This document describes the Salesforce mobile application (Salesforce for Android, Salesforce for iOS, and the mobile web), and addresses security concerns an enterprise may have when evaluating Salesforce for their organization.

This document does not cover Salesforce Classic, Mobile Dashboards, Touch applications, or BlackBerry.
Salesforce uses the Force.com platform, with all application logic and database storage provided by salesforce.com’s hosted application servers. The Salesforce solution consists of the Salesforce application server, and either the client application or mobile browser on the handheld mobile device. Supported operating systems are Apple iOS and Android.

The Salesforce client application communicates across the wireless network to display a subset of the user’s data on the handheld device. The client application or browser on the handheld device pulls feed data on demand to the device. This architecture provides a very high quality of service and a productive working experience for the end user.

Salesforce provides a sandboxed environment for a user to access Salesforce data from a mobile device, while an org administrator can manage user access, even if the mobile device belongs to the user.
Access to Salesforce is “default on” and does not require an administrator to grant permission to use the application. Administrators can edit profile and permission sets to revoke access to any user through the administration console. The Salesforce app provides access to data and functions based upon the core permissions and rights defined for each user by their Salesforce administrator. Mobile users are never able to view or access more than their permissions allow.

Installation

When the Salesforce app is installed on a mobile device, the permissions requested vary for each OS.

- **Android Downloadable App**: At the time of installation, Android requires permission for:
  - Device and App History
  - Identity
  - Calendar
  - Contacts
  - Location
  - Phone
  - Photos/Media/Files
  - Wi-Fi Connection Information
  - Device ID and Call Information

- **iOS Downloadable App**: After installation, iOS requests permission for each item listed above on an individual basis, and the user can approve or deny the request.
The Salesforce app uses SSL/TLS for Over-The-Air (OTA) communication encryption. All Salesforce OAuth authorization endpoints are HTTPS only. Communication requests over HTTP are denied by Salesforce servers, unless the org administrator opts out of and unchecks “Require secure connections (HTTPS)” in the administration console.
All components of Salesforce require user authentication at the point and time of access. Salesforce utilizes OAuth2.0 for authentication through username/password or SSO (single sign-on) credentials.

In this chapter ...

- OAuth Pairing
- Single Sign On (SSO)
- Certificates and Keys
- Identity Providers and Service Providers
- Inactivity Lock
- Session Token
- Restrict Device Platforms
OAuth Pairing

During the initial login, the device is uniquely identified and paired with the mobile user’s account using the OAuth 2.0 protocol (http://tools.ietf.org/html/rfc6749). All requests to the Salesforce service are made using the OAuth token established through the pairing created during activation.

After initial login, there is no exchange of a password in the communication between the mobile client and the Salesforce server. For this reason, the Salesforce password is not stored on the device and is not required even when the password is changed or has expired. A user obtains an access and refresh token after successfully completing the OAuth 2.0 web server authentication. A user can use the refresh token to get a new access token (session ID). Upon logout, the OAuth access and refresh tokens are revoked, and the user set passcode is wiped (if passcode is enabled by org administrator). The user is re-prompted to enter the username/password and reset the passcode.

The org administrator can revoke a refresh token the first time a user uses the app, every time a user uses the app, or on set a schedule (hourly, daily, or monthly) to force a user to re-enter the username/password and reset the passcode. The default token expiration schedule is set at 2 hours, but can be as short as 15 minutes.

OAuth Access Token Storage

- **iOS Downloadable App:** AES-128 with a 256 bit key consisting of a SHA-256 hashed concatenation of a generated RFC 4122 Universally Unique Identifier (persisted to the encrypted keychain) and a Base64 encoded SHA-256 hash of the device passcode (this 4 to 8 digit non-alphanumeric passcode requirement is enabled by the org administrator and is set by the client). Token is stored in the keychain using kSecAttrAccessibleWhenUnlockedThisDeviceOnly to preserve the session for the user, because iOS may terminate the application.

- **Android Downloadable App:** PBKDF2 produced AES-256 encrypted key derived from device unique Android ID and randomly generated string. Token is stored in Android’s AccountManager. The SQLCipher-encrypted key is derived from the passcode, if enabled by org administrator, or UUID (universally unique identifier) if the passcode isn’t enabled.

- **Mobile Browser App:** Access token is never stored on the mobile device. The mobile browser app requires a user to re-enter the username/password to obtain a new access token.

OAuth Refresh Token Storage

- **iOS Downloadable App:** AES-128 with a 256 bit key consisting of a SHA-256 hashed concatenation of a generated RFC 4122 Universally Unique Identifier (persisted to the encrypted keychain) and a Base64 encoded SHA-256 hash of the device passcode (this 4 to 8 digit non-alphanumeric passcode requirement is enabled by the org administrator and is set by the client). Token is stored in the keychain using kSecAttrAccessibleWhenUnlockedThisDeviceOnly.

- **Android Downloadable App:** PBKDF2 produced AES-256 encrypted key derived from device unique Android ID and randomly generated string. Token is stored in Android’s AccountManager. The SQLCipher-encrypted key is derived from the passcode, if enabled by org administrator, or UUID (universally unique identifier) if the passcode isn’t enabled.

- **Mobile Browser App:** The web server authentication flow for the mobile browser app doesn’t use or store a refresh token on the device. The mobile browser app requires a user to re-enter the username/password to obtain a new access token.

Single Sign On (SSO)

Single sign-on is a process that allows network users to access all authorized network resources without having to log in separately to each resource. Single sign-on allows orgs to validate username/password against their user database or other client applications rather than having separate username/password managed by Salesforce.
Federated Authentication Support

When federated authentication is enabled, Salesforce doesn't validate a user’s password. Instead, Salesforce verifies an assertion in the HTTP POST request, and allows single sign-on if the assertion is true. This is the default form of single sign-on.

See “Single Sign-On for Desktop and Mobile Applications using SAML and OAuth” for more information.

Delegated Authentication Support

When delegated authentication is enabled, Salesforce does not validate a user’s password. Instead, Salesforce makes a Web services call to a customer org to establish authentication credentials for the user. Administrators must request delegated authentication support be enabled by Salesforce.

See “Understanding Delegated Authentication Single Sign-On” for more information.

Certificates and Keys

Salesforce certificates and key pairs are used for signatures that verify a request is coming from a customer org. They are used for authenticated SSL communications with an external website, or when using a customer org as an Identity Provider. Customers only need to generate a Salesforce certificate and key pair if they’re working with an external website that wants verification that a request is coming from a Salesforce org.

Salesforce offers two types of certificates:

- **Self-Signed**: A self-signed certificate is signed by Salesforce. Not all external websites accept self-signed certificates.
- **CA-Signed**: A CA-signed certificate is signed by an external certificate authority (CA). Most external websites accept CA-signed certificates. Customers must first generate the certificate signing request to send to a CA, and then import the signed version of the certificate before they can use it.

See “About Salesforce Certificates and Keys” for more information.

Identity Providers and Service Providers

An identity provider is a trusted provider that enables a customer to use single sign-on to access other websites. A service provider is a website that hosts applications. Customers can enable Salesforce as an identity provider, then define one or more service providers, so their users can access other applications directly from Salesforce using single sign-on. This can be a great help to users: instead of having to remember many passwords, they will only have to remember one.

Salesforce is automatically enabled as an identity provider when a domain is created. After a domain is deployed, administrators can add or change identity providers and increase security for their organization by customizing their domain’s login policy.

Enabling Salesforce as an identity provider requires a Salesforce certificate and key pair that is signed by an external certificate authority (CA-signed) or self-signed. If customers haven’t generated a Salesforce certificate and key pair, one is automatically created for them when they enable Salesforce as an identity provider. They also have the option of picking an already generated certificate, or creating one.

Salesforce uses the SAML 2.0 standard for single sign-on and generates SAML assertions when configured as an identity provider.

See “About Identity Providers and Service Providers” for more information.
Inactivity Lock

Upon initial activation, Salesforce prompts the user to create an arbitrary passcode (if required by the org administrator), which is used to unlock the application after reboot, or an administrator defined period of inactivity (1, 5, 10, or 30 minutes).

The passcode lock protects lost or stolen devices that may have their wireless connection disabled, and can’t have their OAuth token revoked.

Passcode Strength and Storage

- **iOS Downloadable App:** 4 to 8 digits (non-alphanumeric). A Base64 encoded SHA-256 hash of the passcode is stored in the secure keychain using kSecAttrAccessibleWhenUnlockedThisDeviceOnly for passcode validation and a component of the AES-128 encryption key for various encryption processes.

- **Android Downloadable App:** 5 or more alphanumeric characters. PBKDF2 produced AES-256 encrypted key derived from device unique Android ID and randomly generated string. Token is stored in Android’s AccountManage. The SQLCipher-encrypted key is derived from the passcode, if enabled by org administrator, or UUID (universally unique identifier) if the passcode isn’t enabled.

- **Mobile Browser App:** Users are prompted to re-enter username/password after 30 minutes of inactivity, or if they navigate to a different site or close the mobile browser.

Salesforce guards against brute force attacks by erasing all locally stored data after 10 failed attempts at entering the passcode. Reactivation is required to continue using the application.

Session Token

Session token is only used for Visualforce pages. It is derived from the OAuth Access Token and is scoped to the Visualforce page. The UIWebView/Webview stores it in the cache.

Restrict Device Platforms

Administrators can restrict Salesforce app access through the administration console by blocking the Salesforce Connected App for either platform (iOS or Android).

Administrators can also enable/disable mobile web through administration console. If the mobile browser app is disabled, the user is taken to the full Salesforce site from the mobile browser.
A mobile device may be lost or stolen at any time. Since mobile devices are small and designed to be highly portable, they may not remain under the physical control of a trusted person. Therefore, Salesforce provides methods to secure the device data if it passes out of control of the user or the user’s organization.

Salesforce has multiple levels of security at the handheld device level. First, device vendors provide the ability to enforce OS-level password access restrictions on any device applications or data. Users must be required to use the device protection in accordance with the owning enterprise’s security policy. If the device is locked by a strong password, it is difficult for unauthorized persons to do anything with it.
Local Data Protection

Salesforce does not currently support any external memory. The data stored locally on the device is saved in the device’s embedded memory and never on an external memory card.

Mobile platforms don’t generally allow data extraction from a local database. To make the system more secure, Salesforce does provide encryption on the device database.

Feed Database Encryption

Feeds are made up of feed items. A feed item is a piece of information posted by a user (for example, a poll) or by an automated process (for example, when a tracked field is updated on a record).

- **Salesforce for iOS:** Feed data is stored using Core Data, and encrypted using NSFileProtectionCompleteUntilFirstUserAuthentication. NSFileProtectionCompleteUntilFirstUserAuthentication dictates how passcodes are exposed internally to access the feed data. The passcode for the feed data is removed from the local keychain when Salesforce is closed or running in the background. Salesforce feed data is only accessible when the app is open and in the foreground.

  Additionally, the feed data storage is time-based. The feed cache purges items if the time last viewed is greater than one week, unless the remainder of feed items after purging is fewer than 25 items. Also feeds that have more than 500 items will have their excess items removed.

- **Salesforce for Android:** Feed data is stored in a SQLCipher-encrypted SQLite database with PBKDF2 produced AES-256 encrypted in CBC (cipher-block chaining) mode with appropriate IV (initialization vector) and PKCS #5 padding.

- **Mobile Browser App:** No encryption required. No data is stored locally on the device when using the mobile browser app.

Files and Attachments

A file or attachment is any file that a user uploads, shares, or attaches to posts, comments, or records. All file types are supported: documents, presentations, spreadsheets, PDFs, images, audio files, and video files.

- **iOS Downloadable App:** Files and attachments are stored on the device’s file system in a double-encrypted format. We use the device’s hardware encryption capability to encrypt the files while the device is locked and in addition we perform our own encryption using AES algorithm (128 bit block size and 256 bit key size). When the file is being viewed, there’s a temporary unencrypted copy kept on the file system (removed when the ‘viewing’ operation is complete).

- **Android Downloadable App:** To store files offline, we require the user to enable device encryption and use the OS’s file encryption system. If enabled, a passcode 5 or more alphanumeric characters adds an additional layer of file encryption. This allows the application to securely store local files.

- **Mobile Browser App:** No encryption required. No data is stored locally on the device when using the mobile browser app.

Offline Sync

If Salesforce users lose their wireless connection, they can enable offline sync to navigate within the app and view most recent items.

- **Salesforce for iOS:** Offline data is stored using Core Data, and encrypted using NSFileProtectionCompleteUntilFirstUserAuthentication. NSFileProtectionCompleteUntilFirstUserAuthentication dictates how passcodes are exposed internally to access the offline data. The passcode for the offline data is removed from the local keychain when Salesforce is closed or running in the background. Salesforce offline data is only accessible when the app is open and in the foreground.
• **Salesforce for Android**: Offline data is stored in the Salesforce Mobile SDK SmartStore, which is a SQLCipher-encrypted SQLite database with PBKDF2 produced AES-256 encrypted key in CBC (cipher-block chaining) mode with appropriate IV (initialization vector) and PKCS #5 padding.

• **Mobile Web**: Offline sync functionality isn’t available in mobile web.

---

**Remote Wipe**

To minimize the risk of information loss when a device is compromised, an org administrator can:

1. Disable a user completely (e.g. termination of an employee) to remove access and wipe the data from the application.

2. View the Connected Apps OAuth Usage report in the administration console to revoke the OAuth refresh token and associated access tokens. This wipes the application, which forces the user to re-authenticate (e.g. employee loses a phone).
CHAPTER 7 Mobile Device Management (MDM)

With version 8.0 or later of the Salesforce for Android and version 10.0 or later of the Salesforce for iOS, Salesforce provides an extra level of security compliance through interoperation with the most popular MDM (mobile device management) suites. Salesforce for Android and Salesforce for iOS, with an MDM, give you enhanced functionality for distribution and control over your users’ devices. The enhanced security functions when you combine Salesforce with an MDM include certificate-based authentication and automatic custom host provisioning.

Note: SAML 2.0 (security assertion markup language) must be enabled and configured for your organization.

There are prerequisites to implement enhanced security for Salesforce for Android.

- First, configure Android for Work for your org. Android for Work is a program that supports enterprise use of Android devices. See Android for Work to learn more about the program and Android for Work Help for setup information.

- Once Android for Work is set up, the next step is to configure your Mobile Device Management (MDM) suite. There are a multitude of MDM solutions in the market place. When you decide on the right product, work with your MDM provider to complete the configuration for your org.

- After you have Android for Work and your MDM suite up and running in your org, you’re ready to implement the enhanced security features of Salesforce for Android.

Certificate-Based Authentication

Using certificates to authenticate simplifies provisioning your mobile users, and your day-to-day mobile administration tasks by eliminating usernames and passwords. Salesforce uses X.509 certificates to authenticate users more efficiently, or as a second factor in the login process.

MDM Settings for Certificate-Based Authentication

To enable certificate-based authentication for your mobile users, you need to configure key-value pair assignments through your MDM suite. Here are the supported keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Data Type</th>
<th>Platform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RequireCertAuth</td>
<td>Boolean</td>
<td>Android, iOS</td>
<td>If true, the certificate-based authentication flow initiates.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>Android</strong>: Uses the user certificate on the device for authentication inside a webview.</td>
</tr>
</tbody>
</table>
### iOS:
Redirects the user to Safari for all authentication requests.

### Alias of the certificate deployed on the device
Picked by the application for user authentication. Required for Android only.

Note: There’s a minimum device OS version requirement to use certificate-based authentication. For Android, the minimum supported version is 5.0. For iOS, the minimum supported version is 7.0.

Once you save your key-value pair assignments, you can push the mobile app with the updated certificate-based authentication flow to your users via your MDM suite.

### Automatic Custom Host Provisioning

You can now push custom login host settings to your mobile users. This spares your mobile users from having to manually type long URLs for login hosts—typically a frustrating and error-prone activity. You can configure key-value pair assignments through your MDM to define multiple custom login hosts for your mobile users.

#### MDM Settings for Automatic Custom Host Provisioning

To push custom login host configurations to your mobile users, you need to configure key-value pair assignments through your MDM suite. Here are the supported keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Data Type</th>
<th>Platform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Login hosts. First value in the array is the default host. <strong>Android</strong>: Requires https:// in the host URL. <strong>iOS</strong>: Doesn't require https:// in the host URL.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>AppServiceHosts</td>
<td>String, String Array</td>
<td>Android, iOS</td>
<td>Login hosts. First value in the array is the default host. <strong>Android</strong>: Requires https:// in the host URL. <strong>iOS</strong>: Doesn't require https:// in the host URL.</td>
</tr>
<tr>
<td>AppServiceHostLabels</td>
<td>String, String Array</td>
<td>Android, iOS</td>
<td>Labels for the hosts. The number of AppServiceHostLabels</td>
</tr>
</tbody>
</table>
Additional Security Enhancements

You can add an extra layer of security for your iOS users by clearing the contents of their clipboard whenever the mobile app is in the background. Users may copy and paste sensitive data as a part of their day-to-day operations, and this enhancement ensures any data they copy onto their clipboards are cleared whenever they background the app.

**MDM Settings for More Security Enhancements**

To clear the clipboards of your iOS users when the mobile app is in the background, you need to configure key-value pair assignments through your MDM suite. Here is the supported key:

<table>
<thead>
<tr>
<th>Key</th>
<th>Data Type</th>
<th>Platform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ClearClipboard OnBackground</td>
<td>Boolean</td>
<td>iOS</td>
<td>If true, the contents of the iOS clipboard are cleared when the mobile app is backgrounded. This prevents the user from accidentally copying and pasting sensitive data outside of the application.</td>
</tr>
</tbody>
</table>

Note: If the mobile app stops working unexpectedly, the copied data can remain on the clipboard. The contents of the clipboard are cleared once the user starts and backgrounds the mobile app.

This security functionality is available through Android for Android devices running OS 5.0 and greater, and that have Android for Work set up. Contact your MDM provider to configure this functionality for your Android users.
Sample Property List Configuration

Note: Setting key-value pair assignments through a plist is only available on iOS.

One method of setting key-value pair assignments is through an XML property list, or plist. The plist contains the key-value pair assignments that an MDM provider sends to a mobile app to enforce security configurations.

Here is a sample plist:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
<dict>
  <key>AppServiceHosts</key>
  <array>
    <string>host1</string>
    <string>host2</string>
  </array>
  <key>AppServiceHostLabels</key>
  <array>
    <string>Production</string>
    <string>Sandbox</string>
  </array>
  <key>RequireCertAuth</key>
  <true/>
  <key>ClearClipboardOnBackground</key>
  <false/>
  <key>OnlyShowAuthorizedHosts</key>
  <false/>
</dict>
</plist>
```
With version 11.0 or later of the Salesforce for Android and Salesforce for iOS, Salesforce provides an extra level of security compliance without the use of an MDM (mobile device management) provider. This lets you configure security attributes, such as disabling copy and paste or disabling sharing files outside of your org, for your users from Setup in the full Salesforce site.

Salesforce for Android and Salesforce for iOS are connected apps. As a result, you can control the users who have access to the apps, as well as other security policies. By default, all users in your organization can log in to Salesforce for Android and Salesforce for iOS.

You can control security and access policies for each of the Salesforce for Android and Salesforce for iOS, using settings components that are installed from the managed Salesforce connected apps package. These components need to be installed in Salesforce:

- Salesforce for Android
- Salesforce for iOS

These components are automatically installed when one of your users installs a Salesforce for Android and Salesforce for iOS from the App Store or Google Play on a mobile device and authenticates with your organization by logging in to the mobile app.

Alternatively, you can manually install the Salesforce and Chatter Apps connected apps package so you can review and modify the default security and access settings before rolling out the Salesforce for Android and Salesforce for iOS to your users.

When the Salesforce connected apps components are installed, they’re added to the Connected Apps page. (From Setup, enter Connected Apps in the Quick Find box, then select the option for managing connected apps.) Here, you can view and edit the settings for each of the apps, including controlling user access with profiles, permissions, and IP range restrictions. An error message is displayed if a restricted user attempts to log in to a Salesforce for Android and Salesforce for iOS.

Several of the Salesforce app custom attributes have a default value that automatically applies when a user logs in to Salesforce for Android or Salesforce for iOS. If the default values are appropriate for your org, you’re all set.

To change a default value, or configure an attribute that doesn’t have a default setting, go to Setup in the full Salesforce site. Enter Connected Apps in the Quick Find box, select Connected Apps, then click Salesforce for Android or Salesforce for iOS. In the Custom Attributes section on the connected app page, click New and enter the attribute name and value.

To configure a security attribute, click Salesforce for Android or Salesforce for iOS from the Connected Apps page. In the Custom Attributes section on the connected app page, click New and enter the details for the attribute.

**Important:** Remember to wrap attribute values in quotation marks.

The following custom attributes are available for Salesforce for Android and Salesforce for iOS, which are also connected apps.
### Salesforce Connected App Security Attributes

<table>
<thead>
<tr>
<th>Attribute Key</th>
<th>Attribute Value</th>
<th>Platform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL_HISTORY</td>
<td>• DISABLED</td>
<td>Android</td>
<td>• If set to DISABLED, removes call logging from the navigation menu.</td>
</tr>
<tr>
<td></td>
<td>• ADMIN_DEFINED</td>
<td></td>
<td>• If set to ADMIN_DEFINED, enables native Android call logging.</td>
</tr>
<tr>
<td></td>
<td>• SIMPLE</td>
<td></td>
<td>• If set to SIMPLE, enables Aura call logging.</td>
</tr>
<tr>
<td>DISABLE_EXTERNAL_PASTE</td>
<td>• TRUE</td>
<td>Android, iOS</td>
<td>• If set to TRUE, lets users copy and paste within the Salesforce app, but disables copying within and pasting outside of the Salesforce app.</td>
</tr>
<tr>
<td></td>
<td>• FALSE</td>
<td></td>
<td>• If set to FALSE (default if attribute value isn’t defined), lets users copy and paste within and outside of the Salesforce app.</td>
</tr>
<tr>
<td>FORCE_EMAIL_CLIENT_TO</td>
<td>The email app’s URI scheme. Can differ by platform. For example, here’s an Android URI scheme example for Blue Mail, and an iOS URI scheme example for Gmail. Android: <a href="https://play.google.com/store/apps/details?id=me.bluemail.mail&amp;hl">https://play.google.com/store/apps/details?id=me.bluemail.mail&amp;hl</a> en iOS: googlemail:///co?to=</td>
<td>Android, iOS</td>
<td>If a user taps on an email action in the Salesforce app, the user is directed to the email app specified in the attribute value. You can specify one email app only. The attribute value you enter depends on the email app and the device platform. • For Android, use the URI listed in the Google Play Store for the desired email app. • For iOS, do an Internet search to locate the URI scheme.</td>
</tr>
</tbody>
</table>
## Salesforce Connected App Security Attributes

<table>
<thead>
<tr>
<th>Attribute Key</th>
<th>Attribute Value</th>
<th>Platform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHOW_OPEN_IN</td>
<td>• TRUE</td>
<td>iOS</td>
<td>• If set to TRUE, lets users share a file from the Salesforce app via a link to the file, or open a Salesforce file in a third-party app.</td>
</tr>
<tr>
<td></td>
<td>• FALSE</td>
<td></td>
<td>• If set to FALSE, disables users from sharing a file from the Salesforce app or opening a Salesforce file in a third-party app.</td>
</tr>
<tr>
<td>SHOW_PRINT</td>
<td>• TRUE</td>
<td>iOS</td>
<td>• If set to TRUE, lets users print from the Salesforce app.</td>
</tr>
<tr>
<td></td>
<td>• FALSE</td>
<td></td>
<td>• If set to FALSE, disables printing from the Salesforce app.</td>
</tr>
</tbody>
</table>

**Tip:** Connected app attribute changes take effect when users force quit the Salesforce app or when they log in to a new session. To ensure that new or modified settings take effect for all users, we recommend that you revoke access to the Salesforce app so everyone is required to log in again.

We also recommend that you warn users about the changes you intend to make, especially if you’re going to restrict activities that were previously available. The Salesforce app doesn’t display messages or indicators that connected app settings have changed.
• iOS: Prior to entering applicationDidEnterBackground, a benign splash screen is displayed to protect sensitive data from automatic iOS snapshotting (iOS uses automatic snapshotting for transition animations). The application prevents any snapshots of customer data during backgrounding.
• Security is not a binary (on/off), but implemented at different levels.
• Salesforce provides multiple levels of security; however, there’s no application that can guarantee a completely secure system.
