or a custom HTML Web form.

Salesforce Certificate and Key Pair
Salesforce certificates and key pairs are used for signatures that verify a request is coming from your organization. They’re used for authenticated SSL communications with an external website, or when using your organization as an Identity Provider. You only must generate a Salesforce certificate and key pair if you’re working with an external website that wants verification that a request is coming from a Salesforce organization.

Salesforce Connect
Salesforce Connect provides access to data that’s stored outside the Salesforce org, such as data in an enterprise resource planning (ERP) system and records in another org. Salesforce Connect represents the data in external objects and accesses the external data in real time via Web service callouts to external data sources.

Salesforce Extensions for Visual Studio Code
The Salesforce extension pack for Visual Studio Code includes tools for developing on the Salesforce platform in the lightweight, extensible VS Code editor. These tools provide features for working with development orgs (scratch orgs, sandboxes, and DE orgs), Apex, Aura components, and Visualforce.

Salesforce Record ID
A unique 15-character or 18-character alphanumeric string that identifies a single record in Salesforce.

Salesforce Service Oriented Architecture
A powerful capability of Lightning Platform that allows you to make calls to external Web services from within Apex.

Sandbox
A nearly identical copy of a Salesforce production organization for development, testing, and training. The content and size of a sandbox varies depending on the type of sandbox and the edition of the production organization associated with the sandbox.
Semi-Join
A semi-join is a subquery on another object in an IN clause in a SOQL query. You can use semi-joins to create advanced queries, such as getting all contacts for accounts that have an opportunity with a particular record type. See also Anti-Join.

Session ID
An authentication token that is returned when a user successfully logs in to Salesforce. The Session ID prevents a user from having to log in again every time they want to perform another action in Salesforce. Different from a record ID or Salesforce ID, which are terms for the unique ID of a Salesforce record.

Session Timeout
The time after login before a user is automatically logged out. Sessions expire automatically after a predetermined length of inactivity, which can be configured in Salesforce from Setup by clicking Security Controls. The default is 120 minutes (two hours). The inactivity timer is reset to zero if a user takes an action in the web interface or makes an API call.

Setter Methods
Methods that assign values. See also Getter Methods.

Setup
A menu where administrators can customize and define organization settings and Lightning Platform apps. Depending on your organization’s user interface settings, Setup can be a link in the user interface header or in the dropdown list under your name.

Sharing
Allowing other users to view or edit information you own. There are different ways to share data:

- Sharing Model—defines the default organization-wide access levels that users have to each other’s information and whether to use the hierarchies when determining access to data.
- Role Hierarchy—defines different levels of users such that users at higher levels can view and edit information owned by or shared with users beneath them in the role hierarchy, regardless of the organization-wide sharing model settings.
- Sharing Rules—allow an administrator to specify that all information created by users within a given group or role is automatically shared to the members of another group or role.
- Manual Sharing—allows individual users to share records with other users or groups.
- Apex-Managed Sharing—enables developers to programmatically manipulate sharing to support their application’s behavior. See Apex-Managed Sharing.

Sharing Model
Behavior defined by your administrator that determines default access by users to different types of records.

Sharing Rule
Type of default sharing created by administrators. Allows users in a specified group or role to have access to all information created by users within a given group or role.

Sites
Salesforce Sites enables you to create public websites and applications that are directly integrated with your Salesforce organization—without requiring users to log in with a username and password.

SOAP (Simple Object Access Protocol)
A protocol that defines a uniform way of passing XML-encoded data.

SOAP API
A SOAP-based Web services application programming interface that provides access to your Salesforce organization’s information.

sObject
The abstract or parent object for all objects that can be stored in the Lightning Platform.

Software as a Service (SaaS)
A delivery model where a software application is hosted as a service and provided to customers via the Internet. The SaaS vendor takes responsibility for the daily maintenance, operation, and support of the application and each customer’s data. The service
alleviates the need for customers to install, configure, and maintain applications with their own hardware, software, and related IT resources. Services can be delivered using the SaaS model to any market segment.

**SOQL (Salesforce Object Query Language)**
A query language that allows you to construct simple but powerful query strings and to specify the criteria that selects data from the Lightning Platform database.

**SOSL (Salesforce Object Search Language)**
A query language that allows you to perform text-based searches using the Lightning Platform API.

**Standard Object**
A built-in object included with the Lightning Platform. You can also build custom objects to store information that is unique to your app.

**System Log**
Part of the Developer Console, a separate window console that can be used for debugging code snippets. Enter the code you want to test at the bottom of the window and click Execute. The body of the System Log displays system resource information, such as how long a line took to execute or how many database calls were made. If the code didn’t run to completion, the console also displays debugging information.

**T**

**Tag**
In Salesforce, a word or short phrases that users can associate with most records to describe and organize their data in a personalized way. Administrators can enable tags for accounts, activities, assets, campaigns, cases, contacts, contracts, dashboards, documents, events, leads, notes, opportunities, reports, solutions, tasks, and any custom objects (except relationship group members). Tags can also be accessed through SOAP API.

**Test Case Coverage**
Test cases are the expected real-world scenarios in which your code is used. Test cases aren’t actual unit tests, but are documents that specify what your unit tests do. High test case coverage means that most or all the real-world scenarios you have identified are implemented as unit tests. See also Code Coverage and Unit Test.

**Test Method**
An Apex class method that verifies whether a particular piece of code is working properly. Test methods take no arguments, commit no data to the database, and can be executed by the `runTests()` system method either through the command line or in an Apex IDE, such as the Salesforce extensions for Visual Studio Code.

**Test Organization**
See Sandbox.

**Transaction, Apex**
An Apex transaction represents a set of operations that are executed as a single unit. All DML operations in a transaction either complete successfully, or if an error occurs in one operation, the entire transaction is rolled back and no data is committed to the database. The boundary of a transaction can be a trigger, a class method, an anonymous block of code, a Visualforce page, or a custom Web service method.

**Trigger**
A piece of Apex that executes before or after records of a particular type are inserted, updated, or deleted from the database. Every trigger runs with a set of context variables that provide access to the records that caused the trigger to fire, and all triggers run in bulk mode—that is, they process several records at once, rather than just one record at a time.

**Trigger Context Variable**
Default variables that provide access to information about the trigger and the records that caused it to fire.
Unit Test
A unit is the smallest testable part of an application, usually a method. A unit test operates on that piece of code to make sure it works correctly. See also Test Method.

Unlimited Edition
Unlimited Edition is Salesforce's solution for maximizing your success and extending that success across the entire enterprise through the Lightning Platform.

Unmanageable Package
A package that can't be upgraded or controlled by its developer.

URL (Uniform Resource Locator)
The global address of a website, document, or other resource on the Internet. For example, https://salesforce.com.

User Acceptance Testing (UAT)
A process used to confirm that the functionality meets the planned requirements. UAT is one of the final stages before deployment to production.

Validation Rule
A rule that prevents a record from being saved if it doesn't meet the standards that are specified.

Version
A number value that indicates the release of an item. Items that can have a version include API objects, fields, and calls; Apex classes and triggers; and Visualforce pages and components.

View
The user interface in the Model-View-Controller model, defined by Visualforce.

View State
Where the information necessary to maintain the state of the database between requests is saved.

Visualforce
A simple, tag-based markup language that allows developers to easily define custom pages and components for apps built on the platform. Each tag corresponds to a coarse or fine-grained component, such as a section of a page, a related list, or a field. The components can either be controlled by the same logic that is used in standard Salesforce pages, or developers can associate their own logic with a controller written in Apex.

Visualforce Controller
See Controller, Visualforce.

Visualforce Lifecycle
The stages of execution of a Visualforce page, including how the page is created and destroyed during a user session.

Visualforce Page
A web page created using Visualforce. Typically, Visualforce pages present information relevant to your organization, but they can also modify or capture data. They can be rendered in several ways, such as a PDF document or an email attachment, and can be associated with a CSS style.

Web Service
A mechanism by which two applications can easily exchange data over the Internet, even if they run on different platforms, are written in different languages, or are geographically remote from each other.
WebService Method
An Apex class method or variable that external systems can use, like a mash-up with a third-party application. Web service methods must be defined in a global class.

Web Services API
Term describing the original Salesforce Platform web services application programming interface (API) that provides access to your Salesforce org’s information. See relevant developer guides for SOAP, REST, or Bulk APIs of interest.

Automated Actions
Automated actions, such as email alerts, tasks, field updates, and outbound messages, can be triggered by a process, workflow rule, approval process, or milestone.

Wrapper Class
A class that abstracts common functions such as logging in, managing sessions, and querying and batching records. A wrapper class makes an integration more straightforward to develop and maintain, keeps program logic in one place, and affords easy reuse across components. Examples of wrapper classes in Salesforce include the AJAX Toolkit, which is a JavaScript wrapper around the Salesforce SOAP API, wrapper classes such as Critical Section in the CTI Adapter for Salesforce CRM Call Center, or wrapper classes created as part of a client integration application that accesses Salesforce using SOAP API.

WSDL (Web Services Description Language) File
An XML file that describes the format of messages you send and receive from a Web service. Your development environment’s SOAP client uses the Salesforce Enterprise WSDL or Partner WSDL to communicate with Salesforce using SOAP API.

XML (Extensible Markup Language)
A markup language that enables the sharing and transportation of structured data. All Lightning Platform components that are retrieved or deployed through the Metadata API are represented by XML definitions.
